Constructor. Initializes the mesh object. The mesh counts are set to 0 and its pointers are set to NULL.

### Prototype:

**Mesh(const Mesh& fromMesh);**

### Remarks:

Constructor. The mesh is initialized equal to **fromMesh**.

### Prototype:

**~Mesh();**

### Remarks:

Destructor. Frees any allocated arrays (faces, verts, tverts, tvfaces).

### Prototype:

**void Init();**

### Remarks:

Initializes the mesh object. The mesh counts are set to 0 and its pointers are set to NULL. Note: This method is not intended to be called by developers. It is used internally.

### Prototype:

**void DeleteThis();**

### Remarks:

This method is available in release 3.0 and later only.

This method deletes this mesh.

## Vertex Methods

### Prototype:

```
BOOL setNumVerts(int ct, BOOL keep=FALSE, BOOL  
synchSel=TRUE);
```

### Remarks:

Sets the number of geometric vertices in the mesh.

### Parameters:

#### **int ct**

Specifies the number of vertices.

#### **BOOL keep=FALSE**

Specifies if the previous vertices should be kept. If TRUE the previous vertices are kept; otherwise they are discarded.

#### **BOOL synchSel=TRUE**

This parameter is available in release 2.0 and later only.

If TRUE the selection set BitArrays are resized to fit the number of vertices; otherwise they are left unaltered.

### Return Value:

TRUE if storage was allocated and the number of vertices was set; otherwise FALSE.

### Prototype:

```
int getNumVerts() const
```

### Remarks:

Returns the number of vertices.

### Prototype:

```
void setVert(int i, const Point3 &xyz);
```

### Remarks:

Sets a single vertex in the **verts** array.

**Parameters:**

**int i**

A zero based index into the **verts** array of the vertex to store.

**const Point3 &xyz**

Specifies the coordinate of the vertex.

**Prototype:**

**void setVert(int i, float x, float y, float z);**

**Remarks:**

Sets a single vertex in the **verts** array.

**Parameters:**

**int i**

A zero based index into the **verts** array of the vertex to store.

**float x**

Specifies the X coordinate of the vertex.

**float y**

Specifies the Y coordinate of the vertex.

**float z**

Specifies the Z coordinate of the vertex.

**Prototype:**

**Point3& getVert(int i);**

**Remarks:**

Returns the 'i-th' vertex.

**Parameters:**

**int i**

Specifies the index of the vertex to retrieve.

**Prototype:**

**Point3\* getVertPtr(int i);**

**Remarks:**

Returns a pointer to the 'i-th' vertex.

**Parameters:**

**int i**

Specifies the index of the vertex address to retrieve.

## **Color Per Vertex Methods**

**Prototype:**

**BOOL setNumVertCol(int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the number of color per vertex vertices.

**Parameters:**

**int ct**

The number of color vertices to set.

**BOOL keep=FALSE**

If TRUE previous values are kept; otherwise they are discarded.

**Return Value:**

TRUE if the value was set; otherwise FALSE.

**Prototype:**

**int getNumVertCol() const;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of color per vertex vertices.

**Prototype:**

**BOOL setNumVCFaces(int ct, BOOL keep=FALSE, int oldCt=0);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the number of color per vertex faces.

**Parameters:**

**int ct;**

The number of color per vertex faces to set.

**BOOL keep=FALSE**

Specifies if the old faces should be kept if the array is being resized. If FALSE they are freed.

**int oldCt=0**

The length of the existing VCFaces array.

**Return Value:**

TRUE if storage has been allocated and the number is set; otherwise FALSE.

**Prototype:**

```
void setVCDisplayData(int mapChan = 0, VertColor  
*VCArray=NULL, TVFace *VCf=NULL);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method would typically be called right before display, as with a node display callback, or through an extension object. If mapChan parameter is set to MESH\_USE\_EXT\_CVARRAY then the data in VCArray and TVFace is stored for internal use and consequent drawing. If the arrays are NULL then the internal source is used.

**Parameters:**

**int mapChan**

the mapping channel to use.

**VertColor \* VCArray**

An external array hosting the vertex colors

**TVFace \* vcf**

An external array of TVFace indexing into the color array

**Prototype:**

```
void setSmoothFlags(int f);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method should be called when the user has clicked on the 'Smooth' check box in a procedural object. It invalidates the appropriate caches of the mesh so the display is updated properly. If this method is not called, the internal topology cache might prevent the mesh from appearing changed.

**Parameters:**

**int f**

Nonzero indicates smoothed; zero unsmoothed.

**Prototype:**

**int getSmoothFlags();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the state of the smooth flags. See **setSmoothFlags()** above.

**Face Methods****Prototype:**

**BOOL setNumFaces(int ct, BOOL keep=FALSE, BOOL synchSel=TRUE);**

**Remarks:**

Sets the number of faces in the mesh.

**Parameters:**

**int ct**

Specifies the number of faces.

**BOOL keep=FALSE**

Specifies if the previous faces should be kept. If TRUE the previous faces are kept; otherwise they are discarded.

**BOOL synchSel=TRUE**

This parameter is available in release 2.0 and later only.

If TRUE the selection set BitArrays are resized to fit the number of faces; otherwise they are left unaltered.

**Return Value:**

TRUE if storage was allocated and the number of faces was set; otherwise FALSE.

**Prototype:**

```
int getNumFaces() const
```

**Remarks:**

Returns the number of faces in the mesh.

**Texture Vertex-Texture Face Methods****Prototype:**

```
BOOL setNumTVerts(int ct, BOOL keep=FALSE);
```

**Remarks:**

Sets the number of texture vertices (in mapping channel 1).

**Parameters:**

**int ct**

Specifies the number of texture vertices.

**BOOL keep=FALSE**

Specifies if the previous texture vertices should be kept. If TRUE the previous texture vertices are kept; otherwise they are discarded.

**Return Value:**

TRUE if storage was allocated and the number of texture vertices was set; otherwise FALSE.

**Prototype:**

```
int getNumTVerts() const
```

**Remarks:**

Returns the number of texture vertices (in mapping channel 1).

**Prototype:**

```
BOOL setNumTVFaces(int ct, BOOL keep=FALSE, int oldCt=0);
```

**Remarks:**

Sets the number of TVFaces. This method is automatically called if you set the number of faces to keep these two in sync (because the number of TVFaces should be the same as the number of faces). The following rules apply:

If you have no TVFaces and **keep** is TRUE then the TVFaces array stays empty.

If you have no TVFaces and **keep** is FALSE they are allocated.

If you have TVFaces and ct = 0 then the TVFaces are freed.

**Parameters:****int ct**

The number of TVFaces.

**BOOL keep=FALSE**

Specifies if the old faces should be kept.

**int oldCt=0**

The length of the existing TVFaces array.

**Return Value:**

TRUE if storage has been allocated and the number is set; otherwise FALSE.

**Prototype:****void setTVert(int i, const UVVert &xyz);****Remarks:**

Sets a single texture vertex in the **tVerts** array.

**Parameters:****int i**

A zero based index into the **tVerts** array of the texture vertex to store.

**const UVVert &xyz**

Specifies the coordinate of the vertex.

**Prototype:****void setTVert(int i, float x, float y, float z);****Remarks:**

Sets a single texture vertex in the **tVerts** array.

**Parameters:**

**int i**

A zero based index into the **tVerts** array of the texture vertex to store.

**float x**

Specifies the X coordinate of the texture vertex.

**float y**

Specifies the Y coordinate of the texture vertex.

**float z**

Specifies the Z coordinate of the texture vertex.

**Prototype:**

**UVVert& getTVert(int i)**

**Remarks:**

Returns the 'i-th' texture vertex.

**Parameters:**

**int i**

Specifies the index of the texture vertex to retrieve.

**Prototype:**

**UVVert\* getTVertPtr(int i)**

**Remarks:**

Returns a pointer to the 'i-th' texture vertex.

**Parameters:**

**int i**

Specifies the index of the texture vertex address to retrieve.

## **Multiple Map Support**

**Prototype:**

**void setNumMaps(int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Set the number of texture maps used by this Mesh. Note that this call is made automatically if **Mesh::setMapSupport()** is called.

**Parameters:**

**int ct**

The number of texture maps to use. This is a value between 2 and **MAX\_MESHMAPS-1**.

**BOOL keep=FALSE**

TRUE to keep the old mapping information after the resize; FALSE to discard it.

**Prototype:**

**int getNumMaps() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of mapping channels in use.

**Prototype:**

**BOOL mapSupport(int mp) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the specified mapping channel is supported; otherwise FALSE.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

**void setMapSupport(int mp, BOOL support=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets whether the specified mapping channels is supported or not.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**BOOL support=TRUE**

TRUE to indicate the channel is supported; otherwise FALSE.

**Prototype:**

**void setNumMapVerts(int mp, int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of texture or vertex color vertices for the specified mapping channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**int ct**

The number of vertices to allocate.

**BOOL keep=FALSE**

If TRUE previous values are kept; otherwise they are discarded.

**Prototype:**

**int getNumMapVerts(int mp) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of texture or vertex color vertices for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

**void setNumMapFaces(int mp, int ct, BOOL keep=FALSE, int**

**oldCt=0);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of texture or vertex color faces for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**int ct**

The number of faces to allocate.

**BOOL keep=FALSE**

If TRUE previous values are kept; otherwise they are discarded.

**Prototype:**

**UVVert \*mapVerts(int mp) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the list of **UVVerts** for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

**TVFace \*mapFaces(int mp) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the list of **TVFaces** for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

```
void setMapVert(int mp, int i, const UVVert&xyz);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets a single texture or vertex color value for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**int i**

The zero based index of the vertex to set.

**const UVVert&xyz**

The value to set.

**Prototype:**

```
void MakeMapPlanar(int mp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Applies a simple planar mapping to the specified channel. This is done by copying the mesh topology and vertex locations into the map.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

```
BitArray GetIsoMapVerts(int mp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a BitArray with a bit set for each isolated vertex (un-referenced by any face) for the specified channel.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

```
void DeleteMapVertSet(int mp, BitArray set, BitArray *fdel=NULL);
```

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the map vertices indicated.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**BitArray set**

Indicates which map verts should be deleted. set.GetSize() should equal this mesh's getNumMapVerts(mp).

**BitArray \*fdel=NULL**

If non-NULL, this points to a BitArray that will be filled in with the faces that will need to be deleted or have new map verts assigned because they used a map vert that was deleted. (The size will be set to this mesh's **numFaces**.)

**Prototype:**

```
void DeleteIsoMapVerts(int mp);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method deletes each isolated vertex (un-referenced by any face) for the specified channel.

**Parameters:**

**int mp=-1**

Specifies the channel. See [List of Mapping Channel Index Values](#). The default value of -1 indicates to do all active maps.

**Prototype:**

```
void DeleteIsoMapVerts();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method deletes each isolated vertex (un-referenced by any face) for the all active maps.

**Prototype:**

```
void freeMapVerts(int mp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the texture or vertex color vertices for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

```
void freeMapFaces(int mp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the texture or vertex color faces for the specified channel of this mesh.

**Parameters:**

**int mp**

Specifies the channel. See [List of Mapping Channel Index Values](#).

## **Vertex Data Methods**

**Prototype:**

```
void setNumVData(int ct, BOOL keep=FALSE);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of channels of vertex data used by the mesh.

**Parameters:**

**int ct**

The number of elements of vertex data to set.

**BOOL keep=FALSE**

If TRUE any old vertex data is kept; otherwise it is discarded.

**Prototype:**

**int getNumVData() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of vertex data channels maintained by this mesh.

**Prototype:**

**BOOL vDataSupport(int vd) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the specified channel of vertex data is available for this mesh; otherwise FALSE.

**Parameters:**

**int vd**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void setVDataSupport(int vd, BOOL support=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the specified channel of vertex data is supported by this mesh.

**Parameters:**

**int vd**

The vertex data channel. See [List of Vertex Data Index Options](#).

**BOOL support=TRUE**

TRUE to indicate the channel is supported; FALSE to indicate it's not. If TRUE is specified then **numVerts** elements are allocated (if needed). If

FALSE is specified the data for the channel is freed.

**Prototype:**

**void \*vertexData(int vd) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the vertex data for the specified channel or NULL if the channel is not supported. If supported then the size of this array is **numVerts**.

**Parameters:**

**int vd**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**float \*vertexFloat(int vd) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point vertex data for the specified channel of this mesh or NULL if the channel is not supported. If supported then the size of this array is **numVerts**.

**Parameters:**

**int vd**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void freeVData(int vd);**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the vertex data for the specified channel.

**Parameters:**

**int vd**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void freeAllVData();**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the vertex data from all the channels and sets the number of supported channels to 0.

**Prototype:**

**float \*getVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point vertex weight data.

**Prototype:**

**void SupportVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the channel support for the vertex weights channel (**VDATA\_WEIGHT**).

**Prototype:**

**void ClearVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Clears (deallocates) the vertex weights channel data.

**Prototype:**

**void freeVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the vertex weights channel data (same as **ClearVertexWeights()** above).

**Prototype:**

**float \*getVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point vertex selection weights data.

**Prototype:**

**void SupportVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the channel support for the vertex weights channel (**VDATA\_SELECT**).

**Prototype:**

**void ClearVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Clears (deallocates) the vertex selection weights channel data.

**Prototype:**

**void freeVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the vertex selection weights channel data (same as **ClearVSelectionWeights()** above).

## **Normals Methods**

**Prototype:**

**void setNormal(int i, const Point3 &xyz);**

**Remarks:**

Sets a single 'rendered' normal in the **rVerts** array of **RVertex** instances.

**Parameters:**

**int i**

A zero based index into the **rVerts** array of the normal to store.

**const Point3 &xyz**

The normal to store in device coordinates. This should be a unit vector.

**Prototype:**

**Point3& getNormal(int i);**

**Remarks:**

Returns the 'i-th' 'rendered' normal from the **rVerts** array.

**Parameters:**

**int i**

A zero based index into the **rVerts** array of the normal to get.

**Prototype:**

**void setFaceNormal(int i, const Point3 &xyz);**

**Remarks:**

Sets the 'i-th' face normal.

**Parameters:**

**int i**

A zero based index into the face normal array of the normal to store.

**const Point3 &xyz**

The face normal to store. This should be a unit vector.

**Prototype:**

**Point3& getFaceNormal(int i);**

**Remarks:**

Returns the 'i-th' face normal.

**Parameters:**

**int i**

Specifies the index of the face normal to retrieve.

**Prototype:**

```
void buildNormals();
```

**Remarks:**

This method resolves the normals on the **RVertex** array. If the Mesh already has normals at each vertex, the normal is just moved to the **RVertex** array. See [Class RVertex](#) and [Class RNormal](#).

If you are creating a **Mesh** by hand, after you are done specifying all the vertices and faces, this method should be called. This allocates the **RVertex** and **RNormal** database for the **Mesh**. This will allow you to query the **Mesh** and ask about normals on the vertices. Also, if you deform a Mesh (i.e. take one of the vertices and move it), you should call this method again. Actually, if you are only moving one normal you only need to smooth the polygons that share the vertex. However, there is no method to smooth a subset of a **Mesh**, you either have to do it by hand or call this method to smooth the entire **Mesh**.

This method also builds the face normals for the mesh.

**Prototype:**

```
void buildRenderNormals();
```

**Remarks:**

This method is similar to **buildNormals()** above, but ignores the material index (**mtlIndex**). In other words, the difference between this and **buildNormals()** is that it doesn't look at the **mtlIndex** of the faces: normals of faces with the same smoothing group are averaged regardless.

**Prototype:**

```
void checkNormals(BOOL illum);
```

**Remarks:**

This method can be used to build the normals and allocate **RVert** space only if necessary. This is a very inexpensive call if the normals are already calculated. When **illum** is FALSE, only the **RVerts** allocation is checked (since normals aren't needed for non-illum rendering). When **illum** is TRUE, normals will also be built, if they aren't already. So, to make sure normals are built, call this with **illum=TRUE**.

**Parameters:**

**BOOL illum**

If TRUE then normals are built. If FALSE then only the **RVert** array is allocated.

**Prototype:**

**RVertex &getRVert(int i)**

**Remarks:**

This method returns the 'i-th' RVertex.

**Parameters:**

**int i**

Specifies the index of the RVertex to retrieve.

**Prototype:**

**RVertex \*getRVertPtr(int i)**

**Remarks:**

This method returns a pointer to the 'i-th' RVertex.

**Parameters:**

**int i**

Specifies the index of the RVertex to retrieve.

## **Material Methods**

**Prototype:**

**MtlID getFaceMtlIndex(int i);**

**Remarks:**

Retrieves the zero based material index of the 'i-th' face.

**Parameters:**

**int i**

Specifies the face index. This is the zero based index into the **faces** array.

**Prototype:**

**void setFaceMtlIndex(int i, MtlID id);**

**Remarks:**

Sets the material index of the 'i-th' face.

**Parameters:**

**int i**

Specifies the face index. This is the zero based index into the **faces** array.

**MtlID id**

The material index for the 'i-th' face.

**Prototype:**

**void setMtlIndex(MtlID i);**

**Remarks:**

This method is no longer used.

**Prototype:**

**MtlID getMtlIndex();**

**Remarks:**

This method is no longer used.

**Prototype:**

**void createFaceMtlIndexList();**

**Remarks:**

This method is no longer used.

**Prototype:**

**void freeFaceMtlIndexList();**

**Remarks:**

This method is no longer used.

## **Render / Hit Test / Snap Methods**

**Prototype:**

```
void render(GraphicsWindow *gw, Material *ma, RECT *rp,  
int compFlags, int numMat=1, InterfaceServer *pi = NULL);
```

**Remarks:**

Renders this Mesh using the specified graphics window and array of materials.

Note: If a display routine makes multiple calls to this method you need to have called:

```
gw->setMaterial(inode->Mtls()[0]);
```

before calling **Mesh::render()**. If you don't then you may get the wrong material for material ID 0.

**Parameters:**

**GraphicsWindow \*gw**

Points to the graphics window to render to.

**Material \*ma**

The list of materials to use to render the mesh. See [Class Material](#), [Class INode - Material methods](#).

**RECT \*rp**

Specifies the rectangular region to render. If the mesh should be rendered to the entire viewport pass NULL.

**int compFlags**

One or more of the following flags:

**COMP\_TRANSFORM**

Forces recalculation of the model to screen transformation; otherwise attempt to use the cache.

**COMP\_IGN\_RECT**

Forces all polygons to be rendered; otherwise only those intersecting the box will be rendered.

**COMP\_LIGHTING**

Forces re-lighting of all vertices (as when a light moves); otherwise only re-light moved vertices

**COMP\_ALL**

All of the above flags.

**COMP\_OBJSELECTED**

If this bit is set then the node being displayed by this mesh is selected.

Certain display flags only activate when this bit is set.

**int numMat=1**

The number of materials for the mesh.

**InterfaceServer \*pi = NULL**

This pointer to an InterfaceServer can be used to get hold of the IXTCAccess pointer.

And IXTCAccess interface can also be obtained from the object by calling

**Object::GetInterface**

**(IXTCACCESS\_INTERFACE\_ID).**

#### Sample Code:

The following code shows this method being used to render the mesh as part of the **BaseObject::Display()** method:

```
int SimpleObject::Display(TimeValue t, INode* inode,
    ViewExp *vpt, int flags)
{
    if (!OKtoDisplay(t)) return 0;
    GraphicsWindow *gw = vpt->getGW();
    Matrix3 mat = inode->GetObjectTM(t);
    UpdateMesh(t); // UpdateMesh() just calls BuildMesh()
    gw->setTransform(mat);
    mesh.render(gw, inode->Mtls(),
        (flags&USE_DAMAGE_RECT) ? &vpt->GetDammageRect() : NULL,
        COMP_ALL, inode->NumMtls());
    return(0);
}
```

#### Prototype:

```
BOOL select(GraphicsWindow *gw, Material *ma,
    HitRegion *hr, int abortOnHit = FALSE, int numMat=1);
```

#### Remarks:

Checks the given HitRecord **hr** to see if it intersects this Mesh object.

#### Parameters:

**GraphicsWindow \*gw**

Points to the graphics window to check.

**Material \*ma**

The list of materials for the mesh.

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**int abortOnHit = FALSE**

If nonzero, the hit testing is complete after any hit; otherwise all hits are checked.

**int numMat=1**

The number of materials for the mesh.

**Return Value:**

TRUE if the item was hit; otherwise FALSE.

**Prototype:**

```
void snap(GraphicsWindow *gw, SnapInfo *snap, IPoint2 *p,  
Matrix3 &tm);
```

**Remarks:**

Checks to see if there is a snap point near the given mouse point.

**Parameters:****GraphicsWindow \*gw**

The graphics window in which to check.

**SnapInfo \*snap**

This structure describes the snap settings used, and the results of the snap test. See [Structure SnapInfo](#).

**IPoint2 \*p**

The mouse point to check.

**Matrix3 &tm**

The object transformation matrix. This is the transformation to place the object into the world coordinate system.

**Sample Code:**

```
// Checks to see if there is a snap point near the given mouse point.  
void TestObject::Snap(TimeValue t, INode* inode, SnapInfo *snap,  
IPoint2 *p, ViewExp *vpt) {
```

```

// Grab the object TM
Matrix3 tm = inode->GetObjectTM(t);
// Grab the graphics window
GraphicsWindow *gw = vpt->getGW();
// Make sure our mesh is up to date
UpdateMesh(t); // UpdateMesh() just calls BuildMesh()
// Set the transform in the GW
gw->setTransform(tm);
// Let the mesh do the work...
mesh.snap( gw, snap, p, tm );
}

```

**Prototype:**

```

BOOL SubObjectHitTest(GraphicsWindow *gw, Material *ma,
HitRegion *hr, DWORD flags,
SubObjHitList& hitList, int numMat=1 );

```

**Remarks:**

This method may be called to perform sub-object hit testing on this mesh.

**Parameters:**

**GraphicsWindow \*gw**

The graphics window associated with the viewport the mesh is being hit tested in.

**Material \*ma**

The list of materials for the mesh. See [Class Material](#), [Class INode - Material methods](#).

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**DWORD flags**

Flags for sub object hit testing. One or more of the following values:

**SUBHIT\_SELONLY**

Selected only.

**SUBHIT\_UNSELONLY**

Unselected only.

## **SUBHIT\_ABORTONHIT**

Abort hit testing on the first hit found.

## **SUBHIT\_SELSOLID**

This treats selected items as solid and unselected items as not solid. Treating an item as solid means the face will be hit if the mouse is anywhere inside the face region and not just over a visible edge.

## **SUBHIT\_USEFACESEL**

When this bit is set, the sel only and unsel only tests will use the faces selection when doing a vertex level hit test

## **SUBHIT\_VERTS**

Hit test vertices.

## **SUBHIT\_FACES**

Hit test faces.

## **SUBHIT\_EDGES**

Hit test edges.

## **SubObjHitList& hitList**

The results are stored here. See [Class SubObjHitList](#).

## **int numMat=1**

The number of materials for the mesh.

## **Return Value:**

TRUE if the item was hit; otherwise FALSE.

## **Prototype:**

**void displayNormals(int b, float sc)**

## **Remarks:**

Controls the display of surface normals on the mesh object.

Note that there may be more than one normal per vertex if faces that share the vertex are in non-overlapping smoothing groups. In this case, all normals associated with the given vertex are drawn.

## **Parameters:**

### **int b**

Nonzero to display the normals; zero to turn off normals display.

This can be a combination of **MESH\_DISP\_FACE\_NORMALS** and

**MESH\_DISP\_VERTEX\_NORMALS.** (The arguments may be or'ed together to display both.) For backwards compatibility, **MESH\_DISP\_FACE\_NORMALS** is #define'd to be "1", so sending in "TRUE" will turn on display of face normals, as before.

**float sc**

This specifies the length that should be used (in world units) to display the normals. Since all normals start out with length =1 they probably would be too small to see unless they were scaled

## **Bounding Box Methods**

**Prototype:**

**void buildBoundingBox();**

**Remarks:**

Computes the bounding box of the Mesh. If surface normals are displayed, they are taken into account in the computation of the box. The bounding box is stored with the Mesh object, use **getBoundingBox()** to retrieve it.

**Prototype:**

**Box3 getBoundingBox(Matrix3 \*tm=NULL);**

**Remarks:**

Retrieves the bounding box of the mesh object.

**Parameters:**

**Matrix3 \*tm=NULL**

The optional TM allows the box to be calculated in any space. NOTE: This computation will be slower because all the points must be transformed.

**Return Value:**

The bounding box of the Mesh.

## **Edge Methods**

**Prototype:**

**void displayAllEdges(int b);**

**Remarks:**

Controls the display of hidden edges of this mesh object. This just sets the Boolean in the mesh that controls whether "hidden" edges (for instance the diagonals on the sides of a cube) are displayed.

**Parameters:****int b**

Nonzero to display all the hidden edges; otherwise zero.

**Prototype:****void EnableEdgeList(int e);****Remarks:**

This method is used internally.

**Prototype:****void BuildVisEdgeList();****Remarks:**

This method is used internally.

**Prototype:****void DivideEdge(DWORD edge, float prop, bool visDiag1=TRUE, bool fixNeighbors=TRUE, bool visDiag2=TRUE);****Remarks:**

This method is available in release 2.5 and later only.

Divides the edge, creating a new point. The face directly using this edge (face edge/3) is also divided in two, and other faces using the edge may optionally be split to use the split edges.

**Parameters:****DWORD edge**

The edge to divide.

**float prop**

The proportion along the edge to make the division. An edge can be expressed as  $ff*3+ee$ , where  $ff$  is a face using this edge and  $ee$  represents which pair of vertices the edge is between, faces[ $ff$ ]->v[ $ee$ ] and faces[ $ff$ ]->v[( $ee+1$ )%3]. The

new point is created at (1-prop) times the first vertex plus prop times the second. prop may vary from 0 to 1. prop=.5 gives the same result that DivideEdge (DWORD edge) would generate.

**bool visDiag1=TRUE**

Indicates whether the "diagonal" used to split the primary face this edge is on (edge/3) is visible or not.

**bool fixNeighbors=TRUE**

Indicates whether other faces using this edge should also be split to use the two new edges, or if they should be left as they were. In a typical mesh, there is one other face using this edge, the face on the "other side" of the edge. If fixNeighbors is FALSE, the "other side" in this case would still use the original edge, while the face on this side would be split to use the two new edges. This would create a "hole" in the mesh.

**bool visDiag2=TRUE**

Indicates whether the "diagonals" used to split other faces using this edge are visible or not. This argument is not used if fixneighbors is FALSE.

**Prototype:**

```
void DivideFace(DWORD face, DWORD e1, DWORD e2, float prop1=.5f, float prop2=.5f, bool fixNeighbors=TRUE, bool split=FALSE);
```

**Remarks:**

This method is available in release 2.5 and later only.

Cuts a face into three faces, arranged as a quad and a triangle, by slicing from a point on one edge to a point on another.

**Parameters:**

**DWORD face**

The face to be divided.

**DWORD e1, e2**

The index of edges to be cut. For instance, if you wanted to cut from the edge between v[0] and v[1], to the edge between v[2] and v[0], you would use e1=0 and e2=2.

**float prop1=.5f**

The proportion along edge e1 to start cutting.

**float prop2=.5f**

The proportion along edge e2 to stop cutting.

**bool fixNeighbors=TRUE**

Indicates whether faces also using the cut edges should be split to use the new, subdivided edges.

**bool split=FALSE**

Indicates that the triangle and quad created by this action should use different vertices. If TRUE, the vertices created by the cut are duplicated, with one set being used for faces on one side and the other set being used by faces on the other side.

**Prototype:**

**void TurnEdge(DWORD edge, DWORD \*otherEdge);**

**Remarks:**

This method is available in release 2.5 and later only.

Turns an edge. The quadrilateral formed by the triangles on either side of this edge essentially has its diagonal switched.

**Parameters:**

**DWORD edge**

The edge to be turned.

**DWORD \*otherEdge**

If non-NULL, this should point to a variable in which the index of the "other side" of this edge should be stored. In essence, the two sides of an edge used by two faces, f1 and f2, are stored in two different locations, f1\*3+e1 and f2\*3+e2, where e1, e2 are 0, 1, or 2. This argument is provided so you have easy access to the other side of the edge, if desired, to make easy selection or visibility changes to the edge or other changes to the faces on both sides.

**Prototype:**

**void DrawVisEdgeList(GraphicsWindow \*gw, DWORD flags);**

**Remarks:**

This is used internally.

**Prototype:**

```
void HitTestVisEdgeList(GraphicsWindow *gw, int useFloats,  
int abortOnHit );
```

**Remarks:**

This is used internally.

**Prototype:**

```
void InvalidateEdgeList();
```

**Remarks:**

This is used internally.

**Prototype:**

```
void InvalidateGeomCache();
```

**Remarks:**

Call this method after the geometry of this Mesh has changed. It invalidates the bounding box, and tosses out the cached normals and edge list.

**Prototype:**

```
void InvalidateTopologyCache();
```

**Remarks:**

Call this method after you alter vertex or face lists or revise edge visibility flags. It will invalidate the edge and strip database maintained by the mesh.

**Prototype:**

```
void FreeAll();
```

**Remarks:**

Cleans up the allocated arrays. This frees the Faces, Verts, TVerts, TVFaces, FaceMtlIndexList and invalidates the geometry cache.

## **Strip Methods**

**Prototype:**

**BOOL BuildStrips();**

**Remarks:**

This method is available in release 2.0 and later only.

It builds the strips database inside the mesh. See the method **BuildStripsAndEdges()** below.

**Prototype:**

**void BuildStripsAndEdges();**

**Remarks:**

This method is available in release 2.0 and later only.

It builds the strips and edges database inside the mesh. When developers create a new mesh for display then this method should be called. See the section on Stripping in the Advanced Topics section [Working with Meshes](#) for details on this method.

**Prototype:**

**void InvalidateStrips();**

**Remarks:**

This method invalidates the strips database.

**Prototype:**

**void Stripify(Strip \*s, StripData \*sd, int vtx);**

**Remarks:**

This method is used internally.

**Prototype:**

**void getStripVertColor(GraphicsWindow \*gw, int cv, int flipped, MtlID mID, DWORD smGroup, Point3 &rgb);**

**Remarks:**

This method is used internally.

**Prototype:**

**void getStripNormal(GraphicsWindow \*gw, int cv, MtlID mID, DWORD smGroup, Point3 &nor);**

**Remarks:**

This method is used internally.

**Prototype:**

```
void Draw3DStrips(GraphicsWindow *gw, Material *ma, int numMat);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
BOOL getStripTVert(GraphicsWindow *gw, int cv, Point3 &uvw);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void DrawStrips(GraphicsWindow *gw, Material *ma, int numMat);
```

**Remarks:**

This method is used internally.

## **Data Flow Evaluation Methods**

**Prototype:**

```
void ShallowCopy(Mesh *amesh, ULONG_PTR channels);
```

**Remarks:**

Makes a copy of the specified channels of the specified Mesh object's data structures (but not all the data in these structures) into this Mesh. For example the **verts**, **tVerts**, **tvFaces**, ... are not copied.

**Parameters:**

**Mesh \*amesh**

Specifies the source Mesh to copy.

**ULONG\_PTR channels**

Specifies the channels to copy. See [List of Channels](#). Note: Prior to R4 this parameter was an unsigned long.

**Prototype:**

```
void DeepCopy(Mesh *amesh, ULONG_PTR channels);
```

**Remarks:**

Makes a complete copy of the specified channels of the specified Mesh object (its data structures and all the data in these structures) into this Mesh.

**Parameters:**

**Mesh \*amesh**

Specifies the source Mesh to copy.

**ULONG\_PTR channels**

Specifies the channels to copy. See [List of Channels](#). Note: Prior to R4 this parameter was an unsigned long.

**Prototype:**

```
void NewAndCopyChannels(ULONG_PTR channels);
```

**Remarks:**

This method replaces the specified channels with newly allocated copies.

**Parameters:**

**ULONG\_PTR channels**

Specifies the channels to copy. See [List of Channels](#). Note: Prior to R4 this parameter was an unsigned long.

**Prototype:**

```
void FreeChannels(ULONG_PTR channels, int zeroOthers=1);
```

**Remarks:**

Release the memory associated with the specified channels. For example if the TOPO\_CHANNEL is specified the faces are freed, if the GEOM\_CHANNEL is specified the vertices are freed, etc.

**Parameters:**

**ULONG\_PTR channels**

Specifies the channels to free. Channels not specified are left intact. See [List of Channels](#). Note: Prior to R4 this parameter was an unsigned long.

**int zeroOthers=1**

If nonzero then the various pointers are set to NULL and their counts are zeroed. For example **faces**, **verts**, **tVerts**, and **tvFace** are set to NULL and **numFaces**, **numVerts** and **numTVerts** are set to 0. If this is passed as 0, these pointers and counts are left unaltered.

## Mesh / Display Flags

### Prototype:

**void SetDispFlag(DWORD f)**

### Remarks:

Sets the state of the display flags. See **Data Members:** above for a list of the display flags.

### Parameters:

**DWORD f**

Specifies the flags to set.

### Prototype:

**DWORD GetDispFlag(DWORD f)**

### Remarks:

Returns the state of the specified display flags. See **Data Members:** above for a list of the display flags.

### Parameters:

**DWORD f**

Specifies the flags to retrieve.

### Prototype:

**void ClearDispFlag(DWORD f)**

### Remarks:

Sets the state of the specified display flags to 0.

### Parameters:

**DWORD f**

Specifies the flags to clear.

**Prototype:**

**void SetFlag(DWORD f)**

**Remarks:**

Sets the state of the mesh flags.

**Parameters:**

**DWORD f**

Specifies the flags to set. See [List of Mesh Flags](#).

**Prototype:**

**DWORD GetFlag(DWORD f)**

**Remarks:**

Returns the state of the specified mesh flags. See **Data Members:** above for a list of the mesh flags.

**Parameters:**

**DWORD f**

Specifies the flags to retrieve. See [List of Mesh Flags](#).

**Prototype:**

**void ClearFlag(DWORD f)**

**Remarks:**

Sets the state of the specified mesh flags to 0.

**Parameters:**

**DWORD f**

Specifies the flags to clear. See [List of Mesh Flags](#).

## **Selection Access**

**Prototype:**

**BitArray& VertSel()**

**Remarks:**

Retrieves the bits representing the vertex selection status. See **Data Members:**

above.

**Return Value:**

The vertex selection status.

**Prototype:**

**BitArray& FaceSel()**

**Remarks:**

Retrieves the bits representing the face selection status. See **Data Members:** above.

**Return Value:**

The face selection status.

**Prototype:**

**BitArray VertexTempSel();**

**Remarks:**

Constructs a vertex selection list based on the current selection level. For example if the selection level is at object level all the bits are set (vertices, faces and edges). If the selection level is at vertex level only the selected vertex bits are set.

**Return Value:**

A BitArray reflecting the current selection level.

**Sample Code:**

```
BitArray sel = mesh->VertexTempSel();
for ( int i = 0; i < mesh->getNumVerts(); i++ ) {
    if ( sel[i] ) {
        ...
    }
}
```

## **Intersect Ray / Weld / Optimize / Apply Mapping**

**Prototype:**

**int IntersectRay(Ray& ray, float& at, Point3& norm);**

**Remarks:**

Calculates the intersection of the specified ray with this mesh object. This allows Mesh objects to easily implement the **Object::IntersectRay()** method.

**Parameters:****Ray& ray**

Specifies the origin and direction of the ray to intersect with the mesh. See [Class Ray](#).

**float& at**

The computed point of intersection on the surface of the mesh.

**Point3& norm**

The face normal at the point of intersection (**at**).

**Return Value:**

Nonzero if the ray intersected the mesh object; otherwise 0. Note that this method ignores backfaces when computing the result.

**Prototype:**

```
int IntersectRay(Ray& ray, float& at, Point3& norm, DWORD  
&fi, Point3 &bary);
```

**Remarks:**

This method is available in release 2.0 and later only.

Calculates the intersection of the specified ray with this mesh object. This new version also returns the face index that was intersected and the barycentric coordinates of that face.

Barycentric coordinates are the coordinates relative to the triangular face. The barycentric coordinates of a point **p** relative to a triangle describe that point as a weighted sum of the vertices of the triangle. If the barycentric coordinates are **b0**, **b1**, and **b2**, then:

$$\mathbf{p} = \mathbf{b0} * \mathbf{p0} + \mathbf{b1} * \mathbf{p1} + \mathbf{b2} * \mathbf{p2};$$

where **p0**, **p1**, and **p2** are the vertices of the triangle. The **Point3** returned by this method has the barycentric coordinates stored in its three coordinates. These coordinates are relative to the triangular face that was intersected. These barycentric coordinates can be used to interpolate any quantity whose value is

known at the vertices of the triangle.

**Parameters:**

**Ray& ray**

Specifies the origin and direction of the ray to intersect with the mesh. See [Class Ray](#).

**float& at**

The computed point of intersection on the surface of the mesh.

**Point3& norm**

The face normal at the point of intersection (**at**).

**DWORD &fi**

The face index of the face that was intersected is returned here.

**Point3 &bary**

The barycentric coordinates of the face that was hit.

**Return Value:**

Nonzero if the ray intersected the mesh object; otherwise 0.

**Prototype:**

```
void WeldCollinear(BitArray &set);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void Optimize(float normThresh, float edgeThresh,  
float bias, float maxEdge, DWORD flags, MeshOpProgress  
*prog=NULL);
```

**Remarks:**

Allows this Mesh to be reduced in complexity by reducing the number of faces based on a surface normal threshold. Adjacent faces whose difference in surface normal angle falls below the specified threshold will be collapsed into a single triangle. The Mesh may also have its edge visibility set based on a surface normal threshold.

**Parameters:**

**float normThresh**

When the angle between adjacent surface normals is less than this value the optimization is performed. This angle is specified in radians.

**float edgeThresh**

When the angle between adjacent surface normals is less than this value the auto edge is performed (if the **OPTIMIZE\_AUTOEDGE** flag is set). This angle is specified in radians.

**float bias**

When optimizing mesh objects, as the optimization increases, you can get lots of long skinny 'degenerate' triangles (that cause rendering artifacts). Increasing the bias parameter keeps triangles from becoming degenerate. The range of values is from 0 to 1 (where 0 turns bias off). Values close to 1 reduce the amount of optimization in favor of maintaining equilateral triangles.

**float maxEdge**

This parameter is available in release 2.0 and later only.

This will prevent the optimize function from creating edges longer than this value. If this parameter is  $\leq 0$  no limit is placed on the length of the edges.

**DWORD flags**

These flags control the optimization. Specify zero or more of the following values:

**OPTIMIZE\_SAVEMATBOUNDRIES**

Specifies that faces won't be collapsed across a material boundary.

**OPTIMIZE\_SAVESMOOTHBOUNDRIES**

Specifies that faces won't be collapsed across a dissimilar smoothing group boundary.

**OPTIMIZE\_AUTOEDGE**

Specifies that the edge visibility should be set automatically based on the angle between adjacent surface normals. This will only set edges as invisible - it will not set edges as visible.

**MeshOpProgress \*prog=NULL**

A callback used for lengthy optimize operations. See [Class MeshOpProgress](#).

**Prototype:**

**void ApplyUVWMap(int type, float utile, float vtile,**

**float wtile,int uflip, int vflip, int wflip,  
int cap,const Matrix3 &tm, int channel=1);**

**Remarks:**

This method may be called to map this Mesh with UVW mapping coordinates.

**Parameters:**

**int type**

The mapping type. One of the following values:

**MAP\_PLANAR**  
**MAP\_CYLINDRICAL**  
**MAP\_SPHERICAL**  
**MAP\_BALL**  
**MAP\_BOX**

**float utile**

Number of tiles in the U direction.

**float vtile**

Number of tiles in the V direction.

**float wtile**

Number of tiles in the W direction.

**int uflip**

If nonzero the U values are mirrored.

**int vflip**

If nonzero the V values are mirrored.

**int wflip**

If nonzero the W values are mirrored.

**int cap**

This is used with **MAP\_CYLINDRICAL**. If nonzero, then any face normal that is pointing more vertically than horizontally will be mapped using planar coordinates.

**const Matrix3 &tm**

This defines the mapping space. As each point is mapped, it is multiplied by this matrix, and then it is mapped.

**int channel=1**

This parameter is available in release 2.0 and later only.

This indicates which channel the mapping is applied to -- **channel==1** corresponds to the original texture mapping channel.

**Prototype:**

**MeshMap & Map(int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the map for the specified map channel.

**Parameters:**

**int mp**

The map channel.

**Default Implementation:**

```
{ return (mp<0) ? hmaps[-1-mp] : maps[mp]; }
```

## **Normals / Smoothing / Edges / Face check Functions**

**Prototype:**

**void FlipNormal(int i);**

**Remarks:**

Flips the surface normal of the 'i-th' face (this just rearranges the indices for the face structure). This also makes sure the edge flags are rearranged as well. If there are UV coordinates these are rearranged appropriately.

**Parameters:**

**int i**

The index of the face to flip.

**Prototype:**

**void UnifyNormals(BOOL selOnly);**

**Remarks:**

Unifies the surfaces normals of this Mesh. This may be for selected faces, or the entire mesh.

**Parameters:**

## **BOOL selOnly**

If TRUE only the selected faces are unified.

### **Prototype:**

```
void AutoSmooth(float angle,BOOL useSel,BOOL  
preventIndirectSmoothing=FALSE);
```

### **Remarks:**

Performs an auto smooth on the mesh, setting the smoothing groups based on the surface normals.

### **Parameters:**

#### **float angle**

The minimum angle between surface normals for smoothing to be applied, in radians.

#### **BOOL useSel**

If TRUE only the selected faces are smoothed.

#### **BOOL preventIndirectSmoothing=FALSE**

This parameter is available in release 2.0 and later only.

TRUE to turn on; FALSE to leave off. This matches the option in the Smooth Modifier UI -- use this to prevent smoothing "leaks" when using this method.

If you use this method, and portions of the mesh that should **not** be smoothed become smoothed, then try this option to see if it will correct the problem.

Note that the problem it corrects is rare, and that checking this slows the Auto Smooth process.

### **Prototype:**

```
Edge *MakeEdgeList(int *edgeCount, int flagdbs=0);
```

### **Remarks:**

This method is used internally.

### **Prototype:**

```
int DeleteFlaggedFaces();
```

### **Remarks:**

This method removes faces from the face list with the **FACE\_WORK** flag

set.

**Return Value:**

The number of faces deleted.

**Prototype:**

**void DeleteSelected();**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes all selected elements of the current selection level.

**Prototype:**

**void DeleteVertSet(BitArray set);**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the vertices as specified by the BitArray.

**Parameters:**

**BitArray set**

Set of bits to indicate the vertices to delete.

**Prototype:**

**void DeleteFaceSet(BitArray set, BitArray \*isoVert=NULL);**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes faces as specified by the BitArray.

**Parameters:**

**BitArray set**

Set of bits to indicate the faces to delete.

**BitArray \*isoVert=NULL**

If non NULL then this method will be setup to flag vertices that were isolated by the face deletion. This set can then be passed to **DeleteVertSet()** to delete isolated vertices.

**Prototype:**

**BOOL DoesFaceExist(DWORD v0, DWORD v1, DWORD v2);**

**Remarks:**

This method may be called to determine if an equivalent face already exists.

**Parameters:**

**DWORD v0**

Index of the first vertex.

**DWORD v1**

Index of the second vertex.

**DWORD v2**

Index of the third vertex.

**Return Value:**

TRUE if an equivalent face already exists; otherwise FALSE.

**Prototype:**

**BOOL RemoveDegenerateFaces();**

**Remarks:**

Removes faces that have two or more equal indices.

**Return Value:**

TRUE if any degenerate faces were found; otherwise FALSE.

**Prototype:**

**BOOL RemoveIllegalFaces();**

**Remarks:**

Removes faces that have indices that are out of range

**Return Value:**

TRUE if any illegal faces were found; otherwise FALSE.

**Prototype:**

**Point3 FaceNormal(DWORD fi, BOOL nrmlize=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns the normal of the specified face. If **nrmlize** is TRUE, it makes this normal unit length. Otherwise, it's the edge cross-product length, which is actually 2 times the area of the face.

**Parameters:**

**DWORD fi**

Specifies the face whose normal is returned.

**BOOL nrmlize=FALSE**

Use TRUE to make the normal unit length.

**Prototype:**

**Point3 FaceCenter(DWORD fi);**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns the center of the specified face.

**Parameters:**

**DWORD fi**

Specifies the face whose center is returned.

**Prototype:**

**float AngleBetweenFaces(DWORD f0, DWORD f1);**

**Remarks:**

Returns the angle between two face surface normals in radians.

**Parameters:**

**DWORD f0**

Index of the first face.

**DWORD f1**

Index of the second face.

**Prototype:**

**Point3 BaryCoords(DWORD face, Point3 p);**

**Remarks:**

Computes and returns the barycentric coordinates of a point in the plane of a

face relative to that face.

**Parameters:**

**DWORD face**

The index of the face to check.

**Point3 p**

The input point.

**Return Value:**

The point **p** barycentric coordinates. If the point **p** is inside the face the returned values will sum to one. Note: If the face (or set of 3 points) is degenerate, ie if it has a zero length normal vector  $((p1-p0) \wedge (p2-p0))$ , the methods return Point3(-1,1,1).

**Prototype:**

**void FaceCenterTessellate(BOOL ignoreSel=FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Tesselates the mesh (or only the selected faces) using the face/center method. This means each face is subdivided by lines from a new vertex at the center to the original vertices.

**Parameters:**

**BOOL ignoreSel=FALSE**

If TRUE the entire mesh is tessellated; otherwise only the selected faces.

**Prototype:**

**void EdgeTessellate(float tens,BOOL ignoreSel=FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Edge tessellates the mesh using the specified tension parameter. This method can operate on the entire mesh or only the selection set. Edge tessellation means that faces are internally subdivided, with additional faces generated from a new vertex in the middle of each face edge.

**Parameters:**

**float tens**

The tension setting. This value can range from -100.0 to 100.0. This value matches the parameter in the Editable Mesh user interface when tessellating faces.

**BOOL ignoreSel=FALSE**

If TRUE the entire mesh is tessellated; otherwise only the selected faces.

**Prototype:**

**void IndentSelFaces(float amount);**

**Remarks:**

This method is available in release 3.0 and later only.

Indents the selected faces, in a manner consistent with the outlining used in Bevel.

**Parameters:**

**float amount**

The amount to indent.

**Prototype:**

**void ExtrudeFaces(BOOL doFace=TRUE);**

**Remarks:**

This method is available in release 2.0 and later only.

Extrudes the selected faces. Note that this is just a topological change. The new extruded faces do not change position but are left on top of the original faces.

**Parameters:**

**BOOL doFace=TRUE**

If TRUE the faces are extruded. If FALSE then the selected edges are extruded.

**Prototype:**

**void BreakVerts(BitArray set);**

**Remarks:**

This method is available in release 2.0 and later only.

Splits the vertices specified in the BitArray so that they are only used by a single face.

**Parameters:**

**BitArray set**

This array of bits, one per vertex in the mesh. If the bit is set, the corresponding vertex in the mesh is copied as required so it is only used by a single face. If the bit is not set the vertex is ignored.

**Prototype:**

**BitArray GetIsoVerts();**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns a BitArray (of size **numVerts**), where isolated verts are selected.

**Prototype:**

**void DeleteIsoVerts();**

**Remarks:**

This method is available in release 2.0 and later only.

Deletes the vertices that aren't used by any faces.

**Prototype:**

**void CloneFaces(BitArray fset);**

**Remarks:**

This method is available in release 2.0 and later only.

Creates a copy of the faces and verts used by those faces as specified by the **BitArray** passed. If texture faces and vertex color faces are present they are cloned as well.

**Parameters:**

**BitArray fset**

There is one bit in this array for each face in the mesh. If the bit is set, the corresponding face in the mesh is cloned. If the bit is zero the face is not

cloned.

**Prototype:**

**void PolyFromFace(DWORD f, BitArray &set, float thresh, BOOL ignoreVisEdges, AdjFaceList \*af=NULL);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets bits for all faces in the same polygon with face **f**. Faces already selected in **set** will not be processed -- so if **f** is "set", nothing happens.

The definition of a polygon is all faces sharing invisible edges with edge angles below "thresh".

**Parameters:**

**DWORD f**

Specifies which face to evaluate -- the zero based index into the **faces** array.

**BitArray &set**

Specifies which faces are not processed. One bit for each face with set bits not considered.

**float thresh**

The angle in radians which is the threshold for defining a polygon. A polygon is all faces sharing invisible edges with edge angles below this angle.

**BOOL ignoreVisEdges**

If TRUE, the edge visibility is ignored but the threshold is still relevant.

**AdjFaceList \*af=NULL**

This adjacent face list can be passed if there's one handy; otherwise a new one will be computed by the method.

**Prototype:**

**void ElementFromFace(DWORD f, BitArray &set, AdjFaceList \*af=NULL);**

**Remarks:**

This method is available in release 3.0 and later only.

This method sets bits for all faces in the same "element", or connected component, with face **f**. Faces already selected in **set** will be considered

"walls" for this processing and will not be evaluated.

**Parameters:**

**DWORD f**

Specifies which face to evaluate -- the zero based index into the **faces** array.

**BitArray &set**

Specifies which faces are considered as barriers to the element and are not processed. One bit for each face with set bits not considered.

**AdjFaceList \*af=NULL**

This adjacent face list can be passed if there's one handy; otherwise a new one will be computed by the method.

**Prototype:**

```
void FindVertsUsedOnlyByFaces(BitArray & fset, BitArray & vset);
```

**Remarks:**

This method is available in release 3.0 and later only.

When faces are deleted in Edit or Editable Mesh, we often want to be able to delete the verts that are isolated by this action. This method generates the list of verts that are used only by the specified set of faces.

**Parameters:**

**BitArray & fset**

This method finds those vertices used only by the faces indicated in this BitArray.

**BitArray & vset**

This BitArray is completely overwritten with the result, and will be set to the right size (numVerts) if needed.

**Prototype:**

```
void FindOpenEdges(BitArray & edges);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method fills in a BitArray with the edges in the mesh that are "open" or "one-sided". (This is the same as the Edit Mesh "Select Open Edges"

function.)

**Parameters:**

**BitArray & edges**

This BitArray will be set to size numFaces\*3, and only the open edge bits will be set.

**Prototype:**

**void FindVertexAngles(float \*vang, BitArray \*set=NULL);**

**Remarks:**

This method is available in release 3.0 and later only.

This method calculates, for each vertex, the sum of the angles of this vertex's corner in each face it's on. So for instance, a point lying in the middle of a grid would always have vertex angle  $2*PI$ , whereas a corner of a box would only have  $3*PI/2$ .

**Parameters:**

**float \*vang**

This should be a pointer to an array of size numVerts. The vertex angle for each vertex is put in this array (in radians).

**BitArray \*set=NULL**

If non-NULL, this points to a BitArray describing which vertices to find angles of. If only some bits are set, some computation time is saved. If NULL, all vertices' angles are found.

**Prototype:**

**void SetRenderData(MeshRenderData \*p);**

**Remarks:**

Sets the mesh render data hung off this Mesh. This method and

**GetRenderData()** allow the renderer to 'hang' data on a mesh. This data can be anything the renderer wants. The data will automatically be deleted when the mesh is deleted via the **DeleteThis()** method.

**Parameters:**

**MeshRenderData \*p**

See [Class MeshRenderData](#).

**Prototype:****MeshRenderData \*GetRenderData();****Remarks:**

Returns the mesh render data hung off this Mesh. See [Class MeshRenderData](#). This method and **SetRenderData()** allow the renderer to 'hang' data on a mesh. This data can be anything the renderer wants. The data will automatically be deleted when the mesh is deleted via the **DeleteThis()** method.

**Operators:****Prototype:****Mesh& operator=(const Mesh& fromMesh);****Remarks:**

Assignment operator. Note: This operator does not copy the **rVerts** array. This means that developers who have specified normals will have to explicitly copy them after a mesh assignment is done using this operator. This is because **rVerts** are instance-specific. In general, normals are computed from smoothing groups, and hence are "generated data". In the case where normals are specified, 3ds max stores the data in the **rVerts** array so as to not waste space. The way 3ds max uses the mesh = operator assumes that the **rVerts** are not copied, and thus developers must do the copying themselves.

**Parameters:****const Mesh& fromMesh**

Specifies the mesh to copy.

**Prototype:****Mesh operator+(Mesh &mesh);****Remarks:**

Performs a boolean union operation.

**Parameters:****Mesh &mesh**

Specifies the mesh to use as the other operand of the boolean operation.

**Return Value:**

A new Mesh resulting from the boolean operation. If the operation fails an empty Mesh is returned.

**Prototype:**

**Mesh operator-(Mesh &mesh);**

**Remarks:**

Performs a boolean difference operation.

**Parameters:**

**Mesh &mesh**

Specifies the mesh to use as the other operand of the boolean operation.

**Return Value:**

A new Mesh resulting from the boolean operation. If the operation fails an empty Mesh is returned.

**Prototype:**

**Mesh operator\*(Mesh &mesh);**

**Remarks:**

Performs a boolean intersection operation.

**Parameters:**

**Mesh &mesh**

Specifies the mesh to use as the other operand of the boolean operation.

**Return Value:**

A new Mesh resulting from the boolean operation. If the operation fails an empty Mesh is returned.

**The following global functions are not part of the Mesh class:****Function:**

**void setUseVisEdge(int b);**

**Remarks:**

This is used internally.

**Function:**

```
int getUseVisEdge();
```

**Remarks:**

This is used internally.

**Boolean Operations / CombineMeshes:**

The following functions are not part of class Mesh but are available for use:

**Prototype:**

```
int CalcBoolOp(Mesh &mesh, Mesh &mesh1, Mesh &mesh2, int  
op,  
MeshOpProgress *prog = NULL, Matrix3 *tm1 = NULL,  
Matrix3 *tm2 = NULL, int whichInv = 0, int weld = TRUE);
```

**Remarks:**

Note: This method is still in the SDK, but it is now obsolete. Calls to **CalcBoolOp()** should be replaced with calls to the new **MNMesh** form of Boolean. Please see the method **MNMesh::MakeBoolean** in [Class MNMesh](#) for details.

This function stores the result of a boolean operation between **mesh1** and **mesh2** into **mesh**. This operation may be a union, intersection or difference. If **tm1** or **tm2** are non-NULL, the points of the corresponding mesh will be transformed by these matrices before the boolean operation. The mesh will be transformed back by either **Inverse(tm1)** or **Inverse(tm2)** depending on **whichInv** (a value of 0 will use **tm1**, a value of 1 will use **tm2**, unless **whichInv** is -1 in which case it will not be transformed back).

**Parameters:****Mesh &mesh**

The result of the boolean operation is stored here. **mesh = mesh1 op mesh2**.

**Mesh &mesh1**

The first operand.

**Mesh &mesh2**

The second operand.

**int op**

The boolean operation. One of the following values:

**MESHBOOL\_UNION**

**MESHBOOL\_INTERSECTION**

**MESHBOOL\_DIFFERENCE**

**MeshOpProgress \*prog = NULL**

A callback to display a progress. See [Class MeshOpProgress](#).

**Matrix3 \*tm1 = NULL**

If non-NULL then the points of mesh1 will transformed by this matrix before the boolean operation.

**Matrix3 \*tm2 = NULL**

If non-NULL then the points of mesh2 will transformed by this matrix before the boolean operation.

**int whichInv = 0**

If 0, the resulting mesh will be transformed by Inverse(tm1). If 1, the resulting mesh will be transformed by Inverse(tm2). If -1, the mesh will not be transformed back.

**int weld = TRUE**

If TRUE, the vertices of the resulting mesh are welded.

**Return Value:**

Nonzero if the operation completed successfully; otherwise zero.

**Prototype:**

```
void CombineMeshes(Mesh &mesh, Mesh &mesh1, Mesh  
&mesh2, Matrix3 *tm1=NULL, Matrix3 *tm2=NULL, int  
whichInv=0);
```

**Remarks:**

This function is available in release 2.0 and later only.

This function may be used to simply combine two meshes into one.

**Parameters:**

**Mesh &mesh**

The result of the combine operation is stored here. **mesh = mesh1+mesh2.**

**Mesh &mesh1**

The first operand.

**Mesh &mesh2**

The second operand.

**Matrix3 \*tm1 = NULL**

If non-NULL then the points of mesh1 will transformed by this matrix before the boolean operation.

**Matrix3 \*tm2 = NULL**

If non-NULL then the points of mesh2 will transformed by this matrix before the boolean operation.

**int whichInv=0**

If 0, the resulting mesh will be transformed by Inverse(tm1). If 1, the resulting mesh will be transformed by Inverse(tm2). If -1, the mesh will not be transformed back.

## **Sub-Object Selection Color Control**

The following functions are not part of class Mesh but are available for use:

**Prototype:**

**void SetSubSelColor(Point3 \*clr);**

**Remarks:**

This methods sets the color used for sub-object selection.

**Parameters:**

**Point3 \*clr**

The color to use.

**Prototype:**

**Point3 GetSubSelColor();**

**Remarks:**

Returns the color used for sub-object selection.

## Class DADMgr

See Also: [Class ReferenceTarget](#), [List of Super Class IDs](#).

```
class DADMgr : public InterfaceServer
```

### Description:

Drag and drop functionality has been expanded to include all map and material buttons<sup>¾</sup>including those in the non-standard materials, plus most cases of bitmap buttons. As a result, whenever you see a button representing a material or map you can drag the button over a like button to display the Swap/Copy/Cancel dialog. Likewise, you can drag any materials or maps from the modeless version of the Materials/Maps Browser.

The drag-and-drop functions distinguish between material maps and bitmaps. A bitmap is an image file, such as a .tga, or .jpg. A map is an image used by the Materials Editor. It might consist of an image file, but could just as easily be a parametric image, such as Checkers or Noise, or it could be a map tree consisting of several different types of maps or bitmaps. Users can drag any map slot or button to any other map slot or button<sup>¾</sup>including the sample slots. Users can drag the Bitmap button in the Bitmap Parameters rollout to the Bitmap button in the Image area of the Displace modifier, and vice-versa.

Users can drag **from**:

- Sample slots
- Browser lists (text or iconic)
- The sample-sphere preview window in the Browser.
- Material map buttons, including:
  - The buttons in the Maps rollout
  - The shortcut map buttons
  - Any map buttons at any level
- Submaterial buttons, such as those found in the Multi/Subobject material
- Projector light map button
- Environment background map button
- Fog Color and Opacity maps buttons

Users can drag **to**:

- Objects in the viewports
- The Type button in the Materials Editor from the Browser.

- All of the items in the FROM list, with this exception: You can only drag to the Browser when it displays the material library.

All methods of this class are implemented by the plug-in. For developers of plug-in textures and materials see [Class TexDADMgr](#), [Class MtlDADMgr](#). These classes provide implementations of these methods and the objects can simply be used.

### Methods:

#### Prototype:

**virtual SClass\_ID GetDragType(HWND hwnd, POINT p)=0;**

#### Remarks:

This method is called on the item that supports drag and drop to see what (if anything) can be dragged from the point **p**. This method returns a super class id to indicate the type of item that can be dragged away. If it does not support anything being dragged from the specified point a SClass\_ID of **0** should be returned.

#### Parameters:

**HWND hwnd**

The source window handle

**POINT p**

The screen point (relative to the window upper left as 0,0).

#### Prototype:

**virtual BOOL IsNew(HWND hwnd, POINT p, SClass\_ID type);**

#### Remarks:

If the method **GetInstance()** creates a new instance every time it is called, then the this method should return TRUE. Otherwise it should return FALSE. This prevents **GetInstance()** from being called repeatedly as the drag progresses.

#### Parameters:

**HWND hwnd**

The source window handle.

**POINT p**

The point to drag from.

**SClass\_ID type**

The super class ID to create.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual ReferenceTarget *GetInstance(HWND hwnd, POINT p,  
SClass_ID type)=0;
```

**Remarks:**

This method should return a pointer to the drag source.

**Parameters:**

**HWND hwnd**

The source window where the mouse down occurred.

**POINT p**

The point to drag from (position within **hwnd**).

**SClass\_ID type**

The super class ID of the item to create.

**Prototype:**

```
virtual BOOL OkToDrop(ReferenceTarget *dropThis, HWND  
hfrom, HWND hto, POINT p, SClass_ID type, BOOL isNew =  
FALSE)=0;
```

**Remarks:**

This method is called on potential dropee to see if can accept the specified type at the specified point.

**Parameters:**

**ReferenceTarget \*dropThis**

A pointer to the item to check.

**HWND hfrom**

The window handle of the source.

**HWND hto**

The window handle of the destination.

**POINT p**

The point to check.

**SClass\_ID type**

The super class ID of **dropThis**.

**BOOL isNew = FALSE**

TRUE if the item is a new instance; otherwise FALSE.

**Return Value:**

TRUE if the specified item can be dropped; otherwise FALSE.

**Prototype:**

```
virtual HCURSOR DropCursor(ReferenceTarget *dropThis,  
HWND hfrom, HWND hto, POINT p, SClass_ID type, BOOL  
isNew = FALSE);
```

**Remarks:**

This method is called on a potential target to allow it to substitute custom cursors. It returns the handle for the custom cursor to use (or NULL to ignore).

**Parameters:**

**ReferenceTarget \*dropThis**

The pointer to the item to check.

**HWND hfrom**

The window handle of the source.

**HWND hto**

The window handle of the destination.

**POINT p**

The point to check.

**SClass\_ID type**

The super class ID of **dropThis**.

**BOOL isNew = FALSE**

TRUE if the item is a new instance; otherwise FALSE.

**Default Implementation:**

```
{ return NULL;}
```

**Prototype:**

```
virtual int SlotOwner();
```

**Remarks:**

Returns a predefined value to indicate the source of the drag.

**Return Value:**

One of the following values:

**OWNER\_MEDIT\_SAMPLE**

From a materials editor sample slot.

**OWNER\_NODE**

From a node in the scene.

**OWNER\_MTL\_TEX**

From a button in a material or texture.

**OWNER\_SCENE**

From a button in a light, modifier, atmospheric effect, etc.

**OWNER\_BROWSE\_NEW**

From the browser in the new category.

**OWNER\_BROWSE\_LIB**

From the browser in the library category.

**OWNER\_BROWSE\_MEDIT**

From the browser in the materials editor category.

**OWNER\_BROWSE\_SCENE**

From the browser in the scene category.

**Default Implementation:**

```
{ return OWNER_MTL_TEX; }
```

**Prototype:**

```
virtual void Drop(ReferenceTarget *dropThis, HWND hwnd,  
POINT p, SClass_ID type)=0;
```

**Remarks:**

This is the method called to actually process the drop operation. This routine is called on the target with the pointer returned by the source's

**GetInstance()**, or possibly a clone of it as the **dropThis**.

**Parameters:**

**ReferenceTarget \*dropThis**

A pointer to the item to drop.

**HWND hwnd**

The destination window handle (where the mouse was released).

**POINT p**

The destination point (within **hwnd**).

**SClass\_ID type**

The type of object being dropped -- the super class ID of **dropThis**.

**Prototype:**

```
virtual void SameWinDragAndDrop(HWND h1, POINT p1,  
POINT p2);
```

**Remarks:**

This method is called when the source and target WINDOW are the same.

**Parameters:**

**HWND h1**

The source/target window handle.

**POINT p1**

The source point.

**POINT p2**

The target point.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual BOOL LetMeHandleLocalDAD();
```

**Remarks:**

This lets the manager know whether to call **LocalDragAndDrop()** if the same DADMgr is handling both the source and target windows, or just ignore this condition. Return TRUE if **LocalDragAndDrop()** should be called;

otherwise FALSE.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void LocalDragAndDrop(HWND h1, HWND h2, POINT  
p1, POINT p2);
```

**Remarks:**

This is called if the same **DADMgr** is handling both the source and target windows, if **LetMeHandleLocalDAD()** returned TRUE.

**Parameters:**

**HWND h1**

The window handle.

**HWND h2**

The window handle.

**POINT p1**

The drag source point.

**POINT p2**

The drop destination point.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL AutoTooltip();
```

**Remarks:**

If this method returns TRUE, then Custom Buttons that use this DAD Manager will automatically support a tooltip that matches the button text. Note that this method will only show a tooltip when the button text is too long and thus exceeds the button size.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual BOOL CopyOnly(HWND hwnd, POINT p, SClass\_ID type);**

**Remarks:**

If a drag source doesn't want any references being made to the instance returned, then this method should return TRUE: it will force a copy to be made; otherwise return FALSE.

**Parameters:**

**HWND hwnd**

The source window handle.

**POINT p**

The source point (within **hwnd**).

**SClass\_ID type**

The type of object being dragged.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual BOOL AlwaysSendButtonMsgsOnDrop();**

**Remarks:**

Normally the mouse down and mouse up messages are not sent to the source window when doing drag and drop, but if you need them, return TRUE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual BOOL OkToDropInstance(ReferenceTarget \*dropThis, HWND hfrom, HWND hto, POINT p, SClass\_ID type);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called on potential target to see if can instance "dropThis" at

the specified point. Returns TRUE if it is okay to drop the specified item and FALSE if not.

**Parameters:**

**ReferenceTarget \*dropThis**

The pointer to the item to check.

**HWND hfrom**

The window handle of the source.

**HWND hto**

The window handle of the destination.

**POINT p**

The point to check.

**SClass\_ID type**

The super class ID of **dropThis**.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

```
virtual INT_PTR Execute(int cmd, ULONG arg1=0, ULONG  
arg2=0, ULONG arg3=0);
```

**Remarks:**

This method is available in release 3.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

This is reserved for future use.

**Parameters:**

**int cmd**

The command to execute.

**ULONG arg1=0**

Optional argument 1 (defined uniquely for each **cmd**).

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value (defined uniquely for each **cmd**).

**Default Implementation:**

```
{ return 0; }
```

## Class TexDADMgr

See Also: [Class DADMgr](#), [Class ParamDlg](#).

```
class TexDADMgr : public DADMgr
```

### **Description:**

This class is available in release 2.0 and later only.

Use this class to provide drag and drop functionality for materials sub-  
Texmaps. It provides implementations of the methods of **DADMgr**. If this  
class is used the **ParamDlg** method **FindSubTexFromHWND()** must be  
implemented.

## Class MtlDADMgr

See Also: [Class DADMgr](#).

class MtlDADMgr: public DADMgr

### Description:

All methods of this class are implemented by the system.

Use this class to implement drag and drop functionality for materials sub-materials. . It provides implementations of the methods of **DADMgr**. If this class is used the **ParamDlg** method **FindSubMtlFromHWND()** must be implemented.

## Class DADBitmapCarrier

See Also: [Class ReferenceTarget](#).

```
class DADBitmapCarrier: public ReferenceTarget
```

### Description:

This class is available in release 2.0 and later only.

It is used to provide drag and drop functionality for Bitmaps. See the following global function for getting a pointer to the instances of this class.

All methods of this class are implemented by the system.

### Function:

```
DADBitmapCarrier *GetDADBitmapCarrier();
```

### Remarks:

This global function returns a pointer to the **BitmapCarrier**. Note that there is only two of these: one for the source, and one for the destination.

Developers should not delete these. Sample code using this class is available in **\MAXSDK\SAMPLES\MATERIALS\BMTEX.CPP**.

### Methods:

#### Prototype:

```
void SetName(TSTR &nm);
```

#### Remarks:

Sets the name of the bitmap carrier.

#### Parameters:

```
TSTR &nm
```

The name to set.

#### Prototype:

```
TSTR& GetName();
```

#### Remarks:

This method is available in release 2.0 and later only.

Returns the name of the bitmap carrier.

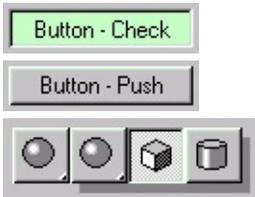

## Class ICustButton

See Also: [Class ICustomControl](#), [Custom Controls](#), [Class ICustToolbar](#), [Class FlyOffData](#), [Class DADMgr](#), [Class MAXBmpFileIcon](#).

```
class ICustButton : public ICustomControl
```

### Description:

Custom buttons may be one of two different forms. A Check button (which stays pressed in until the user clicks on it again), or a Push button (which pops back out as soon as it is released). Buttons may be implemented as a Fly offs. A fly off offers several alternative buttons which fly out from the button after it is press and held briefly.

The buttons may contain text or graphic images. Fly off buttons only use graphic images. The plug-in developer has control over the appearance of the button in each of its four states (Enabled&Out, Enabled&In, Disabled&Out, Disabled&In).

Note: When the user presses a button a **WM\_MENUSELECT** message is sent so that the client can display a status prompt describing the function of the tool. The **fuFlags** parameter is set to this value: **CMF\_TOOLBUTTON**.

In 3dsmax version 4.0 you can remove borders from an ICustButton;

```
ICustButton *cb = ();
```

```
cb->Execute(I_EXE_CB_NO_BORDER);
```

To initialize the pointer to the control call:

### Prototype:

```
ICustButton *GetICustButton(HWND hCtrl);
```

To release the control call:

### Prototype:

```
ReleaseICustButton(ICustButton *ics);
```

The value to use in the Class field of the Custom Control Properties dialog is:

**CustButton**

**Methods:****Prototype:**

**virtual void GetText(TCHAR \*text, int ct)=0;**

**Remarks:**

This retrieves the text displayed by the button.

**Parameters:**

**TCHAR \*text**

Storage for the text to retrieve.

**int ct**

Specifies the maximum length of the string returned.

**Prototype:**

**virtual void SetText(TCHAR \*text)=0;**

**Remarks:**

This specifies the text displayed by the button.

**Parameters:**

**TCHAR \*text**

The text to be displayed by the button.

**Prototype:**

**virtual void SetImage(HIMAGELIST hImage, int iOutEn, int iInEn, int iOutDis, int iInDis, int w, int h)=0;**

**Remarks:**

This method is used to establish the images used for the buttons.

**Parameters:**

**HIMAGELIST hImage**

The image list. An image list is a collection of same-sized images, each of which can be referred to by an index. Image lists are used to efficiently manage large sets of icons or bitmaps in Windows. All images in an image list are contained in a single, wide bitmap in screen device format. An image list may also include a monochrome bitmap that contains masks used to draw images transparently (icon style). The Windows API provides image list

functions, which enable you to draw images, create and destroy image lists, add and remove images, replace images, and merge images.

The next four parameters (**iOutEn**, **iInEn**, **iOutDis**, **iInDis**) are indices into the image list. They indicate which images to use for each of the four possible button states. You may specify a unique image for each one of these states by passing a different index for each state. Or you may supply a single image to be used for all the states by specifying the same index four times.

**int iOutEn**

Out&Enabled.

**int iInEn**

In&Enabled.

**int iOutDis**

Out&Disabled.

**int iInDis**

In&Disabled.

**int w**

The width of the button image.

**int h**

The height of the button image.

**Prototype:**

**virtual void SetIcon(MaxBmpFileIcon\* pIcon, int w, int h) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This sets the icon image used for a button.

**Parameters:**

**MaxBmpFileIcon\* pIcon**

Points to the icon.

**int w**

The width of the button image.

**int h**

The height of the button image.

**Prototype:**

```
virtual void SetInIcon(MaxBmpFileIcon* pInIcon, int w, int h) =  
0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This sets the icon image used when a button is pressed.

**Parameters:**

**MaxBmpFileIcon\* pInIcon**

Points to the icon.

**int w**

The width of the button image.

**int h**

The height of the button image.

**Prototype:**

```
virtual void SetType(CustButType type)=0;
```

**Remarks:**

This method sets the button type.

**Parameters:**

**CustButType type**

One of the following values:

**CBT\_PUSH**

A Push button pops back out as soon as it is released.

**CBT\_CHECK.**

A Check button stays pressed in until the user clicks on it again.

**Prototype:**

```
virtual void SetFlyOff(int count,FlyOffData *data,int timeOut,int  
init,int dir=FLY_VARIABLE)=0;
```

**Remarks:**

This method sets the button to work as a fly off control.

**Parameters:**

**int count**

The number of buttons in the fly off.

**FlyOffData \*data**

An array of instances of the class **FlyOffData** . This class uses four indices into the image list to describe the button in each of the possible states: Out&Enabled, In&Enabled, Out&Disabled and In&Disabled.

In the simple case, where all the buttons have the same image, you can do the following:

```
FlyOffData fod[3] = { // A three button flyoff  
  { 0,0,0,0 }, // The first button uses a single image.  
  { 1,1,1,1 }, // So does the second button...  
  { 2,2,2,2 }, // So does the third...  
};
```

Each button will use the same images regardless of its pressed in / disabled state. Note the button is automatically drawn pushed in (i.e. shaded lighter) when the user is dragging the cursor over the button, but the actual image on the button is not changed.

If you require different images for these states, supply different indices into the image list for each. See the sample program

**\MAXSDK\SAMPLES\HOWTO\CUSTCTRL\CUSTCTRL.CPP**  
for an example of how this is done.

**int timeOut**

This is the time in milliseconds the button must be held pressed before the fly off appears. You may specify 0 if you want the buttons to fly off immediately. To retrieve the value that 3ds max uses internally for its flyoffs use a method of [Class Interface](#) called **GetFlyOffTime()**. This returns a value in milliseconds.

**int init**

This is the initial button displayed.

**int dir=FLY\_VARIABLE**

This parameter is optional. It is used to indicate which direction the buttons should fly off. The choices for direction are:

**FLY\_VARIABLE**

The default. The system will determine the direction of the fly off.

**FLY\_UP**

The buttons fly off above.

**FLY\_DOWN**

The buttons fly off beneath.

**FLY\_HVARIABLE**

The buttons will fly off either left or right with the system determining the direction.

**FLY\_LEFT**

The buttons fly off to the left.

**FLY\_RIGHT**

The buttons fly off to the right.

**Prototype:**

```
virtual void SetCurFlyOff(int f,BOOL notify=FALSE)=0;
```

**Remarks:**

This method establishes which button is displayed by passing its index.

**Parameters:****int f**

The index of the flyoff button to display.

**BOOL notify=FALSE**

This indicates if the call to this method should notify the dialog proc. If TRUE it is notified; otherwise it isn't.

**Prototype:**

```
virtual int GetCurFlyOff()=0;
```

**Remarks:**

Returns the index of the button which is currently displayed.

**Prototype:**

```
virtual BOOL IsChecked()=0;
```

**Remarks:**

Determines if the button is checked. This method returns TRUE if the check

button is currently in the In state (i.e. checked) and FALSE otherwise.

**Prototype:**

**virtual void SetCheck( BOOL checked )=0;**

**Remarks:**

Passing TRUE to this method sets the button to the In or checked state.

**Parameters:**

**BOOL checked**

If TRUE the button is set to the checked state; if FALSE the button is unchecked.

**Prototype:**

**virtual void SetCheckHighlight( BOOL highlight )=0;**

**Remarks:**

This method controls if the check button is displayed in the highlight color when pressed in.

**Parameters:**

**BOOL highlight**

TRUE if you want the button to use the highlight color; otherwise pass FALSE.

**Prototype:**

**virtual void SetButtonDownNotify(BOOL notify)=0;**

**Remarks:**

Specifies if messages are sent when the user clicks or releases the button. If this method is called with TRUE, a message is sent immediately whenever the button is pressed down or released. The message **BN\_BUTTONDOWN** is sent on button down and **BN\_BUTTONUP** is sent when the button is released. The **BN\_BUTTONUP** message is sent even if the button is released outside the button rectangle.

**Parameters:**

**BOOL notify**

TRUE if notification should be send by the button; FALSE if notifications should not be sent.

**Prototype:**

**virtual void SetRightClickNotify(BOOL notify)=0;**

**Remarks:**

Specifies if messages are sent when the user right clicks the button.

**Parameters:**

**BOOL notify**

If TRUE, the **BN\_RIGHTCLICK** message is sent whenever the users right clicks on the button. If FALSE no message are sent on right clicks.

**Prototype:**

**virtual void SetHighlightColor(COLORREF clr)=0;**

**Remarks:**

This methods sets the highlight color for the check button.

**Parameters:**

**COLORREF clr**

The color for the button. It may be specified using the RGB macro, for example: **SetHighlightColor(RGB(0,0,255));**

There are several pre-defined colors which may be used. These are:

**RED\_WASH, BLUE\_WASH** and **GREEN\_WASH**. **GREEN\_WASH** is the standard color used for check buttons in 3ds max that instigate a command mode. While the command mode is active the button should be displayed in **GREEN\_WASH**. When the mode is finished the button should be returned to normal.

**Prototype:**

**virtual COLORREF GetHighLightColor()=0;**

**Remarks:**

This methods returns the highlight color for the check button.

**Prototype:**

**virtual void SetTooltip(BOOL onOff, LPSTR text)=0;**

**Remarks:**

This method allows a developer to add tooltip text to single custom buttons.

**Parameters:****BOOL onOff**

TRUE to turn the tooltip on; FALSE to turn it off.

**LPSTR text**

This may be one of two things:

The tooltip text (as a **TCHAR \***)

This is simply the text to show up in the tooltip.

The symbol **LPSTR\_TEXTCALLBACK**

This indicates a callback will be used. If this is specified, the parent window of the button will get the usual tooltip "need text" notify message (**TTN\_NEEDTEXT**).

**Prototype:**

**virtual void SetDADMgr(DADMgr \*dad)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the drag and drop manager for this button control.

**Parameters:****DADMgr \*dad**

A pointer to the drag and drop manager to set.

**Prototype:**

**virtual DADMgr \*GetDADMgr()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the drag and drop manager for this button control.

**Prototype:**

**virtual void SetMacroButtonData(MacroButtonData \*md)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the macro data for this button.

**Parameters:**

**MacroButtonData \*md**

The data to set. See [Class MacroButtonData](#).

**Prototype:**

**virtual MacroButtonData \*GetMacroButtonData()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to any macro button data for this button. See [Class MacroButtonData](#).

**Prototype:**

**virtual void SetDisplayProc(PaintProc \*proc)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the callback object used to display the button.

Note: This method is only available in 3D Studio VIZ (not MAX).

**Parameters:**

**PaintProc \*proc**

Points to the callback object for displaying the button.

Note: **typedef LRESULT CALLBACK PaintProc(  
HDC hdc, Rect rect, BOOL in, BOOL checked, BOOL  
enabled);**

## Class IDADWindow

See Also: [Class ICustomControl](#), [Class DADMgr](#), [Custom Controls](#).

```
class IDADWindow : public ICustomControl
```

### Description:

This class is available in release 2.0 and later only.

This is a new type of custom control used to provide drag and drop to and from things other than Custom Buttons. An example of an item that uses this control is a sample sphere window in the Material Editor.

To initialize the pointer to the control call:

### Prototype:

```
IDADWindow *GetIDADWindow(HWND hWnd);
```

To release the control call:

### Prototype:

```
void ReleaseIDADWindow(IDADWindow *idw);
```

The value to use in the Class field of the Custom Control Properties dialog is:

### **DragDropWindow**

All methods of this class are implemented by the system.

### Methods:

#### Prototype:

```
virtual void SetDADMgr(DADMgr *dadMgr)=0;
```

#### Remarks:

Set the drag and drop manager for this control.

#### Parameters:

```
DADMgr *dadMgr
```

A pointer to the drag and drop manager for this control.

#### Prototype:

```
virtual DADMgr *GetDADMgr()=0;
```

#### Remarks:

Returns a pointer to the drag and drop manager for this control.

**Prototype:**

```
virtual void SetWindowProc(WindowProc *proc)=0;
```

**Remarks:**

This method establishes a window proc that is called to handle all the normal processing after the drag and drop processing is done.

**Parameters:**

```
WindowProc *proc
```

The window proc. Note the following typedef:

```
typedef LRESULT CALLBACK WindowProc(HWND hwnd,  
UINT message, WPARAM wParam, LPARAM lParam);
```

```
#define SLIDERWINDOWCLASS _T("SliderControl")
```

```
// LOWORD(wParam) = ctrlID,
```

```
// HIWORD(wParam) = TRUE if user is dragging the slider  
interactively.
```

```
// lParam = pointer to ISliderControl
```

```
#define CC_SLIDER_CHANGE WM_USER + 611
```

```
// LOWORD(wParam) = ctrlID,
```

```
// lParam = pointer to ISliderControl
```

```
#define CC_SLIDER_BUTTONDOWN WM_USER + 612
```

```
// LOWORD(wParam) = ctrlID,
```

```
// HIWORD(wParam) = FALSE if user cancelled - TRUE  
otherwise
```

```
// lParam = pointer to ISliderControl
```

```
#define CC_SLIDER_BUTTONUP WM_USER + 613
```

# Class Spline3D

See Also: [Class SplineKnot](#), [Class PolyLine](#), [Structure Knot](#).

class Spline3D

## Description:

General-purpose 3D spline class. The **BezierShape** class has a list of these splines that make up the bezier shape. Methods of this class are used to access the properties of the spline. All methods of this class are implemented by the system.

## Method Groups:

The following hyperlinks take you to the start of groups of related methods within the class:

## Friend Classes:

**friend class BezierShape;**

**friend class SplineShape;**

**Methods:**

## **Constructors / Destructor**

**Prototype:**

```
Spline3D(int itype = KTYPE_CORNER,int dtype =  
KTYPE_BEZIER,  
int ptype = PARM_UNIFORM);
```

**Remarks:**

Constructor. The data members are initialized to the values passed.

**Prototype:**

```
~Spline3D();
```

**Remarks:**

Destructor.

## **NewSpline() / InvalidateGeomCache()**

**Prototype:**

```
void NewSpline();
```

**Remarks:**

This method clears out the spline. It frees the knots attributes array and the bezier points array.

**Prototype:**

```
void InvalidateGeomCache();
```

**Remarks:**

This method makes sure the shape has flushed out any cached data it may have had.

## **KnotCount(), Flags(), Segments(), Closed()**

**Prototype:**

**inline int KnotCount()**

**Remarks:**

Returns the Knot (point) count.

**Prototype:**

**inline int Flags();**

**Remarks:**

Returns the private spline flags.

**SPLINE\_CLOSED**

This indicates if the spline is closed or not.

**Prototype:**

**inline int Segments();**

**Remarks:**

Returns the number of line segments in the spline. For example if you have a 4 knot spline that is open you'll get 3 segments.

**Prototype:**

**inline int Closed();**

**Remarks:**

Returns the closed status. Nonzero if closed; otherwise zero.

**AddKnot(), DeleteKnot(), GetKnot, SetKnot()**

**Prototype:**

**int AddKnot(SplineKnot &k,int where = -1);**

**Remarks:**

Add a knot to the spline at the specified location.

**Parameters:**

**SplineKnot &k**

The knot to add.

**int where = -1**

The location to add the knot. **where** < 0 indicates the end of the spline.

**Return Value:**

Nonzero on success; otherwise zero.

**Prototype:**

**int DeleteKnot(int where);**

**Remarks:**

Delete the specified knot.

**Parameters:**

**int where**

The location of the knot to delete.

**Return Value:**

Nonzero if the knot was deleted; otherwise zero.

**Prototype:**

**void SetKnot(int i, SplineKnot &k);**

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the 'i-th' knot object which contain the knot point, in and out vectors, knot and line types and auxiliary values.

**Parameters:**

**int i**

Specifies the knot to set.

**SplineKnot &k**

The knot to set.

**Prototype:**

**SplineKnot GetKnot(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

This method gets the 'i-th' knot object which contain the knot point, in and out vectors, knot and line types and auxiliary values.

**Parameters:**

**int i**

Specifies the knot to retrieve.

## **Create() / StartInsert()**

**Prototype:**

```
int Create(ViewExp *vpt,int msg, int point, int flags, IPoint2 m,  
Matrix3* mat, IObjParam *ip=NULL);
```

**Remarks:**

This method is used internally by the free form line object **SPLINE.CPP**. This method allows the user to use the mouse to create a line. See the sample code in **\MAXSDK\SAMPLES\OBJECTS\SPLINE.CPP** for an example of this method in use.

New for 3ds max 2.0 is an additional parameter is a pointer to an **IObjParam** object, which is used to access the **DisplayTempPrompt()** mechanism. The parameter is optional; omitting it allows the spline operation to work as in 3ds max 1.x. Adding the parameter causes the spline to display the delta, distance and angle of the current segment being edited.

**Prototype:**

```
int StartInsert(ViewExp *vpt,int msg, int point, int flags,  
IPoint2 theP, Matrix3* mat, int where );
```

**Remarks:**

This method is used internally by the free form line object **SPLINE.CPP**. See the sample code in **\MAXSDK\SAMPLES\OBJECTS\SPLINE.CPP** for an example of this method in use.

## **Get/SetKnotType() / Get/SetLineType()**

**Prototype:**

**inline int GetKnotType(int index);**

**Remarks:**

Returns the knot type from the specified knot. See [List of Spline Knot Types](#).

**Parameters:**

**int index**

The index of the knot type to return.

**Prototype:**

**int SetKnotType(int index,int type);**

**Remarks:**

Sets the knot type of the specified knot.

**Parameters:**

**int index**

The knot to set.

**int type**

See [List of Spline Knot Types](#).

**Return Value:**

Nonzero if set; otherwise zero.

**Prototype:**

**inline int GetLineType(int index);**

**Remarks:**

Returns the type of line segment between knots for the specified segment.

**Parameters:**

**int index**

The index of the segment whose line type to return.

**Return Value:**

See [List of Spline Line Types](#).

**Prototype:**

**int SetLineType(int index,int type);**

**Remarks:**

Sets the line type of the specified segment.

**Parameters:****int index**

The index of the segment.

**int type**

See [List of Spline Line Types](#).

**Return Value:**

Nonzero if set; otherwise zero.

**ComputeBezPoints()****Prototype:**

```
void ComputeBezPoints();
```

**Remarks:**

This method should be called whenever you finish changing points on the spline. This updates all the information internal to the spline needed to calculate all the bezier handles.

**InterpBezier() / InterpBezier3D() / TangentBezier3D() /  
TangentCurve3D()****Prototype:**

```
Point2 InterpBezier(IPoint2 *bez, float t);
```

**Remarks:**

Developers should use **InterpBezier3D()** below instead of this method and just use the x and y values returned.

**Prototype:**

```
Point3 InterpBezier3D(int segment, float t, int  
ptype=SPLINE_INTERP_SIMPLE);
```

**Remarks:**

This method returns a point interpolated on a segment between two knots.

**Parameters:****int segment**

The index of the segment to interpolate.

**float t**

A value in the range of 0.0 to 1.0. 0 is the first knot and 1 is the second knot.

**int ptype=SPLINE\_INTERP\_SIMPLE**

The spline type to use.

**Return Value:**

The interpolated point.

**Prototype:**

```
Point3 InterpCurve3D(float u, int  
ptype=SPLINE_INTERP_SIMPLE);
```

**Remarks:**

This method returns a point interpolated on the entire curve. This method returns a point but you don't know which segment the point falls on. Typically the method **InterpBezier3D()** will give better control of the curve as it interpolates a bezier segment.

**Parameters:****float u**

A value in the range of 0.0 to 1.0 for the entire curve.

**int ptype=SPLINE\_INTERP\_SIMPLE**

The spline type to use.

**Return Value:**

The interpolated point.

**Prototype:**

```
Point3 TangentBezier3D(int segment, float t, int  
ptype=SPLINE_INTERP_SIMPLE);
```

**Remarks:**

This method returns a tangent vector interpolated on a segment between two knots.

**Parameters:****int segment**

The index of the segment.

**float t**

A value in the range of 0.0 to 1.0. 0 is the first knot and 1 is the second knot.

**int ptype=SPLINE\_INTERP\_SIMPLE**

The spline type to use.

**Return Value:**

The tangent vector.

**Prototype:****Point3 TangentCurve3D(float u, int  
ptype=SPLINE\_INTERP\_SIMPLE);****Remarks:**

This method returns a tangent vector interpolated on the entire curve.

**Parameters:****float u**

A value in the range of 0.0 to 1.0 for the entire curve.

**int ptype=SPLINE\_INTERP\_SIMPLE**

The spline type to use.

**Return Value:**

The tangent vector.

**IsAuto() / IsBezierPt() / IsCorner()****Prototype:****int IsAuto(int i);****Remarks:**Returns nonzero if the knot type is **KTYPE\_AUTO** otherwise zero.**Parameters:****int i**

The index of the knot.

**Prototype:**

**int IsBezierPt(int i);**

**Remarks:**

Returns nonzero if the knot type is **KTYPE\_BEZIER** otherwise zero.

**Parameters:**

**int i**

The index of the knot.

**Prototype:**

**int IsCorner(int i);**

**Remarks:**

Returns nonzero if the knot type is **KTYPE\_CORNER** otherwise zero.

**Parameters:**

**int i**

The index of the knot.

## **GetBBox() / Transform()**

**Prototype:**

**void GetBBox(TimeValue t, Matrix3& tm, Box3& box);**

**Remarks:**

Returns the bounding box of the curve in the space specified by the **tm**.

**Parameters:**

**TimeValue t**

This parameter is not used.

**Matrix3& tm**

The **tm** to transform the points by prior to computing the bounding box.

**Box3& box**

The bounding box

**Prototype:**

**void Transform(Matrix3 \*tm);**

**Remarks:**

This method may be used to transform the points of the spline into another space defined by the specified transformation matrix.

**Parameters:**

**Matrix3 \*tm**

The transformation matrix.

**SetClosed / SetOpen()****Prototype:**

**int SetClosed(int flag = 1);**

**Remarks:**

This method may be used to close or open the spline. If the optional parameter is not specified it is closed.

**Parameters:**

**int flag = 1**

Nonzero to close; zero to open.

**Return Value:**

Nonzero if changed, zero if not.

**Prototype:**

**int SetOpen();**

**Remarks:**

Sets the spline to open.

**Return Value:**

Nonzero if changed, zero if not.

**Get/SetInVec() / Get/SetKnotPoint() Get/SetOutVec()****Prototype:**

**Point3 GetInVec(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to retrieve the 'i-th' in vector position in absolute coordinates.

**Parameters:**

**int i**

The vector position to retrieve.

**Prototype:**

**void SetInVec(int i, const Point3 &p);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to set the 'i-th' in vector position in absolute coordinates.

**Parameters:**

**int i**

The position to alter.

**const Point3 &p**

The value to set in absolute coordinates.

**Prototype:**

**Point3 GetRelInVec(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to retrieve the 'i-th' in vector position relative to the knot point.

**Parameters:**

**int i**

The position to retrieve.

**Prototype:**

**void SetRelInVec(int i, const Point3 &p);**

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the 'i-th' bezier in vector position relative to the knot point.

**Parameters:**

**int i**

The vector to set.

**const Point3 &p**

The vector data to set, relative to the knot point.

**Prototype:**

**Point3 GetKnotPoint(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

This methods returns the 'i-th' knot point.

**Parameters:**

**int i**

Specifies which knot point to get.

**Prototype:**

**void SetKnotPoint(int i, const Point3 &p);**

**Remarks:**

This method is available in release 2.0 and later only.

This methods sets the 'i-th' knot point to the specified value.

**Parameters:**

**int i**

Specifies which knot point to set.

**const Point3 &p**

The value to set.

**Prototype:**

**Point3 GetOutVec(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to retrieve the 'i-th' out vector position in absolute coordinates.

**Parameters:****int i**

Specifies which out vector point to get.

**Prototype:****void SetOutVec(int i, const Point3 &p);****Remarks:**

This method is available in release 2.0 and later only.

This method is used to set the 'i-th' out vector position in absolute coordinates.

**Parameters:****int i**

Specifies which out vector point to get.

**const Point3 &p**

The out vector to set in absolute coordinates.

**Prototype:****Point3 GetRelOutVec(int i);****Remarks:**

This method is available in release 2.0 and later only.

This method is used to retrieve the 'i-th' out vector position relative to the knot point.

**Parameters:****int i**

Specifies the point to get.

**Prototype:****void SetRelOutVec(int i, const Point3 &p);****Remarks:**

This method is available in release 2.0 and later only.

This method is used to set the 'i-th' out vector position relative to the knot point.

**Parameters:**

**int i**

Specifies the point to set.

**const Point3 &p**

The out vector position to set relative to the knot point.

**Get/SetVert() / Verts() / KnotPoint()**

**Prototype:**

**inline Point3& GetVert(int i);**

**Remarks:**

Each control point is made up of three points. The in vector coming off the bezier control point, the knot point itself, and the out vector. There are these three points for every control point. This method will return any item in this list.

**Parameters:**

**int i**

The index into the vertex list.

**Prototype:**

**inline void SetVert(int i, const Point3& p);**

**Remarks:**

This method should not be used.

**Prototype:**

**inline int Verts();**

**Remarks:**

Returns the number of vertices. This is always the number of knots times 3.

**Prototype:**

**int GetAux(int knot);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the auxiliary data associated with the specified knot. This is used internally for tracking topological changes to the spline during editing.

Developers can use it for temporary purposes but it will be altered by the EditableSpline (SplineShape) code.

**Parameters:**

**int knot**

The knot to retrieve the data from.

**Prototype:**

**void SetAux(int knot, int value);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the first integer auxiliary data associated with the specified knot.

**Parameters:**

**int knot**

Specifies the knot to whose auxiliary data is set.

**int value**

The value to set.

**Prototype:**

**int GetAux2(int knot);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the second integer auxiliary data associated with the specified knot

**Parameters:**

**int knot**

The knot to retrieve the data from.

**Prototype:**

**void SetAux2(int knot, int value);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the second integer auxiliary data associated with the specified knot.

**Parameters:**

**int knot**

Specifies the knot to whose auxiliary data is set.

**int value**

The value to set.

**Prototype:**

**int GetAux3(int knot);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the third integer auxiliary data associated with the specified knot.

This field is available for any use.

**Parameters:**

**int knot**

Specifies the knot to whose auxiliary data is returned.

**Prototype:**

**void SetAux3(int knot, int value);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the third integer auxiliary data associated with the specified knot. This field is available for any use.

**Parameters:**

**int knot**

Specifies the knot whose auxiliary data is set.

**int value**

The value to set.

**Prototype:**

**int GetKnotAux(int knot, int which);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the specified integer auxiliary data associated with the specified knot.

**Parameters:****int knot**

Specifies the knot whose auxiliary data is returned.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**Prototype:**

```
void SetKnotAux(int knot, int which, int value);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified integer auxiliary data associated with the specified knot.

**Parameters:****int knot**

Specifies the knot whose auxiliary data is set.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**int value**

The value to set.

**Prototype:**

```
int GetInAux(int knot, int which);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the specified integer auxiliary data associated with the specified in vector.

**Parameters:**

**int knot**

Specifies the knot whose auxiliary data is returned.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**Prototype:**

**void SetInAux(int knot, int which, int value);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified integer auxiliary data associated with the specified in vector.

**Parameters:**

**int knot**

Specifies the knot whose auxiliary data is set.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**int value**

The value to set.

**Prototype:**

**int GetOutAux(int knot, int which);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the specified integer auxiliary data associated with the specified out vector.

**Parameters:****int knot**

Specifies the knot whose auxiliary data is returned.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**Prototype:**

**void SetOutAux(int knot, int which, int value);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified integer auxiliary data associated with the specified out vector.

**Parameters:****int knot**

Specifies the knot whose auxiliary data is set.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**int value**

The value to set.

**Prototype:**

**int GetVertAux(int i, int which);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the specified integer auxiliary data associated with the specified bezier vertex.

**Parameters:****int i**

The zero based bezier vertex index.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**Prototype:**

**void SetVertAux(int i, int which, int value);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified integer auxiliary data associated with the specified bezier vertex.

**Parameters:****int i**

The zero based bezier vertex index.

**int which**

Specifies which auxiliary field. One of the following values:

**0**=aux1

**1**=aux2

**2**=aux3

**int value**

The value to set.

**Prototype:**

**MtlID GetMatID(int seg);**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the material ID for the specified spline segment.

**Parameters:****int seg**

The zero based index of the segment.

**Prototype:****void SetMatID(int seg, MtlID id);****Remarks:**

This method is available in release 3.0 and later only.  
Sets the material ID for the specified spline segment.

**Parameters:****int seg**

The zero based index of the segment.

**MtlID id**

The material ID to set.

**Prototype:****void GetSmoothingMap(IntTab &map);****Remarks:**

This method is available in release 3.0 and later only.

This method allows this Spline3D to create a map of smoothing groups that eases the creation of meshes.

It fills in a developer supplied IntTab with smoothing groups for each segment of the spline. A spline with 4 segments will cause the IntTab to be set to 4 entries, for example.

Five smoothing groups are used for this operation, 1<<0 through 1<<4. Once you have them, you can shift them as needed for your application. The smoothing groups are set up so that segments connected by knots with **KTYPE\_SMOOTH** or **KTYPE\_BEZIER** types are smoothed together.

**Parameters:**

## IntTab &map

A table of integers. See [Template Class Tab](#).

## Reverse() / Append() / Prepend()

### Prototype:

```
void Reverse(BOOL keepZero = FALSE, BOOL  
weldCoincidentFirstVertex=TRUE);
```

### Remarks:

This method reverses all the points of the spline.

### Parameters:

**BOOL keepZero = FALSE**

This optional parameter is available in release 2.0 and later only.

This parameter defaults to FALSE in order to retain backwards compatibility. Setting it to TRUE insures that a closed spline will have the same vertex as its first point when it is reversed. The parameter is ignored on open splines.

**BOOL weldCoincidentFirstVertex=TRUE**

Set this to TRUE to weld coincident first vertices. FALSE to disable welding.

### Prototype:

```
void Append(Spline3D *spline, BOOL  
weldCoincidentFirstVertex=TRUE);
```

### Remarks:

This method appends the specified spline onto the end of this one. The splines should both be opened.

### Parameters:

**Spline3D \*spline**

The spline to append.

**BOOL weldCoincidentFirstVertex=TRUE**

Set this to TRUE to weld coincident first vertices. FALSE to disable welding.

### Prototype:

```
void Prepend(Spline3D *spline);
```

**Remarks:**

This method takes the specified spline and puts it on the front of this spline.

**Parameters:**

**Spline3D \*spline**

The spline to prepend.

**IsClockWise() / SelfIntersects() / IntersectsSpline() / SurroundsPoint() / SplineLength()****Prototype:**

**BOOL IsClockWise();**

**Remarks:**

Returns TRUE if the spline is clockwise in the XY plane (it ignores Z); otherwise FALSE. This call is meaningless if the shape self intersects.

**Prototype:**

**BOOL SelfIntersects();**

**Remarks:**

Returns TRUE if the spline intersects itself in the XY plane (it ignores Z); otherwise FALSE.

**Prototype:**

**BOOL IntersectsSpline(Spline3D \*spline);**

**Remarks:**

Returns TRUE if this spline intersects the specified spline in the XY plane (it ignores Z); otherwise FALSE.

**Parameters:**

**Spline3D \*spline**

The spline to check.

**Prototype:**

**BOOL SurroundsPoint(Point2 p);**

**Remarks:**

Returns TRUE if the specified point is surrounded (contained within) this spline.

**Parameters:****Point2 p**

The point to check.

**Prototype:**

**float SplineLength();**

**Remarks:**

Returns the length of the spline.

**Prototype:**

**float SegmentLength(int seg);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the length of the specified segment of this spline.

**Parameters:****int seg**

The zero based index of the segment to check.

**MakePolyLine()****Prototype:**

**void MakePolyLine(PolyLine &line, int steps = -1, BOOL optimize = FALSE);**

**Remarks:**

This creates a PolyLine from this spline given a steps setting and an optimize parameter.

Note the following constraints on this method. When a ShapeObject is asked to output a PolyShape with a given number of steps and FALSE is specified for optimization, it must output a PolyLine with  $[\text{steps} * \text{pieces} + \text{pieces} + 1]$  vertices if it's an open shape and  $[\text{steps} * \text{pieces} + \text{pieces}]$  vertices if it's closed.

**Parameters:****PolyLine &line**

The result is stored here.

**int steps = -1**

The number of steps between knots in the spline.

**BOOL optimize = FALSE**

If TRUE, linear segments between control points in the spline will not generate steps in between. It will just be one line segment.

**Dump()****Prototype:****void Dump(int where);****Remarks:**

This displays data about the specified knot using **DebugPrints()**. See [Debugging](#).

**Parameters:****int where**

The index of the knot.

**Internal Methods / Methods that should not be used by plug-in developers****Prototype:****int ShiftKnot(int where, int direction);****Remarks:**

This method is used internally.

**Prototype:****Point3 AverageTangent(int i);****Remarks:**

This method should not be used.

**Prototype:**

**void MakeBezCont(int i);**

**Remarks:**

This method should not be used.

**Prototype:**

**void RedistTangents(int i, Point3 d);**

**Remarks:**

This method should not be used.

**Prototype:**

**void FixAdjBezTangents(int i);**

**Remarks:**

This method should not be used.

**Prototype:**

**void DrawCurve(GraphicsWindow \*gw, Material \*mtl);**

**Remarks:**

This method should not be used.

**Prototype:**

**inline void SetEditMode(int mode);**

**Remarks:**

This method should not be used.

**Prototype:**

**IPoint2 ProjectPoint(ViewExp \*vpt, Point3 fp, Matrix3 \*mat);**

**Remarks:**

This method is used internally.

**Prototype:**

**Point3 UnProjectPoint(ViewExp \*vpt, IPoint2 p, Matrix3 \*mat);**

**Remarks:**

This method is used internally.

**Prototype:**

**void Snap(GraphicsWindow \*gw, SnapInfo \*snap, IPoint2 \*p, Matrix3 &tm);**

**Remarks:**

This method is used internally.

**Prototype:**

**IOResult Save(ISave \*isave);**

**Remarks:**

This method is used internally to save the class data from disk.

**Prototype:**

**IOResult Load(ILoad \*iload);**

**Remarks:**

This method is used internally to load the class data from disk.

**Prototype:**

**Point3 GetDragVector(ViewExp \*vpt, IPoint2 p, int i, Matrix3\* mat);**

**Remarks:**

This method is used internally.

**Prototype:**

**int AppendPoint(ViewExp \*vpt, const Point3& p, int where = -1);**

**Remarks:**

This method is used internally.

**Prototype:**

**int DrawPhase();**

**Remarks:**

This method is used internally.

**Prototype:**

**int GetiCur();**

**Remarks:**

This method is used internally.

**Prototype:**

**inline int ParmType()**

**Remarks:**

This method is used internally.

**Prototype:**

**int SetParam(int index,float param);**

**Remarks:**

This method is used internally.

**Prototype:**

**float GetParam(int index);**

**Remarks:**

This method is used internally.

**Prototype:**

**virtual void CustomParams()**

**Remarks:**

This method is used internally.

**Prototype:**

**void CompParams();**

**Remarks:**

This method is used internally.

**Operators:****Prototype:**

**Spline3D& operator=(Spline3D& fromSpline);**

**Remarks:**

Assignment operator.

**Prototype:**

**Spline3D& operator=(PolyLine& fromLine);**

**Remarks:**

Assignment operator. This generates a PolyLine from the spline, where points are added in between the knots on the spline. For example if the steps value was 5, it will interpolate 5 points in between each knot on the spline.

## Class ShapeObject

See Also: [Class GeomObject](#), [Class PolyShape](#).

```
class ShapeObject : public GeomObject
```

### Description:

ShapeObjects are open or closed hierarchical shapes made up of one or more pieces. This base class defines a set of methods that plug-in shapes must implement.

Note: Many plug-in shapes may be derived from [Class SimpleSpline](#) rather than this class and have fewer methods to implement. See that class for more details.

In release 2.0 and later of 3ds max, ShapeObjects are now renderable. This has introduced a couple of important ramifications. First, any classes subclassing off of ShapeObject should be sure to call the ShapeObject constructor in their constructor, in order to properly initialize the fields contained in the ShapeObject. At present, this is the thickness field, which specifies the thickness of the mesh generated from the shape at rendering time. For example:

```
LinearShape::LinearShape() : ShapeObject() {  
    ...  
}
```

Second, the ShapeObject now contains Load and Save methods, which handle the storage of the data contained within the ShapeObject. In order to properly store this information, classes which subclass off of ShapeObject need to call the ShapeObject Load and Save methods before storing their information. For example:

```
IOResult LinearShape::Save(ISave *isave) {  
    IOResult res = ShapeObject::Save(isave);  
    if(res != IO_OK)  
        return res;  
    ...  
}
```

```
IOResult LinearShape::Load(ILoad *iload) {  
    IOResult res = ShapeObject::Load(iload);
```

```
if(res != IO_OK)
    return res;
    ...
}
```

The number of ShapeObject references/subanimns are defined as **SHAPE\_OBJ\_NUM\_REFS** and **SHAPE\_OBJ\_NUM\_SUBS** in `\include\object.h` and are set to the number of references and subanimns in the ShapeObject class, you can use them to make your code more bullet-proof should the number of references change in the future. See `maxsdk\include\splshape.h` for an example of how they can be used.

**Methods:**

**Prototype:**

```
void CopyBaseData(ShapeObject &from);
```

**Remarks:**

This method is available in release 2.0 and later only.

In order to simplify things for subclasses of ShapeObject, this method is now available. It should be called whenever the ShapeObject-based object is copied. It takes care of copying all the data to the ShapeObject from another ShapeObject-based object

Implemented by the System.

**Parameters:**

**ShapeObject &from**

The ShapeObject to copy from.

**Prototype:**

```
virtual int IntersectRay(TimeValue t, Ray& ray, float& at, Point3& norm)
```

**Remarks:**

Implemented by the Plug-In.

Computes the intersection point of the ray passed and the shape.

Note: In release 3 and later this method has a default implementation and it is no longer necessary to define this method in classes derived from

## **ShapeObject.**

### **Parameters:**

#### **TimeValue t**

The time to compute the intersection.

#### **Ray& ray**

Ray to intersect.

#### **float& at**

The point of intersection.

#### **Point3& norm**

This parameter is available in release 3.0 and later only.

The surface normal at the point of intersection.

### **Return Value:**

Nonzero if a point of intersection was found; otherwise 0.

### **Default Implementation:**

```
{return FALSE;}
```

## **Access methods**

### **Prototype:**

```
virtual BOOL GetRenderable();
```

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

The ShapeObject class now has a "renderable" flag contained within it. Access to this is via this method and SetRenderable(). If this is set to TRUE and the node is set to renderable, the spline will be rendered. This defaults to FALSE.

### **Prototype:**

```
virtual void SetRenderable(BOOL sw);
```

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Sets the rendering flag to the specified value.

**Parameters:**

**BOOL sw**

TRUE for on; FALSE for off.

**Prototype:**

**virtual float GetThickness(TimeValue t, Interval &ivalid);**

**Remarks:**

Implemented by the System.

Returns the shape's thickness setting.

**Parameters:**

**TimeValue t**

This parameter is available in release 4.0 and later only.

The time to obtain the thickness.

**Interval &ivalid**

This parameter is available in release 4.0 and later only.

The validity interval.

**Prototype:**

**virtual void SetThickness(TimeValue t, float thick);**

**Remarks:**

Implemented by the System.

Sets the thickness setting of the shape to the specified value.

**Parameters:**

**TimeValue t**

This parameter is available in release 4.0 and later only.

The time at which to set the thickness.

**float thick**

The new thickness setting for the shape.

**Prototype:**

**int GetSides(TimeValue t, Interval &ivalid);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the number of sides for the cross-section of the rendering mesh version of the shape for the specified time.

**Parameters:**

**TimeValue t**

The time to obtain the thickness.

**Interval &ivalid**

The validity interval.

**Prototype:**

**void SetSides(TimeValue t, int s);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the number of sides for the rendering mesh version of the shape for the specified time. The allowable ranges for this parameter are 3-100.

**Parameters:**

**TimeValue t**

The time at which to set the number of sides.

**int s**

The number of sides you wish to set.

**Prototype:**

**float GetAngle(TimeValue t, Interval &ivalid);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the angle that the cross-section of the rendering mesh will be rotated to, for the specified time.

**Parameters:**

**TimeValue t**

The time to obtain the thickness.

### **Interval &ivalid**

The validity interval.

### **Prototype:**

**void SetAngle(TimeValue t, float a);**

### **Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the cross-section rotation angle for the rendering mesh version of the shape, in degrees, for the specified time.

### **Parameters:**

#### **TimeValue t**

The time at which to set the angle.

#### **float a**

The angle you wish to set, in degrees.

### **Prototype:**

**float GetViewportThickness();**

### **Remarks:**

This method is available in release 4.0 and later only.

This method returns the thickness of the viewport version of the rendering mesh. This is not an animated parameter.

### **Prototype:**

**int GetViewportSides();**

### **Remarks:**

This method is available in release 4.0 and later only.

This method returns the number of sides for the cross-section for the viewport version of the rendering mesh. This is not an animated parameter.

### **Prototype:**

**void SetViewportSides(int s);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the number of sides for the viewport version of the rendering mesh. This is not an animated parameter.

**Parameters:**

**int s**

The number of viewport sides you wish to set.

**Prototype:**

**float GetViewportAngle();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the angle that the cross-section of the viewport version of the rendering mesh will be rotated to. This is not an animated parameter.

**Prototype:**

**void SetViewportAngle(float a);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the angle that the cross-section of the viewport version of the rendering mesh will be rotated to, in degrees. This is not an animated parameter.

**Parameters:**

**float a**

The viewport angle you wish to set, in degrees.

**Prototype:**

**BOOL GetDispRenderMesh();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns TRUE if the "Display Render Mesh" switch is on. FALSE when the switch is off.

**Prototype:**

**void SetDispRenderMesh(BOOL sw);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to turn the "Display Render Mesh" switch on or off.

**Parameters:**

**BOOL sw**

TRUE or FALSE to set or unset the "Display Render Mesh" switch.

**Prototype:**

**BOOL GetUseViewport();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns TRUE if the "Use Viewport Settings" switch is on.

FALSE when the switch is off.

**Prototype:**

**void SetUseViewport(BOOL sw);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to turn the "Use Viewport Settings" switch on or off.

**Parameters:**

**BOOL sw**

TRUE or FALSE to set or unset the "Use Viewport Settings" switch.

**Prototype:**

**BOOL GetViewportOrRenderer();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the value of the Viewport/Render switch and either returns **GENMESH\_VIEWPORT** or **GENMESH\_RENDER**.

**Prototype:**

**void SetViewportOrRenderer(BOOL sw);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the value of the Viewport/Render switch.

**Parameters:**

**BOOL sw**

Set this parameter to **GENMESH\_VIEWPORT** or **GENMESH\_RENDER**.

**Prototype:**

**virtual BOOL GetGenUVs();**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Returns TRUE if the generate UVs switch is on; FALSE if off.

**Prototype:**

**virtual void SetGenUVs(BOOL sw);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Pass TRUE to set the generate UVs switch to on; FALSE to set it off.

**Parameters:**

**BOOL sw**

TRUE for on; FALSE for off.

**Prototype:**

**void GetRenderMeshInfo(TimeValue t, INode \*inode, View& view, int &nverts, int &nfaces);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns information on the rendering mesh.

Implemented by the System.

**Parameters:**

**TimeValue t**

The time to get the information.

**INode \*inode**

The node associated with the mesh.

**View& view**

Describes properties of the view associated with the render. See [Class View](#).

**int &nverts**

The number of vertices in the render mesh.

**int &nfaces**

The number of faces in the render mesh.

**Prototype:**

**virtual int NumberOfVertices(TimeValue t, int curve = -1);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method is used by the Summary Info and Object Properties dialogs to inform the user how many vertices or CVs are in the object. The method is passed a TimeValue and a curve index; if the curve index is <0, the function should return the number of vertices/CVs in the entire shape. Otherwise, it should return the number of vertices/CVs in the specified curve.

**Parameters:**

**TimeValue t**

The time at which the number of vertices is to be computed.

**int curve = -1**

The curve index. See note above.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual int NumberOfCurves()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the number of polygons in the shape.

**Prototype:**

**virtual BOOL CurveClosed(TimeValue t, int curve)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the specified curve of the shape is closed at the time passed.

**Parameters:**

**TimeValue t**

The time to check.

**int curve**

The index of the curve to check.

**Return Value:**

TRUE if the curve is closed; otherwise FALSE.

**Prototype:**

**virtual Point3 InterpCurve3D(TimeValue t, int curve, float param, int ptype=PARAM\_SIMPLE)=0;**

**Remarks:**

Implemented by the Plug-In.

This method returns a point interpolated on the entire curve. This method returns the point but you don't know which segment the point falls on. See method **InterpPiece3D()**.

**Parameters:**

**TimeValue t**

The time to evaluate.

**int curve**

The index of the curve to evaluate.

**float param**

The 'distance' along the curve where 0 is the start and 1 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The interpolated point on the curve.

**Prototype:**

```
virtual Point3 TangentCurve3D(TimeValue t, int curve, float param, int ptye=PARAM_SIMPLE)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method returns a tangent vector interpolated on the entire curve. Also see method **TangentPiece3D()**.

**Parameters:**

**TimeValue t**

The time at which to evaluate the curve.

**int curve**

The index of the curve to evaluate.

**float param**

The 'distance' along the curve where 0.0 is the start and 1.0 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The tangent vector

**Prototype:**

```
virtual float LengthOfCurve(TimeValue t, int curve)=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the length of the specified curve.

Note: This method makes no allowance for non-uniform scaling in the object transform. To do that, see the following code fragment (**os** is the **ObjectState** with the shape object and **xfm** is the NodeTM of the shape object node).

```
if (os.obj->SuperClassID() == SHAPE_CLASS_ID) {  
    ShapeObject *sobj;  
    sobj = (ShapeObject *) os.obj;  
    int cct = sobj->NumberOfCurves();  
    PolyShape workShape;  
    sobj->MakePolyShape(ip->GetTime(), workShape);  
    workShape.Transform(xfm);  
    float len = 0.0f;  
    for (int i=0; i<cct; i++)  
        len += workShape.lines[i].CurveLength();  
    }
```

**Parameters:**

**TimeValue t**

The time at which to compute the length.

**int curve**

The index of the curve.

**Prototype:**

```
virtual int NumberOfPieces(TimeValue t, int curve)=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the number of sub-curves in a curve.

**Parameters:**

**TimeValue t**

The time at which to check.

**int curve**

The index of the curve.

**Prototype:**

**virtual Point3 InterpPiece3D(TimeValue t, int curve,  
int piece, float param, int ptye=PARAM\_SIMPLE)=0;**

**Remarks:**

Implemented by the Plug-In.

This method returns the interpolated point along the specified sub-curve (segment). For example consider a shape that is a single circle with four knots. If you called this method with curve=0 and piece=0 and param=0.0 you'd get back the point at knot 0. If you passed the same parameters except param=1.0 you'd get back the point at knot 1.

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The curve to evaluate.

**int piece**

The segment to evaluate.

**float param**

The position along the curve to return where 0.0 is the start and 1.0 is the end.

**int ptye=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The point in world space.

**Prototype:**

**virtual Point3 TangentPiece3D(TimeValue t, int curve,  
int piece, float param, int ptye=PARAM\_SIMPLE)=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the tangent vector on a sub-curve at the specified 'distance' along the

curve.

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The curve to evaluate.

**int piece**

The sub-curve (segment) to evaluate.

**float param**

The position along the curve to return where 0 is the start and 1 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The tangent vector.

**Prototype:**

**virtual MtlID GetMatID(TimeValue t, int curve, int piece);**

**Remarks:**

Implemented by the Plug-In.

This method is available in release 3.0 and later only.

This method provides access to the material IDs of the shape. It returns the material ID of the specified segment of the specified curve of this shape at the time passed. There is a default implementation so there is no need to implement this method if the shape does not support material IDs.

Note: **typedef unsigned short MtlID;**

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The zero based index of the curve to evaluate.

**int piece**

The sub-curve (segment) to evaluate.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual BOOL CanMakeBezier()
```

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the shape can be converted to a bezier representation.

**Return Value:**

TRUE if the shape can turn into a bezier representation; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void MakeBezier(TimeValue t, BezierShape &shape);
```

**Remarks:**

Implemented by the Plug-In.

Creates the bezier representation of the shape.

**Parameters:**

**TimeValue t**

The time to convert.

**BezierShape &shape**

The bezier representation is stored here.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual ShapeHierarchy &OrganizeCurves(TimeValue t,  
ShapeHierarchy *hier=NULL)=0
```

**Remarks:**

Implemented by the Plug-In.

This method is called to prepare the shape for lofting, extrusion, etc. This methods looks at the shape organization, and puts together a shape hierarchy. This provides information on how the shapes are nested.

**Parameters:**

**TimeValue t**

The time to organize the curves.

**ShapeHierarchy \*hier=NULL**

This class provides information about the hierarchy. See [Class ShapeHierarchy](#).

**Prototype:**

```
virtual void MakePolyShape(TimeValue t, PolyShape &shape,  
    int steps = PSHAPE_BUILTIN_STEPS, BOOL optimize =  
    FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

Create a PolyShape representation with optional fixed steps.

**Parameters:**

**TimeValue t**

The time to make the **PolyShape**.

**PolyShape &shape**

The **PolyShape** representation is stored here.

**int steps = PSHAPE\_BUILTIN\_STEPS**

The number of steps between knots. Values  $\geq 0$  indicates the use of fixed steps:

**PSHAPE\_BUILTIN\_STEPS**

Use the shape's built-in steps/adaptive settings (default).

**PSHAPE\_ADAPTIVE\_STEPS**

Force adaptive steps.

**BOOL optimize = FALSE**

If TRUE intermediate steps are removed from linear segments.

**Prototype:**

```
virtual int MakeCap(TimeValue t, MeshCapInfo &capInfo, int capType)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method generates a mesh capping info for the shape.

**Parameters:****TimeValue t**

The time to create the cap info.

**MeshCapInfo &capInfo**

The cap info to update.

**int capType**

See [List of Cap Types](#).

**Return Value:**

Nonzero if the cap info was generated; otherwise zero.

**Prototype:**

```
virtual int MakeCap(TimeValue t, PatchCapInfo &capInfo)
```

**Remarks:**

Implemented by the Plug-In.

This method creates a patch cap info out of the shape. Only implement this method if **CanMakeBezier()** returns TRUE.

**Parameters:****TimeValue t**

The time to create the cap info.

**PatchCapInfo &capInfo**

The cap info to update.

**Return Value:**

Nonzero if the cap info was generated; otherwise zero.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual BOOL AttachShape(TimeValue t, INode *thisNode, INode
*attachNode, BOOL weldEnds=FALSE, float
weldThreshold=0.0f);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to attach the shape of **attachNode** to **thisNode** at the specified time. If any endpoints of the curves in the shape being attached are within the threshold distance to endpoints of an existing curve, and the weld flag is TRUE, they should be welded.

**Parameters:****TimeValue t**

The time to attach.

**INode \*thisNode**

This is the node associated with this shape object.

**INode \*attachNode**

The node of the shape to attach.

**BOOL weldEnds=FALSE**

This parameter is available in release 3.0 and later only.

If TRUE the endpoints of the shape should be welded together (based on the threshold below). If FALSE no welding is necessary.

**float weldThreshold=0.0f**

This parameter is available in release 3.0 and later only.

If any endpoints of the curves in the shape being attached are within this threshold distance to endpoints of an existing curve, and the weld flag is TRUE, they should be welded

**Return Value:**

Return TRUE if attached; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual IOResult Save(ISave *isave);
```

**Remarks:**

Implemented by the System.

This method handles the storage of the data contained within the ShapeObject. In order to properly store this information, classes which subclass off of ShapeObject need to call this methods before storing their information.

**Parameters:****ISave \*isave**

An interface for saving data. See [Class ISave](#).

**Prototype:**

**virtual IOResult Load(ILoad \*iload);**

**Remarks:**

Implemented by the System.

This method handles the loading of the data contained within the ShapeObject. In order to properly load this information, classes which subclass off of ShapeObject need to call this methods before loading their information.

**Parameters:****ILoad \*iload**

An interface for loading data. See [Class ILoad](#).

**Prototype:**

**virtual Class\_ID PreferredCollapseType();**

**Remarks:**

Implemented by the System.

This is an implementation of the **Object** method. It simply returns **splineShapeClassID**.

**Prototype:**

**virtual BOOL GetExtendedProperties(TimeValue t, TSTR &prop1Label, TSTR &prop1Data, TSTR &prop2Label, TSTR &prop2Data);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This is an implementation of the **Object** method. It fills in the property fields with the number of vertices and curves in the shape.

**Prototype:**

```
virtual void RescaleWorldUnits(float f);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Objects derived from this class which have RescaleWorldUnits methods implemented need to call this method. The following example is the

**SplineShape** implementation of this method from core.

```
void SplineShape::RescaleWorldUnits(float f) {  
    if (TestAFlag(A_WORK1))  
        return;  
    // Call the base class's rescale (this sets the A_WORK1 flag)  
    ShapeObject::RescaleWorldUnits(f);  
    // Now rescale stuff inside our data structures  
    Matrix3 stm = ScaleMatrix(Point3(f, f, f));  
    shape.Transform(stm);  
}
```

Note that the A\_WORK1 flags is tested first to be sure it isn't processing the rescale twice. The code then calls ShapeObject::RescaleWorldUnits, which sets the A\_WORK1 flag and performs the necessary rescale methods for all references for the object, and scales the renderable thickness value.

**Parameters:**

**float f**

The parameter to scale.

**Prototype:**

```
virtual void GenerateMesh(TimeValue t, int option, Mesh *mesh);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method will generate a mesh based on either the viewport or rendering parameters for the specified time.

**Parameters:****TimeValue t**

The time at which to generate the mesh.

**int option**

The option can be either GENMESH\_VIEWPORT, GENMESH\_RENDER, or GENMESH\_DEFAULT. When using the default definition the mesh generator will use whatever is in the Viewport/Render switch in the parameter block.

**Mesh \*mesh**

A pointer to a Mesh object. If this is set to NULL, the mesh will be generated and cached, but not returned.

**Prototype:**

```
virtual RefResult NotifyRefChanged(Interval changeInt,  
RefTargetHandle hTarget, PartID& partID, RefMessage  
message);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

This method will notify the Shape Object of changes in values in its parameter block. The ShapeObject's parameter block is reference number zero. If subclasses implement this method, they should pass any messages referring to the ShapeObject's parameter block to it. For example:

```
// If this isn't one of our references, pass it on to the ShapeObject...
```

```
if(hTarget == GetReference(0))  
    return ShapeObject::NotifyRefChanged(  
        changeInt, hTarget, partID, message);
```

This is a vital part of the mechanism; When a parameter in the parameter block changes, the ShapeObject must be able to flush its cached mesh which will no longer be valid.

**Parameters:****Interval changeInt**

This is the interval of time over which the message is active.

**RefTargetHandle hTarget**

This is the handle of the reference target the message was sent by. The reference maker uses this handle to know specifically which reference target sent the message.

**PartID& partID**

This contains information specific to the message passed in. Some messages don't use the partID at all. See the section [List of Reference Messages](#) for more information about the meaning of the partID for some common messages.

**RefMessage message**

The msg parameter passed into this method is the specific message which needs to be handled. See [List of Reference Messages](#).

**Return Value:**

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the message was processed. Sometimes, the return value may be **REF\_STOP**. This return value is used to stop the message from being propagated to the dependents of the item.

**Prototype:**

```
virtual RefTargetHandle GetReference(int i);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows the ShapeObject to return a pointer to its parameter block. Any subclasses implementing this method must pass on the call if it indicates the ShapeObject's reference. For example:

```
RefTargetHandle SomeShape::GetReference(int i) {  
    If(i == 0) return ShapeObject::GetReference(i);  
}
```

**Parameters:**

```
int i
```

The reference handle to retrieve.

**Return Value:**

The handle to the Reference Target.

**Prototype:**

```
virtual void SetReference(int i, RefTargetHandle rtarg);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method sets the ShapeObject's parameter block pointer. Any subclasses implementing this method must pass on the call to the ShapeObject if it refers to index 0. For example:

```
void SomeShape::SetReference(int i, RefTargetHandle rtarg) {  
    if(i == 0) ShapeObject::SetReference(i, rtarg);  
}
```

**Parameters:**

**int i**

The virtual array index of the reference to store.

**RefTargetHandle rtarg**

The reference handle to store.

**Prototype:**

```
virtual Animatable* SubAnim(int i);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the ShapeObject's animatable pointer. Derived classes implementing this method must pass on references to index 0 to the ShapeObject. For example::

```
Animatable* SomeShape::SubAnim(int i) {  
    if(i == 0) return ShapeObject::SubAnim(i);  
}
```

**Parameters:**

**int i**

This is the index of the sub-anim to return.

**Prototype:**

**virtual TSTR SubAnimName(int i);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the name of the animatable's name. Derived classes implementing this method must pass on references to index 0 to the ShapeObject. For example:

```
TSTR SomeShape::SubAnimName(int i) {  
    if(i == 0) return ShapeObject::SubAnimName(i);  
}
```

**Parameters:**

**int i**

This is the index of the sub-anim's name to return.

**Prototype:**

**ParamDimension \*GetParameterDim(int pbIndex);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the parameter dimension of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter to return the dimension of.

**Return Value:**

Pointer to a ParamDimension.

**Prototype:**

**TSTR GetParameterName(int pbIndex);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the name of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter to return the dimension of.

**Prototype:**

**virtual int RemapRefOnLoad(int iref);**

**Remarks:**

This method is available in release 4.0 and later only.

This method remaps references at load time so that files saved from previous versions of 3ds max get their references adjusted properly to allow for the new ShapeObject reference. If derived classes implement this method, they must properly pass on the call to the ShapeObject's code. An example from the SplineShape code:

```
int SplineShape::RemapRefOnLoad(int iref) {  
    // Have the ShapeObject do its thing first...  
    iref = ShapeObject::RemapRefOnLoad(iref);  
    if(loadRefVersion == ES_REF_VER_0)  
        return iref+1;  
    return iref;  
}
```

Note that the SplineShape first calls ShapeObject's remapper, then applies its remapping operation to the index returned by the ShapeObject code.

**IMPORTANT NOTE:** For this remapping to operate properly, the derived class **MUST** call ShapeObject::Save as the first thing in its ::Save method, and must call ShapeObject::Load as the first thing in its ::Load method. This allows the ShapeObject to determine file versions and the need for remapping references.

**Parameters:**

**int iref**

The input index of the reference.

**Return Value:**

The output index of the reference.

**Prototype:**

```
virtual int NumRefs();
```

**Remarks:**

This method is available in release 4.0 and later only.

The ShapeObject makes 1 reference; this is where it tells the system. Any derived classes implementing this method must take this into account when returning the number of references they make. A good idea is to implement NumRefs in derived classes as:

```
Int SomeShape::NumRefs() {  
    return myNumRefs + ShapeObject::NumRefs();  
}
```

**Default Implementation:**

```
{return 1;}
```

**Prototype:**

```
void BeginEditParams(IObjParam *ip, ULONG flags,Animatable  
*prev);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows the ShapeObject to create its new "Rendering" rollup. To use it, the derived class simply calls it first thing in its own BeginEditParams method. An example from the SplineShape code:

```
void SplineShape::BeginEditParams(IObjParam *ip, ULONG  
flags,Animatable *prev )  
{  
    ShapeObject::BeginEditParams(ip, flags, prev);  
    // ?  
}
```

**Parameters:**

```
IObjParam *ip
```

The interface pointer passed to the plug-in.

## **ULONG flags**

The flags passed along to the plug-in in **Animatable::BeginEditParams()**.

## **Animatable \*prev**

The pointer passed to the plug-in in **Animatable::BeginEditParams()**.

### **Prototype:**

```
void EndEditParams(IObjParam *ip, ULONG flags,Animatable *next);
```

### **Remarks:**

This method is available in release 4.0 and later only.

Similarly to BeginEditParams, this method allows the ShapeObject to remove its "Rendering" rollup. A derived class simply calls this first thing in its own EndEditParams. An example from the SplineShape code:

```
void SplineShape::EndEditParams( IObjParam *ip, ULONG flags,Animatable *next )
```

```
{  
    ShapeObject::EndEditParams(ip, flags, next);  
    // ?  
}
```

### **Parameters:**

#### **IObjParam \*ip**

The interface pointer passed to the plug-in.

#### **ULONG flags**

The flags passed along to the plug-in in **Animatable::BeginEditParams()**.

#### **Animatable \*prev**

The pointer passed to the plug-in in **Animatable::BeginEditParams()**.

### **Prototype:**

```
Interval GetShapeObjValidity(TimeValue t);
```

### **Remarks:**

This method is available in release 4.0 and later only.

This method gets the validity interval for the ShapeObject's internal

parameters only. It DOES NOT include those of the derived classes. So, if you called this method on a ShapeObject that was a circle with an animated radius, you wouldn't see the effect of the animated radius on the interval. All you'd see would be the interval of the ShapeObject's rendering parameters. To get the entire ShapeObject's interval, you would call **ShapeObject::ObjectShapeObjValidity(t).**

**Parameters:**

**TimeValue t**

The time about which the interval is computed.

**Prototype:**

**int Display(TimeValue t, INode \*inode, ViewExp\* vpt, int flags);**

**Remarks:**

This method is available in release 4.0 and later only.

This method displays the shape's generated mesh if necessary. Objects derived from ShapeObject will want to have the ShapeObject code display the rendering mesh in the viewport; this method will do that for them. Simply set the viewport transform and call this method. An example from the SplineShape code:

**int SplineShape::Display(TimeValue t, INode \*inode, ViewExp\* vpt, int flags)**

```
{  
    Eval(t);  
    GraphicsWindow *gw = vpt->getGW();  
    gw->setTransform(inode->GetObjectTM(t));  
    ShapeObject::Display(t, inode, vpt, flags);  
    // ?  
}
```

If the ShapeObject's "Display Render Mesh" switch is off, it will do nothing. Otherwise, it will display the proper mesh as specified by its parameter block.

**Parameters:**

**TimeValue t**

The time to display the object.

**INode\* inode**

The node to display.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**int flags**

See [List of Display Flags](#).

**Return Value:**

The return value is not currently used.

**Prototype:**

**virtual Box3 GetBoundingBox(TimeValue t, Matrix3 \*tm=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a bounding box for the shape, if it's active, if the "Display Render Mesh" switch is on. It is necessary to include this box when computing the bounding box for a shape, otherwise the viewport display will not work properly.

**Parameters:**

**TimeValue t**

The time to get the bounding box.

**Matrix3 \*tm**

The points of ShapeObject are transformed by this matrix prior to the bounding box computations.

**Prototype:**

**virtual void InvalidateGeomCache();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is very important. It causes the ShapeObject to flush its cached rendering mesh. Most objects have their own "InvalidateGeomCache"

methods; simply call this when a shape derived from ShapeObject changes and it will ensure that the rendering mesh is regenerated the next time it is evaluated. Failure to call this method will result in improper rendering mesh updates.

## Class CollisionObject

See Also: [Class Point3](#).

```
class CollisionObject : public InterfaceServer
```

### Description:

A collision object can be applied to a particle system by a Space Warp. The collision object checks a particle's position and velocity and determines if the particle will collide with it in the next **dt** amount of time. If so, it modifies the position and velocity.

### Methods:

### Prototype:

```
virtual BOOL CheckCollision(TimeValue t,Point3 &pos,  
    Point3 &vel, float dt, int index, float *ct=NULL, BOOL  
    UpdatePastCollide=TRUE)=0;
```

### Remarks:

Implemented by the Plug-In.

This method checks a particles position and velocity to determine if there was a collision between the particle and this collision object. If there was a collision, the particles position and velocity should be modified.

The plug-in may compute a line segment between where the particle is now, and where it will be in **dt** amount of time. The plug-in then checks if the line segment intersects the collision object. If so, it would compute the resulting position, and modify the velocity vector **vel** to point in the new direction (presumably reflected across the surface normal).

3ds max 3.0 introduced interparticle collision (where particles may collide with other particles). In order to implement interparticle collision (IPC) in the presence of collision objects, it became necessary to generalize the operation of the deflectors so that they didn't always work in discrete time intervals.

That is, in the general case of an unidentified number of particles interacting in an unspecified way, it was necessary to allow everything involved in that system to update to specified times without moving **past** that time.

In the absence of IPC enabled, the particle system calls the bound collision objects with the parameter **UpdatePastCollide == TRUE**, and the

deflector checks all collisions, updates particles based on their collisions with deflectors and the ensuing, remaining time intervals in **dt** subsequent to the collisions.

In the presence of IPC that won't work. When IPC is active, all particles need to be updated to the time of the first collision in the system in **dt**, whether that collision be between particles or between particles and deflectors. Thus, in the presence of IPC, all particle updates to bound deflectors are called with **UpdatePastCollide == FALSE**. In that case, the collision objects return both the position and velocity of the updated particles **and** the time at which the collision occurred.

All such times are compared, along with all possible internally calculated IPC event times. If there are any nonnegative times returned greater than or equal to zero, all particle states are reverted to their states at the beginning of the interval and then updated to the precise minimum time returned as the earliest collision. **And then** everything starts up again trying to update itself to the next integral time, when control can pass back to whatever is asking the particles to update themselves. If there are other collisions in that time, it happens again.

This whole set of operations happens after any true returns from the trilinear sort/sweep correlator that looks for the **possibility** of collisions. If there are no possible collisions, everything proceeds through a complete interval normally.

#### **Parameters:**

##### **TimeValue t**

The time to check for collision.

##### **Point3 &pos**

The position of the particle to check and potentially modify.

##### **Point3 &vel**

The velocity vector of the particle to check and potentially modify.

##### **float dt**

This is an increment of time - the step size. The method checks if the particle will collide in this amount of time.

##### **int index**

This parameter is available in release 2.0 and later only.

The index of the particle being collided.

**float \*ct=NULL**

This parameter is available in release 3.0 and later only.

An array of floating point times at which the collisions occurred.

**BOOL UpdatePastCollide=TRUE**

This parameter is available in release 3.0 and later only.

This is a flag to tell the collision object to update the particle past the collision to the remainder of input **dt** or to output the state of the particle at the collision. In the presence of interparticle collision enable, we have to update to the times of collisions and then retest from there. See the Remarks.

**Return Value:**

TRUE if there was a collision and the position and velocity have been modified; otherwise FALSE.

**Prototype:**

**virtual Object \*GetSWObject()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method provides a way of identifying the 'parent' Deflector for a CollisionObject available to a particle system. This must be implemented by all Deflectors. It returns the object pointer to the Deflector from which the Collision object is derived.

# Class ForceField

See Also: [Class Point3](#), [Class WSMObject](#).

class ForceField

## Description:

A Space Warp modifier usually uses an instance of this class and implements the **Force()** method. The force field is then applied to the particle system when the particle system is bound to the Space Warp. This class is similar in some respects to the Deformer class as used by a modifier. The difference is that a deformer modifies the points of the object. A force field is really an acceleration - it modifies velocity rather than position.

The force field provides a function of position in space, velocity and time that gives a force. The force is then used to compute an acceleration on a particle which modifies its velocity. Typically, particles are assumed to have a normalized uniform mass equal to 1 so the acceleration is  $F/M = F$ .

## Methods:

### Prototype:

```
virtual Point3 Force(TimeValue t, const Point3 &pos, const Point3  
&vel, int index)=0;
```

### Remarks:

Implemented by the Plug-In.

This method is called to compute a force on the particle based on its position, velocity and the current time.

### Parameters:

#### **TimeValue t**

The time to compute the force.

#### **const Point3 &pos**

The current position of the particle.

#### **const Point3 &vel**

The current velocity of the particle.

#### **int index**

This parameter is available in release 2.0 and later only.

The index of the particle being forced.

**Return Value:**

The force vector as a Point3. This vector is added to the velocity.

**Prototype:**

**virtual void DeleteThis();**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to delete this instance of the ForceField. This should be called, for example, by developers who use the

**WSMObject::GetForceField()** method.

**Default Implementation:**

```
{}
```

# Class Animatable

See Also: [Class Interface](#), [Class INode](#), [List of Animatable Flags](#), [Class IGraphObjectManager](#), [Class IGraphNode](#), [Class Object](#).

```
class Animatable : public InterfaceServer
```

## Description:

This is the base class for almost all classes related to animation. Methods are available for getting the ClassID and SuperClassID of the plug-in, deleting this instance of the plug-in class, and parameter editing in the command panel. There are also methods that deal with the sub-animatables of the plug-in. Most of the track view related methods are here as well.

## Method Groups

These hyperlinks take you to the start of groups of related methods within the class.

## [Custom Attributes](#)

### **Data Members:**

protected:

#### **unsigned long aflag;**

The flags. These may be manipulated using the methods **SetAFlag()**, **ClearAFlag()**, and **TestAFlag()**. See [List of Animatable Flags](#).

#### **AnimPropertyList aprops;**

This is a table of properties that a plug-in may use for its own storage needs. This table is also used by the system (for example Note Tracks and APP\_DATA). A plug-in may use this, for example, when a class has some data that is used while its user interface is up. It can store the UI data on the property list temporarily and not have to carry around the data when it is not needed. See the methods of [Template Class Tab](#) for how to add and delete items from the list. Also see the methods **GetProperty()** and **SetProperty()** and [Class AnimPropertyList](#).

### **Methods:**

## **Class Name, ClassID and SuperClassID Methods**

### **Prototype:**

```
virtual void GetClassName(TSTR& s)
```

### **Remarks:**

Implemented by the Plug-In.

Retrieves the name of the plug-in class. This name is usually used internally for debugging purposes. For Material plug-ins this method is used to put up the material "type" name in the Material Editor.

### **Parameters:**

```
TSTR& s
```

The string to store the name of the class.

### **Prototype:**

```
virtual Class_ID ClassID();
```

### **Remarks:**

Implemented by the Plug-In.

This method must return the **unique** ID for the object. If two ClassIDs conflict, the system will only load the first one it finds. Therefore all ClassIDs must be unique to ensure they are loaded properly. A program is provided to generate these randomly. [Generate a random Class ID](#).

**Return Value:**

The Class\_ID of the plug-in.

See Also: [Class ClassID](#), [List of Class IDs](#).

**Prototype:**

**virtual SClass\_ID SuperClassID();**

**Remarks:**

Implemented by the Plug-In.

This method returns a system defined constant describing the class this plug-in class was derived from. The entire list of available super class IDs is in the include file **PLUGAPI.H**. Note: **typedef ulong SClass\_ID;**

**Return Value:**

The super class ID of the plug-in. See [List of Super Class IDs](#).

## Memory Management

**Prototype:**

**virtual void DeleteThis();**

**Remarks:**

Implemented by the Plug-In.

When the system needs to delete an instance of a plug-in class it calls this method. The developer must use the same memory manager to allocate and deallocate memory. For example, if the developer used the 'new' operator to allocate memory, he or she should use the 'delete' operator to deallocate it. See the method **ClassDesc::Create()** for details on the allocation of memory.

Note: The default implementation of this method contains an **assert(0)** statement. This is because developers **MUST** override this default implementation. If the memory is not to be deleted this method should be

implemented as `{}` so the assertion doesn't happen. See [Memory Allocation](#).  
See Also: [DLL Functions and Class Descriptors](#), [Class ClassDesc](#).

**Prototype:**

**virtual void BeginEditParams(IObjParam \*ip,ULONG flags,Animatable \*prev=NULL)**

**Remarks:**

Implemented by the Plug-In.

This method is called by the system when the user may edit the item's (object, modifier, controller, etc.) parameters.

**Parameters:**

**IObjParam \*ip**

This is an interface pointer passed in. The developer may use the interface pointer to call methods such as **AddRollupPage()**. Note that this pointer is only valid between **BeginEditParams()** and **EndEditParams()**. A developer should not hang onto and use this pointer outside this interval.

**ULONG flags**

These flags describe which branch of the command panel or dialog the item is being editing in.

**BEGIN\_EDIT\_CREATE**

Indicates an item is being edited in the create branch.

**BEGIN\_EDIT\_MOTION**

Indicates a controller is being edited in the motion branch.

**BEGIN\_EDIT\_HIERARCHY**

Indicates a controller is being edited in the Pivot subtask of the hierarchy branch.

**BEGIN\_EDIT\_IK**

Indicates a controller is being edited in the IK subtask of the hierarchy branch.

**BEGIN\_EDIT\_LINKINFO**

Indicates a controller is being edited in the Link Info subtask of the hierarchy branch.

**Animatable \*prev=NULL**

This parameter may be used in the motion and hierarchy branches of the command panel. This pointer allows a plug-in to look at the ClassID of the previous item that was being edited, and if it is the same as this item, to not replace the entire UI in the command panel, but simply update the values displayed in the UI fields. This prevents the UI from 'flickering' when the current item begins its edit. For example, if you are in the motion branch and are looking at an item's PRS controller values, and then select another item that is displayed with a PRS controller, the UI will not change - only the values displayed in the fields will change. If however you selected a target camera that has a lookat controller (not a PRS controller) the UI will change because a different set of parameters need to be displayed. Note that for items that are edited in the modifier branch this field can be ignored.

**Prototype:**

**virtual void EndEditParams(IObjParam \*ip, ULONG flags,Animatable \*next=NULL)**

**Remarks:**

Implemented by the Plug-In.

This method is called when the user is finished editing an objects parameters. The system passes a flag into the **EndEditParams()** method to indicate if the rollup page should be removed. If this flag is TRUE, the plug-in must unregister the rollup page, and delete it from the panel.

**Parameters:**

**IObjParam \*ip**

This is an interface pointer passed in. The developer may use the interface pointer to call methods such as **DeleteRollupPage()**.

**ULONG flags**

The following flag may be set:

**END\_EDIT\_REMOVEUI**

If TRUE, the item's user interface should be removed.

**Animatable \*next=NULL**

This parameter may be used in the motion and hierarchy branches of the command panel. This pointer allows a plug-in to look at the ClassID of the next item that was being edited, and if it is the same as this item, to not replace

the entire UI in the command panel. Note that for items that are edited in the modifier branch this field can be ignored.

## Bitmap Related Methods

### Prototype:

```
virtual void FreeAllBitmaps();
```

### Remarks:

This method is available in release 2.0 and later only.

This method frees all bitmaps in this **Animatable** but doesn't recurse. This is used for freeing all the scene bitmaps after a render.

### Default Implementation:

```
{ }
```

## Methods for Sub-Anims.

See Also: Advanced Topics [Sub-Anims](#).

### Prototype:

```
virtual int NumSubs()
```

### Remarks:

Implemented by the Plug-In.

The system uses a [= 4\) BSPSPopupOnMouseOver\(event\);">virtual array](#) mechanism to access the sub-anims of a plug-in. This method returns the total number of sub-anims maintained by the plug-in. If a plug-in is using a parameter block to manage its parameters it should just return 1 for all the parameters directed by the parameter block.

### Return Value:

The number of sub-anims used by the plug-in.

### Default Implementation:

```
{ return 0; }
```

### Prototype:

```
virtual Animatable* SubAnim(int i)
```

**Remarks:**

Implemented by the Plug-In.

This method returns a pointer to the 'i-th' sub-anim. If a plug-in is using a parameter block to manage all its parameters it should just return a pointer to the parameter block itself from this method. This method may return NULL so developers need to check the return value before calling other sub anim methods (such as **SubAnimName()**).

**Parameters:**

**int i**

This is the index of the sub-anim to return.

**Default Implementation:**

```
{ return NULL };
```

**Prototype:**

```
virtual TSTR SubAnimName(int i);
```

**Remarks:**

Implemented by the Plug-In.

This method returns the name of the 'i-th' sub-anim to appear in track view. The system has no idea what name to assign to the sub-anim (it only knows it by the virtual array index), so this method is called to retrieve the name to display. Developer need to make sure the 'i-th' **SubAnim()** is non-NULL or this method will fail.

**Parameters:**

**int i**

The index of the parameter name to return

**Return Value:**

The name of the 'i-th' parameter.

**Prototype:**

```
virtual BOOL SelectSubAnim(int subNum);
```

**Remarks:**

This method is available in release 2.0 and later only.

When a user is in Track View in Edit Keys mode and clicks on the green triangle of a controller then this method will be called on the client with the appropriate sub number that corresponds to it. For instance, the Editable Mesh object implements this to allow the user to select vertices that are animated from the Track View.

**Parameters:**

**int subNum**

The index of the sub-anim that was clicked on.

**Return Value:**

TRUE if implemented; otherwise FALSE. (Track View will call **RedrawViewports()** if something returns TRUE from this method).

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual ParamDimension* GetParamDimension(int i)
```

**Remarks:**

Implemented by the Plug-In.

Returns the type of dimension of the 'i-th' sub-anim. A dimension describes the type and order of magnitude of a sub-anim.

**Parameters:**

**int i**

Specifies the sub-anim (parameter) to return the dimension of.

**Return Value:**

The dimension of the 'i-th' sub-anim (parameter).

**Default Implementation:**

```
{return defaultDim;}
```

**Prototype:**

```
virtual DWORD GetSubAnimCurveColor(int subNum);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Return the suggested color to draw a sub-anim's function curve. For example, the independent X, Y, Z position controller implements this method to return the suggested color for each of its sub-controllers. The Euler Angle Controller uses these so its 3 sub-controllers are drawn in different colors.

**Parameters:**

**int subNum**

The index of the sub-anim.

**Return Value:**

One of the following values:

**PAINTCURVE\_GENCOLOR**

**PAINTCURVE\_XCOLOR**

**PAINTCURVE\_YCOLOR**

**PAINTCURVE\_ZCOLOR**

**Default Implementation:**

```
{return PAINTCURVE_GENCOLOR;}
```

**Prototype:**

```
virtual int SubNumToRefNum(int subNum)
```

**Remarks:**

Implemented by the Plug-In.

This method is used for copying and pasting in the track view. It converts an anim index to a reference index or returns -1 if there is no correspondence. If a client does not wish an anim to be copied or pasted then it can return -1 even if there is a corresponding reference num.

**Parameters:**

**int subNum**

The anim index to return the corresponding reference index of.

**Default Implementation:**

```
{ return -1}
```

**Return Value:**

The reference index corresponding to the anim index passed. Return -1 if there

is no correspondence.

**Prototype:**

**virtual BOOL CanCopyAnim()**

**Remarks:**

Implemented by the Plug-In.

In addition to **SubNumToRefNum()**, if an anim doesn't want to be copied (via Track View or the Edit Modifier Stack 'Copy' button) it can return FALSE from this method, otherwise it can use the default implementation to return TRUE.

**Default Implementation:**

**{return TRUE;}**

**Prototype:**

**int HasSubElements(int type=0);**

**Remarks:**

Implemented by the System.

This method is used to determine if this Animatable has children or sub-anim. The type passed indicates what is tested.

**Parameters:**

**int type=0**

One of the following values:

**0:** Test for node children.

**1:** Test for sub-anim.

**Return Value:**

Nonzero if the item has children or sub-anim; otherwise zero.

**Prototype:**

**virtual BOOL CanDeleteSubAnim(int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

Returns TRUE if the specified sub-anim controller can be deleted; otherwise FALSE.

A new "Delete Controller" button has been added to the Track View toolbar that is enabled when one or more delete-able tracks are selected. This method allows a plug-in to indicate to the Track View that one or more of its sub-controllers are delete-able. This provides a way to allow the user to delete node sub-controllers such as the visibility track, "Image Motion Blur Multiplier", "Object Motion Blur On/Off", etc. If the user selects one of the above-mentioned tracks in the Track View the "Delete Controller" button will become available.

**Parameters:**

**int i**

The zero based index of the sub-anim.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void DeleteSubAnim(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method is called to delete the specified sub-anim controller. See the remarks in **CanDeleteSubAnim()** above.

**Parameters:**

**int i**

The zero based index of the sub-anim.

**Default Implementation:**

```
{}
```

## **Controller Assignment**

**Prototype:**

```
virtual BOOL AssignController(Animatable *control, int
```

**subAnim);**

**Remarks:**

Implemented by the Plug-In.

This method is called to assign the controller to the sub-anim whose index is passed.

**Parameters:**

**Animatable \*control**

The controller to assign.

**int subAnim**

The index of the sub-anim to assign the controller to.

**Default Implementation:**

```
{ return FALSE; }
```

**Return Value:**

Returns TRUE if the controller was assigned; otherwise FALSE.

## **Animation Properties**

**Prototype:**

```
virtual BOOL IsAnimated();
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if this animatable actually has animation; otherwise FALSE.

This method is recursive, so for example, if you call **node->IsAnimated()** it will return TRUE if any aspect of the node is animated; otherwise it will return FALSE.

**Default Implementation:**

The default implementation returns TRUE if a child anim has animation.

## **Make Unique Control**

**Prototype:**

```
virtual BOOL CanMakeUnique()
```

**Remarks:**

Implemented by the Plug-In.

An anim can implement this method to return FALSE to prohibit make unique from being applied to it.

**Default Implementation:**

```
{return TRUE;}
```

## **Flag Access**

**Prototype:**

```
void SetAFlag(int mask)
```

**Remarks:**

Implemented by the System.

Sets one or more of the bits of **aflag**.

**Parameters:**

**int mask**

The flags to set.

**Prototype:**

```
void ClearAFlag(int mask)
```

**Remarks:**

Implemented by the System.

Clears (sets to zero) one or more of the bits of **aflag**.

**Parameters:**

**int mask**

The flags to clear.

**Prototype:**

```
int TestAFlag(int mask)
```

**Remarks:**

Implemented by the System.

Used to test the state of one or more bits of **aflag**.

**Parameters:****int mask**

The flags to test.

**Return Value:**

Nonzero if the flags are set; otherwise 0.

**Prototype:****virtual void FreeCaches()****Remarks:**

Implemented by the Plug-In.

This is called to delete any item that can be rebuilt. For example, the procedural sphere object has a mesh that it caches. It could call **Mesh::FreeAll()** on the mesh from this method. This will free the vertex/face/uv arrays. If the sphere is ever evaluated again it can just rebuild the mesh. If an object (like a sphere) has modifiers applied to it, and those modifiers are not animated, then the result of the pipeline is cached in the node. So there is no reason for the sphere to also have a cache of its representation. Therefore when this method is called, the sphere can free the data of the mesh.

**Default Implementation:****{}****AppData, Interfaces, and Properties.**

The following methods deal with AppData. This is application specific data that may be attached to any Animatable in the scene. With these APIs any 3ds max object (controller, object, node, modifier, material, etc.) can have custom data attached by other objects. These chunks are saved in the .MAX file and can be accessed through the object they are attached to. Sample code using these APIs can be found in **\MAXSDK\SAMPLES\UTILITIES\APPDATA.CPP**.

**Prototype:****void AddAppDataChunk(Class\_ID cid, SClass\_ID sid, DWORD sbid, DWORD len, void \*d);****Remarks:**

Implemented by the System.

This method is used to add an AppDataChunk to this Animatable. The chunk is identified using the Class\_ID, and SuperClassID of the owner, and an ID for sub-chunks.

Note: Developers who want to add appdata to the scene should see the method:

**ReferenceTarget \*Interface::GetScenePointer().**

**Parameters:**

**Class\_ID cid**

The Class\_ID of the owner of the chunk.

**SClass\_ID sid**

The SuperClassID of the owner of the chunk.

**DWORD sbid**

An extra ID that lets the owner identify its sub-chunks.

**DWORD len**

The length of the data in bytes.

**void \*d**

Points to the actual data. The data should be allocated using standard **malloc()** as it will be freed by the system using **free()**.

**Prototype:**

**AppDataChunk \*GetAppDataChunk(Class\_ID cid, SClass\_ID sid, DWORD sbid);**

**Remarks:**

Implemented by the System.

This method is used to retrieve a pointer to an AppDataChunk. The chunk is identified using the Class\_ID, SuperClassID and sub-chunk ID of the owner.

**Parameters:**

**Class\_ID cid**

The Class\_ID of the owner of the chunk.

**SClass\_ID sid**

The SuperClassID of the owner of the chunk.

**DWORD sbid**

An extra ID that lets the owner identify its sub-chunks.

**Return Value:**

A pointer to the AppDataChunk or NULL if it could not be found. See [Class AppDataChunk](#).

**Prototype:**

**BOOL RemoveAppDataChunk(Class\_ID cid, SClass\_ID sid, DWORD sbid);**

**Remarks:**

Implemented by the System.

This method is used to delete an AppDataChunk. The chunk is identified using the Class\_ID, SuperClassID and sub-chunk ID of the owner. Returns TRUE if the data was deleted and FALSE if it could not be found.

**Parameters:**

**Class\_ID cid**

The Class\_ID of the owner of the chunk.

**SClass\_ID sid**

The SuperClassID of the owner of the chunk.

**DWORD sbid**

An extra ID that lets the owner identify its sub-chunks.

**Return Value:**

TRUE if the chunk was removed; otherwise FALSE.

**Prototype:**

**void ClearAllAppData();**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Calling this method will remove **all** the AppData associated with this Animatable. Note: Plugins that call this method will erase **all** appdata chunks, not just their own. Therefore, it is usually more appropriate to use the RemoveAppDataChunk() API to remove AppData associated with a specific Class\_ID.

**Prototype:**

**virtual void\* GetInterface(ULONG id)**

**Remarks:**

Implemented by the Plug-In.

This method provides a mechanism for extending the class in the future. In 3ds max 4.0 there are new interfaces that are accessed by passing an id to this method and it will respond by returning the corresponding interface pointer.

This method has been used however for a different purpose. It currently is used to determine if an object is of a particular class. With controllers for example, there is one base class Control, however there are many super classes (**CTRL\_FLOAT\_CLASS\_ID**, **CTRL\_SCALE\_CLASS\_ID**, etc.). If you wanted to find out if a given Animatable was a controller you would need to compare its SuperClassID to all the known types and only if it wasn't one of the known types could you be sure it wasn't a controller. Having to do this is inconvenient for a developer.

Instead the Control class implements this method. It looks at the id, and if it matches a predefined constant **I\_CONTROL**, it returns its **this** pointer. In this way, given any Animatable, it is easy to find out if it is a controller by simply asking for the control interface. There is a macro that does this:

```
#define GetControlInterface(anim)  
((Control*)anim->GetInterface(I_CONTROL))
```

A plug-in developer may use this macro as follows:

```
Control *c = GetControlInterface(anim);
```

This will either be NULL or a pointer to a valid controller.

This is the list of IDs currently defined for use with this macro. Note that these do NOT need to be released with method **ReleaseInterface()**.

```
#define I_CONTROL 0x00001001  
#define I_MASTER 0x00001010  
#define I_EASELIST 0x00001020  
#define I_MULTLIST 0x00001030  
#define I_BASEOBJECT 0x00001040  
#define I_PARTICLEOBJ 0x00001050  
#define I_KEYCONTROL 0x00001060  
#define I_TEXTOBJECT 0x00001070
```

```
#define I_WAVESOUND 0x00001080
#define I_SUBMTLAPI 0x00001090
#define I_MESHSELECT 0x000010A0
#define I_MESHSELECTDATA 0x000010B0
#define I_MAXSCRIPTPLUGIN 0x000010C0
#define I_MESHDELTAUSER 0x000010D0
#define I_MESHDELTAUSERDATA 0x000010E0
#define I_SPLINESELECT 0x000010F0
#define I_SPLINESELECTDATA 0x00001100
#define I_SPLINEOPS 0x00001110
#define I_PATCHSELECT 0x00001120
#define I_PATCHSELECTDATA 0x00001130
#define I_PATCHOPS 0x00001140
#define I_COMPONENT 0x0000F010
#define I_REFARRAY 0x0000F030
#define I_LINK_TARGET 0x0000F020
#define I_LAYER 0x0000F040
#define I_LAYER_MANAGER 0x0000F050
#define I_REAGENT 0x0000F060
```

Note: Plug-in defined interfaces should be greater than the following value:

```
#define I_USERINTERFACE 0x0000ffff
```

These other macros are defined for a similar purpose:

```
#define GetControlInterface(anim)
    ((Control*)anim->GetInterface(I_CONTROL))
#define GetObjectInterface(anim)
    ((BaseObject*)anim->GetInterface(I_BASEOBJECT))
#define GetParticleInterface(anim)
    ((ParticleObject*)anim->GetInterface(I_PARTICLEOBJ))
#define GetKeyControlInterface(anim)
    ((IKeyControl*)anim->GetInterface(I_KEYCONTROL))
#define GetMasterController(anim)
    ((ReferenceTarget*)anim->GetInterface(I_MASTER))
#define GetTextObjectInterface(anim)
    ((ITextObject*)anim->GetInterface(I_TEXTOBJECT))
```

```

#define GetWaveSoundInterface(anim)
    ((IWaveSound*)anim->GetInterface(I_WAVESOUND))
#define GetMeshSelectInterface(anim)
    ((IMeshSelect*)anim->GetInterface(I_MESHSELECT))
#define GetMeshSelectDataInterface(anim)
    ((IMeshSelectData*)anim-
    >GetInterface(I_MESHSELECTDATA))
#define GetMeshDeltaUserInterface(anim)
    ((MeshDeltaUser*)anim-
    >GetInterface(I_MESHDELTAUSER))
#define GetMeshDeltaUserDataInterface(anim)
    ((MeshDeltaUserData*)anim-
    >GetInterface(I_MESHDELTAUSERDATA))

```

If a plug-in implements this method for its own purposes, it would, in general, switch on the id and if it is not aware of the id it would call this method on the base class. Otherwise it could respond to the id as it needed. See the sample code below for the how the Control class implements this method.

**Parameters:**

**ULONG id**

The id of the interface.

**Default Implementation:**

```
{ return NULL; }
```

**Sample Code:**

The following is the Control class implementation of this method. It looks at the **id** passed, and if it matches **I\_CONTROL** it returns its **this** pointer. Otherwise it calls the base class method.

```

void* Control::GetInterface(ULONG id)
{
    if (id==I_CONTROL) {
        return this;
    } else {
        return Animatable::GetInterface(id);
    }

```

}

**Prototype:**

**virtual void ReleaseInterface(ULONG id,void \*i)**

**Remarks:**

Implemented by the Plug-In.

This method is not currently used. It is reserved for future use. Its purpose is for releasing an interface created with **GetInterface()**.

**Prototype:**

**virtual BaseInterface\* GetInterface(Interface\_ID id);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the Base Interface for the interface ID passed. The default implementation of this method retrieves this information from the ClassDesc for the plug-in.

Any future object-based interfaces should be allocated unique Interface\_IDs (you can use Gencid.exe for this) and made available through this call.

The default implementation of GetInterface(Interface\_ID) looks up a standalone interface of the given ID on the object's ClassDesc. This gives access to standalone interfaces via any of a plug-in's objects, without having to dig around for the ClassDesc, so you should fall back to calling the default implementation if you don't recognize an ID in your implementation of GetInterface(Interface\_ID).

**Parameters:**

**Interface\_ID id**

The unique ID of the interface to get. See [Class Interface ID](#).

**Prototype:**

**virtual void ReleaseInterface(Interface\_ID id, void\* i);**

**Remarks:**

This method is available in release 4.0 and later only.

Releases the interface retrieved above.

```

JointParamsPath *jp = (JointParamsPath*)GetProperty(id);
if (jp) {
    *jp = *((JointParamsPath*)data);
    delete (JointParamsPath*)data;
 } else {
    aprops.Append(1,(AnimProperty**)&data);
 }
 }
return 1;
 } else
if (id==PROPID_INTERPUI) {
    if (!data) {
        int index = aprops.FindProperty(id);
        if (index>=0) {
            aprops.Delete(index,1);
         }
     } else {
        InterpCtrlUI *ui = (InterpCtrlUI*)GetProperty(id);
        if (ui) {
            *ui = *((InterpCtrlUI*)data);
         } else {
            aprops.Append(1,(AnimProperty**)&data);
         }
     }
return 1;
 } else {
        return Animatable::SetProperty(id,data);
     }
 }

```

**Prototype:**

**virtual void \*GetProperty(ULONG id)**

**Remarks:**

Implemented by the Plug-In.

This method is used to retrieve a property specified by the id passed (as stored by **SetProperty()**).

Note for 3ds max version 1.1:

Two new property IDs have been added:

**PROPID\_CLEARCACHES:** When passed to a texture map or material, the material should dump any of its caches. For example, the bitmap texture responds to this by freeing the bitmap from memory. For sample code see

**\\MAXSDK\\SAMPLES\\MATERIALS\\BMTEX.CPP.**

**PROPID\_HAS\_WSM:** When passed to an INode, will return TRUE if the node has World Space Modifiers applied to it or FALSE if it does not. For sample code see

**\\MAXSDK\\SAMPLES\\IMPEXP\\3DSEXP.CPP.**

Note for 3ds max version 1.2:

A new **id** has been created and assigned the constant:

**#define PROPID\_EVAL\_STEPSIZE\_BUG\_FIXED 0x1000.**

This only effects the evaluation of objects when rendering them using motion blur. Motion blur works by evaluating the object numerous times (at fractions of a frame apart) and combining these images by blending them together.

Originally, 3ds max would make these evaluations in reverse order within a sub-frame -- from the last one, to the second to the last one, back to the first one. There is a problem with this for certain plug-ins that need to compute their state from time 0 forward. For these objects, the backwards approach may be too computationally intensive.

Both the forward and backward approaches exist in 3ds max and the developer may choose which method to use. 3ds max interrogates the object to see how it should handle the evaluation process -- either going backwards or forwards. It calls this method with **id** set to the constant **PROPID\_EVAL\_STEPSIZE\_BUG\_FIXED**. If a plug-in implements this method to return nonzero, it means the plug-in works correctly using forward stepping, and 3ds max will use that approach. If a plug-in does not implement this method and handle the **id** of **PROPID\_EVAL\_STEPSIZE\_BUG\_FIXED** it will return the default value of zero. This means the older method of backwards evaluation will be used.

Therefore, a plug-in object that wants to handle motion blur using forward

stepping should implement this method, and if passed an **id** of **PROPID\_EVAL\_STEPSIZE\_BUG\_FIXED**, should return nonzero.

**Parameters:**

**ULONG id**

The id of the property to retrieve.

**Default Implementation:**

```
{ return NULL; }
```

**Sample Code:**

This code is from

**\MAXSDK\SAMPLES\CONTROLLERS\PATHCTRL.CPP**. It is used to restore the inverse kinematics user interface parameters of the path controller. It retrieves the property data on the **aprops** property list. See the Data Members at the beginning of Animatable for details on **aprops**.

```
void* PathPosition::GetProperty(ULONG id)
{
    if (id==PROPID_INTERPUI || id==PROPID_JOINTPARAMS) {
        int index = aprops.FindProperty(id);
        if (index>=0) {
            return aprops[index];
        } else {
            return NULL;
        }
    } else {
        return Animatable::GetProperty(id);
    }
}
```

## Clipboard Methods

**Prototype:**

```
virtual BOOL CanCopyTrack(Interval iv, DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if this item can copy its data over the specified range; otherwise returns FALSE.

**Parameters:**

**Interval iv**

The interval of time that would be copied.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL CanPasteTrack(TrackClipObject *cobj,Interval iv,  
DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if this item can paste its data over the specified range; otherwise returns FALSE.

**Parameters:**

**TrackClipObject \*cobj**

The clipboard object that would be pasted. The item should look at the SuperClassID and Class\_ID of the creator of the clip object to determine if it is a suitable object to paste. See [Class TrackClipObject](#).

**Interval iv**

The interval of time that would be pasted.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

## **TIME\_INCRIGHT**

Include the right endpoint.

### **Default Implementation:**

```
{return FALSE;}
```

### **Prototype:**

```
virtual TrackClipObject *CopyTrack(Interval iv, DWORD flags)
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to copy the item's track data over the specified interval.

### **Parameters:**

#### **Interval iv**

The interval of time over which to copy the track data.

#### **DWORD flags**

One or more of the following values:

#### **TIME\_INCLEFT**

Include the left endpoint.

#### **TIME\_INCRIGHT**

Include the right endpoint.

### **Return Value:**

The item should return an instance of a class derived from TrackClipObject that contains the data for the item. See [Class TrackClipObject](#).

### **Default Implementation:**

```
{return NULL;}
```

### **Prototype:**

```
virtual void PasteTrack(TrackClipObject *cobj, Interval iv,  
DWORD flags)
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to paste the specified clip object to this track. This method will not be called unless **CanPasteTrack()** returned TRUE.

**Parameters:**

**TrackClipObject \*cobj**

The data to paste.

**Interval iv**

The interval of time to paste.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Prototype:**

**virtual BOOL CanCopySubTrack(int subNum, Interval iv, DWORD flags);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

If **CanCopyTrack()** returns FALSE then this method is called on the sub-anim (passing the sub number).

This is used in particular for Parameter Blocks. In that case, if there is no controller plugged into the track, the copying and pasting of controllers can't be done (since there is no controller). However, this method allows the Parameter Block to handle it.

**Parameters:**

**int subNum**

Specifies the sub-anim to check.

**Interval iv**

The interval of time over which to copy the track data.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

## **TIME\_INCRIGHT**

Include the right endpoint.

### **Return Value:**

TRUE if the specified item can copy its data over the specified range; otherwise FALSE.

### **Default Implementation:**

```
{return FALSE;}
```

### **Prototype:**

```
virtual BOOL CanPasteSubTrack(int subNum, TrackClipObject  
*cobj, Interval iv, DWORD flags);
```

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns TRUE if the specified item can paste its data over the specified range; otherwise returns FALSE.

Plug-ins can implement pasting for cases where their sub-anim's don't implement it. An example of this is the Parameter Block class. It implements this method to allow pasting parameters that don't have controllers assigned to them. These aren't called on the client unless the sub-anim doesn't implement **CanPasteTrack()**.

### **Parameters:**

**int subNum**

Specifies the sub-anim to check.

**TrackClipObject \*cobj**

The data to paste.

**Interval iv**

The interval of time to paste.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Return Value:**

TRUE if the specified item can paste its data over the specified range;  
otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual TrackClipObject *CopySubTrack(int subNum, Interval iv,  
DWORD flags);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called to copy the specified sub anim's track data over the specified interval.

**Parameters:**

**int subNum**

The number of the sub-anim to copy.

**Interval iv**

The interval of time over which to copy the track data.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Return Value:**

The item should return an instance of a class derived from TrackClipObject that contains the data for the item. See [Class TrackClipObject](#).

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void PasteSubTrack(int subNum, TrackClipObject  
*cobj, Interval iv, DWORD flags);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called to paste the specified clip object to the specified sub-anim track.

**Parameters:**

**int subNum**

The number of the sub-anim to paste.

**TrackClipObject \*cobj**

The data to paste.

**Interval iv**

The interval of time to paste.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Default Implementation:**

```
{}
```

**Interactive Adjustment****Prototype:**

```
virtual void MouseCycleCompleted(TimeValue t);
```

**Remarks:**

This method is available in release 2.0 and later only (previously in Class Control in 1.x).

Implemented by the Plug-In.

This method is called on whatever controller the user is modifying with the

mouse -- when the mouse button is released. For example when the user selects a node in the viewports, then drags, then releases the mouse button, this method is called. This method will also be called when the user clicks on a key in the track view and lets up. If a controller performs extensive calculation in its evaluation this method is handy. The controller could perhaps perform a simplified calculation during interactive adjustment of a node. Then when the user releases the mouse button this method is called and the extensive calculations are performed.

The default implementation of this method is recursive so it gets called on all sub-animis affected by a range bar operation.

**Parameters:**

**TimeValue t**

The time the mouse was released.

**Prototype:**

**virtual void MouseCycleStarted(TimeValue t);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called on whatever controller the user is modifying with the mouse -- when the mouse button is pressed.

The default implementation of this method is recursive so it gets called on all sub-animis affected by a range bar operation.

**Parameters:**

**TimeValue t**

The time the mouse was first pressed.

**Methods called when rendering is started and finished**

**Prototype:**

**virtual int RenderBegin(TimeValue t, ULONG flags=0)**

**Remarks:**

Implemented by the Plug-In.

This method is called once at the beginning of each render. A plug-in can use this method to do any work required before a rendering actually begins. For example, some of the standard 3ds max plug-ins use this method to toggle between their 'viewport' state and the 'rendering' state. The Optimize modifier has two settings, one for the viewports and one for the rendering. When this method is called it then performs the switch from viewport to render.

**Parameters:**

**TimeValue t**

The time that the render is beginning.

**ULONG flags=0**

This is not used in 3ds max 1.x.

In 3ds max 2.0 and later the following flag value may be checked:

**RENDERBEGIN\_IN\_MEDIT**

Indicates that the render is occurring in the Material Editor.

**Return Value:**

Nonzero if the method is implemented; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual int RenderEnd(TimeValue t)
```

**Remarks:**

Implemented by the Plug-In.

This method is called once at the end of each render.

**Parameters:**

**TimeValue t**

The time of the last rendered frame.

**Return Value:**

Nonzero if the method is implemented; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

## System Plug-In Related Methods

### Prototype:

**virtual void GetSystemNodes(INodeTab &nodes, SysNodeContext)**

### Remarks:

Implemented by the Plug-In.

The master controller of a system plug-in should implement this method to give 3ds max a list of nodes that are part of the system. The master controller should fill in the given table with the INode pointers of the nodes that are part of the system. This will ensure that operations like cloning and deleting affect the whole system.

Said another way, **GetSystemNodes()** should be implemented for the master controller of a system, and should return a list of pointers to all nodes that are part of the system. **GetInterface()** should be implemented for the slave TM controllers of the system and return a pointer to the master controller.

3ds max will use **GetInterface()** in the TM controller of each selected node to retrieve the master controller and then call **GetSystemNodes()** on the master controller to get the list of nodes.

### Parameters:

#### **INodeTab &nodes**

The table of nodes that are part of the system.

#### **SysNodeContext**

This parameter is available in release 4.0 and later only.

Previously, this method gathered related (system) nodes during cloning, deleting, file merging and saving.

This parameter can be used to specify the context under that the "system nodes" are used. These are; **kSNCClone**, **kSNCCDelete**, **kSNCFFileMerge**, and **kSNCFFileSave**.

### Default Implementation:

```
{}
```

**The following methods deal with operations to Keys and Track View:**

**Prototype:****virtual BOOL BypassTreeView()****Remarks:**

Implemented by the Plug-In.

This method indicates to the system that this anim should not appear in the Track View. Note: Track View was formally referred to as Tree View. This is what parameter blocks do for example. They don't show up in track view, just their sub-anim's do. This prevents the extra level of the parameter block from appearing.

**Return Value:**

Return TRUE to not appear in the Track View. Note that if you return TRUE your children will appear in the track view regardless.

**Default Implementation:****{ return FALSE; }****Prototype:****virtual BOOL BypassTrackBar();****Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method indicates to the system that this anim should not appear in the Track Bar. The anim won't show up in the Track Bar, just its sub-anim's will. This function is similar to BypassTreeView(), but refers to the Track Bar instead of the Track View.

**Return Value:**

Return TRUE to not appear in the Track Bar. Note that if you return TRUE your children will appear in the Track Bar regardless.

**Default Implementation:****{ return BypassTreeView(); }****Prototype:****virtual BOOL BypassPropertyLevel();**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

Use this method in order to cause parameters in this Animatable (as a sub-anim) to appear to reside at the level of the parent Animatable in the scripiter. Return TRUE and this Animatable won't appear as a property in the scripiter however it's sub-anim's children will. The default implementation returns FALSE indicating it will appear normally.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual BOOL InvisibleProperty();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method controls the visibility of this Animatable and all of its sub-anim's to appear as properties in the scripiter. Return TRUE and it won't nor will its sub-anim's. Returning FALSE (the default implementation) causes this Animatable and its sub-anim's to appear as normal.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual int NumKeys()
```

**Remarks:**

Implemented by the Plug-In.

This method returns the number of keys managed by the plug-in, or **NOT\_KEYFRAMEABLE** if it does not work with keys.

**Default Implementation:**

```
{return NOT_KEYFRAMEABLE;}
```

**Prototype:**

**virtual TimeValue GetKeyTime(int index)**

**Remarks:**

Implemented by the Plug-In.

This method returns the time of the key specified by **index**.

**Parameters:**

**int index**

Specifies the key whose time should be returned.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

**virtual int GetKeyIndex(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

Returns the index of the key at time **t** or **-1** if no key is found at the specified time.

**Parameters:**

**TimeValue t**

Specifies the time at which to retrieve the key index.

**Default Implementation:**

```
{return -1;}
```

**Prototype:**

**virtual BOOL GetNextKeyTime(TimeValue t,DWORD flags,TimeValue &nt)**

**Remarks:**

Implemented by the Plug-In.

An item should implement this method to allow the Key Mode button in 3ds max's UI to function properly. If Key Mode is set, and the user clicks the Previous Key or Next Key button, this method will be called to retrieve the next or previous key.

**Parameters:****TimeValue t**

The current time (frame slider position).

**DWORD flags**

One or more of the following value:

**NEXTKEY\_LEFT**

Search to the left.

**NEXTKEY\_RIGHT**

Search to the right.

**NEXTKEY\_POS**

Next position key.

**NEXTKEY\_ROT**

Next rotation key.

**NEXTKEY\_SCALE**

Next scale key.

**TimeValue &nt**

The time of the previous or next key is returned here.

**Return Value:**

TRUE if the key time was retrieved; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE;}
```

**Prototype:**

```
virtual void CopyKeysFromTime(TimeValue src,TimeValue  
dst,DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to copy or interpolate a new key from a source time to a destination time.

**Parameters:****TimeValue src**

The source time.

**TimeValue dst**

The destination time.

**DWORD flags**

These filter flags are passed to a transform (Matrix3) controller. The TM can decide what to do with them. They have obvious meaning for the PRS controller. One or more of the following values:

**COPYKEY\_POS**

Copy the position key.

**COPYKEY\_ROT**

Copy the rotation key.

**COPYKEY\_SCALE**

Copy the scale key.

**Prototype:**

**virtual void DeleteKeyAtTime(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

This method is called to delete the key at the specified time.

**Parameters:****TimeValue t**

Specifies the time to delete the key.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual BOOL IsKeyAtTime(TimeValue t,DWORD flags)**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if there is a key of the specified type at the specified time; otherwise FALSE.

**Parameters:****TimeValue t**

Specifies the time to check for a key.

### **DWORD flags**

One or more of the following values:

**KEYAT\_POSITION**

**KEYAT\_ROTATION**

**KEYAT\_SCALE**

### **Default Implementation:**

```
{return FALSE;}
```

### **Prototype:**

```
virtual int GetKeyTimes(Tab<TimeValue> &times,Interval  
range,DWORD flags)
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to build a table of time values, one time for each key within the interval passed. The plug-in should load up the table passed with the time of each key present over the specified time range.

### **Parameters:**

**Tab<TimeValue> &times**

The table of time values to build. See [Class Tab](#).

**Interval range**

The range of time over which to retrieve the key times. See [Class Interval](#).

**DWORD flags**

One of the following values:

**KEYAT\_POSITION** - Return for Position keys only.

**KEYAT\_ROTATION** - Return for Rotation keys only.

**KEYAT\_SCALE** - Return for Scale keys only.

### **Return Value:**

The plug-in should return an offset so the system can access the keys using an index. Thus it should return the number of keys skipped because their times were before **range.Start()**. For example, say the first keyframe in the interval passed was actually the third key overall. The plug-in should return 2 (two keys preceded the first one stored). In this way, the system can access the key

as the i-th key in the table plus 2.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual int GetKeySelState(BitArray &sel,Interval range,DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

When this method is called, the plug-in should update the BitArray **sel** to indicate if its keys present in the interval passed are selected or deselected.

**Parameters:**

**BitArray &sel**

The bit array to update, one bit for each key within the interval **range**. If the key is selected, the corresponding bit should be 1, otherwise it should be 0. See [Class BitArray](#).

**Interval range**

The range of time over which to retrieve the key selected state. [Class Interval](#).

**DWORD flags**

One or more of the following values:

**KEYAT\_POSITION** - Return for Position keys only.

**KEYAT\_ROTATION** - Return for Rotation keys only.

**KEYAT\_SCALE** - Return for Scale keys only.

Note: If the flags are passed as 0, use ALL keys within the range.

**Return Value:**

The number of keys skipped because their times were before **range.Start()**.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
void OpenTreeEntry(int type, DWORD tv)
```

**Remarks:**

Implemented by the System.

This method may be called to open the specified Track View entry. The type parameter indicates if the child tree or the sub-anim (parameter) tree is opened.

**Parameters:**

**int type**

This value may be either 0 or 1. If 0, the child tree is opened. If 1, the sub-anim tree is opened.

**DWORD tv**

This parameter is available in release 2.0 and later only.

It specifies which Track View(s) are altered, one bit for each Track View. In 3ds max 2.0 the open/closed state is independent for each Track View. The low-order 16 bits represent the 16 track views.

**Prototype:**

**void CloseTreeEntry(int type, DWORD tv)**

**Remarks:**

Implemented by the System.

This method may be called to close the specified Track View entry. The type parameter indicates if the child tree or the sub-anim tree is closed.

**Parameters:**

**int type**

This value may be either 0 or 1. If 0, the child tree is closed. If 1, the sub-anim (parameter) tree is closed.

**DWORD tv**

This parameter is available in release 2.0 and later only.

It specifies which Track View(s) are altered, one bit for each Track View. In 3ds max 2.0 the open/closed state is independent for each Track View. The low-order 16 bits represent the 16 track views.

**Prototype:**

**int IsTreeEntryOpen(int type, DWORD tv);**

**Remarks:**

Implemented by the System.

Returns nonzero if the specified tree is opened for this item, and zero if it is closed.

**Parameters:**

**int type**

This value may be either 0 or 1. If 0, the child tree is checked. If 1, the sub-anim (parameter) tree is checked.

**DWORD tv**

This parameter is available in release 2.0 and later only.

Specifies which Track View to check -- one bit per Track View.

**Prototype:**

**BOOL GetSelInTrackView(DWORD tv);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Returns TRUE if this animatable is selected in the specified Track View; FALSE if not selected.

**Parameters:**

**DWORD tv**

Specifies which Track View to check -- one bit per Track View.

**Prototype:**

**void SetSelInTrackView(DWORD tv, BOOL sel);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Sets the state of this animatable to selected or deselected in the specified Track View.

**Parameters:**

**DWORD tv**

Specifies which Track View to check -- one bit per Track View.

## **BOOL sel**

TRUE to select; FALSE to deselect.

### **Prototype:**

**BOOL InTrackViewSelSet(int which);**

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Returns TRUE if this animatable is in the specified selection set; otherwise FALSE.

### **Parameters:**

**int which**

Indicates the Track View selection set to check -- this should be  $\geq 0$  and  $< \text{MAX\_TRACKVIEW\_SELSETS}$

### **Prototype:**

**void SetTrackViewSelSet(int which, BOOL inOut);**

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Sets the selected or deselected state of this animatable in the specified selection set.

### **Parameters:**

**int which**

Indicates the Track View selection set to modify -- this should be  $\geq 0$  and  $< \text{MAX\_TRACKVIEW\_SELSETS}$

**BOOL inOut**

TRUE for in; FALSE for out.

## **Operations to a selected block of time.**

### **Prototype:**

## **virtual Interval GetTimeRange(DWORD flags);**

### **Remarks:**

Implemented by the System.

Returns an interval representing the tracks time range, based on the flags passed.

### **Parameters:**

#### **DWORD flags**

One or more of the following values:

##### **TIMERANGE\_SELONLY**

The bounding interval of selected keys only.

##### **TIMERANGE\_ALL**

Whatever the channel's time range is - usually the bounding interval of all keys.

##### **TIMERANGE\_CHILDNODES**

The node's time range should include its child nodes.

##### **TIMERANGE\_CHILDANIMS**

A animatable's child anim ranges should be included.

### **Return Value:**

An interval representing the tracks time range.

### **Prototype:**

#### **virtual void EditTimeRange(Interval range,DWORD flags)**

### **Remarks:**

Implemented by the Plug-In.

This method is called to change the range of the anim (usually a controller) to the given range. This is the range that is used to compute the Out of Range Types. For example, this method may be called when the user is working in Position Range mode in the Track View.

Keyframe controllers generally support this method. Other controllers may or may not support this method. For example, a procedural controller may want to maintain a range upon which the animation is based. The user may then move the range bar around to move the procedural animation around.

The range passed is the range used to compute the Out of Range Types. This

may be used for example with the Loop ORT to extend the range, either past the last key or before the first key, so there is some time to loop back to the start.

The 3ds max keyframe controllers maintain an interval that is their range. It is normally defined to be the first key to the last key. If the user goes into Position Range mode and moves the range around, this method is called. The keyframe controllers set a flag to indicate that the range is no longer linked to the first key or the last key. Then the range is stored in the interval, and this is considered the 'in range' portion of the controller. If time is evaluated outside of this range it applies the ORTs to determine the value.

**Parameters:**

**Interval range**

The new range for the anim.

**DWORD flags**

**EDITRANGE\_LINKTOKEYS**

If this flag is set, the controller should re-establish the link between the start and end keys and its range. This is passed if the user presses the link to keys button in Track View. Thus, if one of the ends of the interval is at a key, link it to the key so that if the key moves, the interval moves.

**Default Implementation:**

{ }

**Prototype:**

**virtual void DeleteTime(Interval iv, DWORD flags);**

**Remarks:**

Implemented by the Plug-In.

This method is called to delete the specified interval of time (or the keys within the interval).

**Parameters:**

**Interval iv**

The interval of time to delete.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**TIME\_NOSLIDE**

Delete any keys in the interval but don't actually remove the block of time.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual void ReverseTime(Interval iv, DWORD flags);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to reverse the data within the specified interval. For example, if the interval passed is from frame 10 to 20, and there is a key at frame 12, the key should be moved to frame 18. Considered another way, if all the times were normalized, and there was a value **n** between 0 and 1, **n** should be changed to **1-n**.

**Parameters:****Interval iv**

The interval of time over which to reverse the data.

**DWORD flags**

One or more of the following values:

**TIME\_INCLEFT**

Include the left endpoint.

**TIME\_INCRIGHT**

Include the right endpoint.

**Default Implementation:**

```
{
```

**Sample Code:**

```
INTERP_CONT_TEMPLATE
```

```
void InterpControl<INTERP_CONT_PARAMS>::ReverseTime(
```

```

Interval iv,
DWORD flags )
{
Interval test = TestInterval(iv,flags);
int n = keys.Count();
HoldTrack();
for ( int i = 0; i < n; i++ ) {
if (keys[i].TimeLocked()) continue;
if ( test.InInterval(keys[i].time) ) {
TimeValue delta = keys[i].time - iv.Start();
keys[i].time = iv.End()-delta;
}
}
keys.KeysChanged();
keys.CheckForDups();
ivalid.SetEmpty();
NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);
}

```

**Prototype:**

**virtual void ScaleTime(Interval iv, float s);**

**Remarks:**

Implemented by the Plug-In.

This method is called to scale an interval of time by the specified scale factor.

**Parameters:**

**Interval iv**

The interval of time to scale. The origin of the scale is at **iv.Start()**.

**float s**

The scale factor for the time.

**Default Implementation:**

**{}**

**Sample Code:**

**INTERP\_CONT\_TEMPLATE**

**void InterpControl<INTERP\_CONT\_PARAMS>::ScaleTime( Interval**

```

iv, float s)
{
int n = keys.Count();
TimeValue delta =
int(s*float(iv.End()-iv.Start())) + iv.Start()-iv.End();
HoldTrack();
for ( int i = 0; i < n; i++ ) {
if (keys[i].TimeLocked()) continue;
if ( iv.InInterval(keys[i].time) ) {
keys[i].time =
int(s*float(keys[i].time - iv.Start())) + iv.Start();
} else
if (keys[i].time > iv.End()) {
keys[i].time += delta;
}
}
keys.KeysChanged();
ivalid.SetEmpty();
NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);
}

```

**Prototype:**

**virtual void InsertTime(TimeValue ins, TimeValue amount)**

**Remarks:**

Implemented by the Plug-In.

This method is called to insert the specified amount of time at the specified insertion point.

**Parameters:**

**TimeValue ins**

The time to begin the insertion.

**TimeValue amount**

The amount of time to insert.

**Default Implementation:**

**{}**

**Prototype:**

**virtual BOOL SupportTimeOperations()**

**Remarks:**

Implemented by the Plug-In.

If an anim supports time operations in the track view (cut, copy, paste, etc.), it should implement this method to return TRUE. When it is FALSE the user cannot select blocks of time in the anim's track.

**Default Implementation:**

**{return FALSE;}**

**Prototype:**

**virtual void MapKeys(TimeMap \*map, DWORD flags);**

**Remarks:**

Implemented by the Plug-In.

The method is called to update the keys specified by the flags, using the TimeMap passed. The plug-in should go through the specified keys and change their **time** to **TimeMap::map(time)**. See the sample code below for how this is done.

**Parameters:**

**TimeMap \*map**

This class provides a method, **map()**, that is applied to the keys. See [Class TimeMap](#).

**DWORD flags**

The flags indicate the keys to operate on. One or more of the following values:

**TRACK\_DOSEL**

Selected keys only.

**TRACK\_DOALL**

All the keys, ignore their selection state.

**TRACK\_SLIDEUNSEL**

Slide unselected keys to the right. Keys are slid by the amount the last key was transformed.

**TRACK\_RIGHTTOLEFT**

Enumerate right to left. If **TRACK\_SLIDEUNSEL** is set, keys will

slide to the left.

### **TRACK\_DOSUBANIMS**

Sub-Animatables keys as well.

### **TRACK\_DOCHILDNODES**

Child Nodes keys as well

### **TRACK\_MAPRANGE**

The range, if not locked to first and last key, should be mapped as well.

#### **Sample Code:**

#### **INTERP\_CONT\_TEMPLATE**

```
void InterpControl<INTERP_CONT_PARAMS>::MapKeys(TimeMap  
*map,DWORD flags )
```

```
{  
int n = keys.Count();  
BOOL changed = FALSE;  
if (!n) goto doneMapKeys;  
HoldTrack();  
if (flags&TRACK_DOALL) {  
for (int i = 0; i < n; i++) {  
if (keys[i].TimeLocked()) continue;  
keys[i].time = map->map(keys[i].time);  
changed = TRUE;  
}  
} else  
if (flags&TRACK_DOSEL) {  
BOOL slide = flags&TRACK_SLIDEUNSEL;  
TimeValue delta = 0, prev;  
int start, end, inc;  
if (flags&TRACK_RIGHTTOLEFT) {  
start = n-1;  
end = -1;  
inc = -1;  
} else {  
start = 0;  
end = n;  
inc = 1;  
}  
}
```

```

for (int i = start; i != end; i += inc) {
    if (keys[i].TimeLocked()) continue;
    if (keys[i].TestKFlag(KEY_SELECTED)) {
        prev = keys[i].time;
        keys[i].time = map->map(keys[i].time);
        delta = keys[i].time - prev;
        changed = TRUE;
    } else if (slide) {
        keys[i].time += delta;
    }
}
}
if (flags&TRACK_MAPRANGE &&
keys.TestTFlag(RANGE_UNLOCKED)) {
    TimeValue t0 = map->map(keys.range.Start());
    TimeValue t1 = map->map(keys.range.End());
    keys.range.Set(t0,t1);
}
if (changed) {
    keys.KeysChanged();
    ivalid.SetEmpty();
    NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);
}
doneMapKeys:
Animatable::MapKeys(map,flags);
}

```

**Prototype:**

**virtual void DeleteKeys(DWORD flags)**

**Remarks:**

Implemented by the Plug-In.

This method is called to delete keys, as specified by the flags passed.

**Parameters:**

**DWORD flags**

One or more of the following values:

### **TRACK\_DOSEL**

Delete selected keys only.

### **TRACK\_DOALL**

Delete all keys (ignore selection state).

### **TRACK\_SLIDEUNSEL**

Slide unselected keys to the right.

### **TRACK\_RIGHTTOLEFT**

Enumerate right to left. If **TRACK\_SLIDEUNSEL** is set, keys will slide to the left.

#### **Default Implementation:**

```
{}
```

#### **Prototype:**

```
virtual void DeleteKeyByIndex(int index);
```

#### **Remarks:**

Implemented by the Plug-In.

Deletes the key specified by the index passed.

#### **Parameters:**

**int index**

The index of the key to delete.

#### **Default Implementation:**

```
{}
```

#### **Prototype:**

```
virtual void SelectKeys(TrackHitTab& sel, DWORD flags);
```

#### **Remarks:**

Implemented by the Plug-In.

This method is called to select or deselect a set of keys identified by the **TrackHitTab** and the specified flags.

#### **Parameters:**

**TrackHitTab& sel**

The table of track hit records. See [Class TrackHitRecord](#) and [Class Tab](#). Note

the following: **typedef Tab<TrackHitRecord> TrackHitTab;**

### **DWORD flags**

Either **SELKEYS\_SELECT**, **SELKEYS\_DESELECT**, or a combination of **SELKEYS\_CLEARKEYS** and **SELKEYS\_CLEARCURVE** will be specified.

One or more of the following values:

#### **SELKEYS\_SELECT**

The keys should be selected.

#### **SELKEYS\_DESELECT**

The keys should be deselected.

#### **SELKEYS\_CLEARKEYS**

All keys should be deselected.

#### **SELKEYS\_CLEARCURVE**

All keys on the function curve should be deselected.

#### **SELKEYS\_FCURVE**

Indicates that we are operating on the keys of a function curve, and not of a track.

### **Default Implementation:**

**{}**

### **Prototype:**

**virtual void SelectSubKeys(int subNum, TrackHitTab& sel, DWORD flags);**

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called on the client when the client takes over control of an anims function curves. It's called to select or deselect a set of keys identified by the **TrackHitTab** and the specified flags.

### **Parameters:**

#### **int subNum**

The index of the sub-anim to select or deselect

## **TrackHitTab& sel**

The table of track hit records. See [Class TrackHitRecord](#) and [Class Tab](#). Note the following: **typedef Tab<TrackHitRecord> TrackHitTab;**

### **DWORD flags**

Either **SELKEYS\_SELECT**, **SELKEYS\_DESELECT**, or a combination of **SELKEYS\_CLEARKEYS** and **SELKEYS\_CLEARCURVE** will be specified.

One or more of the following values:

#### **SELKEYS\_SELECT**

The keys should be selected.

#### **SELKEYS\_DESELECT**

The keys should be deselected.

#### **SELKEYS\_CLEARKEYS**

All keys should be deselected.

#### **SELKEYS\_CLEARCURVE**

All keys on the function curve should be deselected.

#### **SELKEYS\_FCURVE**

Indicates that we are operating on the keys of a function curve, and not of a track.

### **Default Implementation:**

```
{
```

### **Prototype:**

```
virtual void SelectSubCurve(int subNum,BOOL sel);
```

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called to set the selected state of the sub-curve whose index is passed.

### **Parameters:**

**int subNum**

The index of the sub-anim to select or deselect

**BOOL sel**

TRUE to select the curve; FALSE to deselect it.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual void SelectKeyByIndex(int i, BOOL sel);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method is called to set the selected state of the key whose index is passed.

**Parameters:****int i**

The key to select or deselect.

**BOOL sel**

TRUE to select the key; FALSE to deselect it.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual void FlagKey(TrackHitRecord hit);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to have the plug-in flag or mark a specific key identified by the TrackHitRecord.

As an example, when the user goes to move a selection set of keys in the Track View, a yellow marker is drawn. To move the group of keys, the user clicks on a single one. The system needs to track this one key as it is moved, and needs a way to identify it. This method is called so the developer can flag this key as the one that was selected. This is needed because the Track View doesn't know anything about a specific controllers ordering of keys and thus

cannot refer to it by index.

The system will call **GetFlagKeyIndex()** (described below) to retrieve the index of the key that was flagged.

**Parameters:**

**TrackHitRecord hit**

The developer uses this class to identify a key. This is the hit record that the controller gave the Track View in the first place to identify the hit. Thus this is enough information to identify the key. See [Class TrackHitRecord](#).

**Default Implementation:**

```
{}
```

**Sample Code:**

```
INTERP_CONT_TEMPLATE
void
InterpControl<INTERP_CONT_PARAMS>::FlagKey(TrackHitRecord
hit)
{
    int n = keys.Count();
    for ( int i = 0; i < n; i++ ) {
        keys[i].ClearKFlag(KEY_FLAGGED);
    }
    assert(hit.hit>=0&&hit.hit<(DWORD)n);
    keys[hit.hit].SetKFlag(KEY_FLAGGED);
}
```

**Prototype:**

```
virtual int GetFlagKeyIndex();
```

**Remarks:**

Implemented by the Plug-In.

Returns the index of the key that is flagged, or -1 if no keys are flagged. See the method above.

**Default Implementation:**

```
{return -1;}
```

**Sample Code:**

## **INTERP\_CONT\_TEMPLATE**

```
int InterpControl<INTERP_CONT_PARAMS>::GetFlagKeyIndex()
{
    int n = keys.Count();
    for ( int i = 0; i < n; i++ ) {
        if (keys[i].TestKFlag(KEY_FLAGGED)) {
            return i;
        }
    }
    return -1;
}
```

### **Prototype:**

```
virtual int NumSelKeys();
```

### **Remarks:**

Implemented by the Plug-In.

Returns the number of selected keys.

### **Default Implementation:**

```
{return 0;}
```

### **Prototype:**

```
virtual void CloneSelectedKeys(BOOL offset=FALSE);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to make a copy of the selected keys.

### **Parameters:**

**BOOL offset=FALSE**

If TRUE, set the new key time to be centered between the original key and the next key.

### **Prototype:**

```
virtual void AddNewKey(TimeValue t,DWORD flags);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to add a new key at the specified time. The value of the key is set to the value of the previous key, or interpolated between keys, based on the flags passed.

**Parameters:**

**TimeValue t**

The time to add the key.

**DWORD flags**

One or more of the following values:

**ADDKEY\_SELECT**

Select the new key and deselect any other selected keys.

**ADDKEY\_INTERP**

If TRUE then initialize the new key to the interpolated value at that time. If FALSE, initialize the key to the value of the previous key.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void MoveKeys(ParamDimensionBase *dim,float  
delta,DWORD flags);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to move selected keys vertically in the function curve editor. This moves the key values but does not alter the key times. The developer adds the delta to the selected key values, after converting them using the dimension **\*dim** passed. See the sample code below for how this may be done.

**Parameters:**

**ParamDimensionBase \*dim**

This class is used to scale the parameter's values into and out of units used in the user interface. For example, if the parameter was an angle, it would be shown in degrees, but stored in radians. Methods of this class allow the value to be converted back and forth. This is needed because the delta passed is in

user interface units. Thus the selected key values need to be converted before the delta is applied. See [Class ParamDimensBase](#).

### **float delta**

The amount to move the keys (move the values - not the times). This is in the units of the user interface. For example, if an angle has a value in the function curve editor of 100 degrees, 100 would be passed as the delta.

### **DWORD flags**

These are not currently used.

### **Default Implementation:**

```
{}
```

### **Sample Code:**

```
INTERP_CONT_TEMPLATE
void
InterpControl<INTERP_CONT_PARAMS>::MoveKeys(ParamDimensio
*dim,float delta,DWORD flags)
{
int n = keys.Count();
if (!n) return;
float m = 1.0f;
Interval valid;
BOOL changed = FALSE;
HoldTrack();
for (int i = 0; i < n; i++ ) {
for (int j=0;j<ELS;j++) {
if (keys[i].AnyElemSelected()) {
m = GetMultVal(keys[i].time,valid);
}
if (keys[i].ElemSelected(j)) {
keys[i][j] =
dim->UnConvert(dim->Convert(keys[i][j]*m)+delta)/m;
changed = TRUE;
}
}
}
if (changed) {
// FALSE indicates that key times didn't
```

```
// change so sorting isn't necessary.  
keys.KeysChanged(FALSE);  
ivalid.SetEmpty();  
NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);  
}  
}
```

**Prototype:**

```
virtual void ScaleKeyValues(ParamDimensionBase *dim,float  
origin, float scale,DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to scale selected keys values. This scales the key values but does not alter the key times. The developer scales the selected key values about the specified origin, after converting them using the dimension **\*dim** passed.

Note the following macro available for scaling about an origin:

```
#define ScaleAboutOrigin(val,origin,scale)  
(((val)-(origin))*(scale))+(origin))
```

**Parameters:**

**ParamDimensionBase \*dim**

This class is used to scale the parameter's values into and out of units used in the user interface. For example, if the parameter was an angle, it would be shown in degrees, but stored in radians. Methods of this class allow the value to be converted back and forth. See [Class ParamDimensBase](#).

**float origin**

The origin about which the keys are scaled.

**float scale**

The scale factor to apply to the key values.

**DWORD flags**

These are not currently used.

**Default Implementation:**

```
{}
```

**Sample Code:**

```
INTERP_CONT_TEMPLATE
void InterpControl<INTERP_CONT_PARAMS>::ScaleKeyValues(
    ParamDimensionBase *dim,float origin,float scale,DWORD flags)
{
    int n = keys.Count();
    if (!n) return;
    BOOL changed = FALSE;
    HoldTrack();
    for (int i = 0; i < n; i++ ) {
        for (int j=0;j<ELS;j++) {
            if (keys[i].ElemSelected(j)) {
                keys[i][j] = dim->UnConvert( ScaleAboutOrigin(
                    dim->Convert(keys[i][j]),origin,scale) );
                changed = TRUE;
            }
        }
    }
    if (changed) {
        keys.KeysChanged(FALSE);
        ivalid.SetEmpty();
        NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);
    }
}
```

**Prototype:**

```
virtual void SelectCurve(BOOL sel)
```

**Remarks:**

Implemented by the Plug-In.

The plug-in keeps track of whether its function curve is selected or not. This method is called to have the plug-in select or deselect its function curve.

**Parameters:**

**BOOL sel**

TRUE if the curve should be selected; FALSE if it should be deselected.

**Default Implementation:**

```
}
```

**Prototype:**

```
virtual BOOL IsCurveSelected()
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the function curve is selected; otherwise returns FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL IsKeySelected(int index)
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the key specified by the index is selected; otherwise FALSE.

**Parameters:**

**int index**

The index of the key to test.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual int GetSelKeyCoords(TimeValue &t, float &val, DWORD flags);
```

**Remarks:**

Implemented by the Plug-In.

This method is used to determine the commonality of the selected keys for display in the time/value type in fields of Track View. It is also used to retrieve the value and/or time of the selected keys (if there is only one selected, or they are common to the selected keys). The flags parameter specified which values to retrieve. The return value indicates if nothing, or several keys were selected. It also indicates if the selected keys shared a common time and/or common

value.

**Parameters:**

**TimeValue &t**

The time of the selected keys is returned here (if appropriate).

**float &val**

The value of the selected keys is returned here (if appropriate).

**DWORD flags**

One of the following values:

**KEYCOORDS\_TIMEONLY**

Only the time **t** needs to be updated.

**KEYCOORDS\_VALUEONLY**

Only the value **val** needs to be updated.

**Return Value:**

This indicates what was selected, and what these keys had in common. One or more of the following values should be set:

**KEYS\_NONESELECTED**

This indicates that no keys are selected.

**KEYS\_MULTISELECTED**

This indicates that multiple keys are selected.

Both of these last two bits could be set.

**KEYS\_COMMONTIME**

If the selected keys share the same time then this flag should be set. In this case it is appropriate to update **t** if required.

**KEYS\_COMMONVALUE**

If the selected keys share the same value then this flag should be set. In this case it is appropriate to update **val** if required.

**Default Implementation:**

```
{return KEYS_NONESELECTED;}
```

**Prototype:**

```
virtual void SetSelKeyCoords(TimeValue t, float val,DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to update the time and/or value of the selected keys as specified by the flags. This is called if the user uses the time/value type in fields of Track View.

**Parameters:****TimeValue t**

The time to set for the selected keys (if the flags indicate this is needed).

**float val**

The value to set for the selected keys (if the flags indicate this is needed).

**DWORD flags**

One of the following values:

**KEYCOORDS\_TIMEONLY**

Only the time needs to be updated.

**KEYCOORDS\_VALUEONLY**

Only the value needs to be updated.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int SetSelKeyCoordsExpr(ParamDimension *dim, TCHAR *timeExpr, TCHAR *valExpr, DWORD flags);
```

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

This method is similar to **SetSelKeyCoords()** above. In that case you're given a time and a value and are to update the selected keys with these values (based on the flags passed). In this case, you are instead passed time and value **expressions** (as strings). The idea is that these strings are evaluated as expressions and the resulting values are used to update the selected keys. For instance, the user could select a bunch of keys and then type in **n+45**. This would add 45 to all the values of the keys.

Developers can use the 3ds max expression parser (see [Class Expr](#)) to evaluate

the strings. Debug SDK users can see `\MAXSDKDB\SDKSRC\CTRLTEMP.H` for an example (or see the sample code below)). If a plug-in doesn't support this feature it can return `FALSE` from this method and the old `SetSelKeyCoords()` method will be called. Note that the variable names are defined as `KEYCOORDS_TIMEVAR` and `KEYCOORDS_VALVAR`.

#### **Parameters:**

**ParamDimension \*dim**

This is used to convert the parameter value once you get it.

**TCHAR \*timeExpr**

A string containing the time expression.

**TCHAR \*valExpr**

A string containing the value expression.

**DWORD flags**

One of the following values:

**KEYCOORDS\_TIMEONLY**

Only the time **t** needs to be updated.

**KEYCOORDS\_VALUEONLY**

Only the value **val** needs to be updated.

#### **Return Value:**

This indicates what was selected, and what these keys had in common. One or more of the following values should be set:

**KEYCOORDS\_EXPR\_UNSUPPORTED**

Don't implement this method

**KEYCOORDS\_EXPR\_ERROR**

Error in expression

**KEYCOORDS\_EXPR\_OK**

Expression evaluated

#### **Default Implementation:**

```
{return KEYCOORDS_EXPR_UNSUPPORTED;}
```

#### **Sample Code:**

## INTERP\_CONT\_TEMPLATE

```
int InterpControl<INTERP_CONT_PARAMS>::SetSelKeyCoordsExpr(
    ParamDimension *dim,
    TCHAR *timeExpr, TCHAR *valExpr, DWORD flags)
{
    Expr texpr, vexpr;
    float vin, vout=0.0f, tfin, tfout=0.0f;

    if (timeExpr) {
        texpr.defVar(SCALAR_VAR,KEYCOORDS_TIMEVAR);
        if (texpr.load(timeExpr)!=EXPR_NORMAL) return
KEYCOORDS_EXPR_ERROR;
    }
    if (valExpr) {
        vexpr.defVar(SCALAR_VAR,KEYCOORDS_VALVAR);
        if (vexpr.load(valExpr)!=EXPR_NORMAL) return
KEYCOORDS_EXPR_ERROR;
    }

    int n = keys.Count();
    if (!n) return KEYCOORDS_EXPR_OK;
    HoldTrack();
    for (int i = 0; i < n; i++ ) {
        if (!(flags&KEYCOORDS_VALUEONLY)) {
            if (keys[i].TimeLocked()) continue;
            if (keys[i].TestKFlag(KEY_SELECTED)) {
                tfin = float(keys[i].time)/float(GetTicksPerFrame());
                texpr.eval(&tfout, 1, &tfin);
                keys[i].time = int(tfout*GetTicksPerFrame());
            }
        }
        if (!(flags&KEYCOORDS_TIMEONLY)) {
            for (int j=0;j<ELS;j++) {
                if (keys[i].ElemSelected(j)) {
                    vin = dim->Convert(keys[i][j]);
                    vexpr.eval(&vout, 1, &vin);
                    keys[i][j] = dim->UnConvert(vout);
                }
            }
        }
    }
}
```

```

    }
    }
    }
    }
    keys.KeysChanged();
    keys.CheckForDups();
    ivalid.SetEmpty();
    NotifyDependents(FOREVER, PART_ALL, REFMSG_CHANGE);
    return KEYCOORDS_EXPR_OK;

```

### Prototype:

```

virtual void AdjustTangents(TrackHitRecord hit, ParamDimensionBase *dim, Rect& rcGraph, float tzoom, int tscroll, float vzoom, int vscroll, int dx, int dy, DWORD flags)

```

### Remarks:

Implemented by the Plug-In.

If a plug-in has tangent handles, this method is called if the user adjusts them. If a plug-in doesn't have tangent handles, this method may be ignored. This method is called if the user selects one of the handles and moves the mouse. This method is passed the dx, and dy of the mouse motion.

The plug-in may have any types of handles it wishes, and it is responsible for processing whatever needs to be done when the user adjusts them. The method is passed information about the screen space, such as the overall rectangle, and time and value scroll and zoom factors. See [List of Screen-Time-Value Macros](#) for macros to convert in and out of screen space.

### Parameters:

#### **TrackHitRecord hit**

This identifies the handle that was selected (hit).

#### **ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

#### **Rect& rcGraph**

This is the rectangle of the graph viewport.

#### **float tzoom**

This is the time zoom factor.

**int tscroll**

This is the time scroll factor.

**float vzoom**

This is the value zoom factor.

**int vscroll**

This is the value scroll factor.

**int dx**

The mouse movement in screen coordinates in the x direction.

**int dy**

The mouse movement in screen coordinates in the y direction.

**DWORD flags**

One of the following values:

**ADJTAN\_LOCK**

Indicates the tangents are locked.

**ADJTAN\_BREAK**

Indicates the tangents have been broken.

**Default Implementation:**

```
{ }
```

**Drawing and hit testing tracks****Prototype:**

```
virtual int GetTrackVSpace(int lineHeight)
```

**Remarks:**

Implemented by the Plug-In.

Returns the vertical space occupied by the track in units of one line.

**Parameters:****int lineHeight**

The height of a single line in pixels.

**Default Implementation:**

```
{ return 1; }
```

**Prototype:**

**virtual int HitTestTrack(TrackHitTab& hits,Rect& rcHit,Rect& rcTrack,float zoom,int scroll,DWORD flags)**

**Remarks:**

Implemented by the Plug-In.

This method is called to determine which keys lie within the **rcHit** rectangle. Keys that are hit are added to the **hits** table.

**Parameters:****TrackHitTab& hits**

The table of **TrackHitRecords** to update. Each key that lies within the hit rectangle (is hit) should be added to this table. It is up to the plug-in to define a scheme that allows it to identify its hits using the data members of [Class TrackHitRecord](#). Also see [Class Tab](#) for methods to add to the table.

**Rect& rcHit**

This is the region that was selected for hit testing. This may be a small rectangle about the mouse pick point, or a larger rectangle if the user selected by window.

**Rect& rcTrack**

This is the entire rectangular region of the track.

**float zoom**

The is the time zoom factor.

**int scroll**

This is the time scroll factor.

**DWORD flags**

One or more of the following value:

**HITTRACK\_SELONLY**

Selected only.

**HITTRACK\_UNSELONLY**

Unselected only.

**HITTRACK\_ABORTONHIT**

Abort hit testing on first hit.

**HITCURVE\_TESTTANGENTS**

Hit test curve tangents.

**Return Value:**

One of the following values:

**TRACK\_DONE**

This indicates the track was hit tested.

**TRACK\_DORANGE**

This indicates that the system will handle hit testing to the range bar for the item. For example a node returns this value because it does not have any keys. Therefore it just lets the user hit test the range bar. In general, anything that is not a leaf controller will not implement this method and return the default. The system will then simply hit test the range bar.

**TRACK\_ASKCLIENT**

If a plug-in returns this value then the anim's client will be given a chance to paint the track in Track View. If a client returns this value then the method **PaintSubTrack()** will be called.

**Default Implementation:**

```
{ return TRACK_DORANGE; }
```

**Prototype:**

```
virtual int PaintTrack(ParamDimensionBase *dim, HDC  
hdc,Rect& rcTrack,Rect& rcPaint, float zoom, int scroll, DWORD  
flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to display the item in the track view. If an item needs to draw itself in a special fashion, it implements this method to do so. For example, a sound plug-in may draw its waveform using this method. If an item does not need to draw itself, the default implementation may be used. This draws the range bar for the item.

Note: When drawing something to appear in Track View, a developer should not do any clipping of their own. 3ds max will take care of all clipping itself.

**Parameters:**

**ParamDimensionBase \*dim**

This parameter is available in release 2.0 and later only.

The dimension for the parameter of this track.

**HDC hdc**

The handle of the [= 4\) BSPSPopupOnMouseOver\(event\);">device context](#).

**Rect& rcTrack**

The entire rectangle of the inside of the track.

**Rect& rcPaint**

This is the rectangular region that needs to be repainted - the invalid region.

**float zoom**

The time zoom factor.

**int scroll**

The time scroll factor.

**DWORD flags**

One or more of the following values. These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green, and Z as blue.

**DISPLAY\_XCURVE**

**DISPLAY\_YCURVE**

**DISPLAY\_ZCURVE**

**Return Value:**

One of the following values:

**TRACK\_DONE**

Indicates the track was painted.

**TRACK\_DORANGE**

Indicates the system should draw the range bars for the item.

**TRACK\_ASKCLIENT**

Indicates the anim's client will be given a chance to paint the track in Track View. See **Animatable::PaintSubTrack()** which will be called to do this.

**Default Implementation:**

```
{ return TRACK_DORANGE; }
```

**Prototype:**

```
virtual int PaintSubTrack(int subNum, ParamDimensionBase
```

**\*dim, HDC hdc, Rect& rcTrack, Rect& rcPaint, float zoom, int scroll, DWORD flags);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

This method will be called if PaintTrack returns **TRACK\_ASKCLIENT**.

This gives the anim's client a chance to paint the tracks in Track View.

**Parameters:**

**int subNum**

Specifies the sub-anim to paint.

**ParamDimensionBase \*dim**

The dimension for the parameter of this track.

**HDC hdc**

The handle of the [= 4\) BSPSPopupOnMouseOver\(event\);">device context](#).

**Rect& rcTrack**

The entire rectangle of the inside of the track.

**Rect& rcPaint**

This is the rectangular region that needs to be repainted - the invalid region.

**float zoom**

The time zoom factor.

**int scroll**

The time scroll factor.

**DWORD flags**

One or more of the following values. These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green, and Z as blue.

**DISPLAY\_XCURVE**

**DISPLAY\_YCURVE**

**DISPLAY\_ZCURVE**

**Return Value:**

One of the following values:

**TRACK\_DONE**

Indicates the track was painted.

## **TRACK\_DORANGE**

Indicates the system should draw the range bars for the item.

### **Default Implementation:**

```
{return TRACK_DORANGE;}
```

## **Drawing and hit testing function curves**

### **Prototype:**

```
virtual int PaintFCurves(ParamDimensionBase *dim, HDC hdc,  
Rect& rcGraph,Rect& rcPaint, float tzoom, int tscroll, float  
vzoom, int vscroll, DWORD flags);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to draw the function curve of the anim.

### **Parameters:**

#### **ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

#### **HDC hdc**

The handle of the [= 4\) BSPSPopupOnMouseOver\(event\);">device context](#).

#### **Rect& rcGraph**

The entire rectangle of the inside of the graph region.

#### **Rect& rcPaint**

This is the rectangular region that needs to be repainted - the invalid region.

#### **float tzoom**

The time zoom factor.

#### **int tscroll**

The time scroll factor.

#### **float vzoom**

The value zoom factor.

#### **int vscroll**

The value scroll factor.

#### **DWORD flags**

One or more of the following values:

## **PAINTCURVE\_SHOWTANGENTS**

Show the curve tangent handles.

## **PAINTCURVE\_FROZEN**

Show the curve in a frozen state.

These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green and Z as blue.

### **DISPLAY\_XCURVE**

### **DISPLAY\_YCURVE**

### **DISPLAY\_ZCURVE**

## **PAINTCURVE\_GENCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in its standard color.

The following options are passed to float controllers indicating a suggested color for drawing.

### **PAINTCURVE\_XCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in red.

### **PAINTCURVE\_YCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in green.

### **PAINTCURVE\_ZCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in blue.

### **Return Value:**

A plug-in should always return 0.

### **Default Implementation:**

```
{ return 0; }
```

### **Prototype:**

```
virtual int HitTestFCurves(ParamDimensionBase  
*dim,TrackHitTab& hits, Rect& rcHit, Rect& rcGraph,float  
tzoom, int tscroll,float vzoom,int vscroll, DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to hit test the item's function curves. It is called to determine which keys on the curve lie within the **rcHit** rectangle. Keys that are hit are added to the **hits** table.

**Parameters:****ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

**TrackHitTab& hits**

The table of **TrackHitRecords** to update. Each key that lies within the hit rectangle (is hit) should be added to this table. It is up to the plug-in to define a scheme that allows it to identify its hits using the data members of [Class TrackHitRecord](#). Also see [Class Tab](#) for methods to add to the table.

**Rect& rcHit**

This is the region that was selected for hit testing. This may be a small rectangle about the mouse pick point, or a larger rectangle if the user selected by window.

**Rect& rcGraph**

This is the entire rectangle of the graph region.

**float tzoom**

This is the time zoom factor.

**int tscroll**

This is the time scroll factor.

**float vzoom**

This is the time zoom factor.

**int vscroll**

This is the time scroll factor.

**DWORD flags**

One or more of the following values:

**HITTRACK\_SELONLY**

Selected only.

**HITTRACK\_UNSELONLY**

Unselected only.

## **HITTRACK\_ABORTONHIT**

Abort hit testing on first hit.

## **HITCURVE\_TESTTANGENTS**

Hit Test curve tangent handles.

These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green and Z as blue.

### **DISPLAY\_XCURVE**

### **DISPLAY\_YCURVE**

### **DISPLAY\_ZCURVE**

#### **Return Value:**

One of the following values to indicate what was hit:

### **HITCURVE\_KEY**

Hit one or more keys.

### **HITCURVE\_WHOLE**

Hit the curve (anywhere).

### **HITCURVE\_TANGENT**

Hit a tangent handle.

### **HITCURVE\_NONE**

Nothing was hit.

### **HITCURVE\_ASKCLIENT**

Ask the client to hit test the function curve. See **HitTestSubFCurve()** below.

#### **Default Implementation:**

```
{ return HITCURVE_NONE; }
```

#### **Prototype:**

```
virtual int PaintSubFCurves(int subNum, ParamDimensionBase  
*dim, HDC hdc, Rect& rcGraph, Rect& rcPaint, float tzoom, int  
tscroll, float vzoom, int vscroll, DWORD flags);
```

#### **Remarks:**

Implemented by the Plug-In.

This method is called to draw the specified sub-anim function curve. This allows the client to paint its function curve.

## Parameters:

### **int subNum**

The sub-anim number to paint.

### **ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

### **HDC hdc**

The handle of the [= 4\) BSPSPopupOnMouseOver\(event\);">device context](#).

### **Rect& rcGraph**

The entire rectangle of the inside of the graph region.

### **Rect& rcPaint**

This is the rectangular region that needs to be repainted - the invalid region.

### **float tzoom**

The time zoom factor.

### **int tscroll**

The time scroll factor.

### **float vzoom**

The value zoom factor.

### **int vscroll**

The value scroll factor.

### **DWORD flags**

One or more of the following values:

#### **PAINTCURVE\_SHOWTANGENTS**

Show the curve tangent handles.

#### **PAINTCURVE\_FROZEN**

Show the curve in a frozen state.

These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green and Z as blue.

#### **DISPLAY\_XCURVE**

#### **DISPLAY\_YCURVE**

#### **DISPLAY\_ZCURVE**

#### **PAINTCURVE\_GENCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in its standard color.

The following options are passed to float controllers indicating a suggested color for drawing.

### **PAINTCURVE\_XCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in red.

### **PAINTCURVE\_YCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in green.

### **PAINTCURVE\_ZCOLOR**

This option is available in 3ds max 2.0 and later only.

Draw the curve in blue.

### **Return Value:**

A plug-in should always return 0.

### **Default Implementation:**

```
{ return 0; }
```

### **Prototype:**

```
virtual int HitTestSubFCurves(int subNum, ParamDimensionBase *dim, TrackHitTab& hits, Rect& rcHit, Rect& rcGraph, float tzoom, int tscroll, float vzoom, int vscroll, DWORD flags);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called if **HitTestFCurves()** returns **HITCURVE\_ASKCLIENT**. It allows the client to hit test its sub-anim curves.

### **Parameters:**

**int subNum**

The sub-anim number to hit test.

**ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

**TrackHitTab& hits**

The table of **TrackHitRecords** to update. Each key that lies within the hit rectangle (is hit) should be added to this table. It is up to the plug-in to define

a scheme that allows it to identify its hits using the data members of [Class TrackHitRecord](#). Also see [Class Tab](#) for methods to add to the table.

### **Rect& rcHit**

This is the region that was selected for hit testing. This may be a small rectangle about the mouse pick point, or a larger rectangle if the user selected by window.

### **Rect& rcGraph**

This is the entire rectangle of the graph region.

### **float tzoom**

This is the time zoom factor.

### **int tscroll**

This is the time scroll factor.

### **float vzoom**

This is the time zoom factor.

### **int vscroll**

This is the time scroll factor.

### **DWORD flags**

One or more of the following values:

#### **HITTRACK\_SELONLY**

Selected only.

#### **HITTRACK\_UNSELONLY**

Unselected only.

#### **HITTRACK\_ABORTONHIT**

Abort hit testing on first hit.

#### **HITCURVE\_TESTTANGENTS**

Hit Test curve tangent handles.

These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green and Z as blue.

#### **DISPLAY\_XCURVE**

#### **DISPLAY\_YCURVE**

#### **DISPLAY\_ZCURVE**

### **Return Value:**

One of the following values to indicate what was hit:

## **HITCURVE\_KEY**

Hit one or more keys.

## **HITCURVE\_WHOLE**

Hit the curve (anywhere).

## **HITCURVE\_TANGENT**

Hit a tangent handle.

## **HITCURVE\_NONE**

Nothing was hit.

### **Default Implementation:**

```
{ return HITCURVE_NONE; }
```

### **Prototype:**

```
virtual void EditTrackParams(TimeValue t, ParamDimensionBase  
*dim, TCHAR *pname, HWND hParent, IObjParam *ip,  
DWORD flags)
```

### **Remarks:**

Implemented by the Plug-In.

This method is called for the plug-in to put up a modal dialog and let the user edit the tracks parameters for the selected keys. This function should not return until the user has completed editing at which time any windows that were created should be destroyed. Unlike **BeginEditParams()** and **EndEditParams()** this interface is modal.

### **Parameters:**

#### **TimeValue t**

This time represents the horizontal position of where the user right clicked to bring up the modal edit track parameters dialog. See the flags below for when this parameter is valid.

#### **ParamDimensionBase \*dim**

The parameter dimension. See [Class ParamDimensionBase](#).

#### **TCHAR \*pname**

The name of the parameter as given by the client.

#### **HWND hParent**

This is the parent window that should be used to create any dialogs.

## **IObjParam \*ip**

An interface pointer available for calling functions in 3ds max.

## **DWORD flags**

One or more of the following values:

### **EDITTRACK\_FCURVE**

The user is in the function curve editor.

### **EDITTRACK\_TRACK**

The user is in one of the track views.

### **EDITTRACK\_SCENE**

The user is editing a path in the scene.

### **EDITTRACK\_BUTTON**

The user invoked by choosing the properties button. In this case the time parameter is NOT valid.

### **EDITTRACK\_MOUSE**

The user invoked by right clicking with the mouse. In this case the time parameter is valid.

## **Default Implementation:**

```
{}
```

## **Prototype:**

```
virtual int TrackParamsType()
```

## **Remarks:**

Implemented by the Plug-In.

This method returns a value that indicates how the track parameter editing is invoked.

## **Return Value:**

One of the following values:

### **TRACKPARAMS\_NONE**

Has no track parameters. If this is returned then **EditTrackParams()** will not be called.

### **TRACKPARAMS\_KEY**

Entered by right clicking on a selected key. This should be used if the dialog provides parameters for the entire controller (for example as the

Noise controller's dialog does).

### **TRACKPARAMS\_WHOLE**

Entered by right clicking anywhere in the track. This should be used if the dialog will represent the selection of keys (as a key info type dialog does).

#### **Default Implementation:**

```
{return TRACKPARAMS_NONE;}
```

#### **Prototype:**

```
virtual int GetFCurveExtents(ParamDimensionBase *dim,float  
&min, float &max, DWORD flags)
```

#### **Remarks:**

Implemented by the Plug-In.

This method is called to calculate the largest and smallest values of the anim.

#### **Parameters:**

##### **ParamDimensionBase \*dim**

The dimension of the anim. See [Class ParamDimensionBase](#).

##### **float &min**

The smallest value. These are in the units given by the dimension. For example, if it was an angle parameter that was displayed in degrees, the units returned through **min** should be in degrees as well.

##### **float &max**

The largest value. These are in the units given by the dimension. For example, if it was an angle parameter that was displayed in degrees, the units returned through **max** should be in degrees as well.

##### **DWORD flags**

These are filters for controllers with more than one curve. NOTE: RGB controllers interpret X as red, Y as green and Z as blue. One or more of the following values:

**DISPLAY\_XCURVE**

**DISPLAY\_YCURVE**

**DISPLAY\_ZCURVE**

#### **Return Value:**

If this method is processed, return nonzero; otherwise zero.

**Default Implementation:**

```
{return 0;}
```

**Sub-Class Indication****Prototype:**

```
virtual BOOL IsSubClassOf(Class_ID classID)
```

**Remarks:**

Implemented by the Plug-In.

If an object is a sub-class of a particular class, it will have a different **ClassID()** because it is a different class. This method allows an object to indicate that it is a sub-class of a particular class and therefore can be treated as one. For example, a class could be derived from **TriObject**. This derived class would have a different **ClassID()** than the **TriObject's** class ID however it still can be treated (cast) as a **TriObject** because it is derived from **TriObject**. Note the default implementation: a class is considered to also be a subclass of itself.

**Parameters:**

**Class\_ID classID**

The Class\_ID of the item that this class is a sub-class of.

**Return Value:**

TRUE if this class is a sub-class of **classID**; otherwise FALSE.

**Default Implementation:**

```
{return classID==ClassID();}
```

**Enumeration of Anims and Auxiliary Files****Prototype:**

```
int EnumAnimTree(AnimEnum *animEnum, Animatable *client,  
int subNum);
```

**Remarks:**

Implemented by the System.

This method recursively enumerates the Animatable hierarchy. It will call the

**AnimEnum::proc()** method passing it the anim, that anim's parent (the client), and the sub-anim index of that anim to the client, for every anim and sub-anim in the hierarchy.

**Parameters:**

**AnimEnum \*animEnum**

The callback object, called once for each sub anim from 0 to subNum-1. See [Class AnimEnum](#).

**Animatable \*client**

The client anim. This is the Animatable whose sub-anim are enumerated.

**int subNum**

The sub-anim index of the client at which to begin the enumeration. Pass 0 to do them all.

**Return Value:**

One of the following values:

**ANIM\_ENUM\_PROCEED**

**ANIM\_ENUM\_STOP**

**ANIM\_ENUM\_ABORT**

**Prototype:**

**virtual void EnumAuxFiles(NameEnumCallback& nameEnum, DWORD flags)**

**Remarks:**

Implemented by the Plug-In.

This method is used to enumerate any 'auxiliary' files maintained by the item and record the filename with the callback. Entities which actually need to load auxiliary files (for instance texture maps) must implement this method, possibly calling **ReferenceMaker::EnumAuxFiles()** also. The **ReferenceMaker** implementation simply calls itself on all its references (see below).

Class **Interface** has a method that may be used to call this on the entire system. This includes the renderer, materials editor, atmospheric effects, background, video post, lights, etc. -- everything that may have auxiliary files associated with it. After specifying the appropriate flags a list of filenames is created that matched the enumeration conditions as specified by the flags. This

is used for instance by the Archive function in 3ds max to grab a list of bitmap files used by the system.

**Parameters:**

**NameEnumCallback& nameEnum**

The callback object that may be used to record the name. See [Class NameEnumCallback](#).

**DWORD flags**

One or more of the following values. See [List of EnumAuxFiles Flags](#)

**Sample Code:**

This is the default implementation provided by **ReferenceMaker**.

```
void ReferenceMaker::EnumAuxFiles(NameEnumCallback&
nameEnum, DWORD flags) {
    for (int i=0; i<NumRefs(); i++) {
        ReferenceMaker *srm = GetReference(i);
        if (srm) srm->EnumAuxFiles(nameEnum,flags);
    }
}
```

**Prototype:**

**virtual int NumChildren()**

**Remarks:**

This method is used internally.

**Prototype:**

**virtual Animatable\* ChildAnim(int i)**

**Remarks:**

This method is used internally.

**Prototype:**

**virtual TSTR NodeName();**

**Remarks:**

This method is used internally.

## The following methods deal with Note Tracks.

### Prototype:

```
void AddNoteTrack(NoteTrack *note);
```

### Remarks:

Implemented by the System.

This method adds the specified note track.

### Parameters:

**NoteTrack \*note**

The note track to add. The Note Tracks provided by 3ds max are derived from [Class DefNoteTrack](#) (which is derived from **NoteTrack**). See that class for the methods and data members used to access Note Tracks.

### Prototype:

```
void DeleteNoteTrack(NoteTrack *note);
```

### Remarks:

Implemented by the System.

This method deletes the specified note track.

### Parameters:

**NoteTrack \*note**

The note track to delete. The Note Tracks provided by 3ds max are derived from [Class DefNoteTrack](#) (which is derived from **NoteTrack**). See that class for the methods and data members used to access Note Tracks.

### Prototype:

```
BOOL HasNoteTracks();
```

### Remarks:

Implemented by the System.

This method returns TRUE if the track has note tracks; otherwise FALSE.

### Prototype:

```
int NumNoteTracks();
```

**Remarks:**

Implemented by the System.

This method returns the number of note tracks.

**Prototype:**

**NoteTrack \*GetNoteTrack(int i);**

**Remarks:**

Implemented by the System.

This method retrieves the 'i-th' note track.

**Parameters:**

**int i**

Specifies the note track to retrieve.

**Return Value:**

A pointer to a Note Track. The Note Tracks provided by 3ds max are derived from [Class DefNoteTrack](#) (which is derived from **NoteTrack**). See that class for the methods and data members used to access Note Tracks.

**Parameter Block2 Methods****Prototype:**

**virtual int NumParamBlocks();**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method returns the number of ParamBlock2s in this instance.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

**virtual IParamBlock2\* GetParamBlock(int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method return 'i-th' ParamBlock2 in this instance (or NULL if not available).

**Parameters:**

**int i**

The zero based index of the ParamBlock2 to return.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual IParamBlock2* GetParamBlockByID(short id);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method returns a pointer to the ParamBlock2 as specified by the ID passed (or NULL if not available).

**Parameters:**

**short id**

The BlockID of the ParamBlock2 instance.

**Default Implementation:**

```
{ return NULL; }
```

## Schematic View Methods

**Prototype:**

```
bool SvSaveData(ISave *isave, USHORT id);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This is the save method for schematic view data. For classes derived from ReferenceMaker, there is no need to call these. However, **if** you have a class derived from Animatable **and** it appears in the schematic view **and** you want

to save schematic view properties for the object (node position, selection state, etc.) **then** you have to call this in your **Save()** method.

**Parameters:**

**ISave \*isave**

An interface for saving data. See [Class ISave](#).

**USHORT id**

The Chunk id (chosen by the developer).

**Return Value:**

Returns true if saved okay; otherwise false.

**Prototype:**

**bool SvLoadData(ILoad \*iLoad);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This is the load method for schematic view data. For classes derived from ReferenceMaker, there is no need to call these. However, **if** you have a class derived from Animatable **and** it appears in the schematic view **and** you want to load schematic view properties for the object (node position, selection state, etc.) **then** you have to call this in your **Load()** method.

**Parameters:**

**ILoad \*iLoad**

An interface for loading data. See [Class ILoad](#).

**Return Value:**

Returns true if loaded okay; otherwise false.

**Prototype:**

**virtual SvGraphNodeReference**

**SvTraverseAnimGraph(IGraphObjectManager \*gom, Animatable \*owner, int id, DWORD flags);**

**Remarks:**

This method is available in release 3.0 and later only.

This method traverses the graph of objects in the 3ds max scene, adding desired objects to the schematic view. Developers can specialize this behaviour by overriding this method and adding whatever objects are interesting to the schematic view. Objects are added to the schematic view by calling **IGraphObjectManager::AddAnimatable(...)**. Reference lines are added to the schematic view by calling **IGraphObjectManager::AddReference(...)**. Implementers of this method should call it recursively to process other objects in the scene. See [Class IGraphObjectManager](#).

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**Animatable \*owner**

The owning animatable.

**int id**

This is usually the sub-anim number (but can actually be any value the developer chooses).

**DWORD flags**

See [List of Schematic View AddAnimatable Flags](#).

**Return Value:**

A SvGraphNodeReference object.

**Prototype:**

**SvGraphNodeReference**

**SvStdTraverseAnimGraph(IGraphObjectManager \*gom,  
Animatable \*owner, int id);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is a default graph traversal function which can be called from **SvTraverseAnimGraph(...)** above to handle graph traversal in simple cases. This traversal follows the sub-anim and child references. See the code below.

**Parameters:**

## **IGraphObjectManager \*gom**

Points to the schematic view window manager.

## **Animatable \*owner**

The owning animatable.

## **int id**

This is usually the sub-anim number (but can actually be any value the developer chooses).

## **DWORD flags**

See [List of Schematic View AddAnimatable Flags](#).

### **Return Value:**

A SvGraphNodeReference object.

### **Default Implementation:**

```
// A default graph traversal function which can be
// called from SvTraverseAnimGraph(...) to handle
// graph traversal in simple cases. Follows sub-anim
// and child references...
```

### **SvGraphNodeReference**

```
Animatable::SvStdTraverseAnimGraph(IGraphObjectManager
```

```
*gom, Animatable *owner, int id, DWORD flags) {
```

```
int i;
```

```
SvGraphNodeReference nodeRef;
```

```
SvGraphNodeReference childNodeRef;
```

```
gom->PushLevel(this);
```

```
nodeRef = gom->AddAnimatable(this, owner, id, flags);
```

```
if (nodeRef.stat == SVT_PROCEED) {
```

```
for (i = 0; i < NumSubs(); i++) {
```

```
if (SubAnim(i)) {
```

```
childNodeRef = SubAnim(i)->SvTraverseAnimGraph(gom, this, i,
flags);
```

```
if (childNodeRef.stat != SVT_DO_NOT_PROCEED)
```

```
gom->AddReference(nodeRef.gNode, childNodeRef.gNode,
REFTYPE_SUBANIM);
```

```
}
```

```
}
```

```
}  
gom->PopLevel();  
return nodeRef;  
}
```

**Prototype:**

```
virtual bool SvCanInitiateLink(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns true if this animatable can be the initiator of a link operation in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**Prototype:**

```
virtual bool SvCanConcludeLink(IGraphObjectManager *gom,  
IGraphNode *gNode, IGraphNode *initiatingGNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns true if this animatable can be the receiver (parent) of a link operation in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**IGraphNode \*initiatingGNode**

Points to the child node in the schematic view.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual TSTR SvGetName(IGraphObjectManager *gom,  
IGraphNode *gNode, bool isBeingEdited);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the name of the object as it appears in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**bool isBeingEdited**

true if the item is being edited; false if not.

**Default Implementation:**

```
{  
Animatable *owner;  
int subNum;  
TSTR name;  
owner = gNode->GetOwner();  
subNum = gNode->GetID();  
name = owner->SubAnimName(subNum);  
return name;  
}
```

**Prototype:**

```
virtual bool SvCanSetName(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Return true to permit the object's name to be edited in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual bool SvSetName(IGraphObjectManager *gom,  
IGraphNode *gNode, TSTR &name);
```

**Remarks:**

This method is available in release 3.0 and later only.

Called when the user changes the name of the object in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**TSTR &name**

The new name to set.

**Return Value:**

true if the name was changed; false if not.

**Prototype:**

```
virtual bool SvCanRemoveThis(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Return true if this object can be removed in the schematic view; false if not.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual bool SvRemoveThis(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

This is called when the user deletes this object in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to this node in the schematic view.

**Return Value:**

true if deleted; false if not.

**Prototype:**

```
virtual bool SvIsHighlighted(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns true if the object is to be highlighted in the schematic view; otherwise false.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

## **IGraphNode \*gNode**

Points to this node in the schematic view.

### **Default Implementation:**

```
{ return false; }
```

### **Prototype:**

```
virtual COLORREF SvHighlightColor(IGraphObjectManager  
*gom, IGraphNode *gNode);
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns the highlight color for this node. The highlight color is used to outline nodes in the schematic view when **SvIsHighlighted(...)** returns true.

### **Parameters:**

#### **IGraphObjectManager \*gom**

Points to the schematic view window manager.

#### **IGraphNode \*gNode**

Points to this node in the schematic view.

### **Return Value:**

See [COLORREF-DWORD format](#).

### **Default Implementation:**

```
{ return gom-  
>SvGetUIColor(SV_UICLR_PLUGIN_HIGHLIGHT); }
```

### **Prototype:**

```
virtual COLORREF SvGetSwatchColor(IGraphObjectManager  
*gom, IGraphNode *gNode);
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns a color which is used to paint the triangular color swatch that appears in the upper-right hand corner of the node in the schematic view. One can return **SV\_NO\_SWATCH** to indicate that no swatch is to be drawn.

### **Parameters:**

### **IGraphObjectManager \*gom**

Points to the schematic view window manager.

### **IGraphNode \*gNode**

Points to this node in the schematic view.

#### **Return Value:**

See [COLORREF-DWORD format](#).

#### **Default Implementation:**

```
{ return SV_NO_SWATCH; }
```

#### **Prototype:**

```
virtual bool SvIsInactive(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

#### **Remarks:**

This method is available in release 3.0 and later only.

Returns true if this object is inactive; false is active. The schematic view draws inactive nodes in a grayed-out state.

#### **Parameters:**

### **IGraphObjectManager \*gom**

Points to the schematic view window manager.

### **IGraphNode \*gNode**

Points to this node in the schematic view.

#### **Default Implementation:**

```
{ return false; }
```

#### **Prototype:**

```
virtual bool SvLinkChild(IGraphObjectManager *gom,  
IGraphNode *gNodeThis, IGraphNode *gNodeChild);
```

#### **Remarks:**

This method is available in release 3.0 and later only.

This method is called to link this object to the **gNodeChild** passed.

#### **Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNodeThis**

Points to this node in the schematic view.

**IGraphNode \*gNodeChild**

Points to the child node in the schematic view.

**Return Value:**

true if linked; false if not.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual bool SvHandleDoubleClick(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is called when this node is double-clicked in the schematic view.

**Parameters:****IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

**Return Value:**

true is handled; false if not interested in the event.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual MultiSelectCallback*  
SvGetMultiSelectCallback(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is called before a multiple select/deselect operation in the schematic view. Returns a callback used to perform the (de)selection. May return NULL if this object cannot be selected in some principle editor outside the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

**Return Value:**

A pointer to the callback object. See [Class MultiSelectCallback](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual bool SvCanSelect(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

Returns true if this object can be selected in some editor (viewport, material editor, plug-in specific editor, etc.). Selection is actually accomplished by via the **SvGetMultiSelectCallback(...)** mechanism described above.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual bool SvEditProperties(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is reserved for future use.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual TSTR SvGetTip(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a string to be displayed in the tip window for this object in the schematic view.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

**Default Implementation:**

```
{ return SvGetName(gom, gNode, false); }
```

**Prototype:**

```
virtual TSTR SvGetRefTip(IGraphObjectManager *gom,  
IGraphNode *gNode, IGraphNode *gNodeMaker);
```

**Remarks:**

Returns a string to be displayed in the tip window in the schematic view for a reference from "gNodeMaker" to this.

**Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

## **IGraphNode \*gNodeMaker**

Points to the 'maker' node in the schematic view.

### **Sample Code:**

```
{ return gNodeMaker->GetAnim()->SvGetName(gom,  
gNodeMaker, false) + " -> " + SvGetName(gom, gNode, false); }
```

### **Prototype:**

```
virtual bool SvCanDetach(IGraphObjectManager *gom,  
IGraphNode *gNode);
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns true if this object can respond to the **SvDetach(...)** method; false if not.

### **Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

### **Default Implementation:**

```
{ return false; }
```

### **Prototype:**

```
virtual bool SvDetach(IGraphObjectManager *gom, IGraphNode  
*gNode);
```

### **Remarks:**

This method is available in release 3.0 and later only.

This method is called to detach this object from its owner.

### **Parameters:**

**IGraphObjectManager \*gom**

Points to the schematic view window manager.

**IGraphNode \*gNode**

Points to the node in the schematic view.

**Return Value:**

Returns true if detached; otherwise false.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
DWORD SvGetRefIndex();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use only.

**Prototype:**

```
void SvSetRefIndex(DWORD i);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use only.

**Prototype:**

```
bool SvDeleteRefIndex();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use only.

**Operators:****Prototype:**

```
Animatable& operator=(const Animatable& an)
```

**Remarks:**

Implemented by the System.

Assignment operator.

**The following function is not a part of class Animatable but is available for use with note tracks:**

**Prototype:**

**NoteTrack \*NewDefaultNoteTrack();**

**Remarks:**

Implemented by the System.

This function is used internally. It returns a new default note track.

## **Custom Attributes**

**Prototype:**

**ICustAttribContainer \*GetCustAttribContainer();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a pointer to the custom attributes container interface class.

See [Class ICustAttribContainer](#) for more information.

**Prototype:**

**void AllocCustAttribContainer();**

**Remarks:**

This method is available in release 4.0 and later only.

This method allocates space for a custom attributes container.

**Prototype:**

**void DeleteCustAttribContainer();**

**Remarks:**

This method deletes space used by a custom attributes container.

# Animatable

See Also: [Class Animatable](#).

This is the base class for almost all classes related to animation. Most of the track view-related methods are implemented here. Plug-ins implement virtual methods of Animatable to handle things like the editing of an item's parameters in the command panel, and the access to an item's animatable parameters.

## **NumSubs(), SubAnim(i), SubAnimName(i)**

These methods access the plug-ins animatable parameters.

## **BeginEditParams(), EndEditParams()**

These methods are called by the system when the plug-ins parameters are to be edited in the command panel.

## **SuperClassID(), ClassID()**

These methods identify the type of plug-in and its unique class ID.

## **DeleteThis()**

This method is used to delete an instance of a plug-in class.

# BaseObject

See Also: [Class BaseObject](#).

This is the base class for objects. Anything with a representation in the 3ds max 3D viewports is derived from BaseObject (including Modifiers, whose gizmos appear in the viewports).

The main methods of this class are:

## **Display()**

This is called by the system to have the item display itself.

## **HitTest()**

This allows the system to determine if a mouse point intersects the item.

## **Snap()**

This method allows the item to participate in the 3ds max snapping system.

There are several methods to retrieve the bounding box for the object.

## **GetWorldBoundingBox()**

This is the world space bounding box.

## **GetLocalBoundingBox()**

This is the object space bounding box.

There are also methods for sub-object selection. Both procedural objects and modifiers can participate in sub-object selection.

## Class BaseObject

See Also: [Class ReferenceTarget](#), [Class INode](#), [Class ViewExp](#), [Class Box3](#), [Class IPoint2](#), [Class Matrix3](#), [Structure SnapInfo](#), [Class Point3](#), [Class CreateMouseCallBack](#), [Template Class Tab](#), [Class Interface](#).

```
class BaseObject : public ReferenceTarget
```

### Description:

This is the base class for objects and modifiers. Anything with a representation in the 3D viewports is derived from BaseObject (including modifiers and controllers whose gizmos appear in the viewports). The methods here are things such as displaying the object in the viewports, checking for intersection of the object and points the user clicks with the mouse, snapping to the object, and computing various bounding boxes for the object. Also there are methods for returning the name of the object to appear in the modifier stack, a method to deal with creating the object in the viewports (if appropriate), and named selection set related methods. There are also methods that allow other plug-ins to access the changeable parameters of the object. Finally there are several method that deal with sub-object selection, sub-object display, sub-object hit testing, and moving/rotating/scaling sub-object components of the object.

### Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Object Name and Create Callback](#)

[Object Level Display, Hit Test, Snap, and Bounding Box Methods](#)

[Parameter Block Access](#)

[Named Selection Sets](#)

[Topology Change](#)

[Sub-Object Selection](#)

[Sub-Object Cloning](#)

[Sub-Object Display, Hit Testing, and Bound Box Methods](#)

[Sub-Object Center and TM Methods](#)

### Methods:

#### Object Name and Create Callback

**Prototype:**

```
virtual TCHAR *GetObjectName()
```

**Remarks:**

Implemented by the Plug-In.

Returns the name that will appear in the history browser (modifier stack).

**Default Implementation:**

```
{ return _T("Object"); }
```

**Prototype:**

```
virtual CreateMouseButton* GetCreateMouseButton();
```

**Remarks:**

Implemented by the Plug-In.

This method allows the system to retrieve a callback object used in creating an object in the 3D viewports. This method returns a pointer to an instance of a class derived from **CreateMouseButton**. This class has a method **proc()** which is where the programmer defines the user/mouse interaction during the object creation phase.

**Return Value:**

A pointer to an instance of a class derived from **CreateMouseButton**.

**Named Selection Sets**

A modifier that supports sub-object selection can choose to support named sub-object selection sets. Methods in the interface passed to objects allow them to add items to the sub-object selection set drop down list in the 3ds max toolbar. A modifier that wishes to support this capability maintains its list of named sub-object selections. When the user enters sub-object selection mode the modifier adds its named selection sets into the drop down (using **Interface::**

**AppendSubObjectNamedSelSet()**). See the Advanced Topics section on [Sub-Object Selection](#) for details.

**Prototype:**

```
virtual BOOL SupportsNamedSubSels();
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the plug-in supports named sub-object selection sets; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**The following three methods are called when the user picks items from the drop down list.**

**Prototype:**

```
virtual void ActivateSubSelSet(TSTR &setName);
```

**Remarks:**

Implemented by the Plug-In.

When the user chooses a name from the drop down list this method is called.

The plug-in should respond by selecting the set identified by the name passed.

**Parameters:**

**TSTR &setName**

The name of the set to select.

**Prototype:**

```
virtual void NewSetFromCurSel(TSTR &setName);
```

**Remarks:**

Implemented by the Plug-In.

If the user types a new name into the named selection set drop down then this method is called. The plug-in should respond by creating a new set and give it the specified name.

**Parameters:**

**TSTR &setName**

The name for the selection set.

**Prototype:**

```
virtual void RemoveSubSelSet(TSTR &setName);
```

**Remarks:**

Implemented by the Plug-In.

If the user selects a set from the drop down and then chooses Remove Named Selections from the Edit menu this method is called. The plug-in should respond by removing the specified selection set.

**Parameters:****TSTR &setName**

The selection set to remove.

**Prototype:**

```
virtual void SetupNamedSelDropDown();
```

**Remarks:**

This method is available in release 2.0 and later only.

To support the new Edit Named Selections dialog, plug-ins must implement this method.

This method is called to rebuild the named selection set drop down list. This is usually done by calling **Interface::ClearSubObjectNamedSelSets()** followed by calls to **Interface::AppendSubObjectNamedSelSet()**.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int NumNamedSelSets();
```

**Remarks:**

This method is available in release 2.0 and later only.

To support the new Edit Named Selections dialog, plug-ins must implement this method.

Returns the number of named selection sets.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

**virtual TSTR GetNamedSelSetName(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

To support the new Edit Named Selections dialog, plug-ins must implement this method.

Returns the name of the 'i-th' named selection set.

**Parameters:**

**int i**

The index of the selection set whose name is returned.

**Default Implementation:**

```
{return _T("");}
```

**Prototype:**

**virtual void SetNamedSelSetName(int i,TSTR &newName);**

**Remarks:**

This method is available in release 2.0 and later only.

To support the new Edit Named Selections dialog, plug-ins must implement this method.

This methods sets the name of the selection set whose index is passed to the name passed.

Note: Developers need to implement Undo / Redo for modifications to their named selection sets.

**Parameters:**

**int i**

The index of the selection set whose name is to be set.

**TSTR &newName**

The new name for the selection set the plug-in should store.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual void NewSetByOperator(TSTR &newName,Tab<int>**

**&sets,int op);**

**Remarks:**

This method is available in release 2.0 and later only.

To support the new Edit Named Selections dialog, plug-ins must implement this method.

The user may bring up the Edit Named Selections dialog via the Edit / Edit Named Selection ... command. This dialog allows the user to create new selection sets using 'boolean' operations to the sets including 'Combine', 'Subtract (A-B)', 'Subtract (B-A)' and 'Intersection'. This method is called on the plug-in to generate a new selection set via one of these operations.

This method assumes the developer will append a **new** selection set with the name passed. This will result in two sets with identical names. Then the system will call **RemoveSubSelSet()** afterwards, so that the first one that is found (the old one, since the new one was appended) will be deleted.

Note: Developers need to implement Undo / Redo for modifications to their named selection sets. See

**\MAXSDK\SAMPLES\MODIFIERS\MESHSEL.CPP** for an example.

**Parameters:**

**TSTR &newName**

The new name for the selection set is passed here.

**Tab<int> &sets**

A table of the selection sets to operate on. There are **sets.Count()** sets in the table.

**int op**

One of the following values:

**NEWSET\_MERGE**

The sets should be merged.

**NEWSET\_INTERSECTION**

The sets should be intersected -- that is the items common to both sets should appear in the new set.

**NEWSET\_SUBTRACT**

The new set should be the result of subtracting the 1st thru nth set from the

0th set.

**Default Implementation:**

```
{}
```

## **Object Level Display, Hit Test, Snap, and Bounding Box Methods**

**Prototype:**

```
virtual int Display(TimeValue t, INode* inode, ViewExp *vpt, int flags)
```

**Remarks:**

Implemented by the Plug-In.

This is called by the system to have the item display itself (perform a quick render in viewport, using the current TM). Note: For this method to be called the object's validity interval must be invalid at the specified time **t**. If the interval is valid, the system may not call this method since it thinks the display is already valid.

**Parameters:**

**TimeValue t**

The time to display the object.

**INode\* inode**

The node to display.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**int flags**

See [List of Display Flags](#).

**Return Value:**

The return value is not currently used.

**Default Implementation:**

```
{ return 0; };
```

**Prototype:**

```
virtual void SetExtendedDisplay(int flags);
```

**Remarks:**

This method is used for storing mode-dependent display attributes.

Before an object's Display() method is called, the appropriate bits of the extended display flag variable are set and this method is called. After that, the Display() method is called. If the object must display itself differently based on the settings of the extended display bit fields, then the object must save the flags passed into the this method. Otherwise, there is no need for the object to store the flags.

**Parameters:****int flags**

The flags to store.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual int HitTest(TimeValue t, INode* inode, int type, int crossing, int flags, IPoint2 *p, ViewExp *vpt);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the specified screen point intersects the item. The method returns nonzero if the item was hit; otherwise 0.

**Parameters:****TimeValue t**

The time to perform the hit test.

**INode\* inode**

A pointer to the node to test.

**int type**

The type of hit testing to perform. See [Hit Test Types](#) for details.

**int crossing**

The state of the crossing setting. If TRUE crossing selection is on.

**int flags**

The hit test flags. See [Hit Test Flags](#) for details.

**IPoint2 \*p**

The screen point to test.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Return Value:**

Nonzero if the item was hit; otherwise 0.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void Snap(TimeValue t, INode* inode, SnapInfo *snap,  
IPoint2 *p, ViewExp *vpt);
```

**Remarks:**

Implemented by the Plug-In.

Checks the point passed for a snap and updates the **SnapInfo** structure.

Note: The new snapping system introduced in release 2.0 causes this method to no longer be called. Developers wanting to find snap points on an Editable Mesh object should see the method **XmeshSnap::Snap()** in **\MAXSDK\SAMPLES\SNAPS\XMESH\XMESH.CPP**.

**Parameters:**

**TimeValue t**

The time to check.

**INode\* inode**

The node to check.

**SnapInfo \*snap**

The snap info structure to update.

**IPoint2 \*p**

The screen point to check.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Prototype:**

**virtual void GetWorldBoundingBox(TimeValue t, INode \* inode, ViewExp\* vp, Box3& box )**

**Remarks:**

Implemented by the Plug-In.

This method returns the world space bounding box for Objects (see below for the Sub-object gizmo or Modifiers gizmo version). The bounding box returned by this method does not need to be precise. It should however be calculated rapidly. The object can handle this by transforming the 8 points of its local bounding box into world space and take the minimums and maximums of the result. Although this isn't necessarily the tightest bounding box of the objects points in world space, it is close enough.

**Parameters:****TimeValue t**

The time to compute the bounding box.

**INode\* inode**

The node to calculate the bounding box for.

**ViewExp\* vp**

An interface pointer that may be used to call methods associated with the viewports.

**Box3& box**

The bounding box is returned through **box**.

**Prototype:**

**virtual void GetLocalBoundingBox(TimeValue t, INode\* inode, ViewExp\* vp, Box3& box )**

**Remarks:**

Implemented by the Plug-In.

This is the object space bounding box, the box in the object's local coordinates. The system expects that requesting the object space bounding box will be fast.

**Parameters:****TimeValue t**

The time to retrieve the bounding box.

**INode\* inode**

The node to calculate the bounding box for.

**ViewExp\* vp**

An interface pointer that may be used to call methods associated with the viewports.

**Box3& box**

The bounding box is returned through **box**.

## Topology Methods

**Prototype:**

**virtual BOOL OKToChangeTopology(TSTR &modName)**

**Remarks:**

Implemented by the System.

This method is called to see if any modifiers down in the pipeline depend on topology. It sends the message

**REFMSG\_IS\_OK\_TO\_CHANGE\_TOPOLOGY** to see if any modifiers or objects down the pipeline depend on topology.

**Parameters:**

**TSTR &modName**

This parameter is set to the dependent modifier's name if there is an item that depends on topology.

**Return Value:**

Returns TRUE if it is okay to change the topology; FALSE if it is not okay to change the topology.

**Prototype:**

**virtual BOOL ChangeTopology()**

**Remarks:**

Implemented by the Plug-In.

This method asks the question of an object or modifier "Do you change topology"? An object or modifier returns TRUE if it is capable of changing

topology when its parameters are being edited; otherwise FALSE.

When an item is selected for editing, and there is a modifier in the pipeline that depends on topology, the system calls this method to see if it may potentially change the topology. If this method returns TRUE the system will put up a warning message indicating that a modifier exists in the stack that depends on topology.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual void ForceNotify(Interval& i)
```

**Remarks:**

This method is no longer used.

**Parameter Block Access**

**Prototype:**

```
virtual IParamArray *GetParamBlock();
```

**Remarks:**

Implemented by the Plug-In.

An object or modifier should implement this method if it wishes to make its parameter block available for other plug-ins to access it. The system itself doesn't actually call this method. This method is optional.

**Return Value:**

A pointer to the item's parameter block. See [Class IParamArray](#).

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual int GetParamBlockIndex(int id);
```

**Remarks:**

Implemented by the Plug-In.

If a plug-in makes its parameter block available (using **GetParamBlock()**) then it will need to provide #defines for indices into the parameter block. These defines should not be directly used with the parameter block but instead converted by this function that the plug-in implements. This way if a parameter moves around in a future version of the plug-in the #define can be remapped. A return value of -1 indicates an invalid parameter id.

**Parameters:**

**int id**

The parameter block id. See: [List of Parameter Block IDs](#).

**Return Value:**

The parameter block index or -1 if it is invalid.

**Default Implementation:**

```
{return -1;}
```

## Sub-Object Selection

Affine transformation methods

**Prototype:**

```
virtual void Move(TimeValue t, Matrix3& partm, Matrix3& tmAxis, Point3& val, BOOL localOrigin=FALSE )
```

**Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by moving its selected sub-object components.

**Parameters:**

**TimeValue t**

The time of the transformation.

**Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the modifier's space and convert them into world space points. This is constructed as the node's transformation matrix times the inverse of the ModContext's transformation matrix. The node whose transformation is used is the node the user clicked on in the scene - modifiers can be instanced so there could be more than one node.

### **Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

### **Point3& val**

This value is a vector with X, Y, and Z representing the movement along each axis.

### **BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local origin.

### **Prototype:**

```
virtual void Rotate(TimeValue t, Matrix3& partm, Matrix3& tmAxis, Quat& val, BOOL localOrigin=FALSE )
```

### **Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by rotating its selected sub-object components.

### **Parameters:**

#### **TimeValue t**

The time of the transformation.

#### **Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the modifier's space and convert them into world space points. This is constructed as the node's transformation matrix times the inverse of the ModContext's transformation matrix. The node whose transformation is used is the node the user clicked on in the scene - modifiers can be instanced so there could be more than one node.

#### **Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

#### **Quat& val**

The amount to rotate the selected components.

#### **BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local

origin. Note: This information may be passed onto a transform controller (if there is one) so they may avoid generating 0 valued position keys for rotation and scales. For example if the user is rotating an item about anything other than its local origin then it will have to translate in addition to rotating to achieve the result. If a user creates an object, turns on the animate button, and rotates the object about the world origin, and then plays back the animation, the object does not do what the was done interactively. The object ends up in the same position, but it does so by both moving and rotating. Therefore both a position and a rotation key are created. If the user performs a rotation about the local origin however there is no need to create a position key since the object didn't move (it only rotated). So a transform controller can use this information to avoid generating 0 valued position keys for rotation and scales.

**Prototype:**

**virtual void Scale(TimeValue t, Matrix3& partm, Matrix3& tmAxis, Point3& val, BOOL localOrigin=FALSE )**

**Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by scaling its selected sub-object components.

**Parameters:**

**TimeValue t**

The time of the transformation.

**Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the modifier's space and convert them into world space points. This is constructed as the node's transformation matrix times the inverse of the ModContext's transformation matrix. The node whose transformation is used is the node the user clicked on in the scene - modifiers can be instanced so there could be more than one node.

**Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

**Point3& val**

This value is a vector with X, Y, and Z representing the scale along X, Y, and

Z respectively.

**BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local origin. See the note above in the Rotate method.

The following methods may be used to receive notification about the starting and ending phases of transforming the item when in sub-object selection.

**Prototype:**

**virtual void TransformStart(TimeValue t);**

**Remarks:**

Implemented by the Plug-In.

This method is called before the first **Move()**, **Rotate()** or **Scale()** call and before a hold is in effect.

**Parameters:**

**TimeValue t**

The current time when this method is called.

**Prototype:**

**virtual void TransformHoldingStart(TimeValue t);**

**Remarks:**

Implemented by the Plug-In.

This method is called before the first **Move()**, **Rotate()** or **Scale()** call and after a hold is in effect.

**Parameters:**

**TimeValue t**

The current time when this method is called.

**Prototype:**

**virtual void TransformHoldingFinish(TimeValue t);**

**Remarks:**

Implemented by the Plug-In.

This method is called after the user has completed the **Move()**, **Rotate()** or

**Scale()** operation and before the undo object has been accepted.

**Parameters:**

**TimeValue t**

The current time when this method is called.

**Prototype:**

**virtual void TransformFinish(TimeValue t);**

**Remarks:**

Implemented by the Plug-In.

This method is called after the user has completed the **Move()**, **Rotate()** or **Scale()** operation and the undo object has been accepted.

**Parameters:**

**TimeValue t**

The current time when this method is called.

**Prototype:**

**virtual void TransformCancel(TimeValue t);**

**Remarks:**

This method is called when the transform operation is canceled by a right-click and the undo has been canceled.

**Parameters:**

**TimeValue t**

The current time when this method is called.

## **Sub-Object Display, Hit Test, and Bounding Box Methods**

The following methods are for sub-object selection. If the derived class is NOT a modifier, the modContext pointer passed to some of these methods will be NULL.

**Prototype:**

**virtual int Display(TimeValue t, INode\* inode, ViewExp \*vpt, int flags, ModContext\* mc)**

**Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by performing a quick render of the modifier gizmo in viewport using the current TM.

Note for Modifiers: For this method to be called properly, one must send two reference messages using NotifyDependents.

In BeginEditParams send:

```
NotifyDependents(Interval(t,t), PART_ALL,  
REFMSG_MOD_DISPLAY_ON);
```

In EndEditParams send:

```
NotifyDependents(Interval(t,t), PART_ALL,  
REFMSG_MOD_DISPLAY_OFF);
```

**Parameters:****TimeValue t**

The time to display the item.

**INode\* inode**

The node to render.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**int flags**

See [List of Display Flags](#).

**ModContext\* mc**

A pointer to the modifiers ModContext.

**Return Value:**

Nonzero if the item was displayed; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual int HitTest(TimeValue t, INode* inode, int type, int  
crossing, int flags, IPoint2 *p, ViewExp *vpt, ModContext* mc)
```

**Remarks:**

Implemented by the Plug-In.

This method is used in modifier gizmo hit testing. It is called to determine if the specified screen point intersects the gizmo. The method returns nonzero if the item was hit; otherwise 0.

**Parameters:****TimeValue t**

The time to perform the hit test.

**INode\* inode**

A pointer to the node to test.

**int type**

The type of hit testing to perform. See [Hit Test Types](#) for details.

**int crossing**

The state of the crossing setting. If TRUE crossing selection is on.

**int flags**

The hit test flags. See [Hit Test Flags](#) for details.

**IPoint2 \*p**

The screen point to test.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**ModContext\* mc**

A pointer to the modifiers ModContext.

**Return Value:**

Nonzero if the item was hit; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void GetWorldBoundingBox(TimeValue t, INode* inode,  
ViewExp *vpt, Box3& box, ModContext *mc)
```

**Remarks:**

Implemented by the Plug-In.

This method computes the world space bounding box of the modifier gizmo (or any object that when in sub-object mode has a gizmo).

**Parameters:**

**TimeValue t**

The time to compute the bounding box.

**INode\* inode**

The node to calculate the bounding box for.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Box3& box**

The bounding box is returned through **box**.

**ModContext \*mc**

A pointer to the modifiers ModContext.

**Prototype:**

**virtual BOOL HasUVW();**

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

It is called to find out if the object is has UVW coordinates. This method returns TRUE if the object has UVW coordinates; otherwise FALSE. In 3ds max 2.0 and later there is code in the renderer that will automatically turn on the UVW coordinates of the base object if UV's are missing (and needed). The base object has to implement two simple methods to make this work:

**HasUVW()** and **SetGenUVW()**.

Developers are encouraged to put these methods in their objects: it makes using the program easier for the user. If they are not implemented, it doesn't cause any real harm: it will just operate as before and put up the missing UVW's message.

Here is how the procedural sphere implements these methods:

```
BOOL SphereObject::GetGenUVW() {
```

```

BOOL genUVs;
Interval v;
pblock->GetValue(PB_GENUVS, 0, genUVs, v);
return genUVs;
}
void SphereObject::SetGenUVW(BOOL sw) {
if (sw==GetGenUVW()) return;
pblock->SetValue(PB_GENUVS,0, sw);
}

```

Important Note: The **pblock->SetValue()** will cause a call to **NotifyDependents(FOREVER, PART\_TEXMAP, REFMSG\_CHANGE)**, which will invalidate the UVW cache. It is essential that this call be made, so if the 'generate UVW' boolean is not handled by a parameter block, then **NotifyDependents()** needs to be called explicitly.

Also Note: For "modifiable objects" that pass up the pipeline getting modified, such as **TriObject**, **EditTriObject**, etc., which cannot generate their own UVWs, but can carry them in their data structures, only this **HasUVW()** method needs to be implemented. For example, here is the implementation for **TriObject**:

```

BOOL TriObject::HasUVW() { return mesh.tvFace?1:0; }

```

**Default Implementation:**

```

{ return 1; }

```

**Prototype:**

```

virtual BOOL HasUVW(int mapChannel);

```

**Remarks:**

This method is available in release 3.0 and later only.

It is called to find out if the object is has UVW coordinates for the specified mapping channel. This method returns TRUE if the object has UVW coordinates; otherwise FALSE. See the method **HasUVW()** above for more details.

**Parameters:**

**int mapChannel**

See [List of Mapping Channels Values](#).

**Default Implementation:**

```
{ return (mapChannel==1) ? HasUVW() : FALSE; }
```

**Prototype:**

```
virtual void SetGenUVW(BOOL sw);
```

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

This method is called to change the state of its Generate UVW boolean. If the state changes, the object must send a **REFMSG\_CHANGE** up the pipeline by calling **NotifyDependents()**. This applies to map channel 1.

**Parameters:**

**BOOL sw**

The new state for the generate UVW flag.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetGenUVW(int mapChannel, BOOL sw);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is called to change the state of its Generate UVW boolean for the specified mapping channel. If the state changes, the object must send a **REFMSG\_CHANGE** up the pipeline by calling **NotifyDependents()**.

**Parameters:**

**int mapChannel**

The mapping channel index. See [List of Mapping Channel Index Values](#).

**BOOL sw**

The new state for the generate UVW flag.

**Default Implementation:**

```
{ if (mapChannel==1) SetGenUVW(sw); }
```

**Prototype:**

```
virtual void ShowEndResultChanged(BOOL showEndResult);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method notifies the BaseObject that the end result display has been switched (the "Show End Result" button has been toggled). Sometimes this is needed for display changes.

This method is implemented in Edit Mesh, which uses it as shown below:

```
void EditMeshMod::ShowEndResultChanged(BOOL  
showEndResult) {  
    NotifyDependents(FOREVER, PART_DISPLAY,  
REFMSG_CHANGE);  
}
```

This allows the Edit Mesh modifier to update itself in response to a user click of the "Show End Result" button in the modifier panel.

**Parameters:**

**BOOL showEndResult**

TRUE if Show End Result is on; FALSE if off.

**Default Implementation:**

```
{ }
```

## Sub-Object Cloning

**Prototype:**

```
virtual void CloneSelSubComponents(TimeValue t)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to make a copy of the selected sub-object components of

the item. If this is called on an object, the selection level of the object is used to determine which type of sub-objects are cloned. For instance in a Mesh, the selection level determines if selected vertices, edges or faces are cloned. If this is called on a Modifier then the selection level of the modifier is used. Modifiers call **Interface::GetModContexts()** to get a list of ModContexts, one for each object the modifier is applied to. Then the selected sub-objects are cloned for each object in the list.

**Parameters:**

**TimeValue t**

The time at which to clone the selected sub-object components.

**Prototype:**

**virtual void AcceptCloneSelSubComponents(TimeValue t)**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called when the user mouses up after shift-cloning a sub-object selection.

**Parameters:**

**TimeValue t**

The time at which the clone of the selected components is being done.

**Default Implementation:**

**{}**

## **Sub-Object Selection**

**Prototype:**

**virtual void SelectSubComponent(HitRecord \*hitRec, BOOL selected, BOOL all, BOOL invert=FALSE)**

**Remarks:**

Implemented by the Plug-In.

This method is called to change the selection state of the component identified by **hitRec**.

**Parameters:**

## **HitRecord \*hitRec**

Identifies the component whose selected state should be set. See [Class HitRecord](#) .

## **BOOL selected**

TRUE if the item should be selected; FALSE if the item should be de-selected.

## **BOOL all**

TRUE if all components in the HitRecord chain should be selected; FALSE if only the top-level HitRecord should be selected. (A HitRecord contains a Next() pointer; typically you want to do whatever you're doing to all the Next()'s until Next() returns NULL).

## **BOOL invert=FALSE**

This is set to TRUE when **all** is also set to TRUE and the user is holding down the Shift key while region selecting in select mode. This indicates the items hit in the region should have their selection state inverted

### **Prototype:**

```
virtual void ClearSelection(int selLevel);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to clear the selection for the given sub-object level. All sub-object elements of this type should be deselected. This will be called when the user chooses Select None from the 3ds max Edit menu.

### **Parameters:**

**int selLevel**

Specifies the selection level to clear.

### **Default Implementation:**

```
{
```

### **Prototype:**

```
virtual void SelectAll(int selLevel);
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to select every element of the given sub-object level.

This will be called when the user chooses Select All from the 3ds max Edit menu.

**Parameters:**

**int selLevel**

Specifies the selection level to select.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void InvertSelection(int selLevel);
```

**Remarks:**

This method is called to invert the specified sub-object level. If the element is selected it should be deselected. If it's deselected it should be selected. This will be called when the user chooses Select Invert from the 3ds max Edit menu.

**Parameters:**

**int selLevel**

Specifies the selection level to invert.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int SubObjectIndex(HitRecord *hitRec);
```

**Remarks:**

Implemented by the Plug-In.

Returns the index of the sub-object element identified by the HitRecord **hitRec**. See [Class HitRecord](#). The sub-object index identifies a sub-object component. The relationship between the index and the component is established by the modifier. For example an edit modifier may allow the user to select a group of faces and these groups of faces may be identified as group 0, group 1, group 2, etc. Given a hit record that identifies a face, the edit modifier's implementation of this method would return the group index that the face belonged to.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void ActivateSubobjSel(int level, XFormModes& modes )
```

**Remarks:**

Implemented by the Plug-In.

When the user changes the selection of the sub-object drop down, this method is called to notify the plug-in. This method should provide instances of a class derived from [CommandMode](#) to support move, rotate, non-uniform scale, uniform scale, and squash modes. These modes replace their object mode counterparts however the user still uses the move/rotate/scale tool buttons in the toolbar to activate them. If a certain level of sub-object selection does not support one or more of the modes NULL may be passed. If NULL is specified the corresponding toolbar button will be grayed out.

**Parameters:****int level**

The sub-object selection level the command modes should be set to support. A **level** of 0 indicates object level selection. If **level** is greater than or equal to 1 the index refers to the types registered by the object in the order they appeared in the list when registered by **Interface::RegisterSubObjectTypes()**. See [Class Interface](#).

**XFormModes& modes**

The command modes to support

**Sample Code:**

```
void SimpleMod::ActivateSubobjSel(int level, XFormModes& modes )
{
    switch ( level ) {
        case 1: // Modifier box
            modes = XFormModes(moveMode,rotMode,nuscaleMode,
                uscaleMode,squashMode,NULL);
            break;
        case 2: // Modifier Center
            modes =
```

```
XFormModes(moveMode,NULL,NULL,NULL,NULL,NULL);
    break;
}
NotifyDependents(FOREVER,PART_DISPLAY,REFMSG_CHANGE);
}
```

See Also: [Class XFormModes](#).

## Sub-Object Centers and TMs

### Prototype:

```
virtual void GetSubObjectCenters(SubObjAxisCallback
*cb,TimeValue t,INode *node, ModContext *mc)
```

### Remarks:

Implemented by the Plug-In.

When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current modifier being edited so that it can display the axis. This method specifies the position of the center. The plug-in enumerates its centers and calls the callback **cb** once for each.

### Parameters:

**SubObjAxisCallback \*cb**

The callback object whose methods may be called. See [Class SubObjAxisCallback](#).

**TimeValue t**

The time to enumerate the centers.

**INode \*node**

A pointer to the node.

**ModContext \*mc**

A pointer to the ModContext.

### Prototype:

```
virtual void GetSubObjectTMs(SubObjAxisCallback *cb,
TimeValue t,INode *node, ModContext *mc)
```

### Remarks:

Implemented by the Plug-In.

When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current modifier being edited so that it can display the axis. This method returns the axis system of the reference coordinate system. The plug-in enumerates its TMs and calls the callback **cb** once for each. See [Sub-Object Coordinate Systems](#).

**Parameters:**

**SubObjAxisCallback \*cb**

The callback object whose methods may be called.

**TimeValue t**

The time to enumerate the TMs.

**INode \*node**

A pointer to the node.

**ModContext \*mc**

A pointer to the ModContext.

**Prototype:**

```
virtual void NotifyPreCollapse(INode *node, IDerivedObject  
*derObj, int index);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is called before a modifier or object is collapsed. See also [Class NotifyCollapseEnumProc](#).

**Parameters:**

**INode \*node**

Points to the node for the object being collapsed.

**IDerivedObject \*derObj**

If the object associated with **node** above is a Modifier this points to the derived object. If it's an object then this is NULL.

**int index**

If the object associated with **node** above is a Modifier this is the index of this modifier in the DerivedObject.. If it's an object then this is 0.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void NotifyPostCollapse(INode *node, Object *obj,  
IDerivedObject *derObj, int index);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is called after a modifier or object is collapsed. See also [Class NotifyCollapseEnumProc](#).

**Parameters:**

**INode \*node**

Points to the node for the object being collapsed.

**IDerivedObject \*derObj**

If the object associated with **node** above is a Modifier this points to the derived object. If it's an object then this is NULL.

**int index**

If the object associated with **node** above is a Modifier this is the index of this modifier in the DerivedObject. If it's an object then this is 0.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int NumSubObjTypes();
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns the number of sub-object types supported by the object or modifier. In R4 objects or modifier must override this method and GetSubObjType() below.

**Default Implementation:**

```
{ return 0;}
```

**Prototype:**

**virtual ISubObjType \*GetSubObjType(int i);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the sub-object type for the sub-object whose index is passed.

If the parameter **i** passed is -1 the system requests an **ISubObjType** for the current SubObjectLevel that flows up the modifier stack. If the subobject selection of the modifier or base object does not affect the sub-object selection that flows up the stack NULL must be returned. See the sample code in **\MAXSDK\SAMPLES\MODIFIERS\MESHSEL.CPP**.

**Parameters:**

**int i**

The zero based index of the sub-object type to get. See the remarks above.

**Return Value:**

The sub-object type. See [Class ISubObjType](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual int GetSubObjectLevel();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns an integer which indicates the current sub-object level of the modifier or base object.

**Return Value:**

A value of 0 indicates object level. A value of 1 through

**NumSubObjTypes()** are the sub-object levels in the same order as they are returned by **GetSubObjType(int i)** (with an offset of 1 of course).

# CameraObject

See Also: [Class CameraObject](#).

This is the class from which plug-in cameras are derived. Camera objects implement methods that return the properties of the camera. Some of these methods are:

## **EvalCameraState()**

This returns a data structure containing the FOV and distance to the target.

These can also be accessed by:

## **Get/SetFOV()**

Provides access to the field of view of the camera.

## **Get/SetTDist()**

Provides access to the target distance of the camera.

# ConstObject

See Also: [Class ConstObject](#).

Plug-In construction objects such as the Grid Helper Object are subclassed off ConstObject.

# Control

See Also: [Class Control](#).

Controllers are the objects in 3ds max that control animation. Controllers come in different types based on the type of data they control. For example, transform controllers control the 4x3 matrices used to define the position of nodes in the scene while float controllers control simple floating point values.

Control is the class from which you may derived controller objects. Shown below are several of the methods of Control:

## **GetValue()**

Retrieves the value of the controller at the specified time, and updates the validity interval passed in to reflect the interval of the controller.

## **SetValue()**

Sets the value of the controller at the specified time.

## **IsLeaf()**

The controller should return TRUE if it has no sub controllers. For example, a PRS controller is not a leaf controller (because it has sub-controllers for Position, Rotation and Scale), but a simple keyframed float controller is a leaf controller.

## **Copy()**

When a controller is assigned to a track in the track view the new controller is plugged into the parameter and then this method is called on the new controller with a pointer to the old controller passed in. The new controller can then attempt to copy any data that it can from the old controller. At the very least it should initialize itself to the value of the old controller at frame 0.

# GeomObject

See Also: [Class GeomObject](#).

GeomObjects are objects that have geometry and are renderable. The procedural sphere, cylinder and box are examples of GeomObjects. In addition to the regular object methods, objects of this class implement these methods:

## **IsInstanceDependent()**

If an object creates different meshes depending on the particular instance (view-dependent) it should return nonzero; otherwise 0.

## **GetRenderMesh();**

This method provides a mesh representation of the object for use by the renderer.

## **GetRenderPatchMesh()**

This method provides a patch mesh representation of the object for use by the renderer. If this method returns NULL, then **GetRenderMesh()** will be called.

# HelperObject

See Also: [Class HelperObject](#).

This is the class from which plug-in helper objects are derived. These are objects that are used as aids in the scene such as points, tape measurers, dummy objects, etc.

# **INode**

See Also: [Class INode](#).

The INode class is the interface to nodes in the scene. It provides methods to access various properties of a node such as its name, wire-frame color, transformation matrix, etc.

# Class INode

See Also: [Class ReferenceTarget](#), [Class FPMixinInterface](#), [Class Interface](#), [Class INodeTransformed](#), [Class Material](#), [Class Matrix3](#), [Class Quat](#), [Class AngAxis](#), [Class Control](#), [Class Object](#), [Class INodeTab](#).

```
class INode : public ReferenceTarget, public FPMixinInterface
```

## Description:

The INode class is the interface to nodes in the scene. It provides methods to access various parts of a node such as its name, transformation matrices, parents and children, display status, etc. All methods of this class are implemented by the system.

## Method Groups:

These hyperlinks take you to the start of groups of related methods within the class.

## Methods:

### Prototype:

```
virtual const ObjectState& EvalWorldState(TimeValue  
time,BOOL evalHidden=TRUE)=0;
```

### Remarks:

This method should be called when a developer needs to work with an object that is the result of the node's pipeline. This is the object that appears in the scene.

This may not be an object that anyone has a reference to - it may just be an object that has flowed down the pipeline. For example, if there is a Sphere in the scene that has a Bend and Taper applied, **EvalWorldState()** would return an **ObjectState** containing a TriObject. This is the result of the sphere turning into a TriObject and being bent and tapered (just as it appeared in the scene).

If a developer needs to access the object that the node in the scene references, then the method **INode::GetObjectRef()** should be used instead. See [Object Reference Methods](#)

### Parameters:

#### **TimeValue time**

Specifies the time to retrieve the object state.

#### **BOOL evalHidden=TRUE**

If FALSE and the node is hidden, the pipeline will not actually be evaluated (however the TM will).

### Return Value:

The ObjectState that is the result of the pipeline. See [Class ObjectState](#).

### Sample Code:

```
// Get the object from the node  
ObjectState os = node->EvalWorldState(ip->GetTime());
```

```

if (os.obj->SuperClassID()==GEOMOBJECT_CLASS_ID) {
    obj = (GeomObject*)os.obj;
    ...
}

```

The following code shows how a **TriObject** can be retrieved from a node. Note on the code that if you call **ConvertToType()** on an object and it returns a pointer other than itself, you are responsible for deleting that object.

```

// Retrieve the TriObject from the node
int deleteIt;
TriObject *triObject = GetTriObjectFromNode(ip->GetSelNode(0),
    deleteIt);
// Use the TriObject if available
if (!triObject) return;
// ...
// Delete it when done...
if (deleteIt) triObject->DeleteMe();

// Return a pointer to a TriObject given an INode or return NULL
// if the node cannot be converted to a TriObject
TriObject *Utility::GetTriObjectFromNode(INode *node, int
&deleteIt) {
    deleteIt = FALSE;
    Object *obj = node->EvalWorldState(ip->GetTime()).obj;
    if (obj->CanConvertToType(Class_ID(TRIOBJ_CLASS_ID, 0))) {
        TriObject *tri = (TriObject *) obj->ConvertToType(ip->GetTime(),
            Class_ID(TRIOBJ_CLASS_ID, 0));
        // Note that the TriObject should only be deleted
        // if the pointer to it is not equal to the object
        // pointer that called ConvertToType()
        if (obj != tri) deleteIt = TRUE;
        return tri;
    }
    else {
        return NULL;
    }
}

```

## Node Naming

### Prototype:

```
virtual TCHAR* GetName()=0;
```

### Remarks:

Returns the name of the node.

### Prototype:

```
virtual void SetName(TCHAR *s)=0;
```

### Remarks:

Sets the name of the node.

### Parameters:

```
TCHAR *s
```

The name of the node.

### Prototype:

```
virtual ULONG GetHandle();
```

### Remarks:

This method returns the unique node handle. Each node is assigned a unique node handle.

### Return Value:

```
{ return 0; }
```

## Transformation Matrices.

For additional information regarding transformation matrices, see the Advanced Topics section on [Node and Object Offset Transformations](#).

### Prototype:

```
virtual Matrix3 GetNodeTM(TimeValue t, Interval*  
valid=NULL)=0;
```

### Remarks:

This method returns the world space transformation matrix of the node at the

specified time. This matrix contains its parents transformation. This matrix does not include the object-offset transformation, or any world space modifier (Space Warp) affects.

If you select a single node and change the reference coordinate system to 'Local', you'll see the node's axes tripod displayed. This tripod graphically depicts the nodes transformation matrix.

The Node TM may be considered the world space transformation as far as kinematics is concerned. This is almost the complete world space transformation as far as the geometry of the object is concerned, except it does not include the object-offset transformation. See the method **INode::GetObjectTM()** for the complete world space transformation of the geometry of the object.

The Node TM is inherited. When a node asks to retrieve its parents TM, it gets its parents Node TM. It does not get its parents Object TM. The object-offset transformation is not inherited.

**Parameters:**

**TimeValue t**

Specifies the time to retrieve the TM.

**Interval\* valid=NULL**

Points to storage for the validity interval of the transformation matrix. The interval, if passed, is intersected with the validity interval of the NodeTM.

**Return Value:**

The node's world space transform matrix.

**Prototype:**

**virtual void SetNodeTM(TimeValue t, Matrix3& tm)=0;**

**Remarks:**

This methods sets the node's world space transformation matrix (without the object-offset transformation or world space modifier affect). This method will perform the appropriate operation to the node's transform controller. For example, if the node has a parent, this method will take the parent's transformation into consideration when it calls **SetValue()** on the controller.

This method can be used to set the world space position of the node.

**Parameters:**

**TimeValue t**

Specifies the time to set the transformation matrix.

**Matrix3& tm**

The node's world space transformation matrix.

**Prototype:**

```
virtual void Move(TimeValue t, const Matrix3& tmAxis, const Point3& val, BOOL localOrigin=FALSE, BOOL affectKids=TRUE, int pivMode=PIV_NONE, BOOL ignoreLocks=FALSE)=0;
```

**Remarks:**

This method may be called to move the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't move.

**Parameters:****TimeValue t**

The time to transform the node.

**const Matrix3& tmAxis**

The axis system about which the node is transformed.

**const Point3& val**

The amount of the transformation relative to the axis system.

**BOOL localOrigin=FALSE**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

**BOOL affectKids=TRUE**

If TRUE any child nodes are transformed along with the parent node. If FALSE any children of the node are counter transformed so they don't move.

**int pivMode=PIV\_NONE**

One of the following values:

**PIV\_NONE**

Move both the pivot point and the geometry of the object.

**PIV\_PIVOT\_ONLY**

Move the pivot point only.

## **PIV\_OBJECT\_ONLY**

Move the geometry of the object only.

## **BOOL ignoreLocks=FALSE**

If TRUE any transform locks associated with the node are ignored; otherwise the locks govern the application of the transformation.

## **Prototype:**

```
virtual void Rotate(TimeValue t, const Matrix3& tmAxis, const  
AngAxis& val, BOOL localOrigin=FALSE, BOOL  
affectKids=TRUE, int pivMode=PIV_NONE, BOOL  
ignoreLocks=FALSE)=0;
```

## **Remarks:**

This method may be called to rotate the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't rotate.

## **Parameters:**

### **TimeValue t**

The time to transform the node.

### **const Matrix3& tmAxis**

The axis system about which the node is transformed.

### **const AngAxis& val**

The amount of the transformation.

### **BOOL localOrigin=FALSE**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

### **BOOL affectKids=TRUE**

If TRUE any child nodes are transformed along with the parent node. If FALSE any children of the node are counter transformed so they don't rotate.

### **int pivMode=PIV\_NONE**

One of the following values:

#### **PIV\_NONE**

Move both the pivot point and the geometry of the object.

**PIV\_PIVOT\_ONLY**

Move the pivot point only.

**PIV\_OBJECT\_ONLY**

Move the geometry of the object only.

**BOOL ignoreLocks=FALSE**

If TRUE any transform locks associated with the node are ignored; otherwise the locks govern the application of the transformation.

**Prototype:**

```
virtual void Rotate(TimeValue t, const Matrix3& tmAxis, const  
Quat& val, BOOL localOrigin=FALSE, BOOL affectKids=TRUE,  
int pivMode=PIV_NONE, BOOL ignoreLocks=FALSE)=0;
```

**Remarks:**

This method may be called to rotate the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't rotate.

**Parameters:****TimeValue t**

The time to transform the node.

**const Matrix3& tmAxis**

The axis system about which the node is transformed.

**const Quat& val**

The amount of the transformation.

**BOOL localOrigin=FALSE**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

**BOOL affectKids=TRUE**

If TRUE any child nodes are transformed along with the parent node. If FALSE any children of the node are counter transformed so they don't rotate.

**int pivMode=PIV\_NONE**

One of the following values:

**PIV\_NONE**

Move both the pivot point and the geometry of the object.

**PIV\_PIVOT\_ONLY**

Move the pivot point only.

**PIV\_OBJECT\_ONLY**

Move the geometry of the object only.

**BOOL ignoreLocks=FALSE**

If TRUE any transform locks associated with the node are ignored; otherwise the locks govern the application of the transformation.

**Prototype:**

```
virtual void Scale(TimeValue t, const Matrix3& tmAxis, const Point3& val, BOOL localOrigin=FALSE, BOOL affectKids=TRUE, int pivMode=PIV_NONE, BOOL ignoreLocks=FALSE)=0;
```

**Remarks:**

This method may be called to scale the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't scale.

**Parameters:**

**TimeValue t**

The time to transform the node.

**const Matrix3& tmAxis**

The axis system about which the node is transformed.

**const Point3& val**

The amount of the transformation.

**BOOL localOrigin=FALSE**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

**BOOL affectKids=TRUE**

If TRUE any child nodes are transformed along with the parent node. If FALSE any children of the node are counter transformed so they don't scale.

**int pivMode=PIV\_NONE**

One of the following values:

**PIV\_NONE**

Move both the pivot point and the geometry of the object.

**PIV\_PIVOT\_ONLY**

Move the pivot point only.

**PIV\_OBJECT\_ONLY**

Move the geometry of the object only.

**BOOL ignoreLocks=FALSE**

If TRUE any transform locks associated with the node are ignored; otherwise the locks govern the application of the transformation.

**Prototype:**

```
virtual Matrix3 GetObjectTM(TimeValue time, Interval*  
valid=NULL)=0;
```

**Remarks:**

This method returns the transformation matrix the object needs to be multiplied by to transform it into world space.

At times, this matrix may be the identity. For example, a deformable object that has a Space Warp applied to it would already have been translated into world space by the space warp. Since the object is already in world space the matrix needed to get it there is the identity.

This matrix would **not** be the identity for a deformable object with only object space modifiers applied. This object would indeed need to be transformed. In this case the TM returned would include the NodeTM plus the object-offset transformation. So, **GetObjectTM()** is dependent on the context when it is called -- it will either be equal to **GetObjectTMAfterWSM()** or **GetObjectTMBeforeWSM()**.

Developers should use **GetObjectTMBeforeWSM()** if what is wanted is the object TM and not the identity matrix.

For non-deformable objects this matrix may include the NodeTM, the object-offset transformation and the world space modifier affect.

This matrix could be used, for example, if you have a TriObject and wanted to get the world space coordinate of one of its vertices. You could do this by taking the vertex coordinate in object space and multiplying it by the matrix

returned from this method.

This matrix is also often used inside an object's **Display()** and **HitTest()** methods. When an object goes to draw itself (in its **BaseObject::Display()** method) it is given a node pointer. What the object normally does is use the node pointer and calls **GetObjectTM()**. It then takes the matrix returned and sets it into the graphics window (using **GraphicsWindow::setTransform()**). In this way, when the object starts drawing points in object space, they will be transformed with this matrix. This will transform the points into world space when they are drawn.

The Object TM is not inherited.

**Parameters:**

**TimeValue time**

Specifies the time to retrieve the object's transform matrix.

**Interval\* valid=NULL**

Points to storage for the validity interval of the transformation matrix.

**Return Value:**

The object's transformation matrix.

**Prototype:**

```
virtual Matrix3 GetObjTMBeforeWSM(TimeValue time,  
Interval* valid=NULL)=0;
```

**Remarks:**

This method explicitly retrieves the pipeline ObjectState TM before any world space modifiers have been applied. This includes the node's TM and the object-offset transformation (but not any world space modifier affect). See the section on the [Geometry Pipeline](#) for additional details on this method.

**Parameters:**

**TimeValue time**

Specifies the time to retrieve the transform matrix.

**Interval\* valid=NULL**

Points to storage for the validity interval of the transformation matrix.

**Prototype:**

**virtual Matrix3 GetObjTMAfterWSM(TimeValue time, Interval\* valid=NULL)=0;**

**Remarks:**

This method explicitly retrieves the pipeline ObjectState TM after any world space modifiers have been applied. This includes the Node TM, the object-offset transformation, and any world space modifier affects. In some cases a world space modifier can actually deform the TM itself if it cannot deform the object. Examples of this are cameras and lights. These objects do not have any 'object' to deform, so the space warp deforms the TM instead. See the section on the [Geometry Pipeline](#) for additional details on this method.

Note: Beware of calling this method from inside a function that performs a mesh traversal as doing so can invalidate the mesh.

**Parameters:**

**TimeValue time**

Specifies the time to retrieve the object's transform matrix.

**Interval\* valid=NULL**

Points to storage for the validity interval of the transformation matrix.

**Prototype:**

**virtual Matrix3 GetParentTM(TimeValue t)=0;**

**Remarks:**

Retrieves the parent node's transformation matrix. This is simply for convenience. It is the equivalent to the following code:

**node->GetParentNode()->GetNodeTM();**

**Parameters:**

**TimeValue t**

Specifies the time to retrieve the transformation matrix.

**Return Value:**

The parent node's transformation matrix.

**Prototype:**

**virtual int GetTargetTM(TimeValue t, Matrix3& m)=0;**

**Remarks:**

Retrieves the target node's transformation matrix. This is simply for convenience. It is the equivalent to the following code:

```
node->GetTarget()->GetNodeTM();
```

**Parameters:**

**TimeValue t**

Specifies the time to retrieve the transformation matrix.

**Matrix3& m**

The result is stored here.

**Return Value:**

Nonzero if the target matrix was retrieved (the node had a target); otherwise 0.

**Prototype:**

```
virtual int IsTarget()=0;
```

**Remarks:**

Determines if the node is a target node of a lookat controller.

**Return Value:**

Nonzero if the node is a target; otherwise 0.

**Prototype:**

```
virtual void SetIsTarget(BOOL b)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method controls the property of the node indicating if it's a target or not. Calling this is necessary when hooking up targets as the target node must have its **IsTarget()** property set.

**Parameters:**

**BOOL b**

TRUE for set; FALSE for off.

**Prototype:**

```
virtual INode* GetTarget()=0;
```

**Remarks:**

Retrieves this node's target node if any. Returns NULL if this node has no target.

**Prototype:**

**virtual INode\* GetLookatNode()=0;**

**Remarks:**

If this node is a target of a lookat controller, this method finds the node that looks at it.

**Return Value:**

The node that looks at this node or NULL if the node is not a target.

**Prototype:**

**virtual BOOL GetTransformLock(int type, int axis)=0;**

**Remarks:**

Retrieves the specified transform lock state of the node. When the user is doing interactive Moving / Rotating / Scaling these locks simply remove one of the components.

**Parameters:**

**int type**

See [Transform Lock Types](#).

**int axis**

See [Transform Lock Axis](#).

**Return Value:**

TRUE if the lock is set; otherwise FALSE.

**Prototype:**

**virtual void SetTransformLock(int type, int axis, BOOL onOff)=0;**

**Remarks:**

Sets the specified transform lock state of the node. When the user is doing interactive Moving / Rotating / Scaling these locks simply remove one of the components.

**Parameters:**

**int type**

See [Transform Lock Types](#).

**int axis**

See [Transform Lock Axis](#).

**BOOL onOff**

TRUE sets the lock on; FALSE sets the lock off.

## The following methods invalidate the node's caches

**Prototype:**

**virtual void InvalidateTreeTM()=0;**

**Remarks:**

This method will notify the node's subtree that the transformation matrix has changed. **NotifyDependents()** is called with the message **REFMSG\_CHANGE**.

**Prototype:**

**virtual void InvalidateTM()=0;**

**Remarks:**

This method will invalidate the node's transformation matrix cache.

**Prototype:**

**virtual void InvalidateWS()=0;**

**Remarks:**

This method will invalidate the node's world space cache.

## Parent-Child Hierarchy manipulation / Groups

**Prototype:**

**virtual INode\* GetParentNode()=0;**

**Remarks:**

Retrieves the parent node of this node. If the node is not linked, its parent is the root node. This may be checked using **INode::IsRootNode()**.

**Prototype:**

**virtual int IsRootNode()=0;**

**Remarks:**

Determines if this node is the root node (does not have a parent node).

**Return Value:**

Nonzero if the node is the root node; otherwise 0.

**Prototype:**

**virtual void AttachChild(INode\* node, int keepPos=1)=0;**

**Remarks:**

Makes the specified node a child of this node.

**Parameters:**

**INode\* node**

Specifies the node to attach.

**int keepPos=1**

If nonzero, the position of the child node is retained (not moved); otherwise it may be moved.

**Prototype:**

**virtual void Detach(TimeValue t, int keepPos=1)=0;**

**Remarks:**

Detaches this node from its parent.

**Parameters:**

**TimeValue t**

Specifies the time at which to detach the node.

**int keepPos=1**

If nonzero, the position of the detached node is retained (not moved); otherwise it may be moved.

**Prototype:**

**virtual int NumberOfChildren()=0;**

**Remarks:**

Returns the number of children of this node.

**Prototype:**

**virtual INode\* GetChildNode(int i)=0;**

**Remarks:**

Retrieves the 'i-th' child node of this node.

**Parameters:**

**int i**

Specifies the child node to retrieve.

**Prototype:**

**virtual BOOL IsGroupMember()=0;**

**Remarks:**

Returns TRUE if this node is a member of a group; otherwise FALSE.

**Prototype:**

**virtual BOOL IsGroupHead()=0;**

**Remarks:**

Returns TRUE if this node is the head of a group; otherwise FALSE.

**Prototype:**

**virtual BOOL IsOpenGroupMember();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if this node is a member of an open group; otherwise FALSE.

**Default Implementation:**

**{return 0; }**

**Prototype:**

**virtual BOOL IsOpenGroupHead();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if this node is the head of a group and that group is open; otherwise FALSE.

**Default Implementation:**

```
{return 0; }
```

**Prototype:**

```
virtual void SetGroupMember(BOOL b);
```

**Remarks:**

This method is available in release 2.0 and later only.

A node is marked as a group member or not. This method sets this state.

**Parameters:**

**BOOL b**

TRUE to mark the node as a group member; FALSE to indicate it's not in a group.

**Prototype:**

```
virtual void SetGroupHead(BOOL b);
```

**Remarks:**

This method is available in release 2.0 and later only.

A node is marked as the group head or not. This method sets this state.

**Parameters:**

**BOOL b**

TRUE to mark the node as a group head; FALSE to indicate it's not a group head.

**Prototype:**

```
virtual void SetGroupMemberOpen(BOOL b);
```

**Remarks:**

This method is available in release 2.0 and later only.

A node is marked as an open group member or not. This method sets this state.

**Parameters:**

## **BOOL b**

TRUE to mark the node as a open; FALSE to indicate it's not open.

### **Prototype:**

**virtual void SetGroupHeadOpen(BOOL b);**

### **Remarks:**

This method is available in release 2.0 and later only.

A node is marked as being the head of a group and being open or not. This method sets this state.

### **Parameters:**

#### **BOOL b**

TRUE to mark the node as an open group head; FALSE to indicate it's not an open group head.

## **Target / Node Selection**

### **Prototype:**

**virtual void SetTargetNodePair(int onOff);**

### **Remarks:**

This method is available in release 2.0 and later only.

This method is used for hit-testing and selecting node and target as a single unit.

In 3ds max 2.0 and later you can click on the line connecting, say, a camera to its target and drag that around in the viewports. Doing so moves both the camera and its target as a locked pair.

To accomplish this, the camera, light, and tape measure objects (those with two nodes linked by a Look At controller) check for a hit on the object-target line. If they get there (but not at the object or target itself), then they call this method passing TRUE. Then, when a hit is registered, 3ds max checks the value of this variable (by calling **GetTargetNodePair()**), and, if it is TRUE, selects both the target and the node. If it's FALSE, then either the target or the node, but not both, gets selected, as with 3ds max 1.x.

For sample code see **\MAXSDK\SAMPLES\OBJECTS\LIGHT.CPP** or **TAPEHELP.CPP**.

**Parameters:****int onOff**

TRUE for on; FALSE for off.

**Default Implementation:****{ }****Prototype:****virtual int GetTargetNodePair();****Remarks:**

This method is available in release 2.0 and later only.

Returns the target/node pair setting stored by 3ds max. See

**SetTargetNodePair()** above for details.**Default Implementation:****{ return 0; }****Display attributes****Prototype:****virtual void Hide(BOOL onOff)=0;****Remarks:**

Controls the hidden state of the node in the scene.

**Parameters:****BOOL onOff**

Pass TRUE to hide the node in the scene; pass FALSE to make the node visible.

**Prototype:****virtual int IsHidden(DWORD hFlags=0)=0;****Remarks:**

Determines if the node is hidden in the scene.

**Parameters:****DWORD hFlags=0**

If you pass 0, you will get the hidden state of the node. If you pass one or more of the flags shown below, the method checks the Class\_ID of the node to see if it's hidden by the specified category. You may specify one or more of the following values:

**HIDE\_OBJECTS**  
**HIDE\_SHAPES**  
**HIDE\_LIGHTS**  
**HIDE\_CAMERAS**  
**HIDE\_HELPERS**  
**HIDE\_WSMS**  
**HIDE\_SYSTEMS**  
**HIDE\_PARTICLES**  
**HIDE\_ALL**  
**HIDE\_NONE**

See the method **Interface::GetHideByCategoryFlags()** for how you can retrieve the currently set values to use as the flags for this method.

**Return Value:**

Nonzero if the node is hidden; otherwise 0.

**Prototype:**

**virtual int IsNodeHidden()=0;**

**Remarks:**

Returns nonzero if the node is hidden in any way; otherwise returns zero.

**Prototype:**

**virtual int IsFrozen()=0;**

**Remarks:**

Determines if the node is frozen in the scene.

**Return Value:**

Nonzero if the node is frozen; otherwise 0.

**Prototype:**

**virtual void Freeze(BOOL onOff)= 0;**

**Remarks:**

Controls the frozen state of the node in the scene. A frozen node is visible but cannot be picked.

**Parameters:****BOOL onOff**

TRUE if the node should be frozen; FALSE if the node should not be frozen.

**Prototype:**

```
virtual void SetShowFrozenWithMtl(BOOL onOff)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the **NODE\_SHOW\_FRZN\_WITH\_MTL** flag in the node so that the node will be displayed in a frozen state with materials applied.

**Parameters:****BOOL onOff**

TRUE to set the flag; FALSE to disable.

**Prototype:**

```
virtual int ShowFrozenWithMtl()=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the state of the

**NODE\_SHOW\_FRZN\_WITH\_MTL** flag in the node and whether it is enabled or disabled.

**Prototype:**

```
virtual void XRayMtl(BOOL onOff)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

There is a new X-Ray Material display property which allows you to quickly make objects transparent. This method toggles it on or off for this node.

**Parameters:**

**BOOL onOff**

TRUE to use; FALSE to not use.

**Prototype:**

**virtual int HasXRayMtl()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns nonzero if the X-Ray Material display property is on for the node; otherwise zero.

**Prototype:**

**virtual int GetBoxMode()=0;**

**Remarks:**

Determines if the node is displayed in box mode in the scene.

**Return Value:**

Nonzero if the node is displayed in box mode; otherwise 0.

**Prototype:**

**virtual void BoxMode(BOOL onOff)=0;**

**Remarks:**

Controls if the node is displayed with a bounding box representation in the scene.

**Parameters:**

**BOOL onOff**

TRUE to display the node as its bounding box; FALSE for normal display.

**Prototype:**

**virtual void VertTicks(int onOff)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to enable or disable the display of vertex ticks on the

node.

**Parameters:**

**int onOff**

TRUE to enable; FALSE to disable.

**Prototype:**

**virtual int GetVertTicks()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the state of the vertex ticks display. TRUE if enabled; FALSE if disabled.

**Prototype:**

**virtual int GetAllEdges()=0;**

**Remarks:**

Determines if all the edges of the node are displayed.

**Return Value:**

Nonzero if all the edges (including "hidden" ones) are displayed; otherwise 0.

**Prototype:**

**virtual void AllEdges(BOOL onOff)=0;**

**Remarks:**

Controls the display of all the edges of the node (including "hidden" ones).

**Parameters:**

**BOOL onOff**

TRUE to display all the node's edges; FALSE to not display "hidden" edges.

**Prototype:**

**virtual int GetBackCull()=0;**

**Remarks:**

Determines if back-face culling is being used to draw the node.

**Return Value:**

Nonzero if back-face culling is used; otherwise 0.

**Prototype:**

**virtual void BackCull(BOOL onOff)=0;**

**Remarks:**

Controls if the node is displayed using back-face culling (faces whose surface normals are pointing away from the observer are not drawn).

**Parameters:**

**BOOL onOff**

TRUE if the node should be drawn using back-face culling; FALSE if all faces should be drawn.

**Prototype:**

**virtual int GetTrajectoryON();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns nonzero if the trajectory display is on; zero if the trajectory display is off.

**Prototype:**

**virtual void SetTrajectoryON(BOOL onOff);**

**Remarks:**

This method is available in release 2.0 and later only.

This method may be used to turn on or off the trajectory display for the node.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void ShowBone(int boneVis)=0;**

**Remarks:**

Controls the display of Bones in the scene. A bone is just the link (or line) connecting the node to its parent. These are the same options as available in the 3ds max user interface in the Display branch, under Link Display, i.e. Display Links and Link Replaces Object.

**Parameters:**

**int boneVis**

Specifies the display state:

- 0: Bones are not drawn.
- 1: Bones are drawn.
- 2: Only bones are shown.

**Prototype:**

**virtual BOOL IsBoneOnly();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the bone is showing but the object is hidden; FALSE if both the bone and the node is hidden.

**Prototype:**

**virtual void BoneAsLine(int onOff)=0;**

**Remarks:**

Controls the display of Bones as simple lines in the scene.

**Parameters:**

**int onOff**

Nonzero if bones should be shown as lines only; 0 for normal display.

**Prototype:**

**virtual BOOL IsBoneShowing()=0;**

**Remarks:**

Returns TRUE if the node's bone is turned on; otherwise FALSE.

**Prototype:**

**virtual DWORD GetWireColor()=0;**

**Remarks:**

Retrieves the node's wire-frame color. See [COLORREF-DWORD format](#).

**Prototype:**

**virtual void SetWireColor(DWORD newcol)=0;**

**Remarks:**

Sets the node's wire-frame color. This can be any of the 16 million possible colors in 24 bit. See [COLORREF-DWORD format](#).

**Parameters:**

**DWORD newcol**

Specifies the new wire-frame color for the node. It may be specified using the RGB macro, for example: **RGB(0,0,255);**

**Prototype:**

**virtual int Selected()=0;**

**Remarks:**

Determines if the node is selected.

**Return Value:**

Nonzero if the node is selected; otherwise 0.

**Prototype:**

**virtual int Dependent()=0;**

**Remarks:**

Returns nonzero if the node has its dependent flag set; otherwise 0. This is dependent in the sense of 3ds max's Views/Show Dependencies mode. When in the Modify branch, Show Dependencies will show all the nodes that are dependent on the current modifier or object being editing by highlighting them in green. It also set a flag in the node. This method allows a developer to check this flag.

## **Rendering Attributes**

**Prototype:**

**virtual int CastShadows()=0;**

**Remarks:**

Retrieves the shadow casting attribute of the node.

**Return Value:**

Nonzero indicates the node casts shadows; zero if the node does not cast shadows.

**Prototype:**

**virtual void SetCastShadows(BOOL onOff)=0;**

**Remarks:**

Sets the shadow casting attribute of the node to on or off.

**Parameters:**

**BOOL onOff**

TRUE to turn shadow casting on; FALSE to turn it off.

**Prototype:**

**virtual int RcvShadows()=0;**

**Remarks:**

Retrieves the shadow receiving attribute of the node.

**Return Value:**

Nonzero indicates the node receives shadows; zero if the node does not receive shadows.

**Prototype:**

**virtual void SetRcvShadows(BOOL onOff)=0;**

**Remarks:**

Sets the shadow receiving attribute of the node to on or off.

**Parameters:**

**BOOL onOff**

TRUE to turn shadow receiving on; FALSE to turn it off.

**Prototype:****virtual int MotBlur()=0;****Remarks:**

Retrieves the type of motion blur used by the node.

**Return Value:**

One of the following values:

**0:** None.

**1:** Object Motion Blur.

**2:** Image Motion Blur.

**Prototype:****virtual void SetMotBlur(int kind)=0;****Remarks:**

This method is available in release 2.0 and later only.

Sets the type of motion blur used by the node.

**Parameters:****int kind**

The kind of motion blur. One of the following values:

**0:** None.

**1:** Object Motion Blur.

**2:** Image Motion Blur.

**Prototype:****virtual float GetImageBlurMultiplier(TimeValue t);****Remarks:**

This method is available in release 2.0 and later only.

Returns the image motion blur multiplier value at the specified time.

**Parameters:****TimeValue t**

The time to retrieve the value.

**Prototype:**

**virtual void SetImageBlurMultiplier(TimeValue t, float m);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the image blur multiplier value for the node. This is used to increase or decrease the length of the blur 'streak'.

**Parameters:**

**TimeValue t**

The time to set the value.

**float m**

The value to set.

**Prototype:**

**virtual Control \*GetImageBlurMultController();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the controller for the image blur multiplier value.

**Prototype:**

**virtual void SetImageBlurMultController(Control \*cont);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the controller used for the image blur multiplier value.

**Parameters:**

**Control \*cont**

Points for the controller to use.

**Prototype:**

**virtual BOOL GetMotBlurOnOff(TimeValue t);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the object motion blur controller is 'on' at the specified time; otherwise FALSE.

**Parameters:**

**TimeValue t**

The time to check.

**Default Implementation:**

```
{ return 1; }
```

**Prototype:**

```
virtual void SetMotBlurOnOff(TimeValue t, BOOL m);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the object motion blur controller to on or off at the specified time.

**Parameters:**

**TimeValue t**

The time to set the value.

**BOOL m**

TRUE for on; FALSE for off.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual Control *GetMotBlurOnOffController();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the controller handling the object motion blur on / off setting.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual void SetMotBlurOnOffController(Control \*cont);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the controller used for handling the object motion blur on / off setting.

**Parameters:**

**Control \*cont**

Points to the controller to set.

**Default Implementation:**

**{}**

**Prototype:**

**virtual int Renderable()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns nonzero if the renderable flag is on; zero if off.

**Prototype:**

**virtual void SetRenderable(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the state of the node's renderable flag. If this flag is on the node will appear in rendered images; if off it won't.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetRenderOccluded(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the node's 'Render Occluded Object' flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRenderOccluded()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the node's 'Render Occluded Object' flag is set; otherwise FALSE.

**Prototype:**

**virtual void SetApplyAtmospherics(BOOL onOff)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the "apply atmospherics" flag for the node.

**Parameters:**

**BOOL onOff**

TRUE to enable the flag, FALSE to disable.

**Prototype:**

**virtual int ApplyAtmospherics()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the on/off state of the "apply atmospherics" flag.

**Prototype:**

**virtual void SetPrimaryVisibility(BOOL onOff) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the primary visibility flag and define whether or

not the node is visible to the camera.

**Parameters:**

**BOOL onOff**

TRUE to enable the flag, FALSE to disable.

**Prototype:**

**virtual int GetPrimaryVisibility() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the on/off state of the primary visibility to determine whether or not the node is visible to the camera.

**Prototype:**

**virtual void SetSecondaryVisibility(BOOL onOff) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the secondary visibility flag and define whether or not the node is visible to reflections and refractions..

**Parameters:**

**BOOL onOff**

TRUE to enable the flag, FALSE to disable.

**Prototype:**

**virtual int GetSecondaryVisibility() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the on/off state of the secondary visibility to determine whether or not the node is visible to reflections and refractions.

## **Vertex Color Attributes**

**Prototype:**

**virtual int GetCVertMode();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns nonzero if the vertex color flag is on; otherwise zero.

**Prototype:**

**virtual void SetCVertMode(int onOff);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the vertex color flag to on or off. This controls the display of assigned vertex colors. Vertex colors are assigned in the editable mesh in vertex or face sub-object level. Vertex colors only appear in viewports using Smooth or Smooth + Highlight display modes, regardless of the state of this flag.

**Parameters:**

**int onOff**

Nonzero for on; zero for off.

**Prototype:**

**virtual int GetShadeCVerts();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns nonzero if the vertex color shaded flag is on; zero if off.

**Prototype:**

**virtual void SetShadeCVerts(int onOff);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the vertex color shaded flag. This determines whether the vertex colors appear shaded in the viewport. When this is off, the colors are unshaded, and appear in their pure RGB values, looking a little like self-illuminated materials. When on, the colors appear like any other assigned color in the viewports

**Parameters:****int onOff**

Nonzero of on; zero of off.

**Prototype:****void CopyProperties(INode \*from);****Remarks:**

This method is available in release 4.0 and later only.

Calling this method copies the various display, rendering, bone and other general parameters from the "from" object. This is used in Edit(able) Spline and Edit(able) Patch to copy node settings into new nodes created by the "Detach" operations.

**Parameters:****INode \*frame**

A pointer to the INode to copy the properties from.

**Object Reference****Prototype:****virtual Object\* GetObjectRef()=0;****Remarks:**

Returns the object that this node references unless the node has been bound to a Space Warp. In that case this method will not return the WSM derived object even though the node's object reference points at it. Instead it will return the item that the WSM derived object references. Thus, this method will always return essentially the object space portion of the pipeline. In contrast, see **GetObjOrWSMRef()** below.

See the [Geometry Pipeline](#) section for additional details.

**Prototype:****virtual void SetObjectRef(Object \*o)=0;****Remarks:**

Sets the object that this node references. See the [Geometry Pipeline](#) section for

additional details.

**Parameters:**

**Object \*o**

The object this node will reference.

**Prototype:**

**virtual Object \*GetObjOrWSMRef()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the actual object reference of the node directly. So if this node is bound to a Space Warp this method will return a WSM derived object.

If you want the object space portion of the pipeline see **GetObjectRef()** above.

## **Controller Access**

**Prototype:**

**virtual Control\* GetTMController()=0;**

**Remarks:**

Retrieves the node's transform controller. The standard 3ds max transform controllers each have sub -controllers for position, rotation and scale.

To access the data of the node's transform controller you may use [Class IKeyControl](#). The following code fragment shows an example of how this may be done for a PRS controller.

**Control \*c;**

**c = node->GetTMController()->GetPositionController();**

**IKeyControl \*ikeys = GetKeyControlInterface(c);**

With this controller interface you can use its methods to get information about the keys, for example:

**int num = ikeys->GetNumKeys();**

**Prototype:**

**virtual void SetTMController(Control \*m3cont)=0;**

**Remarks:**

Sets the node's transform controller.

**Parameters:**

**Control \*m3cont**

The Matrix3 transform controller to use.

**Prototype:**

**virtual Control \*GetVisController()=0;**

**Remarks:**

Returns the visibility controller for this node.

**Prototype:**

**virtual void SetVisController(Control \*cont)=0;**

**Remarks:**

Sets the visibility controller for this node.

**Parameters:**

**Control \*cont**

The controller to use for visibility control.

## Visibility Related Methods

**Prototype:**

**virtual float GetVisibility(TimeValue t,Interval \*valid=NULL)=0;**

**Remarks:**

Retrieves the visibility of the node at the time passed and updates the validity interval passed. Values < 0 indicate off while values > 0 indicate on. The node is fully visible (opaque) when 1.0 and fully invisible (transparent) when 0.0.

**Parameters:**

**TimeValue t**

The time to get the visibility value.

**Interval \*valid=NULL**

The validity interval to update based on the validity of the visibility.

**Prototype:**

**virtual void SetVisibility(TimeValue t,float vis)=0;**

**Remarks:**

Sets the visibility of the node to the value passed at the time passed.

**Parameters:****TimeValue t**

The time to set the visibility value.

**float vis**

The visibility of the node to set. This is treated like a boolean value where < 0 means off and > 0 means on.

**Prototype:**

**virtual float GetLocalVisibility(TimeValue t,Interval \*valid=NULL)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the local visibility of the node. The value returned from this method is treated like a boolean value where < 0 means off and > 0 means on.

If a node returns TRUE from **GetInheritVisibility()** then its visibility is determined by this method. If **GetInheritVisibility()** method returns FALSE then the visibility of the node is determined by **GetVisibility()**.

**Parameters:****TimeValue t**

The time to get the local visibility value.

**Interval \*valid=NULL**

The validity interval to update based on the validity of the local visibility controller.

**Prototype:**

**virtual BOOL GetInheritVisibility()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the node's visibility is determined by the visibility of the parent of the node; otherwise returns FALSE.

**Prototype:**

**virtual void SetInheritVisibility(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to set the state of the node's inherit visibility flag.

**Parameters:**

**BOOL onOff**

Pass TRUE to have the node inherit its visibility from its parent; otherwise pass FALSE and the node's visibility will be determined by the node itself (not its parent).

## Renderer Materials

**Prototype:**

**virtual Mtl\* GetMtl()=0;**

**Remarks:**

Returns a pointer to the renderer material for the node. If the value returned is NULL the user has not assigned a material yet. See [Class Mtl](#), [Working with Materials and Textures](#).

**Prototype:**

**virtual void SetMtl(Mtl\* matl)=0;**

**Remarks:**

Sets the renderer material used by the node. If the value set is NULL it indicates a material has not been assigned. In this case, the renderer uses the wireframe color of the node for rendering. See [Class Mtl](#), [Working with Materials and Textures](#).

**Parameters:**

**Mtl\* matl**

The materials used to render the node.

## GraphicsWindow Materials

### Prototype:

**virtual Material\* Mtls()=0;**

### Remarks:

Returns a pointer to the **GraphicsWindow** materials. See **NumMtls()** below for the number of entries in this array.

### Prototype:

**virtual int NumMtls()=0;**

### Remarks:

Returns the number of entries in the array of Materials returned by **Mtls()** above.

## Object-Offset methods

### Prototype:

**virtual void SetObjOffsetPos(Point3 p)=0;**

### Remarks:

Sets the position portion of the object offset from the node. See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

### Parameters:

**Point3 p**

Specifies the position portion of the object-offset.

### Prototype:

**virtual Point3 GetObjOffsetPos()=0;**

### Remarks:

Returns the position portion of the object-offset from the node as a Point3. See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

**Prototype:**

```
virtual void SetObjOffsetRot(Quat q)=0;
```

**Remarks:**

Sets the rotation portion of the object-offset from the node. See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

**Parameters:**

**Quat q**

The rotation offset.

**Prototype:**

```
virtual Quat GetObjOffsetRot()=0;
```

**Remarks:**

Returns the rotation portion of the object-offset from the node. See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

**Prototype:**

```
virtual void SetObjOffsetScale(ScaleValue sv)=0;
```

**Remarks:**

Sets the scale portion of the object-offset matrix. See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

**Parameters:**

**ScaleValue sv**

The scale portion of the offset. See [Class ScaleValue](#).

**Prototype:**

```
virtual ScaleValue GetObjOffsetScale()=0;
```

**Remarks:**

Returns the scale portion of the object-offset from the node. See [Class ScaleValue](#). See the Advanced Topics section on [Node and Object Offset Transformations](#) for an overview of the object offset transformation.

## Put Nodes into the Foreground Plane

### Prototype:

```
virtual void FlagForeground(TimeValue t,BOOL  
notify=TRUE)=0;
```

### Remarks:

Flags the node to put it in the foreground. For additional information see [Foreground / Background Planes](#).

### Parameters:

#### **TimeValue t**

The time to put the node in the foreground.

#### **BOOL notify=TRUE**

If TRUE, the reference message **REFMSG\_FLAGDEPENDENTS** with **PART\_PUT\_IN\_FG** is sent.

## Active Grid Object

### Prototype:

```
virtual int IsActiveGrid()=0;
```

### Remarks:

Determines if this node is the active grid object.

### Return Value:

Nonzero indicates the node is the active grid object; zero indicates it is not.

## Temporary Storage of Data with Nodes

### Prototype:

```
virtual void SetNodeLong(LONG l)=0;
```

### Remarks:

This method provides temporary storage of data with the node. Data stored with the node is only valid before you return control.

### Parameters:

## **LONG l**

The data to store with the node.

### **Prototype:**

**virtual LONG GetNodeLong()=0;**

### **Remarks:**

Retrieve the data stored with the node (using **SetNodeLong()**).

### **Return Value:**

The data stored with the node.

## **Access to Render Data**

### **Prototype:**

**virtual RenderData \*GetRenderData()=0;**

### **Remarks:**

Returns the render data for the node. See [Class RenderData](#).

### **Prototype:**

**virtual void SetRenderData(RenderData \*rd)=0;**

### **Remarks:**

Sets the render data for the node.

### **Parameters:**

**RenderData \*rd**

The render data to set.

## **Access user defined property text.**

For additional overview information on these methods see the Advanced Topics section [Custom Node Properties](#).

### **Prototype:**

**virtual void GetUserPropBuffer(TSTR &buf)=0;**

### **Remarks:**

This method allows access to the entire user defined property text buffer.

**Parameters:**

**TSTR &buf**

The buffer to hold the user defined property text.

**Prototype:**

**virtual void SetUserPropBuffer(const TSTR &buf)=0;**

**Remarks:**

This method allows a developer to set to the entire user defined property text buffer.

**Parameters:**

**const TSTR &buf**

The buffer containing the user defined property text.

**Prototype:**

**virtual BOOL GetUserPropString(const TSTR &key,TSTR &string)=0;**

**Remarks:**

This method retrieves a string based on the key passed.

**Parameters:**

**const TSTR &key**

The key (or name) of the user defined property text.

**TSTR &string**

Storage for the string to retrieve.

**Return Value:**

TRUE if the key was found; otherwise FALSE.

**Prototype:**

**virtual BOOL GetUserPropInt(const TSTR &key,int &val)=0;**

**Remarks:**

Retrieves an integer value from the node based on the key passed.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to retrieve.

**int &val**

Storage for the integer value.

**Return Value:**

TRUE if the key was found; otherwise FALSE.

**Prototype:**

**virtual BOOL GetUserPropFloat(const TSTR &key,float &val)=0;**

**Remarks:**

Retrieves a floating point value from the node based on the key passed.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to retrieve.

**float &val**

Storage for the float value.

**Return Value:**

TRUE if the key was found; otherwise FALSE.

**Prototype:**

**virtual BOOL GetUserPropBool(const TSTR &key,BOOL &b)=0;**

**Remarks:**

Retrieves a boolean value from the node based on the key passed.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to retrieve.

**BOOL &b**

Storage for the boolean value.

**Return Value:**

TRUE if the key was found; otherwise FALSE.

**Prototype:**

**virtual void SetUserPropString(const TSTR &key,const TSTR &string)=0;**

**Remarks:**

Stores a string in the node using the key passed. If the key name already exists it is overwritten; otherwise it is created.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to store.

**const TSTR &string**

The string to store.

**Prototype:**

**virtual void SetUserPropInt(const TSTR &key,int val)=0;**

**Remarks:**

Stores an integer value in the node using the key passed. If the key name already exists it is overwritten; otherwise it is created.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to store.

**int val**

The value to store.

**Prototype:**

**virtual void SetUserPropFloat(const TSTR &key,float val)=0;**

**Remarks:**

Stores a floating point value in the node using the key passed. If the key name already exists it is overwritten; otherwise it is created.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to store.

**float val**

The value to store.

**Prototype:**

**virtual void SetUserPropBool(const TSTR &key,BOOL b)=0;**

**Remarks:**

Stores a boolean value in the node using the key passed. If the key name already exists it is overwritten; otherwise it is created.

**Parameters:**

**const TSTR &key**

The key (or name) of the data to store.

**BOOL b**

The value to store.

**Prototype:**

**virtual BOOL UserPropExists(const TSTR &key)=0;**

**Remarks:**

This method simply checks to see if a key exists.

**Parameters:**

**const TSTR &key**

The key string to search for.

**Return Value:**

TRUE if the key was found; otherwise FALSE.

## **Geometry/Graphics (G) Buffer ID Access**

**Prototype:**

**virtual ULONG GetGBufID()=0;**

**Remarks:**

Returns the G-Buffer ID of this node. This is the ID available in the **BMM\_CHAN\_NODE\_ID** channel. See [Working with Bitmaps \(G-Buffer\)](#) for additional details.

**Prototype:**

**virtual void SetGBufID(ULONG id)=0;**

**Remarks:**

Sets the G-Buffer ID of this node. This is the ID available in the **BMM\_CHAN\_NODE\_ID** channel. See [Working with Bitmaps \(G-Buffer\)](#) for additional details.

**Parameters:**

**ULONG id**

The G-Buffer ID.

**Prototype:**

**virtual UWORD GetRenderID();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the G-Buffer render ID of the node. This is set by the renderer during a video post render when the **BMM\_CHAN\_NODE\_RENDER\_ID** is requested.

**Prototype:**

**virtual void SetRenderID(UWORD id);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the G-Buffer render ID of the node. This is set by the renderer during a video post render when the **BMM\_CHAN\_NODE\_RENDER\_ID** is requested.

**IK Related Methods**

The following methods deal with IK parameters associated with a node.

**Prototype:**

**virtual float GetPosTaskWeight();**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the position weight for the node.

**Prototype:**

**virtual float GetRotTaskWeight();**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the rotation weight for the node.

**Prototype:**

**virtual void SetPosTaskWeight(float w);**

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the position weight for the node.

**Parameters:**

**float w**

The position weight for the node. This value is  $\geq 0.0$ .

**Prototype:**

**virtual void SetRotTaskWeight(float w);**

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the rotation weight for the node.

**Parameters:**

**float w**

The rotation weight for the node. This value is  $\geq 0.0$ .

**Prototype:**

**virtual BOOL GetTaskAxisState(int which,int axis);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE of FALSE to indicate if the specified axis is set for position or rotation.

**Parameters:**

**int which**

Indicates if the method returns the position state or the rotation state: **0** specifies position; **1** specifies rotation.

**int axis**

The axis to check. **0** specifies X, **1** specifies Y, **2** specifies Z.

**Prototype:**

```
virtual void SetTaskAxisState(int which,int axis,BOOL onOff);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the specified axis state for position or rotation.

**Parameters:****int which**

Indicates if the method returns the position state or the rotation state: **0** specifies position; **1** specifies rotation.

**int axis**

The axis to check. **0** specifies X, **1** specifies Y, **2** specifies Z.

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

```
virtual DWORD GetTaskAxisStateBits();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the same information as GetTaskAxisState() above.

**Return Value:**

The first three bits indicate position X, Y and Z. Then the next three bits indicate rotation X, Y, Z.

**WSMDerivedObject Access****Prototype:**

**virtual void CreateWSMDerivedObject();**

**Remarks:**

This method is available in release 2.0 and later only.

Calling this method will create a WSM derived object for this node if one doesn't already exist.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual IDerivedObject \*GetWSMDerivedObject();**

**Remarks:**

This method is available in release 2.0 and later only.

This method pointer to the WSM Derived object for this node. Note that there is at most one WSM derived object per node.

**Default Implementation:**

```
{return NULL;}
```

## Deleting The Node

**Prototype:**

**virtual void Delete(TimeValue t, int keepChildPosition);**

**Remarks:**

This method is available in release 2.0 and later only.

This method will delete the node, handle removing it from the hierarchy, and handle undo.

**Parameters:**

**TimeValue t**

The time for the deletion.

**int keepChildPosition**

If TRUE the position of any children of this node are kept the same; otherwise linked children may move due to the deletion.

## **INodeTransformed methods**

### **Prototype:**

**virtual void DisposeTemporary();**

### **Remarks:**

If this was a temporary INode (like an **INodeTransformed**) then this method will delete it. Also see the method **Interface::GetModContexts()**.

### **Prototype:**

**virtual INode \*GetActualINode();**

### **Remarks:**

In the case of **INodeTransformed**, this method retrieves a pointer to the real node.

### **Return Value:**

A pointer to the node.

## **XRef Access**

Scene XRef related methods. These methods are only implemented by root nodes. Note that Scene XRefs are stored as complete scenes with root nodes where the XRef scene root node is a child of the current scene's root node. See Also: [Class IXRefObject](#).

### **Prototype:**

**virtual int GetXRefFileCount();**

### **Remarks:**

This method is available in release 3.0 and later only.  
Returns the number of scene xrefs.

### **Default Implementation:**

**{return 0;}**

### **Prototype:**

**virtual TSTR GetXRefFileName(int i);**

### **Remarks:**

This method is available in release 3.0 and later only.  
Returns the name of the scene xref whose index is passed.

**Parameters:**

**int i**

The zero based index of the scene xref (**0** to **GetXRefFileCount()-1**).

**Default Implementation:**

```
{return TSTR();}
```

**Prototype:**

```
virtual void SetXRefFileName(int i,TCHAR *fname,BOOL  
reload);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the name of the scene xref whose index is passed.

**Parameters:**

**int i**

The zero based index of the scene xref (**0** to **GetXRefFileCount()-1**).

**TCHAR \*fname**

The name to set.

**BOOL reload**

TRUE to reload; FALSE to not reload.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL AddNewXRefFile(TSTR &name, BOOL  
loadNow=TRUE);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Adds the specified file to the scene and optionally updates the scene now.

**Parameters:**

**TSTR &name**

The file name to load.

**BOOL loadNow=TRUE**

If TRUE the file is loaded immediately and the scene updated; if FALSE the scene is now updated until the user requests it.

**Return Value:**

TRUE if the XRef was loaded; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL DeleteXRefFile(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method removes the 'i-th' Scene XRef.

**Parameters:**

**int i**

The zero based index of the Scene XRef to load.

**Return Value:**

TRUE if the file was deleted from the scene; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL BindXRefFile(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

This methods binds the specified XRef. This deletes the XRef after merging it into the scene.

**Parameters:**

**int i**

The zero based index of the XRef to bind.

**Return Value:**

TRUE if the file was deleted; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void DeleteAllXRefs();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method deletes all the XRefs from the scene. This is called when loading a new file, resetting or clearing the scene.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL ReloadXRef(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method will reload (updates from disk) the specified XRef.

**Parameters:**

**int i**

The zero based index of the XRef to reload.

**Return Value:**

TRUE if the XRef was reloaded; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void FlagXrefChanged(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method indicates that the specified XRef has been changed and should be updated.

**Parameters:**

**int i**

The zero based index of the XRef to flag.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL UpdateChangedXRefs(BOOL redraw=TRUE);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method updates all XRefs which have their changed flag set.

**Parameters:**

**BOOL redraw=TRUE**

TRUE to redraw the scene; otherwise FALSE.

**Return Value:**

TRUE if the XRefs were loaded okay; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual INode *GetXRefTree(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the root node of the tree for the specified XRef. This method, when called on a root node, will access the various XRef scenes. Note that these can be nested so calling this on the root node of the scene will return the root node of one of the scene XRefs. Calling it on the root node of the scene XRef will get the root node of a nested XRef and so on. Note that this is not the parent of the XRef (see **GetXRefParent()** below).

**Parameters:**

**int i**

The zero based index of the XRef.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual INode *GetXRefParent(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the parent node of the specified XRef. This is the node in the scene (if any) which the scene XRef is linked to through the special bind function in the scene XRef dialog.

**Parameters:**

**int i**

The zero based index of the XRef.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void SetXRefParent(int i, INode *par);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the parent of the specified XRef to the node passed.

**Parameters:**

**int i**

The zero based index of the XRef.

**INode \*par**

The parent node to set.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual BOOL FindUnresolvedXRefs(Tab<TSTR\*> &fnames);**

**Remarks:**

This method is available in release 3.0 and later only.

Generates a table of names for the unresolved XRefs in the scene.

**Parameters:**

**Tab<TSTR\*> &fnames**

The table of names. See [Template Class Tab](#).

**Return Value:**

Returns TRUE if there are still unresolved XRefs; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

**virtual void AttemptToResolveUnresolvedXRefs();**

**Remarks:**

This method is available in release 3.0 and later only.

This method tries to load any XRefs that are currently unresolved.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual DWORD GetXRefFlags(int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the state of flags for the specified XRef.

**Parameters:**

**int i**

The zero based index of the XRef whose flags are returned.

**Return Value:**

See [List of XRef Flag Bits](#).

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetXRefFlags(int i,DWORD flag,BOOL onOff);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the specified flags in the specified XRef to on or off.

**Parameters:****int i**

The zero based index of the XRef whose flags are set.

**DWORD flag**

See [List of XRef Flag Bits](#).

**BOOL onOff**

TRUE for on; FALSE for off.

**Default Implementation:**

```
{}
```

**Bone Methods****Prototype:**

```
virtual void SetBoneNodeOnOff(BOOL onOff, TimeValue t);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the bone on/off property of the node.

**Parameters:****BOOL onOff**

Pass TRUE for on; FALSE for off.

**TimeValue t**

The time at which to set the property.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetBoneAutoAlign(BOOL onOff);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the bone auto-align property of the node.

**Parameters:**

**BOOL onOff**

Pass TRUE for on; FALSE for off.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetBoneFreezeLen(BOOL onOff);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the bone freeze length property of the node.

**Parameters:**

**BOOL onOff**

Pass TRUE for on; FALSE for off.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetBoneScaleType(int which);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the bone scale (stretch) type to the specified value.

**Parameters:**

**int which**

One of the following values:

**BONE\_SCALETYPE\_SCALE**

**BONE\_SCALETYPE\_SQUASH**

**BONE\_SCALETYPE\_NONE**

**Default Implementation:**

**{}**

**Prototype:**

**virtual void SetBoneAxis(int which);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the bone axis of the node to the specified value.

**Parameters:**

**int which**

One of the following values:

**BONE\_AXIS\_X**

**BONE\_AXIS\_Y**

**BONE\_AXIS\_Z**

**Default Implementation:**

**{}**

**Prototype:**

**virtual void SetBoneAxisFlip(BOOL onOff);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the state of the bone axis flip toggle.

**Parameters:**

**BOOL onOff**

Pass TRUE for on; FALSE for off.

**Default Implementation:**

```
}
```

**Prototype:**

```
virtual BOOL GetBoneNodeOnOff();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns TRUE if the bone property is on; FALSE if off.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL GetBoneAutoAlign();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns TRUE if the bone auto-align property is on; FALSE if off.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL GetBoneFreezeLen();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns TRUE if the freeze length property is on; FALSE if off.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual int GetBoneScaleType();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns a value which indicates the bone scale type.

**Return Value:**

One of the following values:

**BONE\_SCALETYPE\_SCALE**  
**BONE\_SCALETYPE\_SQUASH**  
**BONE\_SCALETYPE\_NONE**

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual int GetBoneAxis();
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns a value which indicates the bone axis.

**Return Value:**

One of the following values:

**BONE\_AXIS\_X**  
**BONE\_AXIS\_Y**  
**BONE\_AXIS\_Z**

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual BOOL GetBoneAxisFlip();
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns TRUE if the axis flip toggle is on; FALSE if off.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void RealignBoneToChild(TimeValue t);
```

**Remarks:**

This method is available in release 4.0 and later only.

Calling this method is the equivalent of pressing the Realign button in the UI.

**Parameters:****TimeValue t**

The time at which to reset the initial child position.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void ResetBoneStretch(TimeValue t) {};
```

**Remarks:**

This method is available in release 4.0 and later only.

Calling this method is the equivalent of pressing the Reset Stretch button in the UI. This will cause the X-axis of the bone to realign to point at the child bone (or average pivot of multiple children).

**Parameters:****TimeValue t**

The time at which to reset the bone stretch.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual Matrix3 GetStretchTM(TimeValue t, Interval  
*valid=NULL);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the stretchTM without the object offset included.

Normally matrix concatenation occurs in the following manner:

**objectTM = objectOffsetTM \* stretchTM \* nodeTM**

A plug-in that uses the objectTM will transparently inherit the effects of the stretchTM. However if a plug-in (such as skin) wants the stretchTM included

but not the object offset, this method will return the stretchTM alone. If the node is not a bone or has no stretching, this method will return the identity.

**Parameters:**

**TimeValue t**

The time at which to obtain the stretchTM.

**Interval \*valid = NULL**

The interval.

**Default Implementation:**

```
{return Matrix3(1);}
```

# LightObject

See Also: [Class LightObject](#).

This is one of the classes from which plug-in lights are derived. Light objects implement methods that return the properties of the light. Some are these methods are:

## **EvalLightState()**

This method provides access to the lights state which contains properties of the light such as color, intensity, etc.

## **CreateLightDesc()**

When the renderer goes to render the scene it asks all of the lights to create an ObjectLighDesc object. This is the method that is called to return this object.

# LinearShape

See Also: [Class LinearShape](#).

Defines a linear shape object class. This is a shape made up of entirely linear segments.

## Class LinearShape

See Also: [Class ShapeObject](#), [Class PolyShape](#), [Working with Shapes and Splines](#).

```
class LinearShape : public ShapeObject
```

### Description:

This class represents a linear shape object. This class is similar to a **SplineShape** except this class uses a **PolyShape** as its data while a **SplineShape** uses a **BezierShape** as its data. Therefore this is a shape made up of entirely linear segments. All methods of this class are implemented by the system.

### Data Members:

public:

**PolyShape shape;**

The PolyShape that holds the linear shape.

### Methods:

#### Prototype:

**LinearShape();**

#### Remarks:

Constructor.

#### Prototype:

**~LinearShape();**

#### Remarks:

Destructor.

#### Prototype:

**PolyShape& GetShape();**

#### Remarks:

Returns the **shape** data member.

**Prototype:**

**void SetPointFlags();**

**Remarks:**

This method does the job of setting all points in the PolyShape to **POLYPT\_KNOT** types, and removing the **POLYPT\_INTERPOLATED** flag. This is because the LinearShape knows nothing about its origin.

**Prototype:**

**virtual MtlID GetMatID(TimeValue t, int curve, int piece);**

**Remarks:**

This method is available in release 3.0 and later only.

This method provides access to the material IDs of the shape. It returns the material ID of the specified segment of the specified curve of this shape at the time passed. There is a default implementation so there is no need to implement this method if the shape does not support material IDs.

Note: **typedef unsigned short MtlID;**

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The zero based index of the curve to evaluate.

**int piece**

The sub-curve (segment) to evaluate.

# Modifier

See Also: [Class Modifier](#).

This is the class from which you may derive modifier object plug-ins. The main methods are:

## **ModifyObject()**

This is the method that actually modifies the input object. This is where the modifier does its work.

## **LocalValidity()**

This is the validity interval of the modifier. It is the intersection of the validity intervals of any controllers the modifier has that are animating the modifier's parameters.

Methods are available to indicate to the system what type of input it needs from the pipeline.

## **ChannelsUsed()**

These are channels that the modifier needs in order to perform its modification.

## **ChannelsChanged()**

These are the channels that the modifier actually modifies.

## **InputType()**

This is the type of object that the modifier knows how to modify. Simple modifiers that just modify points of an object can operate on generic 'Deformable' objects. Deformable objects are any type of object that has points. A modifier could also work on a particular type of object such as a tri object or patch object.

Methods are also available for saving the data a modifier uses and stores internally to manage its operation.

## **LoadLocalData()**

## **SaveLocalData()**

When a 3ds max file is being loaded or saved, these methods are called so that the modifier can load and save data it needs for its operation.

# Mtl

See Also: [Class Mtl](#).

Plug-In Materials are subclassed off Mtl. Some of the methods of Mtl are:

## **Shade()**

This is called by the renderer to compute the color and transparency of the material for a given location.

## **NumSubMtls()**

This method returns the number of sub-materials used by the material.

# MtlBase

See Also: [Class MtlBase](#).

This is the base class for the creation of materials and texture maps plug-ins. The main methods are:

## **Requirements()**

Specifies the requirements for the material or texture map (and its sub-materials or sub-textures if any). These are things such as whether the material is two sided, wire frame, or requires UV bump vectors.

## **CreateParamDlg()**

This gets called when the material or texture is to be displayed in the material editor parameters area.

## Class MtlBase

See Also: [Class ReferenceTarget](#), [Class ISubMap](#), [Class Mtl](#), [Class Texmap](#), [Class ShadeContext](#), [Class RenderMapsContext](#), [Class RenderGlobalContext](#), [Class UVGen](#), [Class XYZGen](#), [Class PStamp](#), [Class Quat](#).

```
class MtlBase : public ReferenceTarget, public ISubMap
```

### Description:

This is the base class from which materials and textures are subclassed. Methods are provided to access the name, flags, and sub-materials/maps. There is also a method that is called when the material or texture is to be displayed in the material editor parameters area.

Note the following about dialog proc processing of sub-map buttons:

When you post the message:

```
PostMessage(hwmedit, WM_TEXMAP_BUTTON, i,  
(LPARAM)theMtl);
```

You are telling the system that the user clicked on the button for the 'i-th' sub-map of **theMtl**. The message doesn't propagate up -- it goes directly to the materials editor. It then uses calls on **theMtl->SetSubTexmap()** and **theMtl->GetSubTexmap()** to assign the new map. So even if your material has some complicated internal hierarchical structure of references, to the system it is still a simple "logical" hierarchy of a material with some sub-textmaps.

### Data Members:

public:

```
Quat meditRotate;
```

This data member is available in release 2.0 and later only.

This describes the rotation of the sample geometry in the materials editor.

```
ULONG gbufID;
```

This is the G-Buffer ID of the material or texmap. This is a "effects number" assigned in the materials editor to a map or material, and it will be written into the effects channel of the G-Buffer when a pixel with that material on it is rendered. To implement this, each map or material, in the beginning of its **Shade()**, **EvalColor()**, or **EvalMono()** methods should have the code:

**if (gbufID) sc.SetGBufferID(gbufID);**

**Method Groups:**

The following hyperlinks take you to the start of groups of related methods within the class:

[Naming Methods](#)

[BuildMaps Method](#)

[Flag Access Methods](#)

[Requirement Methods](#)

[Sub-Mtl-Texture Access](#)

[Update / Reset / Validity](#)

[Loading / Saving Methods](#)

[User Interface Methods](#)

[Multiple Map Display in the Viewports](#)

[G Buffer Methods](#)

[Enumerate Auxilliary Files Implementation](#)

[Postage Stamp Image Methods](#)

[Internal Methods](#)

[Operators](#)

**Methods:**

**Prototype:**

**MtlBase();**

**Remarks:**

Constructor. The flags and G-buffer id are initialized.

**Naming Methods**

**Prototype:**

**TSTR& GetName()**

**Remarks:**

Implemented by the System.

Returns the name of the material or texture.

**Prototype:**

**void SetName(TSTR s);**

**Remarks:**

Implemented by the System.  
Stores the name of the material or texture.

**Prototype:**

**virtual TSTR GetFullName();**

**Remarks:**

Implemented by the System.  
This method returns the name that appears in the track view. It returns the "Instance Name(class Name)". For example "Green Glass (Standard)". The default implementation should be used.

## **Flag Access Methods**

**Prototype:**

**void SetMtlFlag(int mask, BOOL val=TRUE)**

**Remarks:**

Implemented by the System.  
Alters the flags, either setting or clearing them, using the mask and method passed.

**Parameters:**

**int mask**

The flags to alter. See [List of Material Flags](#).

**BOOL val=TRUE**

If TRUE the mask is ORed into the flags (**mtlFlags |= mask**); otherwise (**mtlFlags &= ~mask**).

**Prototype:**

**void ClearMtlFlag(int mask)**

**Remarks:**

Implemented by the System.

Clears the specified flags.

**Parameters:**

**int mask**

The flags to clear. See [List of Material Flags](#).

**Prototype:**

**int TestMtlFlag(int mask)**

**Remarks:**

Implemented by the System.

Tests the specified flags. Returns nonzero if the flags are set; otherwise zero.

See [List of Material Flags](#).

**Parameters:**

**int mask**

The flags to test.

**Prototype:**

**BOOL AnyMulti();**

**Remarks:**

Implemented by the System.

This method may be called to recursively determine if there are any multi-materials or texmaps in the tree.

**Return Value:**

TRUE if the material or texture map has any multi-materials; otherwise FALSE.

## Requirement Methods

**Prototype:**

**virtual ULONG Requirements(int subMtlNum);**

**Remarks:**

Implemented by the Plug-In.

This method returns the cumulative requirements of the material and its sub-

materials and maps. The default implementation just ORs together the local requirements of the material with the requirements of all its children. Most materials will only need to implement **LocalRequirements()**.

**Parameters:**

**int subMtlNum**

Specifies the number of the sub-material whose requirements should be returned. **-1** may be used to return a value generated by looping over all the sub-materials and ORing together the requirements.

**Return Value:**

See [List of Material Requirements](#).

**Default Implementation:**

The default implementation automatically traverses the sub-material/map tree. On any MtlBase that returns TRUE for **IsMultiMtl()** it will only recursively call the sub material (or map) for the **subMtlNum** called. The exception to this is when **subMtlNum<0**: in this case all sub-mtls and submaps are enumerated. Therefore the **LocalRequirements()** method below only needs to consider the material or map itself, not the sub-mtls and sub-maps.

**Prototype:**

**virtual ULONG LocalRequirements(int subMtlNum)**

**Remarks:**

Implemented by the Plug-In.

Specifies various requirements for **this** material. The value returned from this method should **not** include requirements of its sub-materials and sub-maps.

**Parameters:**

**int subMtlNum**

Specifies the number of the sub-material whose requirements should be returned.

**Return Value:**

See [List of Material Requirements](#).

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual void MappingsRequired(int subMtlNum, BitArray &mapreq, BitArray &bumpreq);**

**Remarks:**

This method is available in release 3.0 and later only.

This method gives the UVW channel requirements of the material and its tree. The default implementation just OR's together the local mapping requirements of the material with the requirements of all its children. For most materials, all they need to implement is the **LocalMappingsRequired()** method.

**Parameters:****int subMtlNum**

Specifies the number of the sub-material whose mapping information is retrieved.

**BitArray &mapreq**

This array of bits is initialized to an empty set with MAX\_MESHMAPS elements. Each bit corresponds to a mapping channel. Set a bit to one to indicate the material requires the corresponding UVW channel.

**BitArray &bumpreq**

This array of bits is initialized to an empty set with MAX\_MESHMAPS elements. Each bit corresponds to a mapping channel. Set a bit to one to indicate the material requires the corresponding bump mapping channel.

**Prototype:**

**virtual void LocalMappingsRequired(int subMtlNum, BitArray &mapreq, BitArray &bumpreq);**

**Remarks:**

This method is available in release 3.0 and later only.

This method specifies UVW channel requirements for the material: This method should **not** include UVW channel requirements of any sub-materials and sub-maps.

**Parameters:****int subMtlNum**

Specifies the number of the sub-material whose mapping information is

retrieved.

### **BitArray &mapreq**

This array of bits is initialized to an empty set with MAX\_MESHMAPS elements. Each bit corresponds to a mapping channel. Set a bit to one to indicate the material requires the corresponding UVW channel.

### **BitArray &bumpreq**

This array of bits is initialized to an empty set with MAX\_MESHMAPS elements. Each bit corresponds to a mapping channel. Set a bit to one to indicate the material requires the corresponding bump mapping channel.

### **Default Implementation:**

```
{}
```

### **Sample Code:**

All 2D textures that use UVGen or otherwise select mapping channels need to implement this method Here's an example:

```
void LocalMappingsRequired(int subMtlNum, BitArray &  
mapreq, BitArray &bumpreq) {  
    uvGen->MappingsRequired(subMtlNum,mapreq,bumpreq);  
}
```

All 3D textures that use the XYZGen to put up a coordinates rollup must implement this method. Here's an example:

```
void LocalMappingsRequired(int subMtlNum, BitArray &  
mapreq, BitArray &bumpreq) {  
    xyzGen->MappingsRequired(subMtlNum,mapreq,bumpreq);  
}
```

## **BuildMaps Method**

### **Prototype:**

```
virtual int BuildMaps(TimeValue t, RenderMapsContext &rmc)
```

### **Remarks:**

Implemented by the Plug-In.

This method is called for a plug-in to do any work it needs to do prior to rendering. For example this is used by the 3ds max Mirror and Auto Reflect

materials to render their bitmaps.

**Parameters:**

**TimeValue t**

The current time.

**RenderMapsContext &rmc**

Provides information about the view being rendered and can provide access to the global rendering environment information via **RenderGlobalContext**

**\*gc = rmc.GetGlobalContext()**. See [Class RenderMapsContext](#) and [Class RenderGlobalContext](#).

**Return Value:**

Nonzero on success; zero on failure. In the case of failure the renderer is halted (rendering is cancelled).

## Methods to access sub texture maps of materials or texmaps

**Prototype:**

**virtual BOOL IsMultiMtl()**

**Remarks:**

Implemented by the Plug-In.

This method returns TRUE for materials or textures that select sub-materials based on submaterial number (for example a mesh **faceMtlIndex**).

The only materials for which this method should return TRUE are those that choose to use one of their sub-maps or sub-mtls based on the submaterial number. For the majority of materials and maps, they should return FALSE, and in that case all of the submaterials and maps are enumerated by

**MtlBase::Requirements()**.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**void DeactivateMapsInTree();**

**Remarks:**

Implemented by the System.

This method must be called on a sub-material or sub-map when it is removed, in case it or any of its sub-maps are active in the viewport.

## **Update / Reset / Validity**

### **Prototype:**

**virtual void Update(TimeValue t, Interval& valid)=0;**

### **Remarks:**

Implemented by the Plug-In.

A material has a **Shade()** method, and a texture map has a **EvalColor()** method. These are called by the renderer for every pixel. This method is called before rendering begins to allow the plug-in to evaluate anything prior to the render so it can store this information. In this way this information does not need to be calculated over and over for every pixel when **Shade()** or **EvalColor()** is called. This allows texture and material evaluation to be more efficient. It is generally called once at the start of each frame, or during interactive playback when the time changes. It is **not** guaranteed to get called on every frame, because if you returned a validity interval that covers several frames, your parent material won't bother to call you if the current frame is still in that interval.

### **Parameters:**

#### **TimeValue t**

The current time.

#### **Interval& valid**

The validity interval to update to reflect the validity interval of the material or texture at the time passed.

### **Prototype:**

**virtual void Reset()=0;**

### **Remarks:**

Implemented by the Plug-In.

This method is called to reset the material or texmap back to its default values.

### **Prototype:**

**virtual Interval Validity(TimeValue t)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to determine the validity interval of the material or texture.

**Parameters:**

**TimeValue t**

Specifies the time about which to compute the validity interval.

**Return Value:**

The validity interval of the item at the specified time.

## User Interface Methods

**Prototype:**

**virtual ParamDlg\* CreateParamDlg(HWND hwMtlEdit,  
IMtlParams \*imp)=0;**

**Remarks:**

Implemented by the Plug-In.

This method gets called when the material or texture is to be displayed in the material editor parameters area. The plug-in should allocate a new instance of a class derived from **ParamDlg** to manage the user interface.

**Note:** The following is a discussion of this **CreateParamDlg()** method, and the **SetDlgThing()** method, and the way they relate to the ParamMap2 system. A good example for this discussion is a texture map which typically has several rollouts, say its texmap parameters, a UVW coordinates rollout, and an Output rollout.

The normal way for a texmap to implement these other (common) rollouts is for the it to create a UVGen instance and a TextureOutput instance as 'sub-objects' in the map and then ask them to put up their rollouts when it is asked to do so by the Materials Editor (in CreateParamDlg()). The Materials Editor requires a ParamDlg pointer back from the CreateParamDlg() on which it calls methods to control the UI, such as time change updates or loading up a new texmap of the same class into the UI when the user switches them, so that the whole UI doesn't need to be rebuilt.

Prior to the ParamMap2 system, a texmap would implement its own ParamDlg subclass and would keep track of the UVGen and TextureOutput ParamDialogs and pass on any time change or SetThing() calls to them. ParamMap2 introduced its own ParamDlg subclass ([Class IAutoMParamDlg](#)) that you can ask it to build for you and have manage all interaction with the Materials Editor automatically. As before, this still needs to know about the other (sub-object) ParamDlgs, and so it has the ability to keep a list of 'secondary' ParamDlgs to which it passes on the SetTime()s and SetThing()s. When the Materials Editor asks the texmap to CreateParamDlg(), the texmap asks its ClassDesc2 to build one of these (ClassDesc2::CreateParamDlgs()). If the texmap itself has multiple ParamBlock2s, CreateParamDlgs() builds one ParamDlg per pblock/rollout, makes the first of them a 'master' and adds the rest as secondary ParamDlgs. The texmap then asks the UVGen and TextureOutput objects to CreateParamDlg() for their rollouts and adds them to the master IAutoMParamDlg also.

Now consider the need for the **SetDlgThing()** method below. It is related to the SetThing() method that the Materials Editor calls on the 'master' ParamDlg to switch into the UI a texmap of the same class as that currently in the UI. Normally, the master IAutoParamDlg would propagate the SetThing() to its registered secondary ParamDlgs. In the case of multiple paramblock2s in the texmap, this would be correct, since the 'thing' in this case is the incoming texmap. But this doesn't work for the secondary UVGen and TextureOutput ParamDlgs; their 'things' are the UVGen and TextureOutput subobjects of the incoming map. So, IAutoParamDlg first calls SetDlgThing() on the incoming texmap so that it gets a chance to call the correct SetThing()s on the sub-object ParamDlgs with the appropriate incoming sub-objects. A clear example of this is in **Gradient::SetDlgThing()** in

**\MAXSDK\SAMPLES\MATERIALS\GRADIENT.CPP**. It is called once for each secondary ParamDlg. For those ParamDlgs that have special SetThing() requirements, it does the appropriate sub-object SetThing() and returns TRUE. If it does no special handling for a particular ParamDlg, it returns FALSE, signalling to the IAutoMParamDlg that it should do the standard SetThing() propagation for that dialog.

The Render Effects dialog has a similar arrangement to the Materials Editor for controlling Effect UI and so there is an **IAutoEParamDlg** that works exactly the same way as the **IAuotMParamDlg**.

**Parameters:****HWND hwMtlEdit**

The window handle of the materials editor.

**IMtlParams \*imp**

The interface pointer for calling methods in 3ds max.

**Return Value:**

A pointer to the created instance of a class derived from **ParamDlg**.

**Multiple Map Display in the Viewports****Prototype:****virtual BOOL SupportsMultiMapsInViewport();****Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

Returns TRUE if this material supports the display of multi-maps in the viewports (interactive renderer); FALSE if it doesn't.

**Default Implementation:****{ return FALSE; }****Prototype:****virtual void SetupGfxMultiMaps(TimeValue t, Material \*mtl, MtlMakerCallback &cb);****Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

This method is called to initialize the interactive renderer Material passed with the properties of this MtlBase.

If a **MtlBase** (material or texmap) wants to display multiple textures in the viewports, it implements

**SupportsMultiMapsInViewport()** to return TRUE, and implements **SetupGfxMultiMaps** to store the necessary information in the Material passed in, including the **TextureInfo**'s for each texture.

The **MtlMakerCallback** passed in to **SetupGfxMultiMaps** provides functions to help in setting up the "Material" data structure. The function **NumberTexturesSupported()** lets you know the capabilities of the current hardware, so you can adapt accordingly. The function **GetGfxTexInfoFromTexmap** fills in the fields of a **TextureInfo** except the texHandle and texture ops.

The implementation of **SetupGfxMultiMaps** must create the "texHandle" for each of the textures described in its **TextureInfo** array. It typically does this by calling the submap's **GetVPDisplayDIB()** method, and then creates the texHandle by calling the callback function **MakeHandle(bmi)**. To avoid doing this calculation when not necessary it is best to save the texHandles along with their validity intervals. Then when **SetupGfxMultiMaps** is called, if valid texHandles are already in hand they can just be used without recomputing.

#### **Parameters:**

##### **TimeValue t**

The time at which to evaluate the material.

##### **Material \*mtl**

Points to the interactive renderer material to update.

##### **MtlMakerCallback &cb**

This callback object is provided as a helper to fill in the Material properties above. See [Class MtlMakerCallback](#).

#### **Default Implementation:**

```
{}
```

## **Loading and Saving Methods**

#### **Prototype:**

```
IOResult Load(ILoad *iload);
```

#### **Remarks:**

Implemented by the System.

This method is called to load the material or texture from disk. The common MtlBase data must be loaded as well. See the code below.

#### **Parameters:**

## **ILoad \*iload**

An interface pointer for calling methods to load data. [See Class ILoad](#).

### **Return Value:**

See [List of IOResults](#).

### **Sample Code:**

```
IOResult Gradient::Load(ILoad *iload) {  
    IOResult res;  
    int id;  
    while (IO_OK==(res=iload->OpenChunk())) {  
        switch(id = iload->CurChunkID()) {  
            case MTL_HDR_CHUNK:  
                res = MtlBase::Load(iload);  
                break;  
            case MAPOFF_CHUNK+0:  
            case MAPOFF_CHUNK+1:  
            case MAPOFF_CHUNK+2:  
                mapOn[id-MAPOFF_CHUNK] = 0;  
                break;  
        }  
        iload->CloseChunk();  
        if (res!=IO_OK)  
            return res;  
        }  
        iload->RegisterPostLoadCallback(  
            new  
            ParamBlockPLCB(versions,NUM_OLDVERSIONS,&curVersion,this,1));  
        return IO_OK;  
    }  
}
```

### **Prototype:**

**IOResult Save(ISave \*isave);**

### **Remarks:**

Implemented by the System.

This method saves the plug-in's data to disk.. The common MtlBase data must be saved as well. The base class method must be called in a chunk at the beginning of every Mtl and Texmap.

**Parameters:****ISave \*isave**

An interface pointer available for saving data. See [Class ISave](#).

**Return Value:**

See [List of IOResults](#).

**Sample Code:**

Note in the code below the base class method is called in a chunk before the rest of the plug-ins data is saved.

```
IOResult Gradient::Save(ISave *isave) {  
    IOResult res;  
    // Save common stuff  
    isave->BeginChunk(MTL_HDR_CHUNK);  
    res = MtlBase::Save(isave);  
    if (res!=IO_OK) return res;  
    isave->EndChunk();  
  
    for (int i=0; i<NSUBTEX; i++) {  
        if (mapOn[i]==0) {  
            isave->BeginChunk(MAPOFF_CHUNK+i);  
            isave->EndChunk();  
        }  
    }  
    return IO_OK;  
}
```

**Enumerate Auxilliary Files Implementation****Prototype:**

```
void EnumAuxFiles(NameEnumCallback& nameEnum, DWORD  
flags);
```

**Remarks:**

This method is available in release 2.0 and later only.

This is an implementation of the **Animatable** method. This default implementation simply recurses, skipping inactive subTexmaps if appropriate.

## **GBuffer (system) methods.**

### **Prototype:**

**ULONG GetGBufID();**

### **Remarks:**

Implemented by the System.

Returns the G-buffer ID of this material.

### **Prototype:**

**void SetGBufID(ULONG id);**

### **Remarks:**

Implemented by the System.

Sets the G-buffer ID of this material.

## **Operators:**

### **Prototype:**

**MtlBase& operator=(const MtlBase& m);**

### **Remarks:**

Implemented by the System.

Materials and Texmaps must use this operator to copy the common portion of themselves when cloning.

## **Postage Stamp Image Methods**

The Material / Map Browser supports the display of small and large icon images for material and texture maps. The methods below deal with the creation, access and deletion of these images. The small size image is 32 pixels. The large size is 88 pixels.

### **Prototype:**

**PStamp\* GetPStamp(int sz);**

### **Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Returns a pointer to the postage stamp image for the file.

**Parameters:**

**int sz**

One of the following values:

**PS\_SMALL** for small (32x32) images.

**PS\_LARGE** for large (88x88) images.

**PS\_TINY** for tiny (24x24) images.

**Prototype:**

**PStamp\* CreatePStamp(int sz, BOOL Render = FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Creates a postage stamp image and returns a pointer to it. If the postage stamp image already exists then it is simply returned.

Here's an example using this method to display a small material sample.

```
void DisplayMB(MtlBase *mb, HDC hdc, int x, int y) {  
mb->CreatePStamp(0,TRUE); // create and render a small pstamp  
PStamp *ps = mb->GetPStamp(0);  
if (ps) {  
int d = PSDIM(0);  
int scanw = ByteWidth(d);  
int nb = scanw*d;  
UBYTE *workImg = new UBYTE[nb];  
if (workImg==NULL)  
return;  
ps->GetImage(workImg);  
Rect rect;  
rect.left = x;  
rect.top = y;
```

```
rect.right = x+d;
rect.bottom = y+d;
GetGPort()->DisplayMap(hdc, rect,0,0, workImg, scanw);
delete [] workImg;
    }
}
```

**Parameters:**

**int sz**

One of the following values:

**PS\_SMALL** for small (32x32) images.

**PS\_LARGE** for large (88x88) images.

**PS\_TINY** for tiny (24x24) images.

**BOOL Render = FALSE**

This parameter is available in release 4.0 and later only.

If set to true, the postage stamp bitmap will have the **MtlBase** rendered into it automatically. The bitmap can then be retrieved using **PStamp::GetImage**, for drawing in the UI.

**Prototype:**

```
void DiscardPStamp(int sz);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Discards the postage stamp image.

**Parameters:**

**int sz**

One of the following values:

**PS\_SMALL** for small (32x32) images.

**PS\_LARGE** for large (88x88) images.

**PS\_TINY** for tiny (24x24) images.

## **Internal Methods**

**Prototype:**

**int GetMeditObjType()**

**Remarks:**

This method is used internally.

**Prototype:**

**void SetMeditObjType(int t)**

**Remarks:**

This method is used internally.

**Prototype:**

**int GetMeditTiling()**

**Remarks:**

This method is used internally.

**Prototype:**

**void SetMeditTiling(int t)**

**Remarks:**

This method is used internally.

**Prototype:**

**BOOL TextureDisplayEnabled()**

**Remarks:**

This method is used internally.

**The following methods are for doing interactive texture display.**

**Prototype:**

**virtual BOOL SupportTexDisplay()**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if this texture supports being used in the interactive renderer; otherwise FALSE. If the texture does return TRUE it is expected to implement the methods **ActivateTexDisplay()** and **GetActiveTexHandle()**.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void ActivateTexDisplay(BOOL onoff)
```

**Remarks:**

Implemented by the Plug-In.

This method is called when the usage of the texture the interactive renderer changes. This method must only be implemented if **SupportTexDisplay()** returns TRUE. This method does not cause the texture map to be drawn in the viewport but should be called with TRUE as the argument before this can occur. For viewport drawing of textures refer to **Interface::ActivateTexture()** and **Interface::DeActivateTexture()** instead.

**Parameters:**

**BOOL onoff**

TRUE if the texture is being used; FALSE if it is no longer being used.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual DWORD GetActiveTexHandle(TimeValue t,  
TexHandleMaker& thmaker)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to retrieve a texture handle to this texture map.

**Parameters:**

**TimeValue t**

The time to return the texture handle.

**TexHandleMaker& thmaker**

This class provides methods for creating a texture handle from a 3ds max bitmap and a Windows DIB. It also has a method to retrieve the required size of the texture map. See [Class TexHandleMaker](#).

**Return Value:**

The texture handle.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
void IncrActive();
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void DecrActive();
```

**Remarks:**

This method is used internally.

**Prototype:**

```
int Active();
```

**Remarks:**

This method is used internally.

# ReferenceMaker

See Also: [Class ReferenceMaker](#).

Any entity that makes references must be derived from this class. A reference creates an official record of the dependency between a ReferenceMaker and a ReferenceTarget. 3ds max uses a messaging system to notify ReferenceMakers about changes in their ReferenceTargets.

ReferenceMaker provides two methods associated with this system.

## **NotifyDependents()**

A plug-in calls this method any time it needs to broadcast a message to all its dependents. Typically this is a **REFMSG\_CHANGE** message indicating the plug-in has changed.

## **NotifyRefChanged()**

This method is called by the system when one of the entities a plug-in references calls **NotifyDependents()** to broadcast a message. The plug-in implements **NotifyRefChanged()** to receive the messages.

A reference maker must provide access to its references via the following methods:

## **NumRefs(), GetReference(i), SetReference(i)**

The system calls these methods when the plug-in creates and deletes references.

ReferenceMaker has additional methods for creating, replacing and deleting references.

## **MakeRefByID()**

Makes a new reference given the reference target and the index of the reference within the reference maker.

## **ReplaceReference()**

Deletes a reference if it is non-null and makes a new reference to a new target.

## **DeleteReference()**

Deletes a particular reference.

## **DeleteAllRefsFromMe()**

This method deletes all references that the reference maker has.

## **DeleteAllRefs()**

This deletes all references to AND from the reference maker.

## **EnumDependents()**

This allows a reference target to enumerate all reference to it. All reference targets have a list of backpointers to entities that reference it. This method enumerates those back pointers calling the given callback object once per dependent.

ReferenceMaker also has methods for the loading and saving of plug-ins.

## **Load()**

This method is called when a 3ds max file itself is being loaded. The plug-in would respond by loading its data through the given interface pointer. If the plug-in has references to other sub components, the system will automatically call **Load()** on the sub-components.

## **Save()**

This method is called when a 3ds max file itself is being saved. The plug-in would respond by saving its data through the given interface pointer.

# Class ReferenceMaker

See Also: [Class Animatable](#), [Class ReferenceTarget](#), [List of Reference Messages](#), [References](#), [Class ILoad](#), [Class ISave](#).

```
class ReferenceMaker : public Animatable
```

## Description:

Any entity that makes references must be derived from this class. A reference creates a record of the dependency between a **ReferenceMaker** and a **ReferenceTarget**. 3ds max uses a messaging system to notify dependent entities about changes. This class has a method that receives the notifications its dependents send when they change. It has methods that return the number of references it has, and methods to get and set these references. Also, there are methods for creating, replacing and deleting the references. File input/output is handled via methods of this class (**Load()** and **Save()**).

See the Advanced Topics section on [References](#) for an overview of the 3ds max reference architecture.

## Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Dependent Notification](#)

[Reference Access \(Num/Get/Set\)](#)

[Making / Replacing / Deleting References](#)

[Finding/Checking Reference Targets](#)

[Loading / Saving Methods](#)

## Methods:

### Dependent Notification

#### Prototype:

```
virtual RefResult NotifyRefChanged(Interval changeInt,  
RefTargetHandle hTarget, PartID& partID,RefMessage  
message)=0;
```

#### Remarks:

Implemented by the Plug-In.

A plug-in which makes references must implement a method to receive and respond to messages broadcast by its dependents. This is done by implementing **NotifyRefChanged()**.

The plug-in developer usually implements this method as a switch statement where each case is one of the messages the plug-in needs to respond to.

Note: For developer that need to update a dialog box with data about an object you reference note the following related to this method: This method may be called many times. For instance, say you have a dialog box that displays data about an object you reference. This method will get called many time during the drag operations on that object. If you updated the display every time you'd wind up with a lot of 'flicker' in the dialog box. Rather than updating the dialog box each time, you should just invalidate the window in response to the **NotifyRefChanged()** call. Then, as the user drags the mouse your window will still receive paint messages. If the scene is complex the user may have to pause (but not let up on the mouse) to allow the paint message to go through since they have a low priority. This is the way many windows in 3ds max work.

#### **Parameters:**

##### **Interval changeInt**

This is the interval of time over which the message is active. Currently, all plug-ins will receive **FOREVER** for this interval.

##### **RefTargetHandle hTarget**

This is the handle of the reference target the message was sent by. The reference maker uses this handle to know specifically which reference target sent the message.

##### **PartID& partID**

This contains information specific to the message passed in. Some messages don't use the **partID** at all. See the section [List of Reference Messages](#) for more information about the meaning of the **partID** for some common messages.

##### **RefMessage message**

The **message** parameters passed into this method is the specific message which needs to be handled. See [List of Reference Messages](#).

**Return Value:**

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the message was processed. Sometimes, the return value may be **REF\_STOP**. This return value is used to stop the message from being propagated to the dependents of the item.

**Reference Access**

3ds max manages the access to an items references by using a virtual array. If the plug-in makes references, it must implement these three methods handle access to its references: **NumRefs()**, **GetReference(i)**, **SetReference(i)**.

**Prototype:**

```
virtual int NumRefs();
```

**Remarks:**

Implemented by the Plug-In.

The plug-in implements this method to return the number of references it makes. **NumRefs()** indicates valid values for 'i' when doing a **GetReference(i)** or **SetReference(i)**. An item may return different values at different times if the number of references is changing.

**Return Value:**

The number of references made by the plug-in.

**Default Implementation:**

```
{ return 0;}
```

**Prototype:**

```
virtual RefTargetHandle GetReference(int i);
```

**Remarks:**

Implemented by the Plug-In.

The plug-in implements this method to return its 'i th' reference. The plug-in simply keeps track of its references using an integer index for each one. When the system calls this method, the plug-in returns its 'i th' reference.

**Parameters:**

**int i**

The virtual array index of the reference to get.

**Return Value:**

The reference handle of the 'i-th' reference.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetReference(int i, RefTargetHandle rtarg);
```

**Remarks:**

Implemented by the Plug-In.

The plug-in implements this method to store the reference handle passed into its 'i-th' reference. The plug-in simply keeps track of its references using an integer index for each one. When the system calls this method, the plug-in stores its 'i-th' reference.

**Parameters:**

**int i**

The virtual array index of the reference to store.

**RefTargetHandle rtarg**

The reference handle to store.

**Default Implementation:**

```
{ }
```

## **Making / Replacing / Deleting References**

**Prototype:**

```
RefResult MakeRefByID(Interval refInterval,int which,  
RefTargetHandle htarget)
```

**Remarks:**

Implemented by the System.

This method creates a reference between the object which calls the method,

and the ReferenceTarget specified by the **htarget** parameter.

Note that this method calls **SetReference()** after the reference is made to initialize it.

**Parameters:**

**refInterval**

Currently, all plug-ins must use **FOREVER** for this interval.

Indicates the interval of time over which this reference is active. Outside this interval, the reference is not considered to be a dependency. This allows the plug-in to have dependent relationship over only portions of an entire animation time range. If a plug-in has a dependency over the entire animation it may use the pre-defined interval **FOREVER** for this parameter.

**which**

Indicates which virtual array index this newly created reference is assigned to. The system uses a virtual array mechanism to access the references an item has. The developer simply assigns an integer index to each reference.

**hTarget**

This parameter is the handle of the item we are making a reference to.

**Return Value:**

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the reference was created and is registered by the reference target; otherwise **REF\_FAIL**.

**Prototype:**

**RefResult ReplaceReference(int which, RefTargetHandle newtarg, BOOL delOld=TRUE);**

**Remarks:**

Implemented by the System.

This method is used to replace a reference, for example when cloning reference makers, to delete an old reference and make a new one.

**Parameters:**

**int which**

The virtual array index of the reference to replace.

**RefTargetHandle newtarg**

The new reference target

**BOOL delOld=TRUE**

If TRUE, the old reference is deleted.

**Return Value:**

This is usually **REF\_SUCCEED** indicating the reference was replaced; otherwise **REF\_FAIL**.

**Prototype:**

**RefResult DeleteAllRefsFromMe();**

**Remarks:**

Implemented by the System.

Deletes all references from this ReferenceMaker.

**Return Value:**

This is always **REF\_SUCCEED** indicating the references were deleted.

**Prototype:**

**virtual RefResult DeleteAllRefsToMe()**

**Remarks:**

Implemented by the System.

This method deletes all the references to this reference maker/reference target.

This also sends the **REFMSG\_TARGET\_DELETED** message to all dependents.

**Return Value:**

This is **REF\_SUCCEED** if the references were deleted; otherwise it is **REF\_FAIL**.

**Prototype:**

**RefResult DeleteAllRefs();**

**Remarks:**

Implemented by the System.

Deletes all references both to and from this item.

**Return Value:**

This is **REF\_SUCCEED** if the references were deleted; otherwise it is **REF\_FAIL**.

**Prototype:**

**void DeleteMe();**

**Remarks:**

Implemented by the System.

This deletes all reference to and from the item, sends

**REFMSG\_TARGET\_DELETED** messages, handles UNDO, and deletes the object.

**Prototype:**

**RefResult DeleteReference(int i);**

**Remarks:**

Implemented by the System.

This method deletes the reference whose virtual array index is passed. The other reference indices are not affected, i.e. the number of references is not reduced nor are they re-ordered in any way. Note the system calls

SetReference(i, NULL) to set that reference to NULL. Also, if this is the last reference to the item, the item itself is deleted by calling its **DeleteThis()** method.

**Parameters:**

**int i**

The virtual array index of the reference to delete.

**Return Value:**

This is **REF\_SUCCEED** if the reference was deleted; otherwise it is **REF\_FAIL**.

**Prototype:**

**virtual BOOL CanTransferReference(int i)**

**Remarks:**

This method is used internally. It is used by certain system objects that have references. A reference maker can choose not to let TransferReferences() affect it. Note that plug-ins probably should not use this.

**Default Implementation:**

```
{return TRUE;}
```

## **Finding/Checking Reference Targets**

**Prototype:**

```
int FindRef(RefTargetHandle rtarg)
```

**Remarks:**

Implemented by the System.

This method returns the virtual array index of the reference target passed.

**Parameters:**

**RefTargetHandle rtarg**

The reference target to find the index of.

**Return Value:**

The virtual array index of the reference target to find. If the reference target is not found, -1 is returned.

**Prototype:**

```
virtual BOOL IsRefTarget();
```

**Remarks:**

This function differentiates things subclassed from **ReferenceMaker** from subclasses of **ReferenceTarget**. The implementation of this method (in **ReferenceMaker**) returns FALSE and its implementation in **ReferenceTarget** returns TRUE. This can be useful when tracing back up the reference hierarchy, to know when you run into something that was subclassed directly off of **ReferenceMaker**, and hence to stop the traversal at that point.

**Default Implementation:**

```
{ return FALSE; };
```

**Prototype:**

**virtual BOOL IsRealDependency(ReferenceTarget \*rtarg)**

**Remarks:**

When a reference target's last "real" reference is deleted the target is deleted.

Any leftover "non-real" reference makers will receive a

**REFMSG\_TARGET\_DELETED** notification. This method returns TRUE if the reference dependency is "real". Otherwise it returns FALSE.

Certain references are not considered "real" dependencies. For instance, internally there are certain reference makers such as the object that handles editing key info in the motion branch. This object implements this method to return FALSE because it is not a "real" reference dependency. It's just needed while the editing is taking place. Plug-in developers don't need to concern themselves with this method because it is used internally.

**Parameters:**

**ReferenceTarget \*rtarg**

A pointer to the reference target.

**Default Implementation:**

```
{return TRUE;}
```

## Loading / Saving Methods

**Prototype:**

**virtual IOResult Save(ISave \*isave);**

**Remarks:**

Implemented by the Plug-In.

Called by the system to allow the plug-in to save its data.

**Parameters:**

**ISave \*isave**

This pointer may be used to call methods to write data to disk. See the Advanced Topics section on [Loading and Saving](#) more an overview of the load/save process.

**Return Value:**

**IO\_OK**

The result was acceptable - no errors.

### **IO\_ERROR**

This should be returned if an error occurred.

#### **Default Implementation:**

```
{ return IO_OK; }
```

#### **Prototype:**

```
virtual IOResult Load(ILoad *iload);
```

#### **Remarks:**

Implemented by the Plug-In.

Called by the system to allow the plug-in to load its data. See the Advanced Topics section on [Loading and Saving](#) more an overview of the load/save process.

#### **Parameters:**

##### **ILoad \*iload**

This interface pointer may be used to call methods to read data from disk.

#### **Return Value:**

##### **IO\_OK**

The result was acceptable - no errors.

##### **IO\_ERROR**

This should be returned if an error occurred.

#### **Default Implementation:**

```
{ return IO_OK; }
```

#### **Prototype:**

```
virtual int RemapRefOnLoad(int iref)
```

#### **Remarks:**

This method is used when you have modified a **ReferenceMaker** to add or delete references, and are loading old files. It gets called during the reference mapping process, after the **Load()** method is called. You determine what version is loading in the **Load()**, and store the version in a variable which you can look at in **RemapRefOnLoad()** to determine how to remap references.

The default implementation of this method just returns the same value it is passed, so you don't need to implement it unless you have added or deleted references from your class. This method makes it a lot easier to load old files when the reference topology has changed.

**Parameters:**

**int iref**

The input index of the reference.

**Return Value:**

The output index of the reference.

**Default Implementation:**

```
{ return iref; }
```

**Prototype:**

```
virtual void RescaleWorldUnits(float f);
```

**Remarks:**

This method is available in release 2.0 and later only.

This may be implemented to rescale the size of all world units in reference hierarchy. Developers must call

```
if (TestAFlag(A_WORK1))
```

```
    return;
```

```
    SetAFlag(A_WORK1);
```

before doing this on a reference hierarchy.

See the sub-section 'Scaling Parameter Values' in [Updating MAX 1.0 Plug-Ins to work with MAX 2.0](#) for additional details.

**Parameters:**

**float f**

The scale factor.

**Prototype:**

```
virtual void SaveEnum(SaveEnumProc& sep, BOOL  
isNodeCall=0);
```

**Remarks:**

This method is used internally.

**Prototype:**

**void BlockEval()**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**void UnblockEval()**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**int Evaluating()**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**RefResult StdNotifyRefChanged(Interval changeInt,  
RefTargetHandle hTarget, PartID partID, RefMessage message,  
BOOL propagate=TRUE);**

**Remarks:**

This method is used internally.

**The following methods are for release 4.2 or above**

**Prototype:**

**virtual void\* GetInterface(ULONG id)**

**Remarks:**

Returns a pointer to the interface.

**Parameters:****ULONG id**

The id of the interface.

**Prototype:****virtual BaseInterface\* GetInterface(Interface\_ID id)****Remarks:**

Returns a pointer to the Base Interface for the interface ID passed.

**Parameters:****Interface\_ID id**

The unique ID of the interface to get

## Reference Target

See Also: [Class ReferenceTarget](#).

Almost all plug-ins are derived from ReferenceTarget. And because ReferenceTarget is derived from ReferenceMaker, these plug-ins may also make references.

The primary methods allow deleting any references that have been made to the target, and copying of the reference target.

### **DeleteAllRefsToMe()**

This method deletes all references to the target. This is often used when an item is being deleted and it wants to remove all references from itself.

### **Clone()**

This method copies both the data structure and all the data residing in the data structure of the reference target.

## Class ReferenceTarget

See Also: [Class ReferenceMaker](#), [Class RefList](#), [Class DependentEnumProc](#), [Class RemapDir](#), [References](#).

```
class ReferenceTarget : public ReferenceMaker
```

### Description:

This class is used by anything that may need to have references made to it. Most plug-ins are derived from this class. This class includes methods to send notification of changes by the object, seeing which other objects in the system depend on it (reference it), and a method used to create a copy of the object ('clone' it). See the Advanced Topics section on [References](#) for an overview of the 3ds max reference architecture.

### Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Dependent Notification](#)

[Cyclic Reference Testing / Dependency Testing](#)

[Adding / Deleting / Transferring References](#)

[Dependent Enumeration](#)

[Cloning](#)

### Methods:

#### Dependent Notification

##### Prototype:

```
virtual RefResult NotifyDependents(Interval changeInt, PartID  
partID, RefMessage message, SClass_ID  
sclass=NOTIFY_ALL,BOOL propagate=TRUE, RefTargetHandle  
hTarg=NULL );
```

##### Remarks:

Implemented by the System.

This method broadcasts the message specified by the **message** parameter to all the items which reference this item.

Note the following on how reference messages propagate (that is, travel to the dependents):

When a plug-in sends a message via **NotifyDependents()**, the message propagates to ALL the items that reference it. And also to all the items which reference those items. And so on. The only exceptions to this are as follows:

- 1) The **propagate** parameter passed is **FALSE**. In that case the message only goes to the immediate dependents.
- 2) If the **SClass\_ID sclass=NOTIFY\_ALL** parameter limits the dependents to a certain specified Super Class.
- 3) If one of the items that references the plug-in processes the message inside its **NotifyRefChanged()** and returns **REF\_STOP** instead of **REF\_SUCCEED**. In this case, the message is not further propagated.

Also, whenever a message propagates, the **hTarget** parameter received in **NotifyRefChanged()** is reset to the **this** pointer of the immediate dependent (not the originator) who propagates the message.

#### Parameters:

##### **Interval changeInt**

Currently all plug-ins must pass **FOREVER** for this interval. This indicates the interval of time over which the change reported by the message is in effect.

##### **PartID partID**

This parameter is used to pass message specific information to the items which will receive the message. See the

**ReferenceMaker::NotifyRefChanged()** method for more details.

##### **RefMessage message**

The message to broadcast to all dependents. See the

**ReferenceMaker::NotifyRefChanged()** method for more details. See

[List of Reference Messages](#).

##### **SClass\_ID sclass=NOTIFY\_ALL**

This parameter defaults to **NOTIFY\_ALL**. If this value is passed to **NotifyDependents()** all dependents will be notified. Other super class values may be passed to only send the message to certain items whose SuperClassID matches the one passed.

**BOOL propagate=TRUE**

This parameter defaults to TRUE. This indicates that the message should be sent to all 'nested' dependencies. If passed as FALSE, this parameter indicates the message should only be sent to first level dependents. Normally this should be left to default to TRUE.

**RefTargetHandle hTarg=NULL**

This parameter must always default to NULL.

**Return Value:**

This method always returns **REF\_SUCCEED**.

**Prototype:**

**virtual void NotifyForeground(TimeValue t)**

**Remarks:**

Implemented by the System.

This method is called to flag dependents into the foreground. The default implementation just sends out the notification

**REFMSG\_FLAGDEPENDENTS** with **PART\_PUT\_IN\_FG** as the **partID**. In particular, a slave controller could override this method and call its master's version of this method.

**Parameters:**

**TimeValue t**

The time to send the notification.

**Prototype:**

**virtual void NotifyTarget(int message, ReferenceMaker\* hMaker);**

**Remarks:**

This method is available in release 4.0 and later only.

Used by a ReferenceMaker to send 'reverse' notification messages to its ReferenceTargets.

**Parameters:**

**int message**

The message sent to the reference target. See List of Reference Target Messages. **\*\*aztodo\*\*** link this

## **ReferenceMaker\* hMaker**

The ReferenceMaker sending the message.

## **Cyclic Reference Testing / Dependency Testing**

### **Prototype:**

**RefResult TestForLoop(Interval refInterval, RefMakerHandle hmaker);**

### **Remarks:**

Implemented by the System.

This method may be called to test for cyclical references. Normally developers don't need to call this method since when a developer calls **MakeRefByID()** to make a reference it performs its own test internally and will not succeed if there is a cyclical reference being created.

### **Parameters:**

#### **Interval refInterval**

This interval is reserved for future use. Currently any plug-in should specify FOREVER for this interval.

#### **RefMakerHandle hmaker**

The reference maker performing the loop test.

### **Return Value:**

**REF\_SUCCEED** if a cyclic reference would be created; otherwise **REF\_FAIL**.

### **Prototype:**

**HasDependents()**

### **Remarks:**

Implemented by the System.

Returns nonzero if the reference target has items that reference it; otherwise 0.

### **Prototype:**

**RefList& GetRefList()**

### **Remarks:**

Implemented by the System.

Returns a list of references to this reference target.

**Return Value:**

List of references to this reference target.

**Prototype:**

**void BeginDependencyTest()**

**Remarks:**

Implemented by the System.

To see if this reference target depends on something: first call

**BeginDependencyTest()** then call **NotifyDependents()** on the thing with the message **REFMSG\_TEST\_DEPENDENCY**. If

**EndDependencyTest()** returns TRUE this target is dependent on the thing.

**Prototype:**

**BOOL EndDependencyTest()**

**Remarks:**

Implemented by the System.

To see if this reference target depends on something: first call

**BeginDependencyTest()** then call **NotifyDependents()** on the thing with the message **REFMSG\_TEST\_DEPENDENCY**. If

**EndDependencyTest()** returns TRUE this target is dependent on the thing.

**Return Value:**

Returns TRUE if the target is dependent.

## **Adding / Deleting / Transferring References**

**Prototype:**

**virtual void RefAdded(RefMakerHandle rm)**

**Remarks:**

Implemented by the Plug-In.

This method is called after making a reference. If the target needs to know it can override it.

**Parameters:**

**RefMakerHandle rm**

The ReferenceMaker creating the reference.

**Prototype:**

**RefResult DeleteAllRefsToMe();**

**Remarks:**

Implemented by the System.

This method deletes all references to this reference target.

**Return Value:**

Always returns **REF\_SUCCEED**.

**Prototype:**

**virtual RefResult AutoDelete()**

**Remarks:**

Implemented by the Plug-In.

This method is called when a target's last reference is deleted. Most subclasses will not need to override this. If you don't want to be deleted when the last reference is deleted, plug in a no-op.

More likely, a developer would override **Animatable::DeleteThis()** if they didn't want to be deleted from memory.

**Return Value:**

Always returns **REF\_SUCCEED**.

**Prototype:**

**virtual void RefDeleted()**

**Remarks:**

Implemented by the Plug-In.

This is called after deleting a reference to a reference target, in the case that the target was not deleted. If a target needs to know, it should override this method.

**Prototype:**

**virtual void RefDeletedUndoRedo();**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called when a reference is deleted because of an undo or a redo.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void RefAddedUndoRedo(RefMakerHandle rm);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called when a reference is added because of an undo or a redo.

**Parameters:**

**RefMakerHandle rm**

The reference maker that is now referencing this target.

**Default Implementation:**

**{}**

**Prototype:**

**RefResult TransferReferences(RefTargetHandle oldTarget, BOOL delOld=FALSE);**

**Remarks:**

Implemented by the System.

This method is used to transfer all the references from **oldTarget** to this reference target.

**Parameters:**

**RefTargetHandle oldTarget,**

The previous reference target.

**BOOL delOld=FALSE);**

If this is TRUE the previous reference target is deleted.

**Return Value:**

Always returns **REF\_SUCCEED**.

**Dependent Enumeration****Prototype:**

```
virtual int EnumDependents(DependentEnumProc* dep);
```

**Remarks:**

Implemented by the System.

This allows a reference target to enumerate all reference to it. All reference targets have a list of back pointers to entities that reference it. This method enumerates those back pointers calling the given callback object once per dependent.

**Parameters:**

**DependentEnumProc\* dep**

The callback object called for each dependent.

**Return Value:**

Return 1 to stop the enumeration and 0 to continue.

**Cloning****Prototype:**

```
virtual RefTargetHandle Clone(RemapDir &remap =  
NoRemap());
```

**Remarks:**

Implemented by the Plug-In.

This method is called to have the plug-in clone itself. This method should copy both the data structure and all the data residing in the data structure of this reference target. The plug-in should clone all its references as well.

**Important Note:** See the remarks in method **BaseClone()** below.

**Parameters:**

**RemapDir &remap = NoRemap()**

This class is used for remapping references during a Clone. See [Class](#)

[RemapDir](#).

**Return Value:**

A pointer to the cloned item.

**Prototype:**

**virtual void BaseClone(ReferenceTarget \*from, ReferenceTarget \*to, RemapDir &remap);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

**Important Note:** All plug-ins that implement a **Clone()** method have to call this **BaseClone()** method with the old and the new object as parameters. The ordering in regards to when is method is called is unimportant however it must, of course, be called after the cloned object is created.

This method allows base classes to copy their data into a new object created by the clone operation. All overwrites of **BaseClone()** **must** call the base class implementation. The base class implementation copyies the CustAttrib objects into the newly created object.

**Parameters:**

**ReferenceTarget \*from**

Points to the old object to clone.

**ReferenceTarget \*to**

Points to the new object created.

**RemapDir &remap**

This class is used for remapping references during a Clone. See [Class RemapDir](#).

**Prototype:**

**RefResult MaybeAutoDelete();**

**Remarks:**

This method is used internally.

**The following methods are for release 4.2 and above**

**Prototype:**

**virtual void\* GetInterface(ULONG id)**

**Remarks:**

Returns a pointer to the interface.

**Parameters:**

**ULONG id**

The id of the interface.

**Prototype:**

**virtual BaseInterface\* GetInterface(Interface\_ID id)**

**Remarks:**

Returns a pointer to the Base Interface for the interface ID passed.

**Parameters:**

**Interface\_ID id**

The unique ID of the interface to get

# Object

See Also: [Class Object](#).

The object class is the base class for all objects. An object is one of two things: A procedural object or a derived object. Derived objects are part of the system and may not be created by plug-ins. They are containers for modifiers.

Procedural objects can be many different things such as cameras, lights, helper objects, geometric objects, etc.

These are some of the main methods of Object.

## **InitNodeName()**

This method provides a default name for the node in the scene when the object is first created.

## **DoOwnSelectHilite()**

If a plug-in overrides this method to return TRUE, then the plug-in becomes responsible for drawing itself in a selected state (if it is selected). Otherwise, the system sets the current line/material color appropriately.

## **ObjectValidity()**

This method returns the validity interval for the object. This is the intersection of the validity intervals for all of the object's channels.

## **IsDeformable()**

If an object is deformable as a point object, then it should return TRUE from this method. A deformable object is a generic point object that supports the following methods:

## **NumPoints()**

Returns the number of deformable points

## **GetPoint(i)**

Returns the 'i-th' point.

## **SetPoint(i)**

This method sets the 'i-th' point.

## **PointsWereChanged()**

If a modifier calls **SetPoint()**, when it is finished it should call this method so the object can invalidate and/or update its bounding box and any other data it might cache.

## **Deform()**

This is the preferred method of deforming a deformable object rather than calling **GetPoint(i)** and **SetPoint(i)**. This method applies the given deformable object to its points (or just its selected points if the selected parameter is specified).

### **GetDeformBBox()**

Gets the bounding box of the object in a particular coordinate system specified by the given matrix. This will only be called on an object that is itself deformable.

All objects must be able to convert to **TriObjects**. And optionally they may convert to other types. A modifier specifies the type of object it wishes to operate on (using **InputType()**). The modifier may only be applied if the object is of the type that the modifier requests or is capable of converting to that type.

### **CanConvertToType()**

This method returns a boolean to indicate if the object can be converted to the desired type passed in.

### **ConvertToType()**

If the object can be converted to the type passed in, this method creates a new instance of that object type and returns it.

### **IntersectRay()**

This is used for ray tracing, or defining planes of tangency at a point (for example, defining a construction plane at a specific point on an object). It is also used by commands such as Place Highlight that require the surface normal at a point on an object. The mesh class implements this method so if your object is represented by a mesh this may be calculated automatically.

# ParticleObject

See Also: [Class ParticleObject](#).

This is the base class from which plug-in particle systems may be derived. The main methods are:

## **ApplyForceField()**

A force field can be applied to a particle system by a space warp. The force field provides a function of position in space, velocity and time that gives a force. The force is then used to compute an acceleration on a particle which modifies its velocity. This method adds a force to the list of forces affecting a particle system.

## **ApplyCollisionObject()**

A collision object can be applied to a particle system by a space warp. The collision object checks a particle's position and velocity and determines if the particle will collide with it. This method adds a collision object to the list of collision objects affecting a particle system.

# PatchObject

See Also: Class [PatchObject](#).

A bezier patch object. This class implements many of the methods from BaseObject, Object and GeomObject to work with bezier patches.

# ShapeObject

See Also: [Class ShapeObject](#).

ShapeObjects are open or closed hierarchical shape objects. This is the base class that **SimpleSpline**, **SimpleShape**, **SplineShape**, and **LinearShape** are derived from. A ShapeObject can be made up of one or more splines thus a shape may have multiple 'pieces'.

# SimpleMod

See Also: [Class SimpleMod](#).

The SimpleMod class supplies most of the methods needed to implement a deformation modifier, reducing the amount of work needed to create one. This class is appropriate for modifiers which alter the geometry (vertices or points) of an object. The plug-in must implement a method to return the Deformer (the process which actually modifies the objects). If the plug-in displays any animated parameters to the user it must implement a method to update these parameters if the user has changed the current time slider.

These are the main methods:

## **GetDeformer()**

This gets the deformer callback object from the derived class. This is the class with methods that actually deforms the object.

## **UpdateUI()**

If the modifier is currently being edited, any parameters that appear in the user interface should be updated so that if the current time has changed, the UI will properly reflect the parameter values at that time.

## **GetValidity()**

This method computes the validity interval for the modifier.

# SimpleObject

See Also: [Class SimpleObject](#).

This is a base class to simplify the development of procedural objects. The procedural object must represent itself as a mesh in order to subclass off SimpleObject.

# SimpleParticle

See Also: [Class SimpleParticle](#).

Plug-In particle systems may be derived from SimpleParticle. The main methods are:

## **UpdateParticles()**

Update the state of the particles at the specified time.

## **BuildEmitter()**

Constructs the particle emitter at the time passed.

## **InvalidateUI()**

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

# SimpleShape

See Also: [Class SimpleShape](#).

Plug-In procedural shapes are subclassed from SimpleShape. The main methods are:

## **BuildShape()**

Called to create the spline shape at the specified time.

## **ValidForDisplay()**

Called to determine if the spline may be displayed at the time passed.

## **void InvalidateUI()**

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

# SimpleSpline

See Also: [Class SimpleSpline](#).

This is a class used in the creation of shape plug-ins. Most of the 3ds max shapes and splines are derived from this class. For example, Line, Arc, Circle, Ellipse and Star are all **SimpleSplines**.

# SimpleWSMMod

See Also: [Class SimpleWSMMod](#).

The SimpleWSMMod class supplies most of the methods needed to implement a Space Warp plug-in (world space modifier).

To be a Simple WSM modifier, the following assumptions are made:

The modifier only modifies the geometry channel.

The modifier uses an instance of a class derived from Deformer to do the modifying.

The main methods are:

## **GetDeformer()**

This method is used to retrieve the callback object that will handle the deformation.

## **UpdateUI()**

This method is called when the user has moved the time slider to a new time and the UI parameters need to be updated to reflect the correct value at the new time.

## **GetValidity()**

The SimpleWSMMod class calls this method to retrieve the validity interval of the modifier.

## Class SimpleWSMMod

See Also: [Class Modifier](#), [Class IParamBlock](#), [Class INode](#).

```
class SimpleWSMMod : public Modifier
```

### Description:

The SimpleWSMMod class supplies most of the methods needed to implement a world space modifier.

To be a 'Simple' WSM modifier, the following assumptions are made:

The modifier only modifies the geometry channel.

The modifier uses an instance of a class derived from Deformer to do the modifying.

This class maintains a pointer to a parameter block. If the client of **SimpleWSMMod** uses a single parameter block then **SimpleWSMMod** can manage all the methods associated with SubAnims and References for the client. If the client of **SimpleWSMMod** maintains several parameter blocks then the client must implement the methods **NumSubs()**, **SubAnim(i)**, **SubAnimName(i)**, **NumRefs()**, **GetReference(i)** and **SetReference(i)** and call the **SimpleWSMMod** methods when 'i' refers to the parameters maintained by **SimpleWSMMod**.

### Data Members:

Clients of **SimpleWSMMod** should use the following pointers when the references are created.

protected:

**IParamBlock \*pblock;**

Pointer to a parameter block.

**WSMObject \*obRef;**

Pointer to the world space modifier object referenced by the **WSMModifier**.

**INode \*nodeRef;**

Pointer to the node in the scene referenced by the **WSMModifier**.

**static IObjParam \*ip;**

Storage for the interface pointer.

**static SimpleWSMMod \*editMod;**

Storage for the modifier currently being edited in the command panel.

Clients of **SimpleWSMMod** should use the following values as the reference indexes of the object, node and parameter block.

```
#define SIMPWSMMOD_OBREF 0
```

```
#define SIMPWSMMOD_NODEREF 1
```

```
#define SIMPWSMMOD_PBLOCKREF 2
```

The example code below (from `\MAXSDK\SAMPLES\HOWTO\RIPPLE.CPP`) shows how these are used:

```
MakeRefByID(FOREVER,SIMPWSMMOD_NODEREF,node);  
MakeRefByID(FOREVER, SIMPWSMMOD_PBLOCKREF,  
CreateParameterBlock(descModVer0,  
MODPBLOCK_LENGTH,  
CURRENT_MODVERSION));
```

#### **Methods:**

#### **Prototype:**

```
virtual Deformer& GetDeformer(TimeValue t,ModContext  
&mc,Matrix3& mat,Matrix3& invmat)=0;
```

#### **Remarks:**

Implemented by the Plug-In.

This method is used to retrieve the callback object that will handle the deformation.

#### **Parameters:**

##### **TimeValue t**

Specifies the time the modification is being performed.

##### **ModContext &mc**

A reference to the ModContext.

##### **Matrix3& mat**

A reference to a matrix that describes the space the modification is supposed to happen in. This is computed from the ModContext matrix and the controllers controlling the gizmo and center of the modifier. The plug-in developers job is simply to transform each point to be deformed by this matrix before it performs its own deformation to the point. After the modifier applies its own deformation to the point, the developer transforms the point by the

inverse of this matrix (passed below).

### **Matrix3& invmat**

This is the inverse of the matrix above. See the comment above for how this is used.

### **Return Value:**

A C++ reference to the deformer callback object.

See Also: The Advanced Topics section on the [Geometry Pipeline System](#).

### **Prototype:**

**virtual void InvalidateUI()**

### **Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

### **Example:**

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **pmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that ip and pblock are assumed to be initialized interface and parameter block pointers

```
float newval;
```

```
Interval valid=FOREVER;
```

```
TimeValue t=ip->GetTime();
```

```
// Get the value from the parameter block at the current time.
```

```
pblock->GetValue( PB_ANGLE, t, newval, valid );
```

```
// Set the value. Note that the notify argument is passed as  
FALSE.
```

```
// This ensures no messages are sent when the value changes.
```

**angleSpin->SetValue( newval, FALSE );**

**Prototype:**

**virtual Interval GetValidity(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

The SimpleWSMMod class calls this method to retrieve the validity interval of the modifier. The modifier provides this interval by starting an interval at FOREVER and intersecting it with each of its parameters validity intervals.

**Parameters:**

**TimeValue t**

The time to compute the validity interval.

**Default Implementation:**

**{return FOREVER;}**

**Return Value:**

The validity interval of the modifier.

See Also: The Advanced Topics section on [Intervals](#).

**Prototype:**

**virtual ParamDimension \*GetParameterDim(int pbIndex)**

**Remarks:**

Implemented by the Plug-In.

Returns the dimension of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter.

**Default Implementation:**

**{return defaultDim;}**

**Return Value:**

The dimension of the parameter.

See Also: Class [ParamDimension](#).

**Prototype:**

```
virtual TSTR GetParameterName(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

Returns the name of the parameter whose index is passed.

**Parameters:**

```
int pbIndex
```

Index of the parameter.

**Default Implementation:**

```
{return TSTR(_T("Parameter"));} 
```

**Return Value:**

The name of the parameter.

**Prototype:**

```
WSMObject *GetWSMObject(TimeValue t);
```

**Remarks:**

Implemented by the System.

Evaluates the node reference and returns the WSM object. If you look in `\MAXSDK\SAMPLES\HOWTO\MISC\SIMPMOD.CPP` you'll see that all this method does is call **EvalWorldState()** on the Node reference.

**Parameters:**

```
TimeValue t
```

The time to get the WSMObject.

When clients of SimpleWSMMod are cloning themselves, they should call this method on the clone to copy SimpleWSMMod's data.

```
void SimpleWSMModClone(SimpleMod *smodSource);
```

Clients of SimpleWSMMod probably want to override these. If they do they should call these from within their methods.

```
void BeginEditParams(IObjParam *ip, ULONG flags,Animatable *prev);
```

```
void EndEditParams(IObjParam *ip, ULONG flags,Animatable *next);
```

## SimpleWSMObject

See Also: [Class WSMObject](#).

This is a base class to simplify the development of space warp objects. The space warp must represent itself as a mesh in order to subclass off SimpleWSMObject. The main methods are:

### **BuildMesh()**

This method is called to build the mesh representation of the object using its parameter settings at the time passed.

### **InvalidateUI()**

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

### **OKtoDisplay()**

This method returns a BOOL to indicate if it is okay to draw the object at the time passed.

## Class SimpleWSMObject

See Also: [Class WSMObject](#), [Class IParamBlock](#), [Class Mesh](#), [Class Interval](#).

```
class SimpleWSMObject : public WSMObject
```

### Description:

This is the base class for creating space warp objects. This class implements many of the methods required to create a space warp object. The only limitation for a space warp object using SimpleWSMObject as a base class is that it must represent itself with a mesh.

### Data Members:

Note: Methods of the base class refer to these data members. For example the base class implementations of the bounding box methods use the **mesh** data member. Therefore the plug-in derived from SimpleWSMObject must use these same data members. These are listed below:

public:

#### **IParamBlock \*pblock;**

Pointer to a parameter block. Clients of SimpleWSMObject should use this pointer when the pblock reference is created.

#### **Mesh mesh;**

The mesh object that is built by **BuildMesh()**.

#### **Interval ivalid;**

The validity interval of the mesh.

### Methods:

Space warp object plug-ins which subclass off SimpleWSMObject must implement these methods. The default implementations are noted.

### Prototype:

```
virtual void BuildMesh(TimeValue t)=0;
```

### Remarks:

Implemented by the Plug-In.

This method is called to build the mesh representation of the object using its parameter settings at the time passed.

### Parameters:

## **TimeValue t**

The time at which to build the mesh.

### **Prototype:**

**virtual ParamDimension \*GetParameterDim(int pbIndex)**

### **Remarks:**

Implemented by the Plug-In.

This method returns the parameter dimension of the parameter whose index is passed.

### **Parameters:**

**int pbIndex**

The index of the parameter to return the dimension of.

### **Return Value:**

Pointer to a ParamDimension.

### **Example:**

**return stdNormalizedDim;**

### **Default Implementation:**

The default implementation returns **defaultDim**.

See Also: [ParamDimension](#)

### **Prototype:**

**virtual TSTR GetParameterName(int pbIndex)**

### **Remarks:**

Implemented by the Plug-In.

This method returns the name of the parameter whose index is passed.

### **Parameters:**

**int pbIndex**

The index of the parameter to return the name of.

### **Return Value:**

The name of the parameter.

### **Default Implementation:**

The default implementation returns **TSTR(\_T("Parameter"))**

**Prototype:**

**virtual void InvalidateUI()**

**Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

**Example:**

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **pmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the SetValue() method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that ip and pblock are assumed to be initialized interface and parameter block pointers

```
(IObjParam *ip, IParamBlock *pblock).  
float newval;  
Interval valid=FOREVER;  
TimeValue t=ip->GetTime();  
// Get the value from the parameter block at the current time.  
pblock->GetValue( PB_ANGLE, t, newval, valid );  
// Set the value. Note that the notify argument is passed as  
FALSE.  
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Prototype:**

**virtual BOOL OKtoDisplay(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

This method returns a BOOL to indicate if it is okay to draw the object at the

time passed. Normally it is always OK to draw the object, so the default implementation returns TRUE. However for certain objects it might be a degenerate case to draw the object at a certain time (perhaps the size went to zero for example), so these objects could return FALSE.

**Parameters:**

**TimeValue t**

The time at which the object would be displayed.

**Default Implementation:**

```
{ return TRUE; }
```

**Return Value:**

TRUE if the object may be displayed; otherwise FALSE.

## SoundObj

See Also: [Class SoundObj](#).

There is always one sound object in the scene. A sound object's primary purpose is to provide a sound track for the scene, but it also has another important function; it serves as a clock that controls timing when an animation is played. This ensure the animation is synched to the sound object. It has methods to start and stop the animation playing, play a specified range of the sound, and toggle the sound on and off.

# SplineShape

See Also: [Class SplineShape](#).

Spline shape is an implementation of a shape object. A procedural shape can convert itself to a spline shape if it needs to be deformed.

## Class SplineShape

See Also: [Class ShapeObject](#), [Class BezierShape](#), [Working with Shapes and Splines](#).

```
class SplineShape : public ShapeObject, ISplineOps, ISplineSelect,  
ISplineSelectData, ISubMtlAPI, AttachMatDlgUser
```

### Description:

Defines a spline object class. The **SplineShape** is the object that flows down the 3ds max geometry pipeline. This class is a container for the **BezierShape shape**. All methods of this class are implemented by the system.

Spline Shape plug-ins use a Super Class ID of **SHAPE\_CLASS\_ID**.

### Data Members:

public:

**BezierShape shape;**

The shapes of this SplineShape.

### Methods:

#### Prototype:

**SplineShape();**

#### Remarks:

Constructor. Initialize the member variables.

#### Prototype:

**~SplineShape();**

#### Remarks:

Destructor.

#### Prototype:

**BezierShape& GetShape();**

#### Remarks:

Returns the BezierShape data member maintained by this class.

**Prototype:**

**void SelectBySegment(BOOL interactive = TRUE);**

**Remarks:**

This method is available in release 4.0 and later only.

This method operates in vertex level only, and sets the vertex selection set based on the segments that are selected. Any vertex which is part of a selected segment will be selected.

**Parameters:****BOOL interactive**

If set to FALSE, an Undo object is not created and the method does not initiate a redraw.

**Prototype:**

**void SelectBySpline(BOOL interactive = TRUE);**

**Remarks:**

This method is available in release 4.0 and later only.

This method operates in vertex and segment level only, and sets the vertex or segment selection set based on the splines that are selected. If in vertex mode, any vertex which is part of a selected spline will be selected. If in segment mode, any segment which is part of a selected spline will be selected.

**Parameters:****BOOL interactive**

If set to FALSE, an Undo object is not created and the method does not initiate a redraw.

**Prototype:**

**virtual void GetUIParam(splineUIParam uiCode, int &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**int &ret**

The returned value.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetUIParam(splineUIParam uiCode, int val);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:****splineUIParam uiCode**

This enum is currently empty.

**int val**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void GetUIParam(splineUIParam uiCode, float &ret);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

**Parameters:****splineUIParam uiCode**

This enum is currently empty.

**float &ret**

The returned value.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetUIParam(splineUIParam uiCode, float val);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**float val**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
bool Editing();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method will return TRUE if the SplineShape object or Edit Spline modifier is active in the command panel.

**Default Implementation:**

```
{ return (ip && (editObj==this)) ? TRUE : FALSE; }
```

# StdControl

See Also: [Class StdControl](#).

The purpose of this class is to simplify some aspects of implementing controllers. The only restriction when using this class is that the controller can not evaluate itself as a function of its input. This class handles processing Out of Range Types, ease curves and multiplier curves.

There are a few other methods that StdControl requires:

## **Extrapolate()**

Extrapolate is used to calculate some of the ORTs. There are several types of extrapolations that need to be done and there are template functions implemented in `\MAXSDK\INCLUDE\CONTROL.H` to do them.

## **CreateTempValue()**

When processing the ORTs the system might need a temporary variable to hold an intermediate value. Since the system doesn't actual know the type of the data that the controller is controlling it can't allocate the right amount of temporary storage. It calls this method to do so.

## **DeleteTempValue()**

This method simply deletes the memory allocated by **CreateTempValue()**.

## **ApplyValue()**

Applies the given value to the given input value. For position, rotation, and scale controllers, the input value will be a matrix and the value being applied will be a Point3, quaternion, or ScaleValue, respectively. For other controllers the input value is the same type as the value being applied.

## **MultiplyValue()**

If the controller has multiplier curves then the system will calculate the factor from all the multiplier curves and then ask the controller to multiply the scalar value to the particular data type.

# Texmap

See Also: [Class Texmap](#).

Plug-In 2D and 3D texture maps are subclassed off Texmap. Some of the methods of Texmap are:

## **EvalColor()**

This returns the color of the texture map at a specific location.

## **EvalNormalPerturb()**

This computes a perturbation to apply to a normal for bump mapping.

# TriObject

See Also: [Class TriObject](#).

A triangle mesh object. All procedural objects must be able to convert themselves to TriObjects. TriObjects are "deformable". This means they have points which a modifier may operate upon to deform the geometry. This class provides default implementations of many of the methods from Object and GeomObject.

## Class TriObject

See Also: [Class GeomObject](#), [Class ClassDesc](#), [Class Mesh](#), [Class TessApprox](#).

```
class TriObject : public GeomObject
```

### Description:

This class represents a renderable, deformable, triangle mesh object. All procedural objects must be able to convert themselves to TriObjects. This class provides implementations of all the required methods of Animatable, ReferenceMaker, ReferenceTarget, Base Object, Object, and GeomObject. All methods of this class are implemented by the system.

### Data Members:

public:

#### **Mesh mesh;**

This is the mesh of the TriObject. See [Class Mesh](#) for methods to manipulate this mesh.

The following data members are used by the Displacement Mapping mechanism in 3ds max.

#### **TessApprox mDispApprox;**

The object which describes the properties of the tessellation approximation of the mesh.

#### **bool mSubDivideDisplacement;**

The subdivision displacement flag. When TRUE, displacement mapping mechanism subdivides mesh faces to accurately displace the map, using the method and settings you specify in the Subdivision Presets and Subdivision Method group boxes. When FALSE, the modifier applies the map by moving vertices in the mesh, the way the Displace modifier does.

#### **bool mDisableDisplacement;**

TRUE to disable displacement mapping; FALSE to enable it.

#### **bool mSplitMesh;**

The split mesh flag. This flag affects texture mapping as done by the displacement mapping mechanism. When on, the modifier splits the mesh into individual faces before displacing them: this helps preserve texture mapping. When off, the modifier uses an internal method to assign texture mapping. Default=On.

**Methods:**

**Prototype:**

**Mesh& GetMesh();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to the **mesh** data member of this TriObject.

**Prototype:**

**TessApprox& DisplacmentApprox();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to the **mDispApprox** data member.

**Prototype:**

**bool& DoSubdivisionDisplacment();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to the boolean **mSubDivideDisplacement** data member.

**Prototype:**

**bool& SplitMeshForDisplacement();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to the boolean **mSplitMesh** data member.

**Prototype:**

**void SetDisplacmentApproxToPreset(int preset);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally to set the **mDispApprox** data member to one

of the low/medium/high subdivision presets.

**Prototype:**

**void DisableDisplacementMapping(BOOL disable);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the **mDisableDisplacement** data member to the given state.

**Parameters:**

**BOOL disable**

TRUE to disable; FALSE to enable.

**Related Functions:**

There are several global functions (not part of class TriObject) for dealing with TriObjects and the control of standard TriObject versus Editable TriObjects. These functions are described below:

**Function:**

**TriObject \*CreateNewTriObject();**

**Remarks:**

This method is used to create a new TriObject. Use this instead of **new TriObject**. It will use the registered descriptor if one is registered, otherwise you'll get a default TriObject.

**Function:**

**ClassDesc\* GetTriObjDescriptor();**

**Remarks:**

Returns a pointer to the class descriptor for the regular, standard TriObject.

**Function:**

**ClassDesc\* GetEditTriObjDesc();**

**Remarks:**

Returns a pointer to the class descriptor for the editable TriObject. It returns the default if none has been registered. See below.

**Function:**

**void RegisterEditTriObjDesc(ClassDesc\* desc);**

**Remarks:**

A new descriptor can be registered to replace the default TriObject descriptor. This new descriptor will then be used to create TriObjects.

**Parameters:**

**ClassDesc\* desc**

The class descriptor to replace the default TriObject descriptor.

# WSMObject

See Also: [Class WSMObject](#).

WSM objects are the gizmos for space warps. WSM stands for World Space Modifier, another name for space warp. They are usually non-renderable by the production renderer but may show up in the viewports to allow the user to orient them in the scene. They implement a single method that they implement:

## **CreateWSMMod()**

When the user binds a node to a space warp, a new modifier must be created and added to the node's WSM derived object. This method creates the new modifier.

## Class WSMObject

See Also: [Class Object](#), [Class SimpleWSMObject](#), [Class ForceField](#), [Class CollisionObject](#).

```
class WSMObject : public Object
```

### Description:

This class is a base class used to derived the helper object for a space warp modifier (WSM Modifier).

World Space Object plug-ins use a Super Class ID of **WSM\_OBJECT\_CLASS\_ID**.

### Methods:

#### Prototype:

```
SClass_ID SuperClassID()
```

#### Remarks:

Implemented by the System.

Returns the super class ID of this plug-in type:

**WSM\_OBJECT\_CLASS\_ID**.

#### Prototype:

```
virtual Modifier *CreateWSMMod(INode *node)=0;
```

#### Remarks:

Implemented by the Plug-In.

When the user binds a node to a space warp, a new modifier must be created and added to the node's WSM derived object. This method creates the new modifier.

#### Parameters:

```
INode *node
```

The node of the WSMObject.

#### Return Value:

A pointer to the new modifier.

**Prototype:**

```
virtual int UsesWireColor();
```

**Remarks:**

This method is available in release 2.0 and later only.

This is a method of **Object**. Below is shown the default implementation provided by this class.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual BOOL NormalAlignVector(TimeValue t,Point3 &pt, Point3  
&norm);
```

**Remarks:**

This method is available in release 2.0 and later only.

This is a method of **Object**. Below is shown the default implementation provided by this class.

**Default Implementation:**

```
{pt=Point3(0,0,0);norm=Point3(0,0,-1);return TRUE;}
```

**Prototype:**

```
virtual BOOL SupportsDynamics();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if spacewarp or collision object supports Dynamics; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual ForceField *GetForceField(INode *node);
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to a **ForceField**. This pointer can be used during dynamics calculations, but should not be hung on to after that. For example, you shouldn't have the pointer long enough for it to be possible for the user to delete the space warp object. When you're done using the **ForceField** call its **DeleteThis()** method. This method may be called several times on the same space warp object with different **INode\*** if it is instanced.

**Parameters:**

**INode \*node**

This is the space warp object's node.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual CollisionObject *GetCollisionObject(INode *node);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the collision object for the WSM. This works just like **GetForceField()** documented above.

**Parameters:**

**INode \*node**

This is the space warp object's node.

**Default Implementation:**

```
{return NULL;}
```

## Class IObjParam

See Also: [Class Interface](#).

class IObjParam : public Interface

### **Description:**

This class is identical to [Class Interface](#). Refer to that section for a description of the methods.

## Class IObjCreate

See Also: [Class Interface](#), [Class IObjParam](#).

```
class IObjCreate : public IObjParam
```

### **Description:**

This class is identical to [Class Interface](#). Refer to that section for a description of the methods.

## Class ViewExp

See Also: [List of Snap Flags](#), [Class Ray](#), [Class Point3](#), [Class IPoint2](#), [Class Matrix3](#), [Class ModContext](#), [Class HitData](#), [Class GraphicsWindow](#), [Class INode](#).

```
class ViewExp : public InterfaceServer
```

### Description:

This class provides methods to access properties of the viewport, convert points between viewport and world coordinates, snap points and lengths, etc. Many methods associated with hit testing are also here. All the methods of this class are implemented by the system.

### Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Screen Space - World Space Conversion](#)

[Osnap Related Methods](#)

[Perspective/Camera View Properties](#)

[Snapping](#)

[Access to Viewport Properties](#)

[Node Level Hit Testing](#)

[Sub-Object Level Hit Testing](#)

[Controller Gizmo Hit Testing](#)

[AutoGrid Related Methods](#)

### Methods:

## Screen Space - World Space Conversion

### Prototype:

```
virtual float NonScalingObjectSize()=0;
```

### Remarks:

The value returned from this method may be used as a scale factor that will counteract the viewport zoom. For example, lights, cameras, and tape helper objects use this factor so the size of the node in the scene remains constant when the viewport is zoomed in and out.

This value is affected by the 'Non-Scaling Object Size' spinner in the Viewport Preferences dialog, so the user has some control over this as well.

### Sample Code:

This sample is from

**\MAXSDK\SAMPLES\OBJECTS\TAPEHELP.CPP**. The computed matrix is used in several places like displaying, snapping, hit testing, etc.

```
void TapeHelpObject::GetMat(TimeValue t, INode* inode,
ViewExp* vpt, Matrix3& tm)
{
tm = inode->GetObjectTM(t);
tm.NoScale();
float scaleFactor = vpt->NonScalingObjectSize() *
vpt->GetVPWorldWidth(tm.GetTrans())/(float)360.0;
tm.Scale(Point3(scaleFactor,scaleFactor,scaleFactor));
}
```

### Prototype:

```
virtual Point3 GetPointOnCP(const IPoint2 &ps)=0;
```

### Remarks:

Returns a point in world space on the current construction plane based on the specified screen coordinate.

### Parameters:

```
const IPoint2 &ps
```

The 2D screen point to convert to a 3D world space coordinate.

### Return Value:

The world space coordinate on the current construction plane.

### Prototype:

```
virtual float GetCPDisp(const Point3 base, const Point3& dir,
const IPoint2& sp1, const IPoint2& sp2 )=0;
```

### Remarks:

This method returns a length in world space given a start screen point, an end screen point, a base point and a direction vector. For example, when creating a

cylinder, the user clicks the mouse down to define the center point of the cylinder (**base**), then drags out a radius. They then drag out a height for the cylinder. This method is used to return intermediate and final heights for the cylinder based on the initial base point, the direction vector (the Z axis), the start mouse point, and the current point the user is interactively adjusting.

**Parameters:**

**const Point3 base**

Base point in object space.

**const Point3& dir**

Direction vector in object space.

**const IPoint2& sp1**

Screen start point. This is the point where the user clicked down with the mouse.

**const IPoint2& sp2**

Screen end point. This is the point where the user let up the mouse.

**Return Value:**

The length in world space based on the screen points and their projection onto the direction vector.

**Sample Code:**

```
float h = vpt->SnapLength(vpt-  
>GetCPDisp(p[1],Point3(0,0,1),sp1,m));
```

From `\MAXSDK\SAMPLES\OBJECTS\CYL.CPP` in

```
CylinderObjCreateCallBack::proc
```

**Prototype:**

```
virtual Point3 MapScreenToView( IPoint2& sp, float depth )=0;
```

**Remarks:**

Given a point on the screen (in window coordinates), and a depth in view coordinates, this method maps the point into view coordinates. This is just a scaling operation for parallel projections, but involves a divide by Z for perspective projections.

**Parameters:**

**IPoint2& sp**

Point in window coordinates.

**float depth**

Depth in view coordinates.

**Return Value:**

Point in view coordinates.

**Sample Code:**

```
Point3 p0 = vpt-  
>MapScreenToWorldRay(mBase,GetPerspMouseSpeed());
```

**Prototype:**

```
virtual void MapScreenToWorldRay(float sx, float sy, Ray&  
ray)=0;
```

**Remarks:**

Creates a Ray in world space passing through the specified pixel directed toward the scene in the direction of view.

**Parameters:**

**float sx**

The x screen coordinate.

**float sy**

The y screen coordinate.

**Ray& ray**

The Ray in world space. See [Class Ray](#).

**Prototype:**

```
virtual void GetAffineTM(Matrix3& tm)=0;
```

**Remarks:**

This method retrieves the affineTM which transforms from World coordinates to View coordinates. See the sample code below for an example of its use.

**Parameters:**

**Matrix3& tm**

The matrix to hold the affine TM.

**Sample Code:**

```

// This routine returns the view direction from the active viewport.
Point3 Utility::GetViewDirection() {
  Matrix3 aTM, coordSysTM;
  ViewExp *ve = ip->GetActiveViewport();
  // The affine TM transforms from world coords to view coords
  // so we need the inverse of this matrix
  ve->GetAffineTM(aTM);
  coordSysTM = Inverse(aTM);
  // The Z axis of this matrix is the view direction.
  Point3 viewDir = coordSysTM.GetRow(2);
  ip->ReleaseViewport(ve);
  return viewDir;
}

```

Note: You can also get the view position from this matrix. For example, in the above code, the statement:

```
Point3 viewPt = coordSysTM.GetRow(3);
```

gets the point in space the view is taken from.

**Prototype:**

```
virtual BOOL SetAffineTM(const Matrix3& m)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the viewport affine transformation and returns TRUE if the view is a user view (isometric or perspective). If the view is not a user view then the transformation is not changed and the method returns FALSE. See **SetViewUser()** below.

**Parameters:**

```
const Matrix3& m
```

The transformation matrix to set.

**Prototype:**

```
virtual float GetScreenScaleFactor(const Point3 worldPoint)=0;
```

**Remarks:**

Returns the screen scale factor for a point given in world coordinates. This

factor gives the width in world-space units at the point's distance of the viewport.

**Parameters:**

**const Point3 worldPoint**

The point in world coordinates.

**Return Value:**

The screen scale factor in world space units.

**Prototype:**

**virtual float GetVPWorldWidth(const Point3 wPoint)=0;**

**Remarks:**

Returns the viewport screen width factor in world space at a point in world space.

**Parameters:**

**const Point3 wPoint**

The point in world space.

**Return Value:**

The viewport screen width factor in world space.

**Prototype:**

**virtual Point3 MapCPToWorld(const Point3 cpPoint)=0;**

**Remarks:**

Given a point on the construction plane this method returns the corresponding world space point. For example, if you use **GetPointOnCP()** to convert a screen coordinate to a point on the construction plane, you could then call this method to convert that point on the construction plane to a world space point.

**Parameters:**

**const Point3 cpPoint**

The point on the construction plane.

**Return Value:**

The world space point.

## AutoGrid Related Methods

### Prototype:

```
virtual void TrackImplicitGrid(IPoint2 m, Matrix3* mat = NULL,  
    ULONG hitTestFlags = 0)=0;
```

### Remarks:

This method is available in release 3.0 and later only.

If AutoGrid is enabled, this method determines a grid coordinate system by casting a ray into the scene through the screen coordinate **m**, obtaining a surface normal from the closest node, and using the "arbitrary axis algorithm" to orient the xy axes. You can get this coordinate system back by passing in a pointer to a matrix. A tripod is displayed in the viewports showing the orientation.

### Parameters:

#### **IPoint2 m**

The 2D screen point that the user clicked on.

#### **Matrix3\* mat = NULL**

The implicit grid coordinate system matrix can be retrieved by passing a pointer to a matrix here.

#### **ULONG hitTestFlags = 0**

This parameter is available in release 4.0 and later only.

See [Hit Test Flags](#).

### Prototype:

```
virtual void CommitImplicitGrid(IPoint2 m, int mouseflags,  
    Matrix3* mat = NULL)=0;
```

### Remarks:

This method is available in release 3.0 and later only.

If AutoGrid is enabled, this method creates a grid and activates it. The **mouseflags** parameter is used to determine if the ALT key is down. If it is, this grid will not be deactivated in **ReleaseImplicitGrid()** (below).

### Parameters:

#### **IPoint2 m**

The 2D screen point that the user clicked on.

### **int mouseflags**

These flags describe the state of the mouse buttons. See [List of Mouse Callback Flags](#).

### **Matrix3\* mat = NULL**

Developers can get the implicit grid coordinate system back by passing in a pointer to a matrix here.

### **Prototype:**

```
virtual void ReleaseImplicitGrid()=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

This method deactivates an implicit grid and restores the previously active grid. If the implicit grid was committed with ALT-key held down, then this call does nothing.

## **Osnap Related Methods**

### **Prototype:**

```
virtual void SnapPreview(const IPoint2 &in, IPoint2 &out,  
Matrix3 *plane2d=NULL, DWORD flags=0)=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

This is a method used as part of the osnap system in 3ds max. It is the method that displays the snap marker in the viewports prior to the first point event. It's really just a call to **SnapPoint()** which returns nothing. This method should be called in response to a **MOUSE\_FREEMOVE** event from any creation or transformation proc which calls **SnapPoint()**. Here's an example creation proc:

### **Sample Code:**

```
int PointHelpObjCreateCallBack::proc(ViewExp *vpt,int msg, int  
point, int flags, IPoint2 m, Matrix3& mat ) {  
if (msg == MOUSE_FREEMOVE)
```

```

// Show a preview snap in the viewport prior to the
// first point event.
vpt->SnapPreview(m,m,NULL, SNAP_IN_3D);

if (msg==MOUSE_POINT||msg==MOUSE_MOVE) {
switch(point) {
case 0:
ob->suspendSnap = TRUE;
mat.SetTrans(vpt->SnapPoint(m,m,NULL,SNAP_IN_3D));
break;
case 1:
mat.SetTrans(vpt->SnapPoint(m,m,NULL,SNAP_IN_3D));
if (msg==MOUSE_POINT) {
ob->suspendSnap = FALSE;
return 0;
}
break;
}
} else
if (msg == MOUSE_ABORT) {
return CREATE_ABORT;
}
return 1;
}

```

**Parameters:**

**const IPoint2 &in**

The 2D screen coordinate to snap.

**IPoint2 &out**

The snapped 2D screen coordinate. This is used if you need to move the mouse position to the snapped location.

**Matrix3 \*plane2d = NULL**

This optional argument allows you to use any plane (not just the current construction plane).

**int flags**

See [List of Snap Flags](#).

**Prototype:**

**virtual void GetGridDims(float \*MinX, float \*MaxX, float \*MinY, float \*MaxY) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used internally. It fills up it's arguments with the world space extents of the home grid (i.e. the extents of the grid as **displayed**). It doesn't work for grid helper which always display to their size limits. This was exposed so 3ds max could do the grid snapping and is not needed by plug-in developers.

## **Perspective/Camera View Properties**

**Prototype:**

**virtual BOOL IsPerspView()=0;**

**Remarks:**

Returns TRUE if the viewport is a perspective view; otherwise returns FALSE.

**Prototype:**

**virtual int GetViewType()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the type of view. One of the following values:

**enum ViewType {**

**VIEW\_LEFT,VIEW\_RIGHT,VIEW\_TOP,VIEW\_BOTTOM,VI  
VIEW\_ISO\_USER, VIEW\_PERSP\_USER, VIEW\_CAMERA,**

**VIEW\_GRID, VIEW\_NONE,  
VIEW\_TRACK, VIEW\_SPOT, VIEW\_SHAPE,  
VIEW\_SCHEMATIC, VIEW\_OTHER  
};**

**Prototype:**

**virtual float GetFOV()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the field of view of a perspective viewport in radians.

**Prototype:**

**virtual float GetFocalDist()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the focal distance of a perspective view.

**Prototype:**

**virtual INode \*GetViewCamera()=0;**

**Remarks:**

Returns the INode pointer of the camera associated with this viewport. If this is not a camera view then NULL is returned.

**Prototype:**

**virtual void SetViewCamera(INode \*camNode)=0;**

**Remarks:**

Set this viewport to a camera view.

**Parameters:**

**INode \*camNode**

The camera node to set.

**Prototype:**

**virtual INode \*GetViewSpot();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the INode pointer of the spotlight associated with this viewport. If this is not a spotlight view then NULL is returned.

**Prototype:**

```
virtual void SetViewSpot(INode *spotNode)=0;
```

**Remarks:**

Set this viewport to a spotlight view.

**Parameters:**

**INode \*spotNode**

The spotlight node to set.

**Prototype:**

```
virtual void SetViewUser(BOOL persp)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the viewport to be a user view, with the **persp** argument indicating whether this should be a perspective or iso view. Note that the user viewport defaults are used for field-of-view, etc.

**Parameters:**

**BOOL persp**

TRUE for perspective; FALSE for isometric.

## Snapping

**Prototype:**

```
virtual Point3 SnapPoint(const IPoint2 &in, IPoint2 &out,  
Matrix3 *plane2d = NULL, int flags = 0)=0;
```

**Remarks:**

Given a 2D screen coordinate, this method returns a 3D point on the current construction plane based on the current snap settings and flags passed.

**Parameters:**

**const IPoint2 &in**

The 2D screen coordinate to snap.

**IPoint2 &out**

The snapped 2D screen coordinate. This is used if you need to move the mouse position to the snapped location.

**Matrix3 \*plane2d = NULL**

This optional argument allows you to use any plane (not just the current construction plane).

**int flags**

See [List of Snap Flags](#).

**Return Value:**

The snapped 3D point in world space.

**Prototype:**

**virtual float SnapLength(float in)=0;**

**Remarks:**

Given the distance passed, this method snaps the length to the nearest snap increment and returns the snapped distance.

**Parameters:**

**float in**

The input distance to be snapped.

**Return Value:**

The snapped distance.

## Access to Viewport Properties

**Prototype:**

**virtual GraphicsWindow \*getGW()=0;**

**Remarks:**

Returns a pointer to the instance of **GraphicsWindow** associated with this viewport.

Note: A **GraphicsWindow** always has a transform associated with it, for faster object-to-screen space conversions. The **GraphicsWindow \*** returned

by this method may have a non-identity transform already in place. A developer can call **gw->setTransform()** with a node's transform for fast work in Display routines. But this value must be explicitly set to the identity for world-to-screen displays.

**Prototype:**

**virtual HWND GetHwnd()=0;**

**Remarks:**

This returns the window handle of the viewport - this is the transparent window that catches mouse input. Note that this window handle is different than the handle that can be retrieved from the viewport's GraphicsWindow. **getGW()->getHwnd()** is the window that things are drawn on.

**Return Value:**

The window handle of the viewport.

**Prototype:**

**virtual BOOL setBkgImageDsp(BOOL onOff)=0;**

**Remarks:**

This method is used to turn on and off the background image display in this viewport. Note that it is necessary to redraw the viewports in order to see the effect of this method. Use the method **Interface::RedrawViews()** to do this.

**Parameters:**

**BOOL onOff**

TRUE to turn the background image on; FALSE to turn it off.

**Return Value:**

TRUE if the image was set; otherwise FALSE.

**Prototype:**

**virtual int getBkgImageDsp()=0;**

**Remarks:**

Returns nonzero if the background image is displayed in this viewport; otherwise 0.

**Prototype:**

**virtual void setSFDisplay(int onOff)=0;**

**Remarks:**

This method may be used to turn the safe frame display on and off in this viewport.

**Parameters:**

**int onOff**

Nonzero to turn on the safe frame; zero to turn it off.

**Prototype:**

**virtual int getSFDisplay()=0;**

**Remarks:**

Returns nonzero if the safe frame is displayed in this viewport; otherwise 0.

**Prototype:**

**virtual int IsWire()=0;**

**Remarks:**

Determines if this viewport is in wire-frame rendering mode (as opposed to a shaded mode).

**Return Value:**

Nonzero if the viewport is in wire-frame rendering mode; otherwise 0.

**Prototype:**

**virtual Rect GetDammageRect()=0;**

**Remarks:**

Returns the damaged rectangle of the viewport. This is the area that needs to be updated on the next screen refresh. This can be used for example, to pass into the **Mesh** method **render()** to only display the damaged area of the object. A developer could also use this in the implementation of their own **Display()** method.

**Sample Code:**

**int SimpleObject::Display(TimeValue t, INode\* inode,**

```

ViewExp *vpt, int flags) {
if (!OKtoDisplay(t)) return 0;
GraphicsWindow *gw = vpt->getGW();
Matrix3 mat = inode->GetObjectTM(t);
UpdateMesh(t); // UpdateMesh() just calls BuildMesh()
gw->setTransform(mat);
mesh.render(gw, inode->Mtls(),
(flags&USE_DAMAGE_RECT) ? &vpt->GetDammageRect() : NULL,
COMP_ALL, inode->NumMtls());
return(0);
}

```

**Prototype:**

**virtual void GetConstructionTM( Matrix3 &tm )=0;**

**Remarks:**

Retrieves the transformation matrix of the construction plane.

**Parameters:**

**Matrix3 &tm**

The transformation matrix is returned here.

**Prototype:**

**virtual void SetGridSize(float size)=0;**

**Remarks:**

Sets the size of the construction grid spacing.

**Parameters:**

**float size**

Specifies the grid spacing.

**Prototype:**

**virtual float GetGridSize()=0;**

**Remarks:**

Returns the construction grid spacing. This is the grid spacing on a per viewport basis. It is dependent on how far zoomed in or out the user is. This is

the exact same value that you can see in the right most status panel below the viewports.

**Prototype:**

**virtual BOOL IsGridVisible()=0;**

**Remarks:**

Returns TRUE if the grid is turned on for this viewport; otherwise FALSE.

**Prototype:**

**virtual int GetGridType()=0;**

**Remarks:**

Returns the grid type. One of the following values (from OBJECT.H):

**GRID\_PLANE\_NONE**

**GRID\_PLANE\_TOP**

**GRID\_PLANE\_LEFT**

**GRID\_PLANE\_FRONT**

**GRID\_PLANE\_BOTTOM**

**GRID\_PLANE\_RIGHT**

**GRID\_PLANE\_BACK**

**Prototype:**

**virtual BOOL IsActive()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the viewport is the active on; otherwise FALSE.

**Prototype:**

**virtual BOOL IsEnabled()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the viewport is enabled; FALSE if disabled.

## For node level hit-testing

### Prototype:

**virtual void ClearHitList()=0;**

### Remarks:

Implemented by the System.

Clears the list of node level hit records.

### Prototype:

**virtual INode \*GetClosestHit()=0;**

### Remarks:

Implemented by the System.

Returns the INode pointer of the node that was the closest of all those hit. If none were hit, NULL is returned.

### Prototype:

**virtual INode \*GetHit(int i)=0;**

### Remarks:

This method is available in release 2.0 and later only.

Returns the INode pointer of the 'i-th' node level hit.

### Parameters:

**int i**

The index of the hit to retrieve.

### Prototype:

**virtual int HitCount()=0;**

### Remarks:

Implemented by the System.

Returns the number of hits recorded by the last node level hit test.

## For sub-object level hit-testing

### Prototype:

**virtual void LogHit(Node \*nr, ModContext \*mc, DWORD dist, ulong info, HitData \*hitdat = NULL)=0;**

**Remarks:**

Implemented by the System.

This method records a sub-object level hit record with the system using the specified parameters. This hit can later be retrieved using the method **GetSubObjHitList()** and the methods of class HitLog.

**Parameters:**

**Node \*nr**

The node that was hit.

**ModContext \*mc**

The ModContext of the modifier.

**DWORD dist**

The 'distance' of the hit. What the distance actually represents depends on the rendering level of the viewport. For wireframe modes, it refers to the distance in the screen XY plane from the mouse to the sub-object component. In a shaded mode, it refers to the Z depth of the sub-object component. In both cases, smaller values indicate that the sub-object component is 'closer' to the mouse cursor.

**ulong info**

Identifies the sub-object component that was hit.

**HitData \*hitdat = NULL**

If the **info** data member is insufficient to indicate the sub-object component that was hit, pass an instance of the **HitData** class that contains the needed information.

**Prototype:**

**virtual HitLog& GetSubObjHitList()=0;**

**Remarks:**

Returns the sub-object hit list. See [Class HitLog](#).

**Prototype:**

**virtual void ClearSubObjHitList()=0;**

**Remarks:**

Clears the sub-object hit list. This deletes all previously saved HitRecords.

**Prototype:**

```
virtual int NumSubObjHits()=0;
```

**Remarks:**

Returns the number of sub-object hits recorded.

**For controller apparatus hit testing.****Prototype:**

```
virtual void CtrlLogHit(INode *nr, DWORD dist, ulong info,  
    DWORD infoExtra)=0;
```

**Remarks:**

This method records a controller sub-object level hit record with the system using the specified parameters. This hit can later be retrieved using the method **GetCtrlHitList()** and the methods of class CtrlHitLog.

**Parameters:****INode \*nr**

The node that was hit.

**DWORD dist**

The 'distance' of the hit. What the distance actually represents depends on the rendering level of the viewport. For wireframe modes, it refers to the distance in the screen XY plane from the mouse to the sub-object component. In a shaded mode, it refers to the Z depth of the sub-object component. In both cases, smaller values indicate that the sub-object component is 'closer' to the mouse cursor.

**ulong info**

A general unsigned long value. Most controllers will just need this to identify the sub-object element. The meaning of this value (how it is used to identify the element) is up to the plug-in.

**DWORD infoExtra;**

If the above **hitInfo** data member is not sufficient to describe the sub-object element this data member may be used as well.

**Prototype:**

**virtual CtrlHitLog& GetCtrlHitList()=0;**

**Remarks:**

Returns the list of controller gizmo hits recorded. See [Class CtrlHitLog](#).

**Prototype:**

**virtual void ClearCtrlHitList()=0;**

**Remarks:**

Clears the controller hit list. This deletes all the HitRecords previously recorded.

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new cmd numbers and continue to add functionality to this class without having to 'break' the API.

**Parameters:****int cmd**

The index of the command to execute.

**ULONG arg1=0**

Optional argument 1. See the documentation where the cmd option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value. See the documentation where the cmd option is discussed for more details on the meaning of this value.

## Class ILoad

See Also: [Loading and Saving](#), [Character Strings](#), [Class ISave](#), [Class PostLoadCallback](#), [Class INode](#), [Class ClassDesc](#), [Class ClassDirectory](#), [Class Interface](#).

```
class ILoad : public InterfaceServer
```

### Description:

This class provides methods to load data from disk and to register post load callbacks.

Note: It is not valid, to write two **CStrs** in the same chunk of a 3ds max file, since **ILoad::ReadCStringChunk()** sets the size for the string to the **ChunkSize**. However it is possible to write other data, such as two ints, into the same chunk.

All methods of this class are implemented by the system.

### Methods:

### Prototype:

```
virtual IOResult OpenChunk()=0;
```

### Remarks:

This method is used to open a chunk. If **OpenChunk()** returns **IO\_OK**, use the following 3 functions to get the info about the chunk. If it returns **IO\_END** this indicates there are no more chunks at this level.

### Return Value:

**IO\_OK** - The result was acceptable - no errors.

**IO\_END** - This is returned from **ILoad::OpenChunk()** when the end of the chunks at a certain level have been reached. It is used as a signal to terminate the processing of chunks at that level.

**IO\_ERROR** - This is returned if an error occurred. Note that the plug-in should not put up a message box if a read error occurred. It should simply return the error status. This prevents a overabundance of messages from appearing.

### Prototype:

**virtual USHORT CurChunkID()=0;**

**Remarks:**

This method returns the ID of the most recently opened chunk.

**Prototype:**

**virtual ChunkType CurChunkType()=0;**

**Remarks:**

This method returns the type of the most recently opened chunk. This may be one of the following values:

**NEW\_CHUNK**

**CONTAINER\_CHUNK**

**DATA\_CHUNK**

**Prototype:**

**virtual ULONG CurChunkLength()=0;**

**Remarks:**

This method returns the chunk length NOT including the header.

**Prototype:**

**virtual int CurChunkDepth()=0;**

**Remarks:**

This method is used internally for checking for balanced OpenChunk/CloseChunk pairs.

**Prototype:**

**virtual USHORT PeekNextChunkID()=0;**

**Remarks:**

This method returns the ID of the next chunk without opening it. It returns 0 if there are no more chunks.

**Prototype:**

**virtual IOResult CloseChunk()=0;**

**Remarks:**

This method is used to close the currently opened chunk, and position at the next chunk.

**Return Value:**

A return value of **IO\_ERROR** indicates there is no open chunk to close; otherwise **IO\_OK**.

**Prototype:**

```
virtual IOResult Read(void *buf, ULONG nbytes, ULONG *nread)=0;
```

**Remarks:**

This method is used to read a block of bytes from the output stream.

**Parameters:**

**void \*buf**

A pointer to the buffer to read.

**ULONG nbytes**

The number of bytes to read.

**ULONG \*nread**

The number of bytes that were read.

**Return Value:**

A return value of **IO\_ERROR** indicates an error occurred, otherwise **IO\_OK**.

**Prototype:**

```
virtual IOResult ReadWStringChunk(char** buf)=0;
```

**Remarks:**

This method read a string that was stored as Wide characters. Note: This method reads a string from a string chunk. It is assumed the chunk is already open, it will NOT close the chunk.

**Parameters:**

**char\*\* buf**

A pointer to an array of characters.

**Return Value:**

A return value of **IO\_ERROR** indicates an error occurred, otherwise **IO\_OK**.

**Prototype:**

```
virtual IOResult ReadWStringChunk(wchar_t** buf)=0;
```

**Remarks:**

This method read a string that was stored as Wide chars. Note: This method reads a string from a string chunk. It is assumed the chunk is already open, it will NOT close the chunk.

**Parameters:**

**wchar\_t\*\* buf**

A pointer to an array of wide characters.

**Return Value:**

A return value of **IO\_ERROR** indicates an error occurred, otherwise **IO\_OK**.

**Prototype:**

```
virtual IOResult ReadCStringChunk(char** buf)=0;
```

**Remarks:**

This method reads a string that was stored as single byte characters.

**Parameters:**

**char\*\* buf**

A pointer to an array of single byte characters. This method will allocate an internal buffer, stored in the ILoadImp class that is big enough to hold the string chunk read in. You must then copy or parse out the data and store it in your own area: you can't hang on to the string pointer it hands back because it will not be valid.

**Return Value:**

A return value of **IO\_ERROR** indicates an error occurred, otherwise **IO\_OK**.

**Prototype:**

**virtual IOResult ReadCStringChunk(wchar\_t\*\* buf)=0;**

**Remarks:**

This method may be used to read a string that was stored as single byte characters.

**Parameters:**

**wchar\_t\*\* buf**

A pointer to an array of wide characters. This method will allocate an internal buffer, stored in the ILoadImp class that is big enough to hold the string chunk read in. You must then copy or parse out the data and store it in your own area: you can't hang on to the string pointer it hands back because it will not be valid.

**Return Value:**

A return value of **IO\_ERROR** indicates an error occurred, otherwise **IO\_OK**.

**Prototype:**

**virtual void SetObsolete()=0;**

**Remarks:**

You may call this if you encounter obsolete data to cause a message to be displayed after loading.

**Prototype:**

**virtual void RegisterPostLoadCallback(PostLoadCallback \*cb)=0;**

**Remarks:**

Registers a procedure to be called after loading. These will be called in the order that they are registered. It is assumed that if the callback needs to be deleted, the proc will do it.

**Parameters:**

**PostLoadCallback \*cb**

Points to the callback object.

**Prototype:**

**virtual TCHAR \*GetDir(int which)=0;**

**Remarks:**

Retrieves the specified standard 3ds max directory name (fonts, scenes, images, ...).

**Parameters:**

**int which**

Specifies the directory name to retrieve. See [List of Directory Names](#). The constants are defined in **MAXAPI.H**

**Return Value:**

The name of the specified directory.

**Prototype:**

**virtual void RecordBackpatch(int imaker, void\*\* patchThis, DWORD flags = 0)=0;**

**Remarks:**

This method may be used to load a pointer from disk. This is a pointer that was saved using **ISave::GetRefID()**. You pass the index returned from **GetRefID()** and a pointer to a pointer that will get set. This method will patch the address immediately if it is available, otherwise it will happen later when it is known. During the load process if you need to work with this information you'll have to use a post load callback since all the addresses are not updated immediately. See **RegisterPostLoadCallback()** above.

**Parameters:**

**int imaker**

This is the index returned from **ISave::GetRefID()**.

**void\*\* patchThis**

This is a pointer to the pointer you want patched.

**DWORD flags = 0**

This flag indicates that backpatches (and their subsequent references) should be merged as well.

**Prototype:**

**virtual void\* GetAddr(int imaker)=0;**

**Remarks:**

This method may be used to load a pointer from disk. It returns the memory address of the specified object Scene stream. This may be NULL if the address is not available. See **RecordBackpatch()** above for a work around.

**Parameters:****int imaker**

This is the index returned from **ISave::GetRefID()**. that was used to save the pointer.

**Prototype:****virtual void SetRootAddr(void \*addr)=0;****Remarks:**

This method is used internally.

**Prototype:****virtual void\* GetRootAddr()=0;****Remarks:**

This method is used internally.

**Prototype:****virtual TCHAR \*GetDir(int which)=0;****Remarks:**

Returns the name of various directories used by 3ds max. See [List of Directory Names](#).

**Prototype:****virtual FileIOType DoingWhat()=0;****Remarks:**

Determines if we are loading a standard 3ds max file (**.MAX**) or a material library (**.MAT**).

**Return Value:**

One of the following values:

**IOTYPE\_MAX**  
**IOTYPE\_MATLIB**

**Prototype:**

**virtual INode \*RootNode()=0;**

**Remarks:**

Returns the root node to attach to when loading a node with no parent.

**Prototype:**

**virtual ClassDesc\* GetClassDesc(USHORT refID);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the ClassDesc corresponding to the specified reference ID in the ClassDirectory stream.

**Parameters:**

**USHORT refID**

The reference ID in the ClassDirectory stream.

**Default Implementation:**

**{ return NULL; }**

**Prototype:**

**virtual DWORD GetFileSaveVersion();**

**Remarks:**

This method is available in release 4.0 and later only.

This function is available to plug-ins when loading files. It returns a value describing the version of 3ds max used to save the file. The

value is composed of: **LOWORD(value)** = Build number. For example 41 for build #41. **HIWORD(value)** = **MAX\_RELEASE** (defined as 3ds max release version \* 1000), thus 3ds max version 4.0 is 4000

**Return Value:**

This function returns 0 if the file does not contain this value.

**Default Implementation:**

```
{ return 0; }
```

## Class ISave

See Also: [Loading and Saving](#), [Character Strings](#), [Class ILoad](#), [Class ClassDesc](#), [Class ClassDirectory](#), [Class Interface](#).

```
class ISave : public InterfaceServer
```

### Description:

This class provides methods to save data to disk.

Note: It is not valid, to write two **CStrs** in the same chunk of a 3ds max file, since **ILoad::ReadCStringChunk()** sets the size for the string to the **ChunkSize**. However it is possible to write other data, such as two ints, into the same chunk.

Note about member alignment: Please make sure that when you save data from your plugin you save individual data members using a chunk ID instead of saving the image of a class. Saving (and loading) a class image puts you at risk of running into member alignment problems and as such could potentially corrupt saved files. File IO would be put further at risk when you keep Intel's IA-64 architecture in mind which depends on member alignment. What you should not do is outlined in the following example when loading a class image; **iload->Read(&myclass, sizeof(MyClass), &ab);**

Once you change the class in such a way that it affects the data size you run the risk of having to support different versions, file IO incompatibility, and member alignment issues.

The following global function is not part of this class but is available for use:

### Function:

**DWORD GetSavingVersion();**

### Remarks:

This function is available in release 3.0 and later only.

This function is reserved for future use as of 3ds max 4.

This global function is used to find out if we are saving an old version .3ds max file. If this returns 0, then either we are not in a save or we are saving the current version. If it returns non-zero, it is the max release number being saved, multiplied by 1000. Thus, when saving 3ds max R2 files, it will return 2000. This function can be used in NumRefs() and GetRef() to make an objects references appear as they did in the old 3ds max version.

**Methods:**

All methods of this class are implemented by the system.

**Prototype:**

**virtual void BeginChunk(USHORT id) =0;**

**Remarks:**

This method is used to begin a chunk. The ID passed need only be unique within the plug-ins data itself.

**Parameters:**

**USHORT id**

The id for the chunk.

**Prototype:**

**virtual void EndChunk()=0;**

**Remarks:**

This method is used to end a chunk, and back-patch the length.

**Prototype:**

**virtual int CurChunkDepth()=0;**

**Remarks:**

This method is used internally for checking balanced BeginChunk/EndChunk.

**Prototype:**

**virtual IOResult Write(const void \*buf, ULONG nbytes, ULONG \*nwrite)=0;**

**Remarks:**

This method writes a block of bytes to the output stream.

**Parameters:**

**const void \*buf**

The buffer to write.

**ULONG nbytes**

The number of bytes to write.

## **ULONG \*nwrit**

The number of bytes actually written.

### **Return Value:**

**IO\_OK** - The write was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred. Note that the plug-in should not put up a message box if a write error occurs. It should simply return the error status. This prevents a overabundance of messages from appearing.

### **Prototype:**

```
virtual IOResult WriteWString(const char *str)=0;
```

### **Remarks:**

This method is used to write wide character strings.

### **Parameters:**

**const char \*str**

The string to write.

### **Return Value:**

**IO\_OK** - The write was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

### **Prototype:**

```
virtual IOResult WriteWString(const wchar_t *str)=0;
```

### **Remarks:**

This method is used to write wide character strings.

### **Parameters:**

**const wchar\_t \*str**

The string to write.

### **Return Value:**

**IO\_OK** - The write was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

### **Prototype:**

**virtual IOResult WriteCString(const char \*str)=0;**

**Remarks:**

This method is used to write single byte character strings.

**Parameters:**

**const char \*str**

The string to write.

**Return Value:**

**IO\_OK** - The write was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

**Prototype:**

**virtual IOResult WriteCString(const wchar\_t \*str)=0;**

**Remarks:**

This method is used to write single byte character strings.

**Parameters:**

**const wchar\_t \*str**

The string to write.

**Return Value:**

**IO\_OK** - The write was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

**Prototype:**

**virtual int GetRefID(void \*ptarg)=0;**

**Remarks:**

This method is not normally used because the reference hierarchy is saved automatically. In certain cases however this method is quite useful. This method is used in saving a pointer to some object (or a table of pointers). This is a pointer to one of the objects that the scene saves with the reference hierarchy, but it is not a pointer that itself is a reference. For example the Ring Array plug-in uses this when it saves its table of nodes in the ring array. To save these pointers you can call this method and it will return an ID that you can save to disk. Then when you load this ID from disk you can call

**ILoad::RecordBackpatch()** and get back a pointer.

**Parameters:**

**void \*ptarg**

The pointer to save.

**Return Value:**

The id that may be saved to disk.

**Prototype:**

**virtual FileIOType DoingWhat()=0;**

**Remarks:**

Determines if we are saving a standard 3ds max file (**.MAX**) or a material library (**.MAT**).

**Return Value:**

One of the following values:

**IOTYPE\_MAX**

**IOTYPE\_MATLIB**

**Prototype:**

**virtual DWORD SavingVersion();**

**Remarks:**

This method is available in release 3.0 and later only.

This function is reserved for future use as of 3ds max 4.

This version returns a value to indicate the current version of the file being saved. It returns 0 0 for the current version, 2000 for version 2.0, 3000 for 3.0, etc. This basically duplicates the global function **GetSavingVersion()**. In general, Save routines need not to be concerned that they are saving chunks types that are unknown to the old version, because they will be skipped on load, but there may be cases where the Save routine needs to do things differently.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

```
virtual USHORT GetClassDescID(ReferenceMaker* rm);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method returns a load reference ID for the given Reference Maker's ClassDesc object in the ClassDirectory stream.

**Parameters:**

**ReferenceMaker\* rm**

Points to the reference maker.

**Default Implementation:**

```
{ return 0xffff; }
```

## Class IScene

See Also: [Class ITreeEnumProc](#), [Class INode](#).

class IScene

### Description:

Methods of this class may be used to enumerate the scene and to flag certain nodes in the scene. Nodes chosen by the plug-in may be flagged using the **EnumTree()** method. Selected nodes may be flagged using **FlagFGSelected()**. Animated nodes may be flagged using **FlagFGAnimated()** and dependent nodes may be flagged using **FlagFGDependent()**.

### Methods:

#### Prototype:

```
virtual int EnumTree( ITreeEnumProc *proc )=0;
```

#### Remarks:

Implemented by the System.

This may be called to enumerate every INode in the scene. The callback may flag any of these nodes (using **INode::FlagForeground()**).

#### Parameters:

**ITreeEnumProc \*proc**

This callback object is called once for each INode in the scene.

#### Return Value:

Nonzero if the process was aborted by the callback (**TREE\_ABORT**); otherwise 0.

#### Prototype:

```
virtual void FlagFGSelected( TimeValue t )=0;
```

#### Remarks:

Implemented by the System.

Flags all selected nodes in the scene.

#### Parameters:

**TimeValue t**

The time to flag the nodes.

**Prototype:**

```
virtual void FlagFGAnimated( TimeValue t )=0;
```

**Remarks:**

Implemented by the System.

Flags all animated nodes in the scene.

**Parameters:****TimeValue t**

The time to flag the nodes.

**Prototype:**

```
virtual void FlagFGDependent( TimeValue t, BaseObject *obj )=0;
```

**Remarks:**

Implemented by the System.

Flags nodes that are dependent on the given object.

**Parameters:****TimeValue t**

The time to flag the nodes.

**BaseObject \*obj**

The object whose dependent nodes should be flagged.

## Class IMtlParams

See Also: [Class Mtl](#), [Working with Materials](#), [Class IRollupWindow](#).

class IMtlParams : public InterfaceServer

### Description:

This is the interface that is passed in to the material or texture map when it is in the material editor. All methods of this class are implemented by the system.

### Methods:

#### Prototype:

**virtual void MtlChanged()=0;**

#### Remarks:

This method may be called to causes the viewports to be redrawn. It should be called when any parameter that affects the look of the material in the viewport has been altered. If the material is not on a visible node in a shaded view, nothing will happen. This method should NOT be called as a spinner is being dragged, but only upon release of the mouse button.

#### Prototype:

**virtual HWND AddRollupPage(HINSTANCE hInst, TCHAR \*dlgTemplate, DLGPROC dlgProc, TCHAR \*title, LPARAM param=0,DWORD flags=0, int category = ROLLUP\_CAT\_STANDARD)=0;**

#### Remarks:

This method may be called to add a rollup page to the material editor dialog. It returns the window handle of the dialog that makes up the rollup page.

#### Parameters:

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here. This may be later retrieved using the `GetWindowLong()` call from the Windows API.

**DWORD flags=0**

The following flag is defined:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The window handle of the rollup page.

**Prototype:**

```
virtual HWND AddRollupPage(HINSTANCE hInst,  
DLGTEMPLATE *dlgTemplate, DLGPROC dlgProc, TCHAR  
*title, LPARAM param=0, DWORD flags=0, int category =  
ROLLUP_CAT_STANDARD)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method may be called to add a rollup page to the material editor dialog. It returns the window handle of the dialog that makes up the rollup page. This method is currently not used.

**Parameters:**

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here. This may be later retrieved using the GetWindowLong() call from the Windows API.

**DWORD flags=0**

The following flag is defined:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The window handle of the rollup page.

**Prototype:**

```
virtual HWND ReplaceRollupPage(HWND hOldRollup,  
HINSTANCE hInst, TCHAR *dlgTemplate, DLGPROC dlgProc,  
TCHAR *title, LPARAM param=0,DWORD flags=0, int category  
= ROLLUP_CAT_STANDARD)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to replace the rollup page whose index is passed.

**Parameters:****HWND hOldRollup**

The handle to the rollup to replace.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be

displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USERREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The handle of the replacement page is returned.

**Prototype:**

**virtual HWND ReplaceRollupPage(HWND hOldRollup, HINSTANCE hInst, DLGTEMPLATE \*dlgTemplate, DLGPROC dlgProc, TCHAR \*title, LPARAM param=0, DWORD flags=0, int category = ROLLUP\_CAT\_STANDARD)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to replace the rollup page whose index is passed. This method is currently not being used.

**Parameters:**

**HWND hOldRollup**

The handle to the rollup to replace.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The handle of the replacement page is returned.

**Prototype:**

```
virtual void DeleteRollupPage( HWND hRollup )=0;
```

**Remarks:**

This method may be called to remove a rollup page and destroy it.

**Parameters:****HWND hRollup**

The handle of the rollup window. This is the handle returned from **AddRollupPage()**.

**Prototype:**

```
virtual void RollupMouseMessage(HWND hDlg, UINT message,  
    WPARAM wParam, LPARAM lParam )=0;
```

**Remarks:**

This method allows hand cursor scrolling when the user clicks the mouse in an unused area of the dialog. When the user mouses down in dead area of the material editor, the plug-in should pass mouse messages to this function.

Note: In 3ds max 2.0 and later only use of this method is no longer required -- the functionality happens automatically.

**Parameters:****HWND hDlg**

The window handle of the dialog.

**UINT message**

The message sent to the dialog proc.

**WPARAM wParam**

Passed in to the dialog proc. Pass along to this method.

**LPARAM lParam**

Passed in to the dialog proc. Pass along to this method.

**Example:**

```
case WM_LBUTTONDOWN: case WM_LBUTTONUP: case  
WM_MOUSEMOVE:  
    im->iMtlParams->  
    >RollupMouseMessage(hDlg,message,wParam,lParam);
```

**Prototype:**

```
virtual int IsRollupPanelOpen(HWND hwnd)=0;
```

**Remarks:**

Returns nonzero if the rollup page whose handle is passed is open; otherwise zero.

**Parameters:****HWND hwnd**

The window handle of the rollup page to check.

**Prototype:**

```
virtual int GetRollupScrollPos()=0;
```

**Remarks:**

Returns the rollup scroll position. This is used, for example, by the Standard material because it saves and restores the rollup page positions with the material. This is just a convenience for the user.

**Prototype:**

```
virtual void SetRollupScrollPos(int spos)=0;
```

**Remarks:**

This method may be called to set the rollup scroll position. If the position was previously saved, this method may be called to restore it. The Standard material uses this method because it saves and restores the rollup positions with the material as a convenience for the user.

**Parameters:**

**int spos**

Specifies the rollup scroll position.

**Prototype:**

```
virtual void RegisterTimeChangeCallback(TimeChangeCallback *tc)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Registers a callback object that will get called every time the user changes the 3ds max frame slider.

**Parameters:**

**TimeChangeCallback \*tc**

The callback called when the time changes. See [Class TimeChangeCallback](#).

**Prototype:**

```
virtual void
```

```
UnRegisterTimeChangeCallback(TimeChangeCallback *tc)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method un-registers the time change callback.

**Parameters:**

**TimeChangeCallback \*tc**

The callback called when the time changes. See [Class TimeChangeCallback](#).

**Prototype:**

**virtual void RegisterDlgWnd( HWND hDlg )=0;**

**Remarks:**

This is called automatically in **AddRollupPage()**, so a plug-in doesn't need to do it. It is now obsolete.

**Parameters:**

**HWND hDlg**

The handle of the dialog window.

**Prototype:**

**virtual int UnRegisterDlgWnd( HWND hDlg )=0;**

**Remarks:**

This method is called automatically and is now obsolete.

**Parameters:**

**HWND hDlg**

The handle of the dialog window.

**Prototype:**

**virtual TimeValue GetTime()=0;**

**Remarks:**

Returns the current time (the frame slider position).

**Return Value:**

The current time.

Pick an object from the scene

**Prototype:**

**virtual void SetPickMode(PickObjectProc \*proc)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Calling this methods puts the user into a pick mode where they can select items in the scene.

**Parameters:**

**PickObjectProc \*proc**

This is the callback object for the picking. Its methods allow for filtering the picks, changing cursors over valid hits, and allowing multiple picks. See [Class PickObjectProc](#).

**Prototype:**

**virtual void EndPickMode()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to terminate the pick mode.

**Prototype:**

**virtual IRollupWindow \*GetMtlEditorRollup()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns an interface to Materials Editor rollup.

## Class ITrackBar

See Also: [Class IKeyControl](#), [Class Interface](#).

class ITrackBar

### Description:

This class is available in release 3.0 and later only.

The track bar offers a quick way to manipulate keyframes for selected objects. Keys are displayed on the track bar just like they are in Track View. Developers are able to manipulate the track bar using this class. There is a method of class **Interface** which returns a pointer to an instance of this class:

**ITrackBar\* GetTrackBar().**

All methods of this class are Implemented by the System.

### Methods:

public:

### Prototype:

**virtual void SetVisible(BOOL bVisible) = 0;**

### Remarks:

Sets the visibility of the track bar to on or off.

### Parameters:

**BOOL bVisible**

TRUE to make visible; FALSE to hide.

### Prototype:

**virtual BOOL IsVisible() = 0;**

### Remarks:

Returns TRUE if the track bar is visible; otherwise FALSE.

### Prototype:

**virtual void SetFilter(UINT nFilter) = 0;**

### Remarks:

The track bar shows keys for all parametric animation as well as transforms.

This method sets the filter used which determines which keys are shown in the track bar.

**Parameters:**

**UINT nFilter**

One of the following values:

**TRACKBAR\_FILTER\_ALL**

Specifies to show all keys.

**TRACKBAR\_FILTER\_TMONLY**

Specifies to show transform keys only.

**TRACKBAR\_FILTER\_CURRENTTM**

Specifies to only show keys for the currently active transform (move, rotate or scale).

**TRACKBAR\_FILTER\_OBJECT**

Specifies to show keys for the controllers assigned anywhere in the pipeline to be included in the TrackBar key-display. This is essentially the modifiers and the base objects for the selected nodes (no transforms or materials).

**TRACKBAR\_FILTER\_MATERIAL**

Specifies to show keys for the controllers assigned anywhere for the selected nodes material - all controllers in the whole material tree will be included in the track bar display.

**Prototype:**

**virtual UINT GetFilter() = 0;**

**Remarks:**

Returns the filter value which determines which keys are shown in the track bar. See the list specified in the method above for details.

**Prototype:**

**virtual TimeValue GetNextKey(TimeValue tStart, BOOL bForward) = 0;**

**Remarks:**

This method returns the time of the next key given a start time and a flag

which indicates if the search should proceed forward or backwards. This is similar to the behavior of **Animatable::GetNextKeyTime()**.

**Parameters:**

**TimeValue tStart**

Specifies the time to start looking for the next key.

**BOOL bForward**

TRUE to return the time of the next key; FALSE for the previous key.

**Return Value:**

The time of the next (or previous) key.

**Prototype:**

**virtual void RedrawTrackBar(bool bForce = false) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Redraws the Track Bar if required an optionally forces a redraw (even if not known to be required).

**Parameters:**

**bool bForce = false**

Pass true to force a redraw; false to only redraw if 3ds max deems it required.

**Prototype:**

**virtual void SetShowFrames(bool b) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Controls the visibility of frame numbers in the Track Bar.

**Parameters:**

**bool b**

Pass true to show frame numbers; false to turn them off.

**Prototype:**

**virtual bool GetShowFrames() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns true if frame numbers are visible in the Track Bar; false if not.

**Prototype:**

**virtual void SetShowAudio(bool b) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Controls the visibility of the audio track.

**Parameters:**

**bool b**

Pass true to show the audio track; false to turn it off.

**Prototype:**

**virtual bool GetShowAudio() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns true if the audio track is displayed; false if it is not.

**Prototype:**

**virtual void SetShowSelectionRange(bool b) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Controls if the selection range bar is visible or not.

**Parameters:**

**bool b**

Pass true to display the selection range bar; false to turn it off.

**Prototype:**

**virtual bool GetShowSelectionRange() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns true if the selection range bar is visible; false if it is not.

**Prototype:**

**virtual void SetSnapToFrames(bool b) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Controls the snap to frames setting.

**Parameters:**

**bool b**

Pass true to turn it on; false to turn it off.

**Prototype:**

**virtual bool GetSnapToFrames() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns true if snap to frames is on; false if it is off.

**Prototype:**

**virtual void SetKeyTransparency(int xp) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the transparency of keyframes displayed in the trackbar.

**Parameters:**

**int xp**

The transparency value between 0 and 255.

**Prototype:**

**virtual int GetKeyTransparency() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the transparency of keyframes displayed in the trackbar.

**Return Value:**

The transparency value between 0 and 255.

**Prototype:**

```
virtual void SetSelKeyTransparency(int xp) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the transparency of selected keyframes displayed in the trackbar.

**Parameters:**

**int xp**

The transparency value between 0 and 255.

**Prototype:**

```
virtual int GetSelKeyTransparency() = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the transparency of selected keyframes displayed in the trackbar.

**Return Value:**

The transparency value between 0 and 255.

**Prototype:**

```
virtual void SetCursorTransparency(int xp) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the transparency of the cursor displayed in the trackbar.

**Parameters:**

**int xp**

The transparency value between 0 and 255.

**Prototype:**

```
virtual int GetCursorTransparency() = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the transparency of the cursor displayed in the trackbar.

**Return Value:**

The transparency value between 0 and 255.

## Class IXRefObject

See Also: [Class Object](#), [Class INode](#).

class IXRefObject: public Object

### Description:

This class is available in release 3.0 and later only.

This class is an interface to the parameters of an XRef object. Object XRefs are derived from this class.

If you have an object pointer you can check its super class ID and class ID to see if it is an XRef object. Then you can cast it to an instance of this class and call these methods. For example:

```
INode *node = ip->GetSelNode(0);  
Object *obj = node->GetObjectRef();  
if (obj->SuperClassID()==SYSTEM_CLASS_ID && obj-  
                >ClassID()==Class_ID(XREFOBJ_C  
                {  
    IXRefObject *ix = (IXRefObject *)obj;  
    ix->BrowseFile(FALSE);  
}
```

However you may have an object that depends on an XRef object (for example a Boolean with an XRef object as one of its operands) or you may have a pointer to the object that the XRef object references. In such cases the only way to know for sure is to look up and down the pipeline for XRef objects.

### Methods:

public:

### Prototype:

```
virtual void Init(TSTR &fname, TSTR &oname, Object *ob,  
    BOOL asProxy=FALSE)=0;
```

### Remarks:

This method initializes a newly created XRef object. The caller provides the name of the file (fname), the name of the object in the file (**oname**), and a pointer to the object being XRefed (**ob**).

**Parameters:**

**TSTR &fname**

The file name is set to this string.

**TSTR &oname**

The object name is set to this string.

**Object \*ob**

Points to the object being XRefed.

**BOOL asProxy=FALSE**

If TRUE then the above information is considered to specify the proxy portion of the XRef.

**Prototype:**

```
virtual void SetFileName(TCHAR *name, BOOL proxy=FALSE,  
BOOL update=TRUE)=0;
```

**Remarks:**

Sets the File name or the Proxy file name depending on the value passed.

**Parameters:**

**TCHAR \*name**

The name to set.

**BOOL proxy=FALSE**

TRUE to set the Proxy file name; FALSE for the XRef file name.

**BOOL update=TRUE**

TRUE to update the scene; FALSE to not update immediately.

**Prototype:**

```
virtual void SetObjName(TCHAR *name, BOOL  
proxy=FALSE)=0;
```

**Remarks:**

Sets the Object name or the Proxy name depending on the value passed.

**Parameters:**

**TCHAR \*name**

The name to set.

**BOOL proxy=FALSE**

TRUE to set the Proxy name; FALSE to set the Object name.

**Prototype:**

**virtual void SetUseProxy(BOOL onOff,BOOL redraw=TRUE)=0;**

**Remarks:**

Sets the state of the Use Proxy choice and optionally redraws the viewports.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**BOOL redraw=TRUE**

TRUE to redraw the viewports; otherwise FALSE.

**Prototype:**

**virtual void SetRenderProxy(BOOL onOff)=0;**

**Remarks:**

Sets the state of the Render Proxy option.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetUpdateMats(BOOL onOff)=0;**

**Remarks:**

Sets the state of the Update Materials option.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetIgnoreAnim(BOOL onOff,BOOL redraw=TRUE)=0;**

**Remarks:**

Sets the state of the Ignore Animation choice and optionally redraws the viewports.

**Parameters:****BOOL onOff**

TRUE for on; FALSE for off.

**BOOL redraw=TRUE**

TRUE to redraw the viewports; otherwise FALSE.

**Prototype:**

**virtual TSTR GetFileName(BOOL proxy=FALSE)=0;**

**Remarks:**

Returns the File name or the Proxy file name depending on the value passed.

**Parameters:****BOOL proxy=FALSE**

TRUE to return the Proxy file name; FALSE for the XRef file name.

**Prototype:**

**virtual TSTR GetObjName(BOOL proxy=FALSE)=0;**

**Remarks:**

Returns the Object name or the Proxy name depending on the value passed.

**Parameters:****BOOL proxy=FALSE**

TRUE to return the Proxy name; FALSE to return the Object name.

**Prototype:**

**virtual TSTR &GetCurFileName()=0;**

**Remarks:**

Returns the XRef File Name.

**Prototype:**

**virtual TSTR &GetCurObjName()=0;**

**Remarks:**

Returns the XRef Object Name.

**Prototype:**

**virtual BOOL GetUseProxy()=0;**

**Remarks:**

Returns TRUE if the Use Proxy option is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetRenderProxy()=0;**

**Remarks:**

Returns TRUE if the Render Proxy option is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetUpdateMats()=0;**

**Remarks:**

Returns TRUE if the Update Material option is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetIgnoreAnim()=0;**

**Remarks:**

Returns TRUE if the Ignore Animation option is on; otherwise FALSE.

**Prototype:**

**virtual void BrowseObject(BOOL proxy)=0;**

**Remarks:**

This method brings up the browse object (Merge) dialog.

**Parameters:**

**BOOL proxy**

TRUE to have Use Proxy mode active; FALSE to have it inactive.

**Prototype:**

**virtual void BrowseFile(BOOL proxy)=0;**

**Remarks:**

This method brings up the browse file (Open File) dialog.

**Parameters:**

**BOOL proxy**

TRUE to have Use Proxy mode active; FALSE to have it inactive.

**Prototype:**

**virtual void ReloadXRef()=0;**

**Remarks:**

Reloads this Object XRef.

## Class ILayer

See Also: [Class ReferenceTarget](#), [Class ILayerManager](#), [Class LayerProperty](#), [Class INode](#).

```
class ILayer : public ReferenceTarget
```

### Description:

This class is available in release 3.0 and later only.

This class is an interface to the Layers functionality provided by 3D Studio VIZ. Basically, Layers govern (override) some properties of the nodes which are on the layer. For example, a Layer could be used to freeze all the nodes on it without having to set this property of each node individually.

Some of the methods below are not functional in 3ds max. Such cases are noted in the remarks for the method.

### Data Members:

public:

```
static const SClass_ID kLayerSuperClassID;
```

The super class ID of the layer interface class.

### Methods:

public:

### Prototype:

```
virtual bool AddToLayer(INode *rtarg)=0;
```

### Remarks:

Adds the specified node to this layer.

### Parameters:

```
INode *rtarg
```

The node to add.

### Prototype:

```
virtual bool DeleteFromLayer(INode *rtarg)=0;
```

### Remarks:

Deletes the specified node from this layer. Note: This method does nothing in 3ds max.

**Parameters:**

**INode \*rtarg**

The node to delete from this layer.

**Prototype:**

**virtual void SetName(const TSTR &name)=0;**

**Remarks:**

Sets the name of this layer.

**Parameters:**

**const TSTR &name**

The name for this layer.

**Prototype:**

**virtual TSTR GetName() const=0;**

**Remarks:**

Returns the name of this layer. Note: The user of this method must delete the returned string.

**Prototype:**

**virtual void SetWireColor(DWORD newcol)=0;**

**Remarks:**

Sets the wire frame color.

**Parameters:**

**DWORD newcol**

See [COLORREF](#).

**Prototype:**

**virtual DWORD GetWireColor() const=0;**

**Remarks:**

Returns the wire frame color. See [COLORREF](#).

**Prototype:**

**virtual void Hide(bool onOff)=0;**

**Remarks:**

Sets the hidden state.

**Parameters:**

**bool onOff**

Use true for hidden; false for not hidden.

**Prototype:**

**virtual bool IsHidden() const=0;**

**Remarks:**

Returns true if hidden; false if not hidden.

**Prototype:**

**virtual void Freeze(bool onOff)=0;**

**Remarks:**

Sets the frozen state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool IsFrozen() const=0;**

**Remarks:**

Returns true if frozen; false if not.

**Prototype:**

**virtual void SetRenderable(bool onOff)=0;**

**Remarks:**

Sets the renderable state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool Renderable() const=0;**

**Remarks:**

Returns true if renderable; false if not.

**Prototype:**

**virtual void SetPrimaryVisibility(bool onOff) = 0;**

**Remarks:**

This method allows you to set or unset the primary visibility flag for the layer.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Prototype:**

**virtual bool GetPrimaryVisibility() const = 0;**

**Remarks:**

This method returns TRUE if the primary visibility flag for the layer is set.

**Prototype:**

**virtual void SetSecondaryVisibility(bool onOff) = 0;**

**Remarks:**

This method allows you to set the secondary visibility flag for the layer.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Prototype:**

**virtual bool GetSecondaryVisibility() const = 0;**

**Remarks:**

This method returns TRUE if the secondary visibility flag for the layer is set.

**Prototype:**

**virtual void XRayMtl(bool onOff)=0;**

**Remarks:**

Sets the X-Ray material property.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool HasXRayMtl() const=0;**

**Remarks:**

Returns true if X-Ray material is set; false if not.

**Prototype:**

**virtual void IgnoreExtents(bool onOff)=0;**

**Remarks:**

Sets the ignore extents property.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetIgnoreExtents() const=0;**

**Remarks:**

Returns true if ignore extents is on; false if off.

**Prototype:**

**virtual void BoxMode(bool onOff)=0;**

**Remarks:**

Sets the box mode state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetBoxMode() const=0;**

**Remarks:**

Returns true if box mode is on; false if off.

**Prototype:**

**virtual void AllEdges(bool onOff)=0;**

**Remarks:**

Sets the all edges setting.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetAllEdges() const=0;**

**Remarks:**

Returns true if all edges is on; false if off.

**Prototype:**

**virtual void VertTicks(bool onOff)=0;**

**Remarks:**

Sets the vertex ticks state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetVertTicks() const=0;**

**Remarks:**

Returns true if vertex ticks is on; false if off.

**Prototype:**

**virtual void BackCull(bool onOff)=0;**

**Remarks:**

Sets the backface culling state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetBackCull() const=0;**

**Remarks:**

Returns true if backface culling is on; false if not.

**Prototype:**

**virtual void SetCVertMode(bool onOff)=0;**

**Remarks:**

Sets the color per vertex display mode.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetCVertMode() const=0;**

**Remarks:**

Returns true if the color vertex display mode is on; otherwise false.

**Prototype:**

**virtual void SetShadeCVerts(bool onOff)=0;**

**Remarks:**

Sets the shaded color vertex display mode.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool GetShadeCVerts() const=0;**

**Remarks:**

Returns true if the shaded color vertex mode is on; false if off.

**Prototype:**

**virtual void SetCastShadows(bool onOff)=0;**

**Remarks:**

Sets the cast shadow state.

**Parameters:**

**bool onOff**

Use true for on; false for off.

**Prototype:**

**virtual bool CastShadows() const=0;**

**Remarks:**

Returns true if cast shadow is on; false if off.

**Prototype:**

**virtual void SetRcvShadows(bool onOff)=0;**

**Remarks:**

Sets the receives shadow state.

**Parameters:**

## **bool onOff**

Use true for on; false for off.

### **Prototype:**

**virtual bool RcvShadows() const=0;**

### **Remarks:**

Returns true if receives shadow is on; false if off.

### **Prototype:**

**virtual void SetMotBlur(int kind)=0;**

### **Remarks:**

Sets the type of motion blur used by the layer.

### **Parameters:**

#### **int kind**

The kind of motion blur. One of the following values:

**0:** None.

**1:** Object Motion Blur.

**2:** Image Motion Blur.

### **Prototype:**

**virtual int MotBlur() const=0;**

### **Remarks:**

Returns the type of motion blur used by the layer. One of the following values:

**0:** None.

**1:** Object Motion Blur.

**2:** Image Motion Blur.

### **Prototype:**

**virtual int GetRenderFlags() const=0;**

### **Remarks:**

This method is for internal use.

**Prototype:**

**virtual void SetRenderFlags(int flags)=0;**

**Remarks:**

This method is for internal use.

**Prototype:**

**virtual int GetDisplayFlags() const=0;**

**Remarks:**

This method is for internal use.

**Prototype:**

**virtual int AddProperty(LayerProperty &lprop)=0;**

**Remarks:**

This method is currently unused and reserved for future use.

**Prototype:**

**virtual int SetProperty(LayerProperty &lprop)=0;**

**Remarks:**

This method is currently unused and reserved for future use.

**Prototype:**

**virtual int GetProperty(LayerProperty &lprop) const=0;**

**Remarks:**

This method is currently unused and reserved for future use.

**Prototype:**

**virtual bool Used() const=0;**

**Remarks:**

Returns true if the layer is used (nodes have been added); otherwise false.

**Prototype:**

**virtual bool GetFlag(int mask) const=0;**

**Remarks:**

This method is for internal use.

**Prototype:**

**virtual bool GetFlag2(int mask) const=0;**

**Remarks:**

This method is for internal use.

**Prototype:**

**virtual void UpdateSelectionSet()=0;**

**Remarks:**

This method is for internal use in VIZ. Note: This method does nothing in 3ds max.

**Prototype:**

**virtual int GetRenderFlags(int oldlimits) const = 0;**

**Remarks:**

This method returns the render flags associated with the layer.

**Parameters:**

**int oldlimits**

The old limits flag.

**Prototype:**

**virtual void SetInheritVisibility(bool onOff) = 0;**

**Remarks:**

This method allows you to set the inherit visibility flag for the layer.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Prototype:**

**virtual bool GetInheritVisibility() const = 0;**

**Remarks:**

This method returns TRUE if the inherit visibility flag for the layer is set.

**Prototype:**

**virtual void Trajectory(bool onOff, bool temp = false) = 0;**

**Remarks:**

This method allows you to set the display trajectory flag for the layer.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**bool temp = false**

This is used internally.

**Prototype:**

**virtual bool GetTrajectory() const = 0;**

**Remarks:**

This method returns TRUE if the display trajectory flag for the layer is set.

**Prototype:**

**virtual void SetDisplayByLayer(BOOL onOff, INode \*) = 0;**

**Remarks:**

This method allows you to set the display by layer flag on a per-node basis.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Node \***

The pointer to the node.

**Prototype:**

**virtual void SetRenderByLayer(BOOL onOff, INode \*) = 0;**

**Remarks:**

This method allows you to set the render by layer flag on a per-node basis.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Node \***

The pointer to the node.

**Prototype:**

**virtual void SetMotionByLayer(BOOL onOff, INode \*) = 0;**

**Remarks:**

This method allows you to set the motion by layer flag on a per-node basis.

**Parameters:**

**bool onOff**

TRUE to set; FALSE to unset.

**Node \***

The pointer to the node.

**Prototype:**

**virtual BOOL GetDisplayByLayer(INode \*) = 0;**

**Remarks:**

This method returns the state of the display by layer flag for the specified node.

**Parameters:**

**Node \***

The pointer to the node.

**Return Value:**

TRUE if set; FALSE if not set.

**Prototype:**

**virtual BOOL GetRenderByLayer(INode \*) = 0;**

**Remarks:**

This method returns the state of the render by layer flag for the specified node.

**Parameters:****Node \***

The pointer to the node.

**Return Value:**

TRUE if set; FALSE if not set.

**Prototype:**

```
virtual BOOL GetMotionByLayer(INode *) = 0;
```

**Remarks:**

This method returns the state of the motion by layer flag for the specified node.

**Parameters:****Node \***

The pointer to the node.

**Return Value:**

TRUE if set; FALSE if not set.

**Prototype:**

```
virtual void SelectObjects(void) = 0;
```

**Remarks:**

This method will select the objects of the layer.

**Prototype:**

```
virtual float GetImageBlurMultiplier(TimeValue t) = 0;
```

**Remarks:**

This method allows you to set the image blur multiplier for the layer.

**Parameters:****TimeValue t**

The timevalue to get the image blur multiplier for.

**Prototype:**

**virtual void SetImageBlurMultiplier(TimeValue t, float m) = 0;**

**Remarks:**

This method allows you to set the image blur multiplier.

**Parameters:**

**TimeValue t**

The timevalue to set the image blur multiplier for.

**float m**

The multiplier to set.

**Prototype:**

**virtual bool GetMotBlurOnOff(TimeValue t) = 0;**

**Remarks:**

This method returns the state of the motion blur flag at the specified time.

**Parameters:**

**TimeValue t**

The time at which to get the flag.

**Prototype:**

**virtual void SetMotBlurOnOff(TimeValue t, bool m) = 0;**

**Remarks:**

This method allows you to set the state of the motion blur flag at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the flag.

**bool m**

TRUE to turn on; FALSE to turn off.

## Class IDerivedObject

See Also: [Class Object](#), [Class ModContext](#), [Class Modifier](#), [Class INode](#), [Geometry Pipeline System](#).

```
class IDerivedObject : public Object
```

### Description:

This class provides an interface into derived objects. Methods of this class are provided so developers can access the modifier stack, add and delete modifiers, etc. All methods of this class are implemented by the system.

To use this interface you must #include the following file:

```
#include "modstack.h"
```

To get an **IDerivedObject** pointer from the pipeline of a node in the scene first retrieve the object reference using **INode::GetObjectRef()**. Given this **Object** pointer check its SuperClassID to see if it is **GEN\_DERIVOB\_CLASS\_ID**. If it is, you can cast it to an **IDerivedObject**.

Note: The following functions are not part of class **IDerivedObject** but are available for use in conjunction with its methods.

### Prototype:

```
IDerivedObject *CreateDerivedObject(Object *pob=NULL);
```

### Remarks:

This method creates an object space derived object.

### Parameters:

```
Object *pob=NULL
```

If non-NULL then the derived object will be set up to reference this object.

### Return Value:

A pointer to the derived object.

### Prototype:

```
Object *MakeObjectDerivedObject(Object *obj);
```

### Remarks:

Creates a new empty derived object, sets it to point at the given object and returns a pointer to the derived object.

**Parameters:**

**Object \*obj**

The object reference of the derived object will point at this object.

**Return Value:**

A pointer to the derived object.

**Prototype:**

**IDerivedObject \*CreateWSDerivedObject(Object \*pob=NULL);**

**Remarks:**

This method creates a world space derived object.

**Parameters:**

**Object \*pob=NULL**

If non-NULL then the WS derived object will be set up to reference this object.

**Return Value:**

A pointer to the derived object.

**Methods:**

**Prototype:**

**virtual void AddModifier(Modifier \*mod, ModContext \*mc=NULL, int before=0)=0;**

**Remarks:**

Adds a modifier to this derived object.

**Parameters:**

**Modifier \*mod**

The modifier to add.

**ModContext \*mc=NULL**

The mod context for the modifier.

**int before=0**

If this value is set to 0 then the modifier will be placed at the end of the

pipeline (top of stack). If this value is set to **NumModifiers()** then the modifier will be placed at the start of the pipeline (bottom of stack).

**Prototype:**

**virtual Object \*GetObjRef()=0;**

**Remarks:**

Gets the object that this derived object references. This is the next object down in the stack and may be the base object.

**Return Value:**

The object that this derived object references.

**Prototype:**

**virtual RefResult ReferenceObject(Object \*pob)=0;**

**Remarks:**

Sets the object that this derived object references. This is the next object down in the stack and may be the base object.

**Parameters:**

**Object \*pob**

The object that this derived object should reference.

**Return Value:**

One of the following values:

**REF\_SUCCEED**

**REF\_FAIL**

**Prototype:**

**virtual int NumModifiers()=0;**

**Remarks:**

Returns the number of modifiers this derived object has.

**Prototype:**

**virtual void DeleteModifier(int index=0)=0;**

**Remarks:**

Deletes the specified modifier from the stack.

**Parameters:**

**int index=0**

The index of the modifier to delete.

**Prototype:**

**virtual Modifier \*GetModifier(int index)=0;**

**Remarks:**

Returns the modifier specified by the index.

**Parameters:**

**int index**

The index of the modifier to return.

**Prototype:**

**virtual void SetModifier(int index, Modifier \*mod)=0;**

**Remarks:**

This method replaces the modifier in the stack whose index is passed.

**Parameters:**

**int index**

The index of the modifier in the stack.

**Modifier \*mod**

The modifier that will replace it.

**Prototype:**

**virtual ModContext\* GetModContext(int index)=0;**

**Remarks:**

Returns the ModContext of the specified modifier.

**Parameters:**

**int index**

The index of the modifier in the stack.

**Prototype:**

```
virtual ObjectState Eval(TimeValue t, int modIndex = 0)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to evaluate the pipeline starting with a specific modifier index. Prior to version 4.0 you had to turn all the modApps off, evaluate and then turn them on again. Now this can be easily done by specifying the modifier index.

**Parameters:****TimeValue t**

Specifies the time to evaluate the object.

**int modIndex = 0**

The index of the modifier.

**Return Value:**

The result of evaluating the object as an ObjectState.

## Class ITextObject

See Also: [Class Animatable](#).

class ITextObject

### Description:

This is the text shape object interface. This class gives access to the standard 3ds max text object. It allows the text objects font, string, and style bits to be retrieved and set. All methods of this class are implemented by the system.

To get a pointer to an **ITextObject** interface given a pointer to a object, use the following macro (defined in **ANIMTBL.H** ). Using this macro, given any Animatable, it is easy to ask for the text object interface.

```
#define GetTextObjectInterface(anim)  
((ITextObject*)anim->GetInterface(I_TEXTOBJECT))
```

A plug-in developer may use this macro as follows:

```
ITextObject *ito = GetTextObjectInterface(anim);
```

This return value will either be NULL or a pointer to a valid text object interface. You may then use this pointer to call methods of this class to retrieve and modify the object data. For example:

```
ito->SetUnderline(TRUE);
```

Note: Some aspects of the text are controlled by its parameter block. Developers can access the parameter block by calling **ito->GetParamBlock()**. The following are the indices into the parameter block used to access the size, kerning and leading parameters:

```
TEXT_SIZE  
TEXT_KERNING  
TEXT_LEADING
```

### Methods:

### Prototype:

```
virtual BOOL ChangeText(TSTR string)=0;
```

### Remarks:

This method may be called to change the text string. Note that you can't change the string if the current font is not installed.

**Parameters:**

**TSTR string**

The new text string.

**Return Value:**

TRUE if the string is changed; otherwise FALSE.

**Prototype:**

**virtual BOOL ChangeFont(TSTR name, DWORD flags)=0;**

**Remarks:**

This method may be called to change the text font.

**Parameters:**

**TSTR name**

The name of the font.

**DWORD flags**

One or more of the following values:

**TEXTOBJ\_ITALIC**

**TEXTOBJ\_UNDERLINE**

**Return Value:**

TRUE if the font was successfully changed; otherwise FALSE.

**Prototype:**

**virtual TSTR GetFont()=0;**

**Remarks:**

Returns the name of the text font.

**Prototype:**

**virtual TSTR GetString()=0;**

**Remarks:**

Returns the text string.

**Prototype:**

**virtual BOOL GetItalic()=0;**

**Remarks:**

Returns TRUE if the text is italicized; otherwise FALSE.

**Prototype:**

**virtual BOOL GetUnderline()=0;**

**Remarks:**

Returns TRUE if the text is underlined; otherwise FALSE.

**Prototype:**

**virtual void SetItalic(BOOL sw)=0;**

**Remarks:**

Sets if the text is italicized or not.

**Parameters:**

**BOOL sw**

TRUE if the text should be italicized; FALSE if not.

**Prototype:**

**virtual void SetUnderline(BOOL sw)=0;**

**Remarks:**

Sets if the text is underlined or not.

**Parameters:**

**BOOL sw**

TRUE if the text should be underlined; FALSE if not.

## Class StdMat

See Also: [Class Mtl](#), [Class Color](#), [Working with Materials](#).

```
class StdMat : public Mtl
```

### Description:

This class provides access to the properties of the 3ds max Standard material. All methods of this class are implemented by the system.

Note that some properties such as the texture maps used are accessed using methods of the base class [MtlBase](#). See that class, or the Advanced Topics section [Working with Materials](#) for more details.

### Methods Groups:

The following hyperlinks take you to the beginning of groups of related method within the class.

[Setting material properties](#)

[Retrieving material properties](#)

### Methods:

#### Prototype:

```
virtual void SetShading(int s)=0;
```

#### Remarks:

Sets the shading limit for the material.

#### Parameters:

**int s**

One of the following values:

**SHADE\_CONST**

**SHADE\_PHONG**

**SHADE\_METAL**

**SHADE\_BLINN**

#### Prototype:

```
virtual void SetSoften(BOOL onoff)=0;
```

#### Remarks:

Sets the 'Soften' setting on or off.

**Parameters:**

**BOOL onoff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual void SetFaceMap(BOOL onoff)=0;**

**Remarks:**

Sets the 'Face Map' setting on or off.

**Parameters:**

**BOOL onoff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual void SetTwoSided(BOOL onoff)=0;**

**Remarks:**

Sets the '2 Sided' setting on or off.

**Parameters:**

**BOOL onoff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual void SetWire(BOOL onoff)=0;**

**Remarks:**

Sets the 'Wire' setting on or off.

**Parameters:**

**BOOL onoff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual void SetWireUnits(BOOL onOff)=0;**

**Remarks:**

Sets the wire size to pixels or units.

**Parameters:**

**BOOL onoff**

TRUE for units; FALSE for pixels.

**Prototype:**

**virtual void SetFalloffOut(BOOL onOff)=0;**

**Remarks:**

Sets the opacity falloff setting to out or in.

**Parameters:**

**BOOL onoff**

TRUE for Out; FALSE for In.

**Prototype:**

**virtual void SetTransparencyType(int type)=0;**

**Remarks:**

Sets the additive transparency setting.

**Parameters:**

**int type**

One of the following values:

**TRANSP\_SUBTRACTIVE**

**TRANSP\_ADDITIVE**

**TRANSP\_FILTER**

**Prototype:**

**virtual void SetAmbient(Color c, TimeValue t)=0;**

**Remarks:**

Sets the ambient color to the specified value at the time passed.

**Parameters:**

**Color c**

The color to set.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetDiffuse(Color c, TimeValue t)=0;**

**Remarks:**

Sets the diffuse color to the specified value at the time passed.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetSpecular(Color c, TimeValue t)=0;**

**Remarks:**

Sets the specular color to the specified value at the time passed.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetFilter(Color c, TimeValue t)=0;**

**Remarks:**

Sets the filter color to the specified value at the time passed.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetShininess(float v, TimeValue t)=0;**

**Remarks:**

Sets the shininess to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 1.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetShinStr(float v, TimeValue t)=0;**

**Remarks:**

Sets the shininess strength to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 1.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetSelfIllum(float v, TimeValue t)=0;**

**Remarks:**

Sets the self illumination to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 1.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetOpacity(float v, TimeValue t)=0;**

**Remarks:**

Sets the opacity to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 1.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetOpacFalloff(float v, TimeValue t)=0;**

**Remarks:**

Sets the opacity falloff to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 1.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetWireSize(float s, TimeValue t)=0;**

**Remarks:**

Sets the wire size to the specified value at the time passed.

**Parameters:**

**float s**

The value to set. This value should be > 0.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void SetIOR(float v, TimeValue t)=0;**

**Remarks:**

Sets the index of refraction to the specified value at the time passed.

**Parameters:**

**float v**

The value to set in the range 0 - 10.

**TimeValue t**

The time at which to set the value.

**Prototype:**

**virtual void LockAmbDiffTex(BOOL onOff)=0;**

**Remarks:**

Locks or unlocks the ambient/diffuse textures together.

**Parameters:**

**BOOL onOff**

TRUE to lock; FALSE to unlock.

**Prototype:**

**virtual void EnableMap(int i, BOOL onoff)=0;**

**Remarks:**

Enables or disables the specified map type.

**Parameters:**

**int i**

See [List of Texture Map Indices](#).

**BOOL onoff**

TRUE to enable; FALSE to disable.

**Prototype:**

**virtual BOOL MapEnabled(int i)=0;**

**Remarks:**

Returns TRUE if the specified map is enabled; otherwise FALSE.

**Parameters:**

**int i**

See [List of Texture Map Indices](#).

**Prototype:**

**virtual void SetTexmapAmt(int imap, float amt, TimeValue t)=0;**

**Remarks:**

This method is used to change the 'Amount' setting of the specified map.

**Parameters:**

**int imap**

See [List of Texture Map Indices](#).

**float amt**

The amount to set in the range of 0-1.

**TimeValue t**

The time at which to set the amount.

**Prototype:**

**virtual float GetTexmapAmt(int imap, TimeValue t)=0;**

**Remarks:**

Returns the amount setting of the specified texture map at the time passed.  
The returned range is 0 to 1.

**Parameters:**

**int imap**

See [List of Texture Map Indices](#).

**TimeValue t**

The amount at this time is returned.

**Prototype:**

**virtual void SetSamplingOn(BOOL on)=0;**

**Remarks:**

This method is available in release 3.0 and later only.  
Set super sampling on or off (enabled or disabled).

**Parameters:**

**BOOL on**

TRUE for on; FALSE for off.

**Prototype:**

**virtual int GetShading()=0;**

**Remarks:**

Returns the shading limit. One of the following values:

**SHADE\_CONST**

**SHADE\_PHONG**

**SHADE\_METAL**

**SHADE\_BLINN**

**Prototype:**

**virtual BOOL GetSoften()=0;**

**Remarks:**

Returns TRUE if soften is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetFaceMap()=0;**

**Remarks:**

Returns TRUE if face mapping is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetTwoSided()=0;**

**Remarks:**

Returns TRUE if two sided is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetWire()=0;**

**Remarks:**

Returns TRUE if wire is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetWireUnits()=0;**

**Remarks:**

Returns TRUE if the wire size is in units; FALSE if the wire size is in pixels.

**Prototype:**

**virtual BOOL GetFalloffOut()=0;**

**Remarks:**

Returns the opacity falloff setting: 1 = Out, 0 = In.

**Prototype:**

**virtual int GetTransparencyType()=0;**

**Remarks:**

Returns the transparency type.

**Return Value:**

**int type**

One of the following values:

**TRANSP\_SUBTRACTIVE**

**TRANSP\_ADDITIVE**

**TRANSP\_FILTER**

**Prototype:**

**virtual Color GetAmbient(TimeValue t)=0;**

**Remarks:**

Returns the ambient color setting at the specified time.

**Parameters:**

**TimeValue t**

The time to return the color.

**Prototype:**

**virtual Color GetDiffuse(TimeValue t)=0;**

**Remarks:**

Returns the diffuse color setting at the specified time.

**Parameters:****TimeValue t**

The time to return the color.

**Prototype:**

**virtual Color GetSpecular(TimeValue t)=0;**

**Remarks:**

Returns the specular color setting at the specified time.

**Parameters:****TimeValue t**

The time to return the color.

**Prototype:**

**virtual Color GetFilter(TimeValue t)=0;**

**Remarks:**

Returns the filter color setting at the specified time.

**Parameters:****TimeValue t**

The time to return the color.

**Prototype:**

**virtual float GetShininess( TimeValue t)=0;**

**Remarks:**

Returns the shininess setting at the specified time.

**Parameters:****TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetShinStr(TimeValue t)=0;**

**Remarks:**

Returns the shininess strength setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetSelfIllum(TimeValue t)=0;**

**Remarks:**

Returns the self illumination setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetOpacity(TimeValue t)=0;**

**Remarks:**

Returns the opacity setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetOpacFalloff(TimeValue t)=0;**

**Remarks:**

Returns the opacity falloff setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetWireSize(TimeValue t)=0;**

**Remarks:**

Returns the wire size setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual float GetIOR(TimeValue t)=0;**

**Remarks:**

Returns the index of refraction setting at the specified time.

**Parameters:**

**TimeValue t**

The value at this time is returned.

**Prototype:**

**virtual BOOL GetAmbDiffTexLock()=0;**

**Remarks:**

Returns TRUE if the ambient-diffuse texture lock is set; otherwise FALSE.

## Class BitmapTex

See Also: [Class Texmap](#), [Class StdUVGen](#), [Class TextureOutput](#).

class BitmapTex: public Texmap, public FPMixinInterface

### Description:

This class is an interface into the Bitmap texture. All methods of this class are implemented by the system.

### Methods:

#### Prototype:

**virtual void SetFilterType(int ft)=0;**

#### Remarks:

Sets the bitmap filtering method used.

#### Parameters:

**int ft**

Image filtering types. One of the following values:

**FILTER\_PYR**

Pyramidal.

**FILTER\_SAT**

Summed Area.

**FILTER\_NADA**

None.

#### Prototype:

**virtual void SetAlphaSource(int as)=0;**

#### Remarks:

This method may be used to set the alpha source for the bitmap.

#### Parameters:

**int as**

Alpha source types. One of the following values:

**ALPHA\_FILE**

Image alpha (if present).

## **ALPHA\_RGB**

RGB Intensity.

## **ALPHA\_NONE**

None (opaque).

### **Prototype:**

```
virtual void SetAlphaAsMono(BOOL onoff)=0;
```

### **Remarks:**

The Mono Channel Intensity may be either RGB Intensity or Alpha.

### **Parameters:**

**BOOL onoff**

TRUE for Alpha; FALSE for RGB Intensity.

### **Prototype:**

```
virtual void SetAlphaAsRGB(BOOL onoff)=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

The Alpha Source may be either from the RGB channels or Image Alpha channel.

### **Parameters:**

**BOOL onoff**

TRUE for RGB; FALSE for Alpha channel.

### **Prototype:**

```
virtual void SetMapName(TCHAR *name)=0;
```

### **Remarks:**

Sets the filename of the bitmap used.

### **Parameters:**

**TCHAR \*name**

The filename of the bitmap.

### **Prototype:**

**virtual StdUVGen\* GetUVGen()=0;**

**Remarks:**

Retrieves a pointer to the **StdUVGen** interface for this bitmap. This allows access to the mapping parameters such as UV offsets, blur, angle, noise level, etc.

**The following methods allow access to the values from the 'Time' rollup.**

**Prototype:**

**virtual void SetEndCondition(int endcond)=0;**

**Remarks:**

Sets the end condition setting.

**Parameters:**

**int endcond**

The end condition. One of the following values:

**END\_LOOP**

**END\_PINGPONG**

**END\_HOLD**

**Prototype:**

**virtual void SetStartTime(TimeValue t)=0;**

**Remarks:**

Sets the start time setting.

**Parameters:**

**TimeValue t**

The new start time.

**Prototype:**

**virtual void SetPlaybackRate(float r)=0;**

**Remarks:**

Sets the playback rate setting.

**Parameters:**

**float r**

The new playback rate. This is frames of the bitmap per frame of rendering time. If the value is 1 then you are playing 1 frame for every render frame. If it is 0.5 then the bitmap frame is held for 2 rendering frames.

**Prototype:**

**virtual int GetFilterType()=0;**

**Remarks:**

Returns the filter type.

**Return Value:**

One of the following values:

**FILTER\_PYR**

Pyramidal.

**FILTER\_SAT**

Summed Area Table.

**FILTER\_NADA**

None.

**Prototype:**

**virtual int GetAlphaSource()=0;**

**Remarks:**

Returns the alpha source.

**Return Value:**

One of the following values:

**ALPHA\_FILE**

**ALPHA\_RGB**

**ALPHA\_NONE**

**Prototype:**

**virtual int GetEndCondition()=0;**

**Remarks:**

Returns the end condition setting.

**Return Value:**

One of the following values:

**END\_LOOP**

**END\_PINGPONG**

**END\_HOLD**

**Prototype:**

**virtual BOOL GetAlphaAsMono(BOOL onoff)=0;**

**Remarks:**

The Mono Channel Intensity may be either RGB Intensity or Alpha.

**Parameters:**

**BOOL onoff**

This parameter is ignored.

**Return Value:**

TRUE if Alpha; FALSE if RGB Intensity.

**Prototype:**

**virtual BOOL GetAlphaAsRGB(BOOL onoff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

The Alpha Channel may be either RGB or Image Alpha.

**Parameters:**

**BOOL onoff**

This parameter is ignored.

**Return Value:**

TRUE for RGB; FALSE for Image Alpha.

**Prototype:**

**virtual TCHAR \*GetMapName()=0;**

**Remarks:**

Returns the name of the bitmap file.

**Prototype:**

**virtual TimeValue GetStartTime()=0;**

**Remarks:**

Returns the start frame setting as a TimeValue.

**Prototype:**

**virtual float GetPlaybackRate()=0;**

**Remarks:**

Returns the playback rate setting.

**Prototype:**

**virtual StdUVGen\* GetUVGen()=0;**

**Remarks:**

Retrieves a pointer to the **StdUVGen** interface for this bitmap. This allows access to the mapping parameters such as UV offsets, blur, angle, noise level, etc.

**Prototype:**

**virtual TextureOutput\* GetTexout()=0;**

**Remarks:**

Returns a pointer to a class to access TextureOutput properties of this texture.

**Prototype:**

**virtual Bitmap \*GetBitmap(TimeValue t);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the Bitmap associated with this Bitmap Texture.

**Parameters:**

**TimeValue t**

The time at which to return the bitmap.

**Prototype:**

**virtual void SetBitmap(Bitmap \*bm);**

**Remarks:**

This method is available in release 4.0 and later only.

This will swap the bitmap pointer without updating BitmapInfo.

**Parameters:**

**Bitmap \*bm**

A pointer to the bitmap.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual BitmapLoadDlg();**

**Remarks:**

This method is available in release 3.0 and later only.

This method brings up a bitmap loader dialog.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual ReloadBitmapAndUpdate();**

**Remarks:**

This method is available in release 3.0 and later only.

This method forces the bitmap to reload and the view to be redrawn.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**void fnReload()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method reloads the bitmap texture and operates as if the user pressed the

reload button.

**Prototype:**

**void fnViewImage()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will view the bitmap texture image and operates as if the user pressed the view image button.

# Class IWaveSound

SeeAlso: [Class Interface](#).

class IWaveSound

## Description:

This class provides an interface into 3ds max's default WAV sound object. Use the **Interface** method **GetSoundObject()** to get a pointer to the current sound object and then use the macro **GetWaveSoundInterface()** on the result to see if it supports this interface. See the sample code below:

```
// Retrieve the current sound object
SoundObj *sound = ip->GetSoundObject();
// Attempt to get a wave interface
IWaveSound *iWave = GetWaveSoundInterface(sound);
if (iWave) {
    iWave->SetSoundFileName(_T("LedZep.wav"))
}
```

All methods of this class are implemented by the system.

## Methods:

### Prototype:

```
virtual TSTR GetSoundFileName()=0;
```

### Remarks:

Returns the name of the current sound file.

### Prototype:

```
virtual BOOL SetSoundFileName(TSTR name)=0;
```

### Remarks:

Sets the sound file. This will cause the .WAV to be loaded into the track view.

### Parameters:

**TSTR name**

The name of the sound file to set.

### Return Value:

FALSE if the file can't be opened or no wave track exists; otherwise TRUE.

**Prototype:**

**virtual void SetStartTime(TimeValue t)=0;**

**Remarks:**

Sets the time offset for the wave file.

**Parameters:**

**TimeValue t**

The start time.

**Prototype:**

**virtual TimeValue GetStartTime()=0;**

**Remarks:**

Returns the start time offset for the wave.

**Prototype:**

**virtual TimeValue GetEndTime()=0;**

**Remarks:**

Returns the end time for the wave.

## Class ISplineSelect

See Also: [Class Animatable](#), [Working with Shapes and Splines](#).

class ISplineSelect

### Description:

This class is available in release 3.0 and later only.

This class provides an interface to the Spline Select Modifier. To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_SPLINESELECT**.

For example:

```
ISplineSelect *iss = (ISplineSelect*)anim->GetInterface(I_SPLINESELECT);  
DWORD sl = iss->GetSelLevel();
```

### Methods:

public:

### Prototype:

```
virtual DWORD GetSelLevel()=0;
```

### Remarks:

Returns a value indicating the current selection level of the modifier. One of the following values:

```
SS_VERTEX  
SS_SEGMENT  
SS_SPLINE  
SS_OBJECT
```

### Prototype:

```
virtual void SetSelLevel(DWORD level)=0;
```

### Remarks:

Sets the current level of selection of the modifier.

### Parameters:

```
DWORD level
```

The level to set. One of the following values:

**SS\_VERTEX**

**SS\_SEGMENT**

**SS\_SPLINE**

**SS\_OBJECT**

**Prototype:**

**virtual void LocalDataChanged()=0;**

**Remarks:**

This method must be called when the selection level of the modifier is changed. Developers can use the methods of **ISplineSelect** to get and set the actual selection data. When a developers does set any of these selection sets this method must be called when done.

## Class ISplineSelectData

See Also: [Class ISplineSelect](#), [Class Animatable](#), [Class BitArray](#), [Working with Shapes and Splines](#), [Class GenericNamedSelSetList](#).

class ISplineSelectData

### Description:

This class is available in release 3.0 and later only.

When a developer gets the **LocalModData** from the **ModContext** of the Spline Select Modifier, they may cast it to this class and use these methods. They may be used to get/set the vertex/segment/spline selection state of the modifier as well as the named selection sets.

To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_SPLINESELECTDATA**.

For example:

```
ISplineSelectData *iss = (ISplineSelectData*)anim->GetInterface(I_SPLINESELECTDATA);  
BitArray vs = iss->GetVertSel();
```

### Methods:

public:

### Prototype:

```
virtual BitArray GetVertSel()=0;
```

### Remarks:

Returns a **BitArray** that reflects the current vertex selection. There is one bit for each vertex. Bits that are 1 indicate the vertex is selected.

### Prototype:

```
virtual BitArray GetSegmentSel()=0;
```

### Remarks:

Returns a **BitArray** that reflects the current segment selection. There is one bit for each segment. Bits that are 1 indicate the segment is selected.

### Prototype:

**virtual BitArray GetSplineSel()=0;**

**Remarks:**

Returns a **BitArray** that reflects the current spline selection. There is one bit for each spline. Bits that are 1 indicate the spline is selected.

**Prototype:**

**virtual void SetVertSel(BitArray &set, ISplineSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the vertex selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each vertex. Bits that are 1 indicate the vertex should be selected.

**ISplineSelect \*imod**

Points to the ISplineSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual void SetSegmentSel(BitArray &set, ISplineSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the segment selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each vertex. Bits that are 1 indicate the segment should be selected.

**ISplineSelect \*imod**

Points to the ISplineSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual void SetSplineSel(BitArray &set, ISplineSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the spline selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each spline. Bits that are 1 indicate the spline should be selected.

**ISplineSelect \*imod**

Points to the ISplineSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedVertSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of vertex level named selection sets associated with this modifier.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedSegmentSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of segment level named selection sets associated with this modifier.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedSplineSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of spline level named selection sets associated with this modifier.

## Class ISplineOps

See Also: [Class ISplineSelect](#), [Class Animatable](#), [Working with Shapes and Splines](#).

class ISplineOps

### Description:

This class is available in release 3.0 and later only.

This class provides an interface to the command modes and button press operations of the Editable Spline object. To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_SPLINEOPS**.

For example:

```
ISplineOps *iso = (ISplineOps*)anim-  
>GetInterface(I_SPLINEOPS);  
iso->StartCommandMode(ScmAttach);
```

### Methods:

public:

### Prototype:

```
virtual void StartCommandMode(splineCommandMode mode)=0;
```

### Remarks:

Begins the specified interactive command mode.

### Parameters:

**splineCommandMode mode**

The mode to begin. One of the following values:

**ScmCreateLine**

**ScmAttach**

**ScmInsert**

**ScmConnect**

**ScmRefine**

**ScmFillet**

**ScmChamfer**

**ScmBind**

**ScmRefineConnect**  
**ScmOutline**  
**ScmTrim**  
**ScmExtend**  
**ScmBreak**  
**ScmUnion**  
**ScmCrossInsert**

**Prototype:**

**virtual void ButtonOp(splineButtonOp opcode)=0;**

**Remarks:**

Performs the same operation as a button press inside the Editable Spline UI.

**Parameters:**

**splineButtonOp opcode**

The button operation to execute. One of the following values:

**SopHide**  
**SopUnhideAll**  
**SopDelete**  
**SopDetach**  
**SopDivide**  
**SopBreak**  
**SopCycle**  
**SopUnbind**  
**SopWeld**  
**SopMakeFirst**  
**SopAttachMultiple**  
**SopExplode**  
**SopReverse**  
**SopClose**  
**SopUnion**

**SopSubtract**  
**SopIntersect**  
**SopMirrorHoriz**  
**SopMirrorVert**  
**SopMirrorBoth**  
**SopSelectByID**  
**SopFuse**

**Prototype:**

**virtual void GetUIParam(splineUIParam uiCode, int &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**int &ret**

The returned value.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void SetUIParam(splineUIParam uiCode, int val);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**int val**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void GetUIParam(splineUIParam uiCode, float &ret);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**float &ret**

The returned value.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetUIParam(splineUIParam uiCode, float val);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**splineUIParam uiCode**

This enum is currently empty.

**float val**

The value to set.

**Default Implementation:**

{ }

## Class IPatchSelect

See Also: [Class Animatable](#), [Working with Patches](#).

class IPatchSelect

### Description:

This class is available in release 3.0 and later only.

This class provides an interface to the Patch Select Modifier. To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_PATCHSELECT**.

For example:

```
IPatchSelect *ips = (IPatchSelect*)anim-  
>GetInterface(I_PATCHSELECT);  
DWORD sl = ips->GetSelLevel();
```

### Methods:

public:

### Prototype:

```
virtual DWORD GetSelLevel()=0;
```

### Remarks:

Returns a value indicating the current selection level of the modifier. One of the following values:

```
PO_VERTEX  
PO_EDGE  
PO_PATCH  
PO_OBJECT
```

### Prototype:

```
virtual void SetSelLevel(DWORD level)=0;
```

### Remarks:

Sets the current level of selection of the modifier.

### Parameters:

```
DWORD level
```

The level to set. One of the following values:

**PO\_VERTEX**

**PO\_EDGE**

**PO\_PATCH**

**PO\_OBJECT**

**Prototype:**

**virtual void LocalDataChanged()=0;**

**Remarks:**

This method must be called when the selection level of the modifier is changed. Developers can use the methods of this class to get and set the actual selection data. When a developers does set any of these selection sets this method must be called when done.

## Class IPatchSelectData

See Also: [Class IPatchSelect](#), [Class Animatable](#), [Class BitArray](#), [Working with Patches](#), [Class GenericNamedSelSetList](#).

class IPatchSelectData

### Description:

This class is available in release 3.0 and later only.

When a developer gets the **LocalModData** from the **ModContext** of the Patch Select Modifier, they may cast it to this class and use these methods. They may be used to get/set the vertex/edge/patch sub-object selection state of the modifier as well as the named selection sets.

To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_PATCHSELECTDATA**.

For example:

```
IPatchSelectData *ips = (IPatchSelectData*)anim-  
>GetInterface(I_PATCHSELECTDATA);  
BitArray vs = ips->GetVertSel();
```

### Methods:

public:

### Prototype:

```
virtual BitArray GetVertSel()=0;
```

### Remarks:

Returns a **BitArray** that reflects the current vertex selection. There is one bit for each vertex. Bits that are 1 indicate the vertex is selected.

### Prototype:

```
virtual BitArray GetEdgeSel()=0;
```

### Remarks:

Returns a **BitArray** that reflects the current edge selection. There is one bit for each edge. Bits that are 1 indicate the edge is selected.

### Prototype:

**virtual BitArray GetPatchSel()=0;**

**Remarks:**

Returns a **BitArray** that reflects the current patch selection. There is one bit for each patch. Bits that are 1 indicate the patch is selected.

**Prototype:**

**virtual void SetVertSel(BitArray &set, IPatchSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the vertex selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each vertex. Bits that are 1 indicate the vertex should be selected.

**IPatchSelect \*imod**

Points to the IPatchSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual void SetEdgeSel(BitArray &set, IPatchSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the edge selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each edge. Bits that are 1 indicate the edge should be selected.

**IPatchSelect \*imod**

Points to the IPatchSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual void SetPatchSel(BitArray &set, IPatchSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the patch selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each patch. Bits that are 1 indicate the patch should be selected.

**IPatchSelect \*imod**

Points to the IPatchSelect instance (generally this is a modifier).

**TimeValue t**

The current time at which the call is made.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedVertSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of vertex level named selection sets associated with this modifier.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedEdgeSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of edge level named selection sets associated with this modifier.

**Prototype:**

**virtual GenericNamedSelSetList &GetNamedPatchSelList()=0;**

**Remarks:**

Returns a reference to a class used for manipulating the lists of patch level named selection sets associated with this modifier.

## Class IPatchOps

See Also: [Class Animatable](#), [Working with Patches](#).

class IPatchOps

### Description:

This class is available in release 3.0 and later only.

This class provides an interface to the command modes and button press operations of the Editable Patch object. To obtain a pointer to this class use the method **Animatable::GetInterface()** passing **I\_PATCHOPS**.

For example:

```
IPatchOps *ipo = (IPatchOps*)anim-  
>GetInterface(I_PATCHOPS);  
ipo->StartCommandMode(PcmAttach);
```

### Methods:

public:

### Prototype:

```
virtual void StartCommandMode(patchCommandMode mode)=0;
```

### Remarks:

Begins the specified interactive command mode.

### Parameters:

**patchCommandMode mode**

**PcmAttach**

**PcmExtrude**

**PcmBevel**

**PcmCreate**

**PcmWeldTarget**

**PcmFlipNormal**

**PcmBind**

### Prototype:

**virtual void ButtonOp(patchButtonOp opcode)=0;**

**Remarks:**

Performs the same operation as a button press inside the Editable Patch UI.

**Parameters:**

**patchButtonOp opcode**

The button operation to execute. One of the following values:

**PopBind**

**PopUnbind**

**PopHide**

**PopUnhideAll**

**PopWeld**

**PopDelete**

**PopSubdivide**

**PopAddTri**

**PopAddQuad**

**PopDetach**

**Prototype:**

**virtual void GetUIParam(patchUIParam uiCode, int &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**int &ret**

The returned value.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void SetUIParam(patchUIParam uiCode, int val);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**int val**

The value to set.

**Default Implementation:**

{ }

**Prototype:**

**virtual void GetUIParam(patchUIParam uiCode, float &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**float &ret**

The returned value.

**Default Implementation:**

{ }

**Prototype:**

**virtual void SetUIParam(patchUIParam uiCode, float val);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**float val**

The value to set.

**Default Implementation:**

```
{ }
```

## Template Class IFFDMod

See Also: [Class Control](#), [Class Point3](#), [Class IPoint3](#), [Class Modifier](#).

```
template <class T> class IFFDMod : public T
```

### Description:

This class is available in release 3.0 and later only.

This class is an interface into both FFD OS modifiers and also into helper objects for FFD spacewarps.

Given a pointer to ReferenceTarget **ref**, you can use it as follows:

```
Class_ID id = ref->ClassID();  
if (id==FFDNMOSSQUARE_CLASS_ID ||  
id==FFDNMOSCYL_CLASS_ID ||  
id==FFD44_CLASS_ID || id==FFD33_CLASS_ID ||  
id==FFD22_CLASS_ID)  
IFFDMod<Modifier>* ffd = (IFFDMod<Modifier>*)ref;  
// call various methods  
}  
else if(id==FFDNMWSSQUARE_CLASS_ID || id =  
FFDNMWSCYL_CLASS_ID)  
IFFDMod<WSMObject>* ffd = (IFFDMod<WSMObject>*)ref;  
// call various methods  
}
```

### Methods:

public:

### Prototype:

```
virtual int NumPts()=0;
```

### Remarks:

Returns the number of lattice control points.

### Prototype:

```
virtual int NumPtConts()=0;
```

### Remarks:

Returns the number of Control Points having controllers.

**Prototype:**

**virtual Control\* GetPtCont(int i)=0;**

**Remarks:**

Returns a pointer to the 'i-th' Control Point controller.

**Parameters:**

**int i**

The zero based index of the Control Point.

**Prototype:**

**virtual void SetPtCont(int i,Control \*c)=0;**

**Remarks:**

Sets the controller used by the specified Control Point.

**Parameters:**

**int i**

The zero based index of the Control Point.

**Control \*c**

Points to the controller to set.

**Prototype:**

**virtual Point3 GetPt(int i)=0;**

**Remarks:**

Returns the 'i-th' Control Point.

**Parameters:**

**int i**

The zero based index of the Control Point.

**Prototype:**

**virtual void SetPt(int i, Point3 p)=0;**

**Remarks:**

Sets the 'i-th' control point.

**Parameters:**

**int i**

The zero based index of the Control Point.

**Point3 p**

The point to set.

**Prototype:**

**virtual void SetGridDim(IPoint3 d);**

**Remarks:**

Sets the lattice dimension.

**Parameters:**

**IPoint3 d**

The dimensions to set.

**Default Implementation:**

{ }

**Prototype:**

**virtual IPoint3 GetGridDim();**

**Remarks:**

Returns the lattice dimensions.

**Default Implementation:**

{ return IPoint3(0,0,0); }

**Prototype:**

**virtual void AnimateAll();**

**Remarks:**

This method assigns controllers to all the Control Points.

**Default Implementation:**

{ }

**Prototype:**

**virtual void Conform();**

**Remarks:**

Calling this method is the equivalent of pressing the Conform button in the FFD UI. Note: This method is not valid for WSMObject's.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void SelectPt(int i, BOOL sel, BOOL clearAll=FALSE);**

**Remarks:**

Selects or de-selects the specified Control Point.

**Parameters:**

**int i**

The zero based index of the Control Point.

**BOOL sel**

TRUE to select; FALSE to de-select.

**BOOL clearAll=FALSE**

TRUE to clear all the currently selected Control Points before setting the specified one; FALSE to leave the selected points alone.

**Default Implementation:**

**{ }**

## Class IParamBlock

See Also: [Class ReferenceTarget](#), [Class IParamArray](#), [Parameter Maps](#), [Class ParamBlockDescID](#), [Class Control](#).

```
class IParamBlock : public ReferenceTarget, public IParamArray
```

### Description:

This class provides methods to work with parameter blocks. For more details on parameter blocks see [Parameter Blocks](#).

### Methods:

#### Prototype:

```
virtual BOOL SetValue(int i, TimeValue t, float v)=0;
```

#### Remarks:

Implemented by the System.

Whenever the developer needs to store a value into the parameter block, the **SetValue()** method is used. There are overloaded functions for each type of value to set (int, float, Point3, and Color). Each method has three parameters. Below is the float version - the others are similar.

#### Parameters:

**int i**

This is the index into the **ParamBlockDesc** array of the parameter to set.

**TimeValue t**

The time at which to set the value.

**float v**

The value to store.

#### Return Value:

If the value was set TRUE is returned; otherwise FALSE is returned.

#### Prototype:

```
virtual BOOL SetValue(int i, TimeValue t, int v)=0;
```

#### Remarks:

This is the integer version of above.

**Prototype:**

**virtual BOOL SetValue(int i, TimeValue t, Point3& v)=0;**

**Remarks:**

This is the Point3 version of above.

**Prototype:**

**virtual BOOL SetValue(int i, TimeValue t, Color& v)=0;**

**Remarks:**

This is the Color version of above.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, float &v, Interval &ivalid)=0;**

**Remarks:**

Implemented by the System.

Whenever the developer needs to retrieve a value from the parameter block, the **GetValue()** method is used. There are overloaded functions for each type of value to retrieve (int, float, Point3, and Color).

**Important Note: Developers need to do range checking on values returned from a parameter block -- a spinner custom control will not necessarily ensure that the values entered by a user and stored by a parameter block are fixed to the values allowed by the spinner. For example, the spinner control ensures that it only displays, and the user is only allowed to input, values within the specified ranges. However the spinner is just a front end to a controller which actually controls the value. The user can thus circumvent the spinner constraints by editing the controller directly (via function curves in track view, key info, etc.). Therefore, when a plug-in gets a value from a controller (or a parameter block, which may use a controller) it is its responsibility to clamp the value to a valid range.**

The **GetValue()** method updates the interval passed in. This method is frequently used by developers to 'whittle' down an interval. When a parameter of a parameter block is animated, for any given time there is a interval over

which the parameter is constant. If the parameter is constantly changing the interval is instantaneous. If the parameter does not change for a certain period the interval will be longer. If the parameter never changes the interval will be **FOREVER**. By passing an interval to the `GetValue()` method you ask the parameter block to 'intersect' the interval passed in with the interval of the parameter. Intersecting two intervals means returning a new interval whose start value is the greater of the two, and whose end value is smaller of the two. In this way, the resulting interval represents a combined period of constancy for the two intervals.

This technique is used to compute a validity interval for an object. The developer starts an interval off as **FOREVER**, then intersects this interval with each of its animated parameters (by calling **GetValue()**). **GetValue()** 'whittles' down the interval with each call. When all the parameters have been intersected the result is the overall validity interval of an object at a specific time.

**Parameters:**

**int i**

Index into the **ParamBlockDesc** array of the parameter to retrieve.

**TimeValue t**

The time at which to retrieving a value.

**float v**

The value to store for the parameter at the time.

**Interval &ivalid**

The interval to update.

**Return Value:**

The return value is TRUE if a value was retrieved. Otherwise it is FALSE.

See Also: [Parameter Blocks](#) in the Advanced Topics section, [Intervals](#).

**Prototype:**

```
virtual BOOL GetValue(int i, TimeValue t, int &v, Interval  
&ivalid)=0;
```

**Remarks:**

This is the integer version of above.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, Point3 &v, Interval &ivalid)=0;**

**Remarks:**

This is the Point3 version of above.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, Color &v, Interval &ivalid)=0;**

**Remarks:**

This is the Color version of above.

**Prototype:**

**virtual SClass\_ID GetAnimParamControlType(int anim)=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the super class ID of a parameters controller.

**Parameters:**

**int anim**

Specifies the parameter whose controller super class ID is returned.

**Prototype:**

**virtual ParamType GetParameterType(int i)=0;**

**Remarks:**

Returns the type of the 'i-th' parameter.

**Parameters:**

**int i**

The zero based index of the parameter to retrieve. See [List of Parameter Types](#).

**Prototype:**

**virtual DWORD GetVersion()=0;**

**Remarks:**

Implemented by the System.  
Returns the parameter block version.

**Prototype:**

**virtual void RemoveController(int i)=0;**

**Remarks:**

Implemented by the System.  
Removes the 'i-th' controller.

**Parameters:**

**int i**

The parameter index of the controller to remove.

**Prototype:**

**virtual Control\* GetController(int i)=0;**

**Remarks:**

Implemented by the System.  
Returns the controller of the 'i-th' parameter.

**Parameters:**

**int i**

The parameter index of the controller to return.

**Prototype:**

**virtual void SetController(int i, Control \*c, BOOL  
preserveFrame0Value=TRUE)=0;**

**Remarks:**

Implemented by the System.  
Sets the 'i-th' parameter controller to **c**.

**Parameters:**

**int i**

The index of the parameter to set.

**Control \*c**

The controller to set.

**BOOL preserveFrame0Value=TRUE**

If TRUE the controllers value at frame 0 is preserved.

**Prototype:**

```
virtual void SwapControllers(int j, int k )=0;
```

**Remarks:**

Implemented by the System.

Swaps the two controllers of the parameters whose indices are passed.

**Parameters:**

**int j, int k**

The parameter indices whose controllers should be swapped.

**Prototype:**

```
virtual int GetRefNum(int paramNum)=0;
```

**Remarks:**

Implemented by the System.

Given a parameter index this method will return the reference number of that parameter.

**Parameters:**

**int paramNum**

The parameter index.

**Prototype:**

```
virtual int GetAnimNum(int paramNum)=0;
```

**Remarks:**

Implemented by the System.

Given a parameter index this method will return the anim number.

**Parameters:**

**int paramNum**

The parameter index.

**Prototype:**

```
virtual int AnimNumToParamNum(int animNum)=0;
```

**Remarks:**

Implemented by the System.

Given an anim number this method will return the parameter index.

**Parameters:**

```
int animNum
```

The anim number.

**Prototype:**

```
virtual void RescaleParam(int paramNum, float f)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This is only for use in a **ReferenceMaker::RescaleWorldUnits()**

implementation: The parameter block implementation of

**RescaleWorldUnits()** scales only tracks that have dimension type =

**stdWorldDim**. If letting the parameter block handle the rescaling is not

sufficient, call this on just the parameters you need to rescale. For additional

details on this method see the sub-section called 'Scaling Parameter Values' in

the section [Updating MAX 1.0 Plug-Ins to work with MAX 2.0](#).

**Parameters:**

```
int paramNum
```

The index into the parameter block of the parameter to rescale.

```
float f
```

The value to scale by.

**Prototype:**

```
virtual int LastNotifyParamNum()=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the index into a parameter block of the parameter that generated a notification. You can call this method when you get a **NotifyRefChanged()**

message from your parameter block to determine exactly which parameter it was that changed. When you have a very complicated dialog, for instance the Standard material, you can use this to selectively update controls in the dialog instead of updating all of them, which can feel pretty slow to the user. For smaller dialogs it's not worth the trouble.

**Sample Code:**

```
case REFMSG_CHANGE:  
if (hTarget==pblock) {  
    int np =pblock->LastNotifyParamNum();  
    // ...  
}  
break;
```

The following methods are not part of class `IParamBlock` but are available for use:

**Prototype:**

**`IParamBlock *CreateParameterBlock(ParamBlockDesc *pdesc, int count);`**

**Remarks:**

Implemented by the System.

This method is used to create a parameter block.

**Parameters:**

**`ParamBlockDesc *pdesc`**

This is an array of parameter block descriptors.

**`int count`**

This is the number in the array.

**Return Value:**

A pointer to the created parameter block. On error NULL is returned.

**Prototype:**

**`IParamBlock *CreateParameterBlock(ParamBlockDescID *pdesc, int count, DWORD version);`**

**Remarks:**

Implemented by the System.

This method is used to create a parameter block with a version number to aide in backwards compatibility.

**Parameters:**

**`ParamBlockDesc *pdesc`**

This is an array of parameter block descriptors.

**`int count`**

This is the number in the array.

**`DWORD version`**

This is used to indicate a version of the parameter block. This is used for backwards compatibility when loading 3ds max files that were saved with a previous version of the parameter block structure. There is a mechanism

which allows the older format to be converted to the newer format so the older files may still be loaded and used. See the Advanced Topics section on [Parameter Maps](#) for more information.

**Return Value:**

A pointer to the created parameter block. On error NULL is returned.

**Prototype:**

```
IParamBlock *UpdateParameterBlock(ParamBlockDescID  
*pdescOld, int oldCount, IParamBlock  
*oldPB, ParamBlockDescID *pdescNew, int newCount, DWORD  
newVersion);
```

**Remarks:**

Implemented by the System.

This creates a new parameter block, based on an existing parameter block of a later version. The new parameter block inherits any parameters from the old parameter block whose parameter IDs match.

**Parameters:**

**ParamBlockDescID \*pdescOld**

The existing parameter block descriptor.

**int oldCount**

The number of old parameters.

**IParamBlock \*oldPB**

The old parameter block.

**ParamBlockDescID \*pdescNew**

The new parameter block descriptor.

**int newCount**

The number of new parameters.

**DWORD newVersion**

The version of the new parameter block.

**Return Value:**

The new parameter block.

## Class IParamBlock2

See Also: [Class ReferenceTarget](#), [Class ParamBlockDesc2](#), [List of ParamType2 Choices](#), [Structure ParamDef](#), [Class PBValidator](#), [Class PBAccessor](#), [Class PBBitmap](#), [Class ParamBlock2PLCB](#), [Class ClassDesc2](#), [Class Animatable](#), [Structure ParamAlias](#).

```
class IParamBlock2 : public ReferenceTarget
```

### Description:

This class is available in release 3.0 and later only.

This class provides an interface for working with parameter block2s. There are methods for getting and setting parameters, descriptor access, parameter map access, etc.

### Methods Groups:

The hyperlinks below take you to the start of groups of related methods within the class:

[Version / Parameter Number / Local Name / ParamDef / BlockID Access](#)

[Descriptor Access](#)

[Index-to/from-ID Methods](#)

[Super Class ID Access](#)

[Parameter Type and Local Name](#)

[SetValue\(\) Parameter Accessors](#)

[MAXScript Default Parameter Initialization](#)

[Alias Maintenance](#)

[SubAnim Numbering Related Methods](#)

[Copying Parameter Values Between Blocks](#)

[Finding Parameter IDs](#)

[Reset To Default Values](#)

[PBAccessor Get / Set Methods](#)

[Validity of Parameters](#)

**Methods:**

public:

**Version / Parameter Number / Local Name / ParamDef / BlockID  
/ Owner Access**

**Prototype:**

**virtual DWORD GetVersion()=0;**

**Remarks:**

Returns the version of this parameter block.

**Prototype:**

**virtual int NumParams()=0;**

**Remarks:**

Returns the number of parameters in this parameter block.

**Prototype:**

**virtual TCHAR\* GetLocalName()=0;**

**Remarks:**

Returns the localized name for the parameter block.

**Prototype:**

**virtual ParamDef& GetParamDef(ParamID id)=0;**

**Remarks:**

Returns a reference to the ParamDef structure for this parameter block.

**Parameters:****ParamID id**

The parameter ID.

**Prototype:**

```
virtual BlockID ID()=0;
```

**Remarks:**

Returns the BlockID of the parameter block. Note: **typedef short BlockID;**

**Prototype:**

```
virtual ReferenceMaker* GetOwner()=0;
```

**Remarks:**

Returns a pointer to the owner of this parameter block.

**Descriptor Access****Prototype:**

```
virtual ParamBlockDesc2* GetDesc()=0;
```

**Remarks:**

Acquires the descriptor for this parameter block. Call **ReleaseDesc()** when done.

**Prototype:**

```
virtual void ReleaseDesc()=0;
```

**Remarks:**

Releases the descriptor for this parameter block. See **GetDesc()** above.

**Prototype:**

```
virtual void SetDesc(ParamBlockDesc2* desc)=0;
```

**Remarks:**

Sets the descriptor associated with the parameter block.

**Parameters:**

**ParamBlockDesc2\* desc**

Points to the descriptor to set.

## **Index-to/from-ID Methods**

**Prototype:**

**virtual int IDtoIndex(ParamID id)=0;**

**Remarks:**

Returns the zero based index of the parameter into the parameter definitions array of the given parameter ID or -1 if not found.

**Parameters:**

**ParamID id**

The parameter ID whose index to return.

**Prototype:**

**virtual ParamID IndextoID()=0;**

**Remarks:**

Returns the parameter ID of the parameter given its index into the parameter definitions array.

**Parameters:**

**int i**

The index of the parameter whose ID is to be returned.

## **Super Class ID Access**

**Prototype:**

**virtual SClass\_ID GetAnimParamControlType(int anim)=0;**

**Remarks:**

Returns the Super Class ID of the parameter's controller (specified by sub-anim number).

**Parameters:**

**int anim**

The sub-anim index of the parameter.

**Prototype:**

**virtual SClass\_ID GetParamControlType(ParamID id)=0;**

**Remarks:**

Returns the Super Class ID of the parameter's controller (specified by paramter ID).

**Parameters:**

**ParamID id**

The ID of the parameter.

## **Parameter Type and Local Name**

**Prototype:**

**virtual ParamType2 GetParameterType(ParamID id)=0;**

**Remarks:**

Returns the type of the specified parameter.

**Parameters:**

**ParamID id**

The ID of the parameter.

**Prototype:**

**virtual TSTR GetLocalName(ParamID id, int tabIndex = -1)=0;**

**Remarks:**

Returns the local name for the specified parameter or Tab<> parameter entry.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int tabIndex = -1**

If the parameter is a table this is the zero based index into the table of the parameter.

## **SetValue() Parameter Accessors**

### **Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, float v, int  
tabIndex=0);
```

### **Remarks:**

Sets the floating point value of the specified parameter at the specified time.

### **Parameters:**

#### **ParamID id**

The permanent ID of the parameter.

#### **TimeValue t**

The time at which to set the value.

#### **float v**

The value to set.

#### **int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

### **Return Value:**

TRUE on success; otherwise FALSE.

### **Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, int v, int  
tabIndex=0);
```

### **Remarks:**

Sets the integer value of the specified parameter at the specified time.

### **Parameters:**

#### **ParamID id**

The permanent ID of the parameter.

#### **TimeValue t**

The time at which to set the value.

#### **int v**

The value to set.

#### **int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL SetValue(ParamID id, TimeValue t, Point3& v, int tabIndex=0);**

**Remarks:**

Sets the Point3 value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**Point3& v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL SetValue(ParamID id, TimeValue t, Color& v, int tabIndex=0);**

**Remarks:**

Sets the Color value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**Color& v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, TCHAR* v, int  
tabIndex=0);
```

**Remarks:**

Sets the string value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**TCHAR\* v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, Mtl*v, int  
tabIndex=0);
```

**Remarks:**

Sets the Mtl\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**Mtl\*v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, Texmap* v, int  
tabIndex=0);
```

**Remarks:**

Sets the Texmap\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**Texmap\* v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL SetValue(ParamID id, TimeValue t, PBitmap\* v, int tabIndex=0);**

**Remarks:**

Sets the PBitmap\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**PBitmap\* v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL SetValue(ParamID id, TimeValue t, INode\* v, int tabIndex=0);**

**Remarks:**

Sets the INode\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**INode\* v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t,  
ReferenceTarget*v, int tabIndex=0);
```

**Remarks:**

Sets the ReferenceTarget\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**ReferenceTarget\*v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetValue(ParamID id, TimeValue t, Matrix3& v, int  
tabIndex=0);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the Matrix3 value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to set the value.

**Matrix3& v**

The value to set.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to set.

**Return Value:**

TRUE on success; otherwise FALSE.

**GetValue() Parameter Accessors**

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, float& v,  
Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the floating point value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**float& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL GetValue(ParamID id, TimeValue t, int& v, Interval  
&ivalid, int tabIndex=0);
```

**Remarks:**

Retrieves the integer value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**int& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL GetValue(ParamID id, TimeValue t, Point3& v,  
Interval &ivalid, int tabIndex=0);
```

**Remarks:**

Retrieves the Point3 value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**Point3& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, Color& v, Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the Color value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**Color& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, TCHAR\*& v,**

**Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the string value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**TCHAR\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, Mtl\*& v,  
Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the Mtl\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**Mtl\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, Texmap\*& v, Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the Texmap\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**Texmap\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, PBBitmap\*& v, Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the PBitmap\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**PBitmap\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual BOOL GetValue(ParamID id, TimeValue t, INode\*& v, Interval &ivalid, int tabIndex=0);**

**Remarks:**

Retrieves the INode\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**INode\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL GetValue(ParamID id, TimeValue t,  
ReferenceTarget*& v, Interval &ivalid, int tabIndex=0);
```

**Remarks:**

Retrieves the ReferenceTarget\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**ReferenceTarget\*& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL GetValue(ParamID id, TimeValue t, Matrix3& v,  
Interval &ivalid, int tabIndex=0);
```

**Remarks:**

This method is available in release 4.0 and later only.

Retrieves the Matrix3 value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time at which to get the value.

**Matrix3& v**

The value to retrieve is returned here.

**Interval &ivalid**

This is the validity interval which is updated by the validity of the retrieved parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Return Value:**

TRUE on success; otherwise FALSE.

## Shortcut Get Methods

**Prototype:**

```
virtual Color GetColor(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

Returns the Color value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual Point3 GetPoint3(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Retrieves the value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual int GetInt(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Returns the integer value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual float GetFloat(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Returns the floating point value of the specified parameter at the specified

time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual TimeValue GetTimeValue(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

Returns the TimeValue value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual Mtl* GetMtl(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

Returns the Mtl\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual TCHAR* GetStr(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

Returns the string value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual Texmap* GetTexmap(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

Returns the Texmap\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual PBitmap\* GetBitmap(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Returns the PBitmap\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual INode\* GetINode(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Returns the INode\* value of the specified parameter at the specified time.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

**virtual ReferenceTarget\* GetReferenceTarget(ParamID id, TimeValue t=0, int tabIndex=0)=0;**

**Remarks:**

Returns the ReferenceTarget\* value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual PB2Value& GetPB2Value(ParamID id, int tabIndex=0)=0;
```

**Remarks:**

This methods is used for getting a parameter value as a PB2Value reference.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Prototype:**

```
virtual Matrix3 GetMatrix3(ParamID id, TimeValue t=0, int  
tabIndex=0)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Retrieves the value of the specified parameter at the specified time.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**TimeValue t=0**

The time at which to get the value.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index into the table of the value to get.

**Table (Tab<>) Management****Prototype:****virtual int Count(ParamID id)=0;****Remarks:**

Returns the number of entries being used in the table.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**Prototype:****virtual void ZeroCount(ParamID id)=0;****Remarks:**

Set the number of elements in the table that are actually used to zero.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**Prototype:****virtual void SetCount(ParamID id, int n)=0;****Remarks:**

Set the number of elements in the table that are actually used to **n**.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int n**

The number of elements to set.

**Prototype:**

**virtual int Delete(ParamID id, int start,int num)=0;**

**Remarks:**

List-type delete of **num** elements starting with **start**

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int start**

The start position for element deletion.

**int num**

The number of elements to delete.

**Return Value:**

Returns the number of items left in the table.

**Prototype:**

**virtual int Resize(ParamID id, int num)=0;**

**Remarks:**

Changes the number of allocated items to **num**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The new size of the table.

**Return Value:**

Nonzero if the array was resized; otherwise 0.

**Prototype:**

**virtual void Shrink(ParamID id)=0;**

**Remarks:**

Reallocate so there is no wasted space.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**Prototype:**

```
virtual void Sort(ParamID id, CompareFnc cmp)=0;
```

**Remarks:**

Sorts the array using the compare function.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**CompareFnc cmp**

Type of function to pass to **Sort()**. Note: **Sort()** just uses the C library **qsort** function. The developer must implement the CompareFnc function.

```
typedef int( __cdecl *CompareFnc) (const void *elem1, const void *elem2);
```

The return value of **CompareFnc** is show below in the relationship of **elem1** to **elem2**:

< 0

if **elem1** less than **elem2**

0

if **elem1** identical to **elem2**

> 0

if **elem1** greater than **elem2**

**Sample Code:**

```
static int CompTable( const void *elem1, const void *elem2 ) {  
    TCHAR *a = (TCHAR *)elem1;  
    TCHAR *b = (TCHAR *)elem2;  
    return(_tcscmp(a,b));  
}
```

## Table (Tab<>) Insert Methods

### Prototype:

**virtual int Insert(ParamID id, int at, int num, float\* el)=0;**

### Remarks:

Insert **num** float elements at position **at**.

### Parameters:

#### **ParamID id**

The permanent ID of the parameter.

#### **int at**

Zero based array index where to insert the elements.

#### **int num**

Number of elements to insert.

#### **float\* el**

Array of elements to insert.

### Return Value:

Returns **at**.

### Prototype:

**virtual int Insert(ParamID id, int at, int num, Point3\*\* el)=0;**

### Remarks:

Insert **num** Point3\* elements at position **at**.

### Parameters:

#### **ParamID id**

The permanent ID of the parameter.

#### **int at**

Zero based array index where to insert the elements.

#### **int num**

Number of elements to insert.

#### **Point3\*\* el**

Array of elements to insert.

### Return Value:

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, Color\*\* el)=0;**

**Remarks:**

Insert **num** Color\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**Color\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, TimeValue\* el)=0;**

**Remarks:**

Insert **num** TimeValue elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**TimeValue\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

```
virtual int Insert(ParamID id, int at, int num, TCHAR** vel)=0;
```

**Remarks:**

Insert **num** string (TCHAR\*) elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**TCHAR\*\* vel**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

```
virtual int Insert(ParamID id, int at, int num, Mtl** el)=0;
```

**Remarks:**

Insert **num** Mtl\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**Mtl\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, Texmap\*\* el)=0;**

**Remarks:**

Insert **num** Texmap\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

**Texmap\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, PBBitmap\*\* el)=0;**

**Remarks:**

Insert **num** PBBitmap\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**PBBitmap\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, INode\*\* v)=0;**

**Remarks:**

Insert **num** INode\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**INode\*\* v**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**virtual int Insert(ParamID id, int at, int num, ReferenceTarget\*\* el)=0;**

**Remarks:**

Insert **num** ReferenceTarget\* elements at position **at**.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**ReferenceTarget\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

```
virtual int Insert(ParamID id, int at, int num, Matrix3** el)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Insert **num** Matrix3\* elements at position **at**.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int at**

Zero based array index where to insert the elements.

**int num**

Number of elements to insert.

**Matrix3\*\* el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Table (Tab<>) Append Methods****Prototype:**

```
virtual int Append(ParamID id, int num, float* el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** float elements at the end of the array.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**float\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify a non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, Point3** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** Point3\* elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**Point3\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify a non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, Color** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** Color\* elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**Color\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, TimeValue* el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** TimeValue elements at the end of the array.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**TimeValue\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, TCHAR** el, int
```

**allocExtra=0)=0;**

**Remarks:**

Append **num** string (TCHAR\*) elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**TCHAR\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify a non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

**virtual int Append(ParamID id, int num, Mtl\*\* el, int allocExtra=0)=0;**

**Remarks:**

Append **num** Mtl\* elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**Mtl\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify a non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, Texmap** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** Texmap\* elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**Texmap\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify a non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, PBBitmap** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** PBBitmap\* elements at the end of the array.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**PBBitmap\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, INode** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** INode\* elements at the end of the array.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**INode\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, ReferenceTarget** el, int  
allocExtra=0)=0;
```

**Remarks:**

Append **num** ReferenceTarget\* elements at the end of the array.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**ReferenceTarget\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Prototype:**

```
virtual int Append(ParamID id, int num, Matrix3** el, int  
allocExtra=0)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Append **num** Matrix3\* elements at the end of the array.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int num**

The number of elements to append to the end of the array.

**Matrix3\*\* el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array specify an non-zero value and this many extra slots will be allocated.

**Return Value:**

Returns the number of elements in use prior to appending.

**Keyframe Checking****Prototype:**

```
virtual BOOL KeyFrameAtTime(int i, TimeValue t, int
```

**tabIndex=0);**

**Remarks:**

Checks to see if a keyframe exists for the given parameter at the given time

**Parameters:**

**int i**

Zero based index of the parameter to check.

**TimeValue t**

The time to check.

**int tabIndex=0**

If the parameter is a table this is the zero based index of the element in the table to check.

**Return Value:**

TRUE if a keyframe exists at the specified time; otherwise FALSE.

**Prototype:**

**virtual BOOL KeyFrameAtTime(ParamID id, TimeValue t, int  
tabIndex=0);**

**Remarks:**

Checks to see if a keyframe exists for the given parameter at the given time

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**TimeValue t**

The time to check.

**int tabIndex=0**

If the parameter is a table this is the zero based index of the element in the table to check.

**Return Value:**

TRUE if a keyframe exists at the specified time; otherwise FALSE.

**Controller Access**

**Prototype:**

**virtual void RemoveController(int i, int tabIndex)=0;**

**Remarks:**

Removes the 'i-th' controller.

**Parameters:**

**int i**

Specifies which controller using the zero based index of the parameter in the block.

**int tabIndex**

If the parameter is a table this is the zero based index of the element in the table whose controller is removed.

**Prototype:**

**virtual Control\* GetController(ParamID id, int tabIndex=0)=0;**

**Remarks:**

Returns a pointer to the controller of the specified parameter.

**Parameters:**

**ParamID id**

The permanent ID of the parameter.

**int tabIndex=0**

If the parameter is a table this is the zero based index of the element in the table whose controller is returned.

**Prototype:**

**virtual Control\* GetController(int i, int tabIndex)=0;**

**Remarks:**

Returns a pointer to the controller of the specified parameter.

**Parameters:**

**int i**

Specifies which controller using the zero based index of the parameter in the block.

**int tabIndex**

If the parameter is a table this is the zero based index of the element in the

table whose controller is returned.

**Prototype:**

```
virtual void SetController(int i, int tabIndex, Control *c, BOOL  
preserveFrame0Value=TRUE)=0;
```

**Remarks:**

Sets the 'i-th' parameter controller to the one specified.

**Parameters:**

**int i**

Specifies which controller using the zero based index of the parameter in the block.

**int tabIndex**

If the parameter is a table this is the zero based index of the element in the table.

**Control \*c**

The controller to set.

**BOOL preserveFrame0Value=TRUE**

If TRUE the controllers value at frame 0 is preserved.

**Prototype:**

```
virtual void SwapControllers(int i1, int tabIndex1, int i2, int  
tabIndex2)=0;
```

**Remarks:**

Swaps the two controllers of the parameters whose indices are passed.

**Parameters:**

**int i1**

The zero based index of one of the parameters in the parameter block.

**int tabIndex1**

If the parameter is a table this is the zero based index of the element in the table.

**int i2**

The zero based index of one of the other parameters in the parameter block.

## **int tabIndex2**

If the parameter is a table this is the zero based index of the element in the table.

## **Reference Related Methods**

### **Prototype:**

```
virtual int GetRefNum(int i, int tabIndex=0)=0;
```

### **Remarks:**

Given a parameter index this method will return the reference number of that parameter.

### **Parameters:**

#### **int i**

The zero based index of the parameter in the parameter block.

#### **int tabIndex=0**

If the parameter is a table this is the zero based index of the element in the table.

### **Prototype:**

```
virtual int GetControllerRefNum(int i, int tabIndex=0)=0;
```

### **Remarks:**

Returns the reference number of the specified parameter's controller or -1 if not found.

### **Parameters:**

#### **int i**

The zero based index into the parameter definitions array of the parameter.

#### **int tabIndex=0**

If the parameter is a Tab<> this is the zero based index in the table of the parameter.

### **Prototype:**

```
virtual ParamID LastNotifyParamID(int& tabIndex)=0;
```

### **Remarks:**

This method is available in release 4.0 and later only.

Like **LastNotifyParamID()**, but takes an **int& tabIndex** argument so that it can return both the ID of the changing parameter (as the result) and the changing element index for **Tab<>** parameters.

If the **ParamID** returns -1 because no parameter is currently changing, **tabIndex** is not updated. If the change to a **Tab<>** parameter is not to a single element (such as a sort), the **tabIndex** is set to -1. For multiple inserts, appends, deletes, the **tabIndex** returned is the index of the first element inserted, appended, deleted.

**Parameters:**

**int& tabIndex**

The index of the changing element for **Tab<>** parameters is returned here.

**Prototype:**

**virtual void RefDeleted(ParamID id, int tabIndex=0)=0;**

**Remarks:**

This method should be called when the parameter block owner has deleted the reference to a reference target parameter. This sets the value to NULL and invalidates the UI associated with the pblock. Note that this must only be called on **P\_OWNERS\_REF** parameters.

**Parameters:**

**ParamID id**

The ID of the reference target parameter.

**int tabIndex=0**

If the parameter is a **Tab<>** this is the zero based index into the table of the parameter.

**Prototype:**

**virtual void EnableNotifications(BOOL onOff)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Controls whether **NotifyDependents()** messages are sent when a parameter is changed, such as through

a **SetValue()** call. For example:

```
pblock->EnableNotifications(FALSE);
```

**... param change code ...**

```
pblock->EnableNotifications(TRUE);
```

Notifications are enabled by default. Note that this is a GLOBAL enable/disable, ALL paramblocks will be prevented from sending notifications while **EnableNotifications(FALSE)** is in effect.

**Parameters:**

**BOOL onOff**

TRUE to enable notifications, FALSE to disable them.

## **Anim Num / Param ID Conversion**

**Prototype:**

```
virtual int GetAnimNum(ParamID id, int tabIndex=0)=0;
```

**Remarks:**

Returns the sub-anim number of the parameter whose ID is passed or -1 if not found.

**Parameters:**

**ParamID id**

The parameter ID of the parameter.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index in the table of the parameter.

**Prototype:**

```
virtual int AnimNumToParamNum(int animNum, int& tabIndex)=0;
```

**Remarks:**

Returns the index into the parameter definitions array of the parameter whose sub-anim index is specified or -1 if not found.

**Parameters:**

**int animNum**

The zero based sub-anim index of the parameter.

**int& tabIndex**

If the parameter is a Tab<> this is the zero based index into the table of the parameter.

**Parameter Dimension Related Methods****Prototype:**

```
virtual ParamDimension* GetParamDimension(int subAnim)=0;
```

**Remarks:**

Returns the dimension of the parameter whose sub-anim index is passed or **defaultDim** if not found.

**Parameters:****int subAnim**

The zero based sub-anim index of the parameter.

**Prototype:**

```
virtual void RescaleParam(int paramNum, int tabIndex, float f)=0;
```

**Remarks:**

This is only for use in a RescaleWorldUnits() implementation: The parameter block implementation of RescaleWorldUnits scales only tracks that have dimension type = stdWorldDim. If letting the parameter block handle the rescaling is not sufficient, call this on just the parameters you need to rescale.

**Parameters:****int paramNum**

The index into the parameter block of the parameter to rescale.

**int tabIndex**

If the parameter is a Tab<> this is the zero based index into the table of the parameter.

**float f**

The value to scale by.

## Parameter Map Access

### Prototype:

**virtual void SetMap(IParamMap2\* m, MapID map\_id = 0)=0;**

### Remarks:

This method sets the parameter map2 associated with this parameter block2.

### Parameters:

**IParamMap2\* m**

Points to the parameter map.

**MapID map\_id**

This parameter is available in release 4.0 and later only.

Specifies the ID of the map to set.

### Prototype:

**virtual IParamMap2\* GetMap(MapID map\_id = 0)=0;**

### Remarks:

Returns a pointer to the parameter map2 associated with this parameter block.

### Parameters:

**MapID map\_id**

This parameter is available in release 4.0 and later only.

Specifies the ID of the map to get.

## Rollout Access

### Prototype:

**virtual void SetRolloutOpen(BOOL open, MapID map\_id = 0)=0;**

### Remarks:

Sets the rollout state to open or closed.

Note: Normally, developers don't need to call this method (or the related ones below) explicitly; they are used internally to keep track of rollouts states.

Instead, use the **ClassDesc2** method **RestoreRolloutState()** at the end of a **BeginEditParams()** or **CreateParamDlg()** to reset the rollouts to the state last used for the current object.

**Parameters:**

**BOOL open**

TRUE for open; FALSE for closed.

**MapID map\_id**

This parameter is available in release 4.0 and later only.

Specifies the ID of the map/rollout to set open/closed state for.

**Prototype:**

**virtual BOOL GetRolloutOpen(MapID map\_id = 0)=0;**

**Remarks:**

Returns TRUE if the rollout is open; FALSE if closed. This is normally used internally -- see the note above in **SetRolloutOpen()**.

**Parameters:**

**MapID map\_id**

This parameter is available in release 4.0 and later only.

Specifies the ID of the map/rollout to get open/closed state for.

**Prototype:**

**virtual void SetRolloutScrollPos(int pos, MapID map\_id = 0)=0;**

**Remarks:**

Sets the rollout scroll position. This is normally used internally -- see the note above in **SetRolloutOpen()**.

**Parameters:**

**int pos**

The position to set.

**MapID map\_id**

This parameter is available in release 4.0 and later only.

Specifies the ID of the map/rollout to set scroll position for.

**Prototype:**

**virtual int GetRolloutScrollPos(MapID map\_id = 0)=0;**

**Remarks:**

Returns the rollout scroll position. This is normally used internally -- see the note above in **SetRolloutOpen()**.

**Parameters:**

**MapID map\_id**

This parameter is available in release 4.0 and later only.  
Specifies the ID of the map/rollout to get scroll position for.

## ParamDlg Access

**Prototype:**

**virtual IAutoMParamDlg\* GetMParamDlg()=0;**

**Remarks:**

Returns a pointer to the automatic parameter dialog object for a plug-in material or texmap (which has its interface in the materias editor). See [Class IAutoMParamDlg](#).

**Prototype:**

**virtual IAutoEParamDlg\* GetEParamDlg()=0;**

**Remarks:**

Returns a pointer to the automatic parameter dialog object for the rendering effects plug-in. See [Class IAutoEParamDlg](#).

## MAXScript Default Parameter Initialization

**Prototype:**

**virtual void InitMSParameters()=0;**

**Remarks:**

This method initializes the parameters with MAXScript defaults.

The **ParamBlockDesc2** descriptor lets you specify default values for parameters (using the tag **p\_default**), and these get installed when you first create an object and its paramblocks. Sometimes, the default value needed for interactive creation is not the one you want when creating an object via the scripter. For example, a sphere should start out with radius 0 when you create it interactively, but you want a non-zero default if you create it in the scripter,

say with sphere(), otherwise it would be invisible. There is another tag, p\_ms\_default, that lets you set a separate default for scripter-based creation (the **p\_ms\_default** for sphere radius is 25). This method is used internally by the scripter to set the **p\_ms\_default** values in after a script-based creation. It is not normally used by plug-in developers.

## Alias Maintenance

### Prototype:

```
virtual void DefineParamAlias(TCHAR* alias_name, ParamID id, int tabIndex=-1)=0;
```

### Remarks:

This is used to allow parameter 'aliases' to be set up for MAXScript use. Individual Tab<> parameter elements can have aliases. This is used to set up dynamically-varying parameters, such as the texture maps in the new Standard material, which sets up aliases for elements in the texture map arrays.

### Parameters:

**TCHAR\* alias\_name**

The name of the alias.

**ParamID id**

The permanent ID of the parameter.

**int tabIndex=-1**

If the parameter is a Tab<> this is the zero based index of the parameter in the table.

### Prototype:

```
virtual ParamAlias* FindParamAlias(TCHAR* alias_name)=0;
```

### Remarks:

Returns a pointer to a [Structure ParamAlias](#) object which describes the parameter alias whose name is passed. This includes the name, ParamID and Tab<> index.

### Parameters:

**TCHAR\* alias\_name**

The name of the alias to find.

**Prototype:**

```
virtual TCHAR* FindParamAlias(ParamID id, int  
tabIndex=-1)=0;
```

**Remarks:**

Finds the name of a parameter alias using the ID and Tab<> index passed.

**Parameters:****ParamID id**

The permanent ID of the parameter.

**int tabIndex=-1**

If the parameter is a Tab<> this is the zero based index into the table. If not a Tab<> use the default of -1.

**Return Value:**

The name of the alias or NULL if not found.

**Prototype:**

```
virtual void ClearParamAliases()=0;
```

**Remarks:**

Breaks the association between the aliases and their parameters in this block.  
The method **ParamAliasCount()** below will return 0 following this call.

**Prototype:**

```
virtual int ParamAliasCount()=0;
```

**Remarks:**

Returns the number of aliases currently defined.

**Prototype:**

```
virtual ParamAlias* GetParamAlias(int i)=0;
```

**Remarks:**

Returns a pointer to the 'i-th' alias. See [Structure ParamAlias](#).

**Parameters:****int i**

The zero based index of the alias to return.

## SubAnim Numbering Related Methods

### Prototype:

```
virtual void SetSubAnimNum(ParamID id, int subAnimNum, int  
tabIndex=0)=0;
```

### Remarks:

This method allows for the arbitrary ordering of sub-anim numbers for parameters and Tab<> parameter elements. It sets the sub-anim number for the specified parameter.

This call lets you set arbitrary sub-anim number ordering for the subAnim parameters and Tab<> parameter elements in the block. You must set numbers for ALL subAnims and take care that all numbers are used. Note that in the case of the various ReferenceTarget\* parameter types, NULL values for any parameter or Tab<> elements are **not** included the subAnim count, so if such a parameter is made non-NULL (or vice-versa), you need to reassign the subanim numbers to take that change into account.

### Parameters:

#### **ParamID id**

The permanent parameter ID

#### **int subAnimNum**

The zero based sub-anim number.

#### **int tabIndex=0**

The zero based index into the table of the parameter.

### Prototype:

```
virtual void ClearSubAnimMap()=0;
```

### Remarks:

This method clears any sub-anim map used to allow arbitrary ordering of sub-anim numbers for parameters.

## Copying Parameter Values Between Blocks

### Prototype:

```
virtual void Assign(ParamID id, IParamBlock2* src, ParamID
```

**src\_id)=0;**

**Remarks:**

This method is used for copying parameter values between parameter blocks (which is useful during old-version updating). This method copies from the 'src' block 'src\_id' parameter into this parameter block's 'id' parameter. Developers are responsible for making sure the types are the same, otherwise an assert() may occur.

**Parameters:**

**ParamID id**

This ID specifies the destination parameter.

**IParamBlock2\* src**

Points to the source parameter block 2.

**ParamID src\_id**

The source parameter ID.

## **Finding Parameter IDs**

**Prototype:**

**virtual ParamID FindRefParam(ReferenceTarget\* ref, int& tabIndex)=0;**

**Remarks:**

This method that takes a reference target object **ref** stored somewhere in this parameter block and returns the ParamID and tabIndex of the containing parameter, or -1 if not found in the parameter block.

**Parameters:**

**ReferenceTarget\* ref**

The reference target to find.

**int& tabIndex**

The table index if the parameter is a Tab<>.

## **Reset To Default Values**

**Prototype:**

**virtual void ResetAll(BOOL updateUI = TRUE, BOOL**

**callSetHandlers = TRUE)=0;**

**Remarks:**

This method resets all the parameters in the block to their default values and optionally updates any associated ParamMap2 UI that is currently displaying the contents of the block. It also optionally causing all the PBAccessor Set() methods to be called after the reset.

**Parameters:**

**BOOL updateUI = TRUE**

TRUE to update the user interface; FALSE to not update.

**BOOL callSetHandlers = TRUE**

TRUE to call **PBAccessor::Set()** for all the parameters; otherwise FALSE.

**Prototype:**

**virtual void Reset(ParamID id, int tabIndex=-1, BOOL updateUI = TRUE, BOOL callSetHandlers = TRUE)=0;**

**Remarks:**

This method resets the single parameter specified to its default value. If the parameter is a Tab<> and the tabIndex is -1, all the elements in the table are reset.

**Parameters:**

**ParamID id**

The ID of the parameter to reset.

**int tabIndex=-1**

If the parameter is a Tab<> this is the index into the table of the parameter to reset. A value of -1 causes all the elements in the table to be reset.

**BOOL updateUI = TRUE**

Determines if the user interface is updated for the parameter. TRUE to update; FALSE to not update.

**BOOL callSetHandlers = TRUE**

Determines if the method **PBAccessor::Set()** should be called on the parameter. TRUE to call it; FALSE to not call it.

**PBAccessor Get / Set Methods**

**Prototype:**

**virtual void CallSet(ParamID id, int tabIndex=-1)=0;**

**Remarks:**

This method forces a call to the **PBAccessor::Set()** method for the specified parameter. If the parameter is a Tab<> parameter and the tabIndex is -1, all the elements have the appropriate functions called.

**Parameters:****ParamID id**

The ID of the parameter.

**int tabIndex=-1**

If the parameter is a Tab<> parameter this is the zero based index into the table of the element. A value of -1 causes all the appropriate **Set()** methods to be called.

**Prototype:**

**virtual void CallGet(ParamID id, int tabIndex=-1)=0;**

**Remarks:**

This method forces a call to the **PBAccessor::Get()** method for the specified parameter. If the parameter is a Tab<> parameter and the tabIndex is -1, all the elements have the appropriate functions called.

**Parameters:****ParamID id**

The ID of the parameter.

**int tabIndex=-1**

If the parameter is a Tab<> parameter this is the zero based index into the table of the element. A value of -1 causes all the appropriate **Get()** methods to be called.

**Prototype:**

**virtual void CallSets()=0;**

**Remarks:**

This method forces a call to the **PBAccessor::Set()** method for every parameter in the block. Any parameters which are Tab<> parameters will have

**Set()** call for every appropriate element.

**Prototype:**

**virtual void CallGets()=0;**

**Remarks:**

This method forces a call to the **PBAccessor::Get()** method for every parameter in the block. Any parameters which are Tab<> parameters will have **Get()** call for every appropriate element.

## **Validity of Parameters**

**Prototype:**

**virtual void GetValidity(TimeValue t, Interval &valid)=0;**

**Remarks:**

This method updates the validity interval passed with the cumulative interval for every parameter in the parameter block.

**Parameters:**

**TimeValue t**

The time about which the interval is computed.

**Interval &valid**

The interval to update.

## Class IParamMap

See Also:, [Parameter Maps](#), [Class ParamMapUserDlgProc](#), [Class ParamUIDesc](#), [Parameter Blocks](#), [Class IParamArray](#), [Class Interface](#).

### Description:

This class provides methods to work with parameter maps. These are things like invalidating the parameter map so it gets redrawn, working with the parameter blocks associated with the parameter map, and establishing an optional dialog proc to handle controls not directly handled by the pmap. This section also documents several functions that are available for creating and destroying parameter maps but are not part of this class.

Note: The use of this class requires the explicit inclusion the **IPARAMM.H** header file.

The following functions are not part of this class but are available to create the parameter maps:

**Prototype:**

```
IParamMap *CreateCPPParamMap(ParamUIDesc *desc,int  
count,IParamArray *pb,Interface *ip,HINSTANCE  
hInst,TCHAR *dlgTemplate,TCHAR *title,DWORD flags);
```

**Remarks:**

Creates a parameter map to handle the display of parameters in the command panel. This will add the rollup page to the command panel.

**Parameters:**

**ParamUIDesc \*desc**

The array of ParamUIDescs, one element for each control to be managed.

**int count**

The number of items in the array above.

**IParamArray \*pb**

Pointer to an instance of the class IParamArray. This is the pointer to the [= 4\) BSPSPopupOnMouseOver\(event\);">virtual array](#) of parameters.

**Interface \*ip**

The interface pointer passed into the BeginEditParams() method.

**HINSTANCE hInst**

The DLL instance handle of the plug-in

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A set of flags to control settings of the rollup page.

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**Return Value:**

A pointer to the parameter map that is created.

**Prototype:**

**IParamMap \*ReplaceCPPParamMap(HWND oldhw, ParamUIDesc \*desc,int count, IParamArray \*pb, Interface \*ip, HINSTANCE hInst, TCHAR \*dlgTemplate, TCHAR \*title, DWORD flags);**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows one to switch rollups in the command panel. It creates the new parameter map and calls **Interface:: ReplaceRollupPage()**.

**Parameters:****HWND oldhw**

The window handle of the old rollup.

**ParamUIDesc \*desc**

The array of ParamUIDescs, one element for each control to be managed.

**int count**

The number of items in the array above.

**IParamArray \*pb**

Pointer to an instance of the class IParamArray. This is the pointer to the virtual array of parameters.

**Interface \*ip**

The interface pointer passed into the BeginEditParams() method.

**HINSTANCE hInst**

The DLL instance handle of the plug-in

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A set of flags to control settings of the rollup page.

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**Return Value:**

A pointer to the parameter map that is created.

**Prototype:**

```
void DestroyCPPParamMap(IParamMap *m);
```

**Remarks:**

This function destroys a command panel parameter map. The rollup page from the command panel is removed and the parameter map is deleted.

**Parameters:**

**IParamMap \*m**

A pointer to the parameter map to destroy.

**Prototype:**

```
BOOL CreateModalParamMap(ParamUIDesc *desc,int  
count,IParamArray *pb,TimeValue t,HINSTANCE hInst,TCHAR  
*dlgTemplate,HWND hParent,ParamMapUserDlgProc  
*proc=NULL);
```

**Remarks:**

This function creates a parameter map that will handle a parameter block in a modal dialog where time does not change and the viewport is not redrawn. Note that there is no need to destroy it. It executes the dialog and then destroys itself.

**Parameters:**

**ParamUIDesc \*desc**

The array of ParamUIDescs, one element for each control to be managed.

**int count**

The number of items in the array above.

**IParamArray \*pb**

Pointer to an instance of the class IParamArray. This is the pointer to the [= 4\) BSPSPopupOnMouseOver\(event\);">virtual array](#) of parameters.

**TimeValue t**

This is just the current time when the user is bringing up the dialog.

**HINSTANCE hInst**

The DLL instance handle of the plug-in

**TCHAR \*dlgTemplate**

Dialog template for the dialog box.

## **HWND hParent**

The parent window handle.

## **ParamMapUserDlgProc \*proc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from **ParamMapUserDlgProc** and set it as the parameter map's user callback. See [Class ParamMapUserDlgProc](#).

## **Return Value:**

TRUE if the user selected OK; otherwise FALSE.

## **Prototype:**

```
IParamMap *CreateRParamMap(ParamUIDesc *desc,int  
count,IParamArray *pb, IRenderParams *ip, HINSTANCE  
hInst,TCHAR *dlgTemplate, TCHAR *title, DWORD flags);
```

## **Remarks:**

This function creates a parameter map to handle the display of render parameters or atmospheric plug-in parameters.

## **Parameters:**

### **ParamUIDesc \*desc**

The array of ParamUIDescs, one element for each control to be managed.

### **int count**

The number of items in the array above.

### **IParamArray \*pb**

Pointer to an instance of the class IParamArray. This is the pointer to the array of parameters.

### **IRenderParams \*ip**

The interface pointer passed into **CreateParamDlg()**.

### **HINSTANCE hInst**

The DLL instance handle of the plug-in

### **TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

### **TCHAR \*title**

The title displayed in the rollup page title bar.

### **DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**Return Value:**

A pointer to the parameter map that is created.

**Prototype:**

**void DestroyRParamMap(IParamMap \*m);**

**Remarks:**

This function destroys a parameter map created by **CreateRParamMap()**. The rollup page is removed and the parameter map is deleted.

**Parameters:**

**IParamMap \*m**

A pointer to the parameter map to destroy.

**Prototype:**

**IParamMap \*CreateMParamMap(ParamUIDesc \*desc, int count, IParamArray \*pb, IMtlParams \*ip, HINSTANCE hInst, TCHAR \*dlgTemplate, TCHAR \*title, DWORD flags);**

**Remarks:**

This function is available in release 2.0 and later only.

This function creates a parameter map to handle the display of texture map or material parameters in the material editor.

**Parameters:**

**ParamUIDesc \*desc**

The array of ParamUIDescs, one element for each control to be managed.

**int count**

The number of items in the array above.

**IParamArray \*pb**

Pointer to an instance of the class IParamArray. This is the pointer to the array of parameters.

**IMtlParams \*ip**

The interface pointer. See [Class IMtlParams](#).

**HINSTANCE hInst**

The DLL instance handle of the plug-in

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**Return Value:**

A pointer to the parameter map that is created.

**Prototype:**

**void DestroyMParamMap(IParamMap \*m);**

**Remarks:**

This function is available in release 2.0 and later only.

This function destroys a parameter map created by **CreateMParamMap()**.

The rollup page is removed and the parameter map is deleted.

**Parameters:**

**IParamMap \*m**

A pointer to the parameter map to destroy.

**Methods:**

**Prototype:**

**void Invalidate()**

**Remarks:**

Implemented by the System.

Call this method to update (redraw) the user interface controls. This marks the UI controls as needing to be updated and the parameter map will take care of it.

**Prototype:**

```
void SetParamBlock(IParamArray *pb)
```

**Remarks:**

Implemented by the System.

This method swaps the existing parameter block with a new one and updates the user interface. Consider the following example to understand how this is used: If a user is in create mode, and has created a sphere object, and then goes to create another sphere, the user interface stays up. The parameter map that manages the UI is not deleted. When the user creates the second sphere, the parameter map needs to refer to the new sphere's parameter block (not the previous one any longer). This method is used to set the parameter map to point to the new parameter block.

**Parameters:**

```
IParamArray *pb
```

A pointer to the new parameter block.

**Prototype:**

```
void SetUserDlgProc(ParamMapUserDlgProc *proc=NULL)
```

**Remarks:**

Implemented by the System.

This method allows the developer to provide special handling for a control. The developer provides a dialog proc to process the message from the control. This method is used to tell the parameter map that the developer defined method should be called. The given proc will be called **after** default processing is done. Note that if the proc is non-NULL when the ParamMap is deleted its **DeleteThis()** method will be called.

**Parameters:**

```
ParamMapUserDlgProc *proc=NULL
```

A pointer to the user dialog proc class to process the control.

**Prototype:**

```
virtual void SetPBlockIndex(int mapIndex, int blockIndex)=0;
```

**Remarks:**

Implemented by the System.

This method changes a parameter map entry to refer to a different item in the parameter block. This is used for example by the Optimize modifier. This modifier has two sets of parameters that may be adjusted (L1 and L2).

Optimize only maintains a single parameter block however. This pblock contains both sets of parameters. When the user switches between these two sets, this method is called to point the UI controls at different indices in the parameter block.

**Parameters:**

**int mapIndex**

The map entry to change.

**int blockIndex**

The new parameter block index.

**Prototype:**

**HWND GetHWnd()**

**Remarks:**

Implemented by the System.

Returns the window handle of the rollup page (or dialog).

**Prototype:**

**IParamArray \*GetParamBlock()**

**Remarks:**

Implemented by the System.

Returns a pointer to the parameter block managed by the parameter map.

## Class IParamMap2

See Also: [Class IParamBlock2](#), [Class ParamBlockDesc2](#), [Class ParamMap2UserDlgProc](#).

```
class IParamMap2 : public InterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This class provides methods to work with parameter map2s. Methods are provided for things like invalidating the parameter map so it gets redrawn, working with the parameter blocks associated with the parameter map, and establishing an optional dialog proc to handle controls not directly handled by the parameter map. This section also documents several functions that are available for creating and destroying parameter maps but are not part of this class.

Note: The use of this class requires the explicit inclusion the IPARAMM2.H header file.

### Methods:

#### Prototype:

```
virtual void Invalidate()=0;
```

#### Remarks:

This method marks the user interface as needing to be updated. This affects the entire UI for the parameter map.

#### Prototype:

```
virtual void Validate()=0;
```

#### Remarks:

This methods un-invalidates the entire user interface.

#### Prototype:

```
virtual void Invalidate(ParamID id, int tabIndex=0)=0;
```

#### Remarks:

This methods marks a specific control in the UI as requiring an update.

**Parameters:****ParamID id**

The permanent ID of the control requiring an update.

**int tabIndex=0**

If the control is a Tab<> then this is the zero based index into the table of the value to be invalidated.

**Prototype:**

**virtual Interval& Validity()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Provides access to pmap's validity interval. Returns a reference to the actual interval so it can be modified if desired.

**Prototype:**

**virtual void UpdateUI(TimeValue t)=0;**

**Remarks:**

This method will update the user interface if the current settings are not valid at the given time (i.e., if anything is animated at that time).

**Parameters:****TimeValue t**

The time to check for the update.

**Prototype:**

**virtual void RedrawViews(TimeValue t, DWORD  
flag=REDRAW\_NORMAL)=0;**

**Remarks:**

This method may be called to cause the viewports to be redrawn.

**Parameters:****TimeValue t**

The time at which to redraw the viewports.

**DWORD flag=REDRAW\_NORMAL**

You may specify one of the following:

**REDRAW\_BEGIN**

Call this before you redraw.

**REDRAW\_INTERACTIVE**

This allows the view quality to degrade to maintain interactivity.

**REDRAW\_END**

If during interactive redraw the state degraded, this will redraw the views in the undegraded state.

**REDRAW\_NORMAL**

This redraws the views in the undegraded state.

**Prototype:**

**virtual void SetParamBlock(IParamBlock2 \*pb)=0;**

**Remarks:**

This method swaps the existing parameter block with a new one and updates user interface.

**Parameters:**

**IParamBlock2 \*pb**

Points to the new parameter block2 to use.

**Prototype:**

**virtual void SetUserDlgProc(ParamMap2UserDlgProc \*proc=NULL)=0;**

**Remarks:**

This method allows a developer to provide special handling for one or more controls. The developer provides a dialog proc to process the message from the control. This method is used to tell the parameter map that the developer defined method should be called. The given proc will be called after default processing is done. Note that if the proc is non-NULL when the ParamMap2 is deleted its DeleteThis() method will be called.

**Parameters:**

**ParamMap2UserDlgProc \*proc=NULL**

Points to the user dialog proc object to process the controls.

**Prototype:**

**virtual ParamMap2UserDlgProc \*GetUserDlgProc()=0;**

**Remarks:**

Returns a pointer to the user dialog proc for the parameter map (or NULL if none is defined). See **SetUserDlgProc()** above.

**Prototype:**

**virtual void ReplaceParam(ParamID curParam, ParamID newParam);**

**Remarks:**

This method changes a parameter map entry to refer to a different item in the parameter block.

**Parameters:**

**ParamID curParam**

The parameter ID of the item to change.

**ParamID newParam**

The new parameter ID.

**Prototype:**

**virtual HWND GetHwnd()=0;**

**Remarks:**

Returns the dialog window handle of the parameter map.

**Function:**

**virtual MapID GetMapID()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the parameter map's ID.

**Prototype:**

**virtual IParamBlock2 \*GetParamBlock()=0;**

**Remarks:**

Returns a pointer to the parameter block2 used by this parameter map.

**Prototype:**

**virtual BOOL DlgActive()=0;**

**Remarks:**

Returns TRUE if the parameter map dialog proc is active; otherwise FALSE.

**Prototype:**

**virtual ParamBlockDesc2\* GetDesc()=0;**

**Remarks:**

Returns a pointer to the ParamBlockDesc2 instance for this parameter map.

**Prototype:**

**virtual void ActivateDlg(BOOL onOff)=0;**

**Remarks:**

This method is called to indicate the dialog is going inactive or is becoming active.

**Parameters:**

**BOOL onOff**

TRUE if becoming active; FALSE for inactive.

**Prototype:**

**virtual int FindSubTexFromHWND(HWND hw)=0;**

**Remarks:**

This method is sent to a Material Editor map to find the SubTex index corresponding to the control handle. It should return the index of the sub-  
texmap corresponding to the window whose handle is passed. If the handle is not valid return -1.

**Parameters:**

**HWND hw**

The window handle of the control.

**Prototype:**

```
virtual void Enable(ParamID id, BOOL onOff, int tabIndex=0)=0;
```

**Remarks:**

This method is used to enable or disable an individual user interface control.

**Parameters:****ParamID id**

The parameter ID of the control to enable/disable.

**BOOL onOff**

TRUE to enable; FALSE to disable.

**int tabIndex=0**

If the control is a Tab<> then this is the zero based index in the table of the item to enable/disable.

**Prototype:**

```
virtual void SetText(ParamID id, TCHAR* txt, int tabIndex=0)=0;
```

**Remarks:**

This method sets the text of a parameter user interface control.

**Parameters:****ParamID id**

The ID of the parameter whose user interface text to change.

**TCHAR\* txt**

The new string to display.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index of the parameter in the table.

**Prototype:**

```
virtual void SetTooltip(ParamID id, BOOL onOf, TCHAR* txt, int  
tabIndex=0)=0;
```

**Remarks:**

This method sets the tooltip text of specified parameter and can turn the tooltip on or off.

**Parameters:****ParamID id**

The ID of the parameter.

**BOOL onOf**

TRUE for on; FALSE for off.

**TCHAR\* txt**

The tool tip text.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index of the parameter in the table.

**Prototype:**

```
virtual void SetRange(ParamID id, float low, float high, int  
tabIndex=0)=0;
```

**Remarks:**

This method sets the range of parameter for a spinner or slider control.

**Parameters:****ParamID id**

The ID of the parameter.

**float low**

The low range for the spinner / slider.

**float high**

The high range for the spinner / slider.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index of the parameter in the table.

**Prototype:**

```
virtual void Show(ParamID id, BOOL showHide, int  
tabIndex=0)=0;
```

**Remarks:**

This method will show or hide the specified control.

**Parameters:****ParamID id**

The ID of the parameter.

**BOOL showHide**

TRUE to show; FALSE to hide.

**int tabIndex=0**

If the parameter is a Tab<> this is the zero based index of the parameter in the table.

**Prototype:**

```
virtual void SetThing(ReferenceTarget *m)=0;
```

**Remarks:**

This method is called by any **IAutoXXParamDlg** when it receives a **SetThing()**.

**Parameters:****ReferenceTarget \*m**

The item which was set.

**The following functions are not part of this class but are available for use.**

**Function:**

```
BOOL CreateModalParamMap2(IParamBlock2 *pb, TimeValue t,  
HINSTANCE hInst, TCHAR *dlgTemplate, HWND hParent,  
ParamMap2UserDlgProc *proc=NULL);
```

**Remarks:**

This function creates a parameter map that will handle a parameter block in a modeless dialog where time does not change and the viewports are not redrawn. Note that there is no need to destroy it. It executes the dialog and then destroys itself.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateModalParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**TimeValue t**

The time at which the dialog is launched.

**HINSTANCE hInst**

The plug-ins instance handle.

**TCHAR \*dlgTemplate**

The dialog template.

**HWND hParent**

The parent window.

**ParamMap2UserDlgProc \*proc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns TRUE if the user selected OK, FALSE otherwise.

**Function:**

```
BOOL CreateModalParamMap2(IParamBlock2 *pb, TimeValue t,  
HINSTANCE hInst, DLGTEMPLATE *dlgTemplate, HWND  
hParent, ParamMap2UserDlgProc *proc=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

This function creates a parameter map that will handle a parameter block in a modeless dialog where time does not change and the viewports are not redrawn. Note that there is no need to destroy it. It executes the dialog and then destroys itself. This function is currently not in use.

**Parameters:****IParamBlock2 \*pb**

Points to the parameter block2.

**TimeValue t**

The time at which the dialog is launched.

**HINSTANCE hInst**

The plug-ins instance handle.

**DLGTEMPLATE \*dlgTemplate**

The dialog template.

**HWND hParent**

The parent window.

**ParamMap2UserDlgProc \*proc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns TRUE if the user selected OK, FALSE otherwise.

**Function:**

```
BOOL CreateModalParamMap2(MapID map_id, IParamBlock2  
*pb, TimeValue t, HINSTANCE hInst, TCHAR *dlgTemplate,  
HWND hParent, ParamMap2UserDlgProc *proc=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map that will handle a parameter block in a modeless dialog where time does not change and the viewports are not redrawn. This overload of **CreateModalParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

```
IParamMap2 *CreateCPPParamMap2(IParamBlock2 *pb,  
Interface *ip, HINSTANCE hInst, TCHAR *dlgTemplate,  
TCHAR *title, DWORD flags, ParamMap2UserDlgProc*  
dlgProc=NULL, HWND hOldRollup=NULL, int category =  
ROLLUP_CAT_STANDARD);
```

**Remarks:**

This function creates a parameter map to handle the display of parameters in the command panel. This will add a rollup page to the command panel (or optionally replace an existing one).

Note, in version 4.0 and later, this actually maps to a call on the explicit map

ID overload of **CreateCPPParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**Interface \*ip**

Pass in the plug-ins interface pointer.

**HINSTANCE hInst**

The plug-ins instance handle.

**TCHAR \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**ParamMap2UserDlgProc\* dlgProc=NULL,**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**HWND hOldRollup=NULL**

If non-NULL specifies an existing rollup window in the current UI context that should be replaced with the newly created rollup for this map.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

Returns a pointer to the parameter map2.

**Function:**

```
IParamMap2 *CreateCPPParamMap2(IParamBlock2 *pb,  
Interface *ip, HINSTANCE hInst, DLGTEMPLATE  
*dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL, HWND  
hOldRollup=NULL, int category = ROLLUP_CAT_STANDARD);
```

**Remarks:**

This function is available in release 4.0 and later only.

This function creates a parameter map to handle the display of parameters in the command panel. This will add a rollup page to the command panel (or optionally replace an existing one). This function is currently not used.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**Interface \*ip**

Pass in the plug-ins interface pointer.

**HINSTANCE hInst**

The plug-ins instance handle.

**TCHAR \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**ParamMap2UserDlgProc\* dlgProc=NULL,**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**HWND hOldRollup=NULL**

If non-NULL specifies an existing rollup window in the current UI context that should be replaced with the newly created rollup for this map.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

Returns a pointer to the parameter map2.

**Function:**

```
IParamMap2 *CreateCPPParamMap2(MapID map_id,  
IParamBlock2 *pb, Interface *ip, HINSTANCE hInst, TCHAR  
*dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL, HWND  
hOldRollup=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map to handle the display of parameters in the command panel. This overload of **CreateCPPParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

```
void DestroyCPPParamMap2(IParamMap2 *m);
```

**Remarks:**

This function destroys a parameter map created by **CreateCParamMap2()**. The rollup page is removed and the parameter map is deleted.

**Parameters:**

**IParamMap2 \*m**

A pointer to the parameter map2 to delete.

**Function:**

```
IParamMap2 *CreateChildCPPParamMap2(IParamBlock2 *pb,  
Interface *ip, HINSTANCE hInst, IParamMap2* parent, TCHAR  
*dlgTemplate, TCHAR *title, ParamMap2UserDlgProc*  
dlgProc=NULL);
```

**Remarks:**

This function creates a child dialog of the given parent parammap (for tabbed dialogs, etc.). This version takes an extra parent IParamMap2\* and creates a child dialog window in the parent parammap's window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateChildCPPParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**Interface \*ip**

Pass in the plug-ins rendering parameters interface pointer.

**HINSTANCE hInst**

The plug-ins instance handle.

**IParamMap2\* parent**

The parent parameter map.

**TCHAR \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns a pointer to the parameter map2.

**Function:**

**IParamMap2 \*CreateChildCPPParamMap2(IParamBlock2 \*pb, Interface \*ip, HINSTANCE hInst, IParamMap2\* parent, DLGTEMPLATE \*dlgTemplate, TCHAR \*title, ParamMap2UserDlgProc\* dlgProc=NULL);**

**Remarks:**

This function is available in release 4.0 and later only.

This function creates a child dialog of the given parent parammap (for tabbed dialogs, etc.). This version takes an extra parent IParamMap2\* and creates a child dialog window in the parent parammap's window (rather than a new rollout) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms. This function is currently not used.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

### **Interface \*ip**

Pass in the plug-ins rendering parameters interface pointer.

### **HINSTANCE hInst**

The plug-ins instance handle.

### **IParamMap2\* parent**

The parent parameter map.

### **TCHAR \*dlgTemplate**

The dialog template.

### **TCHAR \*title**

The title displayed.

### **ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

### **Return Value:**

Returns a pointer to the parameter map2.

### **Function:**

```
IParamMap2 *CreateChildCPPParamMap2(MapID map_id,  
IParamBlock2 *pb, Interface *ip, HINSTANCE hInst,  
IParamMap2* parent, TCHAR *dlgTemplate, TCHAR *title,  
ParamMap2UserDlgProc* dlgProc=NULL);
```

### **Remarks:**

This function is available in release 4.0 and later only.

Create a child dialog of the given parent command panel parammap (for tabbed dialogs, etc.) This overload of **CreateChildCPPParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

### **Function:**

```
void DestroyChildCPPParamMap2(IParamMap2 *m);
```

### **Remarks:**

This function destroys a parameter map created by **CreateChildCPPParamMap2()**.

**Parameters:**

**IParamMap2 \*m**

Points to the parameter map2 to destroy.

**Function:**

**IParamMap2 \*CreateRParamMap2(IParamBlock2 \*pb, IRenderParams \*ip, HINSTANCE hInst, TCHAR \*dlgTemplate, TCHAR \*title, DWORD flags, ParamMap2UserDlgProc\* dlgProc=NULL, int category = ROLLUP\_CAT\_STANDARD);**

**Remarks:**

Creates a parameter map to handle the display of render parameters or atmospheric plug-in parameters.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateRParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IRenderParams \*ip**

Pass in the plug-ins rendering parameters interface pointer. See [Class IRenderParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**TCHAR \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

## **ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

## **int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USERREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

### **Return Value:**

Returns a pointer to the parameter map2.

### **Function:**

```
IParamMap2 *CreateRParamMap2(IParamBlock2 *pb,  
IRenderParams *ip, HINSTANCE hInst, DLGTEMPLATE  
*dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL, int category =  
ROLLUP_CAT_STANDARD);
```

### **Remarks:**

Creates a parameter map to handle the display of render parameters or atmospheric plug-in parameters.

### **Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IRendParams \*ip**

Pass in the plug-ins rendering parameters interface pointer. See [Class IRendParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**DLGTEMPLATE \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

Returns a pointer to the parameter map2.

**Function:**

```
IParamMap2 *CreateRParamMap2(MapID map_id,  
IParamBlock2 *pb, IRendParams *ip, HINSTANCE hInst,  
TCHAR *dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map to handle the display of render parameters or atmospheric plug-in parameters. This overload of **CreateRParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

```
void DestroyRParamMap2(IParamMap2 *m);
```

**Remarks:**

This function is available in release 3.0 and later only.

This function destroys a parameter map created by **CreateRParamMap2()**. The rollup page is removed and the parameter map is deleted.

**Parameters:**

```
IParamMap2 *m
```

Points to the parameter map2 to destroy.

**Function:**

```
IParamMap2* CreateChildRParamMap2(IParamBlock2 *pb,  
IRendParams *ip, HINSTANCE hInst, IParamMap2* parent,  
TCHAR *dlgTemplate, TCHAR *title, ParamMap2UserDlgProc*  
dlgProc=NULL);
```

**Remarks:**

This function create a parameter map for render or atmospheric parameters in a child dialog window of the given parammap, used typically to create tab child windows in a tabbed rollout. This version takes an extra parent **IParamMap2\*** and creates a child dialog window in the parent parammap's

window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateChildRParamMap2()** with default map ID of 0.

#### **Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IRendParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IRendParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**IParamMap2\* parent**

The parent parameter map.

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the dialog.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

#### **Return Value:**

Returns a pointer to the parameter map2 created.

#### **Function:**

```
IParamMap2* CreateChildRParamMap2(IParamBlock2 *pb,  
IRendParams *ip, HINSTANCE hInst, IParamMap2* parent,  
DLGTEMPLATE *dlgTemplate, TCHAR *title,  
ParamMap2UserDlgProc* dlgProc=NULL);
```

#### **Remarks:**

This function is available in release 4.0 and later only.

This function create a parameter map for render or atmospheric parameters in a child dialog window of the given parent parammap, used typically to create tab child windows in a tabbed rollout. This version takes an extra parent `IParamMap2*` and creates a child dialog window in the parent parammap's window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the `P_AUTO_UI` mechanisms. This function is currently not being used.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IRendParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IRendParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**IParamMap2\* parent**

The parent parameter map.

**DLGTEMPLATE \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the dialog.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from `ParamMap2UserDlgProc` and set it as the parameter map's user callback.

**Return Value:**

Returns a pointer to the parameter map2 created.

**Function:**

**IParamMap2\* CreateChildRParamMap2(MapID map\_id, IParamBlock2 \*pb, IRendParams \*ip, HINSTANCE hInst, IParamMap2\* parent, TCHAR \*dlgTemplate, TCHAR \*title,**

**ParamMap2UserDlgProc\* dlgProc=NULL);**

**Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map for render or atmospheric parameters in a child dialog window of the given parent parammap. This overload of

**CreateChildRParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

**void DestroyChildRParamMap2(IParamMap2 \*m);**

**Remarks:**

This function destroys a parameter map created by **CreateChildRParamMap2()**.

**Parameters:**

**IParamMap2 \*m**

Points to the parameter map2 to destroy.

**Function:**

**IParamMap2 \*CreateMParamMap2(IParamBlock2 \*pb, IMtlParams \*ip, HINSTANCE hInst, HWND hmedit, TexDADMgr\* dad, MtlDADMgr\* mdad, TCHAR \*dlgTemplate, TCHAR \*title, DWORD flags, ParamMap2UserDlgProc\* dlgProc=NULL, HWND hOldRollup=NULL, int category = ROLLUP\_CAT\_STANDARD);**

**Remarks:**

Creates a parameter map to handle the display of texture map or material parameters in the material editor.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateMParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IMtlParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IMtlParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**HWND hmedit**

The window handle to the materials editor.

**TexDADMgr\* dad**

Points to the manager used to handle drag and drop of textures. See [Class TexDADMgr](#).

**MtlDADMgr\* mdad**

Points to the manager used to handle drag and drop of materials. See [Class MtlDADMgr](#).

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**HWND hOldRollup=NULL**

If non-NULL specifies an existing rollup window in the current UI context that should be replaced with the newly created rollup for this map.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there

exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

#### **Return Value:**

Returns a pointer to the parameter map2 created.

#### **Function:**

```
IParamMap2 *CreateMParamMap2(IParamBlock2 *pb,  
IMtlParams *ip, HINSTANCE hInst, HWND hmedit,  
TexDADMgr* dad, MtlDADMgr* mdad, DLGTEMPLATE  
*dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL, HWND  
hOldRollup=NULL, int category = ROLLUP_CAT_STANDARD);
```

#### **Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map to handle the display of texture map or material parameters in the material editor. This function is currently not in use.

#### **Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IMtlParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IMtlParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**HWND hmedit**

The window handle to the materials editor.

**TexDADMgr\* dad**

Points to the manager used to handle drag and drop of textures. See [Class TexDADMgr](#).

**MtlDADMgr\* mdad**

Points to the manager used to handle drag and drop of materials. See [Class MtlDADMgr](#).

**DLGTEMPLATE \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the rollup page title bar.

**DWORD flags**

A flag to control the settings of the rollup page:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**HWND hOldRollup=NULL**

If non-NULL specifies an existing rollup window in the current UI context that should be replaced with the newly created rollup for this map.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags

argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

Returns a pointer to the parameter map2 created.

**Function:**

```
IParamMap2 *CreateMParamMap2(MapID map_id,  
IParamBlock2 *pb, IMtlParams *ip, HINSTANCE hInst, HWND  
hmedit, TexDADMgr* dad, MtlDADMgr* mdad, TCHAR  
*dlgTemplate, TCHAR *title, DWORD flags,  
ParamMap2UserDlgProc* dlgProc=NULL, HWND  
hOldRollup=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

Creates a parameter map to handle the display of texture map or material parameters in the material editor. This overload of **CreateMParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

```
void DestroyMParamMap2(IParamMap2 *m);
```

**Remarks:**

This function destroys a parameter map created by **CreateMParamMap2()**. The rollup page is removed and the parameter map is deleted.

**Parameters:**

```
IParamMap2 *m
```

Points to the parameter map2 to destroy.

**Function:**

```
IParamMap2 *CreateChildMParamMap2(IParamBlock2 *pb,  
IMtlParams *ip, HINSTANCE hInst, IParamMap2* parent,  
TexDADMgr* tdad, MtlDADMgr* mdad, TCHAR *dlgTemplate,
```

**TCHAR \*title, ParamMap2UserDlgProc\* dlgProc=NULL);**

**Remarks:**

This function creates and returns a child dialog of the given parent parammap (for tabbed dialogs, etc.). This version takes an extra parent IParamMap2\* and create a child dialog window in the parent parammap's window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms.

Note, in version 4.0 and later, this actually maps to a call on the explicit map ID overload of **CreateChildMParamMap2()** with default map ID of 0.

**Parameters:**

**IParamBlock2 \*pb**

Points to the parameter block2.

**IMtlParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IMtlParams\\_](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**IParamMap2\* parent**

The parent parameter map.

**TexDADMgr\* tdad**

Points to the manager used to handle drag and drop of textures. See [Class TexDADMgr](#).

**MtlDADMgr\* mdad**

Points to the manager used to handle drag and drop of materials. See [Class MtlDADMgr\\_](#).

**TCHAR \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the dialog.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns a pointer to the parameter map2 created.

**Function:**

```
IParamMap2 *CreateChildMParamMap2(IParamBlock2 *pb,  
IMtlParams *ip, HINSTANCE hInst, IParamMap2* parent,  
TexDADMgr* tdad, MtlDADMgr* mdad, TCHAR *dlgTemplate,  
TCHAR *title, ParamMap2UserDlgProc* dlgProc=NULL);
```

**Remarks:**

This function is available in release 4.0 and later only.

This function creates and returns a child dialog of the given parent parammap (for tabbed dialogs, etc.). This version takes an extra parent IParamMap2\* and create a child dialog window in the parent parammap's window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms. This function is currently not being used.

**Parameters:****IParamBlock2 \*pb**

Points to the parameter block2.

**IMtlParams \*ip**

Pass in the plug-ins material parameters interface pointer. See [Class IMtlParams](#).

**HINSTANCE hInst**

The plug-ins instance handle.

**IParamMap2\* parent**

The parent parameter map.

**TexDADMgr\* tdad**

Points to the manager used to handle drag and drop of textures. See [Class TexDADMgr](#).

**MtlDADMgr\* mdad**

Points to the manager used to handle drag and drop of materials. See [Class MtlDADMgr](#).

**DLGTEMPLATE \*dlgTemplate**

Dialog template for the rollup page (created using the resource editor)

**TCHAR \*title**

The title displayed in the dialog.

**ParamMap2UserDlgProc\* dlgProc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns a pointer to the parameter map2 created.

**Function:**

**IParamMap2 \*CreateChildMParamMap2(IParamBlock2 \*pb, IMtlParams \*ip, HINSTANCE hInst, IParamMap2\* parent, TexDADMgr\* tdad, MtlDADMgr\* mdad, TCHAR \*dlgTemplate, TCHAR \*title, ParamMap2UserDlgProc\* dlgProc=NULL);**

**Remarks:**

This function is available in release 4.0 and later only.

Creates and returns a child dialog of the given material or texture map parent parammap (for tabbed dialogs, etc.) This overload of

**CreateChildMParamMap2()** has a new parameter, **map\_id**, that specifies the ID of the parameter map/rollup to be created for this particular parameter block. See original function for the rest of the description.

**Function:**

**void DestroyChildMParamMap2(IParamMap2 \*m);**

**Remarks:**

This function destroys a parameter map created by **CreateChildMParamMap2()**.

**Parameters:**

**IParamMap2 \*m**

Points to the parameter map2 to destroy.

**Function:**

**BOOL CreateChildModalParamMap2(MapID map\_id,**

**IParmBlock2 \*pb, HINSTANCE hInst, IParmMap2 \*parent, TCHAR \*dlgTemplate, TCHAR \*title, ParamMap2UserDlgProc \*proc=NULL);**

**Remarks:**

This function is available in release 4.0 and later only.

This function creates a child dialog of the given modal parent parammap (for tabbed dialogs, etc.). Unlike modal parent parammap, you do not need to destroy it. This version takes an extra parent IParmMap2\* and creates a child dialog window in the parent parammap's window (rather than a new rollup) that is mapped by the new parammap. Developers need to call this explicitly once the parent parammap has been created as child parammaps are not created automatically by the **P\_AUTO\_UI** mechanisms.

**Parameters:**

**MapID map\_id**

Specifies the ID of the parameter map/rollup to be created for this particular parameter block.

**IParmBlock2 \*pb**

Points to the parameter block2.

**HINSTANCE hInst**

The plug-ins instance handle.

**IParmMap2\* parent**

The parent parameter map.

**TCHAR \*dlgTemplate**

The dialog template.

**TCHAR \*title**

The title displayed in the dialog.

**ParamMap2UserDlgProc \*proc=NULL**

If there is some custom handling required by a particular control, the client can derive a class from ParamMap2UserDlgProc and set it as the parameter map's user callback.

**Return Value:**

Returns TRUE if the user selected OK, FALSE otherwise.

**Function:**

**BOOL CreateChildModalParamMap2(IParamBlock2 \*pb,  
HINSTANCE hInst, IParamMap2 \*parent, TCHAR  
\*dlgTemplate, TCHAR \*title, ParamMap2UserDlgProc  
\*proc=NULL);**

**Remarks:**

This function is available in release 4.0 and later only.

This is an overload that simply calls the explicit map ID version of **CreateChildMParamMap2()** with default map ID of 0. See that version for description.

**Function:**

**void DestroyChildModalParamMap2(IParamMap2 \*m);**

**Remarks:**

This function destroys a parameter map created by **CreateChildModalParamMap2()**.

**Parameters:**

**IParamMap2 \*m**

Points to the parameter map2 to destroy.

# Class Face

See Also: [Class Mesh](#).

class Face

## Description:

This class represents a single triangular face. The class maintains three indices into the vertex list for the face, a 32-bit smoothing group for the face, and 32-bits of face flags. The flags also store information about the visibility of the face, the visibility of the three edges, and whether or not the face has texture vertices present. The most significant 16-bits of the face flags store the material index. All methods of this class are implemented by the system.

## Data Members:

public:

**DWORD v[3];**

These are 0 based indices into a mesh object's array of vertices.

**DWORD smGroup;**

Smoothing group bits for the face.

Each bit of this 32 bit value represents membership in a smoothing group. The least significant bit represents smoothing group #1 while the most significant bit represents group #32. If two adjacent faces are assigned the same smoothing group bit, the edge between them is rendered smoothly.

**DWORD flags;**

The Face Flags:

Edge visibility bits: If the bit is 1, the edge is visible.

**EDGE\_A**

**EDGE\_B**

**EDGE\_C**

**EDGE\_ALL (EDGE\_A|EDGE\_B|EDGE\_C)**

Face visibility bit: If the bit is 1, the face is hidden.

**FACE\_HIDDEN**

Texture vertices bit: If the bit is 1, texture vertices are present. **FROM R5 THIS IS NOW OBSOLETE. YOU CAN USE MAPSUPPORT METHODS INSTEAD**

## **HAS\_TVERTS**

The material ID is stored in the HIWORD of the face flags.

## **FACE\_MATID\_SHIFT**

This is the number of bits to shift the flags to access the material.

## **FACE\_MATID\_MASK**

This is a mask used to access the material ID.

### **Methods:**

#### **Prototype:**

**Face()**

#### **Remarks:**

Constructor. The smoothing groups and face flags are initialized to zero.

#### **Prototype:**

**MtlID getMatID()**

#### **Remarks:**

Retrieves the zero based material ID for this face. Note: **typedef unsigned short MtlID;**

#### **Prototype:**

**void setMatID(MtlID id)**

#### **Remarks:**

Sets the material ID for this face.

#### **Parameters:**

**MtlID id**

Specifies the zero based material index.

#### **Prototype:**

**void setSmGroup(DWORD i)**

#### **Remarks:**

Sets the smoothing group bits for this face.

#### **Parameters:**

**DWORD i**

Specifies the smoothing group bits for this face.

**Prototype:****DWORD getSmGroup()****Remarks:**

Returns the smoothing group bits for this face.

**Prototype:****void setVerts(DWORD \*vrt)****Remarks:**

Sets the vertices of this face.

**Parameters:****DWORD \*vrt**

An array of the 3 vertices to store. These are zero based indices into the mesh object's array of vertices.

**Prototype:****void setVerts(int a, int b, int c)****Remarks:**

Sets the vertices of this face. The specified indexes are zero based indices into the mesh object's array of vertices.

**Parameters:****int a**

Specifies the first vertex.

**int b**

Specifies the second vertex.

**int c**

Specifies the third vertex.

**Prototype:****void setEdgeVis(int edge, int visFlag);**

**Remarks:**

Sets the visibility of the specified edge.

**Parameters:****int edge**

Specifies the edge to set the visibility of. You may use 0, 1, or 2.

**int visFlag**

One of the following values:

**EDGE\_VIS**

Sets the edge as visible.

**EDGE\_INVIS**

Sets the edge as invisible.

**Prototype:**

```
void setEdgeVisFlags(int va, int vb, int vc);
```

**Remarks:**

Sets the visibility of the all the edges.

**Parameters:****int va**

Specifies the visibility for edge 0. Use either **EDGE\_VIS** or **EDGE\_INVIS**.

**int vb**

Specifies the visibility for edge 1. Use either **EDGE\_VIS** or **EDGE\_INVIS**.

**int vc**

Specifies the visibility for edge 2. Use either **EDGE\_VIS** or **EDGE\_INVIS**.

**Prototype:**

```
int getEdgeVis(int edge)
```

**Remarks:**

Retrieves the edge visibility for the specified edge.

**Parameters:**

**int edge**

Specifies the edge.

**Return Value:**

Nonzero if the edge is visible, zero if the edge is invisible.

**Prototype:**

**DWORD getVert(int index)**

**Remarks:**

Returns the index into the mesh vertex array of the specified vertex.

**Parameters:**

**int index**

Specifies the vertex to retrieve. You may use 0, 1 or 2.

**Prototype:**

**DWORD \*getAllVerts()**

**Remarks:**

Retrieves a pointer to the vertex array.

**Return Value:**

A pointer to the vertex array.

**Prototype:**

**BOOL Hidden()**

**Remarks:**

Determines if the face is hidden or visible.

**Return Value:**

TRUE if the face is hidden; otherwise FALSE.

**Prototype:**

**void Hide()**

**Remarks:**

Hides this face (makes it invisible in the viewports).

**Prototype:**

**void Show()**

**Remarks:**

Shows this face (makes it visible in the viewports).

**Prototype:**

**void SetHide(BOOL hide)**

**Remarks:**

Sets the hidden state of this face.

**Parameters:**

**BOOL hide**

Specifies the hidden state for the face. Pass TRUE to hide the face; FALSE to show it.

**Prototype:**

**DWORD GetOtherIndex(DWORD v0, DWORD v1);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the first vertex in the face that isn't v0 or v1.

**Parameters:**

**DWORD v0**

The zero based index of one of the vertices to check.

**DWORD v1**

The zero based index of the other vertex to check.

**Return Value:**

The zero based index of the vertex found in the Mesh's vertex list.

**Prototype:**

**DWORD GetEdgeIndex(DWORD v0, DWORD v1);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the index of the edge in the face that goes from v0 to v1, or v1 to v0.

**Parameters:****DWORD v0**

The zero based index of the vertex at one end of the edge.

**DWORD v1**

The zero based index of the vertex at the other end of the edge.

**Return Value:**

The zero based index of the edge found in the Fesh's edge list.

**Prototype:**

```
int Direction(DWORD v0, DWORD v1);
```

**Remarks:**

This method is available in release 3.0 and later only.

Indicates order in which vertices v0 and v1 appear in the face.

**Parameters:****DWORD v0**

One vertex on this face.

**DWORD v1**

Another vertex on this face.

**Return Value:**

**1** if v1 follows v0 in sequence (This includes e.g. when Face::v[2] == v0 and Face::v[0] == v1.)

**-1** if v0 follows v1 in sequence

**0** if v0 or v1 are not on the face.

**Prototype:**

```
DWORD GetVertIndex(DWORD v0);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the index of the specified vertex in this face's vertex list (0, 1 or 2). If not found 3 is returned.

**Parameters:**

**DWORD v0**

The zero based index of the vertex to check.

**Prototype:**

```
void OrderVerts(DWORD &v0, DWORD &v1);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method switches v0,v1 if needed to put them in face-order. If v0 and v1 are in the order in which they appear in the face, or if one or both of them are not actually on the face, nothing happens. If however v0 follows v1, the values of the parameters are switched, so that they are then in the correct order for this face.

**Parameters:****DWORD &v0**

One vertex on this face.

**DWORD &v1**

Another vertex on this face.

**Sample Code:**

```
Face & f = mesh.faces[edge.f[0]];  
DWORD v0 = edge.v[0];  
DWORD v1 = edge.v[1];  
// Switch v0, v1 if needed to match orientation in selected face.  
f.OrderVerts(v0,v1);
```

## Class TVFace

See Also: [Class Mesh](#).

class TVFace

### Description:

This class is used for texture faces as well as vertex colors. The class maintains an array of three indices into the object's **tVerts** array. See the Mesh class for details on how its array of TVFaces and tVerts relate. All methods of this class are implemented by the system.

### Data Members:

public:

**DWORD t[3];**

These are indices into the mesh object's **tVerts** array.

### Methods:

#### Prototype:

**TVFace()**

#### Remarks:

Constructor. No initialization is done.

#### Prototype:

**TVFace(DWORD a, DWORD b, DWORD c);**

#### Remarks:

Constructor.

#### Parameters:

**DWORD a**

Specifies the index into the **tVerts** array for vertex 0.

**DWORD b**

Specifies the index into the **tVerts** array for vertex 1.

**DWORD c**

Specifies the index into the **tVerts** array for vertex 2.

**Prototype:**

**void setTVerts(DWORD \*vrt);**

**Remarks:**

Sets the texture vertices.

**Parameters:**

**DWORD \*vrt**

An array of indices into the **tVerts** array for vertices 0, 1, and 2.

**Prototype:**

**void setTVerts(int a, int b, int c);**

**Remarks:**

Sets the textured vertices.

**Parameters:**

**int a**

Specifies the index into the **tVerts** array for vertex 0.

**int b**

Specifies the index into the **tVerts** array for vertex 1.

**int c**

Specifies the index into the **tVerts** array for vertex 2.

**Prototype:**

**DWORD getTVert(int index);**

**Remarks:**

Retrieves one of the texture vertices.

**Parameters:**

**int index**

Specifies the index of the texture vertex to retrieve. You may use 0, 1 or 2.

**Return Value:**

The texture vertex.

**Prototype:**

**DWORD \*getAllTVerts();**

**Remarks:**

Returns a pointer to the array of texture vertices.

**Prototype:**

**DWORD GetVertIndex(DWORD v0);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the index of the specified texture vertex in this texture face's vertex list (0, 1 or 2). If not found 3 is returned.

**Parameters:**

**DWORD v0**

The zero based index of the texture vertex to check.

**Prototype:**

**DWORD GetOtherIndex(DWORD v0, DWORD v1);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the first texture vertex in this texture face that isn't v0 or v1.

**Parameters:**

**DWORD v0**

The zero based index of one of the vertices to check.

**DWORD v1**

The zero based index of the other vertex to check.

**Prototype:**

**int Direction(DWORD v0, DWORD v1);**

**Remarks:**

This method is available in release 3.0 and later only.

Indicates the order in which vertices v0 and v1 appear in the texture face.

**Parameters:****DWORD v0**

One vertex on this texture face.

**DWORD v1**

Another vertex on this texture face.

**Return Value:****1** if v1 follows v0 in sequence.**-1** if v0 follows v1 in sequence.**0** if v0 or v1 are not on the face.**Prototype:****void OrderVerts(DWORD &v0, DWORD &v1);****Remarks:**

This method is available in release 3.0 and later only.

This method switches v0,v1 if needed to put them in face-order. If v0 and v1 are in the order in which they appear in the texture face, or if one or both of them are not actually on the texture face, nothing happens. If however v0 follows v1, the values of the parameters are switched, so that they are then in the correct order for this texture face.

**Parameters:****DWORD &v0**

One vertex on this texture face.

**DWORD &v1**

Another vertex on this texture face.

# Class BitmapInfo

See Also: [Class Bitmap](#), [Working with Bitmaps](#), [List of Bitmap Error Codes](#).

class BitmapInfo

## Description:

This class describes the properties of a bitmap such as its path name or device name, width, height, gamma, number of frames, etc. Methods are available to set and retrieve these properties. All methods are implemented by the system unless noted otherwise.

## Method Groups:

The following hyperlinks jump to the start of groups of methods within the class:

[Flag Access](#)

[Get/Set Bitmap Properties \(Type, Width, Height, etc.\)](#)

[Get/Set Names, Devices.](#)

[Custom Flag Access](#)

[Get/Set Custom Bitmap Properties](#)

[Miscellaneous](#)

[Operators](#)

## Methods:

## Prototype:

**BitmapInfo();**

## Remarks:

Constructor. The following defaults are set by this constructor.

The width = 640;

The height = 480;

The custom width = 320;

The custom height = 200;

The custom flags = BMM\_CUSTOM\_RESFIT |

BMM\_CUSTOM\_FILEGAMMA;

The custom gamma = 1.0f;

The frame number = 0;

The aspect ratio = 1.0f;

The gamma setting = 1.0f;

The name and device name are set to NULL.  
The looping flag = BMM\_SEQ\_WRAP;

**Prototype:**

**BitmapInfo(TCHAR \*n);**

**Remarks:**

Constructor. The defaults are set as above excepting the bitmap name is set.

**Parameters:**

**TCHAR \*n**

The bitmap file name is set.

**Prototype:**

**BitmapInfo(const BitmapInfo &bi);**

**Remarks:**

This method is available in release 3.0 and later only.  
Copy Constructor.

**Parameters:**

**const BitmapInfo &bi**

The BitmapInfo to copy from.

## Flag Access

**Prototype:**

**DWORD Flags()**

**Remarks:**

Returns the flags of this BitmapInfo. See [Bitmap Flags](#).

**Prototype:**

**DWORD SetFlags(DWORD f)**

**Remarks:**

Sets the flags for this BitmapInfo. These are bitwise OR-ed into the current flags.

**Parameters:****DWORD f**

The flag bits to set. See [Bitmap Flags](#).

**Return Value:**

The revised flags are returned.

**Prototype:****BOOL TestFlags(DWORD f)****Remarks:**

Determines if a set of flag bits are set.

**Parameters:****DWORD f**

The flag bits to test. See [Bitmap Flags](#).

**Return Value:**

TRUE if the bits are set; otherwise FALSE.

**Get/Set Bitmap Properties****Prototype:****int Type()****Remarks:**

Returns the type property of this BitmapInfo. See [Bitmap Types](#).

**Prototype:****int SetType(int t)****Remarks:**

Sets the type property of this BitmapInfo to the specified value.

**Parameters:****int t**

Specifies the type of bitmap. See [Bitmap Types](#).

**Return Value:**

The old (previous) type setting.

**Prototype:**

**WORD Width()**

**Remarks:**

Returns the width (horizontal dimension) property of this BitmapInfo.

**Prototype:**

**WORD SetWidth(WORD w)**

**Remarks:**

Sets the width (horizontal dimension) property of this BitmapInfo.

**Parameters:**

**WORD w**

Specifies the width setting in pixels.

**Return Value:**

The old (previously set) width of the bitmap.

**Prototype:**

**WORD Height()**

**Remarks:**

Returns the height (vertical dimension) setting of this BitmapInfo.

**Prototype:**

**WORD SetHeight(WORD h)**

**Remarks:**

Sets the height (vertical dimension) property of this BitmapInfo.

**Parameters:**

**WORD h**

Specifies the height setting in pixels.

**Return Value:**

The old (previous) height setting.

**Prototype:**

## **float Gamma()**

### **Remarks:**

Returns the gamma setting property of this BitmapInfo.

### **Prototype:**

**float SetGamma(float g)**

### **Remarks:**

Sets the gamma property of this BitmapInfo to the value passed.

### **Parameters:**

**float g**

Specifies the gamma setting.

### **Return Value:**

The old (previous) gamma setting.

### **Prototype:**

**float Aspect()**

### **Remarks:**

Returns the aspect ratio property of this BitmapInfo.

### **Prototype:**

**float SetAspect(float a)**

### **Remarks:**

Set the aspect ratio property of this BitmapInfo to the specified value.

### **Parameters:**

**float a**

Specifies the aspect ratio setting.

### **Return Value:**

The old (previous) aspect ratio of the bitmap.

## **Frame Ranges**

### **Prototype:**

## **int FirstFrame()**

### **Remarks:**

Returns the first frame property of this BitmapInfo. Note that for a multi-frame bitmap some sequences may start with something other than 0.

### **Prototype:**

**int SetFirstFrame(int f)**

### **Remarks:**

Sets the first frame property of this BitmapInfo.

### **Parameters:**

**int f**

Specifies the first frame setting.

### **Return Value:**

The old (previous) first frame setting.

### **Prototype:**

**int LastFrame()**

### **Remarks:**

Returns the last frame property of this BitmapInfo.

### **Prototype:**

**int SetLastFrame(int f)**

### **Remarks:**

Sets the last frame property of this BitmapInfo.

### **Parameters:**

**int f**

Specifies the last frame.

### **Return Value:**

The old (previous) frame setting.

### **Prototype:**

## **int NumberFrames()**

### **Remarks:**

Returns the total number of frames setting of this BitmapInfo.

### **Prototype:**

## **int CurrentFrame()**

### **Remarks:**

Returns the current frame setting of this BitmapInfo.

### **Prototype:**

## **int SetCurrentFrame(int v)**

### **Remarks:**

Sets the current frame setting of this BitmapInfo.

### **Parameters:**

#### **int v**

Specifies the current frame.

### **Return Value:**

The old (previous) current frame setting.

### **Prototype:**

## **WORD SequenceOutBound()**

### **Remarks:**

When multi-frame BitmapIO loaders are reading a sequence of frames, this method is called to indicate what to do when reading beyond the end of available frames. The defaults is **BMM\_SEQ\_WRAP**.

### **Return Value:**

One of the following values:

#### **BMM\_SEQ\_WRAP**

Wraps around back to start point.

#### **BMM\_SEQ\_ERROR**

Generates an error if reading goes beyond the end.

#### **BMM\_SEQ\_PINGPONG**

This causes the sequence to turn around and goes the other direction, back and forth.

### **BMM\_SEQ\_HOLD**

When the last frame is reached it is held and used over and over.

#### **Prototype:**

**WORD SetSequenceOutBound(WORD s)**

#### **Remarks:**

Sets the sequence out of bounds property of this BitmapInfo. When reading a sequence of frames, this specifies what to do when reading beyond the end of available frames.

#### **Parameters:**

##### **WORD s**

One of the following values:

##### **BMM\_SEQ\_WRAP**

Wraps around back to start point.

##### **BMM\_SEQ\_ERROR**

Generates an error if reading goes beyond the end.

##### **BMM\_SEQ\_PINGPONG**

This causes the sequence to turn around and goes the other direction, back and forth.

##### **BMM\_SEQ\_HOLD**

When the last frame is reached it is held and used over and over.

#### **Return Value:**

The old (previous) value that was set.

### **Name/Device Access**

#### **Prototype:**

**const TCHAR \*Name()**

#### **Remarks:**

Returns the name property of this BitmapInfo. This is the full path name. See **TCHAR \*Filename()** for just the file name.

**Prototype:**

```
const TCHAR *SetName(const TCHAR *n);
```

**Remarks:**

Sets the name property of this BitmapInfo. When writing **n** should have a fully qualified filename. When reading, it only matters if the image is not in the MAP path. Note that a "feature" of the MAP path system is that if an image with same name is found more than once (in different paths), only the first one is seen.

Note: If loading an image from a device, make sure the name is empty (**bi.SetName(\_T(""))**);). This is automatic if you use

**BitmapManager::SelectDeviceInput()**. If you just create a **BitmapInfo** instance and set the device name by hand (**bi.SetDevice()**), this is also automatic as both name and device names are by default set to NULL ("").

This is only a concern if you reuse a **BitmapInfo** class previously used for image files.

**Parameters:**

```
const TCHAR *n
```

Specifies the name of the bitmap.

**Return Value:**

The old (previous) name that was set.

**Prototype:**

```
const TCHAR *Filename()
```

**Remarks:**

Returns just the file name of this BitmapInfo (not the entire path name).

**Prototype:**

```
const TCHAR *Device()
```

**Remarks:**

Returns the device name responsible for producing this image. For file types, this is just informative. For non-file types (devices) this is the way this image is identified. Therefore, it is important to save both name and device in order to properly identify an image.

**Prototype:**

**const TCHAR \*SetDevice(const TCHAR \*d);**

**Remarks:**

This method is used to set the device name.

**Parameters:**

**const TCHAR \*d**

The name to set.

**Return Value:**

The device name that was set.

**Prototype:**

**BOOL CompareName(BitmapInfo \*bi);**

**Remarks:**

This method will compare names taking in consideration both file names and device names. As devices don't have a file name, this method will first determine what type of image this is, and then perform a proper comparison.

**Parameters:**

**BitmapInfo \*bi**

The other BitmapInfo with which to compare names.

**Return Value:**

TRUE if the BitmapInfos have the same name and device name; otherwise FALSE.

## Custom Input Processing

**Prototype:**

**WORD CustWidth()**

**Remarks:**

Returns the custom width setting of this BitmapInfo.

**Prototype:**

**void SetCustWidth(WORD w)**

**Remarks:**

Sets the custom width setting for this BitmapInfo.

**Parameters:**

**WORD w**

The new custom width setting.

**Prototype:**

**WORD CustHeight()**

**Remarks:**

Returns the custom height setting of this BitmapInfo.

**Prototype:**

**void SetCustHeight(WORD h)**

**Remarks:**

Sets the custom height property of this BitmapInfo.

**Parameters:**

**WORD h**

The new custom height setting.

**Prototype:**

**int StartFrame()**

**Remarks:**

Returns the custom start frame property of this BitmapInfo.

**Prototype:**

**void SetStartFrame(int s)**

**Remarks:**

Sets the custom start frame property to the specified value.

**Parameters:**

**int s**

Specifies the start frame setting.

**Prototype:**

**int EndFrame()**

**Remarks:**

Returns the custom end frame setting of this BitmapInfo..

**Prototype:**

**void SetEndFrame(int e)**

**Remarks:**

Sets the custom end frame property of this BitmapInfo.

**Parameters:**

**int e**

The new end frame setting.

**Prototype:**

**WORD GetCustomX()**

**Remarks:**

Returns the custom x offset setting of this BitmapInfo.

**Prototype:**

**void SetCustomX(int x)**

**Remarks:**

Specifies the optional X coordinate (offset) property of this BitmapInfo. This specifies where to place the image if the image being copied from one Bitmap to another is smaller.

**Parameters:**

**int x**

Specifies the custom X offset.

**Prototype:**

**WORD GetCustomY()**

**Remarks:**

Returns the custom Y offset setting of this BitmapInfo.

**Prototype:**

**void SetCustomY(int y)**

**Remarks:**

Sets the optional Y coordinate (offset) property of this BitmapInfo. This specifies where to place the image if the image being copied from one Bitmap to another is smaller.

**Parameters:**

**int y**

Specifies the custom y offset.

**Prototype:**

**float GetCustomGamma()**

**Remarks:**

Returns the custom gamma setting of this BitmapInfo.

**Prototype:**

**void SetCustomGamma(float g)**

**Remarks:**

Sets a custom gamma setting of this BitmapInfo to the specified value.

**Parameters:**

**float g**

Specifies the custom gamma setting.

**Prototype:**

**int GetCustomStep()**

**Remarks:**

Returns the custom frame step setting of this BitmapInfo.

**Prototype:**

**void SetCustomStep(int s)**

**Remarks:**

Sets the custom frame increment setting of this BitmapInfo.

**Parameters:****int s**

Specifies the frame increment to use.

**Prototype:****int GetPresetAlignment()****Remarks:**

Returns the optional alignment setting of this BitmapInfo. This indicates where to place the image if the image being copied from one Bitmap to another is smaller.

**Return Value:**

See [List of Bitmap Alignment Positions](#).

**Prototype:****void SetPresetAlignment(int p)****Remarks:**

Establishes the optional alignment setting of this BitmapInfo. This specifies where to place the image if the image being copied from one Bitmap to another is smaller.

**Parameters:****int p**

Specifies one of the following nine values that define the position of the bitmap:

See [List of Bitmap Alignment Positions](#).

**Custom Input Flags****Prototype:****DWORD GetCustomFlags()****Remarks:**

Retrieves the custom flags setting of this BitmapInfo . See [List of Custom Bitmap Flags](#).

**Prototype:**

**void SetCustomFlag(DWORD f)**

**Remarks:**

Sets the custom flag(s) for this BitmapInfo.

**Parameters:**

**DWORD f**

Specifies the custom flags. See [List of Custom Bitmap Flags](#).

**Prototype:**

**void ResetCustomFlag(DWORD f)**

**Remarks:**

Clears the specified flag(s) of this BitmapInfo. See [List of Custom Bitmap Flags](#).

**Parameters:**

**DWORD f**

Specifies the flag bits to reset.

**Prototype:**

**BOOL TestCustomFlags(DWORD f)**

**Remarks:**

Tests the custom flags of this BitmapInfo. See [List of Custom Bitmap Flags](#).

**Parameters:**

**DWORD f**

The flag bits to test.

**Return Value:**

Returns TRUE if the specified flags were set; otherwise FALSE.

**Prototype:**

**void CopyImageInfo(BitmapInfo \*from);**

**Remarks:**

Copies the image information of the **from** BitmapInfo to this bitmap. Only the name, device and image characteristics are copied. User info, such as Custom

Width, etc. is not copied.

The following properties of the **from** BitmapInfo are copied:

**from->Name(),from->Device(),from->Width(), from->Height(),  
from->Aspect(), from->Gamma(),from->Type(), from->Flags(),  
from->FirstFrame(), from->LastFrame(), from->CurrentFrame(),  
from->GetCustomFlags()**

**Parameters:**

**BitmapInfo \*from**

The bitmap whose information will be copied.

**Prototype:**

**BOOL Validate()**

**Remarks:**

Implemented by the System.

This method is used to check the width, height, aspect ratio, and gamma settings to make sure they are within an acceptable range of values. The comparison is as follows:

```
if (width < 1 ||  
height < 1 ||  
aspect <= 0.0 ||  
gamma < MINGAMMA ||  
gamma > MAXGAMMA)  
    return (FALSE);  
else  
    return (TRUE);
```

Where:

```
#define MINGAMMA 0.2f  
#define MAXGAMMA 5.0f
```

**Return Value:**

TRUE if the BitmapInfo's settings are valid ; otherwise FALSE.

**Prototype:****HWND GetUpdateWindow()****Remarks:**

Returns the window handle to send progress or check abort messages to.

**Prototype:****void SetUpdateWindow(HWND hwnd)****Remarks:**

This is used internally - the system calls this method. This is how a window handle is sent down to device drivers and filters so they can send progress reports and check for cancel.

**Prototype:****void \*CreateFmtSpecBlock();****Remarks:**

This method is available in release 2.0 and later only.

This method provides some access to device specific data (for instance the compression ratio in a JPEG file). This method will return a buffer containing a given device specific data (or NULL if the device referenced is unknown or doesn't have "specific data"). The buffer structure will depend on the device. For all drivers shipped with the SDK, this structure is defined in their header files (which must be included in the project for which this method is used). Internally, this method validates the driver, calls its **EvaluateConfigure()** method to define the buffer size, creates this buffer and, if the returned size is greater than zero, calls the driver's **SaveConfigure()** method in order to set default values. The developer may then change whatever they want, create and write a file using this **BitmapInfo** which includes the device's specific data.

There is no need to free this buffer as this is handled by the **BitmapInfo** destructor.

Note: The name and/or device properties must be defined before using this method.

**Operators:**

**Prototype:**

**virtual BitmapInfo &operator= (BitmapInfo &from);**

**Remarks:**

Assignment operator. The data members of the specified BitmapInfo are copied to this BitmapInfo.

**Parameters:**

**BitmapInfo &from**

The source BitmapInfo.

## Class Bitmap

See Also: [Class BitmapManager](#), [Class BitmapInfo](#), [Class BitmapStorage](#), [Class GBuffer](#), [Working with Bitmaps](#).

```
class Bitmap : public BaseInterfaceServer
```

### Description:

The **Bitmap** class is the bitmap itself. All image access is done through this class. The **Bitmap** class has methods to retrieve properties of the bitmap such as image width, height, whether it is dithered, has an alpha channel, etc. There are methods to retrieve and store pixels from the image. Additional methods allow a developer to copy bitmaps. This class also has methods to open outputs and write multi-frame files. All methods of this class are implemented by the system.

### Data Members:

protected:

**float gamma;**

The gamma setting for the bitmap.

**Bitmap \*map;**

The bitmap using this output handler.

**BitmapStorage \*storage;**

The storage used by this INPUT handler

**int openMode;**

The mode the bitmap is open in.

**BitmapIO \*prevIO;**

**BitmapIO \*nextIO;**

Linked list pointers for multiple output of a single bitmap.

### Method Groups:

These hyperlinks jump to the start of groups of related methods within the class.

[Memory Deallocation](#)

[Flag Access](#)

[Bitmap Properties \(Size, Aspect, Gamma, etc.\)](#)

[Pixel Access](#)

[Palette Access](#)

[Copying / Cropping / Converting](#)

[Channel Access](#)

[Filtering / Dithering](#)

[Opening / Writing / Closing](#)

[Display \(Virtual Frame Buffer\) Methods](#)

[Storage Change Notificiation](#)

[Execute -- Generic Expansion Method](#)

**Methods:**

**Prototype:**

**inline BitmapManager \*Manager()**

**Remarks:**

Returns a pointer to the bitmap manager being used.

## **Memory Deallocation**

**Prototype:**

**void DeleteThis();**

**Remarks:**

This method is available in release 2.0 and later only.

This method should be called to free the Bitmap. Note that you should not invoke **~Bitmap()** directly by calling **delete** on the Bitmap as was done in 3ds max1.x. An assert will be raised if you call delete on a Bitmap directly. Instead use this method.

## **Flag Access**

**Prototype:**

**inline DWORD Flags()**

**Remarks:**

Returns the state of the bitmap flags. These flags describe properties of the bitmap such as if the bitmap is flipped horizontally or inverted vertically, is paletted, is dithered, etc. See [Bitmap Flags](#)

**Prototype:**

**inline void SetFlag(DWORD flag)**

**Remarks:**

Sets the specified flag bit(s).

**Parameters:**

**DWORD flag**

The flag(s) to set. See [Bitmap Flags](#).

**Prototype:**

**inline void ToggleFlag(DWORD flag)**

**Remarks:**

Toggles the specified flag bit(s) on/off.

**Parameters:**

**DWORD flag**

The flag(s) to toggle. See [Bitmap Flags](#).

**Prototype:**

**inline void ClearFlag(DWORD flag)**

**Remarks:**

Clears the specified flag bit(s) (sets them to zero).

**Parameters:**

**DWORD flag**

The flag(s) to clear. See [Bitmap Flags](#).

## **Bitmap Properties**

The following methods return properties of the bitmap. When these methods are called, they are passed through to the **BitmapStorage** instance maintained by the **Bitmap**. The **BitmapStorage** implements these methods by returning the properties of the **BitmapInfo** instance maintained by the storage. Therefore, the values returned from the methods represent what is returned from the **BitmapInfo** instance associated with the **Bitmap**.

**Prototype:**

### **inline int Width()**

**Remarks:**

Returns the width of the bitmap (the horizontal dimension).

**Return Value:**

If storage has been allocated the width of the bitmap; otherwise 0.

**Prototype:**

### **inline int Height()**

**Remarks:**

Returns the height (vertical dimension) of the bitmap.

**Return Value:**

If storage has been allocated the height of the bitmap; otherwise 0.

**Prototype:**

### **inline float Aspect()**

**Remarks:**

Returns the aspect ratio of the bitmap.

**Return Value:**

If storage has been allocated the aspect ratio of the bitmap; otherwise 0.0f.

**Prototype:**

### **inline float Gamma()**

**Remarks:**

Returns the gamma value for the bitmap.

**Return Value:**

If storage has been allocated the gamma of the bitmap; otherwise 0.0f.

**Prototype:**

### **inline int Paletted()**

**Remarks:**

Returns whether the bitmap uses a palette (is not true color).

**Return Value:**

If storage has been allocated returns nonzero if the bitmap uses a palette (returns the number of palette slots used); otherwise 0.

**Prototype:**

**inline int IsDithered()**

**Remarks:**

Returns whether the bitmap is dithered or not.

**Return Value:**

If storage has been allocated returns nonzero if the bitmap is dithered; otherwise 0.

**Prototype:**

**inline int PreMultipliedAlpha()**

**Remarks:**

Returns whether the bitmap uses pre-multiplied alpha.

**Return Value:**

If storage has been allocated returns nonzero if the bitmap uses pre-multiplied alpha; otherwise 0.

**Prototype:**

**inline int HasAlpha()**

**Remarks:**

Returns whether the bitmap has an alpha channel.

**Return Value:**

If storage has been allocated returns nonzero if the bitmap has an alpha channel; otherwise 0.

**Prototype:**

**inline int MaxRGBLevel()**

**Remarks:**

This method returns the number of bits per pixel for each color component.

For example a 24-bit TARGA has a **MaxRGBLevel()** of 8.

**Prototype:**

**virtual int MaxAlphaLevel() = 0;**

**Remarks:**

Implemented by the System.

Returns the number of bits per pixel in the alpha channel.

**Return Value:**

If storage has not been allocated returns 0.

**Prototype:**

**virtual int IsHighDynamicRange() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns nonzero if this is a bitmap that supports high dynamic range data; zero if it doesn't.

**Prototype:**

**BMMRES GoTo(BitmapInfo \*bi);**

**Remarks:**

This method is used with multi-frame bitmaps (FLI's, AVI's, DDR devices, etc.). It is used to load a frame to replace a previously saved image. To define the desired frame, use:

**bi->SetCurrentFrame(frame);**

**Parameters:**

**BitmapInfo \*bi**

A pointer to the BitmapInfo. The frame number information is passed here.

**Return Value:**

If used with single frame drivers or if the driver doesn't support this function, it returns **BMMRES\_SINGLEFRAME**. If the return value is **BMMRES\_SUCCESS**, a new frame has been loaded into the given bitmap.

## Standard Pixel Access Methods.

Note: The following methods access pixel data one scanline at a time. Thus **x+pixels** must be less than the bitmap width.

### Prototype:

```
inline int Get16Gray(int x,int y,int pixels,float *ptr)
```

### Remarks:

Retrieves the specified 16-bit pixel values from the bitmap. Note: This method provides access to pixel data one scanline at a time.

### Parameters:

**int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**float \*ptr**

Pointer to storage for the retrieved pixel values.

### Return Value:

Returns nonzero if pixels were retrieved; otherwise 0. If storage has not been allocated 0 is returned.

### Prototype:

```
int Put16Gray(int x,int y,int pixels,float *ptr)
```

### Remarks:

Stores the specified 16-bit pixel values into the bitmap. The pixel value pointer you pass to this method may be freed or reused as soon as the function returns. Note: This method provides access to pixel data one scanline at a time.

### Parameters:

**int x**

Destination x location.

**int y**

Destination y location.

**int pixels**

Number of pixels to store.

**float \*ptr**

Pixel values to store.

**Return Value:**

Returns nonzero if pixels were stored; otherwise 0. If storage has not been allocated 0 is returned.

**Prototype:**

**inline int GetPixels(int x,int y,int pixels,BMM\_Color\_fl \*ptr)**

**Remarks:**

Retrieves the specified 64-bit pixel values from the bitmap. Note: This method provides access to pixel data one scanline at a time.

**Parameters:**

**int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**BMM\_Color\_fl \*ptr**

Pointer to storage for the retrieved pixel values. See [Structure BMM\\_Color\\_fl](#).

**Return Value:**

Returns nonzero if pixels were retrieved; otherwise 0. If storage has not been allocated 0 is returned.

**Prototype:**

**int PutPixels(int x,int y,int pixels,BMM\_Color\_fl \*ptr)**

**Remarks:**

Stores the specified 64-bit pixel values into the bitmap's own local storage. The pointer you pass to this method may be freed or reused as soon as the function returns. Note: This method provides access to pixel data one scanline

at a time.

**Parameters:**

**int x**

Destination x location.

**int y**

Destination y location.

**int pixels**

Number of pixels to store.

**BMM\_Color\_fl \*ptr**

Pixel values to store. See [Structure BMM\\_Color\\_fl](#).

**Return Value:**

Returns nonzero if pixels were stored; otherwise 0. If storage has not been allocated 0 is returned.

**Prototype:**

```
inline int GetLinearPixels(int x,int y,int pixels,BMM_Color_64  
*ptr)
```

**Remarks:**

Retrieves the specified 64-bit pixel values from the bitmap. These pixels are NOT gamma corrected (i.e. they have linear gamma - 1.0). Note: This method provides access to pixel data one scanline at a time.

**Parameters:**

**int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**BMM\_Color\_64 \*ptr**

Pointer to storage for the retrieved pixel values. See [Structure BMM\\_Color\\_64](#).

**Return Value:**

Returns nonzero if pixels were retrieved; otherwise 0. If storage has not been

allocated 0 is returned.

**Prototype:**

**inline int GetIndexPixels(int x,int y,int pixels,BYTE \*ptr)**

**Remarks:**

Retrieves the specified pixels from the paletted bitmap. The palette for the image may be accessed using **GetPalette()**. Note: This method provides access to pixel data one scanline at a time.

**Parameters:**

**int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**BYTE \*ptr**

Pointer to storage for the pixel values.

**Return Value:**

Returns nonzero if pixels were retrieved; otherwise 0. If storage has not been allocated 0 is returned.

**Prototype:**

**inline int PutIndexPixels(int x,int y,int pixels,BYTE \*ptr)**

**Remarks:**

Stores the pixels into the specified location of the paletted bitmap. The pixel value pointer you pass to this method may be freed or reused as soon as the function returns. Note: This method provides access to pixel data one scanline at a time.

**Parameters:**

**int x**

Destination x location.

**int y**

Destination y location.

**int pixels**

Number of pixels to store.

**BYTE \*ptr**

Pixels to store.

**Return Value:**

Returns nonzero if pixels were stored; otherwise 0. If storage has not been allocated 0 is returned.

## Palette Access

**Prototype:**

**inline int GetPalette(int start,int count,BMM\_Color\_48 \*ptr)**

**Remarks:**

Retrieves a portion of the palette from the bitmap.

**Parameters:**

**int start**

The index into the palette of where to begin retrieving palette entries.

**int count**

The number of palette entries to retrieve.

**BMM\_Color\_48 \*ptr**

Storage for the palette entries. See [Structure BMM\\_Color\\_48](#).

**Return Value:**

Nonzero if the palette entries were retrieved; otherwise 0.

**Prototype:**

**inline int SetPalette(int start,int count,BMM\_Color\_48 \*ptr)**

**Remarks:**

Sets the specified portion of the palette of this bitmap.

**Parameters:**

**int start**

The index into the palette of where to begin storing palette entries.

**int count**

The number of palette entries to store.

**BMM\_Color\_48 \*ptr**

The palette entries to store. See [Structure BMM\\_Color\\_48](#).

**Return Value:**

Nonzero if the palette entries were stored; otherwise 0.

## Copying / Cropping Methods

**Prototype:**

```
int GetFiltered(float u, float v, float du, float dv, BMM_Color_fl  
*ptr);
```

**Remarks:**

This method uses summed area table or pyramidal filtering to compute an averaged color over the specified area. You must have a filter plugged in for this to work. See **SetFilter()** below.

**Parameters:**

**float u, float v**

The location in the bitmap to filter. These values go from 0.0 to 1.0 across the size of the bitmap.

**float du, float dv**

The size of the rectangle to sample. These values go from 0.0 to 1.0 across the size of the bitmap.

**BMM\_Color\_fl \*ptr**

The result is returned here -- the average over the specified area. See Structure BMM\_Color\_fl. **\*\*aztodo\*\*** link this

**Prototype:**

```
inline int CopyImage(Bitmap *from,int operation,BMM_Color_fl  
fillcolor, BitmapInfo *bi = NULL)
```

**Remarks:**

Copies the specified bitmap to this bitmap.

**Parameters:**

**Bitmap \*from**

The source bitmap.

### **int operation**

The type of copy to perform:

#### **COPY\_IMAGE\_CROP**

Copy image to current map size using cropping if necessary.

#### **COPY\_IMAGE\_RESIZE\_LO\_QUALITY**

Resize the source image to the destination map size (draft quality).

#### **COPY\_IMAGE\_RESIZE\_HI\_QUALITY**

Resize source image to the destination map size (final quality).

#### **COPY\_IMAGE\_USE\_CUSTOM**

Resize based on the Image Input Options (BitmapInfo \*).

### **BMM\_Color\_fl fillcolor**

Vacant areas of the bitmap are filled with **fillcolor** pixels if the operation specified is **COPY\_IMAGE\_CROP** and one of the source bitmap dimensions is less than the size of this bitmap. See [Structure BMM\\_Color\\_fl](#).

### **BitmapInfo \*bi = NULL**

When using custom options (resize to fit, positioning, etc.) this is how the flags are passed down to the Bitmap Manager. This is an optional argument -- for simple copy operations, **\*bi** can default to NULL. If present, the code checks the option flags and acts accordingly.

### **Return Value:**

Nonzero if the copy was performed; otherwise 0.

### **Prototype:**

```
inline int CopyImage(Bitmap *from,int operation,int fillindex)
```

### **Remarks:**

Copies the specified bitmap to this bitmap.

### **Parameters:**

#### **Bitmap \*from**

The source bitmap.

#### **int operation**

The type of copy to perform. See [List of Copy Image Operations](#).

#### **int fillindex**

Vacant areas of the bitmap are filled with **fillindex** pixels if the operation specified is **COPY\_IMAGE\_CROP** and one of the source bitmap dimensions is less than the size of this bitmap.

**Return Value:**

Nonzero if the copy was performed; otherwise 0.

**Prototype:**

**PBITMAPINFO ToDib(int depth = 24, UWORD \*gam=NULL, BOOL dither=FALSE);**

**Remarks:**

Creates a new Windows Device Independent Bitmap (DIB) and returns a pointer to it. The DIB bitmap is created from this Bitmap. The DIB is allocated using **LocalAlloc()**. The pseudo-code below show how one may be created and freed. Note that the DIB is never used or accessed inside 3ds max (the call to **ToDib()** is the first and last time that 3ds max sees this pointer):

```
PBITMAPINFO pDib;  
pDib = bitmap->ToDib();
```

...

When you are done using the DIB call:

```
LocalFree(pDib);
```

**Parameters:**

**int depth = 24**

The bitmap depth; either 24 (BGR) or 32 (BGRO). If not specified the default is 24.

**UWORD \*gam=NULL**

Specifies a pointer to an optional gamma table that is used to apply gamma correction to the color components as part of the conversion to a DIB. The table has RCOLN entries.

**BOOL dither=FALSE**

Specifies if a random dither is applied when reducing the color components from 16 bits per channel to 8 bits per channel (to reduce banding effects).

**Prototype:**

**BOOL FromDib(PBITMAPINFO pbmi);**

**Remarks:**

Converts the DIB to this bitmap's storage type. This bitmap's storage must already be allocated or the call will fail. The source must be 16, 24 or 32 bit. You cannot use an 8 bit DIB.

**Parameters:**

**PBITMAPINFO pbmi**

The source bitmap.

**Return Value:**

TRUE if the conversion was performed; otherwise FALSE.

**Prototype:**

**inline int ResizeImage(int width,int height,int newpalette)**

**Remarks:**

This method is not currently implemented.

## Channel Access

**Prototype:**

**inline void \*GetChannel(ULONG channelId, ULONG& chanType)**

**Remarks:**

Returns a pointer to the specified channel of the bitmap, and determines its type in terms of bits per pixel.

**Parameters:**

**ULONG channelId**

The channel to return a pointer to. See [List of Image Channels](#).

**ULONG& chanType**

The type of the returned channel. One of the following values:

**BMM\_CHAN\_TYPE\_UNKNOWN**

Channel not of a known type.

**BMM\_CHAN\_TYPE\_8**

1 byte per pixel

**BMM\_CHAN\_TYPE\_16**

1 word per pixel

**BMM\_CHAN\_TYPE\_32**

2 words per pixel

**BMM\_CHAN\_TYPE\_48**

3 words per pixel

**BMM\_CHAN\_TYPE\_64**

4 words per pixel

**BMM\_CHAN\_TYPE\_96**

6 words per pixel

**Prototype:**

**GBuffer \*GetGBuffer();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the GBuffer for the bitmap (or NULL if none).

**Prototype:**

**inline ULONG CreateChannels(ULONG channelIDs)**

**Remarks:**

This method creates the specified channels. After creation, these may be accessed using **void \*GetChannel()**.

**Parameters:**

**ULONG channelIDs**

Specifies the channels to create. See [List of Image Channels](#).

**Return Value:**

The channels that are present.

**Prototype:**

**inline void DeleteChannels(ULONG channelIDs)**

**Remarks:**

Delete the specified channels.

**Parameters:**

**ULONG channelIDs**

Specifies the channels to delete. See [List of Image Channels](#).

**Prototype:**

**inline ULONG ChannelsPresent()**

**Remarks:**

Returns the channels that are present. See [List of Image Channels](#).

**Prototype:**

**inline RenderInfo \*GetRenderInfo()**

**Remarks:**

This is used internally. It returns a pointer to the RenderInfo associated with the storage if available; otherwise NULL. See [Class RenderInfo](#).

**Prototype:**

**inline RenderInfo \*AllocRenderInfo()**

**Remarks:**

This is used internally. It returns a pointer to the RenderInfo instance allocated by the storage. If this could not be allocated NULL is returned. See [Class RenderInfo](#).

**Prototype:**

**BOOL PrepareGChannels(BitmapInfo \*bi);**

**Remarks:**

This method is used internally. This method will check with the plug-in (file or device) defined in the given BitmapInfo and prepare (create) the proper channels. If a given channel already exists, no new channel will be created. After creating a bitmap, use this function to define the optional channels that may be required by the given handler.

**Parameters:**

**BitmapInfo \*bi**

Points to an instance of BitmapInfo that defines the properties of the image.

**Return Value:**

TRUE if the channels were created; otherwise FALSE.

**Filtering / Dithering Methods****Prototype:**

```
int GetFiltered(float u, float v, float du, float dv, BMM_Color_fl  
*ptr);
```

**Remarks:**

This method uses summed area table or pyramidal filtering to compute an averaged color over the specified area. You must have a filter plugged in for this to work. See **SetFilter()** below.

**Parameters:**

**float u, float v**

The location in the bitmap to filter. These values go from 0.0 to 1.0 across the size of the bitmap.

**float du, float dv**

The size of the rectangle to sample. These values go from 0.0 to 1.0 across the size of the bitmap.

**BMM\_Color\_fl \*ptr**

The result is returned here -- the average over the specified area.

**Prototype:**

```
int SetFilter(UINT filterType);
```

**Remarks:**

Establishes a filtering algorithm to be used by the bitmap.

**Parameters:**

**UINT filterType**

See [List of Bitmap Filter Types](#).

**Return Value:**

Nonzero if the bitmap filtering was set; otherwise 0.

**Prototype:**

## **inline int HasFilter()**

### **Remarks:**

Determines if the bitmap has a filter.

### **Return Value:**

Returns nonzero if the bitmap has a filter; otherwise 0.

### **Prototype:**

**int SetDither(UINT ditherType);**

### **Remarks:**

Sets the type of dithering used on the bitmap.

### **Parameters:**

**UINT ditherType**

The type of dither to perform.

**BMM\_DITHER\_NONE**

Specifies no dithering is to be performed.

**BMM\_DITHER\_FLOYD**

Specifies the Floyd-Steinberg dithering algorithm.

### **Return Value:**

Nonzero if the bitmap dithering was set; otherwise 0.

### **Prototype:**

**inline BitmapFilter \*Filter()**

### **Remarks:**

This method is used internally. It returns a pointer to the bitmap filter used by the bitmap.

### **Prototype:**

**int SetStorage(BitmapStorage \*storage);**

### **Remarks:**

Establishes a bitmap storage to manage this bitmap.

### **Parameters:**

**BitmapStorage \*storage**

The storage to manage the bitmap.

**Return Value:**

Nonzero if the storage was assigned; otherwise 0.

**Prototype:**

**inline BitmapStorage \*Storage()**

**Remarks:**

Returns the storage that is managing this bitmap.

**Return Value:**

A pointer to the storage.

**Prototype:**

**inline void NullStorage();**

**Remarks:**

Sets the storage pointer to NULL.

## **Output / Writing / Closing Methods**

**Prototype:**

**BMMRES OpenOutput(BitmapInfo \*bi);**

**Remarks:**

This method will open the image for output. This allows the image to be written to. Note that you can pass a **BitmapInfo** to this method where you simply set the name 'by hand' (**bi->SetName()**). This will work and the correct driver will be selected based on the filename extension. However you won't be able to set any driver specific settings (such as compression settings for JPEGs). The alternative way is to use the **BitmapManger** methods.

**Parameters:**

**BitmapInfo \*bi**

Contains the name of the image or device to open for output.

**Return Value:**

**BMMRES\_SUCCESS**

Indicates success.

### **BMMRES\_ERRORTAKENCARE**

Indicates that 3ds max could not find a device to handle the image.

### **BMMRES\_INTERNALERROR**

Indicates the IO module handling the image could not be opened for writing.

### **Prototype:**

**BMMRES Write(BitmapInfo \*bi, DWORD frame =  
BMM\_SINGLEFRAME)**

### **Remarks:**

Write the image from the **BitmapStorage** to disk. Note that you must pass the same **BitmapInfo** used when the file was first "Opened for Output". The main reason is that any device specific settings are kept in the **BitmapInfo** object. Also, the custom options such as gamma value, optional channels, etc (if any) are kept in this **BitmapInfo** instance. These are assigned when the bitmap is first opened (for either read or write).

### **Parameters:**

#### **BitmapInfo \*bi**

Contains the name of the file or device to write to.

#### **DWORD frame = BMM\_SINGLEFRAME**

Specifies the frame number to write. If this is a single image, allow **frame** to default to single frame. This argument determines if the file will have the frame number appended to it. If you want the file to have a normal name (no frame number attached to it), you must set the frame argument to **BMM\_SINGLEFRAME**. Any other value is considered to be a frame number and it will be appended to the given filename.

### **Return Value:**

#### **BMMRES\_SUCCESS**

Indicates success.

#### **BMMRES\_ERRORTAKENCARE**

Indicates that 3ds max could not find a device to handle the image.

#### **BMMRES\_INTERNALERROR**

Indicates the IO module handling the image could not be opened for writing.

**Prototype:**

**BMMRES WriteAll(DWORD frame = BMM\_SINGLEFRAME);**

**Remarks:**

Write the image to all the open outputs.

**Parameters:**

**DWORD frame = BMM\_SINGLEFRAME**

Specifies the frame number to write. If this is a single image, allow **frame** to default to single frame.

**Return Value:**

**BMMRES\_SUCCESS**

Indicates success.

**BMMRES\_ERRORTAKENCARE**

Indicates that 3ds max could not find a device to handle the image.

**BMMRES\_INTERNALERROR**

Indicates the IO module handling the image could not be opened for writing.

**Prototype:**

**int Close(BitmapInfo \*bi, int flag = BMM\_CLOSE\_COMPLETE)**

**Remarks:**

Close the bitmap. This means the bitmap is no longer open for writing.

**Parameters:**

**BitmapInfo \*bi**

Identifies the bitmap to close.

**int flag = BMM\_CLOSE\_COMPLETE**

See [List of Bitmap Close Types](#).

**Return Value:**

Nonzero if the image output was closed without error; otherwise 0.

**Prototype:**

**int CloseAll(int flag = BMM\_CLOSE\_COMPLETE)**

**Remarks:**

Closes all the open outputs.

**Parameters:**

**int flag = BMM\_CLOSE\_COMPLETE**

See [List of Bitmap Close Types](#).

**Return Value:**

Nonzero if the image outputs were closed without error; otherwise 0.

**Prototype:**

**inline void UseScaleColors(int on);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Set whether colors are scaled (on) or clamped (off) when converting from **BMM\_Color\_fl** to **BMM\_Color\_64**. If storage is not allocated, does nothing.

**Prototype:**

**inline int ScaleColors();**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Returns the last value set by **UseScaleColors**. If storage is not allocated, returns 0.

**Prototype:**

**inline static void ClampColor(BMM\_Color\_64& out, const BMM\_Color\_fl& in);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out clamping the RGB components to 0 to 65535. The alpha component is not copied.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

**Prototype:**

```
inline static void ClampColorA(BMM_Color_64& out, const  
BMM_Color_fl& in);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out clamping the RGB components to 0 to 65535.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

**Prototype:**

```
inline void ScaleColor (BMM_Color_64& out, BMM_Color_fl in);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out clamping the RGB components to 0 to 65535. The alpha component is not copied.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

**Prototype:**

```
inline void ScaleColorA(BMM_Color_64& out, const  
BMM_Color_fl& in);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out clamping the RGB components to 0 to 65535.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

**Prototype:**

```
inline void ClampScaleColor (BMM_Color_64& out, const  
BMM_Color_fl& in);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out, using the value of **ScaleColors()** to determine the clamping or scaling. The alpha component is not copied. If the storage is not allocated, the clamping is performed.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

**Prototype:**

```
inline void ClampScaleColorA (BMM_Color_64& out, const  
BMM_Color_fl& in);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Converts in to out, using the value of **ScaleColors()** to determine the clamping or scaling. If the storage is not allocated, the clamping is performed.

**Parameters:**

**BMM\_Color\_64& out**

The result of the conversion.

**BMM\_Color\_fl& in**

The value to convert.

## Display (Virtual Frame Buffer) Methods

**Prototype:**

```
int Display(TCHAR *title=NULL, int position=BMM_CN, BOOL  
autonomous=FALSE, BOOL savebutton=TRUE, CropCallback  
*crop=NULL, Bitmap *cloneMyVFB = NULL)
```

**Remarks:**

This method creates a window for the display of this bitmap and displays it.

**Parameters:**

**TCHAR \*title = NULL**

The title to display in the title bar of the window.

**int position = BMM\_CN**

Specifies how the bitmap should be positioned. One of the following values:

**BMM\_UL** - Upper Left

**BMM\_LL** - Lower Left

**BMM\_UR** - Upper Right

**BMM\_LR** - Lower Right

**BMM\_CN** - Center

**BMM\_RND** - Used internally. Renderer location.

**BMM\_VPP** - Used internally. Video Post Primary location.

**BMM\_VPS** - Used internally. Video Post Secondary location.

**BOOL autonomous = FALSE**

This is reserved for internal use, always let it default to FALSE.

**BOOL savebutton = TRUE**

This is reserved for internal use, always let it default to TRUE.

**CropCallback \*crop=NULL**

This parameter is available in release 2.0 and later only.

When non-NULL this will cause the VFB to display, instead of its normal toolbar, a set of sliders for adjusting cropping and also will allow interactive adjustment of the cropping rectangle in the image window. See [Class CropCallback](#).

**Bitmap \*cloneMyVFB = NULL**

This parameter is available in release 4.0 and later only.

A pointer to a bitmap to clone the VFB to.

**Return Value:**

Nonzero if the bitmap was displayed; otherwise 0.

**Prototype:**

**int UnDisplay();**

**Remarks:**

Close the display window associated with this bitmap (if any).

**Return Value:**

Always returns nonzero.

**Prototype:**

**BOOL IsAutonomousVFB();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the virtual frame buffer (VFB) is autoomous; otherwise FALSE. For instance, Video Post has an associated VFB. When Video Post is closed so is its VFB since it belongs to it. In that case the VFB is **not** autonomous. If the user does a View File command, that VFB is autonomous.

**Prototype:**

**HWND GetWindow();**

**Remarks:**

Get the window handle for the displayed bitmap.

**Return Value:**

Returns the window handle, or NULL if it's not displayed in a window.

**Prototype:**

**void RefreshWindow(RECT \*rect = NULL);**

**Remarks:**

Refreshes the interior of the display window with the bitmap contents. In release 3.0 and later this method respects the **Bitmap::ShowProgressLine()** setting. See that method for more details.

**Parameters:**

**RECT \*rect = NULL**

The region of the display window to refresh (specified in image coordinates). If the pointer is NULL the entire window is refreshed.

**Prototype:**

**void SetCroppingValues(float u, float v, float w, float h, BOOL placeImage);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used when the VFB is being displayed and you want to change the cropping rectangle from your plug-in. An example of this is available in **\MAXSDK\SAMPLES\MATERIALS\BMTEX.CPP**.

**Parameters:**

**float u**

The U value to set.

**float v**

The U value to set.

**float w**

The U value to set.

**float h**

The U value to set.

## **BOOL placeImage**

TRUE for place mode; FALSE for crop.

### **Prototype:**

```
void SetWindowTitle(TCHAR *title);
```

### **Remarks:**

Sets the title displayed in the display window's title bar.

### **Parameters:**

**TCHAR \*title**

The title to display.

## **Storage Change Notification**

### **Prototype:**

```
void SetNotify(BitmapNotify *bmnot=NULL);
```

### **Remarks:**

This method is available in release 2.0 and later only.

This method is used to set a callback to allow the developer to get notified if the storage for the Bitmap has changed.

### **Parameters:**

**BitmapNotify \*bmnot=NULL**

The pointer to the callback object implemented by the developer used to provide notification when the Bitmap's storage changes. See [Class BitmapNotify](#).

### **Prototype:**

```
BitmapNotify *GetNotify();
```

### **Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the callback used to notify a developer when the Bitmap's storage changes.

### **Default Implementation:**

```
{ return bmNotify; };
```

## Execute -- Generic Expansion Method

### Prototype:

```
INT_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0,  
ULONG arg3=0);
```

### Remarks:

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

### Parameters:

#### **int cmd**

The index of the command to execute.

#### **ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

#### **ULONG arg2=0**

Optional argument 2.

#### **ULONG arg3=0**

Optional argument 3.

### Return Value:

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

## Handy built-in functions

### Prototype:

**int Fill(int r,int g,int b,int alpha);**

### Remarks:

Sets every pixel of the bitmap to the specified color and alpha value.

### Parameters:

**int r**

Specifies the red value to fill with.

**int g**

Specifies the green value to fill with.

**int b**

Specifies the blue value to fill with.

**int alpha**

Specifies the alpha value to fill with.

### Return Value:

Nonzero if the operation succeeded; otherwise FALSE.

### Prototype:

**void Print(bool silent = false);**

### Remarks:

This method is available in release 3.0 and later only.

This method is only supported in 3D Studio VIZ.

### Prototype:

**void ShowProgressLine(int y);**

### Remarks:

This method is available in release 3.0 and later only.

This method is used for showing a moving scanline in a virtual frame buffer displaying this bitmap. Here's how it works. If you call

**ShowProgressLine(y)**, it clears any previously set white line, and sets an internal counter: you have to call **Bitmap::RefreshWindow()** to get the

new white line to show up. From then that line will be displayed as white. To Clear it call **ShowProgressLine(-1)**.

**Parameters:**

**int y**

The scanline to display as white (the count begins at zero). Use a value of -1 to hide the line.

# Class BitmapManager

See Also: [Class BitmapInfo](#), [Class Bitmap](#), [Class BitmapIO](#), [Class BitmapStorage](#), [Working with Bitmaps](#), [List of Bitmap Error Codes](#).

```
class BitmapManager : public InterfaceServer
```

## Description:

This class is used to manage the use of bitmaps within 3ds max. There is a global instance of this class provided by 3ds max that developers may use to call these methods. It is called **TheManager**. This class provides methods for things such as creating and loading bitmaps, and access to the bitmap Map Path directories. There are also methods for displaying some general dialogs that let users select input and output files and devices, as well as dialogs for setting options for the bitmap such as its custom width, height and positioning.

Note: In the 3ds max release 3.0 SDK these methods were made virtual.

## Data Members:

public:

**BMMVfbPalette \*pal;**

This is used internally as the virtual framebuffer palette.

## Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class

[New / Creating / Loading Methods](#)

[Display / VFB Related Methods](#)

[User Interface \(Dialog Box\) Methods](#)

[Host Access \(Window handles, Map path directory access, etc.\)](#)

[Error Processing](#)

[Future Expansion](#)

## Methods:

## Error Processing

### Prototype:

**BOOL SilentMode()**

**Remarks:**

Determines if silent mode is on. Silent mode specifies if developers should display error messages. If this method returns FALSE, error messages should be displayed. If TRUE, error message dialogs should not be shown.

**Return Value:**

Returns TRUE if silent mode is on; FALSE otherwise.

**Prototype:**

```
void SysLog(int type, char *format, ...);
```

**Remarks:**

This is reserved for future use.

**Prototype:**

```
BOOL SetSilentMode(BOOL s);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void SetLogLevel(DWORD level);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
DWORD GetLogLevel();
```

**Remarks:**

This method is used internally.

## **Display / VFB Related Methods**

**Prototype:**

```
void RefreshAllVFBs();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method refreshes the interior of all the virtual frame buffer windows with each bitmap's contents.

**Prototype:**

**void DeleteAllAutonomousVFBMaps();**

**Remarks:**

This method is available in release 2.0 and later only.

This method calls **Bitmap::DeleteThis()** on all the bitmaps whose virtual frame buffers are set to autonomous.

## Future Expansion

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

**Parameters:**

**int cmd**

The index of the command to execute.

**ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

## Host Interface

### Prototype:

**virtual HINSTANCE AppInst();**

### Remarks:

Returns the application instance handle of 3ds max itself.

### Prototype:

**virtual HWND AppWnd();**

### Remarks:

Returns the window handle of 3ds max's main window.

### Prototype:

**virtual TCHAR \*GetDir(int i);**

### Remarks:

Implemented by the System.

Retrieves the specified standard 3ds max directory name (fonts, scenes, images, etc.).

### Parameters:

**int i**

Specifies the directory name to retrieve. See [List of Directory Names](#).

### Return Value:

The name of the specified directory.

### Prototype:

**virtual BOOL AddMapDir(TCHAR \*dir,int update);**

### Remarks:

For internal use only - This is used to add a MAP PATH to the Map path list.

### Prototype:

**virtual int GetMapDirCount();**

### Remarks:

Returns the number of map paths (used in conjunction with the method below).

**Return Value:**

The number of map paths.

**Prototype:**

**virtual TCHAR \*GetMapDir(int i);**

**Remarks:**

Map paths are accessed using a virtual array mechanism. This method returns the 'i-th' map path.

**Parameters:**

**int i**

Specifies the map path to retrieve.

**Return Value:**

The name of the 'i-th' map path.

**Prototype:**

**virtual Interface \*Max();**

**Remarks:**

Implemented by the System.

Returns an interface pointer for calling methods provided by 3ds max. See [Class Interface](#).

## **Creation / Loading**

**Prototype:**

**virtual Bitmap \*NewBitmap();**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to allocate and return a pointer to a new instance of the Bitmap class. The default constructor is used.

**Prototype:**

**virtual Bitmap \*Create(BitmapInfo \*bi);**

**Remarks:**

This method creates a new bitmap using the properties of the BitmapInfo passed. For more details on creating bitmaps, see the section [Working with Bitmaps](#). Make sure you delete the Bitmap created when you are done using it.

**Parameters:**

**BitmapInfo \*bi**

A pointer to an instance of the class BitmapInfo describing the bitmap to create.

**Return Value:**

A pointer to a newly created instance of class Bitmap.

**Prototype:**

**virtual Bitmap \*Create(PBITMAPINFO pbmi);**

**Remarks:**

This method is used for creating a new bitmap from an existing Windows Device Independent Bitmap. Make sure you delete the Bitmap created when you are done using it.

**Parameters:**

**PBITMAPINFO pbmi**

An existing Windows DIB. For more details on creating bitmaps, see the section [Working with Bitmaps](#).

**Return Value:**

Pointer to a new instance of class Bitmap created from the DIB.

See Also: To create a Windows DIB from a Bitmap see **Bitmap::ToDib()**

**Prototype:**

**virtual Bitmap \*Load(BitmapInfo \*bi, BMMRES \*status = NULL)**

**Remarks:**

This method loads a bitmap using the parameters specified by the **BitmapInfo** pointer. Make sure you delete the Bitmap created when you are

done using it.

Note: When several plug-ins call this method to load the same image, they all receive the same pointer to one instance of the **BitmapStorage**. So if one plug-in manipulates the image, the changes will get reflected everywhere. A developer may use **BitmapManager::Create()** followed by

**Bitmap::CopyImage()** to create a unique instance of **BitmapStorage**.

Also Note: One of the methods in **BitmapInfo** returns a window handle to send progress report messages. If you want to receive these messages (for purposes of putting up a progress bar during the load), set the window handle (**bi->SetUpdateWindow(hWnd)**) and process **BMM\_PROGRESS** and **BMM\_CHECKABORT** messages.

**Parameters:**

**BitmapInfo \*bi**

Specifies the properties of the bitmap to load.

**BMMRES \*status**

The result of the bitmap load operation. See [Bitmap Error Codes](#).

**Return Value:**

A pointer to a new instance of the class Bitmap.

**Prototype:**

```
virtual BMMRES LoadInto(BitmapInfo *bi, Bitmap **map,  
    BOOL forceReload=FALSE);
```

**Remarks:**

This method loads the bitmap specified by **bi** into the bitmap pointed to by **map**. The normal **Load()** method creates a new bitmap. However, if you already have an existing bitmap and simply want to load in a new frame, this method may be used. Specify which bitmap to use using **bi** and the map to load into using **map**. For instance, if you have an AVI file and you want to load a new frame, you can simply update the frame number specified in the **BitmapInfo** and call this method passing the bitmap associates with the previous frame.

**Parameters:**

**BitmapInfo \*bi**

Specifies the properties of the bitmap to load.

**Bitmap \*\*map**

A pointer to a pointer to a bitmap. This is the bitmap that will be loaded into.

**BOOL forceReload=FALSE**

If an existing bitmap that matches **bi** is already loaded, then calling calling **LoadInto()** won't load from the disk or device. Rather it will just use the existing in memory version. If you want to force the bitmap to be reloaded from the file or device set this to TRUE.

**Return Value:**

The result of the bitmap load operation. See [Bitmap Error Codes](#).

## User Interface Methods

**Prototype:**

**virtual BMMRES GetImageInfoDlg(HWND hWnd, BitmapInfo \*bi, const TCHAR \*filename = NULL);**

**Remarks:**

This method will display information about the given bitmap in a dialog. The source of the information is either defined in **bi->Name()/bi->Device()** or explicitly in the **filename** passed). This method is an interface into **BitmapIO::GetImageInfoDlg()**. It is not normally called by developers. The default implementation is within the Bitmap Manager. There is a generic Image Info dialog that is used unless the proper BitmapIO class implements it own dialog (and notifies the system through the **BitmapIO::Capabilities()** method).

**Parameters:**

**HWND hWnd**

The parent window handle calling the dialog.

**BitmapInfo \*bi**

Defines the name of the bitmap or device (unless specified below). The image information fields of BitmapInfo \*bi are set with the information loaded from the image.

**const TCHAR \*filename = NULL**

Specifies the filename to use explicitly.

**Return Value:**

The result of the operation. See [Bitmap Error Codes](#).

**Prototype:**

```
virtual BMMRES GetImageInfo(BitmapInfo *bi, const TCHAR  
*filename = NULL);
```

**Remarks:**

This method is used to get information about an image, ie things like image resolution (**bi->Width()/bi->Height()**), number of frames, etc. This is an interface into **BitmapIO::GetImageInfo()**. Given an image definition in **bi.Name()** / **bi.Device()** or explicitly in filename (this function will place filename, if not NULL, into **bi.Name()** before calling **BitmapIO::GetImageInfo()**), the proper device will fill the data members in **BitmapInfo \*bi** with information about the image.

**Parameters:**

**BitmapInfo \*bi**

Defines the name of the bitmap or device (unless specified below).

**const TCHAR \*filename = NULL**

Specifies the filename to use explicitly.

**Return Value:**

The result of the operation. See [Bitmap Error Codes](#).

**Prototype:**

```
virtual BOOL ImageInputOptions( BitmapInfo *bi, HWND hWnd  
);
```

**Remarks:**

This method brings up the standard 3ds max Image Input Options dialog box. If the users selects OK from the dialog, the appropriate data members of **BitmapInfo \*bi** are filled specifying the user's choices. These are the 'Custom' fields accessed using methods such as **GetCustomX()**, **GetCustomGamma()**, **GetCustomStep()**, etc.

**Parameters:**

**BitmapInfo \*bi**

The instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**Return Value:**

Returns TRUE if the users selects OK from the dialog; otherwise FALSE.

**Prototype:**

**virtual BOOL SelectDeviceInput(BitmapInfo \*bi, HWND hWnd);**

**Remarks:**

Brings up the standard 3ds max Select Image Input Device dialog box. If the users selects OK from the dialog, then **bi->Device()** is set to the name of the users device choice.

**Parameters:**

**BitmapInfo \*bi**

Points to the instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**Return Value:**

TRUE if the user exited the dialog using OK; otherwise FALSE.

**Prototype:**

**virtual BOOL SelectDeviceOutput(BitmapInfo \*bi, HWND hWnd);**

**Remarks:**

Brings up the standard 3ds max Select Image Output Device dialog box. If the users selects OK from the dialog, then **bi->Device()** is set to the name of the users device choice.

**Parameters:**

**BitmapInfo \*bi**

Points to the instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**Return Value:**

TRUE if the user exited the dialog using OK; otherwise FALSE.

**Prototype:**

```
virtual BOOL SelectFileOutput(BitmapInfo *bi, HWND hWnd,  
TCHAR *title = NULL, ULONG *pflags = NULL);
```

**Remarks:**

Brings up the standard 3ds max Browse Images for Output dialog box. If the users selects OK from the dialog, then **bi->Name()** is set to the name of the users file choice.

**Parameters:****BitmapInfo \*bi**

Points to the instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**TCHAR \*title = NULL**

The optional title string to display in the title bar of the dialog.

**ULONG \*pflags = NULL**

This parameter is available in release 4.0 and later only.

One of the following:

**BMM\_ENABLE\_SAVE\_REGION**

This flag will cause the "SaveRegion" check box to appear in the dialog.

**BMM\_DO\_SAVE\_REGION**

This flag will return the state of the check box.

**Return Value:**

TRUE if the user exited the dialog using OK; otherwise FALSE.

```
virtual BOOL SelectFileOutput ( BitmapInfo *bi, HWND hWnd, TCHAR
```

\*title = NULL, ULONG \*pflags = NULL)

**Prototype:**

**virtual BOOL SelectFileInput(BitmapInfo \*bi, HWND hWnd, TCHAR \*title = NULL);**

**Remarks:**

Brings up the standard 3ds max Browse Images for Input dialog box. If the users selects OK from the dialog, then **bi->Name()** is set to the name of the users file choice.

**Parameters:**

**BitmapInfo \*bi**

The instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**TCHAR \*title = NULL**

The optional title string to display in the title bar of the dialog.

**Return Value:**

TRUE if the user exited the dialog using OK; otherwise FALSE.

**Prototype:**

**virtual BOOL SelectFileInputEx(BitmapInfo \*bi, HWND hWnd, TCHAR \*title = NULL, BOOL viewonly = FALSE);**

**Remarks:**

This method brings up the standard 3ds max Browse Images for Input dialog box (the same as **SelectFileInput()**) but a "Devices" button is present so the user can select both image files and image devices.

**Parameters:**

**BitmapInfo \*bi**

The instance of BitmapInfo that is updated based on the users dialog selections.

**HWND hWnd**

The parent window handle for the dialog.

**TCHAR \*title = NULL**

The optional title string to display in the title bar of the dialog.

**BOOL viewonly = FALSE**

If **viewonly** is set to TRUE, the View button is hidden in the dialog.

**Return Value:**

TRUE if the user exited the dialog using OK; otherwise FALSE.

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

**Parameters:**

**int cmd**

The index of the command to execute.

**ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

**Prototype:**

**virtual void BeginSavingLoadErrorFiles()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used for accumulating the names of bitmap files that didn't load. Instead of having the BitmapManager display the missing file dialog, it now just collects the names (which can be retrieved using **GetLoadErrorFileList()** below).

**Prototype:**

**virtual NameTab &GetLoadErrorFileList()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method will return a list of names of bitmap files that were not found as discussed in the method above. See [Class NameTab](#).

**Prototype:**

**virtual void EndSavingLoadErrorFiles()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method ends the accumulation of a list of bitmap files that didn't load, and frees the list. See the two methods above.

**Prototype:**

**virtual bool CanImport(const TCHAR\* filename)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns true if the extension of the specified file name is one of the supported types (i.e. there is a BitmapIO module for it); otherwise false.

**Parameters:**

**const TCHAR\* filename**

The file name to check.

## Class IPoint2

See Also: [Class Point2](#).

class IPoint2

### Description:

This class describes a 2D point using int x and y coordinates. Methods are provided to add and subtract points, multiply and divide by scalars, normalize and compute the dot product of two IPoint2s. All methods are implemented by the system.

### Data Members:

public:

**int x,y;**

### Methods:

### Prototype:

**IPoint2()**

### Remarks:

Constructor.

### Prototype:

**IPoint2(int X, int Y)**

### Remarks:

Constructor. Data members are initialized to X and Y.

### Prototype:

**IPoint2(const IPoint2& a)**

### Remarks:

Constructor. Data members are initialized to a.x and a.y.

### Prototype:

**IPoint2(int af[2])**

### Remarks:

Constructor. Data members are initialized as  $x = af[0]$  and  $y = af[1]$ .

**Prototype:**

**int DotProd(const IPoint2&) const;**

**Remarks:**

Returns the dot product of two IPoint2's. This is the sum of both x values multiplied together and both y values multiplied together.

**Operators:**

**Prototype:**

**int& operator[](int i)  
const int& operator[](int i) const**

**Remarks:**

Allows access to x, y using the subscript operator.

**Return Value:**

An index of 0 will return x, 1 will return y.

**Prototype:**

**operator int\*()**

**Remarks:**

Returns the address of the IPoint2.x.

**Prototype:**

**IPoint2 operator-() const**

**Remarks:**

Unary -. Negates both x and y.

**Prototype:**

**IPoint2 operator+() const**

**Remarks:**

Unary +. Returns the Ipoint2 unaltered.

**Prototype:**

**IPoint2& operator-=(const IPoint2&);**

**Remarks:**

Subtracts a IPoint2 from this IPoint2.

**Prototype:**

**IPoint2& operator+=(const IPoint2&);**

**Remarks:**

Adds a IPoint2 to this IPoint2.

**Prototype:**

**IPoint2& operator\*=(int);**

**Remarks:**

Multiplies this IPoint2 by an integer value.

**Prototype:**

**IPoint2& operator/=(int);**

**Remarks:**

Divides this IPoint2 by an integer value.

**Prototype:**

**IPoint2 operator-(const IPoint2&) const;**

**Remarks:**

Subtracts a IPoint2 from a IPoint2.

**Prototype:**

**IPoint2 operator+(const IPoint2&) const;**

**Remarks:**

Adds a IPoint2 to a IPoint2.

**Prototype:**

**int operator\*(const IPoint2&) const;**

**Remarks:**

Returns the dot product of two IPoint2's. This is the sum of both x values multiplied together and both y values multiplied together.

**Prototype:**

**int operator==(const IPoint2& p) const**

**Remarks:**

Equality operator. Compare two IPoint2's.

**Return Value:**

Nonzero if the IPoint2's are equal; otherwise 0.

The following functions are not members of class IPoint2 but are available for use:

**Function:**

**int Length(const IPoint2& v);**

**Remarks:**

Returns the length of the IPoint2, ie:

**sqrt(v.x\*v.x+v.y\*v.y);**

**Function:**

**IPoint2 Normalize(const IPoint2&);**

**Remarks:**

Returns a unit vector. This is an IPoint2 with each component divided by the point **Length()**.

**Prototype:**

**IPoint2 operator\*(int, const IPoint2&);**

**IPoint2 operator\*(const IPoint2&, int);**

**Remarks:**

Each returns an IPoint2 multiplied by a scalar.

**Prototype:**

**IPoint2 operator/(const IPoint2&, int);**

**Remarks:**

Returns an IPoint2 whose x and y members are divided by a scalar.

**Prototype:**

**ostream &operator<<(ostream&, const IPoint2&);**

**Remarks:**

Formats the IPoint2 for output as in

**(x, y).**

**Prototype:**

**inline int MaxComponent(const IPoint2& p)**

**Remarks:**

Returns the component with the minimum abs value. 0=x, 1=y.

**Prototype:**

**inline int MinComponent(const IPoint2& p)**

**Remarks:**

Returns the component with the minimum abs value. 0=x, 1=y.

## Class IPoint3

See Also: [Class Point3](#).

class IPoint3

### Description:

This class describes a 3D point using integer x, y and z coordinates. Methods are provided to add and subtract points, multiply and divide by scalars, and element by element multiply and divide two points. All methods are implemented by the system.

### Methods:

### Data Members:

public:

**int x,y,z;**

### Prototype:

**IPoint3()**

### Remarks:

Constructor. No initialization is performed.

### Prototype:

**IPoint3(int X, int Y, int Z)**

### Remarks:

Constructor. x, y, and z are initialized to the values specified.

### Prototype:

**IPoint3(const IPoint3& a)**

### Remarks:

Constructor. x, y, and z are initialized to the IPoint3 specified.

### Prototype:

**IPoint3(int ai[3])**

**Remarks:**

Constructor. x, y, and z are initialized to. ai[0], ai[1], and ai[2] respectively.

**Prototype:**

**int DotProd(const IPoint3&) const;**

**Remarks:**

Returns the dot product of two IPoint3s.

**Prototype:**

**IPoint3 CrossProd(const IPoint3&) const;**

**Remarks:**

Returns the cross product of two IPoint3's (vectors).

**Operators:****Prototype:**

**int& operator[](int i)  
const int& operator[](int i) const**

**Remarks:**

Allows access to x, y and z using the [ ] operator.

**Return Value:**

An index of 0 will return x, 1 will return y, 2 will return z.

**Prototype:**

**operator int\*()**

**Remarks:**

Conversion function. Returns the address of the IPoint3.

**Prototype:**

**IPoint3 operator-() const**

**Remarks:**

Unary - operator. Negates x, y and z.

**Prototype:**

**IPoint3 operator+() const**

**Remarks:**

Unary +. Returns the point unaltered.

**Prototype:**

**IPoint3& operator-=(const IPoint3&);**

**Remarks:**

Subtracts a IPoint3 from this IPoint3.

**Prototype:**

**IPoint3& operator+=(const IPoint3&);**

**Remarks:**

Adds a IPoint3 to this IPoint3.

**Prototype:**

**IPoint3 operator-(const IPoint3&) const;**

**Remarks:**

Subtracts a IPoint3 from a IPoint3.

**Prototype:**

**IPoint3 operator+(const IPoint3&) const;**

**Remarks:**

Adds a IPoint3 to a IPoint3.

**Prototype:**

**int operator\*(const IPoint3&) const;**

**Remarks:**

Returns the dot product of two IPoint3s.

**Prototype:**

**IPoint3 operator^(const IPoint3&) const;**

**Remarks:**

The cross product of two IPoint3's (vectors).

**Prototype:**

**int operator==(const IPoint3& p) const**

**Remarks:**

Test for equality between two IPoint3's.

**Return Value:**

Nonzero if the IPoint3's are equal; otherwise 0.

The following functions are not members of IPoint3 but are available for use:

**Prototype:**

**int MaxComponent(const IPoint3&);**

**Remarks:**

Returns the component with the maximum absolute value. 0=x, 1=y, 2=z.

**Prototype:**

**int MinComponent(const IPoint3&);**

**Remarks:**

Returns the component with the minimum absolute value. 0=x, 1=y, 2=z.

**Prototype:**

**inline float Length(const IPoint3& v)**

**Remarks:**

Returns the 'Length' of the point. This is **sqrt(v.x\*v.x+v.y\*v.y+v.z\*v.z)**

**Prototype:**

**ostream &operator<<(ostream&, const IPoint3&);**

**Remarks:**

Formats the IPoint3 for output as in:

**(x, y, z)**

## Class Box2

See Also: [Class IPoint2](#), [Data Types](#).

```
class Box2 : public RECT
```

### Description:

This class describes a 2D rectangular region using integer coordinates. This class is sub-classed from RECT (from the Windows API). Box2 provides methods that return individual coordinates of the box, scale and translate it, retrieve its center, modify its size, expand it to include points or other boxes, and determine if points are inside the box. All methods are implemented by the system.

### Methods:

#### Prototype:

```
Box2();
```

#### Remarks:

Constructs a Box2 object. The box is initialized such that it is 'empty'. See **IsEmpty()** below.

#### Prototype:

```
Box2(const IPoint2 a, const IPoint2 b);
```

#### Remarks:

Constructs a Box2 object from the specified corners.

#### Parameters:

```
const IPoint2 a
```

The upper left corner of the box.

```
const IPoint2 b
```

The lower right corner of the box.

#### Prototype:

```
int IsEmpty();
```

#### Remarks:

Determines whether the box has been 'Set Empty' (see below). When a box is created using the default constructor it is set to 'empty'.

**Return Value:**

TRUE if the box is empty; FALSE otherwise.

**Prototype:**

```
void SetEmpty();
```

**Remarks:**

Sets the box to 'empty'. This indicates the box has not had specific values set by the developer.

**Prototype:**

```
void Rectify();
```

**Remarks:**

Adjusts the coordinates of the box such that **top<bottom** and **left<right**.

**Prototype:**

```
void Scale(float f);
```

**Remarks:**

Scales the coordinates of the box about the center of the box.

**Parameters:**

**float f**

Specifies the scale factor.

**Prototype:**

```
void Translate(IPoint2 t);
```

**Remarks:**

Translate the box by the distance specified.

**Parameters:**

**IPoint2 t**

The distance to translate the box.

**Prototype:**

```
IPoint2 GetCenter()
```

**Remarks:**

Returns the center of the box (the midpoint between the box corners).

**Prototype:**

**int x()**

**Remarks:**

Returns the minimum x coordinate of the box.

**Prototype:**

**int y()**

**Remarks:**

Returns the minimum y coordinate.

**Prototype:**

**int w()**

**Remarks:**

Returns the width of the box.

**Prototype:**

**int h()**

**Remarks:**

Returns the height of the box.

**Prototype:**

**void SetW(int w)**

**Remarks:**

Sets the box width to the width specified. The 'right' coordinate is adjusted such that:

**right = left + w - 1**

**Parameters:**

**int w**

The new width for the box.

**Prototype:**

**void SetH(int h)**

**Remarks:**

Sets the height of the box to the height specified. The 'bottom' coordinate is adjusted such that:

**bottom = top + h - 1;**

**Parameters:**

**int h**

The new height for the box.

**Prototype:**

**void SetX(int x)**

**Remarks:**

Sets the left coordinate of the box to x.

**Parameters:**

**int x**

The new value for the left coordinate.

**Prototype:**

**void SetY(int y)**

**Remarks:**

Set the top coordinate to y.

**Parameters:**

**int y**

The new value for the top coordinate.

**Prototype:**

**void SetWH(int w, int h)**

**Remarks:**

Sets both the width and height of the box.

**Parameters:**

**int w**

The new width for the box.

**int h**

The new height of the box.

**Prototype:**

**void SetXY(int x, int y)**

**Remarks:**

Sets both the left and top coordinates of the box.

**Parameters:**

**int x**

The new left coordinate.

**int y**

The new top coordinate.

**Prototype:**

**int Contains(const IPoint2& p) const**

**Remarks:**

Determines if the point passed is contained within the box. Returns nonzero if the point is inside the box; otherwise 0.

**Operators:**

**Prototype:**

**Box2& operator=(const RECT& r);**

**Box2& operator=(RECT& r);**

**Remarks:**

Assignment operators. Copies the specified source RECT into this Box2 object.

**Prototype:**

**Box2& operator+=(const Box2& b);**

**Remarks:**

Expands this **Box2** to completely include box **b**.

**Prototype:**

**Box2& operator+=(const IPoint2& p);**

**Remarks:**

Expands this **Box2** to include point **p**.

**Prototype:**

**int operator==( const Box2& b ) const**

**Remarks:**

Equality operator. Determines whether b is equal to Box2. Returns nonzero if the boxes are equal; 0 otherwise.

## Class Box3

See Also: [Class Point3](#), [Class Matrix3](#).

class Box3

### Description:

This class represents a 3D box volume described by two 3D corner coordinates. Box3 provides methods that return individual coordinates of the box, scale and translate it, retrieve its center, modify its size, expand it to include points or other boxes, and determine if points are inside the box. All methods are implemented by the system.

### Data Members:

public:

**Point3 pmin, pmax;**

The corners of the 3D box.

### Methods:

### Prototype:

**Box3();**

### Remarks:

Constructor. The corners of the box are initialized such that the box is 'empty'. See **IsEmpty()**.

### Prototype:

**Box3(const Point3& p, const Point3& q)**

### Remarks:

Constructor. The corners of the box are initialized to the points passed.  
**pmin=p; pmax = q.**

### Prototype:

**void Init();**

### Remarks:

Initializes this box such that **pmin** is a very large value while **pmax** is a small

value. Thus the box is 'empty'. See **IsEmpty()**.

**Prototype:**

**int IsEmpty() const;**

**Remarks:**

Determines if the box is empty. This indicates the box has not had specific values set by the developer.

**Return Value:**

Nonzero if the box is empty; otherwise 0.

**Prototype:**

**void MakeCube(const Point3& p, float side);**

**Remarks:**

Modifies this box such that half the side length is subtracted from **pmin** and added to **pmax**. This creates a cube with the specified center **p** and side length **side**.

**Parameters:**

**const Point3& p**

Specifies the center point of the cube.

**float side**

Specifies the side length.

**Prototype:**

**Point3 Min() const**

**Remarks:**

Returns the value of corner **pmin**.

**Prototype:**

**Point3 Max() const**

**Remarks:**

Returns the value of corner **pmax**.

**Prototype:**

**Point3 Center() const**

**Remarks:**

Returns the center of this Box3 as a Point3.

**Prototype:**

**Point3 Width() const**

**Remarks:**

Returns the width of the box as a Point3. This is **pmax-pmin**.

**Prototype:**

**void Scale(float s);**

**Remarks:**

Scales this box about its center by the specified scale.

**Parameters:**

**float s**

Specifies the scale factor for this Box3.

**Prototype:**

**void Translate(const Point3 &p);**

**Remarks:**

Translates this box by the distance specified. The point is added to each corner.

**Parameters:**

**const Point3 &p**

Specifies the distance to translate the box.

**Prototype:**

**void EnlargeBy(float s);**

**Remarks:**

Enlarges this box. A Point3 is created from **s** as Point3(s,s,s) and added to

**pmax** and subtracted from **pmin**. If the box is 'empty', the box is centered at (0,0,0) and then enlarged.

**Prototype:**

**int Contains(const Point3& p) const;**

**Remarks:**

Determines if the specified point **p** is contained in this box.

**Parameters:**

**const Point3& p**

Specifies the point to check.

**Return Value:**

Nonzero if the specified point is contained in this box; otherwise 0.

**Prototype:**

**int Contains(const Box3& b) const;**

**Remarks:**

Determines if the specified Box3 is contained totally within this box.

**Parameters:**

**const Box3& b**

Specifies the box to check.

**Return Value:**

Nonzero if the specified box is entirely contained within this box; otherwise 0.

**Operators:**

**Prototype:**

**Point3 operator[](int i) const;**

**Remarks:**

Operator[] returns the 'i-th' corner point:

**Mapping : X Y Z**

**[0] : (min,min,min)**

**[1] : (max,min,min)**

**[2] : (min,max,min)**

[3] : (max,max,min)

[4] : (min,min,max)

[5] : (max,min,max)

[6] : (min,max,max)

[7] : (max,max,max)

**Parameters:**

**int i**

Specifies the corner to retrieve ( $0 \leq i \leq 7$ )

**Return Value:**

The 'i-th' corner point as a Point3.

**Prototype:**

**Box3& operator+=(const Point3& p);**

**Remarks:**

Expands this Box3 to include the Point3 **p**.

**Parameters:**

**const Point3& p**

Specifies the point to expand the box to include.

**Prototype:**

**Box3& operator+=(const Box3& b);**

**Remarks:**

Expands this Box3 to include the Box3 **b**.

**Parameters:**

**const Box3& b**

Specifies the Box3 to expand this box to include.

**Prototype:**

**Box3 operator\*(const Matrix3& tm) const;**

**Remarks:**

Returns a box that bounds the 8 transformed corners of the input box.

**Parameters:**

**const Matrix3& tm**

Specifies the matrix to transform the box corners by.

## Class Matrix2

See Also: [Class Point2](#), [Class Point3](#), [Class Matrix3](#).

class Matrix2

### Description:

This class defines a 3x2 2D transformation matrix. Methods are provided to zero the matrix, set it to the identity matrix, translate, rotate and scale it, and compute its inverse. Operators are available for matrix addition, subtraction and multiplication. All methods of this class are implemented by the system.

### Data Members:

public:

**float m[3][2];**

### Methods:

#### Prototype:

**Matrix2()**

#### Remarks:

Constructor. No initialization is done in this constructor. Use **Zero()** or **IdentityMatrix()** to initialize the matrix.

#### Prototype:

**Matrix2(float (\*fp)[2]);**

#### Remarks:

Constructor. The matrix is initialized using **fp**.

### Operators:

#### Prototype:

**Matrix2& operator-=( const Matrix2& M);**

#### Remarks:

Subtracts a Matrix2 from this Matrix2.

#### Prototype:

**Matrix2& operator+=( const Matrix2& M);**

**Remarks:**

Adds a Matrix2 to this Matrix2.

**Prototype:**

**Matrix2& operator\*=( const Matrix2& M);**

**Remarks:**

Matrix multiplication between this Matrix2 and **M**.

**Prototype:**

**operator float\*()**

**Remarks:**

Returns the address of the Matrix2.

**Prototype:**

**void IdentityMatrix();**

**Remarks:**

Sets this Matrix2 to the Identity Matrix.

**Prototype:**

**void Zero();**

**Remarks:**

Set all elements of this Matrix2 to 0.0f

**Prototype:**

**Point2 GetRow(int i) const;**

**Remarks:**

Returns the specified row of this matrix.

**Parameters:**

**int i**

Specifies the row to retrieve (0-2).

**Prototype:**

**void SetRow(int i, Point2 p);**

**Remarks:**

Sets the specified row of this matrix.

**Parameters:**

**int i**

Specifies the row to set (0-2).

**Point2 p**

The values to set.

**Prototype:**

**Point3 GetColumn(int i);**

**Remarks:**

Returns the specified column of this matrix.

**Parameters:**

**int i**

Specifies the column to retrieve (0 or 1).

**Prototype:**

**void SetColumn(int i, Point3 col);**

**Remarks:**

Sets the specified column of this matrix.

**Parameters:**

**int i**

Specifies the column to set (0 or 1).

**Point3 col**

The values to set.

**Prototype:**

**Point2 GetColumn2(int i);**

**Remarks:**

This method returns a Point2 containing the upper two rows of the specified column.

**Parameters:**

**int i**

Specifies the column to get (0 or 1).

**Prototype:**

**void SetTrans(const Point2 p);**

**Remarks:**

Sets the translation row of the matrix to the specified values.

**Parameters:**

**const Point2 p**

The values to set.

**Prototype:**

**void SetTrans(int i, float v);**

**Remarks:**

Sets the specified element of the translation row of this matrix to the specified value.

**Parameters:**

**int i**

Specifies which column to set (0 or 1)

**float v**

The value to store.

**Prototype:**

**Point2 GetTrans();**

**Remarks:**

Returns the translation row of this matrix.

**Prototype:**

**void SetTranslate(const Point2& s);**

**Remarks:**

This method is available in release 3.0 and later only.

Initializes the matrix to the identity then sets the translation row to the specified values.

**Parameters:**

**const Point2& s**

The values to store.

**Prototype:**

**void SetRotate(float angle);**

**Remarks:**

This method is available in release 3.0 and later only.

Initializes the matrix to the identity then sets the rotation to the specified value.

**Parameters:**

**float angle**

The rotation angle in radians.

**Prototype:**

**void Invert();**

**Remarks:**

This method is available in release 3.0 and later only.

This matrix may be used to invert the matrix in place.

**Prototype:**

**void Translate(const Point2& p);**

**Remarks:**

Apply an incremental translation to this matrix.

**Parameters:**

**const Point2& p**

Specifies the amount to translate the matrix.

**Prototype:**

**void Rotate(float angle);**

**Remarks:**

Apply an incremental rotation to this matrix using the specified angle.

**Parameters:**

**float angle**

Specifies the angle of rotation.

**Prototype:**

**void Scale(const Point2& s, BOOL trans);**

**Remarks:**

Apply an incremental scaling to this matrix using the specified scale factors.

**Parameters:**

**const Point2& s**

The scale factors.

**BOOL trans = FALSE**

If set to **TRUE**, the translation component is scaled. If **trans = FALSE** the translation component is unaffected. When 3ds max was originally written there was a bug in the code for this method where the translation portion of the matrix was not being scaled. This meant that when a matrix was scaled the bottom row was not scaled. Thus it would always scale about the local origin of the object, but it would scale the world axes. When this bug was discovered, dependencies existed in the code upon this bug. Thus it could not simply be fixed because it would break the existing code that depended upon it working the incorrect way. To correct this the **trans** parameter was added. If this is set to **TRUE**, the translation component will be scaled correctly. The existing plug-ins don't use this parameter, it defaults to **FALSE**, and the code behaves the old way.

**Prototype:**

**Matrix2 operator\*(const Matrix2& B) const;**

**Remarks:**

Perform matrix multiplication.

**Prototype:**

**Matrix2 operator+(const Matrix2& B) const;**

**Remarks:**

Perform matrix addition.

**Prototype:**

**Matrix2 operator-(const Matrix2& B) const;**

**Remarks:**

Perform matrix subtraction.

The following functions are not members of Matrix2 but are available for use:

**Function:**

**Matrix2 RotateMatrix(float angle);**

**Remarks:**

Builds an identity matrix and sets the rotation components based on the specified angle.

**Parameters:**

**float angle**

Specifies the angle of rotation.

**Return Value:**

A new Matrix2 object with the specified rotation angle.

**Function**

**Matrix2 TransMatrix(const Point2& p);**

**Remarks:**

Builds an identity matrix and sets the specified translation components.

**Parameters:**

**const Point2& p**

Specifies the translation.

**Return Value:**

A new Matrix2 object with the specified translation.

**Function:**

**Matrix2 ScaleMatrix(const Point2& s);**

**Remarks:**

Builds an identity matrix and sets the specified scaling components.

**Parameters:**

**const Point2& s**

Specifies the scale factors.

**Return Value:**

A new Matrix2 object with the specified scale.

**Function:**

**Matrix2 Inverse(const Matrix2& M);**

**Remarks:**

Returns the inverse of the specified Matrix2.

**Parameters:**

**const Matrix2& M**

Specifies the matrix to return the inverse of.

**Return Value:**

The inverse of the specified Matrix2.

**Function:**

**Point2 operator\*(const Matrix2& A, const Point2& V);**

**Point2 operator\*(const Point2& V, const Matrix2& A);**

**Remarks:**

Transforms the specified Point2 with the specified Matrix2.

**Parameters:**

**const Matrix2& A**

The matrix to transform the point with.

**const Point2& V**

The point to transform.

**Return Value:**

The transformed Point2.

**Function:**

**Point2 VectorTransform(const Matrix2& M, const Point2& V);**

**Remarks:**

This method transforms a 2D point by a 2x3 matrix. This is analogous to the 3D case.

**Parameters:**

**const Matrix2& M**

The matrix to transform the point with.

**const Point2& V**

The point to transform.

**Return Value:**

The transformed Point2.

**Function:**

**ostream &operator<< (ostream& s, const Matrix2& A);**

**Remarks:**

Formats the matrix for output.

## Structure AffineParts

See Also: [Class Matrix3](#), [Class Quat](#), [Class Point](#), [Class ScaleValue](#).

### Description:

This structure and the associated functions provide a way to decompose an arbitrary Matrix3 into its translation, rotation, and scale components.

To use these APIs put the following statement in your source file:

```
#include "decomp.h"
```

For a full discussion of this decomposition see Graphics Gems IV - Polar Matrix Decomposition by Ken Shoemake. ISBN 0-12-336155-9.

**T F R U K U'**

**T** - translation matrix

**F** - either an identity matrix or negative identity matrix

**R** - rotation defined by Quat q.

**U** - rotates you into the coordinates system where the scaling or stretching is done

**K** - scaling matrix

**U'** - inverse of u.

### Structure:

```
typedef struct {
```

```
    Point3 t;
```

The translation components.

```
    Quat q;
```

The essential rotation.

```
    Quat u;
```

The stretch rotation. This is the axis system of the scaling application.

```
    Point3 k;
```

The stretch factors. These are the scale factors for x, y and z.

```
    float f;
```

Sign of the determinant.

```
} AffineParts;
```

### Functions:

**Prototype:**

```
void decomp_affine(Matrix3 A, AffineParts *parts);
```

**Remarks:**

This will decompose a matrix into the translation, rotation and scale components and store the results in the **AffineParts** structure passed. This will return correct results for off axis scale. This is a fairly computationally intensive iterative solution operation.

**Parameters:****Matrix3 A**

The input matrix to decompose.

**AffineParts \*parts**

The result. See above.

**Sample Code:**

Note: If you want to rebuild a **Matrix3** from the decomposed parts you get back from **decomp\_affine()** the important thing is the order the parts are combined.

Consider the following matrices constructed from the various affine parts:

**ptm** = position component (t)

**rtm** = "essential" rotation (q)

**srtm** = "stretch" rotation (u)

**stm** = scale component (k)

**ftm** = the flip tm -> ScaleMatrix(Point3(ap.f,ap.f,ap.f));

Here's the correct way of reassembling the decomposed matrix:

```
Matrix3 srtm, rtm, ptm, stm, ftm;
```

```
ptm.IdentityMatrix();
```

```
ptm.SetTrans(ap.t);
```

```
ap.q.MakeMatrix(rtm);
```

```
ap.u.MakeMatrix(srtm);
```

```
stm = ScaleMatrix(ap.k);
```

```
mat = Inverse(srtm) * stm * srtm * rtm * ftm * ptm;
```

**Prototype:**

**void SpectralDecomp(Matrix3 m, Point3 &s, Quat& q);**

**Remarks:**

This is another way to decompose a matrix into the scale and rotation parts (the position part can be retrieved from the bottom row of the matrix). This does not return correct results for off axis scale.

**Parameters:**

**Matrix3 m**

The input matrix to decompose.

**Point3 &s**

The scale from the matrix.

**Quat& q**

The rotation of the matrix.

**Prototype:**

**void invert\_affine(AffineParts \*parts, AffineParts \*inverse);**

**Remarks:**

This is used to take the **AffineParts** and inverts them. This gives you the equivalent parts for the inverse matrix.

**Parameters:**

**AffineParts \*parts**

The input AffineParts pointer.

**AffineParts \*inverse**

The inverse of **parts**.

## Class AngAxis

See Also: [Class Quat](#), [Class Point3](#).

class AngAxis

### Description:

This class provides a representation for orientation in three space using an angle and axis. This class is similar to a quaternion, except that a normalized quaternion only represents  $-\pi$  to  $+\pi$  rotation. This class will have the number of revolutions stored. All methods of this class are implemented by the system.

The rotation convention in the 3ds max API is the left-hand-rule. Note that this is different from the right-hand-rule used in the 3ds max user interface.

### Data Members:

public:

#### **Point3 axis;**

The axis of rotation.

#### **float angle;**

The angle of rotation about the axis in radians. This angle is left handed.

### Methods:

#### Prototype:

**AngAxis()**

#### Remarks:

Constructor. No initialization is performed.

#### Prototype:

**AngAxis(const Point3& axis, float angle)**

#### Remarks:

Constructor. Data members are initialized to the specified values.

#### Prototype:

**AngAxis(float x, float y, float z, float ang);**

#### Remarks:

This method is available in release 3.0 and later only.

Constructor. The AngAxis is initialized from the specified values.

**Parameters:**

**float x**

The x component of the axis.

**float y**

The y component of the axis.

**float z**

The z component of the axis.

**float ang**

The angle component in radians.

**Prototype:**

**AngAxis(const Matrix3& m);**

**Remarks:**

This method is available in release 3.0 and later only.

Constructor. The AngAxis is initialized with the rotation from the specified matrix.

**Parameters:**

**const Matrix3& m**

The rotation used to initialize the AngAxis.

**Prototype:**

**AngAxis(const Quat &q);**

**Remarks:**

Constructor. Data members are initialized equal to the specified Quat.

**Prototype:**

**AngAxis& Set(float x, float y, float z, float ang);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the angle and axis to the specified values.

**Parameters:****float x**

Specifies the x component of the axis.

**float y**

Specifies the xycomponent of the axis.

**float z**

Specifies the z component of the axis.

**float ang**

Specifies the angle to set in radians.

**Return Value:**

A reference to this AngAxis.

**Prototype:****AngAxis& Set(const Point3& ax, float ang);****Remarks:**

This method is available in release 3.0 and later only.

Sets the angle and axis to the specified values.

**Parameters:****const Point3& ax**

Specifies the axis to set.

**float ang**

Specifies the angle to set in radians.

**Return Value:**

A reference to this AngAxis.

**Prototype:****AngAxis& Set(const Quat& q);****Remarks:**

This method is available in release 3.0 and later only.

Sets the angle and axis based on the rotations from the specified quaternion.

**Parameters:****const Quat& q**

Specifies the angle and axis to use.

**Return Value:**

A reference to this AngAxis.

**Prototype:**

**AngAxis& Set(const Matrix3& m);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the angle and axis based on the rotations from the specified matrix.

**Parameters:**

**const Matrix3& m**

Specifies the angle and axis to use.

**Return Value:**

A reference to this AngAxis.

**Prototype:**

**int GetNumRevs();**

**Remarks:**

Returns the number of revolutions represented by the angle. This returns

**int(angle/TWOPI);**

**Prototype:**

**void SetNumRevs(int num);**

**Remarks:**

Sets the number of revolution to **num**. This modifies angle: **angle +=**

**float(num)\*TWOPI;**

# Class ScaleValue

See Also: [Class Point3](#), [Class Quat](#).

class ScaleValue

## Description:

A ScaleValue describes an arbitrary non-uniform scaling in an arbitrary axis system. The Point3 **s** gives the scaling along the x, y, and z axes, and the quaternion **q** defines the axis system in which scaling is to be applied. All methods are implemented by the system.

## Data Members:

public:

**Point3 s;**

Scale components.

**Quat q;**

The axis system of application.

## Methods:

### Prototype:

**ScaleValue()**

### Remarks:

Constructor. No initialization is performed.

### Prototype:

**ScaleValue(const Point3& as)**

### Remarks:

Constructor. The scale data member is initialized to **as**. The quaternion data member is set to the identity.

### Prototype:

**ScaleValue(const Point3& as, const Quat& aq)**

### Remarks:

Constructor. The scale data member is initialized to **as**. The quaternion data

member is set to **aq**.

**Operators:**

**Prototype:**

**ScaleValue& operator+=(const ScaleValue& s)**

**Remarks:**

Adds a ScaleValue to this ScaleValue.

**Prototype:**

**ScaleValue& operator\*=(const float s)**

**Remarks:**

Multiplies this ScaleValue by a float. This updates the scale components.

**Prototype:**

**float& operator[](int el)**

**Remarks:**

Array access operator. This allows the scale components to be accessed using the array operator.

**Parameters:**

**int el**

Specifies the element to access: 0=x, 1=y, 2=z.

**The following operators are not part of the ScaleValue class but are available for use:**

**Prototype:**

**ScaleValue operator+(const ScaleValue& s0, const ScaleValue& s1);**

**Remarks:**

Returns the sum of two ScaleValues. This still multiplies since scale values are multiplicative not additive.

**Prototype:**

**ScaleValue operator-(const ScaleValue& s0, const ScaleValue& s1);**

**Remarks:**

Returns the difference of two ScaleValues.

**Prototype:**

**ScaleValue operator\*(const ScaleValue& s, float f);**

**Remarks:**

Multiplication of a ScaleValue and a float.

**Prototype:**

**ScaleValue operator\*(float f, const ScaleValue& s);**

**Remarks:**

Multiplication of a ScaleValue and a float.

**Prototype:**

**ScaleValue operator+(const ScaleValue& s, float f);**

**Remarks:**

Returns the sum of a ScaleValue and a float. This adds f to s.x, s.y, and s.z.

**Prototype:**

**ScaleValue operator+(float f, const ScaleValue& s);**

**Remarks:**

Returns the sum of a ScaleValue and a float.

## Class GraphicsWindow

See Also: [Interactive Renderer: Graphics Window](#), [Class GWinSetup](#), [Class HitRegion](#), [List of Marker Types](#), [List of Rendering Limits](#), [Class Point3](#), [Class IPoint3](#), [Class Matrix3](#), [Class Interface](#), [Class ViewExp](#).

```
class GraphicsWindow : public InterfaceServer
```

### Description:

The abstract graphics window class. The methods here provide low-level access to 3ds max's graphics system. These methods are available for plug-ins to do any graphics work not possible using the standard high-level graphics methods of 3ds max.

These methods are for use in the existing 3ds max viewports. Note that these APIs are not for casual use, as they are not intended to be a high level graphics library. For example, many steps are required to display a single lit polygon. These APIs are optimized for speed, and not at all for plug-in programmer ease of use.

These methods are provided, however, so that developers can do things that are otherwise impossible using the high-level methods.

**Developers should use these methods with an understanding of exactly what they are doing since it's quite easy to crash 3ds max when inappropriate arguments are supplied. The calls are specifically optimized for exactly the way 3ds max uses them. In no way should the calls in GraphicsWindow be considered an "ordinary" 2D/3D API. (That's what OpenGL, D3D, and HEIDI are for.)**

One final note of warning: most graphics windows methods execute in a separate thread (or in multiple separate threads) that are owned by the graphics window. Thus, due to thread scheduling, when a bad argument or incorrect sequencing of graphics windows calls causes 3ds max to crash, it is not at all easy to figure out where the problem is. In particular, the location of the main 3ds max thread is not relevant.

All the methods of this class are implemented by the system.

### Method Groups:

[Utility Functions](#)

**Methods:**

**Driver/Configuration/Support Methods**

**Prototype:**

```
virtual void postCreate(int ct, GraphicsWindow **gw)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This is called after all four GraphicsWindows used by 3ds max are created.  
SDK users shouldn't need this call

**Prototype:**

```
virtual void shutdown()=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This is used to tell the driver that it is shutting down.

**Prototype:**

```
virtual int getVersion()=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This returns "0x200" to indicate R2.0

**Prototype:**

**virtual TCHAR \*getDriverString()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This identifies the driver (and includes manufacturer info if available)

**Prototype:**

**virtual void config(HWND hWnd)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is called to put up the config dialog if the driver supports  
GW\_SPT\_CAN\_CONFIG

**Parameters:**

**HWND hWnd**

The parent window handle for the dialog.

**Prototype:**

**virtual int querySupport(int what) = 0;**

**Remarks:**

Determines if the driver supports the specified feature.

**Parameters:**

**int what**

One of the following values:

**GW\_SPT\_TXT\_CORRECT**

This is used to enable or gray-out the perspective correction right-click viewport menu option.

**GW\_SPT\_GEOM\_ACCEL**

This is used to indicate to 3ds max (and the mesh class in particular) that the driver wants to handle all of the 3D data natively. In this case, meshes are rendered by passing 3D world space data and letting the driver transform, clip, and light the vertices. If this returns FALSE, then the mesh class handles all xforms/clip/lighting calculations (using a lazy evaluation

algorithm) and then calls the hPolygon or hPolyline 2 1/2D calls for the driver to rasterize. (Primitives that are actually clipped are still sent to the polygon/polyline methods.)

Right now, only the OpenGL driver returns TRUE to this query, but other drivers have been developed that return TRUE, and the HEIDI and D3D drivers may change in the future.

### **GW\_SPT\_TRI\_STRIP**

If this returns TRUE, then 3ds max will try to stripify meshes before calling the rendering methods. Right now, the drivers just return the user preference that is set in the driver config dialog. It defaults to TRUE.

### **GW\_SPT\_DUAL\_PLANES**

If a driver has dual-planes support it returns TRUE. Our OpenGL display driver only returns TRUE for this if the underlying display driver has implemented a custom OpenGL extension that allows us to handle this efficiently.

### **GW\_SPT\_SWAP\_MODEL**

This returns TRUE if 3ds max has to redraw the whole scene any time the viewports are exposed.

### **GW\_SPT\_INCR\_UPDATE**

This returns TRUE if the driver can update a rectangular subset of the viewport without trashing the image outside that rectangle. This is TRUE for most drivers that blit the viewport region and FALSE for those that do page-flipping in the hardware. For OpenGL, this is TRUE if the display driver implements the Microsoft glSwapRectHintWIN extension.

### **GW\_SPT\_1\_PASS\_DECAL**

This is TRUE if the driver can handle decalling with only one pass. Right now, this is TRUE for OpenGL, but FALSE for HEIDI and D3D. (And as with all of these options, it may change in a given driver anytime in the future.)

### **GW\_SPT\_DRIVER\_CONFIG**

This is TRUE if the driver has a configuration dialog box. This is TRUE for all three of our standard drivers.

### **GW\_SPT\_TEXTURED\_BKG**

This is TRUE if the viewport background is implemented as a textured

rectangle, and FALSE if it is a blitted bitmap.

### **GW\_SPT\_VIRTUAL\_VPTS**

This is TRUE if the driver allows viewports to be made larger than the physical window they are attached to. Right now this is only TRUE for OGL.

### **GW\_SPT\_PAINT\_DOES\_BLIT**

This is TRUE if WM\_PAINT messages result in a blit of the backbuffer (as opposed to a page-flipping swap). This allows 3ds max to do quick damage region repair, and works together with the GW\_SPT\_SWAP\_MODEL flag.

### **GW\_SPT\_WIREFRAME\_STRIP**

This is TRUE if the driver wants 3ds max to send down wireframe models using triangle strips instead of a bundle of 2-pt segments. This is only used by the OGL driver, and it is there as a user-choosable performance-accuracy tradeoff (since the strips are faster and are back-culled, but they display hidden edges as though they are visible).

## **Window / Viewport / Transformations Methods**

### **Prototype:**

**virtual HWND getHWnd(void)=0;**

### **Remarks:**

This method is available in release 2.0 and later only.

This returns the "output" window handle. (Input goes to an invisible window above the viewport. The invisible window is owned by MAX.)

### **Prototype:**

**virtual int isPerspectiveView() = 0;**

### **Remarks:**

Returns TRUE if the view is in perspective projection; otherwise FALSE (orthographic projection).

### **Prototype:**

**virtual void getTextExtents(TCHAR \*text, SIZE \*sp)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the size (in pixels) that the specified text string will occupy

**Parameters:**

**TCHAR \*text**

The string to check.

**SIZE \*sp**

The size is returned here. See [Data Types](#).

**Prototype:**

**virtual void setTransform(const Matrix3 &m) = 0;**

**Remarks:**

Sets the current transformation matrix, and updates the modeling coordinates to normalized projection coordinates matrix. This routine also back-transforms each light and the eye point (so that lighting can be done in modeling coordinates).

This method may be used to set a matrix that transforms the point passed to the drawing methods (like **text()**, **marker()**, **polyline()** or **polygon()**).

Normally these methods expect world coordinates. However if this matrix is set to an objects transformation matrix you can pass objects space coordinates and they will be transformed into world space (and then put into screen space when they are drawn). If however this is set to the identity matrix you would pass world space coordinates. You can set this matrix to the objects matrix using the following code:

```
gw->setTransform(inode->GetObjectTM(t));
```

Note: For world-to-screen space conversions by the methods **text()**, **marker()**, **polyline()**, **polygon()**, etc, a developer must explicitly set this matrix to the identity. This is because the **GraphicsWindow** transform may have a non-identity matrix already in place from a previous operation.

**Parameters:**

**const Matrix3 &m**

The new current transformation matrix.

**Prototype:**

**virtual BOOL getFlipped()=0;**

**Remarks:**

This is used internally. It returns if the determinant of the current transform is positive or negative. If it's positive 0 is returned; if it's negative 1 is returned.

**Prototype:**

**virtual void setVirtualViewportParams(float zoom, float xOffset, float yOffset) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to setup a virtual viewport. Note that this is a no-op unless **GW\_SPT\_VIRTUAL\_VPTS** is TRUE. Plug-in developers should not call this method -- it's for internal use only.

**Prototype:**

**virtual void setUseVirtualViewport(int onOff) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to set a virtual viewport as active. Note that this is a no-op unless **GW\_SPT\_VIRTUAL\_VPTS** is TRUE. Plug-in developers should not call this method -- it's for internal use only.

**Parameters:**

**int onOff**

TRUE to set the virtual viewport active; FALSE to make it inactive.

**Position / Size / Depth / Clipping Methods****Prototype:**

**virtual void setPos(int x, int y, int w, int h) = 0;**

**Remarks:**

Sets the size and position of the GraphicsWindow. The coordinates are all Windows coordinates in the space of the GraphicsWindows' parent window.

(The origin is the upper left.)

**Parameters:**

**int x**

Window x origin.

**int y**

Window y origin.

**int w**

Window width.

**int h**

Window height.

**Prototype:**

**virtual void setDisplayState(int s) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

The specified value may be sent to the driver to indicate the display state of the viewport window controlled by the driver.

**Parameters:**

**int s**

The display state to set. One of the following values:

**GW\_DISPLAY\_MAXIMIZED**

**GW\_DISPLAY\_WINDOWED**

**GW\_DISPLAY\_INVISIBLE**

**Prototype:**

**virtual int getDisplayState()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the current state. One of the following values:

**GW\_DISPLAY\_MAXIMIZED**

**GW\_DISPLAY\_WINDOWED**

**GW\_DISPLAY\_INVISIBLE**

**Prototype:****virtual int getWinSizeX()=0;****Remarks:**

This method is available in release 2.0 and later only.

This method gets the current window size in X.

**Prototype:****virtual int getWinSizeY()=0;****Remarks:**

This method is available in release 2.0 and later only.

This method gets the current window size in Y.

**Prototype:****virtual DWORD getWinDepth(void)=0;****Remarks:**

This method is available in release 2.0 and later only.

This method returns the z-buffer depth (in bits)

**Prototype:****virtual DWORD getHitherCoord()=0;****Remarks:**

This method is available in release 2.0 and later only.

This method returns the largest device Z value.

**Prototype:****virtual DWORD getYonCoord()=0;****Remarks:**

This method is available in release 2.0 and later only.

This method returns the smallest device Z value.

**Buffer access methods:****Prototype:**

**virtual BOOL setBufAccess(int which, int b) = 0;**

**Remarks:**

This method is used internally. Most drivers control two image buffers. One is displayed on the screen, and the other is used to rasterize geometric primitives. When rasterization of a complete frame is done, the off-screen buffer is blitted onto the display screen. This is referred to as dual-plane mode. This method will turn dual-plane mode on or off. This is used internally by the File/Preferences... Viewport page Use Dual Planes toggle.

**Parameters:**

**int which**

Specifies which buffer should use dual-planes.

**BUF\_F\_BUFFER**

The image (Framebuffer) buffer.

**BUF\_Z\_BUFFER**

The Z buffer.

**int b**

Nonzero to enable access (toggle on); 0 to toggle off.

**Return Value:**

TRUE if the graphics window has access to the specified buffer; otherwise FALSE.

**Prototype:**

**virtual BOOL getBufAccess(int which) = 0;**

**Remarks:**

This method is used internally. It returns a boolean value indicating if dual plane mode is on or off for the specified buffer.

**Parameters:**

The buffer whose dual-planes setting will be returned.

**int which**

The buffer whose dual-planes setting will be returned. One of the following values:

**BUF\_F\_BUFFER**

The Framebuffer.

## **BUF\_Z\_BUFFER**

The Z buffer.

### **Return Value:**

TRUE if the dual-plane mode is on; otherwise FALSE.

### **Prototype:**

```
virtual BOOL getBufSize(int which, int *size) = 0;
```

### **Remarks:**

This method is used internally. It retrieves the size of the specified buffer in bytes.

### **Parameters:**

#### **int which**

One of the following values:

#### **int \*size**

The size of the buffer in bytes.

Note the following concerning the HEIDI driver. For HEIDI getBufSize() always returns 10 if dual-planes are on (and 0 otherwise). This is because HEIDI actually never returns the image - it keeps its own copy stored away. Thus the "logical" way to think is that we actually get a copy of the buffer by calling getBuf, and that we give it back by calling setBuf. But in reality (with the HEIDI driver) getBuf and setBuf only tell HEIDI to do some internal buffer manipulation.

### **Return Value:**

TRUE if the size was returned; otherwise FALSE.

### **Prototype:**

```
virtual BOOL getBuf(int which, int size, void *buf) = 0;
```

### **Remarks:**

This method is used internally. It retrieves the specified buffer.

### **Parameters:**

#### **int which**

The buffer to retrieve. One of the following values:

**BUF\_F\_BUFFER** - The image Framebuffer.

**BUF\_Z\_BUFFER** - The Z buffer.

**int size**

The number of bytes to retrieve. This must be at least the size returned from **getBufSize()**.

**void \*buf**

Storage for the buffer data.

**Return Value:**

TRUE if the buffer was retrieved; otherwise FALSE.

**Prototype:**

**virtual BOOL setBuf(int which, int size, void \*buf, RECT \*rp) = 0;**

**Remarks:**

Stores the specified buffer.

**Parameters:**

**int which**

The buffer to store. One of the following values:

**BUF\_F\_BUFFER** - The image Framebuffer.

**BUF\_Z\_BUFFER** - The Z buffer.

**int size**

The number of bytes to store.

**void \*buf**

The buffer data.

**RECT \*rp**

This allows only a subset of the saved image rect to be blitted back to the screen.

**Return Value:**

TRUE if the buffer was stored; otherwise FALSE.

## **DIB Methods**

**Prototype:**

**virtual BOOL getDIB(BITMAPINFO \*bmi, int \*size) = 0;**

**Remarks:**

This method returns the viewport image of this graphics window in a packed DIB format. A packed DIB is the standard BMI header followed immediately by all the data bytes (pixels) that make up the image. This is the standard way in Windows to pass a DIB around. See the sample code below for an example of this call in use. Note how it is called twice: once to get the size, once to get the DIB.

**Parameters:****BITMAPINFO \*bmi**

The BITMAPINFO structure defines the dimensions and color information for a Windows device-independent bitmap (DIB). Note that if this parameter is NULL, then only the size value is returned.

**int \*size**

The size of the image in bytes.

**Return Value:**

TRUE if the image was returned; otherwise FALSE.

**Sample Code:**

The following sample code saves the current 3ds max viewport to a user specified file.

```
void TestGetDIB(IObjParam *ip)  
{  
    BITMAPINFO *bmi = NULL;  
    BITMAPINFOHEADER *bmih;  
    BitmapInfo biFile;  
    Bitmap *map;  
    int size;  
    TheManager->SelectFileOutput(&biFile,  
        ip->GetMAXHwnd(), _T("Testing"));  
    if(!biFile.Name()[0])  
        return;  
    ViewExp *vpt = ip->GetActiveViewport();  
    vpt->getGW()->getDIB(NULL, &size);  
    bmi = (BITMAPINFO *)malloc(size);  
    bmih = (BITMAPINFOHEADER *)bmi;
```

```

vpt->getGW()->getDIB(bmi, &size);
biFile.SetWidth((WORD)bmi->biWidth);
biFile.SetHeight((WORD)bmi->biHeight);
biFile.SetType(BMM_TRUE_32);
map = TheManager->Create(&biFile);
map->OpenOutput(&biFile);
map->FromDib(bmi);
map->Write(&biFile);
map->Close(&biFile);
if(bmi)
    free(bmi);
ip->ReleaseViewport(vpt);
}

```

**Prototype:**

**virtual BOOL setBackgroundDIB(int width, int height, BITMAPINFO \*bmi)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
This method is used internally to zoom the viewport.

**Prototype:**

**virtual void setBackgroundOffset(int x, int y) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.  
This method is used internally to pan the viewport.

## **Texture Methods**

**Prototype:**

**virtual int getTextureSize(int bkg=FALSE) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the size of the texture bitmap that the driver wants sent in to the **getTextureHandle()** call (if **bkg** is **FALSE**). If **bkg** is **TRUE**, this returns the size of the texture that 3ds max should send to the **setBackgroundDIB()** call. In general, the return value needs to be a power of 2, though that could be driver-specific

**Parameters:**

**int bkg=FALSE**

**TRUE** to get the size for **setBackgroundDIB()**; **FALSE** to get the size for **getTextureHandle()**.

**Prototype:**

**virtual DWORD getTextureHandle(BITMAPINFO \*bmi) = 0;**

**Remarks:**

This method returns a handle for the specified texture bitmap. This handle is then used with the **setTextureByHandle()** method (there is only one current texture active at any time). The texture dimensions must be a power of 2.

When a material is on an object, and the material has a texture map, and when the button used to display the texture map is pressed, 3ds max calls this method to get the texture handle. This basically loads the texture into the hardware RAM (if available). When this mapped object gets displayed the method **setTextureHandle()** is called. When the material is deleted, or the display in viewport button is turned off, **freeTextureHandle()** is called.

**Parameters:**

**BITMAPINFO \*bmi**

The DIB image to use as a texture.

**Return Value:**

The texture handle.

**Prototype:**

**virtual BOOL setTextureByHandle(DWORD handle) = 0;**

**Remarks:**

This sets the current texture to the image whose handle is passed (see **getTextureHandle()**). The texture dimensions must be a power of 2.

**Parameters:**

**DWORD handle**

The handle of the texture to make current.

**Prototype:**

**virtual void freeTextureHandle(DWORD handle) = 0;**

**Remarks:**

When you are finished with the texture handle, call this method to free it.

**Parameters:**

**DWORD handle**

The texture handle to free.

**Return Value:**

TRUE if the texture was set; otherwise FALSE.

**Prototype:**

**virtual BOOL setTextureTiling(int u, int v, int w=GW\_TEX\_NO\_TILING) = 0;**

**Remarks:**

Sets the way in which textures are tiled across the surface of the object.

**Parameters:**

The following parameters may use one of these values:

**GW\_TEX\_NO\_TILING**

The texture clamped - Any UVW that is bigger than 1 is interpreted as being 1.

**GW\_TEX\_REPEAT**

As the UVW numbers keep getting larger than 1 the image is repeated.

**GW\_TEX\_MIRROR**

If UVW goes beyond 1, the numbers are interpreted as going backwards. So if you had 0 to 2 it would actually go 0 to 1 then 1 down to 0.

**int u**

The type of texturing in the U direction.

**int v**

The type of texturing in the V direction.

**int w=GW\_TEX\_NO\_TILING**

The type of texturing in the W direction.

**Return Value:**

TRUE if the tiling mode was set; otherwise FALSE.

**Prototype:**

**virtual int getTextureTiling(int which) = 0;**

**Remarks:**

Returns the type of texture tiling set for the particular direction.

For example, if **setTextureTiling(GW\_TEX\_NO\_TILING, GW\_TEX\_REPEAT, GW\_TEX\_MIRROR)** were called first, then

**getTextureTiling(0)** would yield **GW\_TEX\_NO\_TILING**, and **getTextureTiling(1)** would yield **GW\_TEX\_REPEAT**.

**Parameters:**

**int which**

This value is 0 or 1 and it represents the U or V direction respectively. The value 2 is not yet implemented.

**Return Value:**

**GW\_TEX\_NO\_TILING**

The texture clamped - Any UVW that is bigger than 1 is interpreted as being 1.

**GW\_TEX\_REPEAT**

As the UVW numbers keep getting larger than 1 the image is repeated.

**GW\_TEX\_MIRROR**

If UVW goes beyond 1, the numbers are interpreted as going backwards. So if you had 0 to 2 it would actually go 0 to 1 then 1 down to 0.

**Prototype:**

**virtual void setTexTransform(const Matrix3 &m) = 0;**

**Remarks:**

This method allows one to put an affine transformation on a texture. This

allows you to translate, rotate or scale a texture on an object.

**Parameters:**

**const Matrix3 &m**

The texture transformation matrix.

**Prototype:**

**virtual void beginFrame() = 0;**

**Remarks:**

If a developer is working with an existing 3ds max instance of GraphicsWindow (one of MAX's viewports) this method should NOT be called.

**Prototype:**

**virtual void endFrame() = 0;**

**Remarks:**

As above, if a developer is working with an existing 3ds max instance of GraphicsWindow (one of MAX's viewports) this method should NOT be called.

**Prototype:**

**virtual void setViewport(int x, int y, int w, int h) = 0;**

**Remarks:**

This method sets the clipping boundaries within a viewport within the graphics window. This allows more than one viewport to appear within a single graphics window. It has the side-effect of building a 4x4 viewport matrix. This routine should be called anytime the graphics window is resized, or else rendering will still occur to the old window size. (And since most drivers do not do range-checking since it is too time-costly, this could cause a system crash.)

**Parameters:**

Note: all coordinates are in Windows format, with the origin in the upper left

**int x**

Specifies the left viewport origin.

**int y**

Specifies the top viewport origin.

**int w**

Specifies the viewport width.

**int h**

Specifies the viewport height.

## **Drawing Setup**

### **Prototype:**

```
virtual void resetUpdateRect() = 0;
```

### **Remarks:**

This method resets the update rectangle. The update rectangle is the region of the screen that needs to be updated to reflect items that have changed. When the system is done rendering items, the goal is to only update the region that has actually been altered. This method sets the update rectangle (the region that will be blitted to the display) to invalid. In this way when **enlargeUpdateRect()** is later called, the RECT passed will be used as the region.

### **Prototype:**

```
virtual void enlargeUpdateRect(RECT *rp) = 0;
```

### **Remarks:**

This method enlarges the update rectangle to include the RECT passed. If **rp** is NULL, then the whole window will later be updated.

### **Parameters:**

**RECT \*rp**

Pointer to a rectangle (or NULL).

### **Prototype:**

```
virtual int getUpdateRect(RECT *rp) = 0;
```

### **Remarks:**

This method retrieves the current update rectangle.

**Parameters:****RECT \*rp**

The current update rectangle.

**Return Value:**

Zero if the update rectangle is invalid; otherwise nonzero.

**Prototype:****virtual void setRndLimits(DWORD l) = 0;****Remarks:**

Sets the rendering limits used by primitive calls.

Note: Setting the rendering limits is used in communication between the various parts of 3ds max that handle the display of objects. For example, setting this limit to **GW\_POLY\_EDGES** and then drawing a polygon won't result in a polygon drawn with edges. It only sets a flag that indicates the edge should be drawn.

What happens is as follows. Inside the upper level MAX, part of the code knows that polygon edges have been turned on. However this is not related through the object oriented architecture to the part of 3ds max that does the actual drawing. When 3ds max goes to draw objects it will see that the polygon edge flag is on. This tells it to do two drawing passes -- one to do the polygon, then it calls **outlinePass()** call with TRUE, draws a bunch of edges, then calls **outline Pass()** with FALSE. Thus, the drawing routine is responsible for looking at the flags and drawing appropriately. This method is only responsible setting the limit which can later be checked.

**Parameters:****DWORD l**

Specifies the rendering limit used by the viewport. See [Rendering Limits](#).

**Prototype:****virtual DWORD getRndLimits() = 0;****Remarks:**

Retrieves the rendering limits used by primitive calls. See [Rendering Limits](#).

**Prototype:**

```
virtual DWORD getRndMode() = 0;
```

**Remarks:**

Returns the current rendering mode used by the viewport. This is a subset of the rendering limit, in that any limits imposed by the rendering limit are forced onto the current mode. See [Rendering Limits](#).

**Prototype:**

```
virtual int getMaxStripLength();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the largest number of triangles that can be in a strip

**Prototype:**

```
virtual void setSkipCount(int n) = 0;
```

**Remarks:**

Sets the number of triangles skipped when the viewport is set as a 'Fast View Display' viewport. To disable fastview, specify 1. Note that the GraphicsWindow class doesn't actually do anything with this number other than store it. Since triangles are handed down to GFX one at a time, it is up to the code that feeds triangles to the GraphicsWindow to skip the specified number of triangles. The mesh rendering in 3ds max uses the skip count in this way.

**Parameters:**

**int n**

Specifies that every 'n-th' triangle should be drawn. If set to 2, every other triangle should be drawn.

**Prototype:**

```
virtual int getSkipCount() = 0;
```

**Remarks:**

Returns the current skip count setting.

## Light and Camera Methods

### Prototype:

**virtual int getMaxLights() = 0;**

### Remarks:

Returns the maximum number of lights that may be used by the interactive renderer.

### Prototype:

**virtual void setLight(int num, const Light \*l) = 0;**

### Remarks:

Turns a light on or off, and sets the light parameters. The light's position is set through the current transformation matrix at the time of this call. A particular light is specified by its light number (-1 through **getMaxLights()-1**). Light number -1 is reserved for ambient light. If a particular field in the Light class is not needed for a particular type of light, that field's value is ignored (for example, only the color field is used for ambient light.)

### Parameters:

**int num**

The light number of the light to set. This is a value in the range -1 to **getMaxLights()-1**.

**const Light \*l**

The light class instance used to set the light parameters. If this is NULL, the light is turned off.

### Prototype:

**virtual void setLightExclusion(DWORD exclVec) = 0;**

### Remarks:

This allows a developer to control if a light is used to render an object. There is one bit per light (bits 0 through **getMaxLights()**). If the bit is set the light is NOT used to render the object. If the bit is off, the light IS used. This method allows you to set the exclusion vector controlling the lights.

### Parameters:

## **DWORD exclVec**

The exclusion vector controlling the lights.

### **Prototype:**

```
virtual void setCamera(const Camera &c) = 0;
```

### **Remarks:**

This method is no longer used.

### **Prototype:**

```
virtual void setCameraMatrix(float mat[4][4], Matrix3 *invTM,  
int persp, float hither, float yon) = 0;
```

### **Remarks:**

Sets the properties of the current camera used by the GraphicsWindow.

### **Parameters:**

**float mat[4][4]**

The transformation matrix times the projection matrix.

**Matrix3 \*invTM**

This is the inverse of the affine part of the camera transformation matrix (not the inverse of the projection part).

**int persp**

Nonzero indicates this is a perspective view; 0 is orthogonal.

**float hither**

Near clip value.

**float yon**

Far clip value.

### **Prototype:**

```
virtual void getCameraMatrix(float mat[4][4], Matrix3 *invTM,  
int *persp, float *hither, float *yon) = 0;
```

### **Remarks:**

Retrieves the properties of the current camera.

### **Parameters:**

**float mat[4][4]**

The transformation matrix times the projection matrix.

**Matrix3 \*invTM**

This is the inverse of the affine part of the camera transformation matrix (not the inverse of the projection part).

**int \*persp**

Nonzero indicates this is a perspective view; 0 is orthogonal.

**float \*hither**

Near clip value.

**float \*yon**

Far clip value.

## Material Methods

### Prototype:

```
virtual void setMaterial(const Material &m, int index=0) = 0;
```

### Remarks:

Sets the current rendering material, and modifies the rendering mode parameter for controlling the rasterizer driver. Note: You must have your rendering limit set BEFORE you set the material because the material setting may lower the rendering mode based on the material limits.

### Parameters:

**const Material &m**

The new material to instantiate

**int index=0**

Indicates which material index refers to the material which gets set.

### Prototype:

```
virtual Material *getMaterial() = 0;
```

### Remarks:

Returns the current rendering material.

**Prototype:**

**virtual void setTransparency(DWORD settings) = 0;**

**Remarks:**

Sets the current transparency flags for the current pass.

**Parameters:****DWORD settings**

This can be a combination of GW\_TRANSPARENCY and GW\_TRANSPARENT\_PASS See [Rendering Limits](#). You also use these settings in the Render limits as well.

## Coordinate Transformation Methods

**Prototype:**

**virtual DWORD hTransPoint(const Point3 \*in, IPoint3 \*out) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method converts coordinates to "h" format device coordinates. Note: This method maps points from the GraphicsWindow's current transform to device space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space. Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:****const Point3 \*in**

The input point.

**IPoint3 \*out**

The output point in integer format values in the native device coords for the device. For HEIDI and OpenGL the origin at the lower left. For Direct3D the origin is at the upper left.

**Return Value:**

DWORD containing the clipping flags for the point. If a flag is set it indicates the transformed point lies outside the view volume. See [List of Clip Flags](#).

**Prototype:**

**virtual DWORD wTransPoint(const Point3 \*in, IPoint3 \*out) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to convert coordinates to "w" format device coordinates. Note: This method maps points from the GraphicsWindow's current transform to device space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space. Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**const Point3 \*in**

The input point.

**IPoint3 \*out**

The output point in integer format with the origin at the upper left.

**Return Value:**

DWORD containing the clipping flags for the point. If a flag is set it indicates the transformed point lies outside the view volume. See [List of Clip Flags](#).

**Prototype:**

**virtual DWORD transPoint(const Point3 \*in, Point3 \*out) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to convert coordinates to "h" **floating point** coordinates. This is just a helper routine to avoid building up round-off error. 3ds max uses it just for IK. Note: This method maps points from the GraphicsWindow's current transform to device space. If the GraphicsWindow's transform is set to

the identity matrix then the mapping is done from points specified in world space. Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**const Point3 \*in**

The input point.

**Point3 \*out**

The output point in floating point format with the origin at the lower left.

**Return Value:**

DWORD containing the clipping flags for the point. If a flag is set it indicates the transformed point lies outside the view volume. See [List of Clip Flags](#).

## Drawing Methods

Note: The old device coordinate calls have been changed (or removed). In 3ds max 2.0 and later, methods that start with "**h**" take integer device coordinates with the origin at the lower-left. Calls with a "**w**" in front take Windows device coordinates with the origin at the upper left. Also Note: These "**h**" and "**w**" routines perform NO clipping unless otherwise noted (clipping at this level would be very expensive). Drawing outside the allowable region is likely to cause 3ds max to crash.

**Prototype:**

**virtual void hText(IPoint3 \*xyz, TCHAR \*s) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Draws 2D fixed font annotation text to the specified location. Note: This routine DOES perform clipping of the text if it is off the screen.

**Parameters:**

**IPoint3 \*xyz**

This is the device coordinate for the text. The origin of the text is at the lower left corner.

**TCHAR \*s**

The text to display.

**Prototype:**

**virtual void hMarker(IPoint3 \*xyz, MarkerType type) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Draws a marker at the specified location.

**Parameters:**

**IPoint3 \*xyz**

This is the device coordinate for the marker (with the origin at the lower left).

**MarkerType type**

See [List of Marker Types](#).

**Prototype:**

**virtual void hPolyline(int ct, IPoint3 \*xyz, Point3 \*rgb, int closed, int \*es) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-segment polyline.

**Parameters:**

**int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

**IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the lower left.

**Point3 \*rgb**

If the shade mode is set to smooth and these colors for the vertices are specified the polyline will be drawn Gourand shaded. This is how 3ds max draws lit wireframes for instance. If you simply want ordinary lines (drawn using the line color) pass NULL.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration.

(This is how OpenGL works.)

### **int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

### **int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

#### **GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

#### **GW\_EDGE\_VIS**

Exists and is solid.

#### **GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

### **Prototype:**

```
void hPolyline(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw, int closed, int *es);
```

### **Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-segment polyline.

### **Parameters:**

#### **int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

#### **IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the lower left.

#### **Point3 \*rgb**

If the shade mode is set to smooth and these colors for the vertices are specified the polyline will be drawn Gourand shaded. This is how 3ds max draws lit wireframes for instance. If you simply want ordinary lines (drawn

using the line color) pass NULL.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

This is not currently used. Pass NULL.

**int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

**int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

**GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

**GW\_EDGE\_VIS**

Exists and is solid.

**GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

**Prototype:**

```
virtual void hPolygon(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw) = 0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-point polygon.

**Parameters:**

**int ct**

The number of points in the polygon.

**IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the lower left.

### **Point3 \*rgb**

The color values at the vertices. The rendering mode must include **GW\_ILLUM** for these values to be used.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

### **Point3 \*uvw**

The UVW coordinates. The rendering mode must include **GW\_TEXTURE** for these values to be used.

### **Prototype:**

```
virtual void hTriStrip(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw) = 0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

This method is used for drawing a series of triangles specified as 'strips'. It takes a count of 3 or more, and builds triangles in a strip. This sends a lot less data and the underlying graphics library has to set up a lot less data since it can use the previous information to start the rasterization. This results in a significant speed increase.

Note that this routine does no clipping so all the points passed must be within view.

### **Parameters:**

#### **int ct**

The total number of points. After the first two points, each new point is used to create a new triangle.

#### **IPoint3 \*xyz**

The point data with the origin at the lower left. For instance, to draw a quad, the first three points specify the first triangle and the next one is combined with the previous two to complete the square.

The order for these points follows the 'standard' conventions for stripping used in most graphics libraries (for example Direct3D, OpenGL and Heidi).

#### **Point3 \*rgb**

The colors for the vertices.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

The UVW texture coordinates for the vertices.

**Prototype:**

**virtual void wText(IPoint3 \*xyz, TCHAR \*s) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Draws 2D fixed font annotation text to the specified location. Note: This routine DOES perform clipping of the text if it is off the screen.

**Parameters:**

**IPoint3 \*xyz**

This is the device coordinate for the text. The origin of the text is at the upper left corner.

**TCHAR \*s**

The text to display.

**Prototype:**

**virtual void wMarker(IPoint3 \*xyz, MarkerType type) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Draws a marker at the specified location.

**Parameters:**

**IPoint3 \*xyz**

This is the device coordinate for the marker.

**MarkerType type**

See [List of Marker Types](#).

**Prototype:**

**virtual void wPolyline(int ct, IPoint3 \*xyz, Point3 \*rgb, int closed, int \*es) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-segment polyline.

**Parameters:**

**int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

**IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the upper left.

**Point3 \*rgb**

If the shade mode is set to smooth and these colors for the vertices are specified the polyline will be drawn Gourand shaded. This is how 3ds max draws lit wireframes for instance. If you simply want ordinary lines (drawn using the line color) pass NULL.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

**int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

**GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

**GW\_EDGE\_VIS**

Exists and is solid.

**GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

**Prototype:**

```
void wPolyline(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw, int closed, int *es);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-segment polyline.

**Parameters:****int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

**IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the upper left.

**Point3 \*rgb**

If the shade mode is set to smooth and these colors for the vertices are specified the polyline will be drawn Gourand shaded. This is how 3ds max draws lit wireframes for instance. If you simply want ordinary lines (drawn using the line color) pass NULL.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

This is not currently used. Pass NULL.

**int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

**int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

**GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

**GW\_EDGE\_VIS**

Exists and is solid.

### **GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

#### **Prototype:**

```
virtual void wPolygon(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw) = 0;
```

#### **Remarks:**

This method is available in release 2.0 and later only.

This method draws a multi-point polygon.

#### **Parameters:**

##### **int ct**

The number of points in the polygon.

##### **IPoint3 \*xyz**

Array of points. These are device coordinates with the origin at the upper left.

##### **Point3 \*rgb**

The color values at the vertices. The rendering mode must include **GW\_ILLUM** for these values to be used.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

##### **Point3 \*uvw**

The UVW coordinates. The rendering mode must include **GW\_TEXTURE** for these values to be used.

#### **Prototype:**

```
virtual void wTriStrip(int ct, IPoint3 *xyz, Point3 *rgb, Point3 *uvw) = 0;
```

#### **Remarks:**

This method is available in release 2.0 and later only.

This method is used for drawing a series of triangles specified as 'strips'. It takes a count of 3 or more, and builds triangles in a strip. This sends a lot less data and the underlying graphics library has to set up a lot less data since it can use the previous information to start the rasterization. This results in a significant speed increase.

Note that this routine does no clipping so all the points passed must be within view.

**Parameters:**

**int ct**

The total number of points. After the first two points, each new point is used to create a new triangle.

**IPoint3 \*xyz**

The point data with the origin at the upper left. For instance, to draw a quad, the first three points specify the first triangle and the next one is combined with the previous two to complete the square.

The order for these points follows the 'standard' conventions for stripping used in most graphics libraries (for example Direct3D, OpenGL and Heidi).

**Point3 \*rgb**

The colors for the vertices.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

The UVW texture coordinates for the vertices.

**Prototype:**

**virtual void text(Point3 \*xyz, TCHAR \*s) = 0;**

**Remarks:**

Draws 2D fixed font annotation text to the specified location. This method does perform clipping.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space. Otherwise the points given are transformed by the GraphicsWindow

transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**Point3 \*xyz**

This is the coordinate for the text.

**TCHAR \*s**

The text to display. Note: This routine DOES perform clipping of the text if it is off the screen.

**Prototype:**

**virtual void marker(Point3 \*xyz, MarkerType type) = 0;**

**Remarks:**

Draws a marker at the specified location in world space. This method does perform clipping.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**Point3 \*xyz**

This is the coordinate for the marker.

**MarkerType type**

See [List of Marker Types](#).

**Prototype:**

**virtual void polyline(int ct, Point3 \*xyz, Point3 \*rgb, Point3 \*uvw, int closed, int \*es) = 0;**

**Remarks:**

Draws a multi-segment polyline with the coordinates specified in world space.

This method does perform clipping.

Note: The arrays of points and vertex related data all must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max may crash.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

### Parameters:

#### **int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

#### **Point3 \*xyz**

Array of points. This array must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max will crash.

#### **Point3 \*rgb**

If the shade mode is set to smooth and these colors for the vertices are specified the polyline will be drawn Gourand shaded. This is how 3ds max draws lit wireframes for instance. If you simply want ordinary lines (drawn using the line color) pass NULL.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

#### **Point3 \*uvw**

This is not currently used. Pass NULL.

#### **int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

**int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

**GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

**GW\_EDGE\_VIS**

Exists and is solid.

**GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

**Prototype:**

```
virtual void polylineN(int ct, Point3 *xyz, Point3 *nor, int closed,  
int *es) = 0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Draws a multi-segment polyline with the coordinates specified in world space. This method takes a polyline with a normal for each vertex. This is used for hardware accelerated lit wireframes (when **GW\_SPT\_GEOM\_ACCEL** is TRUE).

Note: The arrays of points and vertex related data all must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max may crash.

This method does perform clipping.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**int ct**

The number of points in the polyline. The maximum number of points that may be used in drawing a polyline is 32.

**Point3 \*xyz**

Array of points. This array must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max will crash.

**Point3 \*nor**

The normal values at the vertices, one for each vertex.

**int closed**

If nonzero the first point is connected to the last point, i.e. the polyline is closed.

**int \*es**

Edge state array. This is an array that Indicates if the 'i-th' edge is one of three state:

**GW\_EDGE\_SKIP**

Nonexistent - totally invisible.

**GW\_EDGE\_VIS**

Exists and is solid.

**GW\_EDGE\_INVIS**

Exists and is hidden - shown as a dotted line.

You may pass NULL for this array and the method will assume that the edges are all solid.

**Prototype:**

```
virtual void polygon(int ct, Point3 *xyz, Point3 *rgb, Point3 *uvw)  
= 0;
```

**Remarks:**

Draws a multi-point polygon. Note: All arrays (**xyz**, **rgb**, **uvw**) must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max may crash.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space. Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**int ct**

The number of points in the polygon.

**Point3 \*xyz**

Array of points.

**Point3 \*rgb**

The color values at the vertices. The rendering mode must include **GW\_ILLUM** for these values to be used.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

The UVW coordinates. The rendering mode must include **GW\_TEXTURE** for these values to be used.

**Prototype:**

**virtual void startSegments() = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to begin efficiently sending a lot of 3D line segments.

First call this method, then call **segment()** many times (with two points), then call **endSegments()**.

**Prototype:**

**virtual void segment(Point3 \*xyz, int vis) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a single 3D line segment between the specified points. Call **startSegments()** once before calling this method.

**Parameters:**

**Point3 \*xyz**

Points to the two line endpoints in world space.

**int vis**

Nonzero for the segment to be visible; zero for invisible.

**Prototype:**

**virtual void endSegments() = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Call this method after sending 3D line segments with **segment()**.

**Prototype:**

**virtual void polygonN(int ct, Point3 \*xyz, Point3 \*nor, Point3 \*uvw) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Draws a multi-point polygon. Note: All arrays (**xyz**, **nor**, **uvw**) must be at least one element larger than the **ct** parameter that is passed in. The 3D clipper will use the "extra" space to clip as efficiently as possible. If room for the extra element is not provided, 3ds max will crash.

This method sends in normal vectors instead of color for 3D accelerated rendering (when **GW\_SPT\_GEOM\_ACCEL** is TRUE)

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:****int ct**

The number of points in the polygon.

**Point3 \*xyz**

Array of points.

**Point3 \*nor**

The normal values at the vertices, one for each vertex.

**Point3 \*uvw**

The UVW coordinates. The rendering mode must include **GW\_TEXTURE** for these values to be used.

**Prototype:**

```
virtual void triStrip(int ct, Point3 *xyz, Point3 *rgb, Point3 *uvw)  
= 0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is used for drawing a series of triangles specified as 'strips'. It takes a count of 3 or more, and builds triangles in a strip. This sends a lot less data and the underlying graphics library has to set up a lot less data since it can use the previous information to start the rasterization. This results in a significant speed increase.

**Parameters:****int ct**

The total number of points. After the first two points, each new point is used to create a new triangle.

**IPoint3 \*xyz**

The point data. For instance, to draw a quad, the first three points specify the first triangle and the next one is combined with the previous two to complete the square.

The order for these points follows the 'standard' conventions for stripping used in most graphics libraries (for example Direct3D, OpenGL and Heidi).

**Point3 \*rgb**

The colors for the vertices.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Point3 \*uvw**

The UVW texture coordinates for the vertices.

**Prototype:**

```
virtual void triStripN(int ct, Point3 *xyz, Point3 *nor, Point3 *uvw) = 0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is used for drawing a series of triangles specified as 'strips'. It takes a count of 3 or more, and builds triangles in a strip. This sends a lot less data and the underlying graphics library has to set up a lot less data since it can use the previous information to start the rasterization. This results in a significant speed increase. This method sends in normal vectors instead of color for 3D accelerated rendering (when **GW\_SPT\_GEOM\_ACCEL** is TRUE)

**Parameters:**

**int ct**

The total number of points. After the first two points, each new point is used to create a new triangle.

**Point3 \*xyz**

The point data. For instance, to draw a quad, the first three points specify the first triangle and the next one is combined with the previous two to complete the square.

The order for these points follows the 'standard' conventions for stripping used in most graphics libraries (for example Direct3D, OpenGL and Heidi).

**Point3 \*nor**

The normal for each vertex.

**Point3 \*uvw**

The UVW texture coordinates for the vertices.

**Prototype:****virtual void startTriangles() = 0;****Remarks:**

This method is available in release 2.0 and later only.

This method is called to begin sending a series of non-stripped triangles to render. Call this method, then any of the **triangle\*()** methods many times, then **endTriangles()** to finish.

**Prototype:****virtual void triangle(Point3 \*xyz, Point3 \*rgb) = 0;****Remarks:**

This method is available in release 2.0 and later only.

This method sends a single non-stripped triangle to render. Call **startTriangles()** first.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:****Point3 \*xyz**

The three points for the triangle.

**Point3 \*rgb**

The color for each vertex.

Note: The use of these colors is not supported under the OpenGL driver. The rgb values are ignored. Only the current material is taken into consideration. (This is how OpenGL works.)

**Prototype:****virtual void triangleN(Point3 \*xyz, Point3 \*nor, Point3 \*uvw) = 0;****Remarks:**

This method is available in release 2.0 and later only.

This method draws a single triangle by specifying the vertex points in world space, a normal, and texture coordinates for each vertex.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**Point3 \*xyz**

The three points for the triangle.

**Point3 \*nor**

The three normals for the triangle.

**Point3 \*uvw**

The texture coordinate for each vertex.

**Prototype:**

**virtual void triangleNC(Point3 \*xyz, Point3 \*nor, Point3 \*rgb) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a single triangle by specifying the vertex points in world space, a normal, and a color for each vertex.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**Point3 \*xyz**

The three points for the triangle.

**Point3 \*nor**

The normal for each vertex.

**Point3 \*rgb**

The color for each vertex.

**Prototype:**

**virtual void triangleNCT(Point3 \*xyz, Point3 \*nor, Point3 \*rgb,  
Point3 \*uvw) = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method draws a single triangle by specifying the vertex points in world space, a normal, a color, and a texture coordinate for each vertex.

Note: This method maps points from the GraphicsWindow's current transform to screen space. If the GraphicsWindow's transform is set to the identity matrix then the mapping is done from points specified in world space.

Otherwise the points given are transformed by the GraphicsWindow transform, and are **then** considered to be in world space. Thus, to get a world-space to screen-space conversion, you need to set the transform to the identity with **gw->setTransform(Matrix3(1))**.

**Parameters:**

**Point3 \*xyz**

The three points for the triangle.

**Point3 \*nor**

The normal for each vertex.

**Point3 \*rgb**

The color for each vertex.

**Point3 \*uvw**

The texture coordinate for each vertex.

**Prototype:**

**virtual void endTriangles() = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

Call this method to finish rendering triangles. See **startTriangles()** above.

**Prototype:**

```
virtual void lightVertex(const Point3 &pos, const Point3 &nor,  
Point3 &rgb) = 0;
```

**Remarks:**

Lights a vertex, using all the current lights. The vertex appears to be transformed using the current transformation matrix, although actually the calculations are done using back-transformed light coordinates (for speed). The vertex position and normal are passed in, and a color is returned. The rendering uses the current material.

**Parameters:**

**const Point3 &pos**

Vertex position.

**const Point3 &nor**

Vertex normal.

**Point3 &rgb**

Returned color.

**Prototype:**

```
virtual void updateScreen() = 0;
```

**Remarks:**

This method is used internally and should not be called by plug-in developers.

**Prototype:**

```
virtual void setColor(ColorType t, float r, float g, float b) = 0;
```

**Remarks:**

Sets the RGB color used for the specified drawing type (line, fill, text, clear).

**Parameters:**

**ColorType t**

One of the following values:

**LINE\_COLOR**

Line drawing color.

**FILL\_COLOR**

Polygon fill color.

**TEXT\_COLOR**

Text drawing color.

**CLEAR\_COLOR**

The color that the viewport is cleared to when you call **clearScreen()**.

**float r**

Specifies the red amount 0.0 - 1.0.

**float g**

Specifies the green amount 0.0 - 1.0.

**float b**

Specifies the blue amount 0.0 - 1.0.

**Prototype:**

```
virtual void clearScreen(RECT *rp, int useBkg = FALSE) = 0;
```

**Remarks:**

Clears the specified rectangular region of the screen.

**Parameters:****RECT \*rp**

Specifies the rectangular region to clear.

**int useBkg = FALSE**

Specifies if the background should be used to fill the cleared area. Nonzero indicate the background should be used; 0 indicates the 'clear' color should be used (see **setColor()** above).

**Hit Testing Methods**

The following methods are used for hit testing. Typically you use these methods in the following sequence:

You set a hit regions using **setHitRegion()**.

You clear the hit code using **clearHitCode()**.

You 'render' a primitive using the mode **GW\_PICK** and at whatever level you want to check at. For example, if you are interested in vertex hit testing, you would 'render' a series of markers (using **iWinMarker()** with **PLUS\_SIGN\_MRKR**) using a rendering mode that included **GW\_PICK**. The **GW\_PICK** 'rendering' mode will cause the system to perform hit testing rather than actually render the item.

After each item is 'rendered' you check to see if a hit was made using **checkHitCode()**. This method returns TRUE or FALSE based on if a hit was found. If you are looking for just a single hit, you could abort as soon as **checkHitCode()** returns TRUE. If you are interested in the closest hit, you loop through all the items calling **clearHitCode()**, **checkHitCode()** and **getHitDistance()**. After checking all the items you simply choose the smallest hit distance from all the items you've checked.

**Prototype:**

**virtual void setHitRegion(HitRegion \*rgn) = 0;**

**Remarks:**

Sets the hit region used for hit testing. See [Class HitRegion](#).

**Parameters:**

**HitRegion \*rgn**

The hit region to use.

**Prototype:**

**virtual void clearHitCode() = 0;**

**Remarks:**

This method clears the hit code. Call this method before performing a hit test.

**Prototype:**

**virtual BOOL checkHitCode() = 0;**

**Remarks:**

Returns TRUE if the hit code is set indicating a hit was made; otherwise FALSE.

**Prototype:**

```
virtual DWORD getHitDistance() = 0;
```

**Remarks:**

If **checkHitCode()** returns TRUE you may call this method to return the hit distance. In wireframe mode this is the distance to the line. In shaded mode, this is the z distance. This allows you to perform 'smart' hit testing by choosing the item with the smallest hit distance. This method only returns meaningful values when the hit region is a point.

**Prototype:**

```
virtual void setHitCode(BOOL h)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows drawing code to manually set the state of the hit code, which is returned by the **checkHitCode()** method. For more information see the topic on [Hit Testing](#).

The new methods **setHitDistance()** and **setHitCode()** make it possible to work with GraphicsWindow hit-testing in otherwise impossible situations. Why are they necessary? An example from is shown below. The patch object contains bezier spline-based edges which can consist of up to 102 vertices. Since the GraphicsWindow::polyline function can only plot lines with up to 32 vertices, it is impossible to plot these in a single call to the polyline function. Multiple calls to the polyline call do not return a proper hitcode when using a "window"-type hit region. By using the new **setHitCode()** method, code can properly handle this situation. The code below shows the function in use from the **PatchMesh::renderEdge** method:

```
int steps = GetMeshSteps();  
int segNum = steps+2;  
float fsegNum = (float) (segNum-1);  
// If steps are too high for GraphicsWindow's buffer, we must  
draw it manually  
if((steps + 2) > GW_MAX_VERTS) {  
    Point3 line[2];
```

```

Point3 prev,current(.0f,.0f,.0f);
BOOL hitAll = TRUE;
BOOL hitAny = FALSE;
DWORD hitDist = 0xffffffff;
for(int terp = 0; terp < segNum; terp++)
{
    prev = current;
    current = work.InterpCurve3D((float)terp / fsegNum);
    if (terp != 0)
    {
        line[0] = prev;
        line[1] = current;
        gw->clearHitCode();
        gw->polyline(2, line, NULL, NULL, 0, NULL);
        if(gw->checkHitCode()) {
            hitAny = TRUE;
            if(gw->getHitDistance() < hitDist)
                hitDist = gw->getHitDistance();
        }
        else hitAll = FALSE;
    }
}
if(hr && !hr->crossing && hr->type != POINT_RGN)
    gw->setHitCode(hitAll);
else
    gw->setHitCode(hitAny);
gw->setHitDistance(hitDist);
} else {
for(int terp = 0; terp < segNum; terp++)
    fixedBuf[terp] = work.InterpCurve3D((float)terp / fsegNum);
}

```

```
gw->polyline(steps+2, fixedBuf, NULL, NULL, 0, NULL);  
}
```

Note that the **gw->polyline** call is preceded by a call to **clearHitCode()**, and followed by code which checks the hit code, maintaining "hitAny" and "hitAll" flags. When all the segments are drawn, the **gw->setHitCode()** call is made, setting the hit code depending on the hit region type. When the code which called this function checks the GraphicsWindow's hit code, it will contain the proper value. This code also keeps track of the closest hit distance and places that into the GraphicsWindow when all line segments are drawn.

**Parameters:**

**BOOL h**

Set to TRUE if the hit code is set, otherwise FALSE.

**Prototype:**

```
virtual void setHitDistance(DWORD d)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows drawing code to manually set the hit distance, which is returned by the **getHitDistance()** method. For more information see the topic on [Hit Testing](#).

**Parameters:**

**DWORD d**

In wireframe mode this is the distance to the line. In shaded mode, this is the z distance.

**Prototype:**

```
virtual float interpWorld(Point3 *world1, Point3 *world2, float  
sParam, Point3 *interpPt) = 0;
```

**Remarks:**

This method is used internally.

**Utility Functions (not part of class GraphicsWindows):**

**Function:**

**GraphicsWindow \*createGW(HWND hWnd, GWinSetup &gws);**

**Remarks:**

This function is used internally to create a new graphics window. Use of this method is not supported for plug-ins.

**Function:**

**void getRegionRect(HitRegion \*hr, RECT \*rect);**

**Remarks:**

Returns a bounding rectangle that encloses the entire hit region. For example if the hit regions was a fence region, this method would return the smallest rectangle that included the entire set of fence region points.

**Parameters:**

**HitRegion \*hr**

The hit region to check.

**RECT \*rect**

The returned bounding rectangle.

**Function:**

**BOOL pointInRegion(int x, int y, HitRegion \*hr);**

**Remarks:**

Returns TRUE if the specified point is inside the region **hr**; otherwise FALSE.

**Function:**

**int distToLine(int x, int y, int \*p1, int \*p2);**

**Remarks:**

Returns the signed distance from **x,y** to the line defined by **p1->p2**.

**Function:**

**int lineCrossesRect(RECT \*rc, int \*p1, int \*p2);**

**Remarks:**

Returns nonzero if the line defined by **p1->p2** crosses into the RECT and 0

otherwise.

**Function:**

**int segCrossesCircle(int cx, int cy, int r, int \*p1, int \*p2);**

**Remarks:**

Returns nonzero if the line defined by **p1**->**p2** crosses the circle center at (**cx**, **cy**) with a radius of **r** 0 otherwise.

**Function:**

**BOOL insideTriangle(IPoint3 &p0, IPoint3 &p1, IPoint3 &p2, IPoint3 &q);**

**Remarks:**

Returns TRUE if the point passed is inside the specified triangle.

**Parameters:**

**IPoint3 &p0**

The first point of the triangle.

**IPoint3 &p1**

The second point of the triangle.

**IPoint3 &p2**

The third point of the triangle.

**IPoint3 &q**

The point to check.

**Return Value:**

Returns TRUE if the point passed is inside the specified triangle; otherwise FALSE.

**Function:**

**int getZfromTriangle(IPoint3 &p0, IPoint3 &p1, IPoint3 &p2, IPoint3 &q);**

**Remarks:**

Returns the z value of where the projected screen point **q** would intersect the triangle defined by (**p0**, **p1**, **p2**).

**Parameters:**

**IPoint3 &p0**

The first point of the triangle.

**IPoint3 &p1**

The second point of the triangle.

**IPoint3 &p2**

The third point of the triangle.

**IPoint3 &q**

The screen point to check.

**Prototype:**

**HINSTANCE GetGraphicsLibHandle(TCHAR \*driverLibName);**

**Remarks:**

This function is available in release 2.0 and later only.

This function is not supported for use in the SDK.

**Prototype:**

**BOOL GraphicsSystemIsAvailable(HINSTANCE drv);**

**Remarks:**

This function is available in release 2.0 and later only.

This function is not supported for use in the SDK.

**Prototype:**

**BOOL GraphicsSystemCanConfigure(HINSTANCE drv);**

**Remarks:**

This function is available in release 2.0 and later only.

This function is not supported for use in the SDK.

**Prototype:**

**BOOL GraphicsSystemConfigure(HWND hWnd, HINSTANCE drv);**

**Remarks:**

This function is available in release 2.0 and later only.

This function is not supported for use in the SDK.

**Prototype:**

**void FreeGraphicsLibHandle(HINSTANCE drv);**

**Remarks:**

This function is available in release 2.0 and later only.

This function is not supported for use in the SDK.

# Class CommandMode

See Also: [Class MouseCallBack](#), [Class ChangeForegroundCallback](#), [Foreground / Background Planes](#).

class CommandMode

## Description:

This base class allows the developer to create a command mode that handles processing user interaction using the mouse in the viewports.

See Also: The Advanced Topics section [Command Modes and Mouse Procs](#). There are methods in 3ds max's [Interface class](#) to set and get the current command mode.

## Methods:

## Prototype:

```
virtual int Class()=0;
```

## Remarks:

Implemented by the Plug-In.

Returns the Class of the command mode. The class describes the type of command mode this is. If the developer is defining a command mode to be used as part of the sub-object manipulation (Move, Rotate, and Scale) then one of the following pre-defined values should be used:

```
MOVE_COMMAND  
ROTATE_COMMAND  
SCALE_COMMAND  
USCALE_COMMAND  
SQUASH_COMMAND
```

If one of these other values is appropriate it may be used. If not, the developer is free to define their own (as an **int**).

```
VIEWPORT_COMMAND  
SELECT_COMMAND  
HIERARCHY_COMMAND  
CREATE_COMMAND  
MODIFY_COMMAND  
MOTION_COMMAND
```

**ANIMATION\_COMMAND**  
**CAMERA\_COMMAND**  
**NULL\_COMMAND**  
**DISPLAY\_COMMAND**  
**SPOTLIGHT\_COMMAND**  
**PICK\_COMMAND**

**Return Value:**

The Class of the command mode.

**Prototype:**

**virtual int SuperClass()**

**Remarks:**

Implemented by the Plug-In.

This method can be ignored. The default implementation should be used.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual int ID()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ID of the command mode. This value should be the constant **CID\_USER** plus some random value chosen by the developer.

As an example, this method could be implemented as:

**{ CID\_USER+0x1423; }**

In the special case of the developer implementing a custom command mode to be used as part of sub-object manipulation (Move, Rotate or Scale) the value for ID() should be one of the following values:

**CID\_SUBOBJMOVE**  
**CID\_SUBOBJROTATE**  
**CID\_SUBOBJSCALE**  
**CID\_SUBOBJUSCALE**

## **CID\_SUBOBSQUASH**

Note: if two command modes conflict in this ID value, it is **not** a problem, so the uniqueness is not strictly required. However, this **ID()** method is often used to check which mode is active, so unless the value for your command mode is identifiable via this ID, you may not be able to recognize if your mode is indeed the active one.

### **Prototype:**

```
virtual MouseCallback *MouseProc(int *numPoints)=0;
```

### **Remarks:**

Implemented by the Plug-In.

This method establishes the number of points required by the command mode and returns a pointer to the mouse callback object that is used to process the user input.

### **Parameters:**

**int \*numPoints**

This is where to store the number of points used by the CommandMode. If the plug-in needs to use an undetermined number of points it can specify a large number for this value. When the mouse proc has finished processing points it returns FALSE to stop the point processing before the number of points specified here have been entered.

### **Return Value:**

A pointer to the mouse callback object that is used to process the user input.

See Also: [Class MouseCallback](#).

### **Prototype:**

```
virtual ChangeForegroundCallback *ChangeFGProc()=0;
```

### **Remarks:**

Implemented by the Plug-In.

Returns a pointer to a callback procedure that flags nodes that belong in the foreground plane. Plug-ins typically use a standard callback object provided by the system that flags all nodes dependent on the plug-in object. This ensures that when the plug-in object changes, any nodes that change as a result

will be in the foreground plane, making redraw time faster.

These constants may be specified to use one of the standard callback objects instead of an actual FG proc. For example **{return**

**CHANGE\_FG\_SELECTED;}**

**CHANGE\_FG\_SELECTED**

Selected nodes are flagged.

**CHANGE\_FG\_ANIMATED**

Nodes that are animated are flagged.

**Return Value:**

A pointer to a callback procedure that flags nodes that belong in the foreground plane.

See Also: For additional information see the Advanced Topics section [Foreground / Background Planes](#).

**Prototype:**

**virtual BOOL ChangeFG( CommandMode \*oldMode )=0;**

**Remarks:**

Implemented by the Plug-In.

This method returns TRUE if the command mode needs to change the foreground proc (using **ChangeFGProc()**) and FALSE if it does not. A command mode that does not involve any redrawing of the viewports can just return FALSE.

**Parameters:**

**CommandMode \*oldMode**

This is the command mode that is currently in place. This may be used for comparison with a potential new mode. See the sample code below.

**Sample Code:**

The sample code below checks to see if the command mode is already **CHANGE\_FG\_SELECTED**. If it is there is no reason to change to foreground proc to this mode so the method returns FALSE. If a different mode is in place TRUE is returned.

```
BOOL ChangeFG( CommandMode *oldMode )  
{ return (oldMode->ChangeFGProc() !=
```

```
CHANGE_FG_SELECTED); }  
ChangeForegroundCallback *ChangeFGProc()  
{ return CHANGE_FG_SELECTED; }
```

**Prototype:**

```
virtual void EnterMode()=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called when a command mode becomes active. Usually a developer responds by changing the state of a control to indicate to the user that they have entered the mode. Typically this means pushing in a tool button. When the mode is finished the button should be returned to normal (see **ExitMode()** below).

Note: A developer should use the standard color **GREEN\_WASH** for check buttons that instigate a command mode. While the command mode is active the button should be displayed in **GREEN\_WASH**. See [Class ICustButton](#) (specifically the method **SetHighlightColor()**) for more details.

**Sample Code:**

```
iPick->SetHighlightColor(GREEN_WASH);  
iPick->SetCheck(TRUE);
```

**Prototype:**

```
virtual void ExitMode()=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called when the active command mode is replaced by a different mode. Typically a developer implements this method to set the state of the control that invoked the command mode to the 'out' state. See [Class ICustButton](#) (specifically the method **SetCheck()**).

**Sample Code:**

```
iPick->SetCheck(FALSE);
```

# Class MouseCallBack

See Also: [Class CommandMode](#).

```
class MouseCallBack : public BaseInterfaceServer
```

## Description:

This class is used to allow a developer to capture the mouse events entered by the user and process them. To create a mouse call back, derive a sub class of this class and implement the **proc()** method.

## Methods:

### Prototype:

```
virtual int proc(HWND hwnd, int msg, int point, int flags, IPoint2  
m );
```

### Remarks:

Implemented by the Plug-In.

This method is called when a mouse event takes place to handles its processing.

### Parameters:

#### **HWND hwnd**

The window handle of the window the user clicked in. This is one of the viewports. An interface to the viewport can be obtained from the system, given this window handle. See [Class Interface](#) and review the methods below:

#### **ViewExp \*GetViewport( HWND hwnd )**

This method gets a viewport interface given the window handle.

#### **void ReleaseViewport( ViewExp \*vpt )**

When the developer is done with the viewport interface they should call this method to release it.

#### **int msg**

This message describes the type of event that occurred. See [List of Mouse Callback Messages](#).

#### **int point**

The point number. this is 0 for the first click, 1 for the second, etc.

#### **int flags**

These flags describe the state of the mouse buttons. See [List of Mouse Callback Flags](#).

### **IPoint2 m**

The 2D screen point that the user clicked on. Methods in the viewport interface allow this point to be converted into a world space ray or a 3D view space point. A world space ray can be intersected with the active construction plane which results in a point on the active construction plane. See [Class ViewExp](#).

### **Return Value:**

TRUE indicates the proc should continue to process points; FALSE means stop processing points. If a plug-in supplied a large number of points in a command mode that uses this mouse proc, FALSE can be returned to abort the processing before all the points have been entered.

### **Prototype:**

**virtual int override(int mode)**

### **Remarks:**

Implemented by the Plug-In.

This method is used to override the default drag mode. Most plug-in will not need to replace the default implementation of this method. What this does is change the way the messages are sent relative to the mouse clicking.

Normally the messages are sent as follows: When the user clicks down this generates a **MOUSE\_POINT** message. Then the user drags the mouse with the button down and a series of **MOUSE\_MOVE** messages are sent. When they let up on the mouse button a **MOUSE\_POINT** messages is generated. Then as the mouse is moved a series of **MOUSE\_MOVE** messages are sent. Then they click down on the mouse again, but this time a point message is not generated until the button is released. All future points are then only sent after the mouse button has been pressed and released.

### **Parameters:**

**int mode**

The current drag mode. See below.

### **Return Value:**

One of the following drag modes should be returned:

## **CLICK\_MODE\_DEFAULT**

Returned to indicate the use of the system mouse mode.

## **CLICK\_DRAG\_CLICK**

This is the default behavior as described above.

## **CLICK\_MOVE\_CLICK**

In this mode, the first point is entered by clicking the mouse button down and then letting it up. This generates point 0. In other words, a **MOUSE\_POINT** message is only generated after the user has pressed and released the mouse button.

## **CLICK\_DOWN\_POINT**

In this mode, point messages are sent on mouse-down only.

### **Default Implementation:**

```
{ return mode; }
```

### **Sample Code:**

A sample program that uses the override method is **\MAXSDK\SAMPLES\OBJECTS\SPLINE.CPP**. It uses **CLICK\_DOWN\_POINT**.

### **Prototype:**

```
virtual BOOL SupportTransformGizmo();
```

### **Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method returns TRUE if the mouse proc supports a transform gizmo; otherwise FALSE.

This method, and **DeactivateTransformGizmo()** below, are normally implemented by the selection processor and the existing mouse procs. In case a special implementation is done, the following describes what needs to be done:

Since the transform gizmo is dependent on the Command Mode, the **MouseCallback** itself decides if it supports the use of the transform gizmo. When the node axis (or transform gizmo) is redrawn, the system will ask the command mode's mouse proc if it supports transform gizmos, and if it does, it

will draw a gizmo, instead of the regular node axis.

The same things happens with the main selection processor in 3ds max. When the mouse is moved, the selection processor itself asks if the MouseCallback supports transform gizmos, and if it does, it will hit test the gizmo in a **MOUSE\_FREEMOVE** or **MOUSE\_POINT** message. If any of the transform gizmos hit test flags are passed into the mouse procs hit tester, the transform gizmo should be hit tested as well (using **Interface::HitTestTransformGizmo()**)

When hit testing the gizmo, different flags will be passed in:

**HIT\_TRANSFORMGIZMO** is passed in on a **MOUSE\_FREEMOVE** message so that the axis is hit tested and it highlights if it is hit, but it doesn't actually switch the transform mode.

In case of a **MOUSE\_POINT**, the flag will be **HIT\_SWITCH\_GIZMO**, and if the axis is hit, the 'hit' transform mode will be pushed on the transform mode stack.

When the mouse is released (**MOUSE\_POINT** (pt==1), or **MOUSE\_ABORT**, then the axis constraint should pop back to the existing one, and **DeactivateTransformGizmo()** is called. Inside **DeactivateTransformGizmo()** the normal implementation is to pop the axis mode back. It should also maintain a flag (set it if **HitTestTransformGizmo()** returns true and the **HIT\_SWITCH\_GIZMO** is set, and clear it in **DeactivateTransformGizmo()**). The flag is needed because you should not call **Interface::PopAxisMode()** unless the axis mode was previously popped.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void DeactivateTransformGizmo();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method is called to deactivate the transform gizmo. See the note above in

**SupportTransformGizmo().**

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL SupportAutoGrid();
```

**Remarks:**

This method is available in release 3.0 and later only.

Mouse procs wishing to utilize the AutoGrid feature should override this method by returning TRUE and then make the appropriate calls to the **ViewExp** methods **TrackImpliciGrid()**, **CommitImplicitGrid()** and **ReleaseImplicitGrid()** from the body of their classes **proc()** method. For sample code see

```
\\MAXSDK\\SAMPLES\\MODIFIERS\\SURFWRAP\\SURFWRAP.CI
```

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL TolerateOrthoMode();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method returns TRUE if Ortho Mode makes sense for this creation; FALSE if it doesn't. In general this is only TRUE for splines and such.

**Default Implementation:**

```
{return FALSE; }
```

**Prototype:**

```
void setMouseManager(MouseManager *mm)
```

**Remarks:**

This method is used internally.

**Prototype:**

**MouseManager \*getManager()**

**Remarks:**

This method is used internally.

**The following functions are not part of this class but are available for use:**

**Function:**

**BOOL GetInMouseAbort();**

**Remarks:**

This global function is available in release 2.0 and later only.

This function is not part of this class but is available for use. It returns TRUE if **any** mouse proc is currently in the process of aborting a mouse proc; otherwise FALSE.

For instance, a developer may be using the **Animatable::MouseCycleCompleted()** method to put up a dialog box, but need to not put it up if the mouse proc was aborting. This method provides a way to know if indeed the mouse proc is aborting so the dialog won't be displayed inside **MouseCycleCompleted()**.

**Return Value:**

TRUE if aborting; otherwise FALSE.

**Function:**

**float GetPerspMouseSpeed();**

**Remarks:**

This global function is not part of class MouseCallBack but is available for use.

Returns the mouse speed value used in perspective viewports. This value corresponds to the value that the user may set using the 3ds max command in the File / Preferences . . . Move / Rotate Transform area.

**Function:**

**void SetPerspMouseSpeed(float speed);**

**Remarks:**

This global function is not part of class MouseCallBack but is available for use.

Sets the mouse speed value used in perspective viewports. This value corresponds to the value that the user may set using the 3ds max command in the File / Preferences . . . Move / Rotate Transform area.

**Parameters:**

**float speed**

The value to set.

**Function:**

**void SetMoveModeType(int moveType);**

**Remarks:**

This global function is not part of class MouseCallBack but is available for use.

Sets the mouse move mode. This value corresponds to the value that the user may set using the 3ds max command in the File / Preferences . . . Move / Rotate Transform area.

**Parameters:**

**int moveType**

One of the following values:

**MOVE\_INTERSECTION**

**MOVE\_PROJECTION**

**Function:**

**int GetMoveModeType();**

**Remarks:**

This global function is not part of class MouseCallBack but is available for use.

Returns the mouse move mode. This value corresponds to the value that the user may set using the 3ds max command in the File / Preferences . . . Move / Rotate Transform area.

**Return Value:**

One of the following values:

**MOVE\_INTERSECTION**

**MOVE\_PROJECTION**

## Class IParamArray

See Also: [Class IParamBlock](#), [Class IParamMap](#).

class IParamArray

### Description:

This class represents a virtual array of parameters. Parameter are accessed using an integer index and **GetValue()** and **SetValue()** methods. Parameter blocks are one such implementation of this class, but it can also be useful to implement a class that abstracts non-parameter block variables. The ParamMap class uses this base class so that a ParamMap can be used to control UI for not only parameter blocks but also variables stored outside of parameter blocks. The Advanced Topics section on [Parameter Maps](#) discusses how this is done.

### Methods:

Default implementation of these methods are provided which simply return FALSE.

### Prototype:

**virtual BOOL SetValue(int i, TimeValue t, float v);**

### Remarks:

Implemented by the Plug-In.

This method is called when the system needs to store a value into a variable. There are overloaded functions for each type of value to set (int, float, and Point3). Each method has three parameters. Below is the float version - the others are similar.

### Parameters:

**int i**

This is the index into the virtual array of the value to set.

**TimeValue t**

This is the time at which to set the value.

**float v**

This is the value to set.

### Return Value:

This is not currently used.

**Prototype:**

**virtual BOOL SetValue(int i, TimeValue t, int v)**

**Remarks:**

Implemented by the Plug-In.

This is the integer version of above.

**Prototype:**

**virtual BOOL SetValue(int i, TimeValue t, Point3& v)**

**Remarks:**

Implemented by the Plug-In.

This is the Point3 version of above.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, float &v, Interval &ivalid)**

**Remarks:**

Implemented by the Plug-In.

Whenever the developer needs to retrieve a value from the parameter block, the **GetValue()** method is used. There are overloaded functions for each type of value to retrieve (int, float, Point3, and Color). Each method has four parameters:

**Parameters:**

**int i**

This is the index into the virtual array of the value to retrieve.

**TimeValue t**

This is the time at which to retrieve the value. For constants pass 0.

**float &v**

This is the value to retrieve.

**Interval &ivalid**

This is the validity interval to update to reflect the validity of this parameter.

**Return Value:**

If the value was retrieved TRUE is returned; otherwise FALSE is returned.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, int &v, Interval &ivalid)**

**Remarks:**

This is the integer version of above.

**Prototype:**

**virtual BOOL GetValue(int i, TimeValue t, Point3 &v, Interval &ivalid)**

**Remarks:**

This is the Point3 version of above.

**Prototype:**

**IParamBlock \*GetParamBlock()**

**Remarks:**

Implemented by the System.

If the array uses a parameter block, this method will return a pointer to it, otherwise it will return NULL. Note that casting won't work because of multiple inheritance.

**Return Value:**

Returns a pointer to the parameter block if one is used; NULL otherwise.

**Prototype:**

**virtual BOOL KeyFrameAtTime(int i, TimeValue t);**

**Remarks:**

This method is available in release 2.0 and later only.

Checks to see if a keyframe exists for the given parameter at the given time. Returns TRUE if a keyframe exists at the specified time; otherwise FALSE.

**Parameters:**

**int i**

Zero based index of the parameter to check.

**TimeValue t**

The time to check.

**Default Implementation:**

```
{return FALSE;}
```

# Class ICustomControl

See Also: [Custom Controls](#).

class ICustomControl : public InterfaceServer

## Description:

This is the base class from which the 3ds max custom controls are derived. All methods of this class are implemented by the system.

## Methods:

### Prototype:

**virtual HWND GetHwnd()=0;**

### Remarks:

Returns the handle of the control.

### Prototype:

**virtual void Enable(BOOL onOff=TRUE)=0;**

### Remarks:

This method is used to enable the control so it may be operated by the user.

### Parameters:

**BOOL onOff=TRUE**

This parameter is available in release 2.0 and later only.

TRUE to enable; FALSE to disable.

### Prototype:

**virtual void Enable2(BOOL onOff=TRUE)=0;**

### Remarks:

This method is available in release 2.0 and later only.

This method is used internally and should not be called by plug-in developers.

This second enable function is used to disable and enable custom controls when the associated parameter has a non-keyframable parameter. The effective enable state is the AND of these two enable bits.

For example, when a parameter has a controller plugged into it, and the

controller is not keyframable, any spinner control associated with it won't be effective. That's because the controller doesn't take input -- it only outputs values. To prevent the user from being confused by the ineffectiveness of the spinner the control it's automatically disabled by the system using this method.

**Parameters:**

**BOOL onOff=TRUE**

TRUE to enable; FALSE to disable.

**Prototype:**

**virtual void Disable()=0;**

**Remarks:**

This method is used to disable the control so it may not be selected or used. When disabled, the control usually appears grayed out.

**Prototype:**

**virtual BOOL IsEnabled()=0;**

**Remarks:**

This returns TRUE if the control is enabled and FALSE if it is disabled.

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);**

**Remarks:**

This method is available in release 3.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

This is reserved for future use.

**Parameters:**

**int cmd**

The command to execute.

**ULONG arg1=0**

Optional argument 1 (defined uniquely for each **cmd**).

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value (defined uniquely for each **cmd**).

**Default Implementation:**

```
{ return 0; }
```

## Class ICustEdit

See Also: [Class ICustomControl](#), [Custom Controls](#).

```
class ICustEdit : public ICustomControl
```

### Description:

This control is a simple text input control. The user may type any string into the field and the plug-in is notified when the user presses the ENTER key. There are also methods to parse and return integer and floating point values entered in the control.

To initialize the pointer to the control call:

### Prototype:

```
ICustEdit *GetICustEdit(HWND hCtrl);
```

To release the control call:

### Prototype:

```
ReleaseICustEdit(ICustEdit *ice);
```

The value to use in the Class field of the Custom Control Properties dialog is:

### CustEdit

The following messages may be sent by the edit control:

This message is sent when the control gets focus or when the user presses the ENTER key while using the control.

#### **WM\_CUSTEDIT\_ENTER**

**wParam** contains the custom edit control resource ID.

**lParam** contains the **HWND** of custom edit control.

### Methods:

### Prototype:

```
virtual void GetText( TCHAR *text, int ct )=0;
```

### Remarks:

This retrieves the text entered into the control.

### Parameters:

**TCHAR \*text**

Storage for the text to retrieve.

**int ct**

Specifies the maximum length of the string returned.

**Prototype:**

**virtual void SetText( TCHAR \*text )=0;**

**Remarks:**

This method places the text into the control for editing.

**Parameters:**

**TCHAR \*text**

The text to place in the control.

**Prototype:**

**virtual void SetText( int i )=0;**

**Remarks:**

This method allows you to pass in an integer value to the control. The integer is converted to a string and displayed in the control.

**Parameters:**

**int i**

This value is converted to a string and displayed in the control.

**Prototype:**

**virtual void SetText( float f, int precision=3 )=0;**

**Remarks:**

This method allows you to pass in a floating point value to the control. The float is converted to a string and displayed in the control.

**Parameters:**

**float f**

This value is converted to a string and displayed in the control.

**int precision=3**

The precision argument is simply the number of decimal places that get represented in the string that appears in the edit field. So if the arguments were

(1.0f/3.0f, 3) then the string "0.333" would appear in the edit field.

**Prototype:**

**virtual int GetInt(BOOL \*valid=NULL)=0;**

**Remarks:**

This method parses and returns an integer value from the control.

**Parameters:**

**BOOL \*valid=NULL**

This pointer, if passed, is set to TRUE if the input is 'valid'; otherwise FALSE. FALSE indicates that something caused the parsing of the input to terminate improperly. An example is a non-numeric character. So for example, if the user entered "123jkfk sdf" into the field the valid pointer would be set to FALSE.

**Prototype:**

**virtual float GetFloat(BOOL \*valid=NULL)=0;**

**Remarks:**

This method parses and returns a floating point value from the control.

**Parameters:**

**BOOL \*valid=NULL**

This pointer, if passed, is set to TRUE if the input is 'valid'; otherwise FALSE. FALSE indicates that something caused the parsing of the input to terminate improperly. An example is a non-numeric character. So for example, if the user entered "123jkfk sdf" into the field this pointer would be set to FALSE.

**Prototype:**

**virtual void SetLeading(int lead)=0;**

**Remarks:**

A developer doesn't normally need to call this method. This offsets the text vertically in the edit control.

**Parameters:**

**int lead**

This parameter specifies the number of pixels to offset.

**Prototype:**

```
virtual void WantReturn(BOOL yesNo)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method allows custom handling of the RETURN key. If you pass TRUE to this method an **EN\_CHANGE** message will be sent to the control when the RETURN key is pressed. The **EN\_CHANGE** message is sent when the user has taken any action that may have altered text in an edit control so developer need to also call **GotReturn()** (documented below) to see if it was indeed a RETURN keypress.

**Parameters:**

**BOOL yesNo**

If TRUE, then when the user presses the RETURN key in that control, the edit field will send an **EN\_CHANGE** message to the owner, and calling **GotReturn()** will return TRUE.

**Sample Code:**

Below is the way this is handled by the Hit By Name dialog. In that dialog, when the user enters a wild card pattern into the name match field and presses RETURN, the dialog is exited with the items matching the pattern selected. The way this is accomplished is by pass TRUE to **WantReturn()** and then processing the **EN\_CHANGE** message on the control. If **GotReturn()** is TRUE the Win32 function **PostMessage()** is used to send the **IDOK** message to exit the dialog. If this wasn't done, pressing RETURN in the edit control would only enter the text -- the user would have to move the mouse over the OK button and press it.

```
case IDC_HBN_PATTERN:  
if (HIWORD(wParam)==EN_CHANGE) {  
    iName = GetICustEdit( GetDlgItem(hDlg,IDC_HBN_PATTERN) );  
    iName->GetText(buf,256);  
    ct = _tcslen(buf);  
    if(ct && buf[ct-1] != _T('*'))  
        _tcscat(buf, _T("*"));  
    SendMessage(sbn->hList, LB_RESETCONTENT, 0, 0);
```

```
sbn->SetPattern(GetDlgItem(hDlg, IDC_HBN_PATTERN), buf);
sbn->BuildHitList(ct);
if(iName->GotReturn())
    PostMessage(hDlg, WM_COMMAND, IDOK, 0);
ReleaseICustEdit(iName);
}
break;
```

**Prototype:**

**virtual BOOL GotReturn()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method should be called on receipt of an **EN\_CHANGE** message. It return TRUE if pressing the RETURN key generated the message; otherwise FALSE.

**Prototype:**

**virtual void GiveFocus()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Calling this method gives the control the focus to receive input.

**Prototype:**

**virtual BOOL HasFocus()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the control has the focus to receive input; otherwise FALSE.

**Prototype:**

**virtual void WantDlgNextCtl(BOOL yesNo)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Determines whether the TAB key may be used to jump to the next control in

the tab sequence.

**Parameters:**

**BOOL yesNo**

TRUE to enable the TAB key to move to the next control; FALSE to disable the TAB key from moving the focus.

**Prototype:**

**virtual void SetNotifyOnKillFocus(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Normally when a user exits an edit field the notification

**WM\_CUSTEDIT\_ENTER** is sent. Many plug-ins key off this message to finalize the input of values. For instance, if the user is entering a value into an edit field and they hit the TAB key to leave the field the value should be entered. Normally this is the desired behavior. However, as a special case condition, if a developer does not want to update the value, this method may be called so the **WM\_CUSTEDIT\_ENTER** notification won't be sent when the edit control loses focus.

**Parameters:**

**BOOL onOff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual void SetBold(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the text font in the edit control to display in a bold format or normal.

**Parameters:**

**BOOL onOff**

TRUE to turn bolding on; FALSE to turn off.

## Class ISpinnerControl

See Also: [Class ICustomControl](#), [Custom Controls](#).

```
class ISpinnerControl : public ICustomControl
```

### Description:

The spinner control is used (usually in conjunction with the custom edit control) to provide input of values limited to a fixed type. For example, the control may be limited to the input of only positive integers. The input options are integer, float, universe (world space coordinates), positive integer, positive float, positive universal, and time. This control allows the user to increment or decrement a value by clicking on the up or down arrows. The user may also click and drag on the arrows to interactively adjust the value. The Ctrl key may be held to accelerate the value changing speed, while the Alt key may be held to decrease the value changing speed.

The standard size used by 3ds max for the spinner control is 7 wide by 10 high. If you use a larger size, the spinner control arrows will be position in the upper left corner of the control.

**Important Note: The spinner control ensures that it only displays, and the user is only allowed to input, values within the specified ranges. However the spinner is just a front end to a controller which actually controls the value. The user can thus circumvent the spinner constraints by editing the controller directly (via function curves in track view, key info, etc.).**

**Therefore, when a plug-in gets a value from a controller (or a parameter block, which may use a controller) it is its responsibility to clamp the value to a valid range.**

 (Spinner Control)

 (Spinner and Edit control)

To initialize the pointer to the control call:

```
ISpinnerControl *GetISpinner(HWND hCtrl);
```

To release the control call:

```
ReleaseISpinner(ISpinnerControl *isc);
```

The value to use in the Class field of the Custom Control Properties dialog is:

**SpinnerControl**

The following messages may be sent by the spinner control:

This message is sent when the value of a spinner changes.

### **CC\_SPINNER\_CHANGE**

**lParam** contains a pointer to the spinner control. You can cast this pointer to a **ISpinnerControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the spinner. This is the named established in the ID field of the Custom Control Properties dialog.

**HIWORD(wParam)** is TRUE if the user is dragging the spinner interactively.

This message is sent when the user presses down on the spinner buttons.

### **CC\_SPINNER\_BUTTONDOWN**

**lParam** contains a pointer to the spinner control. You can cast this pointer to a **ISpinnerControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the spinner. This is the named established in the ID field of the Custom Control Properties dialog.

This message is sent when the user releases a spinner button.

### **CC\_SPINNER\_BUTTONUP**

**lParam** contains a pointer to the spinner control. You can cast this pointer to a **ISpinnerControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the spinner. This is the named established in the ID field of the Custom Control Properties dialog.

**HIWORD(wParam)** is FALSE if the user canceled and TRUE otherwise.

For example, if the user is interactively dragging the spinner, then does a right click to cancel, the following messages are sent:

- 1 A **CC\_SPINNER\_BUTTONDOWN** message indicating the user has pressed the spinner button.
- 2 A series of **CC\_SPINNER\_CHANGE** where **HIWORD(wParam) = TRUE**. This indicates that the spinner is being dragged interactively.
- 3 A **CC\_SPINNER\_CHANGE** where **HIWORD(wParam) = FALSE**.
- 4 A **CC\_SPINNER\_BUTTONUP** message where **HIWORD(wParam) = FALSE**. This indicates the user has cancelled.

**Methods:**

**Prototype:**

**virtual float GetFVal()=0;**

**Remarks:**

Returns the floating point value of the control.

**Prototype:**

**virtual int GetIVal()=0;**

**Remarks:**

This method returns the integer value of the control.

**Prototype:**

**virtual void SetAutoScale(BOOL on=TRUE)=0;**

**Remarks:**

This method sets the scale for the spinner based on the current value of the spinner. This allows the spinner to cover a larger range of values with less mouse motion. If you wish to use auto scale, pass TRUE to this method.

**Parameters:**

**BOOL on=TRUE**

If you wish to use auto scale pass TRUE to this method; otherwise FALSE.

**Prototype:**

**virtual void SetScale(float s)=0;**

**Remarks:**

This method sets the value which is added to or subtracted from the current control value as the arrow buttons are pressed, or the user interactively drags the spinner.

**Parameters:**

**float s**

The value is added to or subtracted from the current control value.

**Prototype:**

**virtual void SetValue(float v, int notify)=0;**

**Remarks:**

This method sets the value of the control to the specific floating point number passed. You may pass FALSE as the notify parameter so the control won't send a message when you set the value.

**Parameters:**

**float v**

The new value for the control.

**int notify**

If TRUE a message is sent indicating the control has changed.

Note that sometimes the **SetValue()** method is used to update the display of parameters in the user interface. For example, if the user changes the current time and the UI parameters are animated, the user interface controls must be updated to reflect the value at the new time. The programmer calls

**SetValue()** to update the value displayed in the control. This is an example of when to pass FALSE as the notify parameter. If you were to pass TRUE, a message would be sent as if the user had actually enter a new value at this time. These are of course very different conditions.

**Prototype:**

**virtual void SetValue(int v, int notify)=0;**

**Remarks:**

This method sets the value to the specific integer passed. You may pass FALSE as the notify parameter so the control won't send a message when you set the value.

**Parameters:**

**int v**

The new value for the control.

**int notify**

If TRUE a message is sent indicating the control has changed.

**Prototype:**

**virtual void SetLimits(int min, int max, int limitCurValue =**

**TRUE)=0;**

**Remarks:**

This method establishes the allowable limits for integer values entered.

**Parameters:**

**int min**

The minimum allowable value.

**int max**

The maximum allowable value.

**int limitCurValue = TRUE**

You may pass FALSE to the this parameter so the control will not send a spinner changed message when the limits are set.

**Prototype:**

**virtual void SetLimits(float min, float max, int limitCurValue = TRUE)=0;**

**Remarks:**

This method establishes the allowable limits for floating point values entered.

**Parameters:**

**float min**

The minimum allowable value.

**float max**

The maximum allowable value.

**int limitCurValue = TRUE**

You may pass FALSE to the this parameter so the control will not send a spinner changed message when the limits are set.

**Prototype:**

**virtual void LinkToEdit(HWND hEdit, EditSpinnerType type)=0;**

**Remarks:**

When an edit control is used in conjunction with the spinner control, this method is used to link the two, so values entered using the spinner are displayed in the edit control. This method is also used to set the type of value which may be entered.

**Parameters:****HWND hEdit**

The handle of the edit control to link.

**EditSpinnerType type**

The type of value that may be entered. One of the following values:

**EDITTYPE\_INT**

Any integer value.

**EDITTYPE\_FLOAT**

Any floating point value.

**EDITTYPE\_UNIVERSE**

This is a value in world space units. It respects the system's unit settings (for example feet and inches).

**EDITTYPE\_POS\_INT**

Any integer  $\geq 0$

**EDITTYPE\_POS\_FLOAT**

Any floating point value  $\geq 0.0$

**EDITTYPE\_POS\_UNIVERSE**

This is a positive value in world space units. It respects the system's unit settings (for example feet and inches) .

**EDITTYPE\_TIME**

This is a time value. It respects the system time settings (SMPTE for example).

**Prototype:**

```
virtual void SetIndeterminate(BOOL i=TRUE)=0;
```

**Remarks:**

This method is used to show commonality. When several different values are being reflected by the spinner, the value is indeterminate. When TRUE, the value field of the spinner appears empty.

**Parameters:****BOOL i=TRUE**

Pass TRUE to this method to set the value to indeterminate.

**Prototype:**

**virtual BOOL IsIndeterminate()=0;**

**Remarks:**

This method returns TRUE if the current state of the spinner is indeterminate. See **SetIndeterminate()** above.

**Prototype:**

**virtual void SetResetValue(float v)=0;**

**Remarks:**

A 3ds max user may right click on the spinner buttons to reset them to their 'reset' value (after they have been changed). This method specifies the value used when the reset occurs.

**Parameters:**

**float v**

The reset value.

**Prototype:**

**virtual void SetResetValue(int v)=0;**

**Remarks:**

A 3ds max user may right click on the spinner buttons to reset them to their 'reset' value (after they have been changed). This method specifies the value used when the reset occurs.

**Parameters:**

**int v**

The reset value.

**Prototype:**

**virtual void SetKeyBrackets(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the display of the brackets surrounding the spinner control to on. This is used to indicate if a key exists for the parameter controlled by the spinner at

the current time. These brackets turned on and off automatically if you are using a parameter map and parameter block to handle the control. If not you'll need to use this method.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Sample Code:**

This example shows how you do this if you only use a parameter block.

```
case CC_SPINNER_CHANGE:
switch (LOWORD(wParam)) {
case IDC_LENSPINNER:
th->SetLength(th->ip->GetTime(),th->lengthSpin->GetFVal());
th->lengthSpin->SetKeyBrackets(th->pblock->
KeyFrameAtTime(PB_LENGTH,th->ip->GetTime()));
break;
}
return TRUE;
```

The following functions are not part of class **ISpinnerControl** but are available for use with spinner controls.

**Function:**

**void SetSpinnerPrecision(int p);**

**Remarks:**

Sets the precision (number of decimal places displayed) used by the spinner control. Note that this function also affects slider controls. See [Class ISliderControl](#).

**Parameters:**

**int p**

The number of decimal places to display in the edit box linked to the spinner control.

**Function:**

**int GetSpinnerPrecision();**

**Remarks:**

Returns the number of decimal places displayed in the edit box linked to a spinner control. Note that this function also affects slider controls. See [Class ISliderControl](#).

Spinner controls have a global snap setting. This is set in 3ds max using File/Preferences... in the General page by changing the Spinner Snap setting. When enabled this specifies an increment that is applied to the current spinner value each time the UP or DOWN buttons are pressed on the spinner control.

**Prototype:**

**void SetSnapSpinner(BOOL b);**

**Remarks:**

This activates or de-activates the global spinner snap toggle.

**Parameters:**

**BOOL b**

TRUE to activate; FALSE to de-activate.

**Prototype:**

**BOOL GetSnapSpinner();**

**Remarks:**

Returns the global spinner snap setting; TRUE if on; FALSE if off.

**Prototype:**

**void SetSnapSpinValue(float f);**

**Remarks:**

This sets the global spinner snap increment or decrement value.

**Parameters:**

**float f**

The value that is added to or subtracted from the current spinner value when the arrow buttons are pressed.

**Prototype:**

**float GetSnapSpinValue();**

**Remarks:**

Returns the global spinner snap increment or decrement value.

**Function:**

**ISpinnerControl \*SetupFloatSpinner(HWND hwnd, int idSpin, int idEdit, float min, float max, float val, float scale = 0.1f);**

**Remarks:**

This global function (not part of class ISpinnerControl) is used for setting up Spinners. It performs the equivalent of the **GetISpinner()**, **SetLimits()**, **SetValue()**, and **LinkToEdit()**.

**Parameters:**

**HWND hwnd**

The handle of the dialog box in which the spinner appears.

**int idSpin**

The ID of the spinner.

**int idEdit**

The ID of the edit control.

**float min**

The minimum allowable value.

**float max**

The maximum allowable value.

**float val**

The initial value for the spinner.

**float scale = 0.1f**

The initial scale value for the spinner.

**Return Value:**

A pointer to the spinner control.

**Sample Code:**

Sample code to initialize a spinner / edit control.

```
to->custCtrlSpin = GetISpinner(GetDlgItem(hDlg,
IDC_SPIN_SPINNER));
to->custCtrlSpin->SetLimits(0.0f, 100.0f, FALSE);
to->custCtrlSpin->SetValue(100.0f, FALSE);
to->custCtrlSpin->LinkToEdit(GetDlgItem(hDlg,
```

```
IDC_SPIN_EDIT),  
    EDITTYPE_FLOAT);
```

The above code could be replaced with the following simplified code:

```
to->custCtrlSpin = SetupFloatSpinner(hDlg,  
    IDC_SPIN_SPINNER,  
    IDC_SPIN_EDIT, 0.0f, 100.0f, 100.0f);
```

**Function:**

```
ISpinnerControl *SetupIntSpinner(HWND hwnd, int idSpin, int  
idEdit, int min, int max, int val);
```

**Remarks:**

This global function (not part of class ISpinnerControl) is used for setting up Spinners. It performs the equivalent of the **GetISpinner()**, **SetLimits()**, **SetValue()**, and **LinkToEdit()**.

**Parameters:**

**HWND hwnd**

The handle of the dialog box in which the spinner appears.

**int idSpin**

The ID of the spinner.

**int idEdit**

The ID of the edit control.

**int min**

The minimum allowable value.

**int max**

The maximum allowable value.

**int val**

The initial value for the spinner.

**Return Value:**

A pointer to the spinner control.

**Function:**

```
void SetSpinDragNotify(BOOL onOff);
```

**Remarks:**

This global function is available in release 2.0 and later only.

This function controls whether or not spinners send

**CC\_SPINNER\_CHANGE** notifications while the user adjusts them with the mouse.

**Parameters:**

**BOOL onOff**

TRUE to turn on; FALSE to turn off.

**Function:**

**BOOL GetSpinDragNotify();**

**Remarks:**

This global function is available in release 2.0 and later only.

Returns TRUE if **CC\_SPINNER\_CHANGE** notifications are sent by spinners while the user adjusts them with the mouse; FALSE if they are not sent.

## Class ICustImage

See Also: [Class ICustomControl](#), [Custom Controls](#).

```
class ICustImage : public ICustomControl
```

### Description:

The custom image control provides a recessed area in the dialog to display a bitmap image.

To initialize the pointer to the control call:

### Prototype:

```
ICustImage *GetICustImage(HWND hCtrl);
```

To release the control call:

### Prototype:

```
ReleaseICustImage(ICustImage *ici);
```

The value to use in the Class field of the Custom Control Properties dialog is:

**CustImage**

### Methods:

### Prototype:

```
virtual void SetImage(HIMAGELIST hImage, int index, int w, int h)=0;
```

### Remarks:

This method sets the image to display.

### Parameters:

#### **HIMAGELIST hImage**

An image list. An image list is a collection of same-sized images, each of which can be referred to by its index. Image lists are used to efficiently manage large sets of icons or bitmaps in Windows. All images in an image list are contained in a single, wide bitmap in screen device format. An image list may also include a monochrome bitmap that contains masks used to draw

images transparently (icon style). The Windows API provides image list functions, which enable you to draw images, create and destroy image lists, add and remove images, replace images, and merge images.

**int index**

This is the index of the image to display in the image list.

**int w**

The image width.

**int h**

The image height.

## Class ICustStatus

See Also: [Class ICustomControl](#), [Custom Controls](#), [Class ICustStatusEdit](#).

class ICustStatus : public ICustomControl

### Description:

The custom status control provide a recessed area of the dialog which the developer may use as a status prompt display.

(0, 255, 128)

To initialize the pointer to the control call:

### Prototype:

**ICustStatus \*GetICustStatus(HWND hCtrl);**

To release the control call:

### Prototype:

**ReleaseICustStatus(ICustStatus \*ics);**

The value to use in the Class field of the Custom Control Properties dialog is:

**CustStatus**

### Methods:

#### Prototype:

**virtual void SetText(TCHAR \*text)=0;**

#### Remarks:

This method specifies the text message to display.

#### Parameters:

**TCHAR \*text**

Points to the text to display.

#### Prototype:

**virtual void GetText(TCHAR \*text, int ct)=0;**

#### Remarks:

This method is available in release 2.0 and later only.

Retrieves the text currently displayed in the custom status control.

**Parameters:**

**TCHAR \*text**

A pointer to storage for the text to return.

**int ct**

The maximum length of the string to return.

**Prototype:**

**virtual void SetTextFormat(StatusTextFormat f)=0;**

**Remarks:**

This methods controls the formatting of the text in the status control.

**Parameters:**

**StatusTextFormat f**

One of the following options:

**STATUSTEXT\_LEFT**

Left justified in the control.

**STATUSTEXT\_CENTERED**

Centered in the control.

**STATUSTEXT\_RIGHT**

Right justified in the control.

**Prototype:**

**virtual void SetTooltip(BOOL onOff, LPSTR text)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Specifies the tooltip text to use for a custom status control and enables or disables its availability.

**Parameters:**

**BOOL onOff**

If TRUE the tooltip text may appear; if FALSE the tooltip will not appear.

**LPSTR text**

The text to use for the tooltip.

## Class IColorSwatch

See Also: [Class ICustomControl](#), [Custom Controls](#), [COLORREF](#).

```
class IColorSwatch : public ICustomControl
```

### Description:

The color swatch control puts up the standard 3ds max modeless color selector when the control is clicked on. The plug-in may be notified as the user interactively selects new colors.

To initialize the pointer to the control call:

### Prototype:

```
IColorSwatch *GetIColorSwatch(HWND hCtrl, COLORREF col,  
TCHAR *name);
```

For example:

```
custCSw = GetIColorSwatch(GetDlgItem(hDlg,  
IDC_CSWATCH), RGB(255,255,255), _T("New Wireframe  
Color"));
```

This returns the pointer to the control, sets the initial color selected, and displays the text string passed in the title bar of the selection dialog.

To release the control call:

### Prototype:

```
ReleaseIColorSwatch(IColorSwatch *ics);
```

The value to use in the Class field of the Custom Control Properties dialog is:

### ColorSwatch

This message is sent as the color is being adjusted in the ColorPicker.

### CC\_COLOR\_CHANGE

**lParam** = pointer to ColorSwatchControl

**LOWORD(wParam)** contains the ID of the control. This is the named established in the ID field of the Custom Control Properties dialog.

**HIWORD(wParam)** contains 1 if button UP, or 0 if mouse drag.

This message is sent if the color has been clicked on, before bringing up the color picker.

## **CC\_COLOR\_SEL**

**lParam** contains a pointer to the ColorSwatch Control.

**LOWORD(wParam)** contains the ID of the control. This is the named established in the ID field of the Custom Control Properties dialog.

**HWORD(wParam)** contains 0.

This message is sent if another color swatch has been dragged and dropped on this swatch.

## **CC\_COLOR\_DROP**

**lParam** contains a pointer to the ColorSwatch Control.

**LOWORD(wParam)** contains the ID of the control. This is the named established in the ID field of the Custom Control Properties dialog.

**HWORD(wParam)** contains 0.

This message is sent when the color picker is closed.

## CC\_COLOR\_CLOSE

**lParam** contains a pointer to the ColorSwatch Control.

**LOWORD(wParam)** contains the ID of the control. This is the named established in the ID field of the Custom Control Properties dialog.

**HWORD(wParam)** contains 0.

### Methods:

#### Prototype:

```
virtual COLORREF SetColor(COLORREF c, int  
notify=FALSE)=0;
```

#### Remarks:

This method sets the current color value.

#### Parameters:

**COLORREF c**

You can pass specific RGB values in using the RGB macro. For example, to pass in pure blue you would use **RGB(0,0,255)**.

**int notify=FALSE**

If you pass TRUE for this parameter, the dialog proc for the dialog will receive the **CC\_COLOR\_CHANGE** message each time the color is changed.

#### Return Value:

This method returns the old color.

#### Prototype:

```
virtual COLORREF GetColor()=0;
```

#### Remarks:

This method may be used to retrieve the color selected by the user.

#### Return Value:

The **COLORREF** structure returned may be broken down into individual

RGB values by using the **GetRValue(color)**, **GetGValue(color)**, and **GetBValue(color)** macros.

**Prototype:**

**virtual void ForceDitherMode(BOOL onOff)=0;**

**Remarks:**

This method sets if the color shown in the color swatch is dithered on not.

**Parameters:**

**BOOL onOff**

TRUE to force the color to be dithered; otherwise FALSE.

**Prototype:**

**virtual void SetModal()=0;**

**Remarks:**

Call this method to have the color selector comes up in a modal dialog. This forces the user to select OK before the user may operate the rest of the program.

**Prototype:**

**virtual void Activate(int onOff)=0;**

**Remarks:**

This method is called to indicate that the color swatch is in a dialog that has been become active or inactive. A color swatch that is in an inactive dialog will be drawn as dithered due to the limited number of color registers available on an 8-bit display.

**Parameters:**

**int onOff**

If TRUE the color swatch is in an active dialog. If FALSE the control is in an inactive dialog.

**Prototype:**

**virtual void EditThis(BOOL startNew=TRUE)=0;**

**Remarks:**

If there is already a color picker up for a color swatch, this method switches it over to edit the color swatch on which **EditThis()** was called.

**Parameters:****BOOL startNew=TRUE**

If there was no color picker up, if this parameter is set to TRUE, then a color picker is created. If this parameter is set to FALSE, and there was no color picker up, then nothing happens.

## Class ICustToolBar

See Also: [Custom Controls](#). [Class ToolItem](#), [Class MacroButtonData](#), [Class CUIFrameMsgHandler](#), [Class ICustStatusEdit](#), [Class ICustStatus](#), [Class ICustButton](#).

```
class ICustToolBar : public ICustomControl
```

### Description:

This control allows the creation of toolbars containing buttons (push, check, and fly-offs), status fields, separators (spacers), and other Windows or user defined controls. Note: The standard size for 3ds max toolbar button icons is 16x15.

In 3ds max 3.0 and later toolbars may have multiple rows, or appear vertically. They may also have macro buttons (added with the MacroButtonData class) which may have icons or text.

To initialize the pointer to the control call:

### Prototype:

```
ICustToolBar *GetICustToolBar(HWND hCtrl);
```

To release the control call:

### Prototype:

```
ReleaseICustToolBar(ICustToolBar *ict);
```

The value to use in the Class field of the Custom Control Properties dialog is:

**CustToolBar**

Note: The **TB\_RIGHTCLICK** message is sent when the user right clicks in open space on a toolbar:

Also Note: To add tooltips to the toolbar controls you can do so by capturing the **WM\_NOTIFY** message in the dialog proc. For complete sample code see **\MAXSDK\SAMPLES\HOWTO\CUSTCTRL\CUSTCTRL.CPP**. The specific message is processed as shown below.

```
case WM_NOTIFY:
```

```
// This is where we provide the tooltip text for the
```

```
// toolbar buttons...
```

```
if(((LPNMHDR)lParam)->code == TTN_NEEDTEXT) {
```

```

LPTOOLTIPTEXT lpttt;
lpttt = (LPTOOLTIPTEXT)lParam;
switch (lpttt->hdr.idFrom) {
  case ID_TB_1:
    lpttt->lpszText = _T("Do Nothing Up");
    break;
  case ID_TB_2:
    lpttt->lpszText = _T("Do Nothing Down");
    break;
  case ID_TB_3:
    lpttt->lpszText = _T("Do Nothing Lock");
    break;
  case IDC_BUTTON1:
    if (to->custCtrlButtonC->IsChecked())
      lpttt->lpszText = _T("Button Checked");
    else
      lpttt->lpszText = _T("Button Un-Checked");
    break;
  };
}
break;

```

**Methods:**

**Prototype:**

**virtual void SetImage(HIMAGELIST hImage)=0;**

**Remarks:**

This method establishes the image list used to display images in the toolbar.

**Parameters:**

**HIMAGELIST hImage**

The image list. An image list is a collection of same-sized images, each of which can be referred to by an index. Image lists are used to efficiently manage large sets of icons or bitmaps in Windows. All images in an image list are contained in a single, wide bitmap in screen device format. An image list may also include a monochrome bitmap that contains masks used to draw

images transparently (icon style). The Windows API provides image list functions, which enable you to draw images, create and destroy image lists, add and remove images, replace images, and merge images.

**Prototype:**

**virtual void AddTool(const ToolItem& entry, int pos=-1)=0;**

**Remarks:**

The developer calls this method once for each item in the toolbar. The items appear in the toolbar from left to right in the order that they were added using this method. (Note that this method adds tools to the custom toolbar and not the 3ds max toolbar).

**Parameters:**

**const ToolItem& entry**

Describes the item to add to the toolbar.

**int pos=-1**

Controls where the added tool is inserted. The default of -1 indicates the control will be added at the right end of the toolbar.

**Prototype:**

**virtual void AddTool2(ToolItem& entry, int pos=-1)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Currently this method is identical to the AddTool() method.

**Parameters:**

**ToolItem& entry**

Describes the item to add to the toolbar.

**int pos=-1**

Controls where the added tool is inserted. The default of -1 indicates the control will be added at the right end of the toolbar.

**Prototype:**

**virtual void DeleteTools(int start, int num=-1)=0;**

**Remarks:**

This method is used to delete tools from the toolbar.

**Parameters:****int start**

Specifies which tool is the first to be deleted.

**int num=-1**

Specifies the number of tools to delete. If this parameter is -1 (the default) it deletes 'start' through count-1 tools.

**Prototype:**

**virtual void SetTopBorder(BOOL on)=0;**

**Remarks:**

Passing TRUE to this method draws a border above the toolbar. You can see the appearance of the top border in the sample toolbar shown above. If this is set to FALSE, the border is not drawn

**Parameters:****BOOL on**

TRUE to draw the border; FALSE for no border.

**Prototype:**

**virtual void SetBottomBorder(BOOL on)=0;**

**Remarks:**

Passing TRUE to this method draws a border beneath the toolbar. You can see the appearance of the bottom border in the sample toolbar shown above. If this is set to FALSE, the border is not drawn.

**Parameters:****BOOL on**

TRUE to draw the border; FALSE for no border.

**Prototype:**

**virtual int GetNeededWidth(int rows)=0;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the width needed for specified number of rows.

**Parameters:**

**int rows**

The number of rows.

**Prototype:**

**virtual void SetNumRows(int rows)=0;**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the number of rows that the toolbar may hold.

**Parameters:**

**int rows**

The number of rows to set.

**Prototype:**

**virtual ICustButton \*GetICustButton(int id)=0;**

**Remarks:**

This method is used to return a pointer to one of the toolbar's buttons. Using this pointer you can call methods on the button. If you use this method, you must release the control after you are finished with it.

**Parameters:**

**int id**

Specifies the id of the toolbar button.

**Return Value:**

A pointer to one of the toolbar's buttons. If the button is not found it returns NULL. See [Class ICustButton](#).

**Prototype:**

**virtual ICustStatus \*GetICustStatus(int id)=0;**

**Remarks:**

This method is used to return a pointer to one of the toolbars status controls.

Using this pointer you can call methods on the status control. If you use this method, you must release the control after you are finished with it.

**Parameters:**

**int id**

Specifies the id of the toolbar button.

**Return Value:**

A pointer to one of the toolbars status controls. See [Class ICustStatus](#).

**Prototype:**

**virtual ICustStatusEdit \*GetICustStatusEdit(int id)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to return a pointer to the custom status edit control whose id is passed. If you use this method, you must release the control after you are finished with it. See [Class ICustStatusEdit](#).

**Parameters:**

**int id**

Specifies the id of the toolbar button.

**Prototype:**

**virtual HWND GetItemHwnd(int id)=0;**

**Remarks:**

Returns the handle to the toolbar item whose ID is passed.

**Parameters:**

**int id**

Specifies the id of the toolbar button.

**Prototype:**

**virtual int GetNumItems()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of items in the toolbar.

**Prototype:**

**virtual int GetItemID(int index)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Each item in the toolbar has an ID. When items are programatically added to the toolbar via Class `ToolButtonItem` an ID is passed to the `ToolButtonItem` constructor. This method returns the ID for the specified item in the toolbar.

**Parameters:**

**int index**

Specifies which toolbar item to return the id of. This is an index between **0** and **GetNumItems()-1**.

**Return Value:**

When the button is added using [Class ToolButtonItem](#) this is the id that is part of that structure. When the user operates a tool the dialog proc get a **WM\_COMMAND** message and this is also the id in **LOWORD(wParam)**.

**Prototype:**

**virtual int FindItem(int id)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the index into the list of toolbar entries of the item whose id is passed.

**Parameters:**

**int id**

The id of the control to find.

**Prototype:**

**virtual void DeleteItemByID(int id)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Deletes the toolbar item whose id is passed.

**Parameters:**

**int id**

The id of the control to delete.

**Prototype:**

```
virtual void LinkToCUIFrame(HWND hCUIFrame,  
CUIFrameMsgHandler *msgHandler)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method links this toolbar to the CUI frame whose window handle and message handler are passed.

**Parameters:**

**HWND hCUIFrame**

The window handle of the CUI frame to link this toolbar to.

**CUIFrameMsgHandler \*msgHandler**

Points to the message handler for the CUI frame. See [Class CUIFrameMsgHandler](#).

**Prototype:**

```
virtual void GetFloatingCUIFrameSize(SIZE *sz, int rows=1)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to obtain the size of the floating CUI frame.

**Parameters:**

**SIZE \*sz**

The size of the floating frame.

**int rows=1**

The number of rows displayed in the floating frame.

**Prototype:**

```
virtual void ResetIconImages() = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This resets the icons in the toolbar. This tells all the buttons in this toolbar to delete their icon image cache. If a plug-in has created a toolbar with any MaxBmpFileIcons on it, it should register a callback for color changing, and call this method on the toolbar. See [Structure NotifyInfo](#) for registering the color change callback.

## Class IRollupWindow

See Also: [Class ICustomControl](#), [Class IRollupPanel](#), [Custom Controls](#), [Class Interface](#).

```
class IRollupWindow : public ICustomControl
```

### Description:

This control is used to access existing rollup pages or if you are creating a dialog box which will not be used in the command panel. This control may be used to add a container area for rollup pages to be added to the dialog, and provides a scroll bar just like the command panel itself.

Note that this is a special case. Normally, adding rollup pages to the command panel is done using the simple **AddRollupPage()** method of the Interface class. This control is only used when you want to have a scrolling region for rollup pages in a dialog box.

To initialize the pointer to the control call:

```
IRollupWindow *GetIRollup(HWND hCtrl);
```

To release the control call:

```
void ReleaseIRollup(IRollupWindow *irw);
```

The value to use in the Class field of the Custom Control Properties dialog is:  
**RollupWindow**

### Methods:

#### Prototype:

```
virtual void Show()=0;
```

#### Remarks:

This causes all the rollup windows to be visible.

#### Prototype:

```
virtual void Hide()=0;
```

#### Remarks:

This causes all the rollup windows to become invisible.

#### Prototype:

**virtual void Show(int index)=0;**

**Remarks:**

This will make the rollup window whose index is passed visible.

**Parameters:**

**int index**

The index of the rollup to show.

**Prototype:**

**virtual void Hide(int index)=0;**

**Remarks:**

This will make the rollup window whose index is passed invisible.

**Parameters:**

**int index**

The index of the rollup to hide.

**Prototype:**

**virtual HWND GetPanelDlg(int index)=0;**

**Remarks:**

Returns the handle of the rollup page whose index is passed.

**Parameters:**

**int index**

The index of the rollup whose handle is to be returned.

**Prototype:**

**virtual int GetPanelIndex(HWND hWnd)=0;**

**Remarks:**

Returns an index to the rollup page given its handle.

**Parameters:**

**HWND hWnd**

The handle of the rollup.

**Prototype:**

**virtual void SetPanelTitle(int index,TCHAR \*title)=0;**

**Remarks:**

This method sets the title text displayed in the rollup page whose index is passed.

**Parameters:**

**int index**

Specifies the rollup whose title is to be set.

**TCHAR \*title**

The title string.

**Prototype:**

**virtual int AppendRollup(HINSTANCE hInst, TCHAR \*dlgTemplate, DLGPROC dlgProc, TCHAR \*title, LPARAM param=0,DWORD flags=0, int category = ROLLUP\_CAT\_STANDARD)=0;**

**Remarks:**

This method is used to add a rollup page.

**Parameters:**

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The index of the new page is returned.

**Prototype:**

```
virtual int AppendRollup(HINSTANCE hInst, DLGTEMPLATE *dlgTemplate, DLGPROC dlgProc, TCHAR *title, LPARAM param=0, DWORD flags=0, int category = ROLLUP_CAT_STANDARD)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to add a rollup page, but is currently not used.

**Parameters:**

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The index of the new page is returned.

**Prototype:**

```
virtual int ReplaceRollup(int index, HINSTANCE hInst, TCHAR *dlgTemplate, DLGPROC dlgProc, TCHAR *title, LPARAM param=0,DWORD flags=0)=0;
```

**Remarks:**

This method is used to replace the rollup page whose index is passed.

**Parameters:****int index**

Specifies the rollup whose to be replaced.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**Return Value:**

The index of the replacement page is returned.

**Prototype:**

```
virtual int ReplaceRollup(int index, HINSTANCE hInst,  
DLGTEMPLATE *dlgTemplate, DLGPROC dlgProc, TCHAR  
*title, LPARAM param=0,DWORD flags=0, int category =  
ROLLUP_CAT_STANDARD)=0;;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to replace the rollup page whose index is passed, but is currently not used.

**Parameters:****int index**

Specifies the rollup whose to be replaced.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the message sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

Append rollup page flags:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The index of the replacement page is returned.

**Prototype:**

**virtual void DeleteRollup(int index, int count)=0;**

**Remarks:**

This method deletes the rollup pages starting at the index passed. The count parameter controls how many pages are deleted.

**Parameters:****int index**

The starting index.

**int count**

The number of pages.

**Prototype:**

```
virtual void SetPageDlgHeight(int index,int height)=0;
```

**Remarks:**

This method is used to change the height of a rollup page.

**Parameters:****int index**

The index of the rollup to change.

**int height**

The new height of the dialog in pixels.

**Prototype:**

```
virtual void SaveState(RollupState *hState)=0;
```

**Remarks:**

This method saves the state of the rollup (the position of the scroll bars, which pages are open, etc...).

**Parameters:****RollupState \*hState**

Pointer to storage for the rollup state. Note: **typedef void \*RollupState;**

**Prototype:**

```
virtual void RestoreState(RollupState *hState)=0;
```

**Remarks:**

This methods restores a saved state.

**Parameters:**

**RollupState \*hState**

Pointer to storage for the rollup state. Note: **typedef void \*RollupState;**

**Prototype:**

**virtual int GetNumPanels()=0;**

**Remarks:**

This method returns the number of panels used in the rollup.

**Prototype:**

**virtual void DlgMouseMove(HWND hDlg, UINT message, WPARAM wParam, LPARAM lParam)=0;**

**Remarks:**

Passing **WM\_LBUTTONDOWN**, **WM\_MOUSEMOVE**, and **WM\_LBUTTONUP** to this function allows hand cursor scrolling with unused areas in the dialog.

**Parameters:**

**HWND hDlg**

The handle of the dialog.

**UINT message**

The message to pass along: **WM\_LBUTTONDOWN**, **WM\_MOUSEMOVE**, or **WM\_LBUTTONUP**.

**WPARAM wParam**

**LPARAM lParam**

These are passed as part of the message sent in. Pass them along to this method.

**Prototype:**

**virtual BOOL IsPanelOpen(int index) = 0;**

**Remarks:**

This method return TRUE if the rollup page whose index is passed is open and FALSE if it is closed.

**Prototype:**

**virtual void SetPanelOpen(int index, BOOL isOpen, BOOL ignoreFlags = TRUE) =0;**

**Remarks:**

This causes the page whose index is passed to either open or close. If **isOpen** is passed a value of TRUE, the page is opened.

**Parameters:**

**int index**

The page to open or close.

**BOOL isOpen**

If TRUE, the page is opened, if FALSE it is closed.

**BOOL ignoreFlags = TRUE**

The method would close the panel if the **DONTAUTOCLOSE** flag is not set on the rollup. This flag indicates if it should be closed anyway, even if the flag is set.

**Prototype:**

**virtual int GetScrollPos()=0;**

**Remarks:**

This method returns the scroll position of the window.

**Prototype:**

**virtual void SetScrollPos(int spos)=0;**

**Remarks:**

This method sets the scroll position of the window.

**Parameters:**

**int spos**

The scroll position to set.

**Prototype:**

**virtual void MoveRollupPanelFrom(IRollupWindow \*from, HWND hPanel, BOOL top)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This methods moves a RollupPanel to another RollupWindow. It either inserts it at the top, or appends it at the end (depending on the top parameter)

**Parameters:****IRollupWindow \*from**

A pointer to the rollup window you are moving from.

**HWND hPanel**

The handle to the destination panel.

**BOOL top**

TRUE to insert at the top; FALSE to append at the end.

**Prototype:**

```
virtual int GetPanelHeight(int index)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns the height of the specified RollupPanel.

**Parameters:****int index**

The zero based index of the rollup panel.

**Prototype:**

```
virtual int GetScrollHeight()=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns the height of a RollupWindow, that it is longer than the visible area

**Prototype:**

```
virtual IRollupPanel *GetPanel(HWND hWnd)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the rollup panel for the specified window handle. An `IRollupPanel` describes the properties of a single rollup.

**Parameters:**

**HWND hWnd**

The window handle to get the rollup for.

**Prototype:**

**virtual void RegisterRollupCallback(IRollupCallback \*callb)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to register a rollup callback function to handle any custom handling for dragging and dropping rollouts.

**Parameters:**

**IRollupCallback \*callb**

A pointer to the callback function you wish to register.

**Prototype:**

**virtual void UnRegisterRollupCallback(IRollupCallback \*callb)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to unregister a rollup callback function.

**Parameters:**

**IRollupCallback \*callb**

A pointer to the callback function you wish to unregister.

**Prototype:**

**virtual void RegisterRCMenuItem(IRollupRCMenuItem \*item)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to register a rollup right-click menu item which will

be added to the list of items. For rollups that support Drag and Drop this is used to register a ResetCategories RightClickMenu. Reset Categories will get rid of all the changes that have been made through drag and drop and restore the default.

**Parameters:**

**IRollupRCMenuItem \*item**

A pointer to the right-click menu item you wish to register.

**Prototype:**

**virtual void UnRegisterRCMenuItem(IRollupRCMenuItem \*item)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to unregister a rollup right-click menu item.

**Parameters:**

**IRollupRCMenuItem \*item**

A pointer to the right-click menu item you wish to unregister.

**Prototype:**

**virtual void ResetCategories(bool update = true)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will reset the category information on all the panels in the rollup window. The plugin will have to be reloaded (EndEditParams, BeginEditparams) in order to show this in the UI.

**Parameters:**

**bool update = true**

TRUE to update the layout, otherwise FALSE. Leave this on TRUE.

**Prototype:**

**virtual void UpdateLayout()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used internally

**This function is not part of this class but is available for use:**

**Function:**

**BOOL IsRollupPanelOpen(HWND hDlg);**

**Remarks:**

This function returns TRUE if a particular rollup panel is open given a handle to the dialog window in the panel.

**Parameters:**

**HWND hDlg**

Handle to the dialog window in the panel.

## Class IOffScreenBuf

See Also: [Custom Controls](#).

class IOffScreenBuf

### Description:

This control provides an off screen buffer which the developer may draw into, then quickly blit onto the actual display for flicker free image updates.

To initialize the pointer to the control call:

### Function:

**IOffScreenBuf \*CreateIOffScreenBuf(HWND hCtrl);**

To release the control call:

### Function:

**DestroyIOffScreenBuf(IOffScreenBuf \*iBuf);**

### Methods:

### Prototype:

**virtual HDC GetDC()=0;**

### Remarks:

Returns a handle to the display device context (DC) for the off screen buffer. The display device context can be used in subsequent GDI functions to draw in the buffer.

### Prototype:

**virtual void Erase(Rect \*rct=NULL)=0;**

### Remarks:

This method is used to erase the buffer.

### Parameters:

**Rect \*rct=NULL**

Specifies the rectangular region to erase. If NULL the entire buffer is erased.

### Prototype:

**virtual void Blit(Rect \*rct=NULL)=0;**

**Remarks:**

This method blits (transfers the image from) the buffer to the display.

**Parameters:**

**Rect \*rct=NULL**

Specifies the rectangular region to blit. If NULL the entire buffer is blitted.

**Prototype:**

**virtual void Resize()=0;**

**Remarks:**

This method is used to resize the buffer.

**Prototype:**

**virtual void SetBkColor(COLORREF color)=0;**

**Remarks:**

This sets the buffer to the specified color.

**Parameters:**

**COLORREF color**

The color to set. You may use the RGB macro to set the color.

**Prototype:**

**virtual COLORREF GetBkColor()=0;**

**Remarks:**

This methods retrieves the background color of the buffer.

**Return Value:**

The background color of the buffer.

# Class BitArray

See Also: [Template Class Tab](#), [Class BitArrayCallback](#).

Class BitArray

## Description:

This class allows the developer to define a set of bit flags that may be treated as a virtual array and are stored in an efficient manner. The class has methods to set, clear and return the i-th bit, resize the BitArray, etc. All methods are implemented by the system.

## Methods:

### Prototype:

**BitArray()**

### Remarks:

Default constructor. Sets the number of bits to 0.

### Prototype:

**BitArray(int n);**

### Remarks:

Constructor.

### Parameters:

**int i**

The size of the BitArray in bits.

### Prototype:

**BitArray(const BitArray& b);**

### Remarks:

Constructor. Duplicates the BitArray passed.

### Parameters:

**const BitArray& b**

The BitArray to duplicate.

**Prototype:**

**void SetSize(int n, int save=0)**

**Remarks:**

Sets the number of bits used.

**Parameters:**

**int n**

The number of bits in the array.

**int save=0**

If passed as 1, the old bit values will be preserved when the array is resized.

**Prototype:**

**int GetSize()**

**Remarks:**

Returns the size of the bit array in bits.

**Prototype:**

**void ClearAll()**

**Remarks:**

Clears all the bits in the array (sets them to 0).

**Prototype:**

**void SetAll()**

**Remarks:**

Sets all the bits in the array to 1.

**Prototype:**

**void Set(int i)**

**Remarks:**

Set the i-th bit to 1.

**Parameters:**

**int i**

The array index of the bit to set.

**Prototype:**

**void Clear(int i)**

**Remarks:**

Sets the i-th bit to 0.

**Parameters:**

**int i**

The array index of the bit to clear.

**Prototype:**

**void Set(int i, int b);**

**Remarks:**

Set the i-th bit to b.

**Parameters:**

**int i**

The index of the bit to set.

**int b**

The value to set, either 1 or 0.

**Prototype:**

**int NumberSet()**

**Remarks:**

Returns the number of bits set to 1.

**Return Value:**

The number of bits set to 1.

**Prototype:**

**BOOL IsEmpty();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if no bits are set; otherwise FALSE. This method is much faster than checking if **NumberSet()** returns 0.

**Prototype:**

**void Compress()**

**Remarks:**

This is not currently implemented and is reserved for future use.

**Prototype:**

**void Expand()**

**Remarks:**

This is not currently implemented and is reserved for future use.

**Prototype:**

**void Reverse(BOOL keepZero = FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Reverses the bits in the BitArray.

**Parameters:**

**BOOL keepZero = FALSE**

If TRUE the zero bit is kept where it is.

**Prototype:**

**void Rotate(int direction, int count);**

**Remarks:**

This method is available in release 2.0 and later only.

Rotates the bits in the BitArray (with wraparound).

**Parameters:**

**int direction**

The direction to rotate.

**int count**

The number of bits to rotate.

**Prototype:**

**void Shift(int direction, int count, int where=0);**

**Remarks:**

This method is available in release 2.0 and later only.

Shifts the bits in the BitArray (without wraparound).

**Parameters:**

**int direction**

One of the following values:

**LEFT\_BITSHIFT**

**RIGHT\_BITSHIFT**

**int count**

The number of bits to shift.

**int where=0**

This indicates where the shift will begin. For example, if you have a

**BitArray** containing: **10101010**

and you **Shift(LEFT\_BITSHIFT, 1, 4)** you'll get: **10100100**

All the bits from 4 to 8 are shifted one bit left, with zeroes shifted in from the right. The first bit affected is the **where** bit. If you leave off the **where** parameter you'd get the usual: **01010100**

The **RIGHT\_BITSHIFT** starts at that bit; it is unaffected because the operation proceeds to the right: **10101010**.

**Shift(RIGHT\_BITSHIFT, 1, 4)** results in: **10101101**.

**Prototype:**

**void EnumSet(BitArrayCallback &cb);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to enumerate all the elements that have a "1" value, and call the callback **proc()** with the index of the element.

**Parameters:****BitArrayCallback &cb**

The callback object whose **proc()** method is called.

**Prototype:**

```
void DeleteSet(BitArray & dset, int mult=1);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method allows you to delete a selection of elements from this BitArray.

This is useful, for instance, if you're deleting a set of vertices from a mesh and wish to keep the vertSel and vertHide arrays up to date.

**Parameters:****BitArray & dset**

This is a bit array which represents which elements should be deleted.

Typically (if mult==1) dset will have the same size as (this).

**int mult=1**

This is a multiplier which indicates how many elements in (\*this) are deleted for each entry in dset. For instance, when deleting faces in a mesh, you also need to delete the corresponding edge selection data. Since edgeSel[f\*3], edgeSel[f\*3+1], and edgeSel[f\*3+2] correspond to face f, you'd use mult=3:

```
faceSel.DeleteSet (fdel);
```

```
edgeSel.DeleteSet (fdel, 3);
```

**Prototype:**

```
IOResult Save(ISave* isave);
```

**Remarks:**

Saves the BitArray to the 3ds max file.

**Prototype:**

```
IOResult Load(ILoad* iload);
```

**Remarks:**

Loads the BitArray from the 3ds max file.

**Operators:**

**Prototype:**

**int operator[](int i) const;**

**Remarks:**

Gets the i-th bit.

**Parameters:**

**int i**

The index of the bit.

**Prototype:**

**BOOL operator==(const BitArray& b);**

**Remarks:**

This operator is available in release 3.0 and later only.

Comparison operator.

**Parameters:**

**const BitArray& b**

The BitArray to compare with this one.

**Return Value:**

TRUE if the BitArrays are 'equal' (same size and same bits set); otherwise

FALSE.

**Assignment operators: These require arrays of the same size!**

**Prototype:**

**BitArray& operator=(const BitArray& b)**

**Remarks:**

Assignment operator.

**Prototype:**

**BitArray& operator&=(const BitArray& b)**

**Remarks:**

AND= this BitArray with the specified BitArray.

**Prototype:**

**BitArray& operator|=(const BitArray& b)**

**Remarks:**

OR= this BitArray with the specified BitArray.

**Prototype:**

**BitArray& operator^=(const BitArray& b)**

**Remarks:**

XOR= this BitArray with the specified BitArray.

**Binary operators: These require arrays of the same size!**

**Prototype:**

**BitArray operator&(const BitArray&) const**

**Remarks:**

AND two BitArrays

**Prototype:**

**BitArray operator|(const BitArray&) const**

**Remarks:**

OR two BitArrays

**Prototype:**

**BitArray operator^(const BitArray&) const**

**Remarks:**

XOR two BitArrays

**Unary operators**

**Prototype:**

**BitArray operator~()**

**Remarks:**

Unary NOT function

## Class Class\_ID

See Also: [Dll Functions and Class Descriptors](#), [List of Class\\_IDs](#), [Generate a Class\\_ID](#).

class Class\_ID

### **Description:**

This class represents the unique class ID for a 3ds max plug-in. A plug-ins Class\_ID must be **unique**. A program is provided with the SDK to generate these ClassIDs. It is VERY important you use this program to create the ClassIDs for your plug-ins. To generate a random Class\_ID and optionally copy it to the clipboard, click [Generate a Class\\_ID](#). A Class\_ID consists of two unsigned 32-bit quantities. The constructor assigns a value to each of these, for example **Class\_ID(0xCAD834E2, 0x27E47C5A)**.

All the methods of this class are implemented by the system.

### **Important Notes:**

Make sure you use the program provided to create your ClassIDs. This will greatly reduce the likelihood of conflicts between plug-ins.

If you use one of the 3ds max source code examples to create your plug-in, you **MUST** change the existing Class\_ID. If you don't, you'll get a conflict. If two ClassIDs conflict, the system will only load the first one it finds. The system will post a message when it attempts to load the second one noting that there is a Class\_ID conflict.

The sample code plug-ins used in 3ds max use 0 as the second 32-bit quantity of the Class\_ID. Only the built-in classes (those that ship with 3ds max) should have the second 32 bits equal to 0. All plug-in developers should use both 32 bit quantities.

### **Methods:**

#### **Prototype:**

**Class\_ID(ulong aa, ulong bb)**

#### **Remarks:**

Constructor.

This is the standard constructor to be used by 3ds max plug-ins. Each of the 32-bit quantities may be assigned separately.

#### **Parameters:**

**ulong aa**

Assigned to the first 32-bit quantity.

**ulong bb**

Assigned to the second 32-bit quantity.

#### **Prototype:**

**Class\_ID()**

#### **Remarks:**

Constructor.

Assigns a value of **0xFFFFFFFF** to each 32-bit quantity.

#### **Prototype:**

**Class\_ID(const Class\_ID& cid)**

**Remarks:**

Constructor.

Creates a new class ID with the same values as the argument.

**Parameters:**

**const Class\_ID& cid**

A reference to the Class ID to copy.

**Prototype:**

**ULONG PartA()**

**Remarks:**

Returns the first unsigned 32-bit quantity.

**Prototype:**

**ULONG PartB()**

**Remarks:**

Returns the second unsigned 32-bit quantity.

**Operators:**

**Prototype:**

**int operator==(const Class\_ID& cid) const**

**Remarks:**

Checks for equality between two Class IDs.

**Prototype:**

**int operator!=(const Class\_ID& cid) const**

**Remarks:**

Check for Inequality between two Class IDs.

**Prototype:**

**Class\_ID& operator=(const Class\_ID& cid)**

**Remarks:**

Assignment operator. Note: In release 3.0 and later this method checks for self-assignment.

**Prototype:**

**bool operator<(const Class\_ID& rhs) const;**

**Remarks:**

This operator is available in release 4.0 and later only.

Less than operator. This returns true if the specified Class\_ID's two parts are numerically less than this Class\_ID's; false if not.

## Class ClassDesc

See Also: [Class ClassDesc2](#), [Class IParamBlock2](#), [Class ParamBlockDesc2](#), [Class ILoad](#), [Class ISave](#), [Class Interface](#), [Class Class\\_ID](#).

class ClassDesc

### Description:

Class descriptors provide the system with information about the plug-in classes in the DLL. The developer creates a class descriptor by deriving a class from **ClassDesc** and implementing several of its methods.

In release 3.0 and later there are new methods which are supplied and implemented by ClassDesc2. These methods relate to the parameter block2 system.

In release 4.0 plug-ins wishing to use the new Function Publishing system must use **ClassDesc2** rather than this class for their class descriptors. See [Function Publishing System](#).

### Methods Groups:

The hyperlinks below take you to the start of groups of related methods within the class:

[Creation Related Methods](#)

[ClassID / SuperClassID / ClassName, Category Methods](#)

[Class Parameter Related Methods](#)

[Action Table Related Methods](#)

[Manipulator Related Methods](#)

[ParamBlock2 Related Methods](#)

[Function Publishing Related Methods](#)

[Schematic View Related Methods](#)

[Generic Expansion Function](#)

### Methods:

#### Prototype:

```
virtual int IsPublic()=0;
```

#### Remarks:

Implemented by the Plug-In.

Controls if the plug-in shows up in lists from the user to choose from.

### **Return Value:**

If the plug-in can be picked and assigned by the user, as is usually the case, return TRUE. Certain plug-ins may be used privately by other plug-ins implemented in the same DLL and should not appear in lists for user to choose from. These plug-ins would return FALSE.

## **Creation Related Methods**

### **Prototype:**

**virtual void \*Create(BOOL loading=FALSE)=0;**

### **Remarks:**

Implemented by the Plug-In.

3ds max calls this method when it needs a pointer to a new instance of the plug-in class. For example, if 3ds max is loading a file from disk containing a previously used plug-in (procedural object, modifier, controller, etc...), it will call the plug-in's **Create()** method. The plug-in responds by allocating a new instance of its plug-in class. See the Advanced Topic section on [Memory Allocation](#) for more details.

### **Parameters:**

**BOOL loading=FALSE**

This parameter is a flag indicating if the class being created is going to be loaded from a disk file. If the flag is TRUE, the plug-in may not have to perform any initialization of the object because the loading process will take care of it. See the Advanced Topics section on [Loading and Saving](#) for more information.

Note: If this parameter is TRUE, developers must initialize their references to NULL. Otherwise 3ds max may crash.

3ds max provides a default plug-in object creation process. Many plug-ins fit this form. When the system is about to create an instance of the plug-in object it calls a method **BaseObject::GetCreateMouseCallback()**. This method returns a callback object whose **proc()** method handles the mouse input during its creation phase. Most of the work is then handled by the system. The procedural sphere is an example of this type of plug-in. Certain plug-ins may have special creation needs however. The target camera is an example of such a plug-in. Because it needs to create two nodes in the scene (the camera and the

target) it requires a custom creation process. To support these plug-ins the following two methods are provided. They allow the plug-in to manage the creation process themselves. See the Advanced Topics section on [Object Creation Methods](#) for more details.

**Prototype:**

**virtual int BeginCreate(Interface \*i)**

**Remarks:**

Implemented by the Plug-In.

The custom creation process of the plug-in object is handled by this method. For example, a plug-in can create a custom command mode and push it on the command stack to handle the creation process.

Important Note: A plug-in that doesn't want to participate in the standard object creation mechanism using CreateMouseCallBack **must** push a CommandMode on the stack in this method and remove it in **EndCreate()**. This is true even if the plug-in doesn't do anything inside the mode. A mode has to be pushed on the stack and then later popped off otherwise a crash will occur (if the default implementation of this method is not used). For more details on object creation see the Advanced Topics section [Object Creation Methods](#).

**Parameters:**

**Interface \*i**

An interface pointer the plug-in may use to call functions in 3ds max.

**Return Value:**

To use the default creation process (the system implementation for this method) return 0; Return nonzero if the plug-in implements this method.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual int EndCreate(Interface \*i)**

**Remarks:**

Implemented by the Plug-In.

The termination of the custom creation process is managed by the implementation of this method. For example, the plug-in could remove a custom command mode from the command stack. See the Advanced Topics section on [Object Creation Methods](#) for more details.

**Parameters:**

**Interface \*i**

An interface pointer the plug-in may use to call functions in 3ds max.

**Return Value:**

To use the system implementation for this method return 0; Return nonzero if the plug-in implements this method.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual BOOL OkToCreate(Interface *i)
```

**Remarks:**

Implemented by the Plug-In.

This method is used to enable or disable the button that allows the plug-ins class to be created. For example, at certain times it is not appropriate for the Boolean object to be created. When there is not an object of the appropriate type selected the Boolean object cannot be created. At these times the button should be disabled (the button will appear as grayed out in the Create branch of the command panel). The button should be enabled if there is an object of the appropriate type selected. This method allows a plug-in to control the state of the button.

**Parameters:**

**Interface \*i**

An interface pointer the plug-in may use to call functions in 3ds max.

**Return Value:**

TRUE to enable the class creation button; FALSE to disable it.

**Default Implementation:**

```
{ return TRUE; }
```

**Sample Code:**

The following code from `\MAXSDK\SAMPLES\OBJECTS\BOOLOBJ.CPP` demonstrates an implementation of this method. If there is not a node selected, it is not OK to use the command so the button should appear disabled. To disable the button **OkToCreate()** returns FALSE. If the object that is selected is not of the appropriate type it the button is disabled as well.

```
BOOL BoolObjClassDesc::OkToCreate(Interface *i)  
{  
  if (i->GetSelNodeCount()!=1) return FALSE;  
  ObjectState os = i->GetSelNode(0)->GetObjectRef()->Eval(i-  
>GetTime());  
  if (os.obj->SuperClassID()!=GEOMOBJECT_CLASS_ID) {  
    return FALSE;  
  }  
  return TRUE;  
}
```

## **ClassName, ClassID, SuperClass ID, Category Methods**

### **Prototype:**

```
virtual const TCHAR* ClassName()=0;
```

### **Remarks:**

Implemented by the Plug-In.

This method returns the name of the class. This name appears in the button for the plug-in in the 3ds max user interface.

### **Return Value:**

The name of the class.

### **Prototype:**

```
virtual SClass_ID SuperClassID()=0;
```

### **Remarks:**

Implemented by the Plug-In.

This method returns a system defined constant describing the class this plug-in class was derived from. For example, the Bend modifier returns **OSM\_CLASS\_ID**. This super class ID is used by all object space modifiers.

See [List of SuperClassIDs](#).

**Return Value:**

The SuperClassID of the plug-in.

**Prototype:**

**virtual Class\_ID ClassID()=0;**

**Remarks:**

Implemented by the Plug-In.

This method must return the **unique** ID for the object. If two ClassIDs conflict, the system will only load the first one it finds. The ClassID consists of two unsigned 32-bit quantities. The constructor assigns a value to each of these, for example **Class\_ID(0xA1C8E1D1, 0xE7AA2BE5)**. A developer should use the random Class\_ID generator to avoid conflicts ([Generate a random Class\\_ID](#)). See [Class Class\\_ID](#) for more information.

**Return Value:**

The unique ClassID of the plug-in.

**Prototype:**

**virtual Class\_ID SubClassID();**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

This method can be used for further categorizing plugin's. If a plugin has sub-plugins (like light > shadows, particles > operators), this method can be used to differentiate them. sub-plugins can be derived off reference target but return a particular class ID published by the parent plugins SDK headers. Then parent plugin can get a list of all reference targets whose SubClassID matches the published SubClassID

**Default Implementation:**

**{ return Class\_ID(); }**

**Prototype:**

**virtual const TCHAR\* Category()=0;**

## Remarks:

Implemented by the Plug-In.

This methods returns a string describing the category a plug-in fits into. The category is usually selected in the drop down list in the create, or utility branch of the command panel. In the create branch, if this is set to be an existing category (i.e. "Standard Primitives", "Splines", ...) then the plug-in will appear in that category. If the category doesn't yet exists then it is created. If the plug-in does not need to appear in the list, it may simply return a null string as in `_T("")`.

In the modify branch, the category determines which group it appears in the Configure Button Sets / Modifiers list. These are the categories such as "MAX STANDARD", "MAX EDIT", and "MAX SURFACE".

This method is also used to distinguish between the various types of texture maps so they can be separated in the Material/Map Browser. The appropriate string should be returned by this method of the Texmap. For example:

```
const TCHAR* Category() { return TEXMAP_CAT_3D; }
```

The options for texture maps are:

```
TCHAR TEXMAP_CAT_2D[]; - 2D maps.
```

```
TCHAR TEXMAP_CAT_3D[]; - 3D maps.
```

```
TCHAR TEXMAP_CAT_COMP[]; - Composite.
```

```
TCHAR TEXMAP_CAT_COLMOD[]; - Color modifier.
```

```
TCHAR TEXMAP_CAT_ENV[]; - Environment.
```

## Class Parameter Related Methods

The following three methods deal with default settings for plug-in classes. Most plug-in do not need to be concerned with these methods.

In the 3ds max user interface, from the Files / Preferences... menu on the Animation page there is an option for Controller Defaults. There are buttons for 'Set Defaults...' and 'Restore to Factory Settings...'. When the user presses the 'Set Defaults...' button the user is presented with a list of plug-ins that have responded TRUE to the **HasClassParams()** method. These plug-ins have default parameters that the user can edit. These are the defaults used when a new instance of the plug-in class is created. When the user picks an item from the list, its **EditClassParams()** method is called to allow the plug-in to put up a modal dialog to let the user edit the default parameters. If the user presses the 'Reset to

Factory Defaults...' button, the **ResetClassParams()** method is called. The plug-in can then be reset to use any default settings that it has.

**Prototype:**

**virtual BOOL HasClassParams()**

**Remarks:**

Implemented by the Plug-In.

If a plug-in class has default parameters that it needs to allow the user to edit, TRUE should be returned and **EditClassParams()** and **ResetClassParams()** should be implemented. Otherwise return FALSE (the default). See the description above.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

**virtual void EditClassParams(HWND hParent);**

**Remarks:**

Implemented by the Plug-In.

If the user picks the class from the list this method is called. The plug-in should put up a modal dialog that allows the user to edit the plug-ins default parameters. The plug-in should not return until the user has finished editing the parameters. See the description above.

**Parameters:**

**HWND hParent**

The parent window handle.

**Prototype:**

**virtual void ResetClassParams(BOOL fileReset=FALSE);**

**Remarks:**

Implemented by the Plug-In.

When the user executes File / Reset or presses the 'Reset to Factory Settings...' button in the File / Preferences... / Animation tab / Controller Defaults section

this method is called. The plug-in can respond by resetting itself to use its default values. See the description above.

**Parameters:**

**BOOL fileReset=FALSE**

When TRUE, the user has performed a File / Reset operation. When FALSE, the user is in the Preferences... dialog doing a reset controller defaults operation.

## Action Table Related Methods

These two functions return keyboard action tables that plug-ins can use

**Prototype:**

**virtual int NumActionTables();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called at Dll-load time to get the number of action tables from a plug-in. Note: If more than one class uses the table only one of the classes should export the table, but they can all use them. See [Class ActionTable](#).

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual ActionTable\* GetActionTable(int i);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the 'i-th' action table. See [Class ActionTable](#).

**Parameters:**

**int i**

The zero based index of the table to return.

**Default Implementation:**

**{ return NULL; }**

## Manipulator Related Methods

The following methods support manipulators. These methods are called on the class descriptors of manipulators when manipulate mode is entered, or when selection changes while in manipulate mode.

### Prototype:

**virtual BOOL UseSelectionBrackets();**

### Remarks:

This method is available in release 4.0 and later only.

This method allows an object to choose whether or not it will display selection brackets in shaded viewports. The method will return FALSE if no selection brackets are displayed or TRUE if it does display selection brackets.

### Default Implementation:

**{ return TRUE; }**

### Prototype:

**virtual BOOL IsManipulator();**

### Remarks:

This method is available in release 4.0 and later only.

This method is what is used by the system to determine whether the ClassDesc describes a manipulator. Returns TRUE if the class implements a manipulator object; otherwise FALSE.

### Default Implementation:

**{ return FALSE; }**

### Prototype:

**virtual BOOL CanManipulate(ReferenceTarget\* hTarget);**

### Remarks:

This method is available in release 4.0 and later only.

The method returns true if the class is a manipulator and it manipulates the given base object, modifier or controller. When starting "Manipulate" mode, this is called on selected nodes for the base object, all modifiers, the TM controller and the position, rotation and scale controllers, if the TM controller

is a PRSController.

**Parameters:**

**ReferenceTarget\* hTarget**

A pointer to a reference target.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual BOOL CanManipulateNode(INode* pNode);
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns TRUE if the manipulator applies to the given node; otherwise FALSE.

This is a general case if **CanManipulateClassID()** isn't sufficient.

**Parameters:**

**INode\* pNode**

The node to check.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void* CreateObjectManipulator(Object* pObject);
```

**Remarks:**

This method is available in release 4.0 and later only.

When a manipulator returns TRUE to **CanManipulateClassID()**, the system calls this method to create an instance and return a pointer to it.

**Parameters:**

**Object\* pObject**

Points to the Object that the manipulator said it could manipulate.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void* CreateTMControlManipulator(Control* pControl);
```

**Remarks:**

This method is available in release 4.0 and later only.

When a manipulator returns TRUE to **CanManipulateClassID()**, the system calls this method to create an instance and return a pointer to it.

**Parameters:**

**Control\* pControl**

Points to the Controller that the manipulator said it could manipulate.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void* CreateModifierManipulator(Modifier* pModifier);
```

**Remarks:**

This method is available in release 4.0 and later only.

When a manipulator returns TRUE to **CanManipulateClassID()**, the system calls this method to create an instance and return a pointer to it.

**Parameters:**

**Modifier\* pModifier**

Points to the Modifier that the manipulator said it could manipulate.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void* CreateManipulator(ReferenceTarget* hTarget,  
INode* pNode);
```

**Remarks:**

This method is available in release 4.0 and later only.

When a manipulator returns TRUE to **CanManipulateNode(INode\*)**, the system calls this version of **CreateManipulator()** to create an instance.

**Parameters:**

**ReferenceTarget\* hTarget**

Points to the reference target.

**INode\* pNode**

Points to the node that the manipulator said it could manipulate.

**Return Value:**

```
{ return NULL; }
```

## **Load / Save Related Methods**

The following three methods may be used to save data associated with a class in a 3ds max file. If you want to save data associated with the class have **NeedsToSave()** return TRUE and implement the **Save()** and **Load()** methods.

**Prototype:**

```
virtual BOOL NeedsToSave();
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if there is data associated with the class that needs to be saved in the 3ds max file. If this is so, implement the **Save()** and **Load()** methods below. If there is no class data to save return FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual IOResult Save(ISave *is);
```

**Remarks:**

Implemented by the Plug-In.

If **NeedsToSave()** returns TRUE then this method should be implemented to save the data associated with the class.

**Parameters:**

**ISave \*is**

A pointer that may be used to call methods to save data to disk.

**Return Value:**

**IO\_OK** if the save was successful; otherwise **IO\_ERROR**.

**Prototype:**

**virtual IOResult Load(ILoad \*il);**

**Remarks:**

Implemented by the Plug-In.

If **NeedsToSave()** returns TRUE then this method should be implemented to load the data associated with the class.

**Parameters:**

**ILoad \*il**

A pointer that may be used to load data from a file.

**Return Value:**

**IO\_OK** if the load was successful; otherwise **IO\_ERROR**.

## **Parameter Map 2 Related Methods**

**Prototype:**

**virtual DWORD InitialRollupPageState();**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns a DWORD which is used to initialize the rollup state in both the create branch and the modify branch. The semantics are different, however for these two cases. Whenever the rollups are created in the create branch, their state will be that specified by this method. In the modify branch, the first time an object of this type is modified the state will be that of this method, but after that it will remain what it was last set to.

**Return Value:**

The bits of this DWORD set indicate the corresponding rollup page is closed. The zero bit corresponds to the plug-ins first rollup, the first bit is the second rollup, etc. The value **0x7fffffff** is returned by the default implementation so the command panel can detect this method is not being overridden, and just

leave the rollups as is.

**Default Implementation:**

```
{ return 0x7fffffff; }
```

**Prototype:**

```
virtual const TCHAR* InternalName();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

Returns a string which provides a fixed, machine parsable internal name for the plug-in. This name is used by MAXScript.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual HINSTANCE HInstance();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

Returns the DLL instance handle of the plug-in. This is used so that string resources can be loaded by the ParamBlock2 system.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual int NumParamBlockDescs();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns the number of ParamBlockDesc2s used by the plug-in.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual ParamBlockDesc2* GetParamBlockDesc(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns a pointer to the 'i-th' parameter block 2 descriptor.

**Parameters:**

**int i**

The zero based index of the descriptor to return.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual ParamBlockDesc2* GetParamBlockDescByID(BlockID id);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns a pointer to the specified parameter block 2 descriptor.

**Parameters:**

**BlockID id**

The ID of the parameter block.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void AddParamBlockDesc(ParamBlockDesc2* pbd);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Adds the specified parameter block 2 descriptor to the list of those maintained by the class.

**Parameters:**

**ParamBlockDesc2\* pbd**

Points to the parameter block 2 descriptor to add.

**Default Implementation:**

{ }

**Prototype:**

**virtual void BeginEditParams(IObjParam \*ip, ReferenceMaker\* obj, ULONG flags, Animatable \*prev);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This method is called to handle the beginning of the automatic command panel user interface management provided by the param map 2 system. This method is called by the plug-in from its **Animatable::BeginEditParams()** method. The parameters passed to that method are simply passed along to this method.

**Parameters:**

**IObjParam \*ip**

The interface pointer passed to the plug-in.

**ReferenceMaker\* obj**

Points to the plug-in class calling this method.

**ULONG flags**

The flags passed along to the plug-in in **Animatable::BeginEditParams()**.

**Animatable \*prev**

The pointer passed to the plug-in in **Animatable::BeginEditParams()**.

**Default Implementation:**

{ }

**Prototype:**

**virtual void EndEditParams(IObjParam \*ip, ReferenceMaker\* obj, ULONG flags, Animatable \*prev);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This method is called to handle the ending of the automatic command panel user interface management provided by the param map 2 system. This method is called by the plug-in from its **Animatable::EndEditParams()** method. The parameters passed to that method are simply passed along to this method.

**Parameters:**

**IObjParam \*ip**

The interface pointer passed to the plug-in.

**ReferenceMaker\* obj**

Points to the plug-in class calling this method.

**ULONG flags**

The flags passed along to the plug-in in **Animatable::EndEditParams()**.

**Animatable \*prev**

The pointer passed to the plug-in in **Animatable::EndEditParams()**.

**Default Implementation:**

{ }

**Prototype:**

**virtual void InvalidateUI(ParamBlockDesc2\* pbd);**

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Invalidates the user interface for the rollup or dialog managed by the specified descriptor. This will cause the controls in that rollup to be redrawn.

**Parameters:**

**ParamBlockDesc2\* pbd**

Points to the parameter block 2 descriptor whose corresponding UI is

invalidated.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void MakeAutoParamBlocks(ReferenceMaker* owner);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

This method creates the automatic parameter blocks for the specified plug-in.

These are the ones with the **ParamBlockDesc2.flags**

**P\_AUTO\_CONSTRUCT** bit set.

**Parameters:**

**ReferenceMaker\* owner**

Points to the owner of the parameter block.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual int NumParamMaps();
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns the number of parameter map2s used by the plug-in.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual IParamMap2* GetParamMap(int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns a pointer to the 'i-th' parameter map2.

**Parameters:**

**int i**

The zero based index of the parameter map2 to return.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual IParamMap2* GetParamMap(ParamBlockDesc2* pbd);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns a pointer to the parameter map2 whose descriptor is passed.

**Parameters:**

**ParamBlockDesc2\* pbd**

Points to the parameter block2 descriptor.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetUserDlgProc(ParamBlockDesc2* pbd,  
ParamMap2UserDlgProc* proc=NULL);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Sets the parameter map 2 user dialog proc for the specified descriptor.

**Parameters:**

**ParamBlockDesc2\* pbd**

Points to the parameter block 2 descriptor.

**ParamMap2UserDlgProc\* proc=NULL**

This object manages user interface control that require special processing. See [Class ParamMap2UserDlgProc](#).

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual ParamMap2UserDlgProc*  
GetUserDlgProc(ParamBlockDesc2* pbd);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the System.

Returns a pointer to the parameter map 2 user dialog proc (if any) for the specified descriptor.

**Parameters:**

**ParamBlockDesc2\* pbd**

Points to the parameter block 2 descriptor.

**Return Value:**

See [Class ParamMap2UserDlgProc](#).

**Default Implementation:**

```
{ return NULL; }
```

## Function Publishing Related Methods

**Prototype:**

```
virtual int NumInterfaces();
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Returns the number of function publishing interfaces maintained by the class descriptor.

**Prototype:**

**virtual FPInterface\* GetInterface(int i);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Returns a pointer to the 'i-th' function publishing interface.

**Parameters:**

**int i**

The zero based index of the interface to return.

**Prototype:**

**virtual FPInterface\* GetInterface(Interface\_ID id);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the function publishing interface whose ID is specified.

**Parameters:**

**Interface\_ID id**

The interface ID.

**Prototype:**

**virtual FPInterface\* GetInterface(TCHAR\* name);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the function publishing interface whose name is specified.

**Parameters:**

**TCHAR\* name**

The name of the interface.

**Prototype:**

**virtual void AddInterface(FPInterface\* fpi);**

**Remarks:**

This method is available in release 4.0 and later only.

Adds the specified interface to the list maintained by this class descriptor.

**Parameters:**

**FPInterface\* fpi**

Points to the interface to add.

**Prototype:**

**virtual void ClearInterfaces();**

**Remarks:**

This method is available in release 4.0 and later only.

Deletes all the interfaces maintained by the class descriptor.

## **Schematic View Related Methods**

**Prototype:**

**virtual bool DrawRepresentation(COLORREF bkColor, HDC  
hDC, Rect &rect);**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows this plug-in class to provide a custom image for display in Schematic View.

**Parameters:**

**COLORREF bkColor**

The background color. See [COLORREF-DWORD format](#).

**HDC hDC**

The handle for the device context.

**Rect &rect**

The rectangle to draw in.

**Return Value:**

TRUE if this class can draw an image to represent itself graphically; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

## Generic Expansion Function

### Prototype:

```
virtual INT_PTR Execute(int cmd, ULONG arg1=0, ULONG  
arg2=0, ULONG arg3=0);
```

### Remarks:

This method is available in release 3.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

This is reserved for future use.

### Parameters:

**int cmd**

The command to execute.

**ULONG arg1=0**

Optional argument 1 (defined uniquely for each **cmd**).

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

### Return Value:

An integer return value (defined uniquely for each **cmd**).

### Default Implementation:

```
{ return 0; }
```

## Class GammaMgr

See Also: [Class Color](#), [COLORREF](#).

class GammaMgr

### Description:

The gamma manager class. Methods of this class are used to gamma correct and de-gamma colors in various formats. Various settings from the 3ds max user interface are also accessible via data members of this class (for example the display, and file gamma settings). These settings may be read but should not be set by a plug-in developer. All methods of this class are implemented by the system.

There is a global instance of this class (defined in `\MAXSDK\INCLUDE\GAMMA.H`):

**GammaMgr gammaMgr;**

Note the following #defines. These are used to reduce the size of the gamma tables for correcting 16 bit values.

**#define RCBITS 13**

**#define RCOLN (1<<RCBITS)**

This class provides a set of commonly used gamma tables. This class does not provide tables for all types of conversion however. For example if you have a different gamma setting that you are using, or if you are going in a different conversion direction than the tables provided here you may use the classes [GamConvert16](#) and [GamConvert8](#) to build gamma tables.

### Data Members:

public:

**BOOL enable;**

Indicates if gamma correction is enabled or disabled.

**BOOL dithTrue;**

Indicates if output dithering is to be used for true color images.

**BOOL dithPaletted;**

Indicates if output dithering is to be used for paletted images.

**float dispGamma;**

The display gamma setting.

**float fileInGamma;**

The file input gamma setting.

**float fileOutGamma;**

The file output gamma setting.

**UBYTE disp\_gamtab[256];**

Display gamma table for drawing color swatches (8->8)

**UBYTE disp\_gamtabw[RCOLN];**

Display gamma table (RCBITS->8).

**UBYTE file\_in\_gamtab[256];**

File input gamma table (8->8).

**UWORD file\_in\_degamtab[256];**

For de-gamifying bitmaps on input. (8->16)

**UWORD file\_out\_gamtab[RCOLN];**

Gamma correct for file output, before dither (RCBITS->16).

**Methods:**

**Prototype:**

**GammaMgr();**

**Remarks:**

Constructor.

**Prototype:**

**inline COLORREF DisplayGammaCorrect(COLORREF col);**

**Remarks:**

Gamma corrects the specified color using the display gamma setting.

**Parameters:**

**COLORREF col**

The color to gamma correct.

**Return Value:**

The gamma corrected color.

**Prototype:**

## **Color DisplayGammaCorrect(Color c);**

### **Remarks:**

Gamma corrects the specified color using the display gamma setting.

### **Parameters:**

#### **Color c**

The color to gamma correct.

### **Return Value:**

The gamma corrected color.

### **Prototype:**

**void Enable(BOOL onOff);**

### **Remarks:**

Sets the gamma correction enabled setting.

### **Parameters:**

#### **BOOL onOff**

TRUE to enable; FALSE to disable.

### **Prototype:**

**BOOL IsEnabled();**

### **Remarks:**

Returns the gamma correction enabled setting; TRUE if enabled; FALSE if disabled.

### **Prototype:**

**void SetDisplayGamma(float gam);**

### **Remarks:**

Sets the display gamma setting.

### **Parameters:**

#### **float gam**

The value to set.

**Prototype:**

**float GetDisplayGamma();**

**Remarks:**

Returns the display gamma setting.

**Prototype:**

**void SetFileInGamma(float gam);**

**Remarks:**

Sets the file input gamma setting.

**Parameters:**

**float gam**

The value to set.

**Prototype:**

**float GetFileInGamma();**

**Remarks:**

Returns the file input gamma setting.

**Prototype:**

**void SetFileOutGamma(float gam);**

**Remarks:**

Sets the file output gamma setting.

**Parameters:**

**float gam**

The value to set.

**Prototype:**

**float GetFileOutGamma();**

**Remarks:**

Returns the file output gamma setting.

**The following functions are not part of class GammaMgr but are available for use.**

**Prototype:**

**inline COLORREF gammaCorrect(DWORD c);**

**Remarks:**

Returns a gamma corrected version of the specified color using the display gamma setting.

**Parameters:**

**DWORD c**

The color to gamma correct.

**Prototype:**

**inline UBYTE gammaCorrect(UBYTE b);**

**Remarks:**

Returns a gamma corrected version of the specified color using the display gamma setting.

**Parameters:**

**UBYTE b**

The color to gamma correct.

**Prototype:**

**void BuildGammaTab8(UBYTE gamtab[256], float gamma, int onoff=TRUE);**

**Remarks:**

Builds the gamma table that maps 8->8.

**Parameters:**

**UBYTE gamtab[256]**

The table to build.

**float gamma**

The gamma setting.

**int onoff=TRUE**

TRUE to enable; FALSE to disable.

**Prototype:**

**void BuildGammaTab8(UWORD gamtab[256], float gamma, int onoff=TRUE);**

**Remarks:**

Builds a gamma table that maps 8->16.

**Parameters:**

**UBYTE gamtab[256]**

The table to build.

**float gamma**

The gamma setting.

**int onoff=TRUE**

TRUE to enable; FALSE to disable.

**Prototype:**

**void BuildGammaTab(UBYTE gamtab[RCOLN], float gamma, int onoff=TRUE);**

**Remarks:**

Build a gamma table that maps RCBITS->8.

**Parameters:**

**UBYTE gamtab[RCOLN]**

The table to build.

**float gamma**

The gamma setting.

**int onoff=TRUE**

TRUE to enable; FALSE to disable.

**Prototype:**

**void BuildGammaTab(UWORD gamtab[RCOLN], float gamma, int onoff=TRUE);**

**Remarks:**

Build a gamma table that maps RCBITS->16.

**Parameters:**

**UWORD gamtab[RCOLN]**

The table to build.

**float gamma**

The gamma setting.

**int onoff=TRUE**

TRUE to enable; FALSE to disable.

**Prototype:**

**float gammaCorrect(float v, float gamma);**

**Remarks:**

Gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**float v**

The value to gamma correct.

**float gamma**

The gamma setting.

**Return Value:**

The gamma corrected value.

**Prototype:**

**float deGammaCorrect(float v, float gamma);**

**Remarks:**

De-gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**float v**

The value to de-gamma correct.

**float gamma**

The gamma setting.

**Prototype:**

**UBYTE gammaCorrect(UBYTE v, float gamma);**

**Remarks:**

Gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**UBYTE v**

The value to gamma correct.

**float gamma**

The gamma setting.

**Return Value:**

The gamma corrected value.

**Prototype:**

**UBYTE deGammaCorrect(UBYTE v, float gamma);**

**Remarks:**

De-gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**UBYTE v**

The value to de-gamma correct.

**float gamma**

The gamma setting.

**Prototype:**

**UWORD gammaCorrect(UWORD c, float gamma);**

**Remarks:**

Gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**UWORD c**

The value to gamma correct.

**float gamma**

The gamma setting.

**Return Value:**

The gamma corrected value.

**Prototype:**

**UWORD deGammaCorrect(UWORD c, float gamma);**

**Remarks:**

De-gamma corrects the value passed using the specified gamma setting.

**Parameters:**

**UWORD c**

The value to de-gamma correct.

**float gamma**

The gamma setting.

## Class Quantizer

See Also: [BMM\\_Color\\_64](#), [BMM\\_Color\\_48](#), [BMM\\_Color\\_24](#).

class Quantizer

### Description:

Color quantizer, for doing true-color to paletted conversion. All methods of this class are implemented by the system. Create a Quantizer object by calling:

```
Quantizer *BMMNewQuantizer();
```

Be sure to call **Quantizer::DeleteThis()** when done.

### Methods:

#### Prototype:

```
virtual int Partition(BMM_Color_48 *pal, int palsize,  
BMM_Color_64 *forceCol)=0;
```

#### Remarks:

This method uses the histogram and computes the palette.

#### Parameters:

**BMM\_Color\_48 \*pal**

Storage for the palette to compute.

**int palsize**

The size of the palette.

**BMM\_Color\_64 \*forceCol**

If there is a color that you want to make sure is available in the palette, you may pass it here. This is used for the background color of an image for example. If this is not NULL the quantizer will make up a palette and make sure that this color is in it. For backgrounds, this looks much nicer because the background won't be dithered when shown using the palette.

#### Return Value:

Nonzero if the palette was computed; otherwise zero.

#### Prototype:

```
virtual void DeleteThis()=0;
```

**Remarks:**

This method is called to delete the Quantizer when you are done with it.

**Prototype:**

```
virtual int AllocHistogram(void)=0;
```

**Remarks:**

This method allocates the histogram used in doing the conversion.

**Return Value:**

Nonzero if the histogram was allocated; otherwise zero.

**Prototype:**

```
virtual void AddToHistogram(BMM_Color_64 *image, int  
npix)=0;
```

**Remarks:**

Adds the specified colors to the histogram so they are taken into account in the palette computations.

**Parameters:**

```
BMM_Color_64 *image
```

The pixels to include.

```
int npix
```

The number of pixels above.

**Prototype:**

```
virtual void AddToHistogram(BMM_Color_48 *image, int  
npix)=0;
```

**Remarks:**

Adds the specified colors to the histogram so they are taken into account in the palette computations.

**Parameters:**

```
BMM_Color_48 *image
```

The pixels to include.

```
int npix
```

The number of pixels above.

**Prototype:**

```
virtual void AddToHistogram(BMM_Color_24 *image, int  
npix)=0;
```

**Remarks:**

Adds the specified colors to the histogram so they are taken into account in the palette computations.

**Parameters:**

**BMM\_Color\_24 \*image**

The pixels to include.

**int npix**

The number of pixels above.

# Class ColorPacker

See Also: [Palettes](#), [Class Quantizer](#).

class ColorPacker

## Description:

Methods of this class are used for packing colors into a 256 color paletted representation. Create an instance of this class using

**BMMNewColorPacker()** described below. All methods of this class are implemented by the system.

## Prototype:

```
ColorPacker *BMMNewColorPacker(int w, BMM_Color_48 *pal,  
int npal, BYTE* remap=NULL);
```

## Remarks:

This is called to create an instance of a ColorPacker. When done, be sure to call **ColorPacker::DeleteThis()**.

## Parameters:

**int w**

The width of bitmap to be packed.

**BMM\_Color\_48 \*pal**

The palette to use.

**int npal**

The number of entries in the palette.

**BYTE\* remap=NULL**

This is a 256 byte table that maps the numbers into another number. This is used so the palette may be rearranged in Windows order. To make palettes for Windows, the best thing to do is to put the colors in so that colors that Windows uses are either left alone, or they are occupied by the colors that are least important in the image. This is because Windows will come along and alter these colors. This is the first 10 colors and the last 10 colors.

The quantizer creates a palette from 0-239, where 0 is the most used color and 239 is the least used. The color packer uses 0-239 as well, and it operates most efficiently when the colors are sorted as the quantizer orders them.

What can be done is to use **FixPaletteForWindows()** to rearrange the colors for the Windows palette. This creates the **remap** table passed to this method. Then as a last step the remap table is used to reorganize the palette. Below is the documentation for the global function **FixPaletteForWindows()**. Sample code that uses these APIs is in **\MAXSDK\SAMPLES\IO\FLIC\FLIC.CPP**.

**Prototype:**

```
void FixPaletteForWindows(BMM_Color_48 *pal,  
BMM_Color_48 *newpal,int ncols, BYTE *remap=NULL);
```

**Remarks:**

Rearranges the palette **pal** (which has colors 0..**ncols**-1 occupied, in descending order of frequency), into **newpal** so that the colors 10-245 are populated first, then 0-9, then 246-255. Sets the optional array **remap** to map the old palette index values to the new ones.

**Parameters:**

**BMM\_Color\_48 \*pal**

The palette to rearrange.

**BMM\_Color\_48 \*newpal**

The rearranged palette.

**int ncols**

The number of colors in the palette.

**BYTE \*remap=NULL**

An array that maps the old palette index values to the new ones.

**Methods:**

**Prototype:**

```
virtual void DeleteThis()=0;
```

**Remarks:**

This method is called to delete the ColorPacker when you are done with it.

**Prototype:**

```
virtual void EnableDither(BOOL onoff)=0;
```

**Remarks:**

This method is used to enable dithering of the packed pixels. It defaults to the 3ds max default.

**Parameters:****BOOL onoff**

TRUE to enable dithering; FALSE to disable.

**Prototype:**

**virtual void PropagateErrorBetweenLines(BOOL onoff)=0;**

**Remarks:**

This method controls the propagation of error between lines. For static images this is best left to default to on. For animated images, it is better to set this to off and not propagate the error between lines. This defaults to ON.

**Parameters:****BOOL onoff**

TRUE to enable error propagation between lines; FALSE to disable.

**Prototype:**

**virtual void PackLine(BMM\_Color\_64\* in, BYTE \*out, int w)=0;**

**Remarks:**

Packs the specified line of pixels into the 256 color representation.

**Parameters:****BMM\_Color\_64\* in**

The line of pixels to pack.

**BYTE \*out**

The result, the output pixels.

**int w**

The number of pixels in the line.

**Prototype:**

**virtual void PackLine(BMM\_Color\_48\* in, BYTE \*out, int w)=0;**

**Remarks:**

Packs the specified line of pixels into the 256 color representation.

**Parameters:**

**BMM\_Color\_48\* in**

The line of pixels to pack.

**BYTE \*out**

The result, the output pixels.

**int w**

The number of pixels in the line.

## Class CStr

See Also: [Class WStr](#), [Character Strings](#).

class CStr

### Description:

A simple character string class. This is the standard character string class used in MAX. Methods and operators are provided for calculating lengths, concatenation, substring operations, character searching, case conversion, comparison, and formatted writing.

This class automatically allocates the proper amount of space for the string. This is very handy in the case of internationalization / localization. For example, if you code something like:

```
TSTR myString = GetString(IDS_STRING_ID);
```

then **myString**'s constructor will allocate enough space to store the resource string no matter how long it is. This is much better than doing the following:

```
TCHAR myString[64];  
_tcscpy(myString, GetString(IDS_STRING_ID));
```

because the resource string may turn out to be much longer than 64 bytes once it's translated to German or French (or whatever).

As another example, if you have the following code:

```
TSTR str1 = _T("This is string1.");  
TSTR str2 = _T("This is string2.");
```

Then

```
TSTR concatStr = str1 + str2;
```

will again yield a (concatenated) string will enough space to hold the concatenated contents of **str1** and **str2**, automatically.

All methods are implemented by the system.

### Methods:

### Prototype:

```
CStr();
```

### Remarks:

Constructor. The string is set to NULL.

**Prototype:**

**CStr(const char \*cs);**

**Remarks:**

Constructor. The string is initialized to the string passed.

**Prototype:**

**CStr(const wchar\_t \*wcstring);**

**Remarks:**

Constructor. The string is initialized to the string passed.

**Prototype:**

**CStr(const CStr& ws);**

**Remarks:**

Constructor. The string is initialized to the string passed.

**Prototype:**

**~CStr()**

**Remarks:**

Destructor. The string is deleted.

**Prototype:**

**char \*data();**

**Remarks:**

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

**const char \*data() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

**operator char \*();**

**Remarks:**

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

**void Resize(int nchars);**

**Remarks:**

Reallocates the string to contain **nchars** characters. If the string is enlarged it is padded with blanks.

**Parameters:**

**int nchars**

Specifies the new number of characters for the string.

**Prototype:**

**int Length() const;**

**Remarks:**

Returns the number of characters in the string.

**Prototype:**

**int length() const;**

**Remarks:**

Returns the number of characters in the string.

**Prototype:**

**BOOL isNull();**

**Remarks:**

Returns TRUE if the string length is 0; otherwise FALSE.

**Prototype:**

**CStr & operator=(const CStr& cs);**

**Remarks:**

Assignment operator.

**Prototype:**

**CStr & operator=(const wchar\_t \*wcstring);**

**Remarks:**

Assignment operator.

**Prototype:**

**CStr & operator=(const char \*cs);**

**Remarks:**

Assignment operator. In release 3.0 and later this method check for self-assignment.

**Prototype:**

**CStr operator+(const CStr& cs) const;**

**Remarks:**

Concatenation operator. Returns a new string that is this string with string **cs** appended.

**Prototype:**

**CStr& operator+=(const CStr& cs);**

**Remarks:**

Concatenation. Returns this string with **cs** appended.

**Prototype:**

**CStr& Append(const CStr& cs);**

**Remarks:**

Concatenation. Returns this string with **cs** appended.

**Prototype:**

**CStr& append(const CStr& cs);**

**Remarks:**

Concatenation. Returns this string with **cs** appended to the end.

**Prototype:**

**CStr& remove(int pos);**

**Remarks:**

Returns this string with all characters from **pos** to the end removed.

**Parameters:**

**int pos**

Specifies the last position in the string.

**Prototype:**

**CStr& remove(int pos, int N);**

**Remarks:**

Returns this string with N characters removed from **pos** to the end.

**Parameters:**

**int pos**

Specifies the position to begin removing characters.

**int N**

Specifies the number of characters to remove.

**Prototype:**

**CStr Substr(int start, int nchars) const;**

**Remarks:**

Returns a substring of this string, beginning at position **start**, of length **nchars**.

**Prototype:**

**char& operator[(int i)]**

**Remarks:**

Returns a substring of this string beginning at position **i**.

**Prototype:**

**const char& operator[](int i) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a substring of this string beginning at position **i**.

**Prototype:**

**int first(char c) const;**

**Remarks:**

Returns the index of the first occurrence of character **c** in this string. Returns -1 if not found.

**Prototype:**

**int last(char c) const;**

**Remarks:**

Returns the index of the last occurrence of character **c** in this string. Returns -1 if not found.

**Prototype:**

**int operator==(const CStr &cs) const;**

**Remarks:**

Equality operator.

**Return Value:**

Nonzero if the strings are equal; otherwise 0.

**Prototype:**

**int operator<(const CStr &cs) const;**

**Remarks:**

Returns nonzero if this string is less than **cs**; otherwise 0.

**Prototype:**

**int operator<=(const CStr &ws) const;**

**Remarks:**

Returns nonzero if this string is less than or equal to **ws**; otherwise 0.

**Prototype:**

**int operator>(const CStr &ws) const;**

**Remarks:**

Returns nonzero if this string is greater than **ws**; otherwise 0.

**Prototype:**

**int operator>=(const CStr &ws) const;**

**Remarks:**

Returns nonzero if this string is greater than or equal to **ws**; otherwise 0.

**Prototype:**

**void toUpper();**

**Remarks:**

Converts all character of this string to uppercase.

**Prototype:**

**void toLower();**

**Remarks:**

Converts all character of this string to lowercase.

**Prototype:**

**int printf(const char \*format, ...);**

**Remarks:**

Formatted output to this string. The internal buffer size for the output string is 512 bytes.

**Return Value:**

The number of character output or EOF on error.

**Sample Code:**

**TSTR buf;**

**buf.printf(\_T("Rendering In Progress: Frame %d"), curFrame);**

## Class WStr

See Also: [Class CStr](#), [Character Strings](#).

class WStr

### Description:

A wide character string class. This class uses 16 bits to hold each character. Methods and operators are provided for calculating lengths, concatenation, substring operations, character searching, case conversion, comparison, and formatted writing. All methods are implemented by the system.

OLE file IO requires the wide characters of WStr.

### Methods:

#### Prototype:

**WStr();**

#### Remarks:

Constructor. The string is set to NULL.

#### Prototype:

**WStr(const char \*cs);**

#### Remarks:

Constructor. The string is initialized to the string passed.

#### Prototype:

**WStr(const wchar\_t \*wcstring);**

#### Remarks:

Constructor. The string is initialized to the string passed.

#### Prototype:

**WStr(const WStr& ws);**

#### Remarks:

Constructor. The string is initialized to the string passed.

**Prototype:**

`~WStr()`

**Remarks:**

Destructor. The string is deleted.

**Prototype:**

`wchar_t *data();`

**Remarks:**

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

`const wchar_t *data() const;`

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

`const wchar_t *data() const;`

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

`operator wchar_t *();`

**Remarks:**

Returns a pointer to the string. If the string is NULL, 0 is returned.

**Prototype:**

`void Resize(int nchars);`

**Remarks:**

Reallocates the string to contain **nchars** characters. If the string is enlarged it

is padded with blanks.

**Parameters:**

**int nchars**

Specifies the new number of characters for the string.

**Prototype:**

**int Length() const;**

**Remarks:**

Returns the number of characters in the string.

**Prototype:**

**int length() const;**

**Remarks:**

Returns the number of characters in the string.

**Prototype:**

**BOOL isNull();**

**Remarks:**

Returns TRUE if the string length is 0; otherwise FALSE.

**Prototype:**

**WStr & operator=(const WStr& ws);**

**Remarks:**

Assignment operator. In release 3.0 and later this operator checks for self-assignment.

**Prototype:**

**WStr & operator=(const wchar\_t \*wctr);**

**Remarks:**

Assignment operator.

**Prototype:**

**WStr & operator=(const char \*cstr);**

**Remarks:**

Assignment operator.

**Prototype:**

**WStr operator+(const WStr& ws) const;**

**Remarks:**

Concatenation operator. Returns a new string that is this string with string **ws** appended.

**Prototype:**

**WStr & operator+=(const WStr& ws);**

**Remarks:**

Concatenation. Returns this string with **ws** appended.

**Prototype:**

**WStr& Append(const WStr& ws)**

**Remarks:**

Concatenation. Returns this string with **ws** appended.

**Prototype:**

**WStr& append(const WStr& ws);**

**Remarks:**

Concatenation. Returns this string with **ws** appended.

**Prototype:**

**WStr& remove(int pos);**

**Remarks:**

Returns this string with N characters removed from **pos** to the end.

**Parameters:**

**int pos**

Specifies the position to begin removing characters.

**int N**

Specifies the number of characters to remove.

**Prototype:**

**WStr Substr(int start, int nchars) const;**

**Remarks:**

Returns a substring of this string, beginning at position **start**, of length **nchars**.

**Prototype:**

**wchar\_t& operator[](int i)**

**Remarks:**

Returns a substring of this string beginning at position **i**.

**Prototype:**

**int first(wchar\_t c) const;**

**Remarks:**

Returns the index of the first occurrence of character **c** in this string. Returns -1 if not found.

**Prototype:**

**int last(wchar\_t c) const;**

**Remarks:**

Returns the index of the last occurrence of character **c** in this string. Returns -1 if not found.

**Prototype:**

**int operator==(const WStr &ws) const;**

**Remarks:**

Equality operator.

**Return Value:**

Nonzero if the strings are equal; otherwise 0.

**Prototype:**

```
int operator<(const WStr &ws) const;
```

**Remarks:**

Returns nonzero if this string is less than **ws**; otherwise 0.

**Prototype:**

```
int operator<=(const WStr &ws) const;
```

**Remarks:**

Returns nonzero if this string is less than or equal to **ws**; otherwise 0.

**Prototype:**

```
int operator>(const WStr &ws) const;
```

**Remarks:**

Returns nonzero if this string is greater than **ws**; otherwise 0.

**Prototype:**

```
int operator>=(const WStr &ws) const;
```

**Remarks:**

Returns nonzero if this string is greater than or equal to **ws**; otherwise 0.

**Prototype:**

```
void toUpper();
```

**Remarks:**

Converts all character of this string to uppercase.

**Prototype:**

```
void toLower();
```

**Remarks:**

Converts all character of this string to lowercase.

**Prototype:**

```
int printf(const wchar_t *format, ...);
```

**Remarks:**

Formatted output to this string.

**Return Value:**

The number of character output or EOF on error.

**Sample Code:**

```
WStr buf;  
buf.printf(_T("Rendering In Progress: Frame %d"),curFrame);
```

## Class NameTab

See Also: [Class Tab](#).

```
class NameTab : public Tab<TCHAR *>
```

### Description:

This class is used to store a table of names. For example, this class is used by lights for their "Inclusion" and "Exclusion" lists. This class maintains an 'include' flag that specifies whether the list of names is things to be included, or things to be excluded. There is no reason the NameTab class can't be used for other things where inclusion/exclusion is not relevant: in that case one can just ignore the 'include' flag. All methods are implemented by the system.

### Methods:

#### Prototype:

**NameTab()**

#### Remarks:

Constructor. The 'include' flag is set to FALSE.

#### Prototype:

**void SetFlag(ULONG f, BOOL b=1)**

#### Remarks:

Sets the specified flag to the specified value.

#### Parameters:

**ULONG f**

The flag(s) to set. One or more of the following values:

**NT\_INCLUDE**

This bit is used to indicate "Include" mode.

**NT\_AFFECT\_ILLUM**

This bit is used to indicate the "Illumination" check box in the exclusion list dialog.

**NT\_AFFECT\_SHADOWCAST**

This bit is used to indicate the "Shadow Casting" check box in the exclusion list dialog.

**BOOL b=1**

The value to set.

**Prototype:**

**BOOL TestFlag(ULONG f)**

**Remarks:**

Returns TRUE if the specified flag(s) are set; otherwise FALSE.

**Parameters:**

**ULONG f**

The flag(s) to set. One or more of the following values:

**NT\_INCLUDE**

This bit is used to indicate "Include" mode.

**NT\_AFFECT\_ILLUM**

This bit is used to indicate the "Illumination" check box in the exclusion list dialog.

**NT\_AFFECT\_SHADOWCAST**

This bit is used to indicate the "Shadow Casting" check box in the exclusion list dialog.

**Prototype:**

**int AddName(TCHAR \*n);**

**Remarks:**

Appends the specified name to the end of the list.

**Parameters:**

**TCHAR \*n**

The name to add.

**Return Value:**

Returns the number of items in the list prior to appending.

**Prototype:**

**void SetName(int i, TCHAR \*n);**

**Remarks:**

Stores the specified name at the specified position in the list.

**Parameters:**

**int i**

The position in the list for the name.

**TCHAR \*n**

The name to store. If the name is NULL, the 'i-th' entry is set to NULL.

**Prototype:**

**void SetSize(int num);**

**Remarks:**

Sets the size of the list. If the new size is smaller than the current size entries are deleted.

**Parameters:**

**int num**

Specifies the size of the list.

**Prototype:**

**void RemoveName(int i);**

**Remarks:**

Removes the 'i-th' name from the list.

**Parameters:**

**int i**

Specifies the index of the name to remove.

**Prototype:**

**int FindName(TCHAR\* n);**

**Remarks:**

Returns the index of the name passed; otherwise returns -1.

**Parameters:**

**TCHAR\* n**

The name to find.

**Prototype:**

**IOResult Load(ILoad \*iLoad);**

**Remarks:**

Loads this NameTab from disk.

**Parameters:**

**ILoad \*iLoad**

This class provides methods to load data from disk.

**Return Value:**

See Also: [List of IO Results](#).

**Prototype:**

**IOResult Save(ISave \*iSave);**

**Remarks:**

Saves this NameTab to disk.

**Parameters:**

**ISave \*iSave**

This class provides methods to save data to disk.

**Return Value:**

See Also: [List of IO Results](#).

**Operators:**

**Prototype:**

**NameTab& operator=(const NameTab& n);**

**Remarks:**

Assignment operator. The specified **NameTab** is copied to this **NameTab**.

## Template Class Tab

See Also: [Class BitArray](#).

```
template <class T> class Tab
```

### Description:

This is a generic table class. This is a type-safe variable length array which also supports list-like operations of insertion, appending and deleting. Two instance variables are maintained: **nalloc** is the number elements allocated in the array; **count** is the number actual used. (**count** ≤ **nalloc**). Allocation is performed automatically when Insert or Append operations are performed. It can also be done manually by calling **Resize()** or **Shrink()**.

Note: Delete does not resize the storage: to do this call **Shrink()**. If you are going to do a sequence of Appends, its more efficient to first call **Resize()** to make room for them. Beware of using the **Addr()** function: it returns a pointer which may be invalid after subsequent **Insert()**, **Append()**, **Delete()**, **Resize()**, or **Shrink()** operations.

Also note: In 3ds max 1.x, the method **SetCount(n)** will set the count to **n**, but will not assure that only **n** items are allocated. To do that you should call **Resize(n)**. This sets the number allocated. It will also make sure that **count** ≤ **numAlloc**. To make sure that exactly **n** are allocated **and** that **count** = **n**, call both **Resize(n)** and **SetCount(n)**. In 3ds max 2.x and later using **SetCount()** will also effectively call **Resize()**.

The implementation minimizes the storage of empty Tables: they are represented by a single NULL pointer. Also, the major part of the code is generic, shared by different Tabs for different types of elements.

Tabs may be used on the stack, i.e. they may be declared as a local variable of a function or method. You can set the number of elements in the table, work with them, and then when the function returns, the destructor of the Tab is called, and the memory will be deallocated.

Tabs are only appropriate for use with classes that don't allocate memory. For example, Tab<float> is fine while Tab<TSTR> is problematic (TSTR is the class used for strings in 3ds max). In this case, the TSTR class itself allocates memory for the string. It relies on its constructor or destructor to allocate and free the memory. The problem is the Tab class will not call the constructors and

destructors for all the items in the table, nor will it call the copy operator. As an example of this, when you assign a string to another string, the TSTR class does not just copy the pointer to the string buffer (which would result in two items pointing to the same block of memory). Rather it will allocate new memory and copy the contents of the source buffer. In this way you have two individual pointers pointing at two individual buffers. When each of the TSTR destructors is called it will free each piece of memory. So, the problem with using a Tab<TSTR> is that when you assign a Tab to another Tab, the Tab copy constructor will copy all the elements in the table, but it will not call the copy operator on the individual elements. Thus, if you had a Tab<TSTR> and you assigned it to another Tab<TSTR>, you'd have two TSTRs pointing to the same memory. Then when the second one gets deleted it will be trying to double free that memory.

So again, you should only put things in a Tab that don't allocate and deallocate memory in their destructors. Thus, this class should not be used with classes that implement an assignment operator and or destructor because neither are guaranteed to be called. The way around this is to use a table of pointers to the items. For example, instead of Tab<TSTR> use Tab <TSTR \*>. As another example, Tab<int> is OK, while Tab<BitArray> would be no good. In the BitArray case one should use class pointers, i.e. Tab<BitArray \*>.

All methods of this class are implemented by the system except the compare function used in sorting (see **Sort()**).

**Methods:**

**Prototype:**

**Tab(const Tab& tb)**

**Remarks:**

Copy constructor.

**Parameters:**

**const Tab& tb**

The table to copy.

**Prototype:**

**~Tab()**

**Remarks:**

Destructor. The memory associated with the table is freed.

**Prototype:**

**void Init();**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

Provides a way of initializing a **Tab**<> instance outside of its constructor. Can be used to init **Tab**<> instances in malloc'd memory.

**Prototype:**

**int Count() const**

**Remarks:**

Returns the number of entries being used.

**Prototype:**

**void ZeroCount()**

**Remarks:**

Set the number of elements in the array that are actually used to zero.

**Prototype:**

**void SetCount(int n)**

**Remarks:**

Set the number of elements in the array that are actually used to **n**.

**Parameters:**

**int n**

The number of elements in the array that are actually used.

**Prototype:**

**T\* Addr(const int i) const**

**Remarks:**

Returns the address of the i-th element. Beware of using this method as it returns a pointer which may be invalid after subsequent Insert, Append, Delete, Resize, or Shrink operations.

**Parameters:**

**const int i**

Specifies the element to return the address of.

**Return Value:**

Pointer to the i-th element.

**Prototype:**

**int Insert(int at, int num, T \*el)**

**Remarks:**

Insert "num" elements at position "at".

**Parameters:**

**int at**

Array index where to insert the elements.

**int num**

Number of elements to insert.

**T \*el**

Array of elements to insert.

**Return Value:**

Returns **at**.

**Prototype:**

**int Append(int num, T \*el, int allocExtra=0)**

**Remarks:**

Append "num" elements at the end of the array. If you need to enlarge the array, allocate "allocExtra" extra slots

**Parameters:**

**int num**

The number of elements to append to the end of the array.

**T \*el**

The elements to append.

**int allocExtra=0**

If you need to enlarge the array, allocate "allocExtra" extra slots.

**Return Value:**

Returns the number of elements in use (prior to appending).

**Prototype:**

**int Delete(int start,int num)**

**Remarks:**

List-type delete of "num" elements starting with "start"

**Parameters:**

**int start**

The start position for element deletion.

**int num**

The number of elements to delete.

**Return Value:**

Returns the number of items left in the table.

**Prototype:**

**int Resize(int num)**

**Remarks:**

Changes the number of allocated items to "num".

**Parameters:**

**int num**

The new size of the array.

**Return Value:**

Nonzero if the array was resized; otherwise 0.

**Prototype:**

**void Shrink()**

**Remarks:**

Reallocate so there is no wasted space (nalloc = count).

**Prototype:**

```
void Sort(CompareFnc cmp)
```

**Remarks:**

Sorts the array using the compare function.

**Parameters:****CompareFnc cmp**

Type of function to pass to **Sort()**. Note: **Sort()** just uses the C library `qsort` function. The developer must implement the **CompareFnc** function.

```
typedef int( __cdecl *CompareFnc) (const void *elem1, const void *elem2);
```

The return value of **CompareFnc** is show below in the relationship of **elem1** to **elem2**:

< 0

if **elem1** less than **elem2**

0

if **elem1** identical to **elem2**

> 0

if **elem1** greater than **elem2**

**Sample Code:**

```
static int CompTable( const void *elem1, const void *elem2 ) {  
    TCHAR *a = (TCHAR *)elem1;  
    TCHAR *b = (TCHAR *)elem2;  
    return(_tcscmp(a,b));  
}
```

**Operators:****Prototype:**

```
Tab& operator=(const Tab& tb)
```

**Remarks:**

Assignment operator. The **Tab** maintains a pointer to the table buffer. This assignment operator copies the table data from the item you are copying from into the memory buffer of the item you are copying to.

**Parameters:**

**const Tab& tb**

The table to assign.

**Prototype:**

**T& operator[](const int i) const**

**Remarks:**

Accesses the i-th entry.

**Parameters:**

**const int i**

The index of the element to access.

**Return Value:**

The i-th element.

# Class ColorPicker

See Also: [Class HSVCallback](#), [COLORREF - DWORD](#), [Class IPoint2](#).

```
class ColorPicker : public InterfaceServer
```

## Description:

This class allows a plug-in to create a **modeless** color picker dialog box.

Developers may also create a **modal** version of this dialog box. The function available below is defined for this purpose. Note that this is not a class method but a global function.

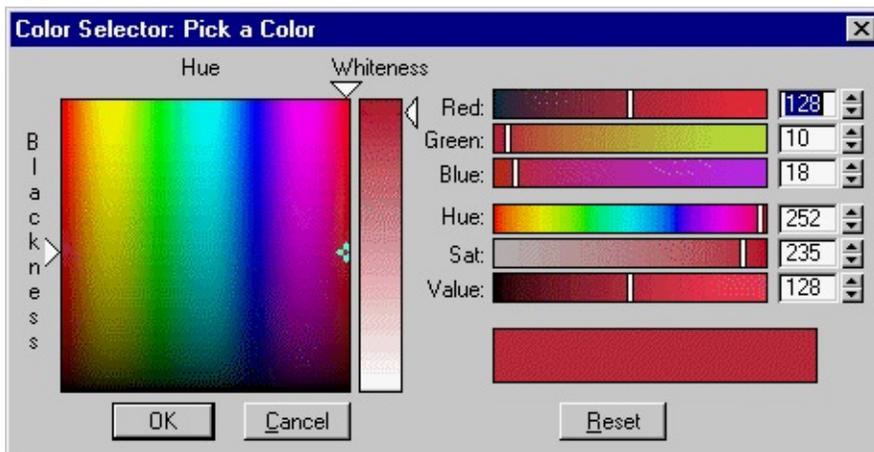

To use these APIs you need to **#include "hsv.h"**.

## Prototype:

```
int HSVDlg_Do(HWND hwndOwner, DWORD *lpc, IPoint2 *spos, HSVCallback *callBack, TCHAR *name);
```

## Remarks:

This method puts up the modal HSV color picker dialog box. This dialog appears below:

## Parameters:

**HWND hwndOwner**

Owner window handle.

**DWORD \*lpc**

Pointer to color to be edited. See [COLORREF](#).

**IPoint2 \*spos**

The starting position of the upper left corner of the dialog window. This is set to the ending position when the user is done. You may pass NULL to get the default location.

**HSVCallback \*callBack**

Callback object whose procs are called when the color changes. See [Class HSVCallback](#).

**TCHAR \*name**

The name of color being edited to appear in the title bar.

**Return Value:**

Returns TRUE if the user exists the dialog with OK, otherwise returns FALSE.

The following functions are also available

**Prototype:**

```
ColorPicker *CreateColorPicker(HWND hwndOwner, DWORD  
initColor, IPoint2* spos, HSVCallback *pcallback, TCHAR *name,  
int objClr=0);
```

**Remarks:**

Call this function to bring up the modeless color picker.

**Parameters:**

**HWND hwndOwner**

The owner window handle.

**DWORD initColor**

The initial color for the color picker.

**IPoint2\* spos**

The initial screen position of the upper left corner. NULL may be passed for the default location.

**HSVCallback \*pcallback**

The callback object to respond to color change events.

**TCHAR \*name**

The title string in the dialog.

**int objClr=0**

A BOOLEAN used to indicate that the ColorPicker is being used to set the object color from the control panel. In all other cases, the default value of 0 should be used.

**Return Value:**

A pointer to a ColorPicker object.

**Prototype:**

```
void SetCPInitPos(IPoint2 &pos);
```

**Remarks:**

Establishes the color picker initial screen position.

**Parameters:**

**IPoint2 &pos**

The upper left corner screen coordinate for the color picker.

**Prototype:**

**IPoint2 GetCPInitPos();**

**Remarks:**

Retrieves the color picker initial screen position.

**Return Value:**

The screen coordinates of the color picker. This is the coordinate of the upper left corner.

**Methods:**

**Prototype:**

**ColorPicker();**

**Remarks:**

Constructor.

**Prototype:**

**virtual ~ColorPicker();**

**Remarks:**

Destructor.

**Prototype:**

**virtual void ModifyColor(DWORD color)=0;**

**Remarks:**

This method changes the current color in the color picker, but does not change the "reset" color.

**Parameters:**

**DWORD color**

The current color.

**Prototype:**

**virtual void SetNewColor(DWORD color, TCHAR \*name)=0;**

**Remarks:**

Sets a new color as current in the dialog.

**Parameters:**

**DWORD color**

The color to set.

**TCHAR \*name**

A new name to display in the title bar.

**Prototype:**

**virtual DWORD GetColor()=0;**

**Remarks:**

Returns the current color.

**Prototype:**

**virtual IPoint2 GetPosition()=0;**

**Remarks:**

Returns the screen position of the upper left corner of the dialog as a IPoint2.

**Prototype:**

**virtual void Destroy()=0;**

**Remarks:**

This is called when the parent is going away.

**Prototype:**

**virtual void InstallNewCB(DWORD col, HSVCallback \*pcb,  
TCHAR \*name)=0;**

**Remarks:**

This method is used to add a different callback, set a new initial color and update the title string.

**Parameters:**

**DWORD col**

The new initial color.

**HSVCallback \*pcb**

The new callback.

**TCHAR \*name**

The new title string.

**Prototype:**

**virtual void RefreshUI();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called when the display gamma changes.

# **COLORREF - DWORD Color Format**

### **From the Windows API:**

The COLORREF value is a 32-bit value used to specify an RGB color.

#### **COLORREF RGB(**

**BYTE bRed, // red component of color**

**BYTE bGreen, // green component of color**

**BYTE bBlue // blue component of color**

**);**

When specifying an explicit RGB color, the COLORREF value has the following hexadecimal form:

**0x00bbggrr**

The low-order byte contains a value for the relative intensity of red; the second byte contains a value for green; and the third byte contains a value for blue. The high-order byte must be zero. The maximum value for a single byte is 0xFF.

Also see the following macros in the Windows API:

**GetBValue, GetGValue, GetRValue, RGB.**

These are used to create COLORREF values and break them down into component values. These can be used as follows:

**COLORREF fillcolor = RGB(48, 96, 192);**

**int r = (int) GetRValue(fillcolor);**

**int g = (int) GetGValue(fillcolor);**

**int b = (int) GetBValue(fillcolor);**

## Class MNMesh

See Also: [Class FlagUser](#), [Class MNFace](#), [Class MNVert](#), [Class MNEdge](#), [Class MNMap](#), [Class PerData](#), [Class MNMeshBorder](#), [Class Mesh](#), [Class BitArray](#), [Template Class Tab](#), [MNMesh Note on Edge Characteristics](#), [Class MNMeshBorder](#), [MNMesh Notes on Debugging](#).

```
class MNMesh : public FlagUser, public BaseInterfaceServer
```

### Description:

This class is available in release 2.0 and later only.

The MNMesh class is provided for temporary use by plug-ins, to help with complex topology-based modifications to Meshes. It has certain capabilities, such as the ability to recognize faces with more than 3 sides, that are useful in some applications. It is not suitable for use as a pipeline object. All methods of this class are implemented by the system.

MNMesh has a winged-edge structure and a highly interlinked topology. This is very useful for some modifiers, but requires far more memory & processing time than an equivalent normal mesh. It's convenient for the programmer, but may be sluggish for the user.

Although some methods can be a bit slow, none of them are non-linear in the amount of time they take. Even the tessellation algorithms, which can as much as quadruple the size of the meshes, operate locally, vertex by vertex, so they are order-of-n algorithms.

Note: You must **#include "MNMATH.H"** to use this class as it's not included by default by **MAX.H**.

## Data Members:

public:

**MNVert \*v;**

This data member is available in release 3.0 and later only.

The array of MNMesh verticies.

**MNEdge \*e;**

This data member is available in release 3.0 and later only.

The array of MNMesh edges.

**MNFace \*f;**

This data member is available in release 3.0 and later only.

The array of MNMesh faces.

**int numv**

This data member is available in release 3.0 and later only.

The number of MNVerts in **v**.

**int nume**

This data member is available in release 3.0 and later only.

The number of MNEdges in **e**.

**int numf**

This data member is available in release 3.0 and later only.

The number of MNFaces in **f**.

**int numm;**

This data member is available in release 3.0 and later only.

The number of MNMaps in **m**.

**PerData \*vd;**

This data member is available in release 3.0 and later only.

The array of PerData objects which maintain and provide access to the floating point vertex data. There is one of these for each supported channel. PerData objects are used to store such information as vertex weighting and weighted selections.

### **BitArray vdSupport;**

This data member is available in release 3.0 and later only.

This bit array indicates if a particular vertex data channel is supported in this MNMesh. If the bit is set the channel is supported.

### **PerData \*ed;**

This data member is available in release 3.0 and later only.

The array of PerData objects which maintain and provide access to the floating point edge data. There is one of these for each supported channel. One PerData object store edge weighting for NURMS-type MeshSmooths.

### **BitArray edSupport;**

This data member is available in release 3.0 and later only.

This bit array indicates if a particular edge data channel is supported in this MNMesh. If the bit is set the channel is supported.

### **DWORD selLevel;**

This data member is available in release 3.0 and later only. Note however that, since MNMeshes are not yet used as pipeline objects, the subobject selection methods are not yet used in 3ds max. Third party developers are welcome to use these methods themselves, but they should be aware that this is a work-in-progress.

The current MNMesh selection level. One of the following values:

**MNM\_SL\_OBJECT** - object level selection.

**MNM\_SL\_VERTEX** - select vertices

**MNM\_SL\_EDGE** - select edges

**MNM\_SL\_FACE** - select polygon faces

### **DWORD dispFlags;**

This data member is available in release 3.0 and later only. Note however that, since MNMeshes are not yet used as pipeline objects, the display methods and flags are not yet used in 3ds max. Third party developers are welcome to use the display methods themselves, but they should be aware that this is a work-

in-progress.

The display flags. One or more of the following values:

**MNDISP\_VERTTICKS** - Display vertex tick marks.

**MNDISP\_SELVERTS** - Display selected verticies.

**MNDISP\_SELFACES** - Display selected faces.

**MNDISP\_SELEDGES** - Display selected edges.

**MNDISP\_NORMALS** - Display face normals.

**MNDISP\_SMOOTH\_SUBSEL** - Analogous to the Mesh display flag MESH\_SMOOTH\_SUBSEL, this indicates whether we should display smooth faces with selection-color outlines (TRUE) or transparent shaded faces (FALSE).

**MNDISP\_BEEN\_DISP** - Set when the MNMesh has been displayed (at the end of the render method.)

**MNDISP\_DIAGONALS** – Set when diagonals should be displayed.

**Tab<int> \*vedg;**

This data member is available in release 3.0 and later only.

This is an array of int Tabs that records which edges use each vertex. For instance, if edges 3, 5, and 6 have an endpoint at vertex 0, vedg[0] would include 3, 5, and 6, though not in any particular order. This replaces the 2.5 MNVert::edg data member. Note that this information is only valid if the MN\_MESH\_FILLED\_IN flag is set.

**Tab<int> \*vfac;**

This data member is available in release 3.0 and later only.

This is an array of int Tabs that records which faces touch each vertex. For instance, if faces 0, 1, 3, 8, and 9 use vertex 0 as one of their corners, vfac[0] would include 0, 1, 3, 8, and 9, though not in any particular order. This replaces the 2.5 MNVert::fac data member. Note that this information is only valid if the MN\_MESH\_FILLED\_IN flag is set.

**Flags:**

For more information on flags, see [Class FlagUser](#).

**MN\_MESH\_NONTRI**

If set, this mesh's faces are not all triangles -- at least one face has more than 3 sides.

## **MN\_MESH\_FILLED\_IN**

If set, all topological links, such as the list of edges, are complete.

## **MN\_MESH\_RATSNEST**

Some regular Meshes have more than two faces referencing the same edge, or more than one referencing it in the same direction. These are termed "rats' nest meshes". Since our edge structure only permits 1 or 2 faces (one in each direction), these meshes are unacceptable. Upon conversion, certain vertices & edges are replicated (increasing the vertex count) to separate these into regular, non-rats'-nest parts. If this happens, this flag is set to let you know this change has occurred. In particular, converting this MNMesh back into a regular Mesh will produce a Mesh with more vertices than you started with.

## **MN\_MESH\_NO\_BAD\_VERTS**

This indicates that the mesh has had its vertices checked and "bad" ones eliminated by `EliminateBadVerts` .

## **MN\_MESH\_VERTS\_ORDERED**

This indicates that the mesh has had its vertices ordered by the method `OrderVerts`.

## **MN\_MESH\_HAS\_VOLUME**

This flag is available in release 2.5 or later only.

This mesh has at least one connected component which contains volume, i.e. represents a solid object with no gaps or holes. The flag is set by the

**MNMesh::FindOpenRegions()** method.

## **MN\_USER(1<<16)**

Flag bits at or above MN\_USER are reserved in all MNMesh components for the plug-in developer, if needed. Since FlagUser-derived classes have 32 flag bits, this allows for up to 16 user-defined flags.

## **Methods:**

## **Initialization & Cleanup**

### **Prototype:**

```
MNMesh();
```

### **Remarks:**

Constructor. Initializes the MNMesh with no components and the default

flags.

**Prototype:**

**MNMesh(Mesh &from);**

**Remarks:**

Constructor. Initializes the MNMesh with the mesh "from", and fills in the topology completely (using FillInMesh).

**Prototype:**

**MNMesh(const MNMesh &from);**

**Remarks:**

This method is available in release 3.0 and later only.  
Copy constructor.

**Prototype:**

**~MNMesh();**

**Remarks:**

Destructor. Frees all allocated memory (using Clear).

**Prototype:**

**MNMap \*M(int mp) const;**

**Remarks:**

This method is available in release 4.0 and later only.  
Access to the MNMaps in each MNMesh is made private. Instead of using the MNMap \*m data member, you must now use this accessor method. This accessor now accepts a value in the range **-NUM\_HIDDENMAPS** to **MNum()**.

**Parameters:**

**int mp**

The map channel

**Prototype:**

**void DefaultFlags();**

**Remarks:**

Clears all flags.

**Prototype:**

**void Init();**

**Remarks:**

This method is available in release 3.0 and later only.

The data members are initialized as follows:

**nv\_alloc = ne\_alloc = nf\_alloc = nm\_alloc = 0;**

**numv = nume = numf = numm = 0;**

**v = NULL;**

**e = NULL;**

**f = NULL;**

**m = NULL;**

**vd = NULL;**

**ed = NULL;**

**vedg = NULL;**

**vfac = NULL;**

**bdgBox.Init();**

**fnorm = NULL;**

**dispFlags = 0;**

**rVerts = NULL;**

**cacheGW = NULL;**

**normalsBuilt = 0;**

**norScale = 0.0f;**

**selLevel = MNM\_SL\_OBJECT;**

**Prototype:**

**void VAlloc(int num, bool keep=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.  
Allocates and inits the specified number of MNVerts.

**Parameters:****int num**

The number of verts to allocate.

**bool keep=TRUE**

If TRUE any previous verts are kept; otherwise they are discarded.

**Prototype:**

```
void VShrink(int num=-1);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Shrinks the nv\_alloc size of the MNVert array to the specified size.

**Parameters:****int num=-1**

The new size of the array. The default -1 means to shrink array allocation to numv.

**Prototype:**

```
void freeVEdge();
```

**Remarks:**

This method is available in release 3.0 and later only.  
Deallocates any MNEdges in the **vedg** table and sets the **vedg** pointer to NULL.

**Prototype:**

```
void VEdgeAlloc();
```

**Remarks:**

This method is available in release 3.0 and later only.  
Allocates the **vedg** array.

**Prototype:**

**void freeVFace();**

**Remarks:**

This method is available in release 3.0 and later only.  
Deallocates the **vfac** array.

**Prototype:**

**void VFaceAlloc();**

**Remarks:**

This method is available in release 3.0 and later only.  
Allocates the **vfac** array.

**Prototype:**

**void EAlloc(int num, bool keep=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.  
Allocates the MNEdge data array **e** with the specified size.

**Parameters:**

**int num**

The number of MNEdges to allocate.

**bool keep=TRUE**

If TRUE any previously allocated edges are kept; otherwise they are discarded.

**Prototype:**

**void EShrink(int num=-1);**

**Remarks:**

This method is available in release 3.0 and later only.  
Reduces the ne\_alloc size of the MNEdge data array **e** to the specified number of elements.

**Parameters:**

**int num=-1**

The new size for the array. The value -1 means to use the current number of edges, nume.

**Prototype:**

**void FAlloc(int num, bool keep=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Allocates the MNFace array **f** with the specified size.

**Parameters:**

**int num**

The number of MNFaces to allocate.

**bool keep=TRUE**

If TRUE any previously allocated faces are kept; otherwise they are discarded.

**Prototype:**

**void FShrink(int num=-1);**

**Remarks:**

This method is available in release 3.0 and later only.

Reduces the nf\_alloc size of the MNFace data array **f** to the specified number of elements.

**Parameters:**

**int num=-1**

The new size for the array. The value -1 means to use the current number of faces, numf.

**Prototype:**

**void MAlloc(int num, bool keep=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Allocates the MNMap array **m** with the specified size.

**Parameters:**

**int num**

The number of MNMap elements to allocate.

**bool keep=TRUE**

If TRUE any previously allocated MNMaps are kept; otherwise they are discarded.

**Prototype:**

**void MShrink(int num=-1);**

**Remarks:**

This method is available in release 3.0 and later only.

Reduces the nm\_alloc size of the MNMap data array **m** to the specified number of elements.

**Parameters:**

**int num=-1**

The new size for the array. The value -1 means to use the current number of maps, numm.

**Prototype:**

**void PrepForPipeline ();**

**Remarks:**

This method is available in release 4.0 and later only.

This method reconciles flags with arrays, checks and modifies data, ensures that the caches are consistent, and prepares the MNMesh pipeline. For instance, if the **MN\_MESH\_FILLED\_IN** flag is absent but there is still an edge array, this will free the edge array. This method is important to call if a **MNMesh** has been subjected to topology changing operations and should be called at the end of any operation on an MNMesh.

**Prototype:**

**BaseInterface\* GetInterface(Interface\_ID id);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a pointer to the base interface of the associated and

provided Interface ID.

**Parameters:**

**Interface\_ID id**

The interface ID.

## **I/O with regular meshes**

**Prototype:**

**void SetFromTri(const Mesh & from);**

**Remarks:**

Clears out all current information, and copies in new faces & vertices from "from".

**Prototype:**

**void AddTri(const Mesh & from);**

**Remarks:**

Adds vertices and faces in "from" to current MNMesh.

**Prototype:**

**void OutToTri(Mesh & tmesh);**

**Remarks:**

Outputs current MNMesh into the mesh given. Note that even if the MNMesh was originally taken from this Mesh, the internal processing may have changed PART\_TOPO, PART\_GEOM, PART\_SELECT, PART\_MAPPING, or PART\_VERTCOLOR.

## **Access to components**

**Prototype:**

**int VNum();**

**Remarks:**

Returns the number of vertices.

**Prototype:**

**MNVert \*V(int i);**

**Remarks:**

Returns a pointer to the i'th MNVert.

**Prototype:**

**Point3 &P(int i);**

**Remarks:**

Returns the point in the i'th MNVert. P(i) is the same as V(i)->p.

**Prototype:**

**int ENum();**

**Remarks:**

Returns the number of edges.

**Prototype:**

**MNEdge \*E(int i);**

**Remarks:**

Returns a pointer to the i'th MNEdge.

**Prototype:**

**int FNum();**

**Remarks:**

Returns the number of faces.

**Prototype:**

**MNFace \*F(int i);**

**Remarks:**

Returns a pointer to the i'th MNFace.

**Prototype:**

**void SetMapNum(int mpnum);**

**Remarks:**

This method is available in release 3.0 and later only.

Allocates and initializes the specified number of MNMap elements in the **m** array. Initializing sets the number of verts and faces in the map to zero and sets the **MN\_DEAD** flag.

**Parameters:**

**int mpnum**

The number of MNMaps to allocate and initialize.

**Prototype:**

**void InitMap(int mp);**

**Remarks:**

This method is available in release 3.0 and later only.

Allocates and initializes basic planar map, or a white map for the vertex color channel.

**Parameters:**

**int mp**

The map channel to initialize:

0: Vertex Color channel.

1: Default mapping channel.

2 through MAX\_MESHMAPS-1: The new mapping channels available in release 3.0.

**Prototype:**

**void ClearMap(int mp);**

**Remarks:**

This method is available in release 3.0 and later only.

Clears and frees the specified map channel, setting the **MN\_DEAD** flag.

**Parameters:**

**int mp**

The map channel to clear.

0: Vertex Color channel.  
1: Default mapping channel.  
2 through MAX\_MESHMAPS-1: The new mapping channels available in release 3.0.

**Prototype:**

**UVVert MV(int mp, int i) const;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the specified UVVert from the specified mapping channel.

**Parameters:**

**int mp**

The map channel.

0: Vertex Color channel.

1: Default mapping channel.

2 through MAX\_MESHMAPS-1: The new mapping channels available in release 3.0.

**int i**

The zero based index of the UVVert to return.

**Prototype:**

**MNMapFace \*MF(int mp, int i) const;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns a pointer to the specified MNMapFace from the specified mapping channel.

**Parameters:**

**int mp**

The map channel:

0: Vertex Color channel.

1: Default mapping channel.

2 through MAX\_MESHMAPS-1: The new mapping channels available in

release 3.0.

**int i**

The zero based index of the MNMapFace to return.

**Prototype:**

**int TriNum() const;**

**Remarks:**

Returns the total number of triangles; this is a sum of the number of triangles in each face that does not have the MN\_DEAD flag set.

**Prototype:**

**void setNumVData(int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the specified number of vertex data elements.

**Parameters:**

**int ct**

The number of vertex data elements to set.

**BOOL keep=FALSE**

If TRUE any previously allocated elements are kept; otherwise they are discarded.

**Prototype:**

**int VNum() const;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the number of vertex data channels maintained by this MNMesh.

**Prototype:**

**BOOL vDataSupport(int vdChan) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the specified channel of vertex data is available for this MNMesh; otherwise FALSE.

**Parameters:**

**int vdChan**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void setVDataSupport(int vdChan, BOOL support=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the specified channel of vertex data is supported by this MNMesh.

**Parameters:**

**int vdChan**

The vertex data channel. See [List of Vertex Data Index Options](#).

**BOOL support=TRUE**

TRUE to indicate the channel is supported; FALSE to indicate it's not. If TRUE is specified then elements are allocated (if needed). If FALSE is specified the data for the channel is freed.

**Prototype:**

**void \*vertexData(int vdChan) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the vertex data for the specified channel or NULL if the channel is not supported.

**Parameters:**

**int vdChan**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**float \*vertexFloat(int vdChan) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point vertex data for the specified channel of this mesh or NULL if the channel is not supported.

**Parameters:**

**int vdChan**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void freeVData(int vdChan);**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes (deallocates) the vertex data for the specified channel.

**Parameters:**

**int vdChan**

The vertex data channel. See [List of Vertex Data Index Options](#).

**Prototype:**

**void freeAllVData();**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the vertex data from all channels and sets the number of supported channels to 0.

**Prototype:**

**float \*getVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point vertex weight data.

**Prototype:**

**void SupportVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the channel support for the vertex weights channel  
(VDATA\_WEIGHT).

**Prototype:**

**void freeVertexWeights();**

**Remarks:**

This method is available in release 3.0 and later only.  
Frees (deallocates) the vertex weight channel data.

**Prototype:**

**float \*getVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns a pointer to the floating point vertex selection weight data.

**Prototype:**

**void SupportVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the channel support for the vertex weights channel  
(VDATA\_SELECT).

**Prototype:**

**void freeVSelectionWeights();**

**Remarks:**

This method is available in release 3.0 and later only.  
Frees (deallocates) the vertex selection weight channel data.

**Prototype:**

**void setNumEData(int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified number of edge data elements.

**Parameters:****int ct**

The number of edge data elements to set.

**BOOL keep=FALSE**

If TRUE any previously allocated elements are kept; otherwise they are discarded.

**Prototype:**

```
int EDNum() const;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of edge data channels maintained by this MNMesh.

**Prototype:**

```
BOOL eDataSupport(int edChan) const;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the specified channel of edge data is available for this MNMesh; otherwise FALSE.

**Parameters:****int edChan**

The edge data channel. See [List of Edge Data Index Options](#).

**Prototype:**

```
void setEDataSupport(int edChan, BOOL support=TRUE);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the specified channel of edge data is supported by this MNMesh.

**Parameters:**

## **int edChan**

The edge data channel. See [List of Edge Data Index Options](#).

## **BOOL support=TRUE**

TRUE to indicate the channel is supported; FALSE to indicate it's not.

### **Prototype:**

```
void *edgeData(int edChan) const;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the edge data for the specified channel or NULL if the channel is not supported.

### **Parameters:**

## **int edChan**

The edge data channel. See [List of Edge Data Index Options](#).

### **Prototype:**

```
float *edgeFloat(int edChan) const;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point edge data for the specified channel of this MNMesh or NULL if the channel is not supported.

### **Parameters:**

## **int edChan**

The edge data channel. See [List of Edge Data Index Options](#).

### **Prototype:**

```
void freeEData(int edChan);
```

### **Remarks:**

This method is available in release 3.0 and later only.

Deletes (deallocates) the edge data for the specified channel.

### **Parameters:**

## **int edChan**

The edge data channel. See [List of Edge Data Index Options](#).

**Prototype:**

**void freeAllEData();**

**Remarks:**

This method is available in release 3.0 and later only.

Deallocates the edge data from all channels and sets the number of supported channels to 0.

**Prototype:**

**float \*getEdgeKnots();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the floating point edge knot data.

**Prototype:**

**void SupportEdgeKnots();**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the channel support for the edge knot channel (**EDATA\_KNOT**).

**Prototype:**

**void freeEdgeKnots();**

**Remarks:**

This method is available in release 3.0 and later only.

Frees (deallocates) the edge knot channel data.

**Prototype:**

**void VClear(int vv);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::Clear method.

Clears and frees the flags and face/edge lists for the specified vertex.

**Parameters:**

**int vv**

The vertex to clear.

**Prototype:**

**void VInit(int vv);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::Init method.

Initializes the specified MNVert, clearing its flags and emptying its face & edge lists (if vfac & edg are allocated).

**Parameters:**

**int vv**

The vertex to initialize.

**Prototype:**

**int VFaceIndex(int vv, int ff, int ee=-1);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::FaceIndex method.

Returns the index of face ff in the vfac[vv] table.

NOTE that if this face cannot be found, or if it cannot be found accompanied by edge ee>-1, it will cause an assertion failure.

**Parameters:**

**int vv**

The vertex to check the face list of.

**int ff**

The face to look for.

**int ee=-1**

In cases where the same face touches this vertex more than once, and is therefore represented twice in the vfac table, an optional edge parameter is

used to specify which instance of the face you want the index of. However, if the parent MNMesh doesn't have its vertices ordered (as indicated by the MN\_MESH\_VERTS\_ORDERED flag), the extra edge parameter is meaningless and should not be used.

**Prototype:**

**int VEdgeIndex(int vv, int ee);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::EdgeIndex method.

Finds the position of edge ee in this MNVert's vedg table. Unlike VFaceIndex (and MNFace's VertIndex and EdgeIndex), each vertex can only touch an edge once, so there's no need for an additional parameter. (There's no such thing as an edge with both ends at the same vertex.)

**Parameters:**

**int vv**

The vertex whose edge list should be searched.

**int ee**

The edge to find.

**Return Value:**

Returns -1 if edge ee is not in the edge table.

**Prototype:**

**void VDeleteEdge(int vv, int ee);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::DeleteEdge method.

Finds edge ee in the vedg[vv] table and removes it.

**Parameters:**

**int vv**

The vertex from whose edge list the edge should be deleted.

**int ee**

The edge to delete from the vertex's edge list.

**Return Value:**

Returns -1 if edge **ee** is not in the edge table.

**Prototype:**

```
void VDeleteFace(int vv, int ff);
```

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old `MNVert::DeleteFace` method.

Finds face **ff** in the **vfac[vv]** table and removes it. NOTE that this method causes an assertion failure if face **ff** is not in the **vfac** table. If **ff** occurs more than once, which is possible on some valid NONTRI meshes, only the first **ff** is removed.

**Parameters:**

**int vv**

The vertex from whose face list the face should be deleted.

**int ff**

The face to delete from the vertex's face list.

**Prototype:**

```
void VReplaceEdge(int vv, int oe, int ne);
```

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old `MNVert::ReplaceEdge` method.

Finds edge **oe** in the **vedg[vv]** table and replaces it with **ne**. NOTE that this method causes an assertion failure if edge **oe** is not in the **vedg** table.

**Parameters:**

**int vv**

The vertex in whose edge list the edge should be replaced.

**int oe**

The edge to replace.

**int ne**

The replacement edge.

**Prototype:**

**void VReplaceFace(int vv, int of, int nf);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::ReplaceFace method.

Finds face **of** in the **vfac[vv]** table and replaces it with **nf**. NOTE that this method causes an assertion failure if face **of** is not in the **vfac** table. If **of** occurs more than once, which is possible on some valid NONTRI meshes, only the first of is replaced.

**Parameters:**

**int vv**

The vertex in whose face list the face should be replaced.

**int of**

The face to replace.

**int nf**

The replacement.

**Prototype:**

**void CopyVert(int nv, int ov);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::operator= by allowing the developer to copy face and edge adjacency information as well as vertex location and flags.

Copies the MNVert data from ov to nv. The face and edge data is copied too if appropriate (ie if MN\_MESH\_FILLED\_IN is set and vfac and vedg are allocated).

**Parameters:**

**int nv**

The destination index.

**int ov**

The source index.

**Prototype:**

```
void MNVDebugPrint(int vv);
```

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old MNVert::MNDebugPrint method.

Uses DebugPrint to print out vertex information to the Debug Results window in DevStudio. The information consists of the position, edge list, and face list. It is generally a good idea to put in a DebugPrint immediately before this with the index of the vertex, so you know which vertex is being printed out:

```
DebugPrint ("Vertex %d: ", vid);  
MNVDebugPrint(vid);
```

**Parameters:**

**int vv**

The zero based index of the MNVert to debug print.

**Prototype:**

```
BOOL SubObjectHitTest(GraphicsWindow *gw, Material *ma,  
HitRegion *hr, DWORD flags, SubObjHitList& hitList, int  
numMat=1 );
```

**Remarks:**

This method is available in release 4.0 and later only.

This method may be called to perform sub-object hit testing on this mesh.

**Parameters:**

**GraphicsWindow \*gw**

The graphics window associated with the viewport the mesh is being hit tested in.

**Material \*ma**

The list of materials for the mesh. See [Class Material](#)

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**DWORD flags**

Flags for sub object hit testing. One or more of the following values:

## **SUBHIT\_MNUSECURRENTSEL**

When this bit is set, the sel only and unsel only tests will use the current level (edge or face) selection when doing a vertex level hit test.) This is like the Mesh hit-testing flag SUBHIT\_USEFACESEL.

## **SUBHIT\_MNVERTS**

## **SUBHIT\_MNFACES**

## **SUBHIT\_MNEDGES**

## **SUBHIT\_MNTYPEMASK**

**(SUBHIT\_MNVERTS|SUBHIT\_MNFACES|SUBHIT\_MNEDGE**

## **SubObjHitList& hitList**

The results are stored here. See [Class SubObjHitList](#).

## **int numMat=1**

The number of materials for the mesh.

## **Return Value:**

TRUE if the item was hit; otherwise FALSE.

## **Prototype:**

**void UpdateDisplayVertexColors ();**

## **Remarks:**

This method is available in release 4.0 and later only.

This method is used to manage the display of vertex colors from any channel (or those that are passed in by some calling routine). For instance, to set the mesh to display the Illumination channel as the current vertex colors, you would call **SetDisplayVertexColors (MAP\_SHADING)**. (Normally, it shows the standard vertex color channel, channel 0.)

**UpdateDisplayVertexColors()** is used to refresh the vertex color pointers just before the MNMesh displays itself.

## **Prototype:**

**void SetDisplayVertexColors (int chan);**

## **Remarks:**

This method is available in release 4.0 and later only.

This method is used to manage the display of vertex colors from any channel

(or those that are passed in by some calling routine). For instance, to set the mesh to display the Illumination channel as the current vertex colors, you would call **SetDisplayVertexColors (MAP\_SHADING)**. (Normally, it shows the standard vertex color channel, channel 0.)

**UpdateDisplayVertexColors()** is used to refresh the vertex color pointers just before the MNMesh displays itself.

**Parameters:**

**int chan**

The channel you wish to use.

**Prototype:**

**void SetDisplayVertexColors (UVVert \*mv, MNMapFace \*mf);**

**Remarks:**

This method is available in release 4.0 and later only.

If you have cached your own vertex color information that isn't in any of the map channels provided, you can use this method to set the internal pointers to use your data.

**Parameters:**

**UVVert \*mv**

The array of UV vertices.

**MNMapFace \*mf**

The map face data.

**Prototype:**

**void FillInFaceEdges ();**

**Remarks:**

This method is available in release 4.0 and later only.

Fills in the faces' edge arrays based on the edge list.

**Prototype:**

**void FillInVertEdgesFaces ();**

**Remarks:**

This method is available in release 4.0 and later only.  
Fills in the vertex edge and face lists based on the edge list.

**Prototype:**

**Box3 getBoundingBox (Matrix3 \*tm=NULL, bool targonly=FALSE);**

**Remarks:**

This method is available in release 4.0 and later only.  
Retrieves a bounding box for the MNMesh.

**Parameters:**

**Matrix3 \*tm**

Like the corresponding method in class Mesh, this method takes an optional transform, so the user can get a bounding box in any desired space (with a slower calculation, as all the points must be transformed).

**bool targonly**

If set, only vertices with the **MN\_TARG** flag set are used to compute the bounding box.

**Prototype:**

**void ComputeNormal (int ff, Point3 & N, Point3 \*ctr=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.  
Computes a "balanced" normal, in that the normal takes the contribution of all vertices equally. (This is significant in the case of nonplanar polygons.)

**Parameters:**

**int ff**

The face you want the normal of.

**Point3 & N**

The place to store the computed normal.

**Point3 \*ctr**

If not NULL, it points to a place where ComputeNormal should put the face center.

**Prototype:**

**void GetVertexSpace (int vrt, Matrix3 & tm);**

**Remarks:**

This method is available in release 4.0 and later only.

Chooses a suitable "local space", and sets tm's rotation to match that space.

Does not set tm's translation component. (This is easily done by setting tm.SetRow (3, v[vrt].p).)

The purpose of this method is to support a consistent definition of "local space" around a given vertex. As usual, Z comes from the local normal; the X direction is chosen to be a particular edge, but then this direction is modified to balance the contribution of the other edges. (Thus it points roughly in the direction of one edge, but moving other edges' far endpoints will rotate which way is considered "X" just as much as moving that edge will.)

**Parameters:**

**int vrt**

The vertex index.

**Matrix3 & tm**

The transformation matrix.

**Prototype:**

**float EdgeAngle (int ed);**

**Remarks:**

This method is available in release 4.0 and later only.

Computes the angle at the given edge. (In other words, the angle between the planes of the faces on either side.) Note that in the case of nonplanar polygons, these planes are the "average" planes for the polygon, not the plane of the triangle nearest the edge.

**Parameters:**

**int ed**

The edge index.

**Return Value:**

The angle in radians.

**Prototype:****void FlipNormal(int faceIndex);****Remarks:**

This method is available in release 4.0 and later only.

Flips the normal of the specified face, as well as the corresponding map faces in active maps. Note that doing this on an isolated face with neighbors will cause an illegal condition. Use the FlipElementNormals method to safely and completely flip the normals of entire elements to avoid this problem.

This method uses the MNFace and MNMapFace methods "Flip", which changes the order of the vertices from (0,1,2...,deg-1) to (0, deg-1, deg-2,...1) and rearrange the edge and diagonal information accordingly.

**Parameters:****int faceIndex**

The face index.

**Prototype:****void AutoSmooth (float angle, BOOL useSel, BOOL preventIndirectSmoothing);****Remarks:**

This method is available in release 4.0 and later only.

Applies new smoothing groups to the whole mesh or to selected faces based on angles between faces.

**Parameters:****float angle**

The threshold angle in radians. Edges with angles above this amount will not be smoothed across.

**BOOL useSel**

Indicates if the auto-smoothing should be done only on selected faces.

**BOOL preventIndirectSmoothing**

Sometimes even though two neighboring faces are more than "angle" apart, there may be a path from one to the other via other faces, crossing only edges that are less than "angle" apart, so they'll wind up sharing the same smoothing group anyway. To prevent this sort of "indirect" smoothing, set this value to

TRUE.

**Prototype:**

**void RestrictPolySize (int maxdeg);**

**Remarks:**

This method is available in release 4.0 and later only.

Subdivides polygons as needed so that no polygon has degree larger than maxdeg. (For instance, if maxdeg was 4, an octagon would have edges added until it was composed of 3 quads, or some combination of quads and tris.)

**Parameters:**

**int maxdeg**

Maximum degrees.

**Prototype:**

**void MakePlanar (float planarThresh);**

**Remarks:**

This method is available in release 4.0 and later only.

Makes all faces planar, within the angle threshold given, by subdividing them as necessary. (See MakeFacePlanar.)

**Parameters:**

**float planarThresh**

The planar angle threshold.

**Prototype:**

**void MakeFacePlanar (int ff, float planarThresh);**

**Remarks:**

This method is available in release 4.0 and later only.

Makes the specified face planar by subdividing if necessary. planarThresh represents an angle in radians. If the angle across any of the face's diagonals is larger than this amount, the face is divided on that diagonal.

**Parameters:**

**int ff**

The face of the index to make planar

**float planarThresh**

The planar angle threshold.

**Prototype:**

**UVVert ExtrapolateMapValue (int face, int edge, Point3 & pt, int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

Given a point near a given edge of a given face, but near to it, this method will extrapolate what that point's mapping coordinates would be in the mapping scheme used by the face.

**Parameters:**

**int face**

The face we want to base mapping information on.

**int edge**

The index of the edge we're closest to on the face. (This should be the face-based index, in the range (0, deg-1), not the index of the edge in the MNMesh.)

**Point3 & pt**

The object-space coordinates of the point.

**int mp**

The map channel we're analyzing.

**Prototype:**

**void EliminateDoubledMappingVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

"Doubled" mapping vertices are individual map vertices that are used to correspond to different regular vertices. For instance, a box could have a single (1,1,0) map vertex that it uses in the upper-right corner of all quads. This design is harmful to some of our algorithms, such as the various Tessellators. So this method is available to fix such vertices. It clones map

vertices as needed to ensure that a given map vertex is only used by one regular vertex. Linear-time algorithm.

**Prototype:**

**BOOL CheckForDoubledMappingVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is a debugging tool. All doubled mapping verts are DebugPrinted. Return value is TRUE if there is at least one doubled mapping vertex (on at least one map channel). FALSE if the mesh is clean. Note that this method is not significantly faster than EliminateDoubledMappingVerts, so you should not use it to determine if EliminateDoubledMappingVerts should be called.

**Prototype:**

**void EliminateIsoMapVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

Deletes isolated mapping vertices - i.e., mapping vertices that aren't used by any mapping faces.

**Prototype:**

**void EliminateIsoMapVerts(int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

Deletes isolated mapping vertices - i.e., mapping vertices that aren't used by any mapping faces. If the "int mp" parameter is given, the algorithm operates only on that map channel. If not, the algorithm operates on all map channels.

**Parameters:**

**int mp**

The map channel to operate on.

**Prototype:**

**int SplitEdge (int ee, float prop, Tab<int> \*newTVerts);**

**Remarks:**

This method is available in release 4.0 and later only.

This new SplitEdge variant allows you to recover information about the new map vertices created at the point where the edge is split. Everything else is the same as the existing SplitEdge (int ee, float prop=.5f) method.

**Parameters:**

**Tab<int> \*newTVerts**

Pointer to a table in which the new map vertices can be stored. This table is set to size (NUM\_HIDDENMAPS + numm)\*2. The two entries for each map channel are used to store the two new map vertices at this edge split: newTVerts[(NUM\_HIDDENMAPS+mp)\*2+0] is the map vertex for map channel mp on the "f1" side of the edge, and newTVerts[mp\*2+1] is the map vertex for the "f2" side if f2>=0 (or otherwise left uninitialized). (These values are often, but not always, the same. They are different if the map has a seam along this edge.)

**Prototype:**

**void FacePointBary (int ff, Point3 & p, Tab<float> & bary);**

**Remarks:**

This method is available in release 4.0 and later only.

Finds "Generalized Barycentric Coordinates" for the point given. Generalized barycentric coordinates are not uniquely determined for polygons of degree greater than 3, but this algorithm should find a reasonable balance, where for instance a point in the center of a polygon would have a significant contribution from all vertices.

Generalized barycentric coordinates are a set of floats, one per vertex in the polygon, such that the sum of all the floats is 1, and the sum of all the floats times the corresponding vertices comes out to the point given.

**Parameters:**

**int ff**

The face we're finding barycentric coordinates on.

**Point3 & p**

The point we're trying to find barycentric coordinates for. If this point is not in

the plane of the polygon, the coordinates produced should represent its projection into the polygon's plane. Points outside the boundary of the polygon should be acceptable; some of the barycentric coordinates will be negative in this case.

**Tab<float> & bary**

The table to put the results in. This table is set to size f[ff].deg.

**Prototype:**

```
void CloneVerts (DWORD cloneFlag = MN_SEL, bool  
clear_orig=TRUE);
```

**Remarks:**

This method is available in release 4.0 and later only.

Clones flagged vertices, creating new vertices that aren't used by any faces.

**Parameters:**

**DWORD cloneFlag = MN\_SEL**

Indicates which vertices should be cloned.

**bool clear\_orig = TRUE**

If true, the original vertices should have the cloneFlag cleared. (The clones will always have this flag set.)

**Prototype:**

```
void CloneFaces (DWORD cloneFlag = MN_SEL, bool  
clear_orig=TRUE);
```

**Remarks:**

This method is available in release 4.0 and later only.

Clones the flagged faces, as well as all the vertices and edges that are used by the faces.

**Parameters:**

**DWORD cloneFlag = MN\_SEL**

Indicates which faces should be cloned.

**bool clear\_orig = TRUE**

If true, the original faces should have the cloneFlag cleared. (The clones will always have this flag set.)

**Prototype:****int DivideFace (int ff, Tab<float> & bary);****Remarks:**

This method is available in release 4.0 and later only.

Divides a face by creating a point in the face's interior and creating an edge from that point to each of the face's vertices. An n-gon becomes n triangles by this method.

**Parameters:****int ff**

The face to divide.

**Tab<float> & bary**

The generalized barycentric coordinates of the point that should be created. (See FacePointBary for details on barycentric coordinates.)

**Return Value:**

The index of the newly created vertex, or -1 if there's an error.

**Prototype:****int CreateFace (int degg, int \*vv);****Remarks:**

This method is available in release 4.0 and later only.

Creates a new face, using the vertices given.

Note that this method, unlike the similar NewFace method, maintains all topological links. If there's an edge between vv[0] and vv[1] which is already used by some other face (on the other side), that edge is modified to use this face on its "f2" side. If there's an edge between two sequential vertices with faces on both sides, the creation fails, because it would create an illegal condition.

This method also creates map faces in any active map channels to maintain the validity of the mesh. These map faces use the map vertices that other faces use for the vertices passed in, or if there are no corresponding map vertices yet, use newly created map vertices with the value (1,1,1).

**Parameters:****int degg**

The degree of the new face.

**int \*vv**

A pointer to an array of degg vertices for the new face.

**Return Value:**

The index of the new face, or -1 if the method was unable to create that face.

**Prototype:**

**bool MakeFlaggedPlanar (int selLev, DWORD flag=MN\_SEL, Point3 \*delta=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Moves the flagged components into their "average plane". (Plane computed using average component positions and normals.)

**Parameters:**

**int selLev**

Selection level, one of MNM\_SL\_VERTEX, MNM\_SL\_EDGE, MNM\_SL\_FACE, or MNM\_SL\_OBJECT.

**DWORD flag=MN\_SEL**

The flag that indicates which components to align. Ignored if msl is set to MNM\_SL\_OBJECT.

**Point3 \*delta=NULL**

If non-NULL, this is presumed to point to an array of size equal to MNMesh::numv, and instead of actually moving the vertices, the algorithm stores offsets in this array such that  $v[i].p + delta[i]$  is in the plane.

**Return Value:**

Indicates whether anything was moved. (Or if delta is non-NULL, if any deltas are nonzero.)

**Prototype:**

**bool MoveVertsToPlane (Point3 & norm, float offset, DWORD flag=MN\_SEL, Point3 \*delta=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Projects the flagged vertices into the specified plane.

**Parameters:**

**Point3 & norm, float offset**

The definition of the plane: DotProd (norm, x) - offset = 0.

**DWORD flag=MN\_SEL**

The flag that indicates which vertices to move.

**Point3 \*delta=NULL**

If non-NULL, this is presumed to point to an array of size equal to MNMesh::numv, and instead of actually moving the vertices, the algorithm stores offsets in this array such that  $v[i].p + delta[i]$  is in the plane.

**Return Value:**

Indicates whether anything was moved. (Or if delta is non-NULL, if any deltas are nonzero.)

**Prototype:**

**bool SplitFlaggedVertices (DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Splits the flagged vertices into a clone for each face using the vertex. For example, if used on the front top left corner of a standard 3ds max box, it splits the vertex into 3, one for the front face, one for the top face, and one for the left face.

**Parameters:**

**DWORD flag=MN\_SEL**

The flag that indicates which vertices to split.

**Return Value:**

TRUE if anything happened, FALSE if none of the vertices were split. (Note that this method will return FALSE if no vertices are flagged, but also if there are flagged vertices but they're all on 1 or 0 faces already.)

**Prototype:**

**bool SplitFlaggedEdges (DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

"Splits" edges by breaking vertices on two or more flagged edges into as many copies as needed. In this way, any path of flagged edges becomes an two open seams.

**Parameters:**

**DWORD flag=MN\_SEL**

Indicates which edges should be split. (Left at the default, selected edges are split.)

**Return Value:**

True if any topological changes happened, false if nothing happened.

**Prototype:**

**bool DetachFaces (DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Detaches specified faces to a separate element, cloning vertices and edges as necessary on the boundary between flagged and unflagged faces.

**Parameters:**

**DWORD flag=MN\_SEL**

Indicates which edges should be split. (Left at the default, selected edges are split.)

**Return Value:**

True if any faces were detached, false if nothing happened. (Note that the algorithm will return false if, for instance, all flagged faces form elements which are already distinct from those formed from non-flagged faces.)

**Prototype:**

**bool DetachElementToObject (MNMESH & nmesh, DWORD fflags=MN\_SEL, bool delDetached=true);**

**Remarks:**

This method is available in release 4.0 and later only.

Detaches specified faces to a new MNMesh.

**Parameters:****MNMesh & mesh**

An empty new mesh into which the detached faces (and accompanying vertices and edges) should be put.

**DWORD fflags=MN\_SEL**

Indicates which faces should be detached.

**Return Value:**

True if any faces were detached, false if nothing happened.

**Prototype:**

**bool ExtrudeFaceClusters (MNFaceClusters & fclust);**

**Remarks:**

This method is available in release 4.0 and later only.

Performs the topological component of an extrusion on all face clusters. Each cluster is "extruded", which means that vertices and edges on the boundary of the cluster are cloned and new faces and edges are created to connect the clones to the originals. (Note that nothing is moved in this process - movement is handled separately. See GetExtrudeDirection for details.)

**Parameters:****MNFaceClusters & fclust**

A list of face clusters. See the constructors in class MNFaceClusters and the face cluster related methods of class MNTempData for information on how to set up these clusters based on edge angles and face flags.

**Return Value:**

True if any faces were extruded, false if nothing happened.

**Prototype:**

**bool ExtrudeFaceCluster (MNFaceClusters & fclust, int cl);**

**Remarks:**

This method is available in release 4.0 and later only.

Performs the topological component of an extrusion on the specified face cluster. This means that vertices and edges on the boundary of the cluster are cloned and new faces and edges are created to connect the clones to the

originals. (Note that nothing is moved in this process - movement is handled separately. See GetExtrudeDirection for details.)

**Parameters:**

**MNFaceClusters & fclust**

A list of face clusters. See the constructors in class MNFaceClusters and the face cluster related methods of class MNTempData for information on how to set up these clusters based on edge angles and face flags.

**int cl**

The cluster we wish to extrude.

**Return Value:**

True if any faces were extruded, false if nothing happened.

**Prototype:**

**bool ExtrudeFaces (DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Performs the topological component of an extrusion on each flagged face individually. (This differs from ExtrudeFaceClusters in that each face is treated like its own cluster.) Extrusion means that the vertices and edges used by each flagged face are cloned, and new faces and edges are created on the "sides" to connect the clones to their originals. (Note that nothing is moved in this process - movement is handled separately. See GetExtrudeDirection for details.)

**Parameters:**

**DWORD flag=MN\_SEL**

The flag that identifies the faces we wish to extrude.

**Return Value:**

True if any faces were extruded, false if nothing happened.

**Prototype:**

**void GetExtrudeDirection (MNChamferData \*mcd,  
MNFaceClusters \*fclust=NULL, Point3 \*clustNormals=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Finds the direction vectors for the geometric component of an extrusion after the topological component has been completed. (See methods `ExtrudeFaceClusters`, `ExtrudeFaceCluster`, and `ExtrudeFaces` for details on the topological component.)

**Parameters:**

**MNChamferData \*mcd**

The data structure in which the extrusion directions are stored. (Note that there is no map support for this operation, as there is no well-defined way to modify mapping values during an extrusion drag.)

**MNFaceClusters \*fclust = NULL**

The face clusters.

**Point3 \*clustNormals = NULL**

The cluster normals.

This information is only needed if we're extruding by cluster normals. If we're extruding clusters by local normals or just extruding faces separately, these parameters can be left at NULL. See [class MNTempData](#) for handy methods to obtain cluster normals.

**Prototype:**

**bool SetVertColor (UVVert clr, int mp, DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets vertex colors for the specified vertices. This is done by finding all map vertices in the specified vertex color channel that correspond to each flagged vertex and setting them to the color given.

**Parameters:**

**UVVert clr**

The color to set the vertices to.

**int mp**

The map channel - use 0 for the standard vertex color channel, `MAP_SHADING` for the vertex illumination channel, or `MAP_ALPHA` for the alpha channel. (Note that alpha color values should always be shades of grey - `clr.r` should equal `clr.g` and `clr.b`.)

**DWORD flag=MN\_SEL**

Indicates which vertices to modify the colors of.

**Return Value:**

Returns true if any vertex colors were modified.

**Prototype:**

**bool SetFaceColor (UVVert clr, int mp, DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets vertex colors for the specified faces. This is done by finding all map vertices used by flagged faces and setting them to the color given. In cases where a map vertex is used by both a flagged and an unflagged face, the map vertex is split so that the unflagged faces' colors are unaffected by this change.

**Parameters:**

**UVVert clr**

The color to set the faces to.

**int mp**

The map channel - use 0 for the standard vertex color channel, MAP\_SHADING for the vertex illumination channel, or MAP\_ALPHA for the alpha channel. (Note that alpha color values should always be shades of grey - clr.r should equal clr.g and clr.b.)

**DWORD flag=MN\_SEL**

Indicates which faces to modify the colors of.

**Return Value:**

Returns true if any vertex colors were modified.

**Prototype:**

**bool ChamferVertices (DWORD flag=MN\_SEL, MNChamferData \*mcd=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Performs the topological component of a vertex chamfer on the flagged vertices, and provides the data needed to do the geometric component. That is

to say, this method clones the flagged vertices and creates the new edges and faces needed in a chamfer operation. It also determines the direction each vertex and mapping vertex will go as the user drags out the chamfer - but it doesn't actually move any vertices.

**Parameters:**

**DWORD flag=MN\_SEL**

Indicates which vertices to chamfer.

**MNChamferData \*mcd=NULL**

If non-NULL, this points to a data structure which should be filled with information needed to perform the geometric component of the chamfer, such as vertex directions and limits. See [class MNChamferData](#) for additional information.

**Return Value:**

True if any vertices were chamfered, false otherwise.

**Prototype:**

**bool ChamferEdges (DWORD flag=MN\_SEL, MNChamferData \*mcd=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Performs the topological component of an edge chamfer on the flagged edges, and provides the data needed to do the geometric component. That is to say, this method clones the flagged edges and creates the new vertices and faces needed in the edge chamfer operation. It also determines the direction each vertex and mapping vertex will go as the user drags out the chamfer - but it doesn't actually move anything.

**Parameters:**

**DWORD flag=MN\_SEL**

Indicates which edges to chamfer.

**MNChamferData \*mcd=NULL**

If non-NULL, this points to a data structure which should be filled with information needed to perform the geometric component of the chamfer, such as vertex directions and limits. See [class MNChamferData](#) for additional information.

**Return Value:**

True if any edges were chamfered, false otherwise.

**Prototype:**

**bool FlipElementNormals (DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Flips the normals of the specified elements in the mesh.

**Parameters:**

**DWORD flag=MN\_SEL**

Indicates which elements should be flipped, in the following way: any element that has at least one flagged face is completely flipped. Elements without any flagged faces are not.

**Return Value:**

Returns true if anything was flipped, false otherwise.

**Prototype:**

**void SmoothByCreases (DWORD creaseFlag);**

**Remarks:**

This method is available in release 4.0 and later only.

This is an auto-smooth algorithm that allows the developer to specify exactly which edges should be creases and which should be smoothed across. All face smoothing groups are rewritten by this algorithm. This algorithm is used, for example, in MeshSmooth, NURMS style, when the user turns on "smooth result" and applies crease values to some edges.

**Parameters:**

**DWORD creaseFlag**

Indicates which edges should be treated as creases. Edges that have the flag (or flags) set should be creases. Those that don't should not be creases.

**Prototype:**

**int CutFace (int f1, Point3 & p1, Point3 & p2, Point3 & Z, bool split);**

**Remarks:**

This method is available in release 4.0 and later only.

Implements the Editable Poly Cut algorithm from the face level - cuts from a point on one face to a point on another face.

**Parameters:****int f1**

The starting face of the Cut.

**Point3 & p1**

The starting point of the Cut, which should lie on face f1.

**Point3 & p2**

The end point of the Cut.

**Point3 & Z**

The view direction. All Cut algorithms require a view direction to establish the plane that the cut occurs in. This plane is defined by this Z vector and by the vector p2-p1. All new vertices created by the cut are in this plane.

**bool split**

If true, the faces on the top and bottom of the cut should have an open seam between them. All the edges and vertices along the cut (except for the first and last vertex) are split into two parts, one copy for the top and one for the bottom.

**Return Value:**

The last vertex created by the cut, or -1 if the cut was unable to finish.

**Prototype:**

```
int CutEdge (int e1, float prop1, int e2, float prop2, Point3 & Z,  
bool split);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implements the Editable Poly Cut algorithm from the edge level - cuts from a point on one edge to a point on another edge.

**Parameters:****int e1**

The starting edge of the Cut.

**float prop1**

The proportion along edge e1 where the cut should begin. That is, the first point should be located at  $(1-prop1)*v[e[e1].v1].p + prop1*v[e[e1].v2].p$ .

**int e2**

The ending edge of the Cut.

**float prop2**

The proportion along edge e2 where the cut should end. That is, the last point should be located at  $(1-prop2)*v[e[e2].v1].p + prop2*v[e[e2].v2].p$ .

**Point3 & Z**

The view direction. All Cut algorithms require a view direction to establish the plane that the cut occurs in. This plane is defined by this Z vector and by the vector between the start and end points. All new vertices created by the cut are in this plane.

**bool split**

If true, the faces on the top and bottom of the cut should have an open seam between them. All the edges and vertices along the cut (except for the first and last vertex) are split into two parts, one copy for the top and one for the bottom.

**Return Value:**

The last vertex created by the cut, or -1 if the cut was unable to finish.

**Prototype:**

**int Cut (int startv, Point3 & end, Point3 & Z, bool split);**

**Remarks:**

This method is available in release 4.0 and later only.

Implements the Editable Poly Cut algorithm from the vertex level - cuts from one vertex to another.

**Parameters:****int startv**

The starting vertex of the Cut.

**Point3 & end**

The location of the end vertex of the Cut.

**Point3 & Z**

The view direction. All Cut algorithms require a view direction to establish the plane that the cut occurs in. This plane is defined by this Z vector and by the vector between the start and end points. All new vertices created by the cut are in this plane.

**bool split**

If true, the faces on the top and bottom of the cut should have an open seam between them. All the edges and vertices along the cut (except for the first and last vertex) are split into two parts, one copy for the top and one for the bottom.

**Return Value:**

The last vertex created by the cut, or -1 if the cut was unable to finish.

**Prototype:**

**bool WeldBorderVerts (int v1, int v2, Point3 \*destination);**

**Remarks:**

This method is available in release 4.0 and later only.

Welds the specified border vertices together.

**Parameters:**

**int v1, int v2**

The vertices to be welded. They must be border vertices, in the sense that each of them must be used by open edges (those on only one face).

**Point3 \*destination**

If non-NULL, this indicates where the joined vertex should be located. (If NULL, it's put at the average location,  $(v[v1].p + v[v2].p)/2$ .)

**Return Value:**

True if anything was welded, false if the operation could not proceed.

**Prototype:**

**bool WeldBorderEdges (int e1, int e2);**

**Remarks:**

This method is available in release 4.0 and later only.

Welds the specified border edges together.

**Parameters:**

**int e1, int e2**

The edges to be welded. They must be border edges, in the sense that each of them must be open (used by only one face). The result is located where edge e2 was. e[e1].v1 is joined to e[e2].v2, and e[e1].v2 is joined to e[e2].v1.

**Return Value:**

True if anything was welded, false if the operation could not proceed.

**Prototype:**

**bool WeldBorderVerts (float thresh, DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Welds the specified border vertices together.

**Parameters:**

**float thresh**

The welding threshold. Vertices further apart than this distance (in object space) will not be welded.

**DWORD flag=MN\_SEL**

Indicates which vertices should be welded. (Non-border vertices, those in the "interior" of the surface, are ignored even if flagged.)

**Return Value:**

True if anything was welded, false otherwise.

## **Adding new components**

NOTE: all face creation methods clear the MN\_MESH\_FILLED\_IN, MN\_MESH\_NO\_BAD\_VERTS, and MN\_MESH\_VERTS\_ORDERED flags. If your calling routine takes care of the work of updating or creating all relevant MNVertices and MNEdges, you may be able to set these flags again -- but be careful! For some convenient face & edge subdivision methods that preserve a complete topology, check out the [Splitting](#) methods.

**Prototype:**

**int NewTri(int a, int b, int c, DWORD smG=0, MtlID mt=0);**

**Remarks:**

Creates a new tri-face. Note that no mapping coords or vertex colors can be specified.

**Parameters:**

**int a,b,c**

The indices of the vertices that form this triangle.

**DWORD smG=0**

The smoothing group(s) assigned to the new face.

**MtlID mt=0**

The material ID assigned to the new face.

**Return Value:**

Returns the index of the new face created.

**Prototype:**

**int NewTri(int \*vv, int \*tt, int \*cc, DWORD smG=0, MtlID mt=0);**

**Remarks:**

Creates a new face of degree 3. Edge selection and visibility flags are set to the default: all visible and not selected.

**Parameters:**

**int \*vv**

The indices of the vertices that form this face. (There must be 3 of these.)

**int \*tt**

If this is not NULL, it points to the indices of 3 mapping coordinates for this face.

**int \*cc**

If this is not NULL, it points to the indices of 3 vertex colors for this face.

**DWORD smG**

The smoothing group(s) assigned to this face.

**MtlID mt**

The material ID assigned to this face

**Return Value:**

The index of the face created.

**Prototype:**

```
int NewQuad(int a, int b, int c, int d, DWORD smG=0, MtlID  
mt=0);
```

**Remarks:**

This method will create a new quad.

Previous to 4.0 this method used two tri-faces that shared and invisible edge.

**Parameters:**

**int a, b, c, d**

The indices of the vertices that form this quad.

**DWORD smG=0**

The smoothing group(s) assigned to the new faces.

**MtlID mt=0**

The material ID assigned to the new faces.

**Return Value:**

Returns the index of the quad face created.

**Prototype:**

```
int NewQuad(int *vv, int *tt, int *cc, DWORD smG=0, MtlID  
mt=0);
```

**Remarks:**

This method will create a new quad.

Previous to 4.0 this method used two tri-faces that shared and invisible edge.

**Parameters:**

**int \*vv**

The indices of the vertices that form this face. (There must be 4 of these.)

**int \*tt**

If this is not NULL, it points to the indices of 4 mapping coordinates for this face.

**int \*cc**

If this is not NULL, it points to the indices of 4 vertex colors for this face.

**DWORD smG**

The smoothing group(s) assigned to this face.

**MtlID mt**

The material ID assigned to this face

**Return Value:**

Returns the index of the quad face created.

**Prototype:**

```
int NewFace(MNFace *ff, int degg=0, int *vv=NULL, bool  
*vis=NULL, bool *sel=NULL);
```

**Remarks:**

This method creates a (single) new face with the characteristics given. The default triangulation for a face of this degree is used; if the face is not convex, this triangulation may be inappropriate. If this is the case, call

**RetriangulateFace()** on this face after it's created.

**Parameters:****MNFace \*ff**

A current face from which smoothing groups, material ID, and flags should be copied. If this is NULL, these values are left at their default values.

**int degg**

The degree of the face to be created.

**int \*vv**

The indices of the vertices that form the new face. (There must be degg of these.)

**bool \*vis**

This is an array of visibility bits for the edges of the new face. If this is NULL, the default of all edges being visible is used. If this is not NULL, there must be degg values.

**bool \*sel**

This is an array of selection bits for the edges of the new face. If this is NULL, the default of all edges not being selected is used. If this is not NULL, there must be degg values.

**Prototype:**

```
int AppendNewFaces(int nfname);
```

**Remarks:**

This method is available in release 3.0 and later only.

Appends the specified number of MNFaces to **f**.

**Parameters:**

**int nfnnum**

The number of MNFaces to append.

**Return Value:**

The index of the first appended face (ie the old numf).

**Prototype:**

**void setNumFaces(int nfnnum);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified number of MNFaces allocated in **f**.

**Parameters:**

**int nfnnum**

The number of MNFaces to set.

**Prototype:**

**int RegisterEdge(int v1, int v2, int f, int fpos);**

**Remarks:**

Edge creation tool. If there is no edge currently joining vertices v1 and v2, it creates such an edge. If there is an edge starting at v2 and ending on v1, it registers face f as being on the "other side" of the edge.

**Parameters:**

**int v1, v2**

The start & end vertices of the edge you wish to register.

**int f**

The face on the "left" side of this edge, if you're looking from v1 towards v2 with the surface normal above.

**int fpos**

The index of this edge in face f. This is used to extract visibility and selection

information from the face.

**Return Value:**

The index of the new edge, or -1 if the edge already exists in the specified direction.

**Prototype:**

**int SimpleNewEdge(int v1, int v2);**

**Remarks:**

Edge creation tool. Simply makes a new edge from v1 to v2, without worrying about whether such an edge may already exist, or what faces may be on either side. Since edges are required to have at least one valid face on them, using this method obligates the developer to assign f1 on the new edge themselves.

**Return Value:**

The index of the new edge.

**Prototype:**

**int NewEdge(int v1, int v2, int f, int fpos);**

**Remarks:**

Edge creation tool. Requires the developer to previously ascertain that there is no edge from v1 to v2 or from v2 to v1.

**Parameters:**

**int v1, v2**

The start & end vertices of the edge you wish to create.

**int f**

The face on the "left" side of this edge, if you're looking from v1 towards v2 with the surface normal above.

**int fpos**

The index of this edge in face f. This is used to extract visibility and selection information from the face.

**Return Value:**

The index of the new edge.

**Prototype:**

**int AppendNewEdges(int nenum);**

**Remarks:**

This method is available in release 3.0 and later only.  
Appends the specified number of edges.

**Parameters:**

**int nenum**

The number of edges to append.

**Prototype:**

**void setNumEdges(int nenum);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the number of MNEdges allocated in **e**.

**Parameters:**

**int nenum**

The number of MNEdges to set.

**Prototype:**

**int NewVert(Point3 &p);**

**Remarks:**

This method is available in release 3.0 and later only.  
Creates a new vertex (increasing numv) and sets it to the specified point.

**Parameters:**

**Point3 &p**

The point to which the new vert should be initialized.

**Prototype:**

**int NewVert(Point3 &p, int vid);**

**Remarks:**

This method is available in release 3.0 and later only. It replaces the old  
MNMesh::NewVert (Point3 &p, MNVert \*mv=NULL) method.

Creates a new vertex (increasing numv) and initializes it to the point p and the flags and other characteristics of vertex vid.

**Parameters:**

**Point3 &p**

The point to which the new vert should be initialized.

**int vid**

The index of the existing MNVert from which flags and PerData info should be copied. (Only the MN\_SEL and MN\_TARG flags are copied.)

**Prototype:**

**int NewVert(int vid);**

**Remarks:**

This method is available in release 3.0 and later only.

Creates a new vertex and initializes it to location, flags and other characteristics of vertex vid.

**Parameters:**

**int vid**

The index of the existing MNVert from which location, flags and PerData info should be copied. (Only the MN\_SEL and MN\_TARG flags are copied.)

**Prototype:**

**int NewVert(int v1, int v2, float prop);**

**Remarks:**

This method is available in release 3.0 and later only.

Creates a new vertex which is a linear combination of two existing vertices. The new vertex has the MN\_SEL and MN\_TARG flags of whichever vertex it's closest to. The location and PerData info is interpolated.

**Parameters:**

**int v1**

The first vertex to combine.

**int v2**

The second vertex to combine.

**float prop**

The proportion along the segment from v1 to v2 where the new vertex should be located.

**Prototype:**

```
int AppendNewVerts(int nvnum);
```

**Remarks:**

This method is available in release 3.0 and later only.

Appends the specified number of MNVerts.

**Parameters:**

**int nvnum**

The number of MNVerts to append.

**Return Value:**

The index of the first appended vertex (ie the old numv).

**Prototype:**

```
void setNumVerts(int nvnum);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of verts, allocating if needed.

**Parameters:**

**int nvnum**

The desired number of vertices in the mesh.

## **Removing & Deleting Components**

**Prototype:**

```
void CollapseDeadVerts();
```

**Remarks:**

Removes all MNVerts with the MN\_DEAD flag from the list of vertices. Also, it re-indexes all the faces' and edges' vertex references to maintain mesh integrity.

**Prototype:****void CollapseDeadEdges();****Remarks:**

Removes all MNEdges with the MN\_DEAD flag from the list of edges. Also, re-indexes all the faces' and vertices' edge references to maintain mesh integrity.

**Prototype:****void CollapseDeadFaces();****Remarks:**

Removes all MNFaces with the MN\_DEAD flag from the list of faces. Also, re-indexes all the edges' and vertices' face references to maintain mesh integrity.

**Prototype:****void CollapseDeadStructs();****Remarks:**

Performs all 5 of the above collapse functions, safely removing all unused components from this mesh.

**Prototype:****void Clear();****Remarks:**

Reinitializes all verts, faces, and edges, freeing the data members of these components, but not freeing the vertex, edge, and face arrays themselves. This option is suitable if you need to clear a MNMesh you will be reusing. numv, etc, are set to 0.

**Prototype:****void ClearAndFree();****Remarks:**

This method is available in release 3.0 and later only.

Deletes everything and frees all relevant memory. Leaves you with an empty

MNMesh with the default flags.

**Prototype:**

**void freeVerts();**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the MNVert array and frees any corresponding vertex data.

**Prototype:**

**void freeEdges();**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the MNEdge array and frees and corresponding edge data.

**Prototype:**

**void freeFaces();**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the MNFace array.

**Prototype:**

**void freeMap(int mp);**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the MNMap on the specified map channel.

**Parameters:**

**int mp**

The map channel.

0: Vertex Color channel.

1: Default mapping channel.

2 through MAX\_MESHMAPS-1: The new mapping channels available in release 3.0.

**Prototype:****void freeMaps();****Remarks:**

This method is available in release 3.0 and later only.

Deletes and frees all the MNMaps.

**Prototype:****void DeleteFlaggedFaces(DWORD deathflags, DWORD  
nvCopyFlags=0x0);****Remarks:**

This method is available in release 2.5 and later only.

Deletes faces with any of the death flags set, as well as delete vertices and edges surrounded by faces with death flags, and correct the mesh components remaining.

**Parameters:****DWORD deathflags**

The collection of flags marking the faces you wish to kill.

**DWORD nvCopyFlags=0x0**

If the NO\_BAD\_VERTS flag is set on this mesh, DeleteFlaggedFaces will preserve this property. This may involve duplicating some vertices. (See EliminateBadVerts for more information.) If you have vertex flags that you want preserved in this duplication, indicate them in nvCopyFlags. MN\_SEL and MN\_TARG are always copied, but all other flags are cleared on the new vertex.

**Prototype:****void SetDispFlag(DWORD f);****Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the display flags.

**Parameters:****DWORD f**

The following flags are supported;

### **MNDISP\_VERTTICKS**

Displays vertices with tick-marks (plus signs).

### **MNDISP\_SELVERTS**

Displays selected vertices in red (and soft-selected vertices in soft selection colors).

### **MNDISP\_SELFACES**

Displays selected faces.

### **MNDISP\_SELEDGES**

Displays selected edges.

### **MNDISP\_NORMALS**

Displays face normals on selected faces.

### **MNDISP\_DIAGONALS**

Displays diagonals (using the same drawing style as regular Meshes use for hidden edges).

#### **Prototype:**

**DWORD GetDispFlag(DWORD f);**

#### **Remarks:**

This method is available in release 4.0 and later only.

This method returns the **displFlags & f**.

#### **Parameters:**

**DWORD f**

The following flags are supported;

### **MNDISP\_VERTTICKS**

Displays vertices with tick-marks (plus signs).

### **MNDISP\_SELVERTS**

Displays selected vertices in red (and soft-selected vertices in soft selection colors).

### **MNDISP\_SELFACES**

Displays selected faces.

### **MNDISP\_SELEDGES**

Displays selected edges.

### **MNDISP\_NORMALS**

Displays face normals on selected faces.

### **MNDISP\_DIAGONALS**

Displays diagonals (using the same drawing style as regular Meshes use for hidden edges).

#### **Prototype:**

**void ClearDispFlag(DWORD f);**

#### **Remarks:**

This method is available in release 4.0 and later only.

This method allows you to clear the specified display flags.

#### **Parameters:**

##### **DWORD f**

The following flags are supported;

##### **MNDISP\_VERTTICKS**

Displays vertices with tick-marks (plus signs).

##### **MNDISP\_SELVERTS**

Displays selected vertices in red (and soft-selected vertices in soft selection colors).

##### **MNDISP\_SELFACES**

Displays selected faces.

##### **MNDISP\_SELEDGES**

Displays selected edges.

##### **MNDISP\_NORMALS**

Displays face normals on selected faces.

##### **MNDISP\_DIAGONALS**

Displays diagonals (using the same drawing style as regular Meshes use for hidden edges).

### **Internal computation**

#### **Prototype:**

**void FillInMesh();**

#### **Remarks:**

If this mesh does not have the `MN_MESH_FILLED_IN` flag, this method completely recomputes all combinatorial information. It re-creates all `MNEdges` and `MNFace::edg`, `MNVert::edg`, and `MNVert::fac` lists based on the information in the `MNFace::vtx` lists.

Since this routine completely reconstructs the combinatorics, it clears the `MN_MESH_VERTS_ORDERED` flag.

**Prototype:**

**bool EliminateBadVerts (DWORD flag=0);**

**Remarks:**

A "bad" vertex in this context is one which is shared between two distinct boundaries for this mesh. As an example, imagine a union between two circles, converted to meshes, that touch at a single vertex. This causes a vertex to exist which is on two faces, but four edges. Since most vertices are on equal numbers of faces and edges (if they're not on a boundary) or on one more edge than face (if they are on a boundary), these types of vertices can mess up some forms of processing. This method eliminates such vertices by duplicating them, assigning one vertex to each boundary. A `MNMesh` that has gone through this method will have the `MN_MESH_NO_BAD_VERTS` flag set until a method (such as `NewFace`) is called that could conceivably create bad vertices.

`EliminateBadVerts` requires a filled in mesh, and will call `FillInMesh` if the `MN_MESH_FILLED_IN` flag is not set.

**Parameters:**

**DWORD flag:**

This parameter is available in release 4.0 and later only.

If nonzero, it indicates that only flagged vertices should be split up if "bad".

**Return Value:**

False if nothing changed, true if at least one bad vertex was found and split.

**Prototype:**

**void OrderVert (int vid);**

**Remarks:**

This method is available in release 4.0 and later only.

This routine organizes the face and edge lists of the specified vertex such that going counterclockwise around the vertex (with the surface normal pointing towards you), you'll encounter `edg[0]`, `fac[0]`, `edg[1]`, `fac[1]`, etc, ending in either the last face if the vertex is not on a boundary or the last edge if the vertex is on a boundary. (If the vertex is on a boundary, the first & last edges are part of that boundary.)

NOTE: `OrderVert` requires a filled-in mesh with no "bad" vertices. Failing to adequately prepare your mesh may result in a crash. (See the methods `FillInMesh` and `EliminateBadVerts` for details.)

**Prototype:**

**`void OrderVerts();`**

**Remarks:**

This routine organizes the face and edge lists of each vertex such that going counterclockwise around the vertex (with the surface normal pointing up), you'll encounter `edg[0]`, `fac[0]`, `edg[1]`, `fac[1]`, etc, ending in either the last face if the vertex is not on a boundary or the last edge if the vertex is on a boundary. (If the vertex is on a boundary, the first & last edges are part of that boundary.)

`OrderVerts` requires a filled-in mesh with no bad vertices, so it will call `FillInMesh` and/or `EliminateBadVerts` as needed.

**Prototype:**

**`void Triangulate();`**

**Remarks:**

Converts a `MN_MESH_NONTRI` mesh, with polygon faces and possibly hidden vertices, into a completely triangulated mesh, wherein all faces have degree 3. This routine is called from `OutToTri` if the `MN_MESH_NONTRI` flag is set.

**Prototype:**

**`void TriangulateFace(int ff);`**

**Remarks:**

Triangulates the specified face, splitting it into as many faces as are needed ( $\text{deg}-2+\text{hdeg}*2$ ) to represent all the triangles.

**Parameters:**

**int ff**

Specifies the face to triangulate.

**Prototype:**

**void InvalidateTopoCache();**

**Remarks:**

Clears out topology-dependent cache information. Note that this method clears topology-dependent flags such as **MN\_MESH\_FILLED\_IN**, and thus invalidates the edge list. If you have taken pains to preserve the integrity of your edge list, you should set the **MN\_MESH\_FILLED\_IN** flag immediately after calling **InvalidateTopoCache()**.

**Prototype:**

**void Transform(Matrix3 &xfm);**

**Remarks:**

Transforms all vertices & hidden vertices by xfm.

**Prototype:**

**bool IsClosed();**

**Remarks:**

Figures out if this mesh is completely closed. Meshes with the **MN\_MESH\_RATSNEST** flags are automatically considered open. Otherwise, each edge is checked to see if it has a face on both sides. If so, the mesh is closed. Otherwise, it's open.

**Prototype:**

**void BBox(Box3 & bbox, bool targonly=FALSE);**

**Remarks:**

Calculates the bounding box of the vertices & hidden vertices of this mesh.

**Parameters:****Box3 & bbox**

The computed bounding box is placed here.

**bool targonly**

If this is TRUE, only targeted vertices are used to compute the bounding box. Hidden vertices, which are also normally used, will be ignored in this case, since they cannot be targeted.

**Prototype:**

```
void checkNormals (BOOL illum);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method can be used to build the normals and allocate RVert space only if necessary. This is a very inexpensive call if the normals are already calculated. When illum is FALSE, only the RVerts allocation is checked (since normals aren't needed for non-illum rendering). When illum is TRUE, normals will also be built, if they aren't already. So, to make sure normals are built, call this with illum=TRUE.

**Parameters:****BOOL illum**

If TRUE normals are built. If FALSE only the RVert array is allocated.

**Prototype:**

```
void buildNormals ();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method resolves the normals on the RVertex array. If the MNMesh already has normals prescribed on each vertex, the normal is just moved to the RVertex array. See [Class RVertex](#) and [Class RNormal](#).

If you are creating or modifying a MNMesh, after you are done specifying all the vertices and faces, this method should be called. This allocates the RVertex and RNormal database for the MNMesh. This will allow you to query the MNMesh and ask about normals on the vertices.

This method also builds the face normals for the mesh if needed.

**Prototype:**

**void buildRenderNormals();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is similar to **buildNormals()** above, but ignores the material index (mtlIndex). In other words, the difference between this and **buildNormals()** is that it doesn't look at the mtlIndex of the faces: normals of faces with the same smoothing group are averaged regardless.

**Prototype:**

**void UpdateBackfacing (GraphicsWindow \*gw, bool force);**

**Remarks:**

This method is available in release 4.0 and later only.

Updates the **MN\_BACKFACING** flag in all components based on the specified view.

**Parameters:**

**GraphicsWindow \*gw**

A pointer to the current graphics window.

**bool force**

If the gw points to the same GraphicsWindow that it did last time this method was called, it doesn't necessarily need to update the flags. If force is true, it will update them anyway. (Useful if you think the GraphicsWindow perspective may have changed.)

**Prototype:**

**void render(GraphicsWindow \*gw, Material \*ma, RECT \*rp, int compFlags, int numMat=1, InterfaceServer \*pi=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Causes the MNMesh to display itself in the indicated GraphicsWindow.

**Parameters:****GraphicsWindow \*gw**

Points to the graphics window to render to.

**Material \*ma**

The list of materials to use to render the mesh. See [Class Material](#).

**RECT \*rp**

Specifies the rectangular region to render. If the mesh should be rendered to the entire viewport pass NULL.

**int compFlags**

One or more of the following flags:

**COMP\_TRANSFORM**

Forces recalculation of the model to screen transformation; otherwise attempt to use the cache.

**COMP\_IGN\_RECT**

Forces all polygons to be rendered; otherwise only those intersecting the box will be rendered.

**COMP\_LIGHTING**

Forces re-lighting of all vertices (as when a light moves); otherwise only re-light moved vertices

**COMP\_ALL**

All of the above flags.

**COMP\_OBJSELECTED**

If this bit is set then the node being displayed by this mesh is selected. Certain display flags only activate when this bit is set.

**int numMat=1**

The number of materials for the MNMesh.

**Prototype:**

```
void renderFace (GraphicsWindow *gw, int ff);
```

**Remarks:**

This method is available in release 4.0 and later only.

Displays the indicated face in the GraphicsWindow. This method is usually called only by **MNMesh::render()**.

**Parameters:**

**GraphicsWindow \*gw**

The GraphicsWindow in which to display this face.

**int ff**

The face to display.

**Prototype:**

**void render3DFace (GraphicsWindow \*gw, int ff);**

**Remarks:**

This method is available in release 4.0 and later only.

Displays the indicated face in the GraphicsWindow using hardware acceleration for texture and lighting if available. This method is usually called only by **MNMesh::render()**.

**Parameters:**

**GraphicsWindow \*gw**

The GraphicsWindow in which to display this face.

**int ff**

The face to display.

**Prototype:**

**void render3DDiagonals (GraphicsWindow \*gw, DWORD compFlags);**

**Remarks:**

This method is available in release 4.0 and later only.

Displays all face diagonals in the GraphicsWindow using hardware acceleration for texture and lighting if available. See the render method for a description of the parameters. This method is usually called only by **MNMesh::render()**.

**Prototype:**

**void renderDiagonals (GraphicsWindow \*gw, DWORD compFlags);**

**Remarks:**

This method is available in release 4.0 and later only.

Displays all face diagonals in the GraphicsWindow. See the render method for a description of the parameters. This method is usually called only by **MNMesh::render()**.

**Prototype:**

```
void renderDiagonal (GraphicsWindow *gw, int ff, bool  
useSegments=false, bool *lastColorSubSel=NULL);
```

**Remarks:**

This method is available in release 4.0 and later only.

Displays diagonals for the specified face in the GraphicsWindow. This method is usually called only by **MNMesh::render()**.

**Parameters:**

**GraphicsWindow \*gw**

The GraphicsWindow in which to display these diagonals.

**int ff**

The face to display the diagonals of.

**bool useSegments = false**

Indicates if we are in segment-drawing mode. See [class GraphicsWindow](#), method **segment()** for details.

**bool \*lastColorSubSel=NULL**

If non-NULL, it points to a bool variable which should be true if the last color set was the subobject selection color (**GetSubSelColor()**), and false if the color is set to the selected object color (**GetSelColor()**). This saves processing time that would be needed to switch between the two colors.

**Prototype:**

```
void render3DEdges (GraphicsWindow *gw, DWORD  
compFlags);
```

**Remarks:**

This method is available in release 4.0 and later only.

Displays all edges in the GraphicsWindow using hardware acceleration for

texture and lighting if available. See the render method for a description of the parameters. This method is usually called only by **MNMesh::render()**.

**Prototype:**

**void renderEdges (GraphicsWindow \*gw, DWORD compFlags);**

**Remarks:**

This method is available in release 4.0 and later only.

Displays all edges in the GraphicsWindow. See the render method for a description of the parameters. This method is usually called only by **MNMesh::render()**.

**Prototype:**

**void renderEdge (GraphicsWindow \*gw, int ee, bool useSegments=false, bool \*lastColorSubSel=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

Displays an edge in a GraphicsWindow. This method is usually called only by **MNMesh::render()**.

**Parameters:**

**GraphicsWindow \*gw**

The GraphicsWindow in which to display this edge.

**int ee**

The edge to display.

**bool useSegments = false**

Indicates if we are in segment-drawing mode. See [class GraphicsWindow](#), method **segment()** for details.

**bool \*lastColorSubSel=NULL**

If non-NULL, it points to a bool variable which should be true if the last color set was the subobject selection color (**GetSubSelColor()**), and false if the color is set to the selected object color (**GetSelColor()**). This saves processing time that would be needed to switch between the two colors.

**Prototype:**

**BOOL select (GraphicsWindow \*gw, Material \*ma, HitRegion \*hr, int abortOnHit=FALSE, int numMat=1);**

**Remarks:**

This method is available in release 4.0 and later only.

Checks the given HitRegion to see if it intersects this Mesh object.

**Parameters:**

**GraphicsWindow \*gw**

Points to the graphics window to check.

**Material \*ma**

The list of materials for the mesh.

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**int abortOnHit = FALSE**

If nonzero, the hit testing is complete after any hit. Note that although there is only one object to hit, setting this to TRUE prevents the algorithm from finding the closest hit on the MNMesh.

**int numMat=1**

The number of materials for the mesh.

**Return Value:**

TRUE if the item was hit; otherwise FALSE.

## **Component Targeting & Flag methods**

**Prototype:**

**void ClearVFlags(DWORD fl);**

**Remarks:**

Clears all specified flag bits in all MNVerts.

**Prototype:**

**void ClearEFlags(DWORD fl);**

**Remarks:**

Clears all specified flag bits in all MNEdges.

**Prototype:**

**void ClearFFlags(DWORD fl);**

**Remarks:**

Clears all specified flag bits in all MNFaces.

**Prototype:**

**void PaintFaceFlag(int ff, DWORD fl, DWORD fenceflags=0x0);**

**Remarks:**

This method is available in release 2.5 and later only.

Recursively sets flag on given face and all faces connected to it.

**Parameters:**

**int ff**

The face to begin painting the face flag on.

**DWORD fl**

The flag to set on these faces.

**DWORD fenceflags=0x0**

If nonzero, this represents flags of edges that should not be crossed. In this way you can set up a "fence" of edges and set a particular face flag on all the faces within that fence.

**Prototype:**

**void VertexSelect(const BitArray & vsel);**

**Remarks:**

This method is available in release 3.0 and later only.

Selects or deselects the verticies as specified by on bits in the given bit array.

If the bit array size is smaller than the number of verticies then only those verticies in the bit array are modified.

**Parameters:**

**const BitArray & vsel**

Specifies which verticies to select or deselect.

**Prototype:**

**void EdgeSelect(const BitArray & esel);**

**Remarks:**

This method is available in release 3.0 and later only.

Selects or deselects the edges as specified by on bits in the given bit array. If the bit array size is smaller than the number of edges then only those edges in the bit array are modified.

**Parameters:**

**const BitArray & esel**

Specifies which edges to select or deselect.

**Prototype:**

**void FaceSelect(const BitArray & fsel);**

**Remarks:**

This method is available in release 3.0 and later only.

Selects or deselects the faces as specified by on bits in the given bit array. If the bit array size is smaller than the number of faces then only those faces in the bit array are modified.

**Parameters:**

**const BitArray & fsel**

Specifies which faces to select or deselect.

**Prototype:**

**bool getVertexSel(BitArray & vsel);**

**Remarks:**

This method is available in release 3.0 and later only.

Fills the given bit array with the current vertex selection state.

**Parameters:**

**BitArray & vsel**

The results are stored here. Bits which are on indicate selected vertices.

**Prototype:**

**bool getEdgeSel(BitArray & esel);**

**Remarks:**

This method is available in release 3.0 and later only.

Fills the given bit array with the current edge selection state.

**Parameters:**

**BitArray & esel**

The results are stored here. Bit which are on indicate selected edges.

**Prototype:**

**bool getFaceSel(BitArray & fsel);**

**Remarks:**

This method is available in release 3.0 and later only.

Fills the given bit array with the current face selection state.

**Parameters:**

**BitArray & fsel**

The results are stored here. Bit which are on indicate selected faces.

**Prototype:**

**bool getVerticesByFlag(BitArray & vset, DWORD flags, DWORD fmask=0x0);**

**Remarks:**

This method is available in release 3.0 and later only.

Creates a BitArray of all vertices using the specified flags.

**Parameters:**

**BitArray & vset**

The BitArray which is filled in. vset is set to size numv.

**DWORD flags**

The flags to search for.

**DWORD fmask=0x0**

This optional parameter allows the user to look for particular combinations of on and off flags. For instance, if flags is MN\_DEAD and fmask is 0, the method finds vertices with the MN\_DEAD flag set. But if flags is MN\_SEL and fmask is MN\_SEL|MN\_DEAD, it would find vertices that have MN\_SEL set, but don't have MN\_DEAD set.

**Prototype:**

```
bool getEdgesByFlag(BitArray & eset, DWORD flags, DWORD  
fmask=0x0);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Creates a BitArray of all edges using the specified flags.

**Parameters:****BitArray & eset**

The BitArray which is filled in. eset is set to size nume.

**DWORD flags**

The flags to search for.

**DWORD fmask=0x0**

This optional parameter allows the user to look for particular combinations of on and off flags. For instance, if flags is MN\_DEAD and fmask is 0, the method finds edges with the MN\_DEAD flag set. But if flags is MN\_SEL and fmask is MN\_SEL|MN\_DEAD, it would find edges that have MN\_SEL set, but don't have MN\_DEAD set.

**Prototype:**

```
bool getFacesByFlag(BitArray & fset, DWORD flags, DWORD  
fmask=0x0);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Creates a BitArray of all faces using the specified flags.

**Parameters:****BitArray & fset**

The BitArray which is filled in. fset is set to size numf.

**DWORD flags**

The flags to search for.

**DWORD fmask=0x0**

This optional parameter allows the user to look for particular combinations of on and off flags. For instance, if flags is MN\_DEAD and fmask is 0, the method finds faces with the MN\_DEAD flag set. But if flags is MN\_SEL and

fmask is MN\_SEL|MN\_DEAD, it would find faces that have MN\_SEL set, but don't have MN\_DEAD set.

**Prototype:**

**void ElementFromFace(int ff, BitArray & fset);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets bits for all faces in the same "element", or connected component, with face ff. Faces already selected in fset will be considered "walls" for this processing and will not be evaluated. That is, if ff is not selected, but there's a ring of faces around it that is, the algorithm will stop at that ring.

**Parameters:**

**int ff**

The zero based index of the face.

**BitArray & fset**

The bits of the faces in the element are selected in this array.

**Prototype:**

**void BorderFromEdge(int ee, BitArray & eset);**

**Remarks:**

This method is available in release 3.0 and later only.

Takes a one-sided edge and sets the bits representing this edge's "border". (All one-sided edges in MNMeshes can be grouped into chains, end to end, that represent boundaries of the mesh. For instance, in a box with one side deleted, all the one-sided edges are part of the chain that goes around the hole.

**Parameters:**

**int ee**

The edge to start looking from. (Note that edge ee should be one-sided – e[ee].f2 should be -1.

**BitArray & eset**

The bitarray to return the border's edge set in.

**Prototype:**

**void SetEdgeVis(int ee, BOOL vis=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

This not only sets the edge's MN\_EDGE\_INVIS flag, it also sets the visedg state of the faces on either side. This is the proper way to set edge visibility permanently, as the MNEdge flag will be lost if the edge list needs to be reconstructed.

**Parameters:**

**int ee**

The edge whose visibility should be set.

**BOOL vis=TRUE**

The desired visibility – TRUE for visible, FALSE for invisible.

**Prototype:**

**void SetEdgeSel(int ee, BOOL sel=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

This not only sets the edge's MN\_SEL flag, it also sets the edgsel state of the faces on either side. This is the proper way to set edge selection permanently, as the MNEdge flag will be lost if the edge list needs to be reconstructed.

**Parameters:**

**int ee**

The edge whose selection state should be set.

**BOOL sel=TRUE**

The desired selection state.

**Prototype:**

**int TargetVertsBySelection(DWORD selLevel);**

**Remarks:**

Sets vertex MN\_TARG flags based on the existing MN\_SEL flags.

**Parameters:**

**DWORD selLevel**

Specifies which components to check for MN\_SEL flags. If selLevel is MNM\_SL\_OBJECT, all vertices are targeted. If selLevel is MNM\_SL\_VERTEX, the vertices with MN\_SEL flags set also have their MN\_TARG flags set. If selLevel is MNM\_SL\_FACE or MNM\_SL\_EDGE, vertices that touch selected faces or edges, respectively, have their MN\_TARG flags set.

**Return Value:**

The (highly) approximate number of targeted vertices.

**Prototype:**

**int TargetEdgesBySelection(DWORD selLevel);**

**Remarks:**

Sets edge MN\_TARG flags based on the existing MN\_SEL flags.

**Parameters:**

**DWORD selLevel**

Specifies which components to check for MN\_SEL flags. If selLevel is MNM\_SL\_OBJECT, all edges are targeted. If selLevel is MNM\_SL\_EDGE, the edges with MN\_SEL flags set also have their MN\_TARG flags set. If selLevel is MNM\_SL\_FACE or MNM\_SL\_VERTEX, edges that touch selected faces or vertices, respectively, have their MN\_TARG flags set.

**Return Value:**

The (highly) approximate number of targeted edges.

**Prototype:**

**int TargetFacesBySelection(DWORD selLevel);**

**Remarks:**

Sets face MN\_TARG flags based on the existing MN\_SEL flags.

**Parameters:**

**DWORD selLevel**

Specifies which components to check for MN\_SEL flags. If selLevel is MNM\_SL\_OBJECT, all faces are targeted. If selLevel is MNM\_SL\_FACE, the faces with MN\_SEL flags set also have their MN\_TARG flags set. If selLevel is MNM\_SL\_EDGE or MNM\_SL\_VERTEX, faces that touch

selected edges or vertices, respectively, have their MN\_TARG flags set.

**Return Value:**

The (highly) approximate number of targeted faces.

**Prototype:**

```
int PropegateComponentFlags(DWORD slTo, DWORD flTo,  
DWORD slFrom, DWORD flFrom, bool ampersand=FALSE, bool  
set=TRUE);
```

**Remarks:**

This method is available in release 3.0 and later only.

This allows the developer to set flags in one type of component based on what the nearby flags of another type of component are. For instance, you might want to set MN\_TARG on all vertices that are used by faces with the MN\_SEL flag set; that would be PropegateComponentFlags (MESH\_VERTEX, MN\_TARG, MESH\_FACE, MN\_SEL);

Another example:

```
PropegateComponentFlags (MNM_SL_OBJECT, MN_MESH_FILLED_IN,  
MNM_SL_EDGE, MN_DEAD, FALSE, FALSE);
```

This would clear the MN\_MESH\_FILLED\_IN flag from the MNMesh if any of its MNEdges were dead.

**Parameters:**

**DWORD slTo**

The selection level of the components you wish to set. This would be one of MNM\_SL\_OBJECT, MNM\_SL\_VERTEX, MNM\_SL\_EDGE, or MNM\_SL\_FACE.

**DWORD flTo**

The flag to set.

**DWORD slFrom**

The selection level of the components you wish to base the selection upon. This would be one of MNM\_SL\_OBJECT, MNM\_SL\_VERTEX, MNM\_SL\_EDGE, or MNM\_SL\_FACE.

**DWORD flFrom**

The flag to test.

**bool ampersand=FALSE**

When **slFrom** and **slTo** are different, this indicates whether the flags of the nearby components should be "or'd" or "and'd". If it's false, then any flagged components in the "from" level will cause the component in the "to" level to be affected. If true, then all the components in the "from" level that touch a component in the "to" level must be flagged in order for the "to" level component to be affected. (i.e., if from is faces and to is vertices, a vertex would only be modified if all faces that use it have the **flFrom** flag set.)

**bool set=TRUE**

If TRUE (as would be usual) the slTo components have flags flTo set. If FALSE, these flags would be cleared instead.

**Return Value:**

Returns the number of slFrom components that tested positive for the flFrom flags. (If 0, nothing happened.)

**Prototype:****void DetargetVertsBySharpness(float sharpval);****Remarks:**

Clears the MN\_TARG flag on vertices representing relatively flat areas, keeping the flag on vertices at sharper corners. The purpose of this method is to avoid working on smooth areas of the mesh in, for instance, tessellation algorithms which are designed to smooth an area. An example of this is the sharpness option in 3ds max's MeshSmooth modifier, although the parameter there is 1.0 - this value.

Note that this method requires filled in geometry and ordered vertices, and will call FillInMesh and OrderVerts as needed.

**Parameters:****float sharpval**

The threshold for determining whether a vertex is sharp enough to continue being targeted. A value of 0 indicates that all vertices are sharp enough; a value of 1 would de-target all vertices. The actual determination is made by comparing the dot product of any two consecutive face normals is less than  $1 - 2 * \text{sharpval}$ .

The following "fence" methods are useful for algorithms such as SabinDoo wherein you don't want to mix faces with different characteristics.

**Prototype:**

**void FenceMaterials();**

**Remarks:**

Sets the MN\_EDGE\_NOCROSS flag on all edges that lie between faces with different material IDs.

**Prototype:**

**void FenceSmGroups();**

**Remarks:**

Sets the MN\_EDGE\_NOCROSS flag on all edges that lie between faces with exclusive smoothing groups.

**Prototype:**

**void FenceFaceSel();**

**Remarks:**

Sets the MN\_EDGE\_NOCROSS flag on all edges that lie between selected & non-selected faces. (This checks the MN\_SEL, not the MN\_TARG, flags on the faces.)

**Prototype:**

**void FenceOneSidedEdges();**

**Remarks:**

Sets the MN\_EDGE\_NOCROSS flag on all edges that are on the boundary.

**Prototype:**

**void FenceNonPlanarEdges(float thresh=.9999f, bool makevis=FALSE);**

**Remarks:**

This method is available in release 2.5 and later only.

Sets **MN\_EDGE\_NOCROSS** flags on edges between faces that aren't in

the same plane.

**Parameters:**

**float thresh=.9999f**

This is the threshold used to determine if two adjacent faces have the same normals, i.e. lie in the same plane. If the dot product between the normals is less than thresh, they are considered different, otherwise they're considered the same. The threshold angle between faces is the arc cosine of this amount, so for instance to set a threshold angle of .5 degrees, you would call FenceNonPlanarEdges with a thresh of  $\cos(.5 * \text{PI} / 180.)$ . The default value is equivalent to about .81 degrees.

**bool makevis=FALSE**

Indicates whether nonplanar edges should be made visible, i.e. have their MN\_EDGE\_INVIS flag cleared. (This is sometimes done before MakePolyMesh, so it can be used to influence whether nonplanar faces are joined together.)

**Prototype:**

**void SetMapSeamFlags ();**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the MN\_EDGE\_MAP\_SEAM on all edges that are "seams" for any active map(s). A map seam is an edge where the faces on either side use different mapping vertices for at least one end.

**Prototype:**

**void SetMapSeamFlags (int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the MN\_EDGE\_MAP\_SEAM on all edges that are "seams" for the specified map(s). A map seam is an edge where the faces on either side use different mapping vertices for at least one end.

**Parameters:**

**int mp**

The map to use to set the seams. If left at the default -1, it'll check all active maps.

**Prototype:**

**void SetTVSeamFlags();**

**Remarks:**

Sets the **MN\_EDGE\_TV\_SEAM** flag on all edges whose endpoints on one face have mapping coordinates that are offset from the mapping coordinates of the same endpoints on the other face by the same amount. Operating on a standard cylinder with mapping coordinates assigned, for instance, this will set the **MN\_EDGE\_TV\_SEAM** flag on the column of edges that forms the "wrap" boundary for the mapping coordinates.

**Prototype:**

**void PrepForPipeline ();**

**Remarks:**

This method is available in release 4.0 and later only.

Prepares MNMesh for pipeline. This just does a few basic checks and modifies data caches to be consistent. In particular it throws away the edge list if the **MN\_MESH\_FILLED\_IN** flag is not set, and it frees any data in **MN\_DEAD** map channels. This is a good method to call at the end of any operation on an MNMesh.

## **Component information methods**

In the following face center methods, hidden vertices have no effect.

**Prototype:**

**void ComputeCenters(Point3 \*ctr, bool targonly=FALSE);**

**Remarks:**

Finds the centers of all the faces, using repeated calls to ComputeCenter.

**Parameters:**

**Point3 \*ctr**

An array of at least FNum() points for storing the centers.

**bool targonly**

If this is TRUE, centers will only be computed for targeted faces. (The rest of the ctr array will remain unmodified.)

**Prototype:**

```
void ComputeCenter(int ff, Point3 & ctr);
```

**Remarks:**

Finds the center of face ff by finding the average of all its vertices.

**Prototype:**

```
void ComputeSafeCenters(Point3 *ctr, bool targonly=FALSE, bool  
detarg=FALSE);
```

**Remarks:**

Finds the "safe" centers of all the faces, using repeated calls to ComputeSafeCenter.

**Parameters:****Point3 \*ctr**

An array of at least FNum() points for storing the centers.

**bool targonly**

If this is TRUE, centers will only be computed for targeted faces. (The rest of the ctr array will remain unmodified.)

**bool detarg**

If TRUE, this will remove the MN\_TARG flag from faces where safe centers could not be found.

**Prototype:**

```
bool ComputeSafeCenter(int ff, Point3 & ctr);
```

**Remarks:**

Finds the "safe" center of face ff, if possible. For non-convex faces, the average point found in ComputeCenter is unsuitable for some applications because it can lie outside the face completely, or in a region where it cannot "see" all the faces' vertices. (I.e., line segments from the center to the corner pass outside of the face.)

This routine provides a better solution in some cases by finding the center of the convex hull of the face. The convex hull is defined as the region in a face with a clear line-of-sight to all the corners. Some faces, such as the top face in an extruded letter M, have an empty convex hull, in which case this routine fails and merely provides the regular center given by ComputeCenter.

**Return Value:**

Returns TRUE if a safe center was found, FALSE if no such center could be found.

**Prototype:**

**void RetriangulateFace(int ff);**

**Remarks:**

This method is available in release 2.5 and later only.

Throws out the current triangulation for face ff and computes a new one. Note that hidden vertices that actually fall outside of the region of the face will be thrown out during this routine, since they cannot be incorporated into any triangulation and don't make sense anyway.

**Prototype:**

**void BestConvexDiagonals (int ff, int \*diag=NULL);**

**Remarks:**

This method is available in release 2.5 and later only.

If the given face is convex, this will often produce a better diagonals than RetriangulateFace would. The diagonals are less likely to overuse any single vertex. The face is not checked for convexity, but if it is not convex the diagonals produced will probably be self-overlapping.

**Parameters:**

**int ff**

The face to find a diagonal for.

**int \*diag=NULL**

If NULL, the new diagonals are put into the face's tri array. If this tri is non-NULL, the diagonals are put here instead. Be sure that tri is allocated with space for at least  $(deg-2+hdeg)*3$  elements.

**Prototype:**

```
void BestConvexDiagonals (int deg, int *vv, int *diag);
```

**Remarks:**

This method is available in release 4.0 and later only.

Uses a triangulation scheme optimized for convex polygons to find a set of diagonals for this sequence of vertices, creating a triangulation for the polygon they form.

**Parameters:**

**int deg**

The number of vertices in the sequence.

**int \*vv**

The array of vertices.

**int \*diag**

A pointer to an array of size  $(deg-3)*2$  where the diagonals can be put.

**Prototype:**

```
void FindDiagonals (int ff, int *diag);
```

**Remarks:**

Finds a diagonal of face ff that does not include any hidden vertices. This can be used with the method FindFacePointTri to get a sub-triangle and barycentric coordinates for a hidden vertex, so that vertex can be kept in the face when the non-hidden vertices are moved in some way.

**Parameters:**

**int ff**

The face to get an external diagonal of.

**int \*diag**

An array of at least  $(F(ff)->deg-2)*3$  elements to store the diagonals in.

**Prototype:**

```
void FindDiagonals (int deg, int *vv, int *diag);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method finds diagonals for this sequence of vertices, creating a triangulation for the polygon they form.

**Parameters:**

**int deg**

The number of vertices in the sequence.

**int \*vv**

The array of vertices.

**int \*diag**

A pointer to an array of size  $(deg-3)*2$  where the diagonals can be put.

**Prototype:**

**void FaceBBox(int ff, Box3 & bbox);**

**Remarks:**

Finds the bounding box of all vertices and hidden vertices used by face ff.

**Prototype:**

**int FindEdgeFromVertToVert(int vrt1, int vrt2);**

**Remarks:**

Finds an edge connecting these two vertices, if one exists. This algorithm is relatively fast, since it just checks the edges in  $V(vrt1)$ 's edge list. However, it requires that the MNMesh be filled in, and it WILL call the much slower FillInMesh routine if the MN\_MESH\_FILLED\_IN flag is not set.

**Return Value:**

The index of the desired edge, or -1 if no such edge could be found.

**Prototype:**

**void GetVertexSpace (int vrt, Matrix3 & tm);**

**Remarks:**

This method is available in release 4.0 and later only.

Chooses a suitable "local space", and sets tm's rotation to match that space.

Does not set tm's translation component. This is easily done by setting `tm.SetRow (3, v[vrt].p)`.

**Parameters:****int vrt**

The vertex index.

**Matrix3 & tm**

The transformation matrix.

**Prototype:****Point3 GetVertexNormal(int vrt);****Remarks:**

Returns the surface normal at the vertex **vrt**. It computes the normal by taking the average of the face normals from faces that **V(vrt)** is on, weighted by the angles of the **vrt** corners of each of those faces. That is, if **vrt** is at a very acute angle on one face, but a very obtuse angle on the next, the face with the obtuse **vrt** corner will count much more heavily. The return value has a length of 1.

This normal is not related to the normals used in rendering.

**Prototype:****Point3 GetEdgeNormal(int ed);****Remarks:**

Returns the surface normal at the edge **ed**. This is just the average of the face normals on either side, or, if this is an edge with only one face, it's just that face's normal. The return value has a length of 1.

This normal is not related to the normals used in rendering.

**Prototype:****Point3 GetFaceNormal(int fc, bool nrmlz=FALSE);****Remarks:**

Returns the surface normal of face **fc**. If this face has degree 3, this is the same as the regular 3ds max normal for this face. However, if the face is more complex, the normal may not be the same as the ones for the component triangles.

**Parameters:****int fc**

The index of the face to find the normal for.

**bool nrmlz**

Whether or not to scale the result to length 1. If this is FALSE, the length of the return value corresponds (in planar faces) to the area of the face, times 2.

**Prototype:**

**void FlipNormal(int faceIndex);**

**Remarks:**

This method is available in release 4.0 and later only.

This method flips the normal of the indicated face. This is done by reordering the vertices. The faces for any assigned texture map is handled as well.

**Parameters:**

**int faceIndex**

The index of the face for which to flip the normal.

**Prototype:**

**Point3 GetEdgeNormal(int vrt1, int vrt2);**

**Remarks:**

This merely combines GetEdgeNormal (int ed) with FindEdge (int vrt1, int vrt2). It returns the normal of the edge connecting vrt1 to vrt2, if such an edge can be found. (If there is no such edge, it returns Point3(0.0f, 0.0f, 0.0f).)

**Prototype:**

**int FindFacePointTri(int ff, Point3 & pt, double \*bary, int \*tri);**

**Remarks:**

Finds the sub-triangle and (optionally) barycentric coordinates within that triangle of a point that lies on this face. For faces that are not themselves triangles, this helps in particular to create mapping coordinates or vertex colors for new points on this face. To use this method, you must now call **MNFace::GetTriangles** to get a triangle table, then pass the contents of that table to this method. Note that the optional size of the triangulation array was removed; this is assumed to be (f[ff].deg-2)\*3.

**Parameters:**

**int ff**

The face.

**Point3 & pt**

The point.

**double \*bary**

An array of 3 double-precision values to store the barycentric coordinates in. If this is NULL, barycentric coordinates are not computed.

**int \*tri**

An optional alternative triangulation, such as that produced by FindExternalTriangulation. (If NULL, the face's regular triangulation is used.)

**Return Value:**

3 times the index of the triangle the point is found in, or -1 if this point doesn't seem to lie on this face. That is, if this point is found in the triangle represented by tri[6], tri[7], and tri[8], this routine will return 6.

**Prototype:**

**UVVert FindFacePointMapValue(int ff, Point3 & pt, int mp);**

**Remarks:**

This method is available in release 3.0 and later only. It's the generalized version of the old FindFacePointCV and FindFacePointTV.

Uses FindFacePointTri and the mapping coordinates of the endpoints of the relevant triangle to compute a map vertex corresponding to the point pt. If the point is not on face ff, UVVert (0,0,0) is returned.

This method is useful e.g. for getting map coordinates to match a new vertex when dividing up a face.

**Parameters:**

**int ff**

The face to find map coordinates on.

**Point3 & pt**

The point (lying on the face) to find map coordinates for.

**int mp**

The map channel to get map coordinates in.

**Prototype:****VertColor FindFacePointCV(int ff, Point3 & pt);****Remarks:**

Uses FindFacePointTri and the vertex colors of the endpoints of the relevant triangle to compute a vertex color corresponding to the point pt. If the point is not on face ff, VertColor (0.0f,0.0f,0.0f) (black) is returned.

**Prototype:****UVVert FindFacePointTV(int ff, Point3 & pt);****Remarks:**

Uses FindFacePointTri and the mapping coordinates of the endpoints of the relevant triangle to compute mapping coordinates corresponding to the point pt. If the point is not on face ff, UVVert (0.0f,0.0f,0.0f) is returned.

**Prototype:****int IntersectRay (Ray& ray, float& at, Point3& norm);****Remarks:**

This method is available in release 4.0 and later only.

Provides the intersection point and normal for the ray with this mesh.

**Parameters:****Ray & ray**

The ray we want an intersection point for.

**float & at**

This is filled in with a value giving the intersection point along the ray. (The actual point is computed by  $\text{ray.p} + \text{ray.dir} * \text{at}$ .)

**Point3 & norm**

Filled in with the surface normal at the intersection point.

**Return Value:**

Returns TRUE if an intersection point was found, or FALSE if the ray doesn't intersect this MNMesh.

**Prototype:**

**int IntersectRay (Ray& ray, float& at, Point3& norm, int &fi, Tab<float> & bary);**

**Remarks:**

This method is available in release 4.0 and later only.

Provides the intersection point and normal for the ray with this mesh.

**Parameters:**

**Ray & ray**

The ray we want an intersection point for.

**float & at**

This is filled in with a value giving the intersection point along the ray. (The actual point is computed by  $\text{ray.p} + \text{ray.dir} * \text{at}$ .)

**Point3 & norm**

Filled in with the surface normal at the intersection point.

**int & fi**

Filled in with the face index for the face that was hit by the ray.

**Tab<float> & bary**

Filled in with the "generalized barycentric coordinates" of the intersection point on the face. This is a table of floats of size  $f[\text{fi}].\text{deg}$ , where each float represents the contribution of the corresponding face vertex, and where the floats all sum to 1.

**Return Value:**

Returns TRUE if an intersection point was found, or FALSE if the ray doesn't intersect this MNMesh.

**Prototype:**

**BitArray VertexTempSel (DWORD fmask=MN\_DEAD|MN\_SEL, DWORD fset=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

Gets the current vertex selection, based on the current selection level. That is, if the current selection level is **MNM\_SL\_VERTEX** and the parameters are at their defaults, it'll return the current vertex selection, but if the selection level is **MNM\_SL\_FACE**, for instance, it'll return the vertices used by

currently selected faces.

This method is used, e.g. in `PolyObject::Deform` to determine which vertices to affect by pipeline modifiers.

**Parameters:**

**DWORD fmask=MN\_DEAD|MN\_SEL**

Indicates the flags we're trying to match in the components at the current selection level.

**DWORD fset=MN\_SEL**

Indicates which flags (from fmask) we want to see set. The default values mean "find components with **MN\_SEL** set and **MN\_DEAD** cleared".

**Prototype:**

**void ShallowCopy(MNMesh \*amesh, ULONG\_PTR channels);**

**Remarks:**

This method is available in release 4.0 and later only.

Provides the guts of pipeline shallow copying. Used by

**PolyObject::ShallowCopy()**.

**Prototype:**

**void NewAndCopyChannels(ULONG\_PTR channels);**

**Remarks:**

This method is available in release 4.0 and later only.

Provides the guts of pipeline new & copying. Used by

**PolyObject::NewAndCopyChannels()**.

**Prototype:**

**void FreeChannels (ULONG\_PTR channels, BOOL zeroOthers=1);**

**Remarks:**

This method is available in release 4.0 and later only.

Provides the guts of pipeline channel freeing. Used by

**PolyObject::FreeChannels()**.

## Smoothing-group & Material methods

### Prototype:

```
void Resmooth(bool smooth=TRUE, bool targonly=FALSE,  
DWORD targmask=~0x0);
```

### Remarks:

Applies new smoothing (or removes smoothing groups) from selected areas of the MNMesh. With the default parameters, it smoothes all faces with the same group.

### Parameters:

#### **bool smooth**

If TRUE, Resmooth will generate a new smoothing group (using GetNewSmGroup) to apply to the relevant faces. All smoothing groups previously assigned to the faces will be removed. If FALSE, Resmooth will strip all smoothing groups, leaving the faces faceted.

#### **bool targonly**

If TRUE, Resmooth will not affect faces that do not have the MN\_TARG flag set.

#### **DWORD targmask**

Resmooth will only affect faces whose smoothing groups are included in targmask. Some examples: with the default value of ~0x0, this is no restriction at all. With a value of 0, Resmooth will only affect faces that previously had no smoothing group assigned. With a value of 0x02, Resmooth will only affect faces that either had smoothing group 2 (and nothing else) or no smoothing group.

Note: if **targonly** is TRUE and targmask is not at the default, a face must both be targeted and have its smoothing groups fall into targmask in order to be affected.

### Prototype:

```
DWORD CommonSmoothing(bool targonly=FALSE);
```

### Remarks:

Finds what smoothing groups, if any, are common to all faces in this MNMesh.

**Parameters:**

**bool targonly**

If this is TRUE, this routine will find smoothing groups that are common to all faces with MN\_TARG set, ignoring the rest.

**Prototype:**

**DWORD GetAllSmGroups(bool targonly=FALSE);**

**Remarks:**

This method is available in release 2.5 and later only.

Find all smoothing groups used in this mesh.

**Parameters:**

**bool targonly=FALSE**

If TRUE, this method will return only smoothing groups set in targeted faces, i.e. those with the MN\_TARG flag set.

**Return Value:**

The return value is a DWORD with every used smoothing bit set.

**Prototype:**

**DWORD GetNewSmGroup(bool targonly=FALSE);**

**Remarks:**

Produces a single smoothing group that is not currently used in the MNMesh. If this is impossible because all smoothing groups are used (a rare condition), it produces the least commonly used group.

**Parameters:**

**bool targonly**

If TRUE, this routine will find a smoothing group not used by any of the faces with MN\_TARG set. If this is impossible because all smoothing groups are used in targeted faces, it produces the least commonly used group.

**Prototype:**

**DWORD FindReplacementSmGroup(int ff, DWORD os);**

**Remarks:**

This method is available in release 2.5 and later only.

Finds available smoothing groups you can use to replace the given smoothing

group without messing up the mesh's shading. This method recursively looks at the entire region of faces sharing this smoother with this face, and it finds all smoothing groups used by neighboring faces. Then it returns the bits which are not used by any of them.

This is useful if, for instance, you want to attach two separate mesh components, but you don't want smooth shading across the join. It's used internally by `SeparateSmGroups`.

**Parameters:**

**int ff**

The face to start the examination on.

**DWORD os**

The old smoothing group you wish to replace.

**Return Value:**

All bits that are available to replace the old smoothing group with.

**Prototype:**

**void PaintNewSmGroup(int ff, DWORD os, DWORD ns);**

**Remarks:**

This method is available in release 2.5 and later only.

Recursively replaces the old smoothing group with the new smoothing group. The recursion traverses all faces with the old smoother that share an edge or a vertex.

**Parameters:**

**int ff**

The face to begin the replacement on

**DWORD os**

The old smoothing group

**DWORD ns**

The new smoothing group

**Prototype:**

**bool SeparateSmGroups(int v1, int v2);**

**Remarks:**

This method is available in release 2.5 and later only.

Changes the smoothing groups on faces using v2 so that they are distinct from any smoothing groups on faces using v1. This is used, for instance, in joining the seam between the operands MakeBoolean. Before welding each pair of vertices, this method is called to prevent smoothing across the boolean seam.

**Return Value:**

If, due to overuse of the 32 smoothing groups, the algorithm can't find enough new ones to replace the overlapping smoothing groups around v2, it will do the best it can and return FALSE. If it succeeds, it returns TRUE.

**Prototype:**

**MtlID GetNewMtlID(bool targonly = FALSE);**

**Remarks:**

Produces the lowest material ID not used in any faces in the MNMesh.

**Parameters:**

**bool targonly**

If TRUE, this routine will instead find the lowest material ID not used in the targeted faces of this MNMesh.

**Prototype:**

**DWORD GetOldSmGroup(bool targonly=FALSE);**

**Remarks:**

Returns a smoothing group that is currently used somewhere in the mesh, or returns zero if all faces have no smoothing.

**Parameters:**

**bool targonly**

If TRUE, this routine will find a smoothing group used in one of the targeted faces, or return zero if all targeted faces have no smoothing.

**Prototype:**

**void AutoSmooth(float angle,BOOL useSel,BOOL preventIndirectSmoothing);**

**Remarks:**

This method is available in release 4.0 and later only.

This method performs an auto smooth on the mesh, setting the smoothing groups based on the surface normals.

**Parameters:**

**float angle**

The minimum angle between surface normals for smoothing to be applied, in radians.

**BOOL useSel**

If TRUE only the selected faces are smoothed.

**BOOL preventIndirectSmoothing=FALSE**

TRUE to turn on; FALSE to leave off. This matches the option in the Smooth Modifier UI -- use this to prevent smoothing "leaks" when using this method. If you use this method, and portions of the mesh that should not be smoothed become smoothed, then try this option to see if it will correct the problem. Note that the problem it corrects is rare, and that checking this slows the Auto Smooth process.

**Prototype:**

```
void ApplyMapper (UVWMapper & mp, BOOL channel=0,  
BOOL useSel=FALSE);
```

**Remarks:**

This method is available in release 4.0 and later only.

Applies UVW Mapper to create the desired mapping in the specified channel.

**Parameters:**

**UVWMapper & mp**

The mapping scheme. See [class UVWMapper](#) for details.

**BOOL channel=0**

The channel to apply the map to. Channel 0 is normally the vertex color channel. Channels 1-99 are the normal user-accessible mapping channels. Channels **MAP\_SHADING** and **MAP\_ALPHA** are used for vertex illumination and alpha.

**BOOL useSel=FALSE**

Indicates whether the specified mapping should be applied only to selected faces (instead of the whole object). In cases where the map channel was previously unused, a default map will be applied to nonselected faces, and the

specified map will be applied to the selected faces.

## Face-joining methods

### Prototype:

```
void MakePolyMesh();
```

### Remarks:

Turns a mesh with triangle faces into a mesh with (fewer) polygon faces by removing all hidden edges. This method can take unusually long if there are faces of ridiculously high degree, such as the top of a cylinder with 200 sides but only 1 cap segment. (It can be up to an n-squared routine where n is the number of invisible edges removed to make a given face.)

This routine is essentially a bunch of calls to **RemoveEdge()**, followed by a call to **EliminateCollinearVerts()**.

### Prototype:

```
void MakeConvexPolyMesh();
```

### Remarks:

This method is available in release 2.5 and later only.

Turns a mesh with triangle faces into a mesh with (fewer) convex polygon faces by removing all hidden edges that aren't necessary to maintain convexity. As of the 2.5 release this method has not been thoroughly tested to ensure that the result is indeed always convex and that it doesn't leave edges that should ideally be removed. Therefore a call to **MakeConvex** is recommended after use. What we can say about it is that it will not produce any hidden vertices, as **MakePolyMesh** does, and that if you're going to use **MakeConvex** anyway, **MakeConvexPolyMesh** and **MakeConvex** are more efficient than **MakePolyMesh** and **MakeConvex** are.

**MakeConvex** essentially undoes a lot of the work done by **MakePolyMesh**. **MakeConvexPolyMesh** gives it much less (if anything) to undo.

### Prototype:

```
void RemoveEdge(int edge);
```

### Remarks:

Kills the edge and joins the faces on either side. Does not work with one-sided

edges. Re-indexes triangulation in the resulting face to maintain MN\_MESH\_FILLED\_IN integrity. This routine also checks the resulting face for "dangling" edges: if two faces share a common boundary of 3 edges, and the middle edge is removed, the other two edges will actually have the same face on both sides. This is silly, so such edges are also removed & killed, reducing the degree of the face and adding a hidden vertex.

**Prototype:**

**void MakeConvex();**

**Remarks:**

Calls **MakeFaceConvex()** on all (non-dead) faces, producing a mesh with 100% convex faces.

**Prototype:**

**void MakeFaceConvex(int ff);**

**Remarks:**

Makes face ff convex, essentially by chopping off corners. The corners themselves become new faces. This routine is actually recursive: if this face is already convex, it returns without affecting it. If not, it finds a suitable line (between outside vertices) to divide the face along, and then calls **MakeFaceConvex()** again on both of the smaller faces. It is crucial that the face given to MakeFaceConvex has a valid triangulation.

**Prototype:**

**void EliminateCollinearVerts();**

**Remarks:**

This routine scans through a mesh from which invisible edges have been removed, looking for vertices that essentially seem to lie in the middle of edges. Such "collinear vertices" actually lie between two edges that are parallel, with the same faces on either side, and with no other edges incident on them. These are easily removed, and if not removed, they can cause unpleasant artifacts in some tessellation algorithms.

The removal of these vertices consists of deleting them, merging the parallel edges into one (longer) edge, and correcting the faces on either side to have

one less vertex and edge.

Note that this is essentially the opposite of the method `SplitEdge`.

**Prototype:**

**void EliminateCoincidentVerts(float thresh=MNEPS);**

**Remarks:**

This merges vertices that lie extremely close together, similar to what's done in Edit Mesh's `Weld` function, but it only affects vertices that are joined by an edge. Another way of looking at it is that it uses `weld` to remove extremely small edges.

**Parameters:**

**float thresh=MNEPS**

This is the maximum length of an edge that will be welded away. The default value of `MNEPS` is defined in `MNCommon.h` to be `.0001` -- generally we use this to delete edges of more or less zero length.

**Splitting methods**

**Prototype:**

**int SplitEdge(int ee, float prop=.5f);**

**Remarks:**

This method is available in release 2.5 and later only.

Creates a new vertex somewhere in the middle of an edge, splitting the edge into two edges. Incident faces are updated in their vertex, edge, mapping coordinate, and vertex color lists, as well as in their triangulation. This method requires that `MN_MESH_FILLED_IN` be set (otherwise it will cause an assertion failure), and maintains the combinatorics completely.

**Parameters:**

**int ee**

The edge to split.

**float prop=.5f**

The proportion along the edge where the new vertex should go. This proportion should be between 0 and 1. The new vertex location is  $P(E(ee) \rightarrow v1) * (1.0f - prop) + P(E(ee) \rightarrow v2) * prop$ .

**Return Value:**

The index of the new vertex.

**Prototype:**

```
int SplitEdge(int ff, int ed, float prop, bool right, int *nf=NULL, int *ne=NULL, bool neVis=FALSE, bool neSel=FALSE, bool allconvex=FALSE);
```

**Remarks:**

This method is available in release 2.5 and later only.

Splits an edge that is specified from the face level, and splits off triangles from the adjacent faces. This method is often preferable in convex meshes, when it's important that no nonconvex faces are introduced. The other SplitEdge methods leave faces with three vertices in a line, which is not strongly convex. This version makes a triangle out of half of the split edge, the next face edge, and a diagonal.

Note: This method absolutely requires that the faces on either side of the edge being split are Convex. Use MakeFaceConvex if needed.

**Parameters:**

**int ff**

One of the faces which uses the edge you wish to split.

**int ed**

The index of the edge in face ff.

**float prop**

The proportion along the edge where the new vertex should go. This proportion should be between 0 and 1. The new vertex location is  $P(E(ee) \rightarrow v1) * (1.0f - prop) + P(E(ee) \rightarrow v2) * prop$ .

**bool right**

If FALSE, the new triangle is formed from the lower or "left" half of the split edge. If TRUE, it's formed from the higher or "right" half. (These orientations make sense if you imagine viewing the face from above with the split edge on the bottom, as pictured.) If you want the triangle to be formed from the smaller half, use  $(prop \leq .5f)$  for this argument.

**int \*nf=NULL**

If non-NULL, this should point to an array of at least 2 elements where the new face indices should be put. Nf[0] is set to the new face created from face ff, while nf[1] is set to the new face created from the face on the other side of

the edge, if any.

**int \*ne=NULL**

If non-NULL, this should point to an array of at least 3 elements where the new edge indices should be put. Ne[0] is set to the new edge created from the second half of the edge we're splitting. Ne[1] represents the diagonal edge on face ff, while ne[2] represents the diagonal edge on the face on the other side of the split edge (if any).

**bool neVis=FALSE**

Indicates whether the new edges ne[1] and ne[2] should be visible.

**bool neSel=FALSE**

Indicates whether the new edges ne[1] and ne[2] should be selected.

**bool allconvex=FALSE**

Indicates whether the original faces on both sides of the edge are guaranteed to be convex. If so, these faces are retriangulated with BestConvexTriangulation; otherwise, RetriangulateFace is used.

**Return Value:**

The index of the new vertex.

**Prototype:**

**int SplitTriEdge(int ee, float prop=.5f, float thresh=MNEPS, bool neVis=TRUE, bool neSel=FALSE);**

**Remarks:**

Creates a new vertex in the middle of an edge, splitting the edge into two edges. Unlike SplitEdge, this routine requires a triangle face on each side. Since it has this, it also creates new edges connecting the new vertex with the point opposite the split edge on each face. This in turn splits the faces. So two triangles sharing this single edge become four triangles with four shared edges meeting at a single new vertex.

This method requires that MN\_MESH\_FILLED\_IN be set (otherwise it will cause an assertion failure), and maintains the combinatorics completely.

**Parameters:**

**int ee**

The edge to split. Note that if the faces on either side do not have deg=3 and hdeg=0, an assertion failure will result.

**float prop**

The proportion along the edge for the new vertex to be located. This ranges from 0, at v1, to 1, at v2. A value of .3, for instance, would create a new vertex at  $.7 * P(v1) + .3 * P(v2)$ .

**float thresh**

If prop is less than thresh or more than 1-thresh, the method will not split the edge, and will return v1 or v2 respectively. This is so that calling routines can safely pass values anywhere from 0 to 1, without worrying about creating tiny "shard" faces.

**bool neVis**

This tells whether the new edges that split the faces should be visible. (The new edge formed from part of the old edge takes such characteristics from the old edge.)

**bool neSel**

This tells whether the new edges that split the faces should be selected. (The new edge formed from part of the old edge takes such characteristics from the old edge.)

**Return Value:**

The index of the new vertex created, or the index of the old vertex you can use instead if you're within thresh of the endpoints.

**Prototype:**

```
int IndentFace(int ff, int ei, int nv, int *ne=NULL, bool nevis=TRUE, bool nesel=FALSE);
```

**Remarks:**

This method is available in release 2.5 and later only.

Uses a new vertex to "indent" one of the sides of the face. The indentation triangle is split off as a new face, which is returned.

**Parameters:****int ff**

The face to be "indented".

**int ei**

The index of the edge which will be replaced by the indentation.

**int nv**

The index of the new vertex. This vertex should lie within the face, in the face's plane, and should not be connected to any faces or edges.

**int \*ne=NULL**

If non-NULL, this should point to an array of at least 2 elements where the new edges should be stored.

**bool nevis=TRUE**

Indicates whether the new edges should be visible.

**bool nesel=FALSE**

Indicates whether the new edges should be selected.

**Return Value:**

The index of the new face representing the indentation triangle.

**Prototype:**

**void SeparateFace(int ff, int a, int b, int & nf, int & ne);**

**Remarks:**

This routine is used in MakeFaceConvex, but can be used outside of it too. It takes a larger face and divides it into two smaller faces, creating a new edge in the process.

It is crucial that the face given to SeparateFace has a valid triangulation.

**Parameters:**

**int ff**

The face to divide.

**int a,b**

The indices (in the face's vtx list) of the vertices used to divide the face. Note that a and b should be at least two units apart in each direction: a can't be (b+1) mod deg, and b can't be (a+1) mod deg. Also, the straight line connecting MNVerts V(vtx[a]) and V(vtx[b]) should not cross any of the edges of the face, otherwise the results will be truly screwed.

**int & nf**

A variable to hold the new face created by this division. (Half the face remains as face ff, the other half is the new face nf.)

**int & ne**

A variable to hold the new edge created by this division.

**Prototype:**

```
void SeparateFace(int ff, int a, int b, int & nf, int & ne, bool neVis,  
bool neSel);
```

**Remarks:**

This method is available in release 2.5 and later only.

This routine takes a larger face and divides it into two smaller faces, creating a new edge in the process. It is crucial that the face given to SeparateFace has a valid triangulation.

**Parameters:****int ff**

The face to divide.

**int a, b**

The indices (in the face's vtx list) of the vertices used to divide the face. Note that a and b should be at least two units apart in each direction: a can't be  $(b+1) \bmod \text{deg}$ , and b can't be  $(a+1) \bmod \text{deg}$ . Also, the straight line connecting MNVerts  $V(\text{vtx}[a])$  and  $V(\text{vtx}[b])$  should not cross any of the edges of the face, otherwise the results will not be valid.

**int & nf**

A variable to hold the new face created by this division. (Half the face remains as face ff, the other half is the new face nf.)

**int & ne**

A variable to hold the new edge created by this division.

**bool neVis**

Indicates whether the new edge should be visible. (The other version of SeparateFace always leaves the edge invisible.)

**bool neSel**

Indicates whether the new edge should be selected. (The other version of SeparateFace always leaves the edge unselected.)

**Prototype:**

```
void Slice(Point3 & N, float off, float thresh, bool split, bool  
remove, DWORD selLevel);
```

**Remarks:**

This method is available in release 2.5 and later only.

Slices the MNMesh along a specified plane, splitting edges and faces as needed to divide faces into those above and those below the plane. Equivalent to the Slice modifier.

**Parameters:**

**Point3 & N**

The normal to the slice plane. This should be a unit vector.

**float off**

The offset of the slice plane. For any point X in the plane,  $\text{DotProd}(\text{N}, \text{X}) = \text{off}$ .

**float thresh**

If a vertex lies within thresh of the splitting plane, ie if  $\text{abs}(\text{DotProd}(\text{N}, \text{X}) - \text{offset}) < \text{thresh}$  for a point X, it's considered to be on the plane. This prevents some points being created extremely close to each other. Zero is an acceptable value; the constant MNEPS is what's used in the Slice Modifier.

**bool split**

Indicates whether the points and edges along the slice should be replicated, dividing the mesh into separate "above" and "below" connected components. Equivalent to the Slice modifier's "Split Mesh".

**bool remove**

Indicates whether the portion of the mesh above the split plane should be removed. Equivalent to the Slice modifier's "Remove Top". (To "Remove Bottom", just multiply N and off by -1.)

**DWORD selLevel**

Indicates whether the Slice effect should be restricted to selected faces. There is no support currently for slicing selected edges or vertices, but if  $\text{selLevel} == \text{MNM\_SL\_FACE}$ , only selected faces will be sliced or removed.

**Prototype:**

```
int SplitTriFace(int ff, double *bary=NULL, float thresh=MNEPS, bool neVis=TRUE, bool neSel=FALSE);
```

**Remarks:**

Adds a vertex somewhere in a triangle face, and also adds edges from that vertex to each of the corners, splitting the face into 3 smaller triangle faces. The triangle face used here can have hidden vertices, as long as it is of degree

3. However, if the threshold parameter comes into play and this routine calls SplitTriEdge, both this face and the one across the relevant edge will need to have both degree 3. (Otherwise there's an assertion failure.)

This method requires that MN\_MESH\_FILLED\_IN be set (otherwise it will cause an assertion failure), and maintains the combinatorics completely.

**Parameters:**

**int ff**

The face to split.

**double \*bary**

The barycentric coordinates of the new point you wish to add. If this is NULL, the default values of (1/3, 1/3, 1/3) (the middle of the triangle) are used. These values MUST all fall between 0 and 1, and they MUST add up to 1 (give or take a floating point error) to get a sensible result.

**float thresh**

If one of the barycentric coordinates is greater than 1-thresh, that vertex dominates completely. No splitting is done, and that vertex is returned. If not, but if one of the barycentric coordinates is less than thresh, the new point must fall on the opposite edge. SplitTriEdge is therefore called on that edge, and passes along the value this returns.

**bool neVis**

Whether or not the new edges connecting the new vertex to the corners should be visible.

**bool neSel**

Whether or not the new edges connecting the new vertex to the corners should be selected.

**Return Value:**

The index of the new vertex created, or the index of the old vertex you can use instead if you're within thresh of one of the corners.

**Prototype:**

**void SplitTri6(int ff, double \*bary=NULL, int \*nv=NULL);**

**Remarks:**

This is another way to subdivide a face on a triangular mesh into sub-triangles. In this case, 4 new vertices are produced, and this face becomes 6 new faces.

**MN\_MESH\_FILLED\_IN** is required and preserved, and **MN\_MESH\_NONTRI** cannot be true when this method is called.

The subdivision technique is as follows: a new point is added at the barycentric coordinates given on the face given. New points are also added in each edge of the original face, such that a line from each of these three new edge points to the opposite original vertex passes through the new center point. These three edge points have edges drawn between them, and have edges to the new center point, dividing the face into 3 large outer triangles and 3 smaller inner triangles. Neighboring faces are split into 2 triangles, since the common edge is divided. This is a useful subdivision technique when you know you're going to want to add a lot of detail to a specific region of a face.

**Parameters:**

**int ff**

The face to split.

**double \*bary=NULL**

The barycentric coordinates for the center point. If bary is NULL, the default barycentric coordinates of (1/3, 1/3, 1/3) are used.

**int \*nv=NULL**

This is a pointer to an array of at least 4 int's in which the 4 new vertex indices should be stored. (This is mainly if the calling routine needs to know what these new vertices are.) If this is NULL, it is ignored.

## **Border methods**

**Prototype:**

```
void GetBorder(MNMeshBorder & brd, DWORD  
selLevel=MESH_OBJECT);
```

**Remarks:**

Finds border loops composed of all one-sided edges. (One-sided edges on a mesh must necessarily be organizable into closed loops along the borders of the mesh.)

**Parameters:**

**MNMeshBorder & brd**

The class in which to put the border loops. See [Class MNMeshBorder](#) for

details.

### **DWORD selLevel**

The selection level in the mesh to use to decide whether the border loops are targeted or not. For instance, with the default `MNM_SL_OBJECT`, all border loops are targeted, but with a value of `MNM_SL_VERTEX`, only those border loops containing at least one selected vertex will be targeted. Same for `MNM_SL_EDGE`. For `MNM_SL_FACE`, those loops touching at least one selected face will be targeted.

### **Prototype:**

```
void FillInBorders(MNMeshBorder *b=NULL);
```

### **Remarks:**

Fills in all the borders of a mesh. This is what the 3ds max CapHoles modifier does. It creates new faces on the other side of each of the loops.

### **Parameters:**

#### **MNMeshBorder \*b**

If this is `NULL`, `FillInBorders` finds all the borders with a call to `GetBorders`. If you have already found the borders, however, you can save time by passing a pointer to the `MNMeshBorder` class here. (This is especially convenient if you wish to modify the border targeting; only targeted borders are filled in.)

### **Prototype:**

```
void FindOpenRegions();
```

### **Remarks:**

This method is available in release 2.5 and later only.

Scans mesh to determine what parts of it are open or closed. Consider a "submesh" to be one connected components of faces and edges. Each submesh is open if it has any holes, i.e. if there's at least one edge which has only one face. (The hole is on the other side.) A submesh is closed if it doesn't have any. This method sets the `MN_FACE_OPEN_REGION` flag on all faces in open submeshes, and sets the `MN_MESH_HAS_VOLUME` flag if at least one submesh is closed.

### **Examples:**

A 3ds max box has one submesh, itself, and it is closed.

A 3ds max teapot has four distinct submeshes (handle, spout, lid, and body),

and they are all open.

**Prototype:**

```
void FindEdgeListTCVerts(const IntTab & lp, IntTab & tv, IntTab  
& cv);
```

**Remarks:**

Given a complete loop boundary of edges in the MNMesh, this method will find mapping coordinates and/or vertex colors for the vertices of the loop.

**Parameters:**

(**IntTab** means **Tab<int>**)

**const IntTab & lp**

The loop of edges.

**IntTab & tv**

The location to put the mapping coordinates' indices. Since each vertex on the loop lies can lie on two faces, one corresponding to each border edge touching the vertex, there are  $2 * lp.Count()$  of these values.  $tv[i*2]$  is the mapping vertex used for vertex  $E(lp[i]) \rightarrow v1$  in face  $E(lp[i]) \rightarrow f1$ , while  $tv[(i-1)*2+1]$  is the mapping vertex used for vertex  $E(lp[i-1]) \rightarrow v2$  (which is also  $E(lp[i]) \rightarrow v1$ ) in face  $E(lp[i-1]) \rightarrow f1$ .

**IntTab & cv**

The location to put the vertex colors' indices. Since each vertex on the loop lies can lie on two faces, one corresponding to each border edge touching the vertex, there are  $2 * lp.Count()$  of these values.  $cv[i*2]$  is the vertex color used for vertex  $E(lp[i]) \rightarrow v1$  in face  $E(lp[i]) \rightarrow f1$ , while  $cv[(i-1)*2+1]$  is the vertex color used for vertex  $E(lp[i-1]) \rightarrow v2$  (which is also  $E(lp[i]) \rightarrow v1$ ) in face  $E(lp[i-1]) \rightarrow f1$ .

## **Tessellation & related methods**

**Prototype:**

```
void Relax(float relaxval, bool targonly=TRUE);
```

**Remarks:**

Similar to the 3ds max "Relax" modifier: this modifier moves each MNVert towards the average of all vertices to which it is connected (by MNEdges).

**Parameters:****float relaxval**

The proportion to move it. If  $p$  is the original location of this vertex and  $q$  is the average point of all vertices it's connected to, this vertex is moved to  $p*(1-relaxval) + q*relaxval$ . A value of 0 generates no "relaxation", 1 is maximum relaxation, and values below 0 or above 1 generate non-relaxing results.

**bool targonly**

If this is set, only those MNVerts with the MN\_TARG flag set will be moved.

**Prototype:**

```
void FindEdgeListMapVerts(const Tab<int> & lp, Tab<int> & mv,  
int mp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns map verts for both ends of each edge (from f1's perspective) (Very useful for creating new faces at borders.)  $mv[j*2]$  is the map vertex corresponding to edge  $j$ 's  $v1$ .

**Parameters:****const Tab<int> & lp**

A loop of border edges, such as is generated by MNMesh::FindBorders.

**Tab<int> & mv**

The table into which the map vertices should be put. The size is set to  $2*lp.Count()$ .

**int mp**

The map channel we're analyzing.

**Prototype:**

```
bool AndersonDo(float interp, DWORD selLevel,  
MeshOpProgress *mop=NULL, DWORD subdivFlags=0);
```

**Remarks:**

This is a tessellation routine. It breaks every MNFace into  $deg$  new faces with four sides. The four vertices of each of these new quads come from the center point of the original face, one corner of the original face, and the middles of

the two edges on either side of that corner. For a demonstration of the effect this algorithm has on meshes, apply 3ds max's MeshSmooth modifier with the "Quad Output" box checked. Note that this algorithm roughly quadruples the size of the MNMesh.

**Parameters:**

**float interp**

This is the proportion of relaxation applied to the original vertices to produce a smoothed result. Vertices in the result correspond to three sources: all the original vertices are still included, new vertices are produced at the center of each face, and new vertices are produced in the middle of each edge. Face-vertices are always at the exact center of the original faces, but edge-vertices and vertex-vertices are relaxed into the mesh to improve smoothness.

**DWORD selLevel**

The selection level that the Mesh we're modifying was set to. If this selection level is MNM\_SL\_FACE, we'd want to keep non-selected faces as unmodified as possible, whereas if the selection level is MNM\_SL\_OBJECT or MNM\_SL\_VERTEX, we could break off chunks of some unselected faces that touch modified vertices. Again, observe the result of MeshSmooth, with Quad Output, on various selection sets of a mesh for examples of this behavior.

**MeshOpProgress \*mop=NULL**

This optional parameter points to an instance of the virtual class MeshOpProgress, which is used to allow the user to abort out of lengthy calculations. (SabinDoo is a lengthy calculation.) See [class MeshOpProgress](#).

**DWORD subdivFlags=0**

This parameter is available in release 4.0 and later only.

There is currently only one flag for the extra argument,

**MNM\_SUBDIV\_NEWMAP**. If this flag is set, the new mapping scheme will be used.

**Prototype:**

```
void TessellateByEdges(float bulge, MeshOpProgress  
*mop=NULL);
```

**Remarks:**

This is a tessellation routine similar to AndersonDo. It produces the same topology, but bulges new vertices outward to maintain even curvature instead of bringing the original vertices inward. For a demonstration of the effect this algorithm has on meshes, apply 3ds max's Tessellate modifier with the "Edge" and "Operate On: Polygons" options selected. Note that this algorithm roughly quadruples the size of the MNMesh.

**Parameters:**

**float bulge**

The factor to "push out" new vertices by in the direction of the surface curvature. Values of about .25 are reasonable. This value is equivalent to one hundredth of the value specified as "Tension" in the Tessellate modifier.

**MeshOpProgress \*mop=NULL**

A pointer to a MeshOpProgress. See [Class MeshOpProgress](#) for details.

**Prototype:**

**void TessellateByCenters();**

**Remarks:**

This is a tessellation routine. Note that this algorithm roughly triples the size of the MNMesh. For an example of how it works, apply 3ds max's Tessellate modifier with the "Face" and "Operate On: Polygons" options selected. This algorithm splits each face into deg triangles, where each triangle contains the center of the face and one edge from the perimeter.

**Prototype:**

**void SabinDoo(float interp, DWORD selLevel, MeshOpProgress \*mop=NULL, Tab<Point3> \*offsets=NULL);**

**Remarks:**

This is a tessellation routine. Note that this algorithm roughly triples the size of the MNMesh. For an example of how it works, apply 3ds max's MeshSmooth modifier with "classic" MeshSmooth Type.

This technique for tessellation is based on a paper, "A Subdivision Algorithm for Smoothing Down Irregularly Shaped Polygons", published by D. W. H. Doo of Brunel University, Middlesex, England, in IEEE in 1978. It essentially creates a new face for every vertex, face, and edge of the original mesh. The

new vertices this technique requires are made by creating one vertex for each corner of each original face. These vertices are located on a line from the original face corner to its center. All the faces around a given (targeted) vertex will create such a point; these points form the corners of the face created from this vertex. The original faces become smaller, as they use the new points instead of their old corners. And the four new points created on the faces on either side of an edge, for the endpoints of that edge, become the four corners of the new face representing the edge. Apply a MeshSmooth with default values to a 3ds max box to see how this plays out.

### **Parameters:**

#### **float interp**

The position along the line from a vertex to the center of each face to create the new vertex at. If this value is near 0, the original faces will shrink very little, and the new faces at the vertices and edges will be very small. If this value is near 1, the original faces will shrink to almost nothing, and the new vertex faces will be dominant. Again, adjust the Strength parameter in MeshSmooth to gain an understanding of this parameter.

#### **DWORD selLevel**

This parameter is included so that special handling can be applied to selected faces, if we're at the MNM\_SL\_FACE selection level. Generally, this algorithm works on all targeted vertices, affecting all faces that contain at least one targeted vertex. However, if the vertices are targeted by whether or not they're on selected faces, we'll wind up "spilling" the algorithm over into the non-selected faces. Generally in such routines as MeshSmooth, the user would want non-selected faces not to be affected at all. If this is the case, setting this value to MNM\_SL\_FACE will prevent faces without the MN\_SEL flag from being affected.

#### **MeshOpProgress \*mop=NULL**

This optional parameter points to an instance of the virtual class MeshOpProgress, which is used to allow the user to abort out of lengthy calculations. (SabinDoo is a lengthy calculation.) See [Class MeshOpProgress](#).

#### **Tab<Point3> \*offsets=NULL**

The SabinDoo algorithm is typically used to go from one polygonal approximation of a smooth surface to another polygonal approximation of 4 times the size, but it never actually returns the vertices as they would appear on the "limit surface". If this parameter is non-NULL, it's filled in with offsets

that will, when added to the vertices in the SabinDoo result, take those vertices onto the limit surface. This makes a smoother result that matches better between different iterations.

**Prototype:**

```
void SabinDooVert(int vid, float interp, DWORD selLevel, Point3  
*ctr, MeshOpProgress *mop=NULL, Tab<Point3>  
*offsets=NULL);
```

**Remarks:**

This applies the Sabin-Doo tessellation technique described above to a single vertex. The vertex is split into as many new vertices as there are faces using this vertex. The incident faces are shrunk back to make use of these new vertices, and a new face is created from them representing the vertex. Incident edges are split into triangles using their other end and the appropriate edge from the new vertex-face. To see the result of this algorithm, apply MeshSmooth (with default parameters) to an EditableMesh with a single vertex selected.

**Parameters:**

**int vid**

The vertex to SabinDoo.

**float interp**

The proportion from this vertex to the center of each of the incident faces to put the new vertex for that face.

**DWORD selLevel**

If this is equal to MNM\_SL\_FACE, faces without the MN\_SEL flag will not be affected.

**Point3 \*ctr**

This is a list of centers of all the faces, which cannot be NULL. Since this algorithm changes the original faces, merely computing face centers on the fly won't work. (When SabinDooing two vertices on a given face, the second vertex will get bad center information.) Thus the user should compute all the face centers in advance using ComputeCenters or (preferably) ComputeSafeCenters.

**MeshOpProgress \*mop=NULL**

This optional parameter points to an instance of the virtual class MeshOpProgress, which is used to allow the user to abort out of lengthy calculations. (SabinDoo is a lengthy calculation.) See [Class MeshOpProgress](#).

**Tab<Point3> \*offsets=NULL**

The SabinDoo algorithm is typically used to go from one polygonal approximation of a smooth surface to another polygonal approximation of 4 times the size, but it never actually returns the vertices as they would appear on the "limit surface". If this parameter is non-NULL, it's filled in with offsets that will, when added to the vertices in the SabinDoo result, take those vertices onto the limit surface. This makes a smoother result that matches better between different iterations.

(In SabinDooVert, the offsets for the vertices created by this method are filled in. The offsets table is resized if necessary to accommodate this.)

**Prototype:**

**void CubicNURMS(MeshOpProgress \*mop=NULL, Tab<Point3> \*offsets=NULL, DWORD subdivFlags=0);**

**Remarks:**

This method is available in release 3.0 and later only.

This is a tessellation routine. Note that this algorithm roughly quadruples the size of the MNMesh. For an example of how it works, apply 3ds max's MeshSmooth modifier with "NURMS" MeshSmooth Type.

This technique for tessellation is based loosely on a 1998 SIGGraph paper, "Non-Uniform Recursive Subdivision Surfaces", by Sederberg, Zheng, Sewell, and Sabin, with additional work by Autodesk staff. Topologically, it's quite simple, as it creates a vertex in the center of every edge and face and connects these vertices with quads. However, the geometry is a non-uniform rational extension of the old Catmull-Clark standard cubic subdivision.

To set the vertex and edge weights used by the algorithm, use the EdgeKnots and VertexWeights methods of MNMesh. Like other subdivision routines, this routine only subdivides areas of the MNMesh indicated by the MN\_TARG flag on vertices, and uses the MNEdge::Uncrossable method to determine where the regional boundaries should be.

**Parameters:**

**MeshOpProgress \*mop=NULL**

See [Class MeshOpProgress](#) – provides a way to abort the calculation.

**Tab<Point3> \*offsets=NULL**

Unused for now.

**DWORD subdivFlags=0**

This parameter is available in release 4.0 and later only.

There is currently only one flag for the extra argument,

**MNM\_SUBDIV\_NEWMAP**. If this flag is set, the new mapping scheme will be used.

**Prototype:**

**BOOL CheckForDoubledMappingVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used as a debugging tool. All double mapping vertices will be debugprinted. "Doubled" mapping verts are individual map vertices that are used to correspond to different regular vertices. For example, the standard map on the box object uses the same mapping vertices on the top as on the bottom. This can be a problem if the user wants to change the map in one region, but not the other. It also causes problems in NURMS MeshSmooth, where the user can change weights in one region but not in the other.

**Prototype:**

**void EliminateDoubledMappingVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

This method will allow you to eliminate double mapping vertices. "Doubled" mapping verts are individual map vertices that are used to correspond to different regular vertices. For example, the standard map on the box object uses the same mapping vertices on the top as on the bottom. This can be a problem if the user wants to change the map in one region, but not the other. It also causes problems in NURMS MeshSmooth, where the user can change weights in one region but not in the other.

**Prototype:**

**void EliminateIsoMapVerts();**

**Remarks:**

This method is available in release 4.0 and later only.

Eliminates mapping vertices that aren't used by any mapping faces.

**Prototype:**

**void EliminateIsoMapVerts(int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

Eliminates mapping vertices that aren't used by any mapping faces.

**Parameters:**

**int mp**

If  $mp \geq 0$ , it indicates the mapping channel that should have its isolated verts removed. If left at the default, all mapping channels are cleared of iso verts.

## **Welding methods**

**Prototype:**

**bool WeldVerts(int a, int b);**

**Remarks:**

This method is available in release 2.5 and later only.

Welds vertices a and b, correcting the mesh topology to match. All references to b are moved to a, and b is killed. If there is a topological problem preventing the weld from occurring, the method does nothing and returns FALSE. If there is no such problem, the weld goes ahead and returns TRUE. Note that if a and b are joined by an edge, this method just calls WeldEdge on that edge.

**Prototype:**

**bool WeldEdge(int ee);**

**Remarks:**

This method is available in release 2.5 and later only.

Welds the endpoints of edge ee, correcting the mesh topology to match. All references to  $E(ee) \rightarrow v2$  are moved to  $E(ee) \rightarrow v1$ , and both ee and  $E(ee) \rightarrow v2$

are killed. If there is a topological problem preventing the weld from occurring, the method does nothing and returns FALSE. If there is no such problem, the weld goes ahead and returns TRUE.

**Prototype:**

**bool WeldBorderVerts (int v1, int v2, Point3 \*destination);**

**Remarks:**

This method is available in release 4.0 and later only.

This method welds vertices v1 and v2 together. Both vertices must be on borders, and they cannot share an edge. If destination isn't NULL, it indicates where the welded vertex should be located. (If it is NULL, the welded vertex is placed at the midpoint of the inputs.)

**Parameters:**

**int v1, v2**

The vertex indices to weld.

**Point3 \*destination**

The destination of the welded vertex.

**Return Value:**

TRUE if something was welded, FALSE otherwise.

**Prototype:**

**bool WeldBorderEdges (int e1, int e2);**

**Remarks:**

This method is available in release 4.0 and later only.

This method welds edges e1 and e2 together. Both edges must be on borders.

**Parameters:**

**int e1, e2**

The two edges you want to weld.

**Return Value:**

TRUE if something was welded, FALSE otherwise.

**Prototype:**

**bool WeldBorderVerts (float thresh, DWORD flag=MN\_SEL);**

**Remarks:**

This method is available in release 4.0 and later only.

This method welds all flagged border vertices within "thresh" of each other. Vertices are only welded pairwise. If vert A's closest target is vert B, but vert B is closer to vert C, verts B and C are welded and A is left out in the cold.

**Parameters:**

**float thresh**

The threshold.

**DWORD flag=MN\_SEL**

This indicates the vertices we look at. If left at the default, selected vertices' colors are analyzed. If flag were to equal **MN\_WHATEVER**, then vertices with the **MN\_WHATEVER** flag would have their colors analyzed.

**Return Value:**

TRUE if something was welded, FALSE otherwise.

**Prototype:**

**bool DetachElementToObject (MNMesh & nmesh, DWORD fflags=MN\_SEL, bool delDetached=true);**

**Remarks:**

This method is available in release 4.0 and later only.

Detaches specified faces (and related vertices and edges) to a new MNMesh. As indicated by the name, the specified region should be a single element; crashes will occur if faces that are flagged share vertices or edges with nonflagged faces.

**Parameters:**

**MNMesh & nmesh**

The new mesh. This is assumed to be empty. The flagged elements are put here, and reindexed so there are no unused components. (This occurs for all map channels as well - only the necessary map vertices are copied over.)

**DWORD fflags**

The flags that indicate the faces which compose the element we want to detach.

**bool delDetached=true**

Indicates whether the specified element should be deleted from this MNMesh.

**Return Value:**

true if anything was detached, false otherwise.

## **Boolean operations**

**Prototype:**

**void PrepForBoolean();**

**Remarks:**

This method is available in release 2.5 and later only.

Prepares a MNMesh for a Boolean operation. This is required for successful Booleans. Generally, it makes the mesh into a convex poly mesh, removing any hidden vertices, finds open regions, and collapses dead structures.

**Prototype:**

**bool BooleanCut(MNMesh & m2, int cutType, int fstart=0,  
MeshOpProgress \*mop=NULL);**

**Remarks:**

This method is available in release 3.0 and later only.

BooleanCut uses the same techniques as MakeBoolean to cut the faces of this with the faces of m2. As with Boolean, both this and m2 should be prepared with the PrepForBoolean method.

**Parameters:**

**MNMesh & m2**

The MNMesh to use to cut this one.

**int cutType**

One of the following:

**BOOLOP\_CUT\_REFINE**

Slice the faces of this with the surface of m2, but do not separate the mesh along the seam.

**BOOLOP\_CUT\_SEPARATE**

Slice and separate the faces of this along the surface of m2.

## **BOOLOP\_CUT\_REMOVE\_IN**

Slice the faces of this with the surface of m2, then remove all the faces of this that are inside m2.

## **BOOLOP\_CUT\_REMOVE\_OUT**

Slice the faces of this with the surface of m2, then remove all the faces of this that are inside m2.

### **int fstart=0**

Indicates the face (of this) we should start checking for cuts by m2. This can be useful if, for example, you know that the first 100 faces of this are nowhere near m2.

### **MeshOpProgress \*mop=NULL**

See [Class MeshOpProgress](#). Provides a way to abort the calculation.

### **Return Value:**

TRUE if finished successfully; FALSE if aborted by the MeshOpProgress.

### **Prototype:**

```
bool MakeBoolean(MNMesh & m1, MNMesh & m2, int type,  
MeshOpProgress *mop=NULL);
```

### **Remarks:**

This method is available in release 2.5 and later only.

Makes this MNMesh into a Boolean result of the given MNMeshes. The operands are not modified during this process. The Boolean algorithm is identical to the one used in the Boolean 2 compound object. Notice that there are no transform arguments, as there are in the previously used CalcBoolOp – transforms should be applied to the operands beforehand using the MNMesh::Transform method.

### **Parameters:**

#### **MNMesh & m1**

The first operand mesh, which should have had PrepForBoolean called.

#### **MNMesh & m2**

The second operand mesh, which should have had PrepForBoolean called.

#### **int type**

The type of Boolean. The Boolean types are defined in mesh.h, and are one of MESHBOOL\_UNION, MESHBOOL\_INTERSECTION, or

MESHBOOL\_DIFFERENCE. If MESHBOOL\_DIFFERENCE is selected, operand m2 is subtracted from operand m1. (To get the opposite result, just switch the order of m1 and m2.)

### **MeshOpProgress \*mop=NULL**

A pointer to a MeshOpProgress. See [Class MeshOpProgress](#) for details. The mop is initialized with the number of faces in mesh 1 plus the number of faces in mesh 2 plus 10. MakeBoolean aborts acceptably if mop->Progress returns FALSE, in which case the partially Booleaned MNMesh is returned. (Usually this consists of mesh 1 partially cut by mesh 2, or mesh 1 fully cut and mesh 2 partially cut, with no faces removed.) This argument may safely be left at NULL if you do not wish to be updated on the Boolean progress or have the capability to abort.

### **Return Value:**

Returns FALSE if the operation was cancelled by the MeshOpProgress or if it was unable to match the seams of the two operands at the end, resulting in a mesh with holes. It returns TRUE if everything went well, producing a solid, hole-free mesh.

Note that it will always return FALSE if one of the operands has holes.

### **Sample Code:**

Sample code: the following code can be used to replace the old CalcBoolOp method.

```
BOOL CalcNewBooleanOp(Mesh & mesh, Mesh & mesh1, Mesh  
& mesh2, int op, MeshOpProgress *prog=NULL, Matrix3  
*tm1=NULL, Matrix3 *tm2=NULL, int whichinv=0) {  
    MNMesh m1(mesh1);  
    MNMesh m2(mesh2);  
    if(tm1) m1.Transform(*tm1);  
    if(tm2) m2.Transform(*tm2);  
    m1.PrepForBoolean();  
    m2.PrepForBoolean();  
    MNMesh mOut;  
    mOut.MakeBoolean(m1, m2, op, prog);  
    if(whichinv==0) mOut.Transform(Inverse(*tm1));  
    if(whichinv==1) mOut.Transform(Inverse(*tm2));  
    mOut.OutToTri(mesh);
```

```
    return TRUE;
}
```

**Prototype:**

```
void ConnectLoops (Tab<int> & loop1, Tab<int> & loop2, int segs,  
float tension, DWORD smGroup, MtlID mat, bool sm_ends);
```

**Remarks:**

This method is available in release 4.0 and later only.

Connects two border loops by filling in new geometry between them, as is done in the Connect compound object.

**Parameters:**

**Tab<int> & loop1**

**Tab<int> & loop2**

These parameters, which are interchangeable, are lists of edges that represent border loops in the MNMesh. It is assumed that the MNMesh is filled in, that each of the edges in the loops is in fact one-sided ( $e[\text{loop1}[i]].f2 == -1$ ), and that the edges go in counterclockwise order when looking from outside the mesh (so  $e[\text{loop1}[i]].v1 == e[\text{loop1}[i+1]].v2$ ). (These are the sort of border loops you find in an MNMeshBorder class.)

**int segs**

The number of segments in the bridge.

**float tension**

The tension of the bridge - this controls how much the surface tangents at each end of the bridge affect the bridge's shape.

**DWORD smGroup**

These smoothing group(s) should be applied to the entire bridge. (Use 0 for a faceted bridge.)

**MtlID mat**

This is the material used for the bridge faces.

**bool sm\_ends**

If TRUE, additional smoothing groups are applied to the end faces of the bridge to ensure that the bridge smoothes with the existing faces around each border loop.

**Prototype:**

```
void Connect (MNMeshBorder & borderList, int segs, float  
tension, bool sm_bridge, bool sm_ends, Tab<int> *vsep=NULL);
```

**Remarks:**

This method is available in release 4.0 and later only.

Connect automatically figures out which loops in the given MNMeshBorder would make good candidates for connecting, and calls ConnectLoop on them all to connect them. Good candidates are pairs of loops that face each other. Centers and normals of each of the "holes" are compared to find the best matches.

**Parameters:****MNMeshBorder & borderList**

The boundary information for the MNMesh mesh.

**int segs**

The number of segments in each bridge.

**float tension**

The tension of each bridge - this controls how much the surface tangents at each end of the bridge affect the bridge's shape.

**bool sm\_bridge**

If TRUE, each bridge should be smoothed with some unused smoothing group.

**bool sm\_ends**

If TRUE, additional smoothing groups are applied to the end faces of each bridge to ensure that the bridge smoothes with the existing faces around each border loop.

**Tab<int> \*vsep=NULL**

If not NULL, this points to a "separation list" of vertices. Frequently the user wishes to connect two distinct object (as with the Connect compound object). In these cases, the vertices of the different connected components are often grouped in distinct sets: vertices 0 through 26 come from the first component, 27 through 118 from the second, etc. Generally the user would not want a component to connect to itself, but rather only to other components. So if non-NULL, this is assumed to point to a list describing the vertex ranges for each component - (0, 27, 119, etc). The list should have size (number of

components+1), and the last element should be MNMesh::numv. Given such an input, the Connect algorithm will only connect loops to loops in other components.

**Prototype:**

**void InvalidateGeomCache();**

**Remarks:**

This method is available in release 3.0 and later only.

Invalidates information, like bounding box and face normals, that's dependent on Geometry. Call after changing the geometry.

**Prototype:**

**void InvalidateTopoCache();**

**Remarks:**

This method is available in release 3.0 and later only.

Invalidates information, like the edge list and the render verts, that's dependent on Topology. Clears the MN\_MESH\_FILLED\_IN and related flags in MN\_MESH\_CACHE\_FLAGS.

**Prototype:**

**void allocRVerts();**

**Remarks:**

This method is available in release 3.0 and later only.

Allocates the "render vertices" used to optimize display routines. Called by the system as needed.

**Prototype:**

**void updateRVerts(GraphicsWindow \*gw);**

**Remarks:**

This method is available in release 3.0 and later only.

Fills in the render vertices with display coordinates based on the specified view.

**Prototype:****void freeRVerts();****Remarks:**

This method is available in release 3.0 and later only.

Frees the "render vertices" used to optimize display routines.

**Debugging Methods**

Please see the [MNMesh Notes on Debugging](#) for more information.

**Prototype:****void MNDebugPrint(bool triprint=FALSE);****Remarks:**

This method is available in release 2.5 and later only.

Uses DebugPrint to print out the entire MNMesh to the Debug Results window in DevStudio. This can be useful for tracking down bugs. Be careful not to leave MNDebugPrint calls in your final build; they will slow down your effect to no purpose.

**Parameters:****bool triprint=FALSE**

Controls whether or not triangulation information is printed out for each face. Usually this information isn't desired.

**Prototype:****void MNDebugPrintVertexNeighborhood(int vv, bool triprint=FALSE);****Remarks:**

This method is available in release 2.5 and later only.

Uses DebugPrint to print out information about all the edges, faces, and vertices in the immediate vicinity of vertex vv.

**Parameters:****int vv**

The vertex whose information is output.

**bool triprint=FALSE**

Controls whether or not triangulation information is printed out for each face.

Usually this information isn't desired.

**Prototype:**

**bool CheckAllData();**

**Remarks:**

This method is available in release 2.5 and later only.

Thoroughly checks a MNMesh to make sure that no components refer to dead components; that when one component refers to another, the other refers back to the first; and that orientation is correctly matched between faces and edges. If everything checks out, TRUE is returned. If any errors are detected, DebugPrint is used to send a message to the DevStudio Debug Results window and FALSE is returned. Be careful not to leave CheckAllData calls in your final build; they will slow down your effect to no purpose.

Here is the sort of debug output you can expect. CheckAllData always outputs one of the following messages:

Checking all data in filled-in MNMesh: (if the mesh has the MN\_MESH\_FILLED\_IN flag set)

Checking all data in MNMesh: (if the mesh does not)

These errors will be detected for any mesh:

Face %d has an out-of-range vertex: %d

Face %d has an out-of-range tvert: %d

Face %d has an out-of-range cvert: %d

Face %d refs dead edge %d.

Face %d has bad triangulation index: %d

These errors will be detected only for filled-in meshes:

Face %d has an out-of-range edge: %d

Face %d uses dead edge %d.

Face %d refs edge %d, but edge doesn't ref face.

Face %d refs edge %d from vert %d to vert %d, but edge doesn't go there.

Orientation mismatch between face %d and edge %d.

Face %d refs vertex %d, but vertex doesn't ref face.

Edge %d refs dead vertex %d.

Edge %d refs vertex %d, but vertex doesn't ref edge.

Edge %d has no face-1

Edge %d refs dead face %d.

Edge %d refs face %d, but face doesn't ref edge.

Vertex %d refs dead edge %d.

Vertex %d refs edge %d, but edge doesn't ref vertex.

Vertex %d references more faces than edges.

Vertex %d refs dead face %d.

Vertex %d refs face %d, but face doesn't ref vertex.

## Operators

### Prototype:

**MNMesh & operator=(const MNMesh & from);**

### Remarks:

Assignment operator. Allocates space & copies over all data from "from".

### Prototype:

**MNMesh & operator+=(const MNMesh & from);**

### Remarks:

Union operator. Adds all data from "from" to this MNMesh. Flags MN\_MESH\_NONTRI and MN\_MESH\_RATSNEST are or'd together, while flags MN\_MESH\_FILLED\_IN, MN\_MESH\_NO\_BAD\_VERTS, and MN\_MESH\_VERTS\_ORDERED are and'd together. (Uniting a rat's nest with a non-rat's nest makes a rat's nest, but uniting a mesh with mapping coordinates and one without makes one without.)

### Prototype:

**void ClearSpecifiedNormals ();**

### Remarks:

This method is available in release 5 and later only.

Clears out the specified normal interface, if present. Removes it

completely, so it won't flow up the stack, etc.

**Prototype:**

**void SpecifyNormals ();**

**Remarks:**

This method is available in release 5 and later only.

Creates the user-specified normal interface in this mesh. Initializes the MNNormalSpec's "Parent" to this mesh, but does not allocate normal faces or otherwise prepare the normals. Note that this interface will flow up the pipeline, in the PART\_GEOM and PART\_TOPO channels.

**Prototype:**

MNNormalSpec \*GetSpecifiedNormals();

**Remarks:**

This method is available in release 5 and later only.

Returns a pointer to the user-specified normal interface, if present.

**Return Value:**

A pointer to this mesh's MNNormalSpec interface, or NULL if the interface has not been created in this mesh.

**Prototype:**

**MNNormalSpec \*GetSpecifiedNormalsForDisplay();**

**Remarks:**

This method is available in release 5 and later only.

Returns a non-NULL MNNormalSpec interface pointer only if the interface is present, and is prepared for use in display - otherwise, it returns NULL, and we fall back on the smoothing groups.

A MNNormalSpec is considered "prepared for display" only if the MNNORMAL\_NORMALS\_BUILT and MNNORMAL\_NORMALS\_COMPUTED flags are set.  
(See the MNNormalSpec methods BuildNormals and ComputeNormals.)

**Prototype:**

**void CopyBasics (const MNMesh & from, bool copyEdges = false);**

**Remarks:**

This method is available in release 4.5 and later only.  
Copies bare geometry only - no per-vertex data, maps, or normals.  
Useful for keeping low-memory local caches of a mesh where map, vertex data, edge data, normals, and other interfaces are not required.

**Parameters:**

**const MNMesh & from**

The mesh to copy into this mesh.

**bool copyEdges = false**

Indicates if the winged-edge array, as well as vertex and face references to edges, should be copied. If false, the MN\_MESH\_FILLED\_IN flag is cleared in this mesh.

## Structure NotifyInfo

See Also: [Class Interface \(callback methods\)](#), [List of Notification Codes](#).

### Description:

3ds max supports a system where a plug-in can ask to receive a callback when certain events occur. These are events such as the system unit settings changing, system time setting changing, or the user executing File/Reset, File/New, etc.

This structure is part of this system. It is available in release 2.0 and later only.

```
typedef struct {  
    int intcode;  
    void *callParam;
```

This pointer is available in release 3.0 and later only.

This parameter can be passed in with the function

```
BroadcastNotification(int code, void *callParam).
```

```
} NotifyInfo;
```

The plug-in creates a callback function to process the notification. The notification callback function (**NOTIFYPROC**) is defined as follows:

```
typedef void (* NOTIFYPROC)(void *param, NotifyInfo *info);
```

The **NotifyInfo** structure is passed to the **NOTIFYPROC** to inform it of what it's being notified about.

The sample code below shows how this system may be used.

### Sample Code:

```
// Declare the callback function  
static void TimeUnitsChanged(void *param, NotifyInfo *info) {  
    // Handle the units changing...  
}  
  
// Register the callback  
RegisterNotification(TimeUnitsChanged,this,  
    NOTIFY_TIMEUNITS_CHANGE);  
  
// When done, unregister the callback  
UnRegisterNotification(TimeUnitsChanged,this,  
    NOTIFY_TIMEUNITS_CHANGE);
```

## Related Functions:

### Function:

**int RegisterNotification(NOTIFYPROC proc, void \*param, int code);**

### Remarks:

This global function is called to establish the connection between the event and the callback.

### Parameters:

**NOTIFYPROC proc**

The callback function called when the event occurs.

**void \*param**

A pointer to a parameter which will be passed to the callback function.

**int code**

Specifies which notification to register. See [List of Notification Codes](#).

### Return Value:

Nonzero if the event was registered; otherwise zero.

### Function:

**int UnRegisterNotification(NOTIFYPROC proc, void \*param, int code);**

### Remarks:

This global function is called to break the connection between the event and the callback. After this function executes the callback is no longer invoked when the event occurs.

### Parameters:

**NOTIFYPROC proc**

The callback function called when the event occurs.

**void \*param**

This parameter must be identical to the param sent into

**RegisterNotification()**. This function will only unregister a callback if this parameter equals the param sent in to the **RegisterNotification()** function.

**int code**

Specifies which notification to unregister. See [List of Notification Codes](#).

**Return Value:**

Nonzero if the event was unregistered; otherwise zero.

**Function:**

**void BroadcastNotification(int code);**

**Remarks:**

Calling this global function causes the callback corresponding to the specified code to be called.

**Parameters:**

**int code**

Specifies which notification to broadcast. See [List of Notification Codes](#).

**Prototype:**

**void BroadcastNotification(int code, void \*callParam);**

**Remarks:**

This global function is available in release 3.0 and later only.

This causes the callback corresponding to the specified code to be called and passes the specified **void\*** parameter along to the callback.

**Parameters:**

**int code**

Specifies which notification to broadcast. See [List of Notification Codes](#).

**void \*callParam**

This parameter is passed to the callback. See the code

**NOTIFY\_BITMAP\_CHANGED** for an example of this in use.

**Function:**

**int UnRegisterNotification(NOTIFYPROC proc, void \*param);**

**Remarks:**

This global function unregisters the callback from **all** codes

**Parameters:**

**NOTIFYPROC proc**

The callback function called when the event occurs.

**void \*param**

A pointer to a parameter which will be passed to the callback function.

**Return Value:**

Nonzero if the events were unregistered; otherwise zero.

## Class SimpleOSMToWSMObject

See Also: [Class SimpleWSMObject](#), [Class SimpleMod](#), [Class Deformer](#), [Class IParamMap](#).

```
class SimpleOSMToWSMObject : public SimpleWSMObject
```

### Description:

This class is used to allow any Object Space Modifier derived from **SimpleMod** to easily be turned into a World Space Modifier (Space Warp).

This is very simple to do because a modifier version already contains just about everything that needs to be done. This is because the modifier works the same -- it is just in world space instead of object space.

All a developer needs to do to turn their **SimpleMod** modifier into the WSM version is implement a class derived from this one and call the **SimpleOSMToWSMObject** constructor from their constructor. See the sample code below (for the full sample code using this class see `\MAXSDK\SAMPLES\MODIFIERS\BEND.CPP`).

```
class BendWSM : public SimpleOSMToWSMObject {
public:
    BendWSM() {}
    BendWSM(BendMod *m) : SimpleOSMToWSMObject(m) {}
    void DeleteThis() { delete this; }
    SClass_ID SuperClassID() {return
WSM_OBJECT_CLASS_ID;}
    Class_ID ClassID() {return BENDWSM_CLASSID;}
    TCHAR *GetObjectName() {return
GetString(IDS_RB_BEND2);}
};
```

These new modifier-based space warps are accessed in the drop-down category list of the Space Warps branch of the Create command panel. Choose Modifier-Based from the list to display buttons for each of the new space warps.

### Data Members:

```
public:
```

```
    SimpleMod *mod;
```

Points to the simple modifier instance this is based on.

**static IParamMap \*pmapParam;**

Points to the parameter map used to handle the user interface for this WSM.

These are the parameter block indices for the pmap:

**#define PB\_OSMTOWSM\_LENGTH 0**

**#define PB\_OSMTOWSM\_WIDTH 1**

**#define PB\_OSMTOWSM\_HEIGHT 2**

**#define PB\_OSMTOWSM\_DECAY 3**

**Methods:**

**Prototype:**

**SimpleOSMToWSMObject();**

**Remarks:**

Constructor.

**Prototype:**

**SimpleOSMToWSMObject(SimpleMod \*m);**

**Remarks:**

Constructor.

**Parameters:**

**SimpleMod \*m**

This is a pointer to the **SimpleMod** instance this WSM is based on.

**Prototype:**

**Deformer &GetDecayDeformer(TimeValue t,Deformer  
&mdef,Point3 origin,Interval &iv);**

**Remarks:**

Implemented by the System.

This class enhances the deformation done by the object space modifier to include a decay parameter. This allows the deformation to decay over distance. This helper method is used internally in this.

## Class ImageFilterInfo

See Also: [Class ImageFilter](#), [Class BitmapInfo](#), [Class FrameRange](#), [Class ITrackViewNode](#), [Class Class\\_ID](#).

class ImageFilterInfo

### Description:

This class provides information to an image filter plug-in. This is information such as state of any masks used, and the various frame ranges for the video post queue. It is analogous to the BitmapInfo class in the Bitmap Manager.

### Data Members:

public:

#### **BOOL maskenabled;**

TRUE if the filter has a mask; otherwise FALSE.

#### **BOOL evCopy;**

This is used internally as a flag indicating this object is a temporary copy, and not the real thing. It is only an issue when filters have Track View Nodes. This is only used internally.

#### **BOOL invertedmask;**

TRUE if the mask is inverted; otherwise FALSE.

#### **BitmapInfo mask;**

The image used as the mask.

#### **WORD maskflag;**

This is used internally. It indicates what part of the mask image is used to create the grayscale mask. It may be one of the following values: **MASK\_R**, **MASK\_G**, **MASK\_B**, **MASK\_A**, **MASK\_L**, **MASK\_Z**, **MASK\_MTL\_ID**, **MASK\_NODE\_ID**.

#### **BitmapInfo imgQueue;**

This is a BitmapInfo that holds information about the current Video Post main queue image buffer. This can be used to get Video Post's (or the target image's) resolution, etc.

#### **FrameRange QueueRange;**

This defines the entire Video Post Queue range. This is the range defined between VP Start Time and VP End Time in the video post user interface.

**FrameRange ExecutionRange;**

When the queue is executed, this is the range of frames being rendered.

**FrameRange FilterRange;**

The FilterRange is where this filter starts and ends.

**Methods:****Prototype:**

**virtual void SetResource(const TCHAR \*n);**

**Remarks:**

Filters may want to identify themselves by something more specific than their names when they appear in the video post queue. By default, the name of a filter is used to identify it in the video post queue, ie the Negative filter appears as Negative. Some filters may want a more descriptive name to appear. For instance a gradient filter that allows the user to save named settings may want the name of the set to appear rather than simply the name of the filter itself. Thus, "Flowing gradient - Red to Blue" may appear rather than "Gradient". This method is available for filters that that give such names to parameter sets. If not empty, the resource name will be used to identify the filter in the Video Post Queue. This is saved along with everything else by the system (3ds max).

**Parameters:**

**const TCHAR \*n**

The name to appear, instead of the filter name, in the video post queue.

**Prototype:**

**virtual const TCHAR \*Resource();**

**Remarks:**

Returns the resource name.

**Prototype:**

**virtual const TCHAR \*Name();**

**Remarks:**

Returns the name of the filter.

**Operators:**

**Prototype:**

**virtual ImageFilterInfo &operator= ( ImageFilterInfo &from );**

**Remarks:**

Assignment operator.

**Parameters:**

**ImageFilterInfo &from**

The source ImageFilterInfo.

**Prototype:**

**ITrackViewNode \*Node();**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to return the Track View node for this filter. Because Video Post Filter plug-ins have a short life, in other words, they are only loaded when they are actually needed and deleted right after, the Track View node information is kept in the **ImageFilterInfo** class kept by Video Post for each filter event.

**Prototype:**

**void SetNode(ITrackViewNode \*n);**

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the Track View node associated with this ImageFilter.

**Parameters:**

**ITrackViewNode \*n**

The Track View node to set.

**Prototype:**

**Class\_ID NodeID();**

**Remarks:**

This method is available in release 2.0 and later only.  
Returns the Class\_ID of the Track View node (if any).

**Prototype:**

**void SetNodeID(Class\_ID id);**

**Remarks:**

This method is available in release 2.0 and later only.  
Sets the stored Class\_ID of the Track View node (if any).

**Parameters:**

**Class\_ID id**

The id to set.

**Prototype:**

**TCHAR \*UserLabel();**

**Remarks:**

This method is available in release 2.0 and later only.  
Returns the optional label entered by the user while adding or editing a filter.  
This label replaces the filter's name in Video Post's tracks in Track View for easier identification. This is the name that is entered in the 'Edit Filter Event' dialog Filter Plug-In Label field. The label defaults to Unnamed in which case the Filter's name appears (for example 'Negative').

**Prototype:**

**int FilterType();**

**Remarks:**

This method is available in release 2.0 and later only.  
This method is used so dual mode filters can detect what mode they are running in (as a filter or as a compositor). In the 3ds max 1.x SDK, filters that ran both as filters and layers had no way to determine what mode they were running while in "Setup" mode (in **ShowControl()**). At run time they would check for a foreground bitmap. If it was NULL, they were to assume they were running as simple filters. Now this method may be used to determine what mode they are running in.

**Return Value:**

One of the following values:

**FLT\_FILTER**

**FLT\_LAYER**

**Prototype:**

**void SetFilterType(int type);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used internally.

## Class ITrackViewNode

See Also: [Class ReferenceTarget](#), [Class Interface](#), [Class Control](#), [Class ImageFilter](#), [Class TVNodeNotify](#).

```
class ITrackViewNode : public ReferenceTarget
```

### Description:

This class provides an interface to Track View Nodes. A Track View Node is simply a class that has zero or more sub-track view nodes and zero or more sub-controllers. This is mainly used to provide a place for Global Variable tracks (labeled "Global Tracks" in Track View) and Video Post tracks (labelled "Video Post" in Track View).

The TrackViewNode sub-nodes and sub-controllers are identified by a unique ID in the form of a Class\_ID variable. This does not necessarily have to be the Class\_ID of an existing plug-in, however plug-ins may wish to use their Class\_ID for any items they add to be sure they are unique.

The Interface class provides access to the root track view node:

```
virtual ITrackViewNode *GetTrackViewRootNode()=0;
```

From the root track view node, new nodes may be added. There are two defined sub nodes identified by the following **#defined** Class\_IDs:

```
#define GLOBAL_VAR_TVNODE_CLASS_ID
```

```
Class_ID(0xb27e9f2a, 0x73fad370)
```

```
#define VIDEO_POST_TVNODE_CLASS_ID
```

```
Class_ID(0x482b8d30, 0xb72c8511)
```

These can be retrieved by calling **GetNode()** on the track view root node and passing in one of the above IDs.

All methods of this class are implemented by the system.

Note: Developers can also create their own track view node using the following global function:

### Function:

```
ITrackViewNode *CreateITrackViewNode(BOOL  
hidden=FALSE);
```

### Remarks:

This method is used to add a track view node.

**Parameters:**

**BOOL hidden=FALSE**

If FALSE the node is hidden; otherwise it is visible in the viewports.

**Methods:**

**Prototype:**

```
virtual void AddNode(ITrackViewNode *node, TCHAR *name,  
Class_ID cid, int pos=TVNODE_APPEND)=0;
```

**Remarks:**

This method is used to add a track view node.

**Parameters:**

**ITrackViewNode \*node**

Points to the Track View Node to add.

**TCHAR \*name**

The name for the node that appears in Track View.

**Class\_ID cid**

The Class\_ID which identifies the plug-in that added the node.

**int pos=TVNODE\_APPEND**

The position in the list of nodes where this one is added. If this defaults to **TVNODE\_APPEND** the node is added at the end of the list.

**Prototype:**

```
virtual void AddController(Control *c, TCHAR *name, Class_ID  
cid, int pos=TVNODE_APPEND)=0;
```

**Remarks:**

This method is used to add a track view controller.

**Parameters:**

**Control \*c**

Points to the controller to add.

**TCHAR \*name**

The name that will appear in Track View.

**Class\_ID cid**

The Class\_ID of the plug-in that adds the controller.

**int pos=TVNODE\_APPEND**

The position in the list where the controller is added. If this defaults to **TVNODE\_APPEND** the controller is added at the end of the list.

**Prototype:****virtual int FindItem(Class\_ID cid)=0;****Remarks:**

A Track View Node maintains a table that contains the sub-nodes and sub-controllers. This method returns the index into the table of the node or controller whose Class\_ID is passed. If the Class\_ID could not be found then -1 is returned.

**Parameters:****Class\_ID cid**

The Class\_ID to find.

**Prototype:****virtual void RemoveItem(int i)=0;****Remarks:**

A Track View Node maintains a table that contains the sub-nodes and sub-controllers. This method removes the 'i-th' sub-node or sub-controller of the table.

**Parameters:****int i**

The zero based index into the table of the item to remove.

**Prototype:****virtual void RemoveItem(Class\_ID cid)=0;****Remarks:**

A Track View Node maintains a table that contains the sub-nodes and sub-controllers. This method removes the sub-node or sub-controller whose

Class\_ID is passed from the table.

**Parameters:**

**Class\_ID cid**

The Class\_ID used when the node or controller was added.

**Prototype:**

**virtual Control \*GetController(int i)=0;**

**Remarks:**

This method returns a pointer to the 'I-th' sub-controller.

**Parameters:**

**int i**

The zero based index of the sub-controller.

**Prototype:**

**virtual Control \*GetController(Class\_ID cid)=0;**

**Remarks:**

This method returns a pointer to the sub-controller whose Class\_ID is passed.

**Parameters:**

**Class\_ID cid**

The Class\_ID used when the controller was added.

**Prototype:**

**virtual ITrackViewNode \*GetNode(int i)=0;**

**Remarks:**

This method returns a pointer to the 'i-th' sub-node.

**Parameters:**

**int i**

The zero based index of the sub-node.

**Prototype:**

**virtual ITrackViewNode \*GetNode(Class\_ID cid)=0;**

**Remarks:**

This method returns a pointer to the sub-node whose Class\_ID is passed.

**Parameters:**

**Class\_ID cid**

The Class\_ID used when the controller was added.

**Prototype:**

**virtual int NumItems()=0;**

**Remarks:**

This method returns the total number of sub-nodes and/or sub-controllers in the table.

**Prototype:**

**virtual void SwapPositions(int i1, int i2)=0;**

**Remarks:**

This method is used to rearrange the elements in the table so item **i1** is where **i2** was and **i2** is where **i1** was.

**Parameters:**

**int i1**

The zero based index into the table of one of the items to swap.

**int i2**

The zero based index into the table of the other item to swap.

**Prototype:**

**virtual TCHAR \*GetName(int i)=0;**

**Remarks:**

Returns the name of the 'i-th' sub-node or sub-controller.

**Parameters:**

**int i**

The zero based index into the table of the item whose name to return.

**Prototype:**

**virtual void SetName(int i,TCHAR \*name)=0;**

**Remarks:**

Sets the name of the 'i-th' sub-node or sub-controller to the name passed.

**Parameters:**

**int i**

The zero based index into the table of the item whose name to set.

**TCHAR \*name**

The new name for the sub-node or sub-controller.

**Prototype:**

**virtual void RegisterTVNodeNotify(TVNodeNotify \*notify)=0;**

**Remarks:**

Registers the track view notify callback object so it receives reference messages.

**Parameters:**

**TVNodeNotify \*notify**

Points to the callback object to register.

**Prototype:**

**virtual void UnRegisterTVNodeNotify(TVNodeNotify \*notify)=0;**

**Remarks:**

Un-Registers the track view notify callback object.

**Parameters:**

**TVNodeNotify \*notify**

Points to the callback object to register.

**Prototype:**

**virtual void HideChildren(BOOL chide)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This may be used to prevent child nodes from showing up in Track View.

**Parameters:**

**BOOL `hide`**

Pass TRUE to have children hidden; FALSE to have them visible.

## List of Image (G-Buffer) Channels

See Also: [Class GBuffer](#), [Class ImageFilter](#), [Class Bitmap](#), [Class MtlBase](#), [Class Interface](#), [Class INode](#), [Structure RealPixel](#), [Structure Color24](#).

Below is an overview of the image channels. The number of bits per pixel occupied by the channel is listed. The way the channel is accessed and cast to the appropriate data type is also shown.

Note: 3ds max users may store the G-Buffer data in offline storage in RLA or RPF files. For the definition of the RLA or RPF format you can look at the source code in `\MAXSDK\SAMPLES\IO\RLA\RLA.CPP`.

Also Note: The term 'fragment' is used in the descriptions of the channels below. A 'fragment' is the portion of a triangle of a mesh that's seen by a particular pixel being rendered. It's as if the pixel was a cookie-cutter and chopped a visible section of the triangle off for rendering -- that cut piece is called a fragment.

### **BMM\_CHAN\_Z**

Z-buffer, stored as a float. The size is 32 bits per pixel. This is the channel that would be used by a depth of field blur routine for instance. The Z value is at the center of the fragment that is foremost in the sorted list of a-buffer fragments. The Z buffer is an array of float values giving the Z-coordinate in camera space of the point where a ray from the camera through the pixel center first intersects a surface. All Z values are negative, with more negative numbers representing points that are farther from the camera. The Z buffer is initialized with the value **-1.0E30**. Note that this is a change over 3ds max 1.x where the Z buffer was previously initialized with **1.0E30**. The negative value is more appropriate since more negative values represent points farther from the camera.

Note that for non-camera viewports (such as Front, User, Grid, Shape, etc.) the values may be both positive and negative. In such cases the developer may as well add a large value onto all the values to make them all positive. This is because positive versus negative doesn't really mean anything. It is just the distance between values that matters.

As noted above, the Z values in the A buffer are in camera space. The projection for a point in camera space to a point in screen space is:

```
Point2 RenderInfo::MapCamToScreen(Point3 p) {  
    return (projType==ProjPerspective)?
```

```

Point2(xc + kx*p.x/p.z, yc + ky*p.y/p.z):
Point2(xc + kx*p.x, yc + ky*p.y);
}

```

This function is supplied by the RenderInfo data structure which can be obtained from the bitmap output by the renderer using the function **Bitmap::GetRenderInfo()**. Note that this outputs a **Point2**. There is no projection for Z. As noted before, the Z buffer just uses the camera space Z.

```

float *zbuffer = (float *)GetChannel(BMM_CHAN_Z,type);
BMM_CHAN_MTL_ID

```

The ID assigned to the material via the Material Editor. The size is 8 bits per pixel. This channel is currently settable to a value between 0 and 8 by the 'Material Effects Channel' flyoff in the Material Editor. A plug-in material can generated up to 255 different material ID's (since this is an 8-bit quantity). This channel would be used to apply an effect (i.e., a glow) to a specific material.

```

BYTE *bbuffer = (BYTE
*)GetChannel(BMM_CHAN_MTL_ID,type);
BMM_CHAN_NODE_ID

```

This is the ID assigned to node via the Object Properties / G-buffer ID spinner. The size is 16 bits per pixel. This channel would be used to perform an effect (for example a flare) on a specific node.

```

WORD *wbuffer = (WORD
*)GetChannel(BMM_CHAN_NODE_ID,type);
BMM_CHAN_UV

```

UV coordinates, stored as a Point2. The size is 64 bits per pixel. If you have UV Coordinates on your object this channel provides access to them. This channel could be used by 3D paint programs or image processing routines to affect objects based on their UVs. The UV coordinate is stored as a Point2, using Point2::x for u and Point2::y for v. The UV coordinates are values prior to applying the offset, tiling, and rotation associated with specific texture maps.

```

Point2 *pbuffer = (Point2
*)GetChannel(BMM_CHAN_UV,type);
BMM_CHAN_NORMAL

```

Normal vector in view space, compressed. The size is 32 bits per pixel. Object normals are available for image processing routines that take advantage of the normal vectors to do effects based on curvature (for example), as well as for 3D paint programs. The normal value is at the center of the fragment that is foremost in the sorted list of a-buffer fragments.

**DWORD \*dbuffer = (DWORD \*)GetChannel(BMM\_CHAN\_NORMAL,type);**

Note: The following function is available to decompress this value to a standard normalized **Point3** value (**DWORD** and **ULONG** are both 32 bit quantities):

**Point3 DeCompressNormal(ULONG n);**

The decompressed vector has absolute error < 0.001 in each component.

### **BMM\_CHAN\_REALPIX**

Non clamped colors in "RealPixel" format. The size is 32 bits per pixel. See [Structure RealPixel](#). These are 'real' colors that are available for physically-correct image processing routines to provide optical effects that duplicate the way the retina works.

**RealPixel \*rbuffer =**

**(RealPixel \*)GetChannel(BMM\_CHAN\_REALPIX,type);**

### **BMM\_CHAN\_COVERAGE**

Pixel coverage of the front surface. This provides an 8-bit value (0..255) that gives the coverage of the surface fragment from which the other G-buffer values are obtained. This channel is being written and read with RLA files, and shows up in the Virtual Frame Buffer. This may be used to make the antialiasing in 2.5D plug-ins such as Depth Of Field filters much better.

**UBYTE \*gbufCov =**

**(UBYTE\*)GetChannel(BMM\_CHAN\_COVERAGE,type);**

### **BMM\_CHAN\_BG**

The RGB color of what's behind the front object. The size is 24 bits per pixel.

If you have the image color at a pixel, and the Z coverage at the pixel, then when the Z coverage is < 255, this channel tells you the color of the object that was partially obscured by the foreground object. For example, this info will let you determine what the "real" color of the foreground object was before it was blended (antialiased) into the background.

```
Color24 *bgbuffer = (Color24  
*)GetChannel(BMM_CHAN_BG,type);  
BMM_CHAN_NODE_RENDER_ID
```

System node number (valid during a render). The size is 16 bits per pixel.

The renderer will set the RenderID of all rendered nodes, and will set all non-rendered nodes to **0xffff**. Video Post plug-ins can use the

**Interface::GetINodeFromRenderID()** method to get a node pointer from an ID in this channel. Note that this channel is NOT saved with RLA files, because the IDs would not be meaningful unless the scene was the one rendered.

```
UWORD *renderID = (UWORD  
*)GetChannel(BMM_CHAN_NODE_RENDER_ID,type);  
INode *node = ip->GetINodeFromRenderID(*renderID);  
BMM_CHAN_COLOR
```

This option is available in release 3.0 and later only.

This is the color returned by the material shader for the fragment. It is a 24 bit RGB color (3 bytes per pixel).

```
Color24 *c1 = (Color24  
*)GetChannel(BMM_CHAN_COLOR,type);  
BMM_CHAN_TRANSP
```

This option is available in release 3.0 and later only.

This is the transparency returned by the material shader for the fragment. It is a 24 bit RGB color (3 bytes per pixel).

```
Color24 *transp = (Color24  
*)GetChannel(BMM_CHAN_TRANSP,type);  
BMM_CHAN_VELOC
```

This option is available in release 3.0 and later only.

This gives the velocity vector of the fragment relative to the screen, in screen coordinates. It is a Point 2 (8 bytes per pixel).

```
Point2 *src = (Point2  
*)GetChannel(BMM_CHAN_VELOC,type);  
BMM_CHAN_WEIGHT
```

This option is available in release 3.0 and later only.

This is the sub-pixel weight of a fragment. It is a 24 bit RGB color (3 bytes per pixel). It is the fraction of the total pixel color contributed by the fragment. The sum of (color \*weight) for all the fragments should give the final pixel color. The weight ( which is an RGB triple) for a given fragment takes into account the coverage of the fragment and the transparency of any fragments which are in front of the given fragment.

If c1, c2, c3.. etc are the fragment colors, and w1, w2, w3... etc are the fragment weights, then

$$\text{pixel color} = c1*w1 + c2*w2 + c3*w3 + \dots + cN*wN;$$

The purpose of the sub-pixel weight is to allow post processes to weight the contribution of a post-effect from a particular fragment. It may also be necessary to multiply by the fragment's own transparency, which is *not* included in its weight. Note that for fragments that have no transparent fragments in front of them, the weight will be equal to the coverage.

**Color24 \*w1 = (Color24  
\*)GetChannel(BMM\_CHAN\_WEIGHT,type);**

**BMM\_CHAN\_NONE**

None of the channels above.

**BMM\_CHAN\_MASK**

This option is available in release 4.0 and later only.

The 4x4 (16 bits = 1 word) pixel coverage mask.

# Required Changes to MAX 2.x Plug-Ins to Run in MAX 3.0

See Also: [What's New in the MAX 3.0 SDK](#).

## Overview

This section provides general information on the changes required to all plug-ins to get them running in 3ds max 3.0. It also provides links to topics which discuss the specific changes for many affected plug-in types. Some of these changes are required while others are optional but advantageous.

## Current Compiler Version

A new version of the compiler is required. Visual C++ 6.0 is used for 3ds max 3.0. Prior versions of the compiler are no longer supported.

## DLL and File Loading Changes

The following changes were made affecting the loading of previous version DLLs and 3ds max files:

The value **MAX\_API\_NUM** was changed to 6 and thus DLL's compiled with the R2 API won't load.

The value **MAX\_RELEASE** was changed from 2500 to 3000 to indicate the current release.

The name of the class directory in 3ds max R3 files from was changed from "ClassDirectory2" to "ClassDirectory3". This will prevent 3ds max R3 files from being loaded into 3ds max R2 (3ds max will put up an Invalid File message).

## Library Files Renamed and Eliminated

The old **\MAXSDK\LIB\UTIL.LIB** file has been renamed to **MAXUTIL.LIB**. This prevents a conflict with a library file provided by VC++ 6.0. Therefore, developers will need to update their projects to point to the new LIB file instead.

**PATCH.LIB** has been eliminated from the SDK. Now simply use **CORE.LIB**.

## Parameter Block and Parameter Map Improvements

There is a new scheme for parameter blocks and parameter maps in release 3. While the old system still exists and will run fine, developers are encouraged to support this new system in their plug-ins. This makes them available to the macro recorder, 3ds max Scripter and Schematic View. See the Advanced Topics section [Parameter Blocks and Maps in Release 3](#) for implementation details.

## Miscellaneous Changes in R3 That May Affect Plug-Ins

### Floating Dialogs

This section relates to two common bugs in previous versions of 3ds max and thus likely many plug-ins that have copied or imitated 3ds max's source code. The problems are that modal dialogs aren't "truly" modal, and that modeless dialogs aren't getting disabled when other modal dialogs are presented.

The first condition to be on the look out for is the "Orphaned Dialog" type of bug. An example of this occurs when a user brings up a modal dialog, then hits a 3ds max toolbar button like "Undo", and the object that brought the dialog up goes away. The problem here is that the dialogs aren't "modal enough". That is, when a modal dialog is displayed, one should never be able to hit any toolbar button or menu entry from 3ds max's main user interface. The problem is that modal dialogs created with "DialogBox" or "DialogBoxParam" are only modal relative to their parent window. The solution is to use 3ds max's main window as the parent window of any modal dialog created. Developers can get the proper window handle to use with **Interface::GetMAXHwnd()**. Once this is done, users can't hit "Undo" or any other operation from 3ds max's main user interface while a modal dialog is displayed.

The second condition, where modeless dialogs aren't disabled, occurs because the dialog is not registered with Windows. Developers using modeless dialogs must call **Interface::RegisterDlgWnd()** to prevent this problem.

**In Summary:** ALL modeless dialogs in 3ds max have to be registered with **Interface::RegisterDlgWnd()** and ALL modal dialogs in 3ds max have to be a direct child of 3ds max (developers must use **Interface::GetMAXHwnd()** when the dialog is created).

### Getting the Mesh from a TriObject

The method **TriObject::Mesh()** method has been renamed to **TriObject::GetMesh()**. Plug-ins using the old method name will have to be changed.

### **SaveRequired API Change**

Two existing functions have been renamed and one has been added. This change will cause many existing plug-ins to fail to build, however the fix is trivial. See below:

The existing function:

**void SetSaveRequired(int b=TRUE)**

has been renamed to:

**void SetSaveRequiredFlag(BOOL b=TRUE)**

The existing function:

**BOOL GetSaveRequired()**

has been renamed to:

**BOOL GetSaveRequiredFlag()**

There is also a new function:

**BOOL IsSaveRequired().**

The reason for these changes is that these two functions had misleading names. **GetSaveRequired()** does not tell you if saving is required, it just returns the value of the 'save required' bit. To really know if saving is required, you have to check the undo buffer as well as this flag. This is what the new function **IsSaveRequired()** is doing. If this function reports true, then you'll get the prompt at reset, file open, etc. The same goes for **SetSaveRequired()**, **SetSaveRequired(TRUE)** will cause the "save changes" prompt to appear, but **SetSaveRequired(FALSE)** will not prevent it from coming up unless you also reset the undo buffer.

### **Middle Mouse Button**

The middle mouse button may now be used to perform the arc-rotate function (by holding down the Alt-key). This new functionality necessitated an internal change where the viewport transformation might change inside a plug-ins mouse proc. To avoid problems plug-ins should not cache the viewport transformation at the start of the mouse proc as it may change due to the user performing an arc-rotate. Very few plug-ins do this currently, but those that do must not rely on this any longer.

## **Links to Topics By Plug-In Type**

This section provides links to topics on the required and optional changes for each plug-in type.

Note that all developers should be sure to look over the "Miscellaneous Changes in R3 That May Affect Plug-ins" section above since there may be important changes listed there as well.

# MAXScript SDK

See Also: [Must Read Sections for All Developers](#).

The MAXScript SDK is a set of Visual C++ headers and import libraries that C++ programmers can use to extend MAXScript. These extensions can be in the form of new built-in functions, new system globals or descriptors for new MAX plug-in class properties. This is useful for 3rd-party plug-in developers to write custom scripting interfaces for their plug-ins, and for programmers to do custom C++ performance code and drive it with scripts for hybrid tools.

The scripter SDK allows extensions to be added either incrementally through a MAXScript-specific DLL file type that is loaded by MAXScript or by runtime calls directly to MAXScript from within an existing plug-in.

The following topics describe the SDK:

## Class DataClassDesc

See Also: [Class ClassDesc](#), [Class ClassEntry](#), [Class BitmapIO](#), [Class SceneImport](#), [Class SceneExport](#).

```
class DataClassDesc : public ClassDesc
```

### Description:

This class is available in release 3.0 and later only.

This is a "partial" class descriptor for classes in plug-ins described by Registry entries. The registry is a system-defined database that applications and system components use to store and retrieve configuration data. This class provides a "stub" or partial class description, as read from the Registry, which provides basic descriptive information about the class (which proves adequate for certain purposes). Proper use of the method **ClassEntry::FullCD()** ensures that the partial class description will be replaced by the full one, which includes the **ClassDesc::Create()** method and other functionality. Note: With the addition of delay-loaded plugins, the method **ClassEntry::CD()** may return a pointer to an instance of this class. This derived class implements **Create()** by returning NULL. Developers need to call **FullCD()** in order to ensure that the class is actually there.

For additional details see [Class ClassEntry](#) and the Advanced Topics section [Deferred Loading of Plug-Ins](#).

### Data Members:

public:

These data members are initialized from the Registry.

**TSTR category;**

The category string (**ClassDesc::Category()**).

**DWORD classIDA;**

The first ulong of the Class\_ID (**ClassDesc::ClassID()**).

**DWORD classIDB;**

The second ulong of the Class\_ID (**ClassDesc::ClassID()**).

**DWORD superClassID;**

The SuperClassID (**ClassDesc::SuperClassID()**).

**TSTR className;**

The class name (**ClassDesc::ClassName()**).

**DWORD isPublic;**

The **ClassDesc::ISPublic()** return value.

**DWORD okToCreate;**

The **ClassDesc::OkToCreate()** return value.

**DWORD extCount;**

Returns the number of file name extensions supported

(**SceneImport::ExtCount()**,**SceneExport::ExtCount()**,

**BitmapIO::ExtCount()**).

**TSTR ext;**

The file name extension (**SceneImport::Ext(0)**, **SceneExport::Ext(0)**,

**BitmapIO::Ext(0)**).

**TSTR shortDesc;**

The short ASCII description (**SceneImport::ShortDesc()**,

**SceneExport::ShortDesc()**).

**TSTR longDesc;**

The long ASCII description (**SceneImport::LongDesc()**,

**SceneExport::LongDesc()**).

**DWORD supportsOptions;**

The export options (**SceneExport::SupportsOptions()**).

**DWORD capability;**

The BitmapIO module capability flags (**BitmapIO::Capability()**).

**DWORD inputTypeA;**

The first ulong of the **Modifier::InputType()** Class\_ID.

**DWORD inputTypeB;**

The second ulong of the **Modifier::InputType()** Class\_ID.

## **Methods:**

public:

The following are the meaningful methods from the base class ClassDesc which are provided by this class. Other methods not listed have basically NULL (i.e. non-functional) implementations.

## **Prototype:**

**int IsPublic();**

**Remarks:**

Returns the **isPublic** setting.

**Prototype:**

**const TCHAR \*ClassName();**

**Remarks:**

Returns the class name for the plug-in (**className**).

**Prototype:**

**SClass\_ID SuperClassID();**

**Remarks:**

Returns the SuperClassID (**superClassID**). Note: **typedef ulong SClass\_ID;**

**Prototype:**

**Class\_ID ClassID();**

**Remarks:**

Returns the Class\_ID. This is **Class\_ID(classIDA, classIDB)**.

**Prototype:**

**const TCHAR \*Category();**

**Remarks:**

Returns the **category** string.

**Prototype:**

**BOOL OkToCreate(Interface \*i);**

**Remarks:**

Returns the **okToCreate** state.

## Class ClassEntry

See Also: [Class DllDir](#), [Class SubClassList](#), [Class ClassDesc](#), [Class DataClassDesc](#), [Class Class\\_ID](#).

class ClassEntry

### Description:

This class is available in release 2.0 and later only.

This class provides information about a class in the **SubClassList** table of classes. This is information such as the class ID, category, public status, usage count, etc.

All methods of this class are implemented by the system.

### Methods:

#### Prototype:

**ClassDesc \*CD();**

#### Remarks:

Returns a pointer to the class descriptor for this entry. Note: With the addition of deferred-loaded plug-ins introduced in 3ds max 3.0, this method may return a pointer to an instance of class **DataClassDesc** (a sub-class of **ClassDesc**). A developer can tell if the returned class is a **DataClassDesc** object if **ClassEntry::IsLoaded()** returns FALSE. This derived class implements **ClassDesc::Create()** by returning NULL. Developers need to call **ClassEntry::FullCD()** in order to ensure that the class is actually present. Developers can call this method to retrieve data about the plug-in without forcing a load. It may also be called to get a 'full' **ClassDesc** if it is known that the plug-in is loaded (**IsLoaded()** returns TRUE).

#### Prototype:

**ClassDesc \*FullCD();**

#### Remarks:

This method is available in release 3.0 and later only.

This method fetches the class descriptor from a class entry. Unlike **CD()** above, this method will load the relevant DLL if its loading was deferred, and

will return a pointer to the loaded class descriptor. See [Deferred Loaded of Plug-Ins](#) for more details.

**Prototype:**

**int IsPublic();**

**Remarks:**

Returns nonzero if the class is public; otherwise zero. Non-public classes are those that are meant for private use by other plug-ins.

**Prototype:**

**Class\_ID ClassID();**

**Remarks:**

Returns the Class\_ID of the entry.

**Prototype:**

**TSTR &ClassName();**

**Remarks:**

Returns the class name of the entry.

**Prototype:**

**TSTR &Category();**

**Remarks:**

Returns a reference to the category string for this entry.

**Prototype:**

**int UseCount();**

**Remarks:**

Returns the number of instance of this class used in 3ds max.

**Prototype:**

**void IncUseCount();**

**Remarks:**

This is used internally to increment the usage count for this entry.

**Prototype:**

**void SetUseCount(int i);**

**Remarks:**

This is used internally to set the usage count for this entry.

**Prototype:**

**int IsAccType(int accType);**

**Remarks:**

Returns nonzero if this entry matches the specified access type; otherwise zero.

**Parameters:**

**int accType**

One of the following values:

**ACC\_PUBLIC** - public classes

**ACC\_PRIVATE** - non-public classes

**Prototype:**

**int DllNumber();**

**Remarks:**

Returns the index into the master DLL list of this entry.

**Prototype:**

**bool IsLoaded();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if loaded; otherwise FALSE.

**Prototype:**

**int ClassNumber();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the index of the class within the DLL

**Prototype:**

**void Set(ClassDesc \*cld, int dllN, int index);**

**Remarks:**

This method is used internally.

**Prototype:**

**int GetScroll();**

**Remarks:**

This method is used internally.

**Prototype:**

**void SetScroll(int s);**

**Remarks:**

This method is used internally.

**Prototype:**

**BOOL GetPageState(int i);**

**Remarks:**

This method is used internally.

**Prototype:**

**void SetPageState(int i,BOOL state);**

**Remarks:**

This method is used internally.

**Operators:**

**Prototype:**

**ClassEntry& operator=(const ClassEntry &ce);**

**Remarks:**

Assignment operator.

**Prototype:**

**int operator==(const ClassEntry &ce) const;**

**Remarks:**

Equality operator.

## Class NURBSTextureChannelSet

See Also: [Class NURBSTextureChannel](#), [NURBSSurface](#), [Template Class Tab](#).

```
class NURBSTextureChannelSet
```

### Description:

This class is available in release 3.0 and later only.

This class holds a table of pointers to all the **NURBSTextureChannel** data for a surface. There are methods to returns the table data by channel or by index and a method to add a new texture channel.

### Friend Classes:

```
friend class NURBSSurface;
```

### Data Members:

```
private:
```

```
    Tab<NURBSTextureChannel*> mTextureChannels;
```

A table of pointers to the texture channel data.

### Methods:

```
private:
```

### Prototype:

```
    NURBSTextureChannel* GetChannelByIndex(int index);
```

### Remarks:

Returns a pointer to the texture channel object whose index is specified.

### Parameters:

```
    int index
```

The zero based index into the table of texture channels in the set.

### Prototype:

```
    NURBSTextureChannel* GetChannel(int channel);
```

### Remarks:

Returns a pointer to the specific texture channel object. If not found a new channel is added with the specified index.

**Parameters:**

**int channel**

The channel to get. This is a number in the range 0 and 98 which correspond to 1 to 99 in the user interface.

**Prototype:**

**NURBSTextureChannel\* AddChannel(int channel);**

**Remarks:**

Adds the specified channel and returns a pointer to the allocated texture object.

**Parameters:**

**int channel**

The texture channel. This is a number in the range 0 and 98 which correspond to 1 to 99 in the user interface.

**Prototype:**

**int NumChannels();**

**Remarks:**

Returns the number of channels in the set.

## Class NURBSTextureChannel

See Also: [Class NURBSTextureSurface](#), [Class NURBSTextureChannelSet](#), [Class NURBSSurface](#), [Class Point2](#).

```
class NURBSTextureChannel
```

### Description:

This class is available in release 3.0 and later only.

This class holds the data associated with a single texture channel. This includes the **NURBSTextureSurface**, texture vertices, channel number, tiling, offset, and rotation settings. The tiling, offset and angle values are applied after the texture surface is applied. This gives the user more control of the mapping.

### Friend Classes:

```
friend class NURBSSurface;
```

```
friend class NURBSTextureChannelSet;
```

### Data Members:

```
private:
```

```
int mChannel;
```

The UV coordinates channel. This value can range from 0 to 98. A single surface can use up to 99 texture channels.

```
BOOL mGenUVs;
```

TRUE if the generate UV setting is on for this channel; otherwise FALSE.

```
Point2 mTexUVs[4];
```

The texture vertices (UV coordinates).

```
float mUTile;
```

The U tiling.

```
float mVTile;
```

The V tiling.

```
float mUOffset;
```

The U offset.

```
float mVOffset;
```

The V offset.

```
float mAngle;
```

The rotation angle in radians.

**NURBSTextureSurface mTexSurface;**

The texture surface associated this channel.

**Methods:**

private:

**Prototype:**

**NURBSTextureChannel(int channel);**

**Remarks:**

Constructor. The data members are initialized as follows:

```
mChannel = channel;  
mGenUVs = FALSE;  
mTexUVs[0] = Point2(0.0f, 0.0f);  
mTexUVs[1] = Point2(1.0f, 0.0f);  
mTexUVs[2] = Point2(0.0f, 1.0f);  
mTexUVs[3] = Point2(1.0f, 1.0f);  
mUTile = 1.0f;  
mVTile = 1.0f;  
mUOffset = 0.0f;  
mVOffset = 0.0f;  
mAngle = 0.0f;
```

**Prototype:**

**int GetChannel();**

**Remarks:**

Returns the UV coordinate channel.

**Prototype:**

**BOOL GenerateUVs();**

**Remarks:**

Returns TRUE if the generate UVs state is on; otherwise FALSE.

**Prototype:**

**void SetGenerateUVs(BOOL state);**

**Remarks:**

Sets the generate UV state.

**Parameters:**

**BOOL state**

TRUE for on; FALSE for off.

**Prototype:**

**Point2 GetTextureUVs(TimeValue t, int i);**

**Remarks:**

Returns the 'i-th' texture corner at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the texture vertex.

**int i**

The index of the texture vertex. This is a value in the range 0 to 3.

**Prototype:**

**void SetTextureUVs(TimeValue t, int i, Point2 pt);**

**Remarks:**

Sets the specified texture coordinate.

**Parameters:**

**TimeValue t**

The time at which to set the texture UV.

**int i**

The index of the UV to set. This is a value in the range 0 to 3.

**Point2 pt**

The UV point to set.

**Prototype:**

**void GetTileOffset(TimeValue t, float &ut, float &vt, float &uo,**

**float &vo, float &a);**

**Remarks:**

Retrieves the tiling, offset and angle values at the specified time.

**Parameters:**

**TimeValue t**

The time at which to get the values.

**float &ut**

The U tiling.

**float &vt**

The V tiling.

**float &uo**

The U offset.

**float &vo**

The V offset.

**float &a**

The angle.

**Prototype:**

**void SetTileOffset(TimeValue t, float ut, float vt, float uo, float vo, float a);**

**Remarks:**

Sets the tiling, offset and angle values at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the values.

**float ut**

The U tiling.

**float vt**

The V tiling.

**float uo**

The U offset.

**float vo**

The V offset.

**float a**

The angle.

**Prototype:**

**NURBSTextureSurface& GetTextureSurface();**

**Remarks:**

Returns a reference to the **NURBSTextureSurface** maintained by the class.

**Prototype:**

**void SetTextureSurface(NURBSTextureSurface& texSurf);**

**Remarks:**

Set the **NURBSTextureSurface** maintained by the class.

**Parameters:**

**NURBSTextureSurface& texSurf**

The texture surface to set.

## Class NURBSTexturePoint

See Also: [Class NURBSTextureSurface](#), [Class NURBSObject](#), [Class Point2](#).

```
class NURBSTexturePoint : public NURBSObject
```

### Description:

This class is available in release 3.0 and later only.

This class holds a single texture vertex in a NURBS texture surface. Methods are available to get and set the point in various formats.

### Data Members:

protected:

**double mX, mY;**

The position of the point.

### Methods:

public:

### Prototype:

**NURBSTexturePoint();**

### Remarks:

Constructor. The data members (from **NURBSObject**) are initialized as follows:

**mKind = kNURBSTexturePoint;**

**mType = kNTexturePoint;**

### Prototype:

**virtual Point2 GetPosition(TimeValue t);**

### Remarks:

Returns the position of the texture point at the specified time (as a Point2).

### Parameters:

**TimeValue t**

The time at which to get the position.

### Prototype:

**virtual void GetPosition(TimeValue t, float& x, float& y);**

**Remarks:**

Retrieves the position of the texture point at the specified time (as floats).

**Parameters:**

**TimeValue t**

The time at which to get the position.

**float& x**

The x position is returned here.

**float& y**

The y position is returned here.

**Prototype:**

**virtual void GetPosition(TimeValue t, double& x, double& y);**

**Remarks:**

Retrieves the position of the texture point at the specified time (as doubles).

**Parameters:**

**TimeValue t**

The time at which to get the position.

**double& x**

The x position is returned here.

**double& y**

The y position is returned here.

**Prototype:**

**void SetPosition(TimeValue t, Point2 pt);**

**Remarks:**

Sets the position of the point at the specified time (using a Point2).

**Parameters:**

**TimeValue t**

The time at which to set the position.

**Point2 pt**

The position to set.

**Prototype:**

**void SetPosition(TimeValue t, float x, float y);**

**Remarks:**

Sets the position of the point at the specified time (using floats).

**Parameters:**

**TimeValue t**

The time at which to set the position.

**float x**

The x coordinate to set.

**float y**

The y coordinate to set.

**Prototype:**

**void SetPosition(TimeValue t, double x, double y);**

**Remarks:**

Sets the position of the point at the specified time (using doubles).

**Parameters:**

**TimeValue t**

The time at which to set the position.

**double x**

The x coordinate to set.

**double y**

The y coordinate to set.

## Class NURBSSurfaceEdgeCurve

See Also: [Class NURBSCurve](#).

```
class NURBSSurfaceEdgeCurve : public NURBSCurve
```

### Description:

This class is available in release 3.0 and later only.

This class defines a dependent edge curve. There are methods available to get/set the parent surface index and id, and get/set the parameter which determines the location on the surface the curve matches.

All methods of this class are implemented by the system.

### Friend Classes:

```
friend class NURBSSet
```

### Methods:

protected:

### Prototype:

```
void Clean(NURBSIdTab ids);
```

### Remarks:

This method is available in release 3.0 and later only.

This methods breaks the relation between this **NURBSObject** and a **NURBSSet**.

### Parameters:

**NURBSIdTab ids**

A table with the IDs of each object in the **NURBSSet**.

public:

### Prototype:

```
NURBSSurfaceEdgeCurve();
```

### Remarks:

Constructr. The data members are initialized as follows:

```
mType = kNSurfaceEdgeCurve;
```

```
mpObject = NULL;
```

```
mpNSet = NULL;  
mParentId = 0;  
mParentIndex = -1;  
mSeed = Point2(0.0, 0.0);
```

**Prototype:**

```
virtual ~NURBSSurfaceEdgeCurve();
```

**Remarks:**

Destructor.

**Prototype:**

```
void SetParent(int index);
```

**Remarks:**

Sets the **NURBSId** of the specified parent.

**Parameters:**

**int index**

The index into the **NURBSSet** of the parent surface.

**Prototype:**

```
void SetParentId(NURBSId id);
```

**Remarks:**

Sets the **NURBSId** of the specified parent.

**Parameters:**

**NURBSId id**

The id to set.

**Prototype:**

```
int GetParent();
```

**Remarks:**

Returns the index in the **NURBSSet** of the parent object.

**Prototype:**

**NURBSId GetParentId();**

**Remarks:**

Returns the **NURBSId** of the parent. Note that a **NURBSId** won't be valid until the object has been instantiated in the scene.

**Prototype:**

**Point2 GetSeed();**

**Remarks:**

Returns the UV location of the seed value on the curve.

**Prototype:**

**void SetSeed(Point2& seed);**

**Remarks:**

Sets the UV location of the seed value on the curve.

**Parameters:**

**Point2& seed**

The seed value to set.

**Operators:**

**Prototype:**

**NURBSSurfaceEdgeCurve &operator=(const  
NURBSSurfaceEdgeCurve& curve);**

**Remarks:**

Assignment operator.

**Parameters:**

**const NURBSSurfaceEdgeCurve& curve**

The curve to assign from.

## Class NURBSFilletSurface

See Also: [Class NURBSSurface](#).

```
class NURBSFilletSurface : public NURBSSurface
```

### Description:

This class is available in release 3.0 and later only.

This class provides access to the NURBS Fillet Surface. Methods are provided to get / set the parent surfaces, get / set the radius, and get / set the trim and trim flip settings.

### Methods:

protected:

### Prototype:

```
void Clean(NURBSIdTab ids);
```

### Remarks:

This method is available in release 3.0 and later only.

This methods breaks the relation between this **NURBSObject** and a **NURBSSet**.

### Parameters:

**NURBSIdTab ids**

A table with the IDs of each object in the **NURBSSet**.

public:

### Prototype:

```
NURBSFilletSurface();
```

### Remarks:

Constructor. The data members are initialized as follows:

```
mType = kNFilletSurface;
```

```
mpObject = NULL;
```

```
mpNSet = NULL;
```

```
mParentId[0] = mParentId[1] = 0;
```

```
mParentIndex[0] = mParentIndex[1] = -1;
```

```
mRadius[0] = mRadius[1] = 10.0f;  
mSeed[0] = mSeed[1] = Point2(0.0, 0.0);  
mCubic = TRUE;
```

**Prototype:**

```
virtual ~NURBSFilletSurface();
```

**Remarks:**

Destructor.

**Prototype:**

```
void SetParent(int pnum, int index);
```

**Remarks:**

Sets the specified parent surface (by **NURBSSet** index) for the fillet.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**int index**

The index in the **NURBSSet**.

**Prototype:**

```
void SetParentId(int pnum, NURBSId id);
```

**Remarks:**

Sets the specified parent surface (by **NURBSId**) for the fillet.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**NURBSId id**

The ID of the surface.

**Prototype:**

```
int GetParent(int pnum);
```

**Remarks:**

Returns the index in the **NURBSSet** of the specified parent surface.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Prototype:**

**NURBSId GetParentId(int pnum);**

**Remarks:**

Returns the NURBSId of the specified parent surface.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Prototype:**

**Point2 GetSeed(int pnum);**

**Remarks:**

Returns the UV location of the seed value on the specified surface.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Prototype:**

**void SetSeed(int pnum, Point2& seed);**

**Remarks:**

Sets the UV location of the seed value on the specified surface.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Point2& seed**

The seed value to set.

**Prototype:**

**BOOL IsCubic();**

**Remarks:**

Returns TRUE if the cubic setting is on; FALSE if off. When off, the radius is always linear. When on, the radius is treated as a cubic function, allowing it to change based on the parent surface's geometry.

**Prototype:**

**void SetCubic(BOOL cubic);**

**Remarks:**

Sets the cubic setting to on or off.

**Parameters:**

**BOOL cubic**

TRUE for on; FALSE for off.

**Prototype:**

**float GetRadius(TimeValue t, int rnum);**

**Remarks:**

Returns the specified radius at the time passed.

**Parameters:**

**TimeValue t**

The time at which to get the radius.

**int rnum**

Specifies which radius to get: 0 for start, 1 for end.

**Prototype:**

**void SetRadius(TimeValue t, int rnum, float radius);**

**Remarks:**

Sets the specified radius at the time passed.

**Parameters:**

**TimeValue t**

The time at which to set the radius.

**int rnum**

Specifies which radius to set: 0 for start, 1 for end.

**float radius**

The radius to set.

**Prototype:**

**BOOL GetTrimSurface(int pnum);**

**Remarks:**

Returns the trim surface setting for the specified parent surface. TRUE if on (trims the parent surface at the edge of the fillet); FALSE if off.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Prototype:**

**void SetTrimSurface(int pnum, BOOL trim);**

**Remarks:**

Sets the trim surface setting for the specified parent surface.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**BOOL trim**

TRUE for on (trims the parent surface at the edge of the fillet); FALSE for off.

**Prototype:**

**BOOL GetFlipTrim(int pnum);**

**Remarks:**

Returns the state of the trim flip setting. When set this reverses the direction of the trim.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**Prototype:**

**void SetFlipTrim(int pnum, BOOL flip);**

**Remarks:**

Sets the state of the trim flip setting. When set this reverses the direction of the trim.

**Parameters:**

**int pnum**

The parent surface: 0 or 1.

**BOOL flip**

TRUE for on; FALSE for off.

**Prototype:**

**NURBSFilletSurface & operator=(const NURBSFilletSurface& curve);**

**Remarks:**

Assignment operator.

**Parameters:**

**const NURBSFilletSurface& curve**

The surface to assign.

# Class NURBSProceduralCurve

See Also: [Class NURBSCVCurve](#), [Class NURBSCurve](#).

class NURBSProceduralCurve

## Description:

This class is available in release 3.0 and later only.

This is the base class for procedurally defined curves. Note that this is not subclassed from **NURBSObject**. You must use the **GenNURBSCVCurveProcedurally()** function.

The following typedef-ed functions are used by the **GenNURBSCVCurveProcedurally()** function.

## Prototype:

```
typedef NURBSResult (*CurveParamRangeProc)(double& tMin,  
double& tMax);
```

## Remarks:

The curve parameter range procedure. This retrieves the minimum and maximum valid values for u as passed to the **CurveEvalProc()**.

## Parameters:

**double& tMin**

The minimum value.

**double& tMax**

The maximum value.

## Return Value:

See [List of NURBS Results](#) .

## Prototype:

```
typedef NURBSResult (*CurveEvalProc)(double u, Point3& pt);
```

## Remarks:

The curve evaluation procedure. This retrieves the point on the curve based on the u parameter.

## Parameters:

**double u**

Specifies the U point along the curve to evaluate.

**Point3& pt**

The output point on the curve at U.

**Return Value:**

See [List of NURBS Results](#) .

**Prototype:**

```
typedef NURBSResult (*CurveEvalTan)(double u, Point3& pt,  
Point3& tan);
```

**Remarks:**

The curve point and tangent evaluation procedure. This retrieves the point and tangent at the point on the curve based on the U parameter.

**Parameters:**

**double u**

Specifies the point along the curve to evaluate.

**Point3& pt**

The output point at U.

**Point3& tan**

The output tangent at U.

**Return Value:**

See [List of NURBS Results](#) .

**Prototype:**

```
typedef NURBSResult (*CurveArcLengthProc)(double&  
arcLength);
```

**Remarks:**

Retrieves the length of the curve.

**Parameters:**

**double& arcLength**

The output arc length.

**Return Value:**

See [List of NURBS Results](#) .

## Data Members:

public:

**CurveParamRangeProc mParamProc;**

The curve parameter range procedure. Note: This procedure must be implemented.

**CurveEvalProc mEvalProc;**

The curve evaluate procedure. Note: This procedure must be implemented.

**CurveEvalTan mEvalTanProc;**

The curve evaluate tangent procedure. Note: This procedure is optional.

**CurveArcLengthProc mArcLengthProc;**

The curve arc length procedure. Note: This procedure is optional.

## Methods:

public:

### Prototype:

**NURBSProceduralCurve(CurveParamRangeProc param,  
CurveEvalProc eval, CurveEvalTan tan, CurveArcLengthProc  
arclen);**

### Remarks:

Constructor. The data members are initialized to the values passed.

**The following global function is not part of this class but is available for use:**

### Function:

**NURBSResult  
GenNURBSCVCurveProcedurally(NURBSProceduralCurve  
\*pCrv, double tolerance, NURBSCVCurve& crv);**

### Remarks:

This global function is available in release 3.0 and later only.

To use this API you need to create an instance of

**NURBSProceduralCurve** setting at least the ParameterRange and Eval procedures. The others can be NULL unless you have fast versions of them.

The call to this function then fills in a **NURBSCVCurve** with the curve that is defined by the procedures and the tolerance.

**Parameters:**

**\*pCrv**

Points to the **NURBSProceduralCurve** object used to generate the curve procedurally.

**double tolerance**

The tolerance is the allowable deviation of the approximating NURBS surface to the surface defined by the procs.

**NURBSCVCurve& crv**

The generated curve is returned here.

**Return Value:**

See [List of NURBS Results](#) .

## Class NURBSProceduralSurface

See Also: [Class NURBSCVSurface](#), [Class NURBSSurface](#).

class NURBSProceduralSurface

### Description:

This class is available in release 3.0 and later only.

This is the base class for a procedurally defined surface. Note: This class is not subclassed from **NURBSObject**. You must use the **GenNURBSCVSurfaceProcedurally()** function.

The following typedef-ed functions are used by the **GenNURBSCVSurfaceProcedurally()** function.

### Prototype:

```
typedef NURBSResult (*SurfParamRangeProc)(double& uMin,  
double& uMax, double& vMin, double& vMax);
```

### Remarks:

The surface parameter range procedure. This retrieves the minimum and maximum valid values for u and v as passed to the **SurfEvalProc()**.

### Parameters:

**double& uMin**

The min U value.

**double& uMax**

The max U value.

**double& vMin**

The min V value.

**double& vMax**

The max V value.

### Return Value:

See [List of NURBS Results](#) .

### Prototype:

```
typedef NURBSResult (*SurfEvalProc)(double u, double v,  
Point3& pt);
```

**Remarks:**

This evaluates the surface for the point or position at a given U and V parameter.

**Parameters:****double u**

Specifies the U point along the surface to evaluate. This value must be between the **uMin** and **uMax** as returned from **SurfParamRangeProc()**.

**double v**

Specifies the V point along the surface to evaluate. This value must be between the **vMin** and **vMax** as returned from **SurfParamRangeProc()**.

**Point3& pt**

The output point on the surface at (u,v).

**Return Value:**

See [List of NURBS Results](#) .

**Prototype:**

```
typedef NURBSResult (*SurfEvalTan)(double u, double v,  
Point3& uTan, Point3& vTan);
```

**Remarks:**

This evaluates the surface for the partial derivative with respect to U and the partial derivative with respect to V at a given U and V parameter. That partial derivative with respect to U is a tangent vector in the U direction and the partial derivative with respect to V is a tangent vector in the V direction.

**Parameters:****double u**

Specifies the U point along the curve to evaluate. This value must be between the **uMin** and **uMax** as returned from **SurfParamRangeProc()**.

**double v**

Specifies the V point along the surface to evaluate. This value must be between the **vMin** and **vMax** as returned from **SurfParamRangeProc()**.

**Point3& uTan**

The tangent along u.

**Point3& vTan**

The tangent along v.

**Return Value:**

See [List of NURBS Results](#) .

**Prototype:**

```
typedef NURBSResult (*SurfEvalMixedProc)(double u, double v,  
Point3& mixed);
```

**Remarks:**

This evaluates the surface for the mixed partial derivative with respect to U and V at a given U and V parameter.

**Parameters:**

**double u**

Specifies the U point along the curve to evaluate. This value must be between the **uMin** and **uMax** as returned from **SurfParamRangeProc()**.

**double v**

Specifies the V point along the surface to evaluate. This value must be between the **vMin** and **vMax** as returned from **SurfParamRangeProc()**.

**Point3& mixed**

This is the resulting mixed partial derivative vector that has been evaluated.

**Return Value:**

See [List of NURBS Results](#) .

**Data Members:**

public:

**SurfParamRangeProc mParamProc;**

The surface parameter range procedure. Note: This procedure must be implemented.

**SurfEvalProc mEvalProc;**

The surface evaluation procedure. Note: This procedure must be implemented.

**SurfEvalTan mEvalTanProc;**

The surface tangent evaluation procedure. Note: This procedure is optional.

**SurfEvalMixedProc mEvalMixedProc;**

The mixed partial derivative procedure. Note: This procedure is optional.

**Methods:**

public:

**Prototype:**

**NURBSProceduralSurface(SurfParamRangeProc param,  
SurfEvalProc eval, SurfEvalTan tan, SurfEvalMixedProc mixed);**

**Remarks:**

Constructor. The data members are initialized to the values passed.

Both (**\*SurfEvalTan**) and (**\*SurfEvalMixedProc**) are optional. If NULLs are provided for either of these functions then 3ds max will resort to a finite differences based solution.

**Parameters:**

**The following global function is not part of this class but is available for use:**

**Function:**

**NURBSResult  
GenNURBSCVSurfaceProcedurally(NURBSProceduralSurface  
\*pSurf, double tolerance, NURBSCVSurface& surf);**

**Remarks:**

This global function is available in release 3.0 and later only.

To use this function you need to create an instance of

**NURBSProceduralSurface** setting at least the ParameterRange and Eval procedures. The others can be NULL unless you have fast versions of them.

This call then fills in a NURBSCVSurface with the surface that is defined by the procedures and the tolerance.

**Parameters:**

**NURBSProceduralSurface \*pSurf**

Points to the **NURBSProceduralSurface** to generate CV surfaces from.

**double tolerance**

The tolerance is the allowable deviation of the approximating NURBS surface to the surface defined by the procs.

**NURBSCVSurface& surf**

The generated NURBSCVSurface is returned here.

**Return Value:**

See [List of NURBS Results](#) .

## List of Notification Codes

See Also: [Structure NotifyInfo](#), [Class Interface](#), [Class Bitmap](#), [Class RenderGlobalContext](#).

The following pre-defined system notification codes may be passed to the global functions **RegisterNotification()**, **UnRegisterNotification()**, **BroadcastNotification()**.

### **NOTIFY\_UNITS\_CHANGE**

Sent if the user changes the unit setting

### **NOTIFY\_TIMEUNITS\_CHANGE**

Sent if the user changes the time format setting

### **NOTIFY\_VIEWPORT\_CHANGE**

Sent if the user changes the viewport layout

### **NOTIFY\_SPACEMODE\_CHANGE**

Sent if the user changes the reference coordinate system.

### **NOTIFY\_SYSTEM\_PRE\_RESET**

Sent before 3ds max is reset. This is available in release 2.0 and later only.

### **NOTIFY\_SYSTEM\_POST\_RESET**

Sent after 3ds max is reset. This is available in release 2.0 and later only.

### **NOTIFY\_SYSTEM\_PRE\_NEW**

Sent before 3ds max is NEW'd-out. This is available in release 2.0 and later only.

### **NOTIFY\_SYSTEM\_POST\_NEW**

Sent after 3ds max is NEW'd-out. This is available in release 2.0 and later only.

### **NOTIFY\_FILE\_PRE\_OPEN**

Sent before a new file is opened. This is available in release 2.0 and later only.

### **NOTIFY\_FILE\_POST\_OPEN**

Sent after a new file is opened successfully. This is available in release 2.0 and later only.

### **NOTIFY\_FILE\_PRE\_MERGE**

Sent before a file is merged. This is available in release 2.0 and later only.

Note: When merge is called to load an XRef, developers can be aware of this by testing **void \* callParam** to see if it's non-null. If it is then an XRef is

being loaded.

### **NOTIFY\_FILE\_POST\_MERGE**

Sent after a file is merged. This is available in release 2.0 and later only.

Note: When merge is called to load an XRef, developers can be aware of this by testing **void \* callParam** to see if it's non-null. If it is then an XRef is being loaded.

### **NOTIFY\_FILE\_PRE\_SAVE**

Sent before a file is saved. This is available in release 2.5 and later only.

### **NOTIFY\_FILE\_POST\_SAVE**

Sent after a file is saved. This is available in release 2.5 and later only.

### **NOTIFY\_FILE\_PRE\_SAVE\_OLD**

This option is reserved for future use as of 3ds max 3.0.

### **NOTIFY\_FILE\_POST\_SAVE\_OLD**

This option is reserved for future use as of 3ds max 3.0.

### **NOTIFY\_SELECTIONSET\_CHANGED**

This option is available in release 3.0 and later only.

Sent after the selection set has changed.

### **NOTIFY\_BITMAP\_CHANGED**

This option is available in release 3.0 and later only.

Sent after the bitmap is reloaded (the **NotifyInfo** structure pointer **callParam** is passed the **TCHAR \*** to the bitmap file name). This is used for updating bitmaps that have changed. The **callParam** is used to pass the name of the bitmap file in case it is used in multiple changes. If the **callParam** is NULL, this notification will apply to all bitmaps (as is the case when the input file gamma changes).

### **NOTIFY\_PRE\_RENDER**

This option is available in release 3.0 and later only.

Sent before rendering is started.

### **NOTIFY\_POST\_RENDER**

This option is available in release 3.0 and later only.

Sent after rendering has finished.

### **NOTIFY\_PRE\_RENDERFRAME**

This option is available in release 3.0 and later only.

Sent before rendering each frame (the `NotifyInfo` structure pointer **callParam** is passed a pointer to the **RenderGlobalContext**).

Note: At the time of this call the scene **cannot** be modified. The renderer has already called **GetRenderMesh()** on all the object instances, and the materials and lights are already updated. If you don't modify anything that is rendered, then it is okay to use this callback.

### **NOTIFY\_POST\_RENDERFRAME**

This option is available in release 3.0 and later only.

Sent after rendering each frame (the `NotifyInfo` structure pointer **callParam** is passed a pointer to the **RenderGlobalContext**). See the note in **NOTIFY\_PRE\_RENDERFRAME** above.

### **NOTIFY\_PRE\_IMPORT**

This option is available in release 3.0 and later only.

Sent before a file is imported (always).

### **NOTIFY\_POST\_IMPORT**

This option is available in release 3.0 and later only.

Sent after a file is imported successfully.

### **NOTIFY\_IMPORT\_FAILED**

This option is available in release 3.0 and later only.

Sent if an import fails or is otherwise cancelled.

### **NOTIFY\_PRE\_EXPORT**

This option is available in release 3.0 and later only.

Sent before a file is exported (always).

### **NOTIFY\_POST\_EXPORT**

This option is available in release 3.0 and later only.

Sent after a file is exported successfully.

### **NOTIFY\_EXPORT\_FAILED**

This option is available in release 3.0 and later only.

Sent if an export fails or is otherwise cancelled.

### **NOTIFY\_NODE\_RENAMED**

This option is available in release 3.0 and later only.

Sent if a node is renamed. (the `NotifyInfo` structure pointer **callParam** is passed a pointer to a `struct{ TCHAR* oldname; TCHAR* newname;`

} See **\MAXSDK\SAMPLES\OBJECTS\LIGHT.CPP** for an example of this notification in use.

### **NOTIFY\_PRE\_PROGRESS**

This option is available in release 3.0 and later only.

Sent before the progress bar is displayed. The progress bar is displayed, for example, when the Render Preview command is run. Note: If a plug-in uses a modeless window it should hide the window between this event and

### **NOTIFY\_POST\_PROGRESS.**

### **NOTIFY\_POST\_PROGRESS**

This option is available in release 3.0 and later only.

Sent after the progress bar is finished.

### **NOTIFY\_MATLIB\_PRE\_OPEN**

This option is available in release 3.0 and later only.

Sent before loading a material library.

### **NOTIFY\_MATLIB\_POST\_OPEN**

This option is available in release 3.0 and later only.

Sent after loading a material library. The **callParam** is a pointer to the MtlBaseLib if successful, otherwise it's NULL.

### **NOTIFY\_MATLIB\_PRE\_SAVE**

This option is available in release 3.0 and later only.

Sent before saving a material library.

### **NOTIFY\_MATLIB\_POST\_SAVE**

This option is available in release 3.0 and later only.

Sent after saving a material library.

### **NOTIFY\_MATLIB\_PRE\_MERGE**

This option is available in release 3.0 and later only.

Sent before merging a material library.

### **NOTIFY\_MATLIB\_POST\_MERGE**

This option is available in release 3.0 and later only.

Sent after merging a material library.

### **NOTIFY\_MODPANEL\_SEL\_CHANGED**

This option is available in release 3.0 and later only.

Sent when the Modify Panel focuses on a new object (via opening the Modify

Panel or changing the selection)

### **NOTIFY\_RENDER\_PREEVAL**

This option is available in release 4.0 and later only.

Sent before the render start evaluating objects

### **NOTIFY\_NODE\_CREATED**

This option is available in release 4.0 and later only.

Sent when a node is created (callParam is pointer to node)

### **NOTIFY\_NODE\_LINKED**

This option is available in release 4.0 and later only.

Sent when a node is linked (callParam is pointer to node)

### **NOTIFY\_NODE\_UNLINKED**

This option is available in release 4.0 and later only.

Sent when a node is unlinked (callParam is pointer to node)

### **NOTIFY\_NODE\_HIDE**

This option is available in release 4.0 and later only.

Sent when a node is hidden (callParam is pointer to node)

### **NOTIFY\_NODE\_UNHIDE**

This option is available in release 4.0 and later only.

Sent when a node is unhidden (callParam is pointer to node)

### **NOTIFY\_NODE\_FREEZE**

This option is available in release 4.0 and later only.

Sent when a node is frozen (callParam is pointer to node)

### **NOTIFY\_NODE\_UNFREEZE**

This option is available in release 4.0 and later only.

Sent when a node is unfrozen (callParam is pointer to node)

### **NOTIFY\_NODE\_PRE\_MTL**

This option is available in release 4.0 and later only.

Node is about to get a new material (callParam is pointer to node)

### **NOTIFY\_NODE\_POST\_MTL**

This option is available in release 4.0 and later only.

Node just got a new material (callParam is pointer to node)

### **NOTIFY\_WM\_ENABLE**

This option is available in release 4.0 and later only.

Sent when the main window gets an WM\_ENABLE (BOOL enabled)

### **NOTIFY\_SYSTEM\_SHUTDOWN**

This option is available in release 4.0 and later only.

Sent when 3ds max is about to exit

### **NOTIFY\_SYSTEM\_SHUTDOWN2**

This option is available in release 4.0 and later only.

Sent after the scene is destroyed. Most plug-ins will most likely not live long enough to receive the notification. It is important to unregister this notification when your plug-in dies. If not, 3ds max will try to notify objects that don't exist anymore.

### **NOTIFY\_SYSTEM\_STARTUP**

This option is available in release 4.0 and later only.

Sent when 3ds max starts up.

### **NOTIFY\_PLUGIN\_LOADED**

This option is available in release 4.0 and later only.

Sent when a plug-in was just loaded. (callParam is pointer to DllDesc)

### **NOTIFY\_SEL\_NODES\_PRE\_DELETE**

This option is available in release 4.0 and later only.

Sent when selected nodes will be deleted. (callParam is pointer to Tab<INode\*>)

### **NOTIFY\_SEL\_NODES\_POST\_DELETE**

This option is available in release 4.0 and later only.

Sent when selected nodes have just been deleted.

### **NOTIFY\_SYSTEM\_SHUTDOWN2**

This option is available in release 4.0 and later only.

Sent when the 3ds max system shutdown is completed. This is the last broadcast sent before exit.

### **NOTIFY\_ANIMATE\_ON**

This option is available in release 4.0 and later only.

Sent when the Animate user interface mode is activated.

### **NOTIFY\_ANIMATE\_OFF**

This option is available in release 4.0 and later only.

Sent when the Animate user interface mode is de-activated.

## **NOTIFY\_COLOR\_CHANGE**

This option is available in release 4.0 and later only.

Sent when the system is updating its custom colors.

If a plug-in has created a toolbar with any **MaxBmpFileIcons** on it, it should register this callback for color changing, and call **ICustToolbar::ResetIconImages()** on the toolbar. See [Class ICustToolbar](#), and [Class MAXBmpFileIcon](#).

## **REFMSG\_NODE\_MATERIAL\_CHANGED**

This option is available in release 4.0 and later only.

This notification indicates that the material changed.

## **REFMSG\_NODE\_WSCACHE\_UPDATED**

This option is available in release 4.0 and later only.

Sent whenever the mod stack gets re-evaluated.

## **NOTIFY\_PRE\_EDIT\_OBJ\_CHANGE**

This option is available in release 4.0 and later only.

Sent just before the current edit object is about to change. This notifications are sent whenever the object returned by **Interface::GetCurEditObject()** changes.

## **NOTIFY\_POST\_EDIT\_OBJ\_CHANGE**

This option is available in release 4.0 and later only.

Sent just after the current edit object changes. This notifications are sent whenever the object returned by **Interface::GetCurEditObject()** changes.

## **NOTIFY\_BEGIN\_RENDERING\_REFLECT\_REFRACT\_MAP**

This option is available in release 5.0 and later only.

Sent when the render begins to render the Reflect/Refract map

## **NOTIFY\_BEGIN\_RENDERING\_ACTUAL\_FRAME**

This option is available in release 5.0 and later only.

Sent when the render begins to render the full frame

## **NOTIFY\_BEGIN\_RENDERING\_TONEMAPPING\_IMAGE**

This option is available in release 5.0 and later only.

Sent when the render begins to render the Tone map

## **NOTIFY\_RADIOSTYPROCESS\_STARTED**

This option is available in release 5.0 and later only.

Sent when radiosity processing is started

**NOTIFY\_RADIOSITYPROCESS\_STOPPED**

This option is available in release 5.0 and later only.

Sent when radiosity processing is stopped, but not done

**NOTIFY\_RADIOSITYPROCESS\_RESET**

This option is available in release 5.0 and later only.

Sent when radiosity processing is reset

**NOTIFY\_RADIOSITYPROCESS\_DONE**

This option is available in release 5.0 and later only.

Sent when radiosity processing is done

**NOTIFY\_RADIOSITY\_PLUGIN\_CHANGED**

This option is available in release 5.0 and later only.

Sent when radiosity plugin is changed.

**NOTIFY\_LIGHTING\_UNIT\_DISPLAY\_SYSTEM\_CHANGE**

This option is available in release 5.0 and later only.

Sent when the lighting unit display system is changed

**NOTIFY\_TIMERANGE\_CHANGE**

This option is available in release 5.1 and later only.

Sent after the animate time range has been changed

# Class ViewWindow

See Also: [Class Interface](#).

```
class ViewWindow : public InterfaceServer
```

## Description:

This class is available in release 3.0 and later only.

This is the base class for the creation of non-3D windows that appear in a 3ds max viewport. These views are called "Extended Viewports". In order for a window to appear inside a viewport, you need to derive a class from this class. An instance of the derived class must be registered via the **RegisterViewWindow()** call in the **Interface** class. A given **ViewWindow** derivative should only be registered once.

When developers have registered their window types, the list of available extended views will appear in the view selection pop-up (either in the right-click viewport menu or the Viewport Configuration dialog) as a submenu of the "Extended" view label.

There are two items which should be made in the extended viewport dialog procedure:

**Interface::MakeExtendedViewportActive()** should be called whenever the user clicks in the non-3D window (so as to deactivate the current 3D window, and redirect commands like the Min/Max toggle to the non-3D viewport window).

**Interface::PutUpViewMenu()** should be called when the user right-clicks in a dead region of the non-3D window. This brings up the view selection menu so that the user can choose to replace the current window with a 3D or other non-3D window without having to go to the Views | Viewport Config dialog directly.

All methods of this class are implemented by the plug-in.

## Sample Code:

```
class TestViewWindow : public ViewWindow {
public:
    TCHAR *GetName() { return _T("TestViewWindow"); }
    HWND CreateViewWindow(HWND hParent, int x, int y, int w,
```

```
int h);  
void DestroyViewWindow(HWND hWnd);  
};
```

```
HWND TestViewWindow::CreateViewWindow(HWND hParent,  
int x, int y, int w, int h) {  
    return CreateWindow("button", "Test Button", WS_VISIBLE  
    | WS_CHILD, x, y, w, h, hParent, NULL,  
    (HINSTANCE)GetWindowLong(hParent,  
    GWL_HINSTANCE), NULL);  
}
```

```
void TestViewWindow::DestroyViewWindow(HWND hWnd) {  
    DestroyWindow(hWnd);  
}  
static TestViewWindow tww;
```

**Methods:**

public:

**Prototype:**

```
virtual TCHAR *GetName()=0;
```

**Remarks:**

Returns the name of the window type. For example, "Asset Manager".

**Prototype:**

```
virtual HWND CreateViewWindow(HWND hParent, int x, int y,  
int w, int h)=0;
```

**Remarks:**

Creates and returns a handle to a new extended view window.

**Parameters:**

**HWND hParent**

The handle of the parent window.

**int x**

The x coordinate of the window's upper left corner.

**int y**

The y coordinate of the window's upper left corner.

**int w**

The window width.

**int h**

The window height.

**Prototype:**

**virtual void DestroyViewWindow(HWND hWnd)=0;**

**Remarks:**

Destroys the previously created window as specified by the handle.

**Parameters:**

**HWND hWnd**

The handle of the window to destroy.

**Prototype:**

**virtual BOOL CanCreate();**

**Remarks:**

Returns TRUE if the ViewWindow can be created; otherwise FALSE. This method can be overridden to return FALSE if a ViewWindow can only have a single instance, and that instance is already present. If this method returns FALSE, then the menu item for this ViewWindow will be grayed out.

**Default Implementation:**

**{ return TRUE; }**

**Prototype:**

**virtual int NumberCanCreate();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the number of instances of a given window that can be

created. This allows, for example, the UI to know without physically creating a window that only a limited number of windows of that type can be created. A -1 implies that the count is not known.

**Default Implementation:**

```
{ return -1; }
```

# Keyboard Shortcut System

[Class ShortcutTable](#), [Class ShortcutOperation](#), [Class ShortcutCallback](#)

**Important Note:** A new system to handle keyboard accelerators was added for R4. This system supercedes those used in previous release. For information on this system see the [class ActionTable](#). The information shown below applies to previous version of the SDK APIs.

## Overview

The following is a discussion of the plug-in definable keyboard shortcut system available in release 3.0 and later. The pre-R3 system remains in place for backwards compatibility.

The keyboard preferences dialog has been expanded to allow the editing of keyboard shortcuts for plug-ins. There is a new radio button added to the set of shortcuts, labeled "Plug-Ins". When this is selected a drop-down list next to the button is activated which lists all the plug-ins that have registered keyboard shortcut tables. After selecting one from the drop-down list, you can change the shortcuts in the same way the main UI shortcuts are changed. This provides a clean way for all plug-ins to make their keyboard shortcuts available in a uniform manner.

The basic process works like this: A developer assigns an ID and name to each shortcut (these are stored in a **Shortcut Description**). The ID identifies each shortcut and the name appears in the 3ds max user interface where the shortcuts are assigned to keys by the user. An array of these shortcuts is used to make up something called a **Shortcut Table**. This table stores and provides access to the shortcut data. These data items are referred to as **Shortcut Operations**.

A developer provides 3ds max with the shortcut table data for a plug-in at Dll load time using two new methods of the Class Descriptor. These methods return the number of shortcut tables used by the plug-in and return a pointer to the 'i-th' table. These methods are **ClassDesc::NumShortcutTables()** and **ClassDesc::GetShortcutTable(int i)**.

The tables become active and inactive as a whole by using two methods provided by the **Interface** class. These are **ActivateShortcutTable()** and **DeactivateShortcutTable()**. These will normally be called by a developer inside **BeginEditParams()** and **EndEditParams()**.

## Principal Classes

The following is an overview of the principal classes and structures involved in making this happen:

[Class ShortcutTable](#): This class provides storage for and access to the **ShortcutOperations**.

[Class ShortcutOperation](#): This class describes an operation that can be attached to a keyboard shortcut. There is an ID sent to the window proc when the shortcut is executed, a name for the operation that appears in the 3ds max user interface where the shortcuts are assigned.

[Class ShortcutCallback](#): When the user presses a shortcut key that is assigned in an active table, it calls this class's **KeyboardShortcut(int id)** method with the id of the operation. Here the plug-in should execute the operation. If the state of the plug-in is such that the operation should not be performed it can return FALSE from this method. In this case any system defined shortcut will be executed instead. If the plug-in returns TRUE then only the plug-in defined shortcut is executed. A developer derives a class from this class and passes an instance of it to the method

**Interface::ActivateShortcutTable()**.

[Structure ShortcutDescription](#): This structure provides a description of a command for building shortcut tables from static data. The structure holds the command ID that is sent to

**ShortcutCallback::KeyboardShortcut()** method and a resource ID for the string that describes the shortcut. A pointer to an array of these is passed to the **ShortcutTable** constructor.

[Class ClassDesc](#): Two methods have been added to this class that are called at Dll load time to get the shortcut table(s) from the plug-in.

[Class Interface](#): There are new functions added to this class to activate and deactivate a shortcut table. These are normally called by a plug-in in **BeginEditParams()** and **EndEditParams()**. There are also methods that allow one to access the names and command IDs from a specific keyboard shortcut table. See [Keyboard Shortcut Table Related Methods](#) in class Interface.

## Sample Code

For an example of using this mechanism see the code in the directory

**\MAXSDK\SAMPLES\MODIFIERS\FD.**

## Class MacroButtonData

See Also: [Class ToolMacroItem](#), [Class MacroEntry](#), [Class MacroDir](#), [Class ICustButton](#), [Class ICustomControl](#), [Class ShortcutTable](#), [Class ShortcutCallback](#), [Class ActionItem](#), [Keyboard Shortcut System](#).

class MacroButtonData

### Description:

This class is available in release 3.0 and later only.

A Macro Button is a button which can execute either a keyboard macro or macro script. This class contains the data and access methods for such a UI button. This data includes a macro type, command ID, macro script ID, label, tooltip, image name, and image ID.

This object is used in the **ToolMacroItem** constructor. There are also methods of class **ICustButton** to get and set the macro button data.

### Data Members:

public:

**int macroType;**

The macro type. One of the following values:

**MB\_TYPE\_KBD**

A keyboard macro.

**MB\_TYPE\_SCRIPT**

A Script macro.

**ActionTableId tblID;**

The Shortcut Action Table ID.

**void \*cb;**

The ShortcutCallback. See [Class ShortcutCallback](#). This is currently not used.

**int cmdID;**

The command ID. There are method of class **Interface** that provide access to the command IDs for various keyboard shortcut tables. See [Keyboard Shortcut Related Methods](#).

**int macroScriptID;**

The macroScriptID holds the id of the macroScript associated with this button. This id is the **MacroID** that is used by the methods in the **MacroDir** and

**MacroEntry** classes (at one time it was an indirect reference to this id and so was typed as an int). The id can have values from 0 to the number of macro scripts currently defined in the running 3ds max or the special value **UNDEFINED\_MACRO**.

**TCHAR \*label;**

The label text for a text button. This is used if **imageID** is -1.

**TCHAR \*tip;**

The tooltip text.

**TCHAR \*imageName;**

This is the name for the button image. This is the 'base' name only. For example if the actual image name was **Spline\_16i.bmp** then the name supplied here would be **Spline**. See the remarks in [Class CUIFrameMgr](#) for details on the image naming scheme the CUI system uses.

**int imageID;**

The image ID. If this is set to -1 it indicates to use the **label**. If it is set to 0 or greater it indicates this is an image based button and this is the zero based index of the button that was added. This then is an ID into an image group as specified by **imageName**. Said another way, 3ds max builds one large image list internally and uses the **imageName** to get an offset into the list and then uses this **imageID** as an additional offset from the start as indicated by the name (each **imageName** may contain multiple icons in the single BMP).

**ActionItem\* actionItem;**

This data member is available in release 4.0 and later only.

A pointer to the ActionItem.

**DWORD flags;**

This data member is available in release 4.0 and later only.

These flags contain the last state when redrawing

**Methods:**

public:

**Prototype:**

**MacroButtonData();**

**Remarks:**

Constructor. The data members are initialized as follows:

```
label = tip = imageName = NULL; imageID = -1;
```

**Prototype:**

```
MacroButtonData(long tID, void *cb, int cID, TCHAR *lbl,  
TCHAR *tp=NULL, int imID=-1, TCHAR *imName=NULL);
```

**Remarks:**

Constructor. This one is used for keyboard macro buttons (**MB\_TYPE\_KBD**). The data members are initialized to the values passed as shown:

```
macroType=MB_TYPE_KBD; tblID=tID; this->cb=cb;  
cmdID=cID; imageID=imID; label=NULL; SetLabel(lbl);  
tip=NULL; SetTip(tp); imageName=NULL;  
SetImageName(imName);
```

**Prototype:**

```
MacroButtonData(int msID, TCHAR *lbl, TCHAR *tp=NULL,  
int imID=-1, TCHAR *imName=NULL);
```

**Remarks:**

Constructor. This one is used for macro script buttons (**MB\_TYPE\_SCRIPT**). The data members are initialized to the values passed as shown:

```
macroType=MB_TYPE_SCRIPT; macroScriptID=msID;  
imageID=imID; label=NULL; SetLabel(lbl); tip=NULL;  
SetTip(tp); imageName=NULL; SetImageName(imName);
```

**Prototype:**

```
~MacroButtonData();
```

**Remarks:**

Destructor. Any label, tooltip or image name strings are deleted.

**Prototype:**

**void SetLabel(TCHAR \*lbl);**

**Remarks:**

Sets the label text.

**Parameters:**

**TCHAR \*lbl**

The label to set.

**Prototype:**

**TCHAR \*GetLabel();**

**Remarks:**

Returns the label text.

**Prototype:**

**void SetTip(TCHAR \*tp);**

**Remarks:**

Sets the tooltip text.

**Parameters:**

**TCHAR \*tp**

The text to set.

**Prototype:**

**TCHAR \*GetTip();**

**Remarks:**

Returns the tooltip text.

**Prototype:**

**void SetCmdID(int id);**

**Remarks:**

Sets the command ID.

**Parameters:**

**int id**

The command ID to set.

**Prototype:**

**int GetCmdID();**

**Remarks:**

Returns the command ID.

**Prototype:**

**void SetScriptID(int id);**

**Remarks:**

Sets the script ID.

**Parameters:**

**int id**

The script ID to set.

**Prototype:**

**int GetScriptID();**

**Remarks:**

Returns the script ID.

**Prototype:**

**void SetImageName(TCHAR \*imName);**

**Remarks:**

Sets the image name. See the **imageName** data member above for details on the name format.

**Parameters:**

**TCHAR \*imName**

The name to set.

**Prototype:**

**TCHAR \*GetImageName();**

**Remarks:**

Returns the image name.

**Prototype:**

**void SetImageID(int id);**

**Remarks:**

Sets the image ID.

**Parameters:**

**int id**

The image ID to set.

**Prototype:**

**int GetImageID();**

**Remarks:**

Returns the image ID.

**Prototype:**

**void SetTblID(ActionTableId id);**

**Remarks:**

This method is available in release 4.0 and later only.

This method sets the ActionTableID ID.

**Parameters:**

**ActionTableId id**

The ActionTableID ID to set.

**Prototype:**

**ActionTableId GetTblID();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the ActionTableID ID.

**Prototype:**

**void SetActionItem(ActionItem\* pAction);**

**Remarks:**

This method is available in release 4.0 and later only.  
This method allows you to set the ActionItem.

**Parameters:**

**ActionItem\* pAction**

A point to the ActionItem to set.

**Prototype:**

**ActionItem\* GetActionItem();**

**Remarks:**

This method is available in release 4.0 and later only.  
This method returns a pointer to the ActionItem.

**Prototype:**

**BOOL IsActionButton();**

**Remarks:**

This method is available in release 4.0 and later only.  
This method returns TRUE if the button is an Action button. FALSE if it is not.

**Prototype:**

**MacroButtonData & operator=(const MacroButtonData& mbd);**

**Remarks:**

Assignment operator.

## Class ICUIFrame

See Also: [Class CUIFrameMgr](#), [Class CUIFrameMsgHandler](#), [Class ICustToolbar](#), [Class ICustomControl](#).

```
class ICUIFrame : public ICustomControl
```

### Description:

This class is available in release 3.0 and later only.

This class provides access to an individual CUI Frame (the name given to the windows that contain toolbars, menus, the command panel, etc.)

To create a floating tool palette, for example, you create a CUIFrame, create a toolbar, and then attach the two (similar to creating a custom edit field, and custom spinner, then attaching the two). This is done using the method

**ICustToolbar::LinkToCUIFrame()**.

When a Toolbar is part of a CUI frame it's called a Tool Palette. Tool Palettes can either float or dock (whereas a Toolbar must be placed by the developer in a dialog using the resource editor).

**The following global functions are not part of this class but are available for use:**

### Function:

```
ICUIFrame *GetICUIFrame(HWND hCtrl);
```

### Remarks:

Initializes the pointer to the CUI Frame control.

### Parameters:

**HWND hCtrl**

The window handle of the control.

### Function:

```
void ReleaseICUIFrame(ICUIFrame *icf);
```

### Remarks:

Releases the specified control.

### Parameters:

## **ICUIFrame \*icf**

Points to the frame to release.

### **Function:**

**HWND CreateCUIFrameWindow(HWND hParent, TCHAR \*title, int x, int y, int cx, int cy);**

### **Remarks:**

Creates a CUI Frame Window with the specified window handle, size and title parameters. Values of 0 may be passed for x, y, cx and cy. This indicates that the initial size doesn't matter. For example, when the 3ds max CUI is created initially everything is docked. 3ds max then calls

**CUIFrameMgr::RecalcLayout()** which computes all the sizes. Thus the values passed don't matter since they are all going to be recalculated anyway.

### **Parameters:**

#### **HWND hParent**

The handle of the parent window for the frame.

#### **TCHAR \*title**

The title for the frame. This effectively calls **SetName()** below to establish a name for the frame.

#### **int x**

The x coordinate of the upper left corner.

#### **int y**

The y coordinate of the upper left corner.

#### **int cx**

The x size.

#### **int cy**

The y size.

### **Return Value:**

If the function succeeds, the return value is the window handle to the dialog box. If the function fails, the return value is NULL.

### **Methods:**

public:

**Prototype:**

**virtual void SetName(TCHAR \*name)=0;**

**Remarks:**

Sets the name for the frame. This name shows up as a tooltip and also on the window border if the frame is floated. Note that the name is also used to store position information in the CUI file. Therefore developers must use a name and not simply set it to NULL.

**Parameters:**

**TCHAR \*name**

The name to set.

**Prototype:**

**virtual TCHAR \*GetName()=0;**

**Remarks:**

Returns the name of the frame.

**Prototype:**

**virtual void SetPosType(DWORD t)=0;**

**Remarks:**

Sets the position type. This determines the possible locations for the frame.

**Parameters:**

**DWORD t**

The position to set. See [List of CUI Frame Position Types](#).

**Prototype:**

**virtual DWORD GetPosType()=0;**

**Remarks:**

Returns a DWORD which describes the position options for this CUI Frame. See [List of CUI Frame Position Types](#).

**Prototype:**

**virtual void SetPosRank(int rank, int subrank=0)=0;**

**Remarks:**

This method is for internal use only. Developers must not assign the rank and subrank as these are computed internally. Developers should create their toolbars 'floating'. Then when a user docks the toolbar it will be docked automatically when 3ds max starts up the next time.

**Prototype:**

**virtual int GetPosRank()=0;**

**Remarks:**

Returns the position rank. Consider three docked toolbars, one alone on the top line, and two side by side on the line below. The top toolbar would have a rank of 0 (and a subrank of 0). The toolbar on the left in the line below would have a rank of 1 and a subrank of 0. The toolbar beside it to the right would have a rank of 1 and a subrank of 1.

**Prototype:**

**virtual int GetPosSubrank()=0;**

**Remarks:**

Returns the position subrank. See **GetPosRank()** above.

**Prototype:**

**virtual BOOL IsFloating()=0;**

**Remarks:**

Returns TRUE if the frame is floating (not docked); otherwise FALSE.

**Prototype:**

**virtual void Hide(BOOL b)=0;**

**Remarks:**

Sets the frame to hidden or not. Note that if a developer is doing something like showing their toolbars at **BeginEditParams()** and hiding them at **EndEditParams()** then this method can be used. In such a case, if the toolbar is docked then **RecalcLayout()** needs to be called to update the layout. If the toolbars are floating then **RecalcLayout()** does not need to be called.

**Parameters:**

**BOOL b**

TRUE for hidden; FALSE for not hidden.

**Prototype:**

**virtual BOOL IsHidden()=0;**

**Remarks:**

Returns TRUE if the frame is hidden; FALSE if visible.

**Prototype:**

**virtual void SetCurPosition(DWORD pos)=0;**

**Remarks:**

This method is for internal use only.

**Prototype:**

**virtual DWORD GetCurPosition()=0;**

**Remarks:**

Returns the current position of the frame. One of the following values.

**CUI\_TOP\_DOCK**

Docked at the top.

**CUI\_BOTTOM\_DOCK**

Docked at the bottom.

**CUI\_LEFT\_DOCK**

Docked on the left.

**CUI\_RIGHT\_DOCK**

Docked on the right.

**CUI\_FLOATING**

The frame is floating (not docked).

**Prototype:**

**virtual void SetContentType(DWORD t)=0;**

**Remarks:**

Sets the frame contents type. This specifies if this frame holds a toolbar, menu or a floating panel.

**Parameters:**

**DWORD t**

One or more of the following flags:

**CUI\_TOOLBAR**

Set if frame holds toolbars and / or tool palettes.

**CUI\_MENU**

This is used internally to set if the frame holds a menu. Note: Developers should not create their own menus. 3ds max assumes that only one menu exists.

**CUI\_HWND**

Set if frame hold a generic window handle. The command panel (which can be floated) is an example of a generic window.

**Prototype:**

**virtual DWORD GetContentType()=0;**

**Remarks:**

Returns a value which indicates the frame contents type. One of the following flags:

**CUI\_TOOLBAR**

Set if frame holds toolbars and / or tool palettes.

**CUI\_MENU**

Set if the frame holds a menu.

**CUI\_HWND**

Set if frame hold a generic window handle.

**Prototype:**

**virtual void SetContentHandle(HWND hContent)=0;**

**Remarks:**

Sets the content handle. This is the window handle for the toolbar, or menu handle for a menu. Developers typically create Tool Palettes by linking a toolbar to a CUIFrame using **ICustToolbar::LinkToCUIFrame()** and do

not need to call this method as it's done automatically.

**Parameters:**

**HWND hContent**

The handle to set.

**Prototype:**

**virtual HWND GetContentHandle()=0;**

**Remarks:**

Returns the content handle.

**Prototype:**

**virtual void SetTabbedToolbar(BOOL b)=0;**

**Remarks:**

Sets if this frame represents a tabbed toolbar. A tabbed toolbar may have individual tabs added and deleted.

**Parameters:**

**BOOL b**

TRUE for tabbed; FALSE for not tabbed.

**Prototype:**

**virtual BOOL GetTabbedToolbar()=0;**

**Remarks:**

Returns TRUE if this frame is a tabbed toolbar; otherwise FALSE.

**Prototype:**

**virtual void AddToolbarTab(HWND hTBar,  
CUIFrameMsgHandler \*msgHandler, TCHAR \*name, int pos =  
-1)=0;**

**Remarks:**

Adds the toolbar tab whose window handle is passed to the list of tabs maintained by this class.

**Parameters:**

**HWND hTBar**

The window handle of the toolbar tab to add.

**CUIFrameMsgHandler \*msgHandler**

The message handler for the tab or NULL if not used.

**TCHAR \*name**

The name for the tab.

**int pos = -1**

The position for the tab. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**. A value of -1 adds the tab to the end of the list of tabs. Also, for example, if you specify a value of 0 for an existing tabbed toolbar, the new tab is inserted at position 0 and the others are moved to the right.

**Prototype:**

```
virtual void DeleteToolBarTab(int pos)=0;
```

**Remarks:**

Deletes the specified toolbar tab.

**Parameters:****int pos**

Specifies the position of the tab to delete. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**.

**Prototype:**

```
virtual int GetToolBarCount()=0;
```

**Remarks:**

Returns the number of toolbar tabs in this frame.

**Prototype:**

```
virtual HWND GetToolBarHwnd(int pos)=0;
```

**Remarks:**

Returns the window handle of the toolbar tab whose position is passed.

**Parameters:**

**int pos**

Specifies the position of the tab. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**.

**Prototype:**

**virtual TCHAR \*GetTabName(int pos)=0;**

**Remarks:**

Returns the name of the specified toolbar tab.

**Parameters:**

**int pos**

Specifies the position of the tab. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**.

**Prototype:**

**virtual void SetCurrentTab(int pos)=0;**

**Remarks:**

Sets the currently active tab.

**Parameters:**

**int pos**

Specifies the position of the tab. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**.

**Prototype:**

**virtual int GetCurrentTab()=0;**

**Remarks:**

Returns the position of the currently active tab. This is the zero based index where 0 is at left edge of those in the frame and the max value is **GetToolBarCount()-1**.

**Prototype:**

**virtual int GetSize(int sizeType, int dir, int orient)=0;**

**Remarks:**

Returns the size of this frame for the specified size type, direction (width or height) and orientation.

Note: If this frame has a custom message handler (a **CUIFrameMsgHandler** object, it's **ProcessMessage()** method is called passing **CUI\_POSDATA\_MSG** which is used to determine the size.

**Parameters:****int sizeType**

The size type. See [List of CUI Frame Size Types](#).

**int dir**

The direction of the frame.

**CUI\_HORIZ**: Width.

**CUI\_VERT**: Height.

**int orient**

The orientation. See [List of CUI Frame Orientations](#).

**Prototype:**

```
virtual BOOL InstallMsgHandler(CUIFrameMsgHandler  
*msgHandler)=0;
```

**Remarks:**

Installs a custom message processing routine.

**Parameters:****CUIFrameMsgHandler \*msgHandler**

Points to the handler to install. See [Class CUIFrameMsgHandler](#) for details.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

```
virtual BOOL SetMenuDisplay(int md)=0;
```

**Remarks:**

Sets the menu display state.

**Parameters:**

**int md**

One of the following values:

**CUI\_MENU\_HIDE**

**CUI\_MENU\_SHOW\_ENABLED**

**CUI\_MENU\_SHOW\_DISABLED**

**Prototype:**

**virtual int GetMenuDisplay()=0;**

**Remarks:**

Returns the state of the menu display. One of the following values:

**CUI\_MENU\_HIDE**

**CUI\_MENU\_SHOW\_ENABLED**

**CUI\_MENU\_SHOW\_DISABLED**

**Prototype:**

**virtual void SetSystemWindow(BOOL b)=0;**

**Remarks:**

System windows are those that come up automatically inside MAX. So command panel, the main toolbar, the tab panel and the main menu are all system windows. It is not therefore appropriate for developers to declare themselves as system windows and this method should not be called passing TRUE.

**Parameters:**

**BOOL b**

TRUE to set as a system window; otherwise FALSE.

**Prototype:**

**virtual BOOL GetSystemWindow()=0;**

**Remarks:**

Returns TRUE if this CUIFrame is a system window; otherwise FALSE. See **SetSystemWindow()** above.

**Prototype:**

**virtual BOOL ReadConfig(TCHAR \*cfg, int startup=FALSE)=0;**

**Remarks:**

This method is for internal use only.

**Prototype:**

**virtual void WriteConfig(TCHAR \*cfg)=0;**

**Remarks:**

This method is for internal use only.

## Class CUIFrameMgr

See Also: [Class ICUIFrame](#), [Class CUIFrameMsgHandler](#), [Class ICustToolbar](#), [Class ICustomControl](#), [Class ICustStatus](#), [Class MAXBmpFileIcon](#).

```
class CUIFrameMgr : public BaseInterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

\*\*\*reflect changes with MAXBMPFileIcon class\*\*\*

This object controls the overall operation of the individual CUI Frames (the name given to the windows that contain toolbars, menus, the command panel, etc.). There is one instance of this CUIFrameMgr class (obtained by calling the global function **GetCUIFrameMgr()**). Methods of this class are available to do things like float and dock individual windows, get pointers to frames, get pointers to button and status controls, and bring up the standard toolbar right click menu .

Note: Developers may use their own images on icon buttons that are managed by this class but the following guidelines must be followed:

BMP files must be put in the **\UIIcons** folder. This is the UI directory under the 3ds max EXE directory. This is hard coded because it must be retrieved before 3ds max is fully started and thus there is no configurable path for it. There is a command line option however, (-c), which specifies for 3ds max to look in an alternate directory for the CUI file. In that case the bitmap files should be located in the same directory.

For more information on the new icon image system refer to the chapter on [external icons](#).

**The following global functions are not part of this class but are available for use:**

### Function:

```
CUIFrameMgr *GetCUIFrameMgr();
```

### Remarks:

Returns a pointer to the CUIFrameMgr which controls the overall operation of CUI Frames (the windows which contain toolbars, menus, the command panel, etc).

**Function:**

**void DoCUICustomizeDialog();**

**Remarks:**

This global function presents the Customize User Interface dialog.

**Function:**

**BOOL AllFloatersAreHidden();**

**Remarks:**

This global function is available in release 4.0 and later only.  
Returns TRUE if all floaters are hidden; otherwise FALSE.

**Methods:**

public:

**Prototype:**

**CUIFrameMgr();**

**Remarks:**

Constructor.

**Prototype:**

**~CUIFrameMgr();**

**Remarks:**

Destructor.

**Prototype:**

**CUIFrameMsgHandler \*GetDefaultMsgHandler();**

**Remarks:**

Returns a pointer to the default CUI Frame Message Handler.

**Prototype:**

**void SetAppHWND(HWND hApp);**

**Remarks:**

This method is for internal use only.

**Prototype:****TCHAR \*GetCUIDirectory();****Remarks:**

Returns the directory name of the custom user interface (CUI) file location.

**Prototype:****void ProcessCUIMenu(HWND hWnd, int x, int y);****Remarks:**

This brings up the CUI right click menu (with the Add Tab, Delete Tab, etc selections). Also see the global function **DoCUICustomizeDialog()**.

**Parameters:****HWND hWnd**

The handle of the window where the mouse was clicked.

**int x**

The x coordinate of the mouse when right clicked.

**int y**

The y coordinate of the cursor when right clicked.

**Prototype:****void DockCUIWindow(HWND hWnd, int panel, RECT \*rp = NULL, int init = FALSE);****Remarks:**

This method docks the CUI window whose handle is passed. Developers who want to dock a window should use this method by passing a rectangle which specifies the general area of the screen where the window is to be docked. This will cause 3ds max reorganize the existing windows.

**Parameters:****HWND hWnd**

The handle of the window to dock.

**int panel**

The CUI docking panel location. One of the following values:

**CUI\_TOP\_DOCK**

Docked at the top.

### **CUI\_BOTTOM\_DOCK**

Docked at the bottom.

### **CUI\_LEFT\_DOCK**

Docked on the left.

### **CUI\_RIGHT\_DOCK**

Docked on the right.

### **RECT \*rp = NULL**

This is the rectangle which specifies where to dock the window. This is the rectangle that a user moves around the screen when dragging a floating window over top of a docking region. This is specified in screen coordinates. If NULL is passed the window is docked using **CUI\_TOP\_DOCK**.

### **int init = FALSE**

This is used internally by 3ds max when it's starting up. This should always default to FALSE (don't override this and pass TRUE).

### **Prototype:**

```
void FloatCUIWindow(HWND hWnd, RECT *rp = NULL, int init = FALSE);
```

### **Remarks:**

Floats (un-docks) the specified CUI Window.

### **Parameters:**

#### **HWND hWnd**

The window to float.

#### **RECT \*rp = NULL**

Specifies the rectangle in screen coordinates where the floating window should reside. If NULL is passed the window is restored to the position it was before it was docked (this information is stored in the CUI file).

Note: Calling this method on an already floating window will explicitly NOT resize the window, but rather just move it to the new origin. Said another way, only the left and top members of the rectangle are used on an already floating window. Developers should call the Win32 API MoveWindow or SetWindowPlacement to size the window. See

**GetFloatingCUIFrameSize()** below to compute a size.

**int init = FALSE**

This is used internally by 3ds max when it's starting up. This should always default to FALSE (don't override this and pass TRUE).

**Prototype:**

**virtual void GetFloatingCUIFrameSize(SIZE \*sz, int rows=1)=0;**

**Remarks:**

Computes the required size of a floating CUI Frame which is linked to a toolbar. The values returned will be zero if the frame is not linked to a toolbar.

**Parameters:**

**SIZE \*sz**

The computed size is returned here. **sz.cx** is the width, **sz.cy** is the height.

**int rows=1**

The number of rows for the toolbar used in the computation.

**Prototype:**

**void SetReservedSize(int panel, int size);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetReservedSize(int panel);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetPanelSize(int panel, int incReserved = FALSE);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**void RecalcLayout(int entireApp=FALSE);**

**Remarks:**

This method may be called to recalculates the layout of the CUI. Developers need to call this method after they, for example, add new tool palettes. A developer would create the new palettes and then call this method when done. Otherwise the changes wouldn't be reflected until the user redrew the viewports or resized MAX.

**Parameters:**

**int entireApp=FALSE**

TRUE to recalculate the entire application, including the viewports. This can be expensive (basically like an **Interface::ForceCompleteRedraw()**); FALSE will recalculate the top, botton, left and right panels but won't redraw the viewports.

**Prototype:**

**void DrawCUIWindows(int panels=CUI\_ALL\_PANELS);**

**Remarks:**

This method redraws the specified panels. Typically developers don't need to call this method.

**Parameters:**

**int panels=CUI\_ALL\_PANELS**

See [List of CUI Docking Panel Locations](#).

**Prototype:**

**void SetMacroButtonStates(BOOL force);**

**Remarks:**

This method is available in release 4.0 and later only.

This is a very important method. It redraws all the visible CUI buttons in MAX, calling the "IsEnabled" and "IsChecked" handlers on the ActionItems associated with each button (if it has one). If a the "IsEnabled" handler returns FALSE, the button is grayed out. If the "IsChecked" handler return TRUE, the button is draw pressed in.

This method is called internally by the system on selection changes and command mode changes. This handles the majority of the cases where buttons need to be redrawn. However, if a 3rd party plug-in changes some sort of

internal state that might affect the return value of an ActionItem's IsEnables or IsChecked handler, then the plug-in should call this method to update the button states. If this method isn't called, buttons may look disabled or pressed (or visa versa) when they shouldn't be. See [Class ActionItem](#).

**Parameters:**

**BOOL force**

This parameter, if TRUE, tells the system to redraw the button even if its state hasn't changed since the last time it was redrawn. Normally this argument is FALSE so it only redraws the buttons that changed state.

**Prototype:**

**void ResetIconImages();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is for internal use only. This is automatically called when the system changes its custom colors. It tells all the buttons on toolbars to toss their icon image cache.

This method only resets the icons for toolbars that are part of the CUI system, not for toolbars created by other code, which is why the **ICustToolbar** method **ResetIconImages()** is needed. See the method **ICustToolbar::ResetIconImages**.

**Prototype:**

**int OverDockRegion(LPPOINT pt, DWORD posType, int override = FALSE);**

**Remarks:**

Given a point and a position type this method returns nonzero if the point is over the specified docking region; otherwise zero.

**Parameters:**

**LPPOINT pt**

The input point to check in screen coordinates.

**DWORD posType**

See [List of CUI Frame Position Types](#).

**int override = FALSE**

Passing TRUE overrides the docking function so that it won't dock. Passing FALSE will cause it to dock. Also note that if the UI layout is locked, passing TRUE here will override that lock.

In the code fragment below the state of the Ctrl key is checked and used as the docking override.

**Sample Code:**

```
GetCursorPos(&pt);  
overDockRegion = GetCUIFrameMgr()->OverDockRegion(&pt,  
cf->GetPosType(), (GetKeyState(VK_CONTROL) & 0x8000));
```

**Prototype:**

```
HWND GetItemHwnd(int id);
```

**Remarks:**

Returns the window handle for the item whose ID is passed. This correspond to the method in **ICustToolBar** but which should no longer be called for Tool Palettes. It is now also a method of this class because the CUI system doesn't know which toolbar a particular button is on. For example, a 3ds max user in 3.0 can drag a button from one tool palette to another. No longer then can one use the previous **GetItemHwnd()** method since the button has moved to a different toolbar.

**Parameters:**

**int id**

The ID of the control.

**Prototype:**

```
ICustButton *GetICustButton(int id);
```

**Remarks:**

Returns a pointer to the custom button whose ID is passed (or NULL if not found). In the **CUIFrameMgr** implementation of this method it loops through each toolbar that it has control over and calls **ICustToolBar::GetICustButton()** on it. That method returns NULL if it doesn't find the specified ID. The CUIFrameMgr keeps looping through the

toolbars until it gets a non-NULL value. When it finds it it returns the **ICustButton** pointer.

**Parameters:**

**int id**

The ID of the control.

**Prototype:**

**ICustStatus \*GetICustStatus(int id);**

**Remarks:**

Returns a pointer to the custom status control whose ID is passed.

Returns a pointer to the custom status control whose ID is passed (or NULL if not found). In the **CUIFrameMgr** implementation of this method it loops through each toolbar that it has control over and calls

**ICustToolBar::GetICustStatus()** on it. That method returns NULL if it doesn't find the specified ID. The **CUIFrameMgr** keeps looping through the toolbars until it gets a non-NULL value. When it finds it it returns the **ICustStatus** pointer.

**Parameters:**

**int id**

The ID of the control.

**Prototype:**

**ICUIFrame \*GetICUIFrame(int i);**

**Remarks:**

Returns a pointer to the CUI Frame as specified by the index passed.

**Parameters:**

**int i**

The zero based index in the list of frames (between **0** and **GetCount()-1**).

**Prototype:**

**ICUIFrame \*GetICUIFrame(TCHAR \*name);**

**Remarks:**

Returns a pointer to the CUI Frame as specified by the name passed.

**Parameters:**

**TCHAR \*name**

The name of the frame.

**Prototype:**

**ICUIFrame \*GetICUIFrame(int panel, int rank, int subrank);**

**Remarks:**

Returns a pointer to the CUI Frame as specified by the panel, rank and subrank passed.

**Parameters:**

**int panel**

One of the following values:

**int rank**

The zero based rank index.

**int subrank**

The zero based sub-rank index.

**Prototype:**

**TCHAR \*GetConfigFile();**

**Remarks:**

This returns the path to the CUI file in use. This may be a UNC name.

**Prototype:**

**int GetButtonHeight(int sz=0);**

**Remarks:**

Returns the bitmap button image height for the specified size.

**Parameters:**

**int sz=0**

The size to check. If 0 is passed then the current icon size is checked. One of the following values:

**CUI\_SIZE\_16**

## **CUI\_SIZE\_24**

### **Prototype:**

**int GetButtonWidth(int sz=0);**

### **Remarks:**

Returns the bitmap button image width for the specified size.

### **Parameters:**

**int sz=0**

The size to check. One of the following values:

**CUI\_SIZE\_16**

**CUI\_SIZE\_24**

### **Prototype:**

**void SetMode(int md);**

### **Remarks:**

This method is for internal use only.

### **Prototype:**

**int GetMode();**

### **Remarks:**

This method is for internal use only.

### **Prototype:**

**void ExpertMode(int onOff);**

### **Remarks:**

This method is for internal use only. Calling this method alone will not put 3ds max in Expert mode.

### **Prototype:**

**void HorizTextButtons(BOOL b);**

### **Remarks:**

This method is for internal use only.

**Prototype:**

**int GetHorizTextButtons();**

**Remarks:**

This method is for internal use only.

**Prototype:**

**void FixedWidthTextButtons(BOOL b);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetFixedWidthTextButtons();**

**Remarks:**

This method is for internal use only.

**Prototype:**

**void SetTextButtonWidth(int w);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetTextButtonWidth();**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetCount();**

**Remarks:**

Returns the number of frames that exist.

**Prototype:**

**int SetConfigFile(TCHAR \*cfg);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int DeleteSystemWindows(int toolbarsOnly = TRUE);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int CreateSystemWindows(int reset = FALSE);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**void SetImageSize(int size);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetImageSize();**

**Remarks:**

This method is for internal use only.

**Prototype:**

**void SetDefaultData(CUIFrameMsgHandler \*msg,  
HIMAGELIST img16, HIMAGELIST img24=NULL);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int GetDefaultImageListBaseIndex(SClass\_ID sid, Class\_ID cid);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used internally to create a MaxBmpFileIcon for a given object type. These methods retrieve the file name and base index in the file of the icon for the given object class. They are used in the constructor for MaxBmpFileIcon that takes a class ID and super class ID. This method is for internal use only.

**Prototype:**

**TSTR\* GetDefaultImageListFilePrefix(SClass\_ID sid, Class\_ID cid);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used internally to create a MaxBmpFileIcon for a given object type. These methods retrieve the file name and base index in the file of the icon for the given object class. They are used in the constructor for MaxBmpFileIcon that takes a class ID and super class ID. This method is for internal use only.

**Prototype:**

**int AddToRawImageList(TCHAR\* pFilePrefix, int sz, HBITMAP image, HBITMAP mask);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is for internal use only. It is used to add images to the icon manager. The icon manager, which is used to implement the **MaxBmpFileIcon** class, reads all the .bmp files in the UI/Icons directory at startup time. These icons are specified by an image file and an alpha mask. The icons support two sizes. Large, which is 24 by 24 and small, which is 15 by 16. The icon manager stores the unprocessed image and alpha masks (the "raw" images). Whenever an instance of MaxBmpFileIcon needs to draw itself, it gets the image list and index of the icon in the imagelist using

**GetSmallImageIndex** or **GetLargeImageIndex**.

**Prototype:**

**int LoadBitmapFile(TCHAR \*filename);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int LoadBitmapImages();**

**Remarks:**

This method is for internal use only.

**Prototype:**

**int ReadConfig();**

**Remarks:**

Plug-In developers should not call this method -- it is for internal use only.

**Prototype:**

**int WriteConfig();**

**Remarks:**

Plug-In developers should not call this method -- it is for internal use only.

**Prototype:**

**void SetLockLayout(BOOL lock);**

**Remarks:**

This method is for internal use only.

**Prototype:**

**BOOL GetLockLayout();**

**Remarks:**

Returns TRUE if the layout is locked; FALSE if unlocked.

**Prototype:**

**void EnableAllCUIWindows(int enabled);**

**Remarks:**

This method is for internal use only.

## Class CUIFrameMsgHandler

See Also: [Class ICUIFrame](#), [Class CUIFrameMgr](#), [Class CUIPosData](#), [Class ICustomControl](#).

class CUIFrameMsgHandler

### Description:

This class is available in release 3.0 and later only.

This class provides a way for messages received by a **CUIFrame** to be processed in a context-specific fashion.

Since the CUI Frame is just a window, it needs a window proc. There is one built into the CUI system, but it may need additional information that is specific to how the frame is being used. For example, in 3ds max the command panel can't be resized horizontally and the default window proc can't manage this.

For such situations, the application must install a **CUIFrameMsgHandler** object. You establish that this is the handler for the frame using the method **ICUIFrame::InstallMsgHandler(CUIFrameMsgHandler \*msgHandler)**.

These message handlers have one significant class method: **ProcessMessage()**. If **ProcessMessage()** returns TRUE, then the CUI system assumes that the message is completely handled. If it returns FALSE, then the standard CUI processing takes place. (Note that the message handler may still return FALSE, even if it does some processing...).

There is a special message (**CUI\_POSDATA\_MSG**) that is sent by the CUI system to the message handler to get information on window size constraints, etc. An example of processing this message is shown below. In this case **editPosData** is a static instance of **CUIPosData**. That object has **GetWidth()** and **GetHeight()** methods which return the proper width and height size for various orientations. See [Class CUIPosData](#) for details.

```
case CUI_POSDATA_MSG: {
    CUIPosData **cpd = (CUIPosData **)lParam;
    cpd[0] = &editPosData;
}
return TRUE;
```

**Methods:**

public:

**Prototype:**

```
virtual int ProcessMessage(UINT message, WPARAM wParam,  
LPARAM lParam);
```

**Remarks:**

This method is called to handle any processing not done by the default CUI window proc.

This method should return TRUE if the message is handled and FALSE if not. If FALSE is returned (or no handler is defined), then the CUIFrame simply passes WM\_COMMAND messages on to its parent. Window position messages are passed from the CUIFrame to the HWND of the 'content' (either a toolbar or menu). Other messages are passed on to the default window proc.

Note: Developers should **not** return TRUE for the **entire** ProcessMessage routine, since if this is done, the right-click menu functionality will not work (e.g. docking, floating, move-to-shelf, customize, etc.).

Also Note: Developers should not use IDs that may conflict with the ones used by the default processing provide by MAX. **The IDs which should be avoided are in the 40000, 47000, and 61000 range.** For instance the following IDs are all invalid since they are in those ranges: 40005, 47900, 61102. The reason this is a problem is that if you return FALSE after processing a particular ID, then 3ds max will go ahead and process that ID also. And if the ID matches one already in MAX, an unintended function may get called.

**Parameters:****UINT message**

Specifies the message.

**WPARAM wParam**

Specifies additional message information. The contents of this parameter depend on the value of the **message** parameter.

**LPARAM lParam**

Specifies additional message information. The contents of this parameter depend on the value of the **message** parameter.

**Default Implementation:**

```
{ return FALSE; }
```

## Class CUIPosData

See Also: [Class CUIFrameMsgHandler](#), [Class ICustomControl](#).

class CUIPosData

### Description:

This class is available in release 3.0 and later only.

This is the object that provides the position data when the **CUIFrameMsgHandler::ProcessMessage()** method receives a **CUI\_POSDATA\_MSG** message. The developer creates an instance of this class and implements the **GetWidth()** and **GetHeight()** methods which return size information based on the size type and orientation passed.

### Methods:

public:

### Prototype:

```
virtual ~CUIPosData();
```

### Remarks:

Destructor.

### Default Implementation:

```
{}
```

### Prototype:

```
virtual int GetWidth(int sizeType, int orient);
```

### Remarks:

Returns the width for the specified size type and orientation. A return value of -1 indicates that the frame doesn't have a specific needed value (it doesn't care).

### Parameters:

**int sizeType**

The size type. [See List of CUI Frame Size Types](#).

**int orient**

The orientation. [See List of CUI Frame Orientations](#).

**Default Implementation:**

```
{ return 50; }
```

**Prototype:**

```
virtual int GetHeight(int sizeType, int orient);
```

**Remarks:**

Returns the height for the specified size type and orientation.

**Parameters:**

**int sizeType**

The size type. See [List of CUI Frame Size Types](#).

**int orient**

The orientation. See [List of CUI Frame Orientations](#).

**Default Implementation:**

```
{ return 50; }
```

## Class ToolMacroItem

See Also: [Class ToolItem](#), [Class MacroButtonData](#), [Class ICustButton](#), [Custom Controls](#).

```
class ToolMacroItem : public ToolItem
```

### Description:

This class is available in release 3.0 and later only.

This class allows a macro item control to be added to the toolbar.

### Data Members:

public:

**MacroButtonData md;**

Points to the macro button data for this tool item.

### Methods:

public:

### Prototype:

```
ToolMacroItem(int wd, int ht, MacroButtonData *data, int or =  
CTB_HORIZ|CTB_VERT|CTB_FLOAT);
```

### Remarks:

Constructor.

### Parameters:

**int wd**

The width of the item.

**int ht**

The height of the item.

**MacroButtonData \*data**

Points to the macro button data.

**int or = CTB\_HORIZ|CTB\_VERT|CTB\_FLOAT**

Specifies the orientation. One or more of the following values:

**CTB\_HORIZ**

**CTB\_VERT**

**CTB\_FLOAT**

## Class MacroDir

See Also: [Class MacroEntry](#), [Class MacroButtonData](#).

```
class MacroDir : public InterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This class provides access to Macro scripts. Macro scripts (or macros) are scripts that live in buttons and menus in the customizable UI. Methods of this class are available to access macros using IDs or category and name strings, methods to edit macro scripts, methods to execute macros, and methods for directory scanning and loading.

The directory instance (access via the global function **GetMacroScriptDir()**) is used by the CUI to provide a list of available macros in the toolbar/menu editor. The API also provides a way for the CUI to open a macro editor to allow on-the-fly creation of macro scripts.

The macro script manager keeps a directory of all known macros and provides an API for running and editing macros and for accessing and updating the directory.

Macros are normally entered into the directory by the MAXScript compiler as a side-effect of compiling a macro definition. Anyone using MAXScript can at any time eval a macro definition and thereby add CUI macro scripts.

Consequently, macros can be stored in any script file and be loaded just by executing the file. The macro definition syntax permits any number of macros per file.

Most macros will be stored in files in a special CUI macro or config directory so that a user can take all his custom UI stuff with him by copying directories. (This directory supports recursive scanning of sub-dirs, so users can organize their macros). On-the-fly macro creation in the CUI editor or by text drag-and-drop onto the shelf or by evaling a definition in the listener will generate a file in this directory to provide permanent storage.

Note: **typedef short MacroID;**

Note: In order to use these methods you need to **#include "IMACROSCRIPT.H"** and link to **"MAXSCRIPT.LIB"**.

**The following global functions are not part of this class but are available for use:**

**Function:**

**MacroDir& GetMacroScriptDir();**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns a reference to the macro script directory.

**Function:**

**void InitMacroScriptDir();**

**Remarks:**

This global function is available in release 3.0 and later only.

This is an internal only function used by 3ds max during startup to get the macroScript system initialized.

**Methods:**

public:

**Prototype:**

**virtual MacroEntry\* GetMacro(MacroID mid)=0;**

**Remarks:**

Returns a pointer to the MacroEntry for the macro script whose ID is passed.

**Parameters:**

**MacroID mid**

The ID of the macro.

**Prototype:**

**virtual MacroEntry\* FindMacro(TCHAR\* category, TCHAR\* name)=0;**

**Remarks:**

Returns a pointer to the MacroEntry corresponding to the given category and name strings passed (or NULL if not found).

**Parameters:**

**TCHAR\* category**

The category name.

**TCHAR\* name**

The macro script name.

**Prototype:**

**virtual BOOL ValidID(MacroID mid)=0;**

**Remarks:**

Returns TRUE if the macro ID is valid (or unused); otherwise FALSE.

**Parameters:**

**MacroID mid**

The ID to check.

**Prototype:**

**virtual int Count()=0;**

**Remarks:**

Returns the number of macro entries in this macro directory.

**Prototype:**

**virtual MacroEntry\* GetMacro(int index)=0;**

**Remarks:**

Returns a pointer to the macro entry whose index in the directory is passed.

**Parameters:**

**int index**

The zero based index of the entry. This is a value between 0 and **Count()-1**.

**Prototype:**

**virtual MacroEntry\* AddMacro(TCHAR\* category, TCHAR\* name, TCHAR\* tooltip, TCHAR\* buttonText, TCHAR\* sourceFile, int sourceOffset)=0;**

**Remarks:**

Adds the macro whose parameters are passed and returns a pointer to the new

macro entry. This form allows you to define a macro that is already in a file, by giving a source file name and seek offset into that file. This is typically used by the MAXScript compiler and .mcr file scanner to register macro definitions they come across.

**Parameters:**

**TCHAR\* category**

The category for the macro.

**TCHAR\* name**

The name for the macro.

**TCHAR\* tooltip**

The tooltip text.

**TCHAR\* buttonText**

The button text.

**TCHAR\* sourceFile**

The source file name.

**int sourceOffset**

The line number of the first line of the script in the source file.

**Prototype:**

```
virtual MacroEntry* AddMacro(TCHAR* category, TCHAR*  
name, TCHAR* tooltip, TCHAR* buttonText, TCHAR*  
sourceText)=0;
```

**Remarks:**

Add or replaces a macro using given source text as the body of the macro. In this overload, name can be NULL in which case a unique name is generated.

This form takes the body of the actual macro script as the **sourceText** argument and places it in a newly-created file in the UI directory and registers that file and a zero offset as the macro definition. All macroScripts need to be in files somewhere so that they are persistent if referenced in a CUI toolbar that the user saves. This form is used, for example, by the toolbar manager when you drag a piece of selected text onto a toolbar to cause a script button to be created.

**Parameters:**

**TCHAR\* category**

The category for the macro.

**TCHAR\* name**

The name for the macro or NULL to generate a unique name.

**TCHAR\* tooltip**

The tooltip text.

**TCHAR\* buttonText**

The button text.

**TCHAR\* sourceText**

The source text.

**Prototype:**

```
virtual BOOL SetMacro(MacroID mid, TCHAR* tooltip,  
TCHAR* btnText, TCHAR* sourceFile, int sourceOffset)=0;
```

**Remarks:**

Sets the parameters for the macro entry whose ID is passed.

**Parameters:**

**MacroID mid**

The macro ID.

**TCHAR\* tooltip**

The tooltip text.

**TCHAR\* btnText**

The button text.

**TCHAR\* sourceFile**

The source file name.

**int sourceOffset**

The source offset.

**Return Value:**

TRUE if set; FALSE if the ID was not found.

**Prototype:**

```
virtual TCHAR* MakeNameValid(TCHAR* s)=0;
```

**Remarks:**

This method modifies the string in place to be a valid macro name (no punctuations other than spaces).

**Parameters:**

**TCHAR\* s**

The name string.

**Prototype:**

**virtual TCHAR\* MakeCategoryValid(TCHAR\* s)=0;**

**Remarks:**

This method modifies the string in place to be a valid category name (no punctuations other than spaces).

**Parameters:**

**TCHAR\* s**

The category string.

**Prototype:**

**virtual BOOL EditMacro(MacroID mid)=0;**

**Remarks:**

This methods brings up the editor for editing the specified macro script text.

**Parameters:**

**MacroID mid**

The ID of the macro script to edit.

**Prototype:**

**virtual Value\* Execute(MacroID mid)=0;**

**Remarks:**

Executes the macro script whose ID is passed.

**Parameters:**

**MacroID mid**

The ID of the macro to execute.

**Return Value:**

A pointer to the result of executing the macro. If a developer doesn't care about the result of executing a macroScript, which is usually the case, then the **Value\*** returned from this method can just be ignored. If a developer does care, then the necessary information about working with **Value\***'s is in the [MAXScript SDK](#) documentation.

**Prototype:**

**virtual void LoadMacroScripts(TCHAR\* path\_name = NULL, BOOL recurse = TRUE)=0;**

**Remarks:**

This method loads all the macro scripts found in the specified path and optionally its sub-directories. You can point this method at any directory and it will scan it for .mcr files and scan those for macroScript definitions. 3ds max uses this during startup to scan the UI directory (recursively) for .mcr files.

**Parameters:**

**TCHAR\* path\_name = NULL**

The path to check. If NULL the default path is used.

**BOOL recurse = TRUE**

If TRUE nested sub-directories are scanned and loaded as well.

**Prototype:**

**virtual void SetMacroScriptPath(TCHAR\* path\_name)=0;**

**Remarks:**

Sets the default path for storing / searching macro script files.

**Parameters:**

**TCHAR\* path\_name**

The path to set.

**Prototype:**

**virtual TCHAR\* GetMacroScriptPath()=0;**

**Remarks:**

Returns the default path for storing / searching macro script files.

## Class MacroEntry

See Also: [Class MacroDir](#), [Class MacroButtonData](#).

```
class MacroEntry : public BaseInterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This class provides access to a single macro entry. There are methods provided to access the macro ID, name, category, file name, tooltip, UI button text, and the UI button icon. MacroEntries are returned from methods of **class**

### MacroDir.

Macro scripts (or macros) are scripts that live in buttons and menus in the new customizable UI. The macro script manager keeps a directory of all known macros and provides an API for running and editing macros and for accessing and updating the directory.

All macro scripts have a name and a category. The category is used to organize the macros into groupings and is given to the macro script at definition time. If you look at the macro scripts list in the UI Customize dialog, you see a Category dropdown with things like 'Cameras', 'DragandDrop', 'LightTools', etc., which is derived from the all categories present in the currently-defined macroscripts.

Note that the normal way to define a macroScript is through MAXScript, the .mcr files in the UI\MacroScripts directory contain examples, and they all have category definitions.

Note: In order to use these methods you need to **#include** "**IMACROSCRIPT.H**" and link to "**MAXSCRIPT.LIB**".

### Methods:

public:

### Prototype:

```
virtual MacroID GetID()=0;
```

### Remarks:

Returns the ID for this macro script. Note: **typedef short MacroID;**

### Prototype:

```
virtual TSTR& GetName()=0;
```

**Remarks:**

Returns the name for this macro script.

**Prototype:**

**virtual TSTR& GetCategory()=0;**

**Remarks:**

Returns the category for this macro script.

**Prototype:**

**virtual TSTR& GetFileName()=0;**

**Remarks:**

Returns the file name of the script source text for this script.

**Prototype:**

**virtual void SetFileName(TCHAR\* fn)=0;**

**Remarks:**

Sets the file name for the script source.

**Parameters:**

**TCHAR\* fn**

The file name to set.

**Prototype:**

**virtual void SetOffset(int o)=0;**

**Remarks:**

Sets the offset for this macro script entry. There can be any number of macroScripts in a single source file and the offset keeps track of the beginning of its definition in the file.

**Parameters:**

**int o**

The offset to set.

**Prototype:**

**virtual long GetOffset()=0;**

**Remarks:**

Returns the offset for this macro script entry. See **SetOffset()** above.

**Prototype:**

**virtual Value\* GetCode()=0;**

**Remarks:**

When the macroScript is defined, only its source file and source offset are registered. When the user first runs it, the MAXScript compiler is used to compile the definition into executable code, which is then cached and used for any later executions and is what this method returns. If this returns NULL, the macro hasn't been compiled or run yet. Another way to run the macro is via the **MacroEntry::Execute()** and this causes the code to be cached as a side effect also. Normally, developers only ever need to use the **Execute()** method, but if they are using the MAXScript SDK, they can grab the code using **GetCode()** and work with it directly.

**Prototype:**

**virtual TSTR& GetToolTip()=0;**

**Remarks:**

Returns the tooltip text for the UI button.

**Prototype:**

**virtual void SetToolTip(TCHAR\* tt)=0;**

**Remarks:**

Sets the tooltip text for the UI button.

**Parameters:**

**TCHAR\* tt**

The tooltip text to set.

**Prototype:**

**virtual TSTR& GetButtonText()=0;**

**Remarks:**

Returns the UI button text (for label buttons).

**Prototype:**

**virtual void SetButtonText(TCHAR\* bt)=0;**

**Remarks:**

Sets the UI button text (for label buttons).

**Parameters:**

**TCHAR\* bt**

The button text.

**Prototype:**

**virtual void SetButtonIcon(TCHAR\* icnf, int indx)=0;**

**Remarks:**

Sets the UI button icon via a base icon file name and index into the specified BMP bitmap.

**Parameters:**

**TCHAR\* icnf**

The file name of the BMP file. See the remarks in [Class CUIFrameMgr](#) for details on the naming scheme.

**int indx**

The zero based index of the icon in the BMP file. The first icon is 0, the second is 1, etc.

**Prototype:**

**virtual TSTR& GetButtonIconFile()=0;**

**Remarks:**

Returns the file name of the icon file.

**Prototype:**

**virtual int GetButtonIconIndex()=0;**

**Remarks:**

Returns the zero based index of the icon in the icon file.

**Prototype:**

**virtual void SetFlags(short mask)=0;**

**Remarks:**

Sets the specified flags.

**Parameters:**

**short mask**

The flags to set. One or more of the following values:

**ME\_DROPPED\_SCRIPT**

Macro made from some drag-and-dropped text.

**ME\_SILENT\_ERRORS**

Macro won't report any runtime errors.

**Prototype:**

**virtual void ClearFlags(short mask)=0;**

**Remarks:**

Clears the specified flags.

**Parameters:**

**short mask**

The flags to clear. One or more of the following values:

**ME\_DROPPED\_SCRIPT**

Macro made from some drag-and-dropped text.

**ME\_SILENT\_ERRORS**

Macro won't report any runtime errors.

**Prototype:**

**virtual short GetFlags(short mask)=0;**

**Remarks:**

Returns the state of the specified flags.

**Parameters:**

**short mask**

The flags to get. One or more of the following values:

**ME\_DROPPED\_SCRIPT**

Macro made from some drag-and-dropped text.

**ME\_SILENT\_ERRORS**

Macro won't report any runtime errors.

**Prototype:**

**virtual Value\* Execute()=0;**

**Remarks:**

Executes this macro entry.

**Return Value:**

A pointer to the result of executing the macro. If a developer doesn't care about the result of executing a macro script, which is usually the case, then the

**Value\*** returned from this method can just be ignored. If a developer does care, then the necessary information about working with **Value\***'s is in the

[MAXScript SDK](#) documentation.

## Class ISliderControl

See Also: [Class ICustomControl](#), [Class ISpinnerControl](#).

```
class ISliderControl : public ICustomControl
```

### Description:

This class is available in release 3.0 and later only.

**Important Note: The slider control ensures that it only displays, and the user is only allowed to input, values within the specified ranges. However the slider is just a front end to a controller which actually controls the value. The user can thus circumvent the slider constraints by editing the controller directly (via function curves in track view, key info, etc.). Therefore, when a plug-in gets a value from a controller (or a parameter block, which may use a controller) it is its responsibility to clamp the value to a valid range.**

(Slider Control)

('Bracketed' Slider Control)

The custom slider control is functionality similar to the custom spinner control. It supports the following features:

- can link to custom edit box.
- right click reset of value.  
if not dragging, resets to default reset value.  
if dragging, resets to previous value.
- shift+right click sets an animation key.
- red highlight for animated key positions.

It also supports the following functionality:

- dynamically set tick marks segment the slider track.
- default reset value and last value are visually indicated.
- left click in slider track moves button to that position.
- ctrl key snaps to nearest tick mark.

Also Note: Developers should use the functions **Get/SetSpinnerPrecision()** for controlling precision of edit boxes linked to slider controls. Those functions affect both spinners and sliders.

To initialize the pointer to the control call:

**Function:****ISliderControl \*GetISlider(HWND hCtrl);**

To release the control call:

**Function:****void ReleaseISlider(ISliderControl \*isc);**

The value to use in the Class field of the Custom Control Properties dialog is:

**SliderControl**

The following messages may be sent by the slider control:

This message is sent when the value of a slider changes.

**CC\_SLIDER\_CHANGE**

**lParam** contains a pointer to the slider control. You can cast this pointer to a **ISliderControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the slider. This is the ID established in the ID field of the Custom Control Properties dialog.

**HIWORD(wParam)** is TRUE if the user is dragging the slider interactively.

This message is sent when the user presses down on the slider.

**CC\_SLIDER\_BUTTONDOWN**

**lParam** contains a pointer to the slider control. You can cast this pointer to a **ISliderControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the slider. This is the ID established in the ID field of the Custom Control Properties dialog.

This message is sent when the user releases a slider.

**CC\_SLIDER\_BUTTONUP**

**lParam** contains a pointer to the slider control. You can cast this pointer to a **ISliderControl** type and then call methods of the control.

**LOWORD(wParam)** contains the ID of the slider. This is the ID established in the ID field of the Custom Control Properties dialog.

**HIWORD(wParam)** is FALSE if the user canceled and TRUE otherwise.

**Methods:**

public:

**Prototype:**

**virtual float GetFVal()=0;**

**Remarks:**

Returns the floating point value of the control.

**Prototype:**

**virtual int GetIVal()=0;**

**Remarks:**

Returns the integer value of the control.

**Prototype:**

**virtual void SetNumSegs(int num)=0;**

**Remarks:**

Sets the number of segments (tick marks) used by the control.

**Parameters:**

**int num**

The number to set.

**Prototype:**

**virtual void SetValue(float v, int notify)=0;**

**Remarks:**

This method sets the value of the control to the specific floating point number passed. You may pass FALSE as the notify parameter so the control wont send a message when you set the value.

**Parameters:**

**float v**

The new value for the control.

**int notify**

If TRUE a message is sent indicating the control has changed; if FALSE no message is sent.

**Prototype:**

**virtual void SetValue(int v, int notify)=0;**

**Remarks:**

This method sets the value of the control to the specific integer number passed. You may pass FALSE as the notify parameter so the control wont send a message when you set the value.

**Parameters:**

**int v**

The new value for the control.

**int notify**

If TRUE a message is sent indicating the control has changed; if FALSE no message is sent.

**Prototype:**

**virtual void SetLimits(int min, int max, int limitCurValue = TRUE)=0;**

**Remarks:**

This method establishes the allowable limits for integer values entered.

**Parameters:**

**int min**

The minimum allowable value.

**int max**

The maximum allowable value.

**int limitCurValue = TRUE**

You may pass FALSE to the this parameter so the control will not send a spinner changed message when the limits are set.

**Prototype:**

**virtual void SetLimits(float min, float max, int limitCurValue = TRUE)=0;**

**Remarks:**

This method establishes the allowable limits for floating point values entered.

**Parameters:**

**float min**

The minimum allowable value.

**float max**

The maximum allowable value.

**int limitCurValue = TRUE**

You may pass FALSE to the this parameter so the control will not send a spinner changed message when the limits are set.

**Prototype:**

**virtual void LinkToEdit(HWND hEdit, EditSpinnerType type)=0;**

**Remarks:**

When an edit control is used in conjunction with the slider control, this method is used to link the two, so values entered using the slider are displayed in the edit control. This method is also used to set the type of value which may be entered.

**Parameters:****HWND hEdit**

The handle of the edit control to link.

**EditSpinnerType type**

The type of value that may be entered. One of the following values:

**EDITTYPE\_INT**

Any integer value.

**EDITTYPE\_FLOAT**

Any floating point value.

**EDITTYPE\_UNIVERSE**

This is a value in world space units. It respects the system's unit settings (for example feet and inches).

**EDITTYPE\_POS\_INT**

Any integer  $\geq 0$

**EDITTYPE\_POS\_FLOAT**

Any floating point value  $\geq 0.0$

**EDITTYPE\_POS\_UNIVERSE**

This is a positive value in world space units. It respects the system's unit

settings (for example feet and inches) .

### **EDITTYPE\_TIME**

This is a time value. It respects the system time settings (SMPTE for example).

#### **Prototype:**

**virtual void SetIndeterminate(BOOL i=TRUE)=0;**

#### **Remarks:**

This method is used to show commonality. When several different values are being reflected by the slider, the value is indeterminate. When TRUE, the value field of the slider appears empty.

#### **Parameters:**

**BOOL i=TRUE**

Pass TRUE to this method to set the value to indeterminate.

#### **Prototype:**

**virtual BOOL IsIndeterminate()=0;**

#### **Remarks:**

This method returns TRUE if the current state of the slider is indeterminate; otherwise FALSE. See **SetIndeterminate()** above.

#### **Prototype:**

**virtual void SetResetValue(float v)=0;**

#### **Remarks:**

A user may right click on a slider to reset it to its 'reset' value (after it has been changed). This method specifies the value used when the reset occurs.

#### **Parameters:**

**float v**

The reset value.

#### **Prototype:**

**virtual void SetResetValue(int v)=0;**

**Remarks:**

A user may right click on a slider to reset it to its 'reset' value (after it has been changed). This method specifies the value used when the reset occurs.

**Parameters:**

**int v**

The reset value.

**Prototype:**

**virtual void SetKeyBrackets(BOOL onOff)=0;**

**Remarks:**

Sets the display of the 'brackets' surrounding the slider control. This is used to indicate if a key exists for the parameter controlled by the slider at the current time. These brackets turned on and off automatically if you are using a parameter map and parameter block to handle the control. If not you'll need to use this method. For a slider, the 'brackets' appear as a colored dot in the position marker.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**The following functions are not members of this class but are available for use:**

**Function:**

**ISliderControl \*SetupIntSlider(HWND hwnd, int idSlider, int idEdit, int min, int max, int val, int numSegs);**

**Remarks:**

This global function is used for setting up integer sliders. It performs the equivalent of the **GetISlider()**, **SetLimits()**, **SetValue()**, and **LinkToEdit()**.

**Parameters:**

**HWND hwnd**

The handle of the dialog box in which the slider appears.

**int idSlider**

The ID of the slider.

**int idEdit**

The ID of the edit control.

**int min**

The minimum allowable value.

**int max**

The maximum allowable value.

**int val**

The initial value for the spinner.

**int numSegs**

The number of segments to use for the control.

**Return Value:**

A pointer to the slider control.

**Function:**

**ISliderControl \*SetupFloatSlider(HWND hwnd, int idSlider, int idEdit, float min, float max, float val, int numSegs);**

**Remarks:**

This global function is used for setting up floating point sliders. It performs the equivalent of the **GetISlider()**, **SetLimits()**, **SetValue()**, and **LinkToEdit()**.

**Parameters:****HWND hwnd**

The handle of the dialog box in which the slider appears.

**int idSlider**

The ID of the slider.

**int idEdit**

The ID of the edit control.

**float min**

The minimum allowable value.

**float max**

The maximum allowable value.

**float val**

The initial value for the spinner.

**int numSegs**

The number of segments to use for the control.

**Return Value:**

A pointer to the slider control.

**Function:**

**ISliderControl \*SetupUniverseSlider(HWND hwnd, int idSlider, int idEdit, float min, float max, float val, int numSegs);**

**Remarks:**

This global function is used for setting up 'universal' value sliders (**EDITTYPE\_UNIVERSE** -- these display world space units). It performs the equivalent of the **GetISlider()**, **SetLimits()**, **SetValue()**, and **LinkToEdit()**.

**Parameters:****HWND hwnd**

The handle of the dialog box in which the slider appears.

**int idSlider**

The ID of the slider.

**int idEdit**

The ID of the edit control.

**float min**

The minimum allowable value.

**float max**

The maximum allowable value.

**float val**

The initial value for the spinner.

**int numSegs**

The number of segments to use for the control.

**Return Value:**

A pointer to the slider control.

**Function:**

**void SetSliderDragNotify(BOOL onOff);**

**Remarks:**

This function controls whether or not sliders send **CC\_SLIDER\_CHANGE** notifications while the user adjusts them with the mouse.

**Parameters:**

**BOOL onOff**

TRUE to turn on; FALSE to turn off.

**Function:**

**BOOL GetSliderDragNotify();**

**Remarks:**

Returns TRUE if **CC\_SLIDER\_CHANGE** notifications are sent by sliders while the user adjusts them with the mouse; FALSE if they are not sent.

## Class ICurveCtl

See Also: [Class ReferenceTarget](#), [Class ICurve](#), [Class CurvePoint](#), [Class ResourceMakerCallback](#), [Class BitArray](#), [Class Interval](#).

```
class ICurveCtl : public ReferenceTarget
```

### Description:

This class is available in release 3.0 and later only.

This class is an interface to the curve custom control. An example of this control in the 3ds max user interface can be seen in the Color Map section of the Output rollup of a 2D Texture map. Sample code using these APIs is available in `\MAXSDK\SAMPLES\UTILITIES\CCUTIL\CCUTIL.CPP`.

### Methods:

public:

### Prototype:

```
virtual BOOL IsActive()=0;
```

### Remarks:

This method indicates if the dialog box for the control is up or not. Returns TRUE if active; otherwise FALSE.

### Prototype:

```
virtual void SetActive(BOOL sw)=0;
```

### Remarks:

This method is used to bring up or close the dialog box.

### Parameters:

**BOOL sw**

TRUE to open; FALSE to close.

### Prototype:

```
virtual HWND GetHWND()=0;
```

### Remarks:

Returns the window handle of the control.

**Prototype:**

**virtual void SetNumCurves(int iNum, BOOL doUndo=FALSE)=0;**

**Remarks:**

Sets the number of curves used in this control.

**Parameters:**

**int iNum**

The number of curves to use.

**BOOL doUndo=FALSE**

This parameter is available in release 4.0 and later only.

This will cause the function to register an Restore Object if set to TRUE.

**Prototype:**

**virtual int GetNumCurves()=0;**

**Remarks:**

Returns the numbers of curves used by the control.

**Prototype:**

**virtual void SetXRange(float min, float max, BOOL rescaleKeys = TRUE)=0;**

**Remarks:**

Sets the absolute position of the first and last CurvePoints.

**Parameters:**

**float min**

The minimum value.

**float max**

The maximum value.

**BOOL rescaleKeys = TRUE**

This parameter is available in release 4.0 and later only.

This parameter controls whether changing the X range will rescale the keys and key tangents or not. When this is TRUE, the default, the keys and tangents get rescaled to the total X range. Setting this to FALSE allow developers to have move control over the exact placement of keys and tangents when the X

range changes. This also allow developers to set ranges from within the points changed message handler without getting into a loop.

**Prototype:**

**virtual void SetYRange(float min, float max)=0;**

**Remarks:**

This determines the absolute upper and lower Y-constraint. This method only has an effect if the **CC\_CONSTRAIN\_Y** flag is set.

**Parameters:**

**float min**

The minimum value.

**float max**

The maximum value.

**Prototype:**

**virtual Point2 GetXRange()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the X Range.

**Prototype:**

**virtual Point2 GetYRange()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the Y Range.

**Prototype:**

**virtual void RegisterResourceMaker(ReferenceMaker \*rmak)=0;**

**Remarks:**

This methods registers a callback object used to handle certain aspects of the control. The callback object will be used for updating of the display button image list and tool tip text for the curve control. It also gets called when the

user executes a Reset or creates a new control.

This registers a reference maker which implements the method **Animatable::GetInterface()** for the id **I\_RESMAKER\_INTERFACE** by returning an object derived from class **ResourceMakerCallback**.

**Parameters:**

**ReferenceMaker \*rmak**

Points to the reference maker which returns the callback object.

**Prototype:**

**virtual BOOL GetZoomValues(float \*h, float \*v)=0;**

**Remarks:**

Returns the current zoom values.

**Parameters:**

**float \*h**

Points to storage for the horizontal zoom value.

**float \*v**

Points to storage for the vertical zoom value.

**Return Value:**

TRUE if valid values were returned; otherwise FALSE.

**Prototype:**

**virtual void SetZoomValues(float h, float v)=0;**

**Remarks:**

Sets the zoom values. To determine the values to use developers should use the CCUtil plug-in, create a pop-up window as big as is appropriate for the final control, adjust the zoom and scroll values interactively, and then simply read out the values from the CCUtil user interface (GetZoom and GetScroll).

**Parameters:**

**float h**

The horizontal value to set.

**float v**

The vertical value to set.

**Prototype:**

**virtual BOOL GetScrollValues(int \*h, int \*v)=0;**

**Remarks:**

Returns the horizontal and vertical scroll values.

**Parameters:**

**int \*h**

Points to storage for the horizontal scroll value.

**int \*v**

Points to storage for the vertical scroll value.

**Return Value:**

TRUE if valid values were returned; otherwise FALSE.

**Prototype:**

**virtual void SetScrollValues(int h, int v)=0;**

**Remarks:**

Sets the scroll values. To determine the values to use developers should use the CCUtil plug-in, create a pop-up window as big as is appropriate for the final control, adjust the zoom and scroll values interactively, and then simply read out the values from the CCUtil user interface (GetZoom and GetScroll).

**Parameters:**

**int h**

The horizontal scroll value to set.

**int v**

The vertical scroll value to set.

**Prototype:**

**virtual void ZoomExtents()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Performs a zoom extents operation to the curve view.

**Prototype:**

**virtual void SetTitle(TCHAR \*str)=0;**

**Remarks:**

Sets the title of the dialog box to the specified string. This is only used if the **CC\_ASPOPUP** is used to create a pop-up dialog.

**Parameters:**

**TCHAR \*str**

The title string to display.

**Prototype:**

**virtual ICurve \*GetControlCurve(int numCurve)=0;**

**Remarks:**

Returns and interface to the specified curve. This interface allows you to set the color of the curve and retrieve the Y value of the curve given an X value.

**Parameters:**

**int numCurve**

The zero based index of the curve.

**Prototype:**

**virtual void SetDisplayMode(BitArray &mode)=0;**

**Remarks:**

Determines which curves are toggled on.

**Parameters:**

**BitArray &mode**

The BitArray to control curve visibility -- one bit for each curve. If the bit is set the curve is toggled on; otherwise it is toggled off.

**Prototype:**

**virtual BitArray GetDisplayMode()=0;**

**Remarks:**

Returns a BitArray which indicates which curves are toggled on or off.

**Prototype:**

**virtual void EnableDraw(BOOL enable)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to turn on/off the display code. It is useful when you are doing lots of changes and don't want the window to continually redraw.

**Parameters:**

**BOOL enable**

TRUE to enable; FALSE to disable.

**Prototype:**

**virtual void SetCCFlags(DWORD flags)=0;**

**Remarks:**

Sets the curve control flags to those passed.

**Parameters:**

**DWORD flags**

See [List of Custom Curve Control Flags](#).

**Prototype:**

**virtual DWORD GetCCFlags()=0;**

**Remarks:**

Returns the curve control flags. See [List of Custom Curve Control Flags](#).

**Prototype:**

**virtual void SetCustomParentWnd(HWND hParent)=0;**

**Remarks:**

Sets the parent window for the control if the control is not a popup window.

**Parameters:**

**HWND hParent**

The window handle of the parent.

**Prototype:**

**virtual void SetMessageSink(HWND hWnd)=0;**

**Remarks:**

Call this method and the following window messages will be sent to the window whose handle is passed. The contents of the **lParam** and **wParam** parameters passed to the window proc are shown.

**WM\_CC\_SEL\_CURVEPT**

Sent when a point is selected or deselected.

**lParam = ICurve \* , LOWORD(wParam)** = The number of points which are selected.

**WM\_CC\_CHANGE\_CURVEPT**

Sent when a point is changed.

**lParam = ICurve \* , LOWORD(wParam)** = The zero based index of the changed point.

**WM\_CC\_CHANGE\_CURVETANGENT**

Sent when a point's in or out tangent is changed.

**lParam = ICurve \* , LOWORD(wParam)** = The zero based index of the changed point,

**HIWORD(wParam)** contains a flag, that indicates if the changed tangent is the in, or out tangent. You can check these flags as **HIWORD(wParam) & IN\_CURVETANGENT\_CHANGED** and **HIWORD(wParam) & OUT\_CURVETANGENT\_CHANGED**, for the in and out tangent respectively.

**WM\_CC\_DEL\_CURVEPT**

Sent when a point is deleted.

**lParam = ICurve \* , LOWORD(wParam)** = The zero based index of the deleted point.

**WM\_CC\_INSERT\_CURVEPT**

This option is available in release 4.0 and later only.

**lParam = ICurve \* , LOWORD(wParam)** = The zero based index of the inserted point.

**Parameters:**

**HWND hWnd**

The handle of the window which will receive the messages.

**Prototype:****virtual void SetCommandMode(int ID)=0;****Remarks:**

Sets the command mode in use by the control.

**Parameters:****int ID**

One of the following values (which correspond directly to toolbar buttons in the UI. See the 2D texture map Output rollup for example):

**CID\_CC\_MOVE\_XY****CID\_CC\_MOVE\_X****CID\_CC\_MOVE\_Y****CID\_CC\_SCALE****CID\_CC\_INSERT\_CORNER****CID\_CC\_INSERT\_BEZIER****Prototype:****virtual int GetCommandMode()=0;****Remarks:**

Returns a value which indicates the current command mode. One of the following values (which correspond directly to toolbar buttons in the UI. See the 2D texture map Output rollup for example):

**CID\_CC\_MOVE\_XY****CID\_CC\_MOVE\_X****CID\_CC\_MOVE\_Y****CID\_CC\_SCALE****CID\_CC\_INSERT\_CORNER****CID\_CC\_INSERT\_BEZIER****Prototype:****virtual void Redraw()=0;****Remarks:**

This method redraws the custom curve control.

**Prototype:**

**virtual Interval GetValidity(TimeValue t)=0;**

**Remarks:**

Returns an **Interval** which reflects the validity of every point of every curve used by the curve control.

**Parameters:**

**TimeValue t**

The time about which the interval is computed.

**Prototype:**

**virtual void Update(TimeValue t, Interval& valid)=0;**

**Remarks:**

Updates the validity interval passed with the overall validity of the curves in the control. This simply does:

**valid &= GetValidity(t);**

**Parameters:**

**TimeValue t**

The time about which the interval is computed.

**Interval& valid**

The interval which is updated.

**Prototype:**

**virtual void SetCurrentXValue(float val)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This sets the position of the vertical line drawn over the graph showing the current X value. See flag **CC\_SHOW\_CURRENTXVAL** in [List of Custom Curve Control Flags](#).

**Parameters:**

**float val**

The value to set.

## Class RightClickMenuManager

See Also: [Class RightClickMenu](#), [Class Interface](#).

class RightClickMenuManager

### Description:

Methods of this class allow a developer to extend the menu presented when a user right clicks on an item in the viewports. All methods of this class are implemented by the system.

### Methods:

#### Prototype:

```
void Register(RightClickMenu *menu);
```

#### Remarks:

This method is used to register an instance of a class derived from **RightClickMenu**. This allows its methods to be called when the user right clicks on an object in a viewport.

#### Parameters:

**RightClickMenu \*menu**

The menu to set as register.

#### Prototype:

```
void Unregister(RightClickMenu *menu);
```

#### Remarks:

This method is used to un-register a registered right click menu.

#### Parameters:

**RightClickMenu \*menu**

The menu to set as un-register.

#### Prototype:

```
int AddMenu(RightClickMenu *menu, UINT flags, UINT id,  
LPCTSTR data);
```

#### Remarks:

This method is called to add items to the right click menu passed. A string or separator may be added. Strings may be checked or unchecked. They may also be disabled and grayed.

**Parameters:**

**RightClickMenu \*menu**

The menu to add the item to.

**UINT flags**

Describes the item being added. One or more of the following values:

**MF\_CHECKED**

**MF\_UNCHECKED**

**MF\_STRING**

**MF\_DISABLED**

**MF\_GRAYED**

**MF\_SEPARATOR**

**UINT id**

The **id** of the selection. This is the **id** passed to the

**RightClickMenu::Selected()** method when the user makes a selection from the menu.

**LPCTSTR data**

The string to display in the menu (or NULL if adding a separator).

**Return Value:**

Nonzero if the item was added; otherwise 0.

**Prototype:**

**int BeginSubMenu(LPCTSTR name);**

**Remarks:**

This method is available in release 3.0 and later only.

This begins a new sub menu. Items added after this call will appear as sub choices of this one until **EndSubMenu()** is called.

**Parameters:**

**LPCTSTR name**

The name to appear for the sub menu item.

**Return Value:**

Always returns TRUE.

**Prototype:**

```
int EndSubMenu();
```

**Remarks:**

This method is available in release 3.0 and later only.

This ends a sub menu. Items added after this call will appear as they did prior to calling **BeginSubMenu()**.

**Return Value:**

Always returns TRUE.

**Prototype:**

```
void CleanUp();
```

**Remarks:**

This method is available in release 3.0 and later only.

This removes all sub menus from the right click menu.

**Prototype:**

```
void Init(HMENU menu, int startId, int limit, HWND hWnd,  
IPoint2 m);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void Process(UINT id);
```

**Remarks:**

This method is used internally.

## Class DataEntryMouseProc

See Also: [Class MouseCallBack](#), [Class ViewExp](#), [Class Object](#), [Class Interface](#), [Class Point3](#), [Class Matrix3](#), [Class CreateMouseCallBack](#).

```
class DataEntryMouseProc : public MouseCallBack
```

### Description:

This class is available in release 3.0 and later only.

This mouse proc allows drawing in multiple viewports, offsetting from the construction plane, and orthogonal and angle snapping. This allows developers to support orthogonal snapping and angle snapping on creation (as the Bezier line tool does). If the user presses Shift while dragging the mouse, the point is snapped to the nearest quadrant (ortho snapping). If the Alt key is held, the point is snapped using the setting of the angle snap system.

The typical control flow of this class is that the **OnPointSelected()** method is called every time the user clicks in the viewport, and **OnMouseAbort()** is called when the user right clicks to finish the curve. **RemoveLastPoint()** is called when backspace is pressed, and **OnMouseMove(Point3& p)** is called every time the mouse moves (this lets the developer update the curve continuously).

This class is a sub-class of MouseCallBack, but it can also be used as a CreateMouseCallBack to create curves from the creation panel. To do this you embed a DataEntryMouseProc in a CreateMouseCallBack as show below. Notice the implementation of the virtual member StartNewCreation(). This is a new virtual method on CreateMouseCallBack that tells the system whether the mouse proc is in a state ready to create a new object. This was required, because the "proc" function now always returns "CREATE\_STOP" in order to implement multi-viewport input.

```
class TopCVCurveCreateMouseProc : public  
Em3DDataEntryMouseProc {  
public:  
TopCVCurveCreateMouseProc() :  
Em3DDataEntryMouseProc() {}  
virtual BOOL OnPointSelected();  
virtual void OnMouseMove(Point3& p);  
virtual BOOL AllowAnyViewport();
```

```

virtual void RemoveLastPoint();
virtual int OnMouseAbort();
virtual BOOL PerformRedraw() { return FALSE; }
void SetObj(EditableCVCurve* o) { mpOb = o; }
virtual BOOL StartNewCreation() { return mMouseClicked == 0; }
friend class EditableCVCurve;
private:
EditableCVCurve * mpOb;
};

```

```

class EditableCVCurveCreateCallBack: public
CreateMouseCallBack {
public:
EditableCVCurveCreateCallBack() {}

```

```

virtual int proc( ViewExp* vpt,int msg, int point, int flags, IPoint2
m, Matrix3& mat );
friend class CVBackspaceUser;
friend class EditableCVCurve;
virtual BOOL StartNewCreation() { return
mMouseProc.StartNewCreation(); }
private:
void RemoveLastPoint();
TopCVCurveCreateMouseProc mMouseProc;
};

```

```

int EditableCVCurveCreateCallBack::proc(ViewExp* vpt,int msg,
int point, int flags, IPoint2 m, Matrix3& mat)
{
spTransformMat = &mat;
return mMouseProc.proc(vpt->GetHWnd(), msg, point, flags, m);
}
static EditableCVCurveCreateCallBack nsCreateCB;

```

```

CreateMouseCallBack*
EditableCVCurve::GetCreateMouseCallBack()
{
nsCreateCB.mMouseProc.SetObj(this);
nsCreateCB.mMouseProc.SetParams(hInstance, mpEM, 0);
return(&nsCreateCB);
}

```

#### **Data Members:**

protected:

**Object\* mpObject;**

This a pointer to the object that is using the mouse proc.

**int mMouseClicked;**

The number of clicks (i.e. selected points) the user has entered in creating this object. It is like the "point" parameter to "proc".

**Tab<Point3> mPoints;**

These are the 3D values of the points the user has selected.

**Tab<IPoint2> mClickPoints;**

These are the 2D viewport coordinates the user selected.

**BOOL mLiftOffCP;**

TRUE when in the mode where we lift off the construction plane

#### **Methods:**

public:

#### **Prototype:**

**DataEntryMouseProc(Object\* pObj, int cursor, HINSTANCE hInst);**

#### **Remarks:**

Constructor. The data members are initialized as follows:

**mpObject = pObj;**

**mCursor = cursor;**

**mInstance = hInst;**

**mMouseClicked = 0;**

```
mDoNotDouble = TRUE;  
mLiftOffCP = FALSE;  
mPreviousFlags = 0;
```

**Prototype:**

```
DataEntryMouseProc();
```

**Remarks:**

Constructor. The data members are initialized as follows:

```
mpObject = NULL;  
mpIp = NULL;  
mMouseClicked = 0;  
mDoNotDouble = TRUE;  
mCursor = 0;  
mLiftOffCP = FALSE;  
mPreviousFlags = 0;  
mInstance = 0;
```

**Prototype:**

```
virtual BOOL OnPointSelected();
```

**Remarks:**

Implemented by the Plug-In.

This method is called every time the user clicks in the viewport to enter data. This is the method in NURBS curves, for example, that adds a new CV or point to the curve. The method can query the **mMouseClicked** member to see which point this is in the sequence (like the "point" parameter to traditional MouseCallback classes), and the 3D value of the point can be determined from **mPoints[mMouseClicked]**. The data member **mPoints** contains all the 3D points selected, and **mClickPoints** is a table of the 2d points where the user clicked in the viewport.

**Return Value:**

The return value is used to determine whether the creation should continue or not. If it returns TRUE, more points are selected. If it returns FALSE, then the

creation is done. In the case of NURBS, this is used to implement the feature that asks users if they want to close a curve when they click on the same point where they started the curve. If the answer is yes, this method returns FALSE, otherwise it always return TRUE.

**Default Implementation:**

```
{return TRUE; }
```

**Prototype:**

```
virtual void OnMouseMove(Point3& p);
```

**Remarks:**

Implemented by the Plug-In.

This method is called on every mouse move event.

**Parameters:**

**Point3& p**

The current point in world space of the mouse position.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL AllowAnyViewport();
```

**Remarks:**

Implemented by the Plug-In.

This method tells the system when to allow drawing in mutiple viewports.

**Return Value:**

TRUE to allow drawing between viewports; FALSE to not allow drawing between viewports.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

```
virtual void RemoveLastPoint();
```

**Remarks:**

Implemented by the Plug-In.

This method is called when the backspace key is pressed. Typically this deletes the last point entered by the user so they may correct its entry.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual int OnMouseAbort();
```

**Remarks:**

Implemented by the Plug-In.

This method is called when the creation is finished.

**Return Value:**

Return one of the following value to indicate the state of the creation process:

**CREATE\_CONTINUE**

The creation process should continue.

**CREATE\_STOP**

The creation process has terminated normally.

**CREATE\_ABORT**

The creation process has been aborted. The system will delete the created object and node.

**Default Implementation:**

```
{ return CREATE_ABORT; }
```

**Prototype:**

```
virtual BOOL PerformRedraw();
```

**Remarks:**

Implemented by the Plug-In.

This method indicates whether the mouse proc should perform redraws. When used in a **CreateMouseCallBack**, this should return FALSE.

**Return Value:**

TRUE to have the mouse proc perform redraws; otherwise FALSE.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

```
virtual void SetUseConstructionLine(BOOL useLine) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to tell the object to draw offset lines. This is called passing TRUE when the system enters the mode where points are lifted off the construction plane. It is telling the object that it needs to draw a line between the points supplied by **SetConstructionLine(int i, Point3 p)**. It is called passing FALSE when the offset procedure is complete.

To see an example of how this is used, create a NURBS Point curve, and press the Control key while laying down a point. It enters a mode that lets you lift the point off the construction plane, and draws a red dotted line back to the CP to give some visual feedback.

**Parameters:**

**BOOL useLine**

TRUE if the mode is beginning; FALSE if it is ending.

**Prototype:**

```
virtual void SetConstructionLine(int i, Point3 p) = 0;
```

**Remarks:**

These methods need to be implemented to get the offset line drawn

This method is called with  $i==0$  for the start point and with  $i==1$  for the end point.

**Parameters:**

**int i**

The point index: 0 for the start or 1 for the end.

**Point3 p**

The point to draw to or from.

**Prototype:**

**int proc(HWND hwnd, int msg, int point, int flags, IPoint2 m);**

**Remarks:**

Implemented by the System.

This is the method where the developer defines the user / mouse interaction that takes place.

**Parameters:**

**HWND hwnd**

The window handle of the window the user clicked in. This is one of the viewports.

**int msg**

This message describes the type of event that occurred. See [List of Mouse Callback Messages](#).

**int point**

The point number. This is 0 for the first click, 1 for the second, etc.

**int flags**

These flags describe the state of the mouse buttons. See [List of Mouse Callback Flags](#).

**IPoint2 m**

The 2D screen point that the user clicked on.

**Return Value:**

**CREATE\_STOP** is returned.

Note: Notice the implementation of the virtual member

**StartNewCreation()**. This is a virtual method on **CreateMouseButton**

that tells the system whether the mouse proc is in a state ready to create a new object. This was required, because this method now always returns

**CREATE\_STOP** in order to implement the multi-viewport input

**Prototype:**

**void ClearCreationParams();**

**Remarks:**

Implemented by the System.

This method clears the creation parameters. The data members are reset as follows:

```
mMouseClicked = 0;  
mPoints.SetCount(0);  
mClickPoints.SetCount(0);  
mLiftOffCP = FALSE;  
mPreviousFlags = 0;
```

**Prototype:**

```
void SetParams(HINSTANCE hInst, Object* pObj, int cursor);
```

**Remarks:**

Implemented by the System.

This method sets the parameters as follows:

```
mpObject = pObj;  
mCursor = cursor;  
mInstance = hInst;
```

## Class IGraphObjectManager

See Also: [Class IGraphNode](#), [Class IGraphRef](#), [Class Animatable](#).

class IGraphObjectManager

### Description:

This class is available in release 3.0 and later only.

This class essentially represents an instance of a schematic view window and provides methods for adding nodes and node pointers, refreshing the schematic view, accessing filter bits and updating and controlling the various editors within 3ds max in ways that are not surfaced in the general interface.

### Methods:

public:

### Prototype:

```
virtual SvGraphNodeReference AddAnimatable(Animatable  
*anim, Animatable *owner, int id, DWORD flags = 0)=0;
```

### Remarks:

Adds an Animatable to the schematic view. Note that “owner” and “id” are actually arbitrary – they are used to provide context for this Animatable. This means that the plug-in developer can set them to any value. They are not used internally by the schematic view except in the "Sv\*" methods (which the developer can override). So, when you add an Animatable to the schematic view, you would typically add the owner (parent) Animatable as well as the sub-anim id. This allows you to, for example, easily return the name of the object when queried by the SvGetName(...) call (whose default implementation is shown below):

```
TSTR Animatable::SvGetName(IGraphObjectManager *gom,  
IGraphNode *gNode, bool isBeingEdited)  
{  
    Animatable *owner;  
    int subNum;  
    TSTR name;
```

```
owner = gNode->GetOwner();
subNum = gNode->GetID();
name = owner->SubAnimName(subNum);

return name;
}
```

**Parameters:**

**Animatable \*anim**

Points to the animatable to add.

**Animatable \*owner**

Points to the owner of **anim** above (typically).

**int id**

When nodes are added to the schematic view via this method this integer is provided. This value is not used internally by the schematic view. Rather, it is available to implementers of the **Animatable::Sv\*()** methods to aid in identifying the node.

**DWORD flags = 0**

This flag is some combination of the following bit flags. See [List of Schematic View AddAnimatable Flags](#).

**Return Value:**

A SvGraphNodeReference object.

**Prototype:**

```
virtual void PushLevel(Animatable *anim, int id = SV_NO_ID)=0;
```

**Remarks:**

During traversal of the Animatable graph via **SvTraverseAnimGraph(...)**, this method (and **PopLevel()** below) should be called appropriately to maintain an ownership stack. This is required by the schematic view when nodes are added to the graph with the **SV\_DUPLICATE\_INSTANCES** flag set. Note: In 3ds max 3.0, **SV\_DUPLICATE\_INSTANCES** is always on (i.e., the flag is ignored). Because of this, **PushLevel()** and **PopLevel()** should always be called in **SvTraverseAnimGraph(...)**.

See the sample code in **Animatable::SvStdTraverseAnimGraph()** for an example of this.

**Parameters:**

**Animatable \*anim**

This is the Animatable that you are, in all likelihood, about to add to the graph via the **AddAnimatable()** call.

**int id = SV\_NO\_ID**

This is also the same "id" you'd pass into **AddAnimatable()**. The "id" is only required in cases where it's impossible for the schematic view to distinguish between two (or more) children in the tree that have the same Animatable but represent different sub-anim. For example, a box has both its width and height set to the same controller (instanced). In the schematic view, this is still shown in tree form so we need the ID to distinguish between the "width" and "height" children.

**Prototype:**

**virtual void PopLevel()=0;**

**Remarks:**

Pops a level off the animatable ownership stack. See **PushLevel()** above for details.

**Prototype:**

**virtual IGraphRef \*AddReference(IGraphNode \*maker, IGraphNode \*target, SvReferenceType type)=0;**

**Remarks:**

This method adds a reference from the specified "maker" node to the specified "target" node.

**Parameters:**

**IGraphNode \*maker**

Points to the 'maker' node in schematic view.

**IGraphNode \*target**

Points to the 'target' node in schematic view.

**SvReferenceType type**

One of the following enum values:

**REFTYPE\_CHILD**

**REFTYPE\_SUBANIM**

**REFTYPE\_PLUGIN**

**Return Value:**

A pointer to an IGraphRef object.

**Sample Code:**

**SvGraphNodeReference**

**Control::SvTraverseAnimGraph(IGraphObjectManager \*gom,  
Animatable \*owner, int id, DWORD flags)**

**{**

**int i;**

**SvGraphNodeReference nodeRef;**

**SvGraphNodeReference childNodeRef;**

**//**

**// Test filter to see if "Controllers" are active.**

**// Bail out if they're off (being filtered out)...**

**//**

**if (!gom->TestFilter(SV\_FILTER\_CONTROLLERS))**

**return SvGraphNodeReference();**

**//**

**// Push this level in the tree. Note that the sub-anim id is passed**

**// in here because it's possible that the same instance of this control**

**// may exist in multiple tracks of "owner".**

**//**

**gom->PushLevel(this, id);**

**//**

**// Some flags are set here pertaining to the control being added.**

**// Note that the flags are also propagated down the tree**

**// by passing them on to SubAnim(i)-**

**>SvTraverseAnimGraph(gom, this, i, flags);**

```
// SV_DUPLICATE_INSTANCES tells the schematic view not to  
// represent multiple instances with a single node. Instead they  
// are represented by multiple nodes in the schematic view  
// with the "triangle thingy" attached to the side to indicate  
// shared instances. This flag is ignored in R3 because  
// this mode of operation is globally enabled  
// SV_INITIALLY_HIDDEN tells the schematic view that this  
// control's node is to be initially displayed in the closed state.  
// Note that this has no effect if the node already exists  
// in the graph -- it only applies to newly added nodes.  
//
```

```
flags |= SV_DUPLICATE_INSTANCES |  
SV_INITIALLY_HIDDEN;
```

```
//
```

```
// The control is added to the schematic view...
```

```
//
```

```
nodeRef = gom->AddAnimatable(this, owner, id, flags);
```

```
if (nodeRef.stat == SVT_PROCEED)
```

```
{
```

```
//
```

```
// This control's sub-anim's are iterated over...
```

```
//
```

```
for (i = 0; i < NumSubs(); i++)
```

```
{
```

```
if (SubAnim(i))
```

```
{
```

```
//
```

```
// SvTraverseAnimGraph(...) is recursively called to add this sub-  
anim (and all its descendents) to the graph...
```

```
//
```

```
childNodeRef = SubAnim(i)->SvTraverseAnimGraph(gom, this,  
i, flags);
```

```

//
// Now a link (node pointer) is created in the schematic between
// the control (nodeRef.gNode) and its child sub-anim
// (childNodeRef.gNode)....
//
    if (childNodeRef.stat != SVT_DO_NOT_PROCEED)
        gom->AddReference(nodeRef.gNode, childNodeRef.gNode,
REFTYPE_SUBANIM);
    }
}
}

//
// The tree level is popped. Note: a PopLevel() call must always be
// paired with a PushLevel() call!
//
    gom->PopLevel();

    return nodeRef;
}

```

**Prototype:**

**virtual void SvEditSelectedNodeProperties()=0;**

**Remarks:**

Pops up the property editor dialog on the selected nodes in the schematic view.

**Prototype:**

**virtual void SvSelectInMaterialEditor(IGraphNode \*gNode)=0;**

**Remarks:**

Selects the given node in the material editor. Does nothing if "gNode" does not represent a material or map.

**Parameters:**

## **IGraphNode \*gNode**

Points to the node in schematic view.

### **Prototype:**

```
virtual void SvSetCurEditObject(IGraphNode *gNode)=0;
```

### **Remarks:**

Selects the given node in the modifier panel. Does nothing if "gNode" does not represent an object.

### **Parameters:**

## **IGraphNode \*gNode**

Points to the node in schematic view.

### **Prototype:**

```
virtual void SvInvalidateView()=0;
```

### **Remarks:**

Invalidates the schematic view window.

### **Prototype:**

```
virtual void SvInvalidateNode(IGraphNode *gNode)=0;
```

### **Remarks:**

Invalidates a node in the schematic view window.

### **Parameters:**

## **IGraphNode \*gNode**

Points to the node in schematic view.

### **Prototype:**

```
virtual void SvUpdateMaterialEditor()=0;
```

### **Remarks:**

Forces the material editor to update.

### **Prototype:**

```
virtual void SvUpdateModifierPanel()=0;
```

**Remarks:**

Forces the modifier panel to update.

**Prototype:**

**virtual void SetFilter(DWORD mask)=0;**

**Remarks:**

Sets the specified filter bits.

**Parameters:**

**DWORD mask**

See [List of IGraphObjectManager Filter Bits](#).

**Prototype:**

**virtual void ClearFilter(DWORD mask)=0;**

**Remarks:**

Clears the specified filter bits.

**Parameters:**

**DWORD mask**

See [List of IGraphObjectManager Filter Bits](#).

**Prototype:**

**virtual bool TestFilter(DWORD mask)=0;**

**Remarks:**

Tests the specified filter bits. Returns true if set; otherwise false.

**Parameters:**

**DWORD mask**

See [List of IGraphObjectManager Filter Bits](#).

## Class IGraphNode

See Also: [Class IGraphObjectManager](#), [Class Object](#), [Class Animatable](#).

class IGraphNode

### Description:

This class is available in release 3.0 and later only.

This class represents a node in the schematic view graph and provides a few methods for querying information about the node.

### Methods:

public:

### Prototype:

**virtual Animatable \*GetAnim()=0;**

### Remarks:

Returns the Animatable associated with this node.

### Prototype:

**virtual IGraphNode \*GetParentNode()=0;**

### Remarks:

Returns the "primary parent" of this node. Nodes can have multiple parents (objects referencing this node) so this function is not strictly accurate. That said, many nodes have the concept of an owner node, which is what this function returns.

### Prototype:

**virtual bool IsObjectOrModifier()=0;**

### Remarks:

Returns true if this node represents a 3ds max object or modifier; otherwise false.

### Prototype:

**virtual bool IsMaterial()=0;**

**Remarks:**

Returns true if this node represents a 3ds max material or texmap; otherwise false.

**Prototype:**

**virtual Animatable \*GetOwner()=0;**

**Remarks:**

Returns the "owner" of this node. Some nodes have multiple owners. When this is the case, this function returns the "first" owner (the object that first added this node to the schematic view).

**Prototype:**

**virtual int GetID()=0;**

**Remarks:**

Return the ID of this node. When nodes are added to the schematic view (via the **IGraphObjectManager::AddAnimatable(...)** method), an integer is provided. This value is not used internally by the schematic view. Rather, it is available to implementers of the **Animatable::Sv\*()** methods to aid in identifying the node.

## Class IGraphRef

[Class IGraphObjectManager](#), [Class IGraphNode](#), [Class Object](#).

class IGraphRef

### **Description:**

This class is available in release 3.0 and later only.

This class represents a node pointer and, currently, has no methods.

## Class SubClassList

See Also: [Class DllDir](#), [Class ClassDirectory](#), [Class ClassEntry](#), [Class ClassDesc](#), [Class SClassUIInfo](#).

class SubClassList

### Description:

This class is available in release 2.0 and later only.

A sub class list is a table of **ClassEntry** objects that provide information on plug-in classes as well as usage counts for these classes within 3ds max. These sub class lists are organized by super class ID by the **ClassDirectory** class.

All methods of this class are implemented by the system.

### Methods:

#### Prototype:

**int FindClass(Class\_ID subClassID);**

#### Remarks:

Returns the index in the list of sub-classes of the class whose Class\_ID is passed.

#### Parameters:

**Class\_ID subClassID**

Specifies which class to return the index of.

#### Prototype:

**ulong SuperID();**

#### Remarks:

Returns the Super class ID corresponding to this sub-class list.

#### Prototype:

**int Count(int accType);**

#### Remarks:

Returns the number of sub-classes that match the specified access type.

#### Parameters:

## **int accType**

One of the following values:

**ACC\_PUBLIC** - public classes

**ACC\_PRIVATE** - non-public classes

**ACC\_ALL** - both of the above (**ACC\_PUBLIC|ACC\_PRIVATE**).

### **Prototype:**

**int FindClass(const TCHAR \*name);**

### **Remarks:**

Returns the index in the list of sub-classes of the class whose **ClassName()** is passed.

### **Parameters:**

**const TCHAR \*name**

Specifies which class to return the index of.

### **Prototype:**

**int GetFirst(int accType);**

### **Remarks:**

Returns the index of the first **ClassDesc** of the specified type in the list of sub-classes.

### **Parameters:**

**int accType**

One of the following values:

**ACC\_PUBLIC** - public classes

**ACC\_PRIVATE** - non-public classes

### **Prototype:**

**int GetNext(int accType);**

### **Remarks:**

Returns the index of the next **ClassDesc** of the specified type (or -1 at the end).

### **Parameters:**

## **int accType**

One of the following values:

**ACC\_PUBLIC** - public classes

**ACC\_PRIVATE** - non-public classes

### **Prototype:**

```
void AddClass(ClassDesc *cld, int dllNum, int index);
```

### **Remarks:**

This method is used internally.

### **Prototype:**

```
void SetUIInfo(SClassUIInfo *uiInfo);
```

### **Remarks:**

This method is available in release 3.0 and later only.

Allows developer to provide some additional information on a superclass.

Currently this includes a color, and a method which draws a representative image in a Windows DC.

### **Parameters:**

**SClassUIInfo \*uiInfo**

Points to the information to set.

### **Prototype:**

```
SClassUIInfo *GetUIInfo();
```

### **Remarks:**

This method is available in release 3.0 and later only.

This method returns additional user interface related information on a given superclass. Returns NULL if no superclass information was assigned.

### **Prototype:**

```
void ReplaceClass(int idx, ClassDesc *cld, int dllNum, int index,  
bool load);
```

### **Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use only.

**Operators:**

**Prototype:**

**int operator==(const SubClassList& lst) const;**

**Remarks:**

Equality operator.

**Prototype:**

**int operator==(const SubClassList &sl);**

**Remarks:**

Equality operator.

**Prototype:**

**ClassEntry& operator[](int i);**

**Remarks:**

Returns a reference to the 'i-th' **ClassEntry** for this super class.

**Parameters:**

**int i**

The index of the entry to return. Valid values begin at an index of 1.

# Class Random

See Also: [Class Interface](#).

class Random

## Description:

This class is available in release 3.0 and later only.

This class defines a Pseudo-random number generator that precisely matches the behavior of the MSVCRT 6.0 random routines. That is to say, for equivalent calls to `::srand()` and `Random::srand()`, both `::rand()` and `Random::rand()` will produce the same results.

The benefit, however, in having this class is that each instantiation is independent, permitting several uncoupled random number generators to be present in the system at once. Moreover, each instantiation is automatically "pre-seeded", making calls to `Random::srand` unnecessary in most uses. Even arrays of `Random` items will operate independently.

In addition to providing the analogues to the "stdlib" functions, this class also provides two useful member functions which can be used to get a random number bounded in either a float or int interval.

Note: To use this class be sure to link to **MAXUTIL.LIB**.

## Sample Code:

```
#include "random.h"
...
Random r;
r.srand(1); // generally unnecessary, seeds generator like stdlib.h's
srand()
r.rand(); // returns a random number a la stdlib.h's rand()
r.get(); // ditto
r.get(16); // returns 1 of 16 possible random numbers from 0 to 15
inclusive
r.get(5,2); // returns 1 of 3 possible random numbers from 2 to 4
inclusive
r.get(1.0f); // returns 1 of "Random::s_rand_max+1" floats, 0 <=
value < 1
```

**r.get(1.0f,0.5f); // as above, but limits the result to 0.5 <= value < 1**  
**Random::s\_rand\_max; // similar to stdlib.h's RAND\_MAX**

...

Note in all "get" cases that contain limits they are specified (max, min). Also be aware that the min value can be attained, but the max cannot. That is to say min <= value < max.

### **Data Members:**

public:

**static const int s\_rand\_max;**

This is akin to the Windows API global **RAND\_MAX**. The constant **RAND\_MAX** is the maximum value that can be returned by the **rand** function. **RAND\_MAX** is defined as the value 0x7fff.

### **Methods:**

public:

### **Prototype:**

**Random();**

### **Remarks:**

The constructor will automatically initialize the seed.

### **Prototype:**

**void srand(unsigned int seed = 1);**

### **Remarks:**

This method is akin to the global **srand()** function. From the Windows API documentation:

The **srand** function sets the starting point for generating a series of pseudorandom integers.

### **Parameters:**

**unsigned int seed = 1**

To reinitialize the generator, use 1 as the seed argument. Any other value for seed sets the generator to a random starting point. **rand** retrieves the pseudorandom numbers that are generated. Calling **rand** before any call to

**srand** generates the same sequence as calling **srand** with seed passed as 1.

**Prototype:**

```
int rand();
```

**Remarks:**

This method is akin to the global **rand()** function. From the Windows API documentation:

The **rand** function returns a pseudorandom integer in the range 0 to **RAND\_MAX**. Use the **srand** function to seed the pseudorandom-number generator before calling **rand**.

**Prototype:**

```
inline int get(int max_exclusive = s_rand_max+1, int min_inclusive = 0);
```

**Remarks:**

Returns a random number in the half-open interval [min, max) such that  $r = \text{get}(\text{max}, \text{min}) := \text{min} \leq r < \text{max}$ . Note that max is the first arg, and min is the second, permitting one to select, for example, an int in  $[0,5) = [0,4]$  with "get(5)". With no arguments, **Random::get()** is equivalent to **Random::rand()**.

**Parameters:**

```
int max_exclusive = s_rand_max+1
```

The maximum value.

```
int min_inclusive = 0
```

The minimum value.

**Prototype:**

```
inline float getf(float max_exclusive = 1.0f, float min_inclusive = 0.0f);
```

**Remarks:**

Returns a random number in the half-open interval [min, max) such that  $r = \text{get}(\text{max}, \text{min}) := \text{min} \leq r < \text{max}$ . Note that max is the first arg, and min is the second, permitting one to select, for example, a float in  $[0.0, 5.0)$  with

"getf(5)". With no arguments, **Random::getf()** returns a float in [0.0, 1.0).

**Parameters:**

**float max\_exclusive = 1.0f**

The maximum value.

**float min\_inclusive = 0.0f**

The minimum value.

# Class MacroRecorder

See Also: [Class ClassDesc](#), [Class INode](#), [Class IParamBlock](#), [Class IParamBlock2](#), [Class Matrix3](#), [Class ReferenceTarget](#).

```
class MacroRecorder : public BaseInterfaceServer
```

## Description:

This class is available in release 3.0 and later only.

This class provides various methods to emit pieces of script to the Macro Recorder. There are also methods to specify the nature of the scripts generated by the user operating 3ds max. Additionally there are methods to enable or disable the recording of scripts.

This class may be used by plug-ins but is also used internally as part of the 3ds max Macro Recorder. Inside key areas of 3ds max macro scripts are emitted corresponding to the operation being performed. For example when a call goes to a parameter block to set a value 3ds max internally call this classes method **ParamBlock2SetValue(...)** to emit script to record the change. Thus, many operations a plug-in performs are recorded automatically. There are however operations a plug-in can perform which won't be recorded automatically. In these cases methods of this class may be used to emit script to record these operations. Several of the functions in this class use an ellipsis argument (...). This ellipsis is the var-args style of passing information to a method. This allows a developer to pass a variable number of values to the method. These are typically a set of tag values followed by some C++ types. The sample code shown with many of the methods shows how this is done. For a starting point for more general information on variable argument lists see **va\_arg** in the Window help file.

Developers use the following global instance of this class to call these methods:

```
MacroRecorder *macroRecorder;
```

## Methods:

```
public:
```

## Prototype:

```
virtual void SetProperty(ReferenceTarget* targ, TCHAR*  
prop_name, BYTE type, ...)=0;
```

## Remarks:

This provides a simple way to emit a properly assignment script. An example of this type of script is shown below:

```
$sphere01.radius = 50
```

**Parameters:**

**ReferenceTarget\* targ**

Points to the object whose property is changing.

**TCHAR\* prop\_name**

The string which is the name of the property. This is the fixed machine-parsable name.

**BYTE type**

One of the type tags from [List of Macro Recorder Value Types](#).

...

This ellipsis is the var-args style of passing information to a method. This allows a developer to pass a variable number of values to a method. These are typically a set of 'tags' followed by some C++ data types.

**Prototype:**

```
virtual void SetSelProperty(TCHAR* prop_name, BYTE type,  
...)=0;
```

**Remarks:**

This provides a simple way to emit a properly assignment script for the current selection set.

**Parameters:**

**TCHAR\* prop\_name**

The name of the property to set.

**BYTE type**

One of the type tags from [List of Macro Recorder Value Types](#).

...

This ellipsis is the var-args style of passing information to a method. This allows a developer to pass a variable number of values to a method. These are typically a set of 'tags' followed by some C++ types.

**Sample Code:**

```
macroRecorder->SetSelProperty(_T("material"), mr_reftarg,
```

**(Mtl\*)dropThis);**

**Prototype:**

**virtual void FunctionCall(TCHAR\* op\_name, int arg\_count, int keyarg\_count, ...)=0;**

**Remarks:**

This method is used to build a MAXScript function call. In the general case, such a call may have positional arguments followed by keyword arguments.

**Parameters:**

**TCHAR\* op\_name**

The name of the function to call.

**int arg\_count**

The number of positional arguments in the varargs section.

**int keyarg\_count**

The number of keyword arguments in the varargs section.

...

This ellipsis is the var-args style of passing information to a method. This allows a developer to pass a variable number of values to a method. These are typically a set of 'tags' followed by some C++ types.

See [List of Macro Recorder Value Types](#) for a list of potential tags and arguments.

**Sample Code:**

```
macroRecorder->FunctionCall(_T("addModifier"), 2, 1,  
mr_reftarg, this, mr_create, mod->ClassID(), mod->  
SuperClassID(), 0, _T("before"), mr_int, before);
```

This generates an addModifier() function call, such as:

```
addModifier $foo (bend()) before:3
```

The call has 2 positional arguments and 1 keyword argument (hence the **2, 1**). The first positional is given as **mr\_reftarg, this** which refers to the current node, the second positional is given as **mr\_create, mod->ClassID(), mod->SuperClassID(), 0** which causes a 0-argument constructor to be emitted for the modifier, and finally the single keyword argument is given as **\_T("before"), mr\_int, before** which is the keyword name followed by the

arg value.

**Prototype:**

**virtual void ScriptString(TCHAR\* s)=0;**

**Remarks:**

Emits a piece of macro script as a literal string. To understand when this is used consider the following example. Say you have a button in your user interface which does a certain thing but there is no way using the other macro recorder calls of constructing the piece of script that you need emitted. For instance the button may invoke a for loop. In such a case you can use this method to emit a macro script string which does a for loop. This is a string, just as you would type it into the MAXScript Listener.

**Parameters:**

**TCHAR\* s**

The string to emit.

**Prototype:**

**virtual void Assign(TCHAR\* var\_name, BYTE type, ...)=0;**

**Remarks:**

This method is called to emit script to record the assignment to a MAXScript variable.

**Parameters:**

**TCHAR\* var\_name**

The variable name.

**BYTE type**

One of the type tags from [List of Macro Recorder Value Types](#).

...

This ellipsis is the var-args style of passing information to a method. This allows a developer to pass a variable number of values to a method. These are typically a set of 'tags' followed by some C++ types.

**Prototype:**

**virtual void SetCopy(ReferenceTarget\* to\_copy)=0;**

**Remarks:**

This method is used to signal that an `mr_reftarg` argument in the currently accumulating script should be emitted as a copy. For example, when maps or materials are dragged onto sub-map/mtl buttons in the material editor, an instance/copy requester dialog is presented and depending on the choice, either a direct assignment or assignment of a copy is appropriate:

```
meditMaterials[4].materialList[2] = meditMaterials[11] --  
instance
```

```
meditMaterials[4].materialList[2] = copy meditMaterials[11] --  
copy
```

The actual assignment script is set up using a **macroRecorder-> SetProperty()** call with the dropped map/material supplied as an **mr\_reftarg** argument. In situations where the copy/instance status is known, you can emit directly an **mr\_funcall** argument for the copy, but there may be situations in which this choice is decided in some piece of remote code or control flow and so you can use this method to condition the emitted script to apply a 'copy' call.

**Parameters:**

**ReferenceTarget\* to\_copy**

The ReferenceTarget\* object which should be copied.

**Prototype:**

```
virtual void Cancel()=0;
```

**Remarks:**

This cancels and clears the currently accumulating script. This would be used for example, if the operation that is being accumulated can be canceled by the user, such as right-clicking out of a transform or a geometry node create.

There are calls to **macroRecorder()->Cancel()** in the **MOUSE\_ABORT** processing in the default creation manager.

**Prototype:**

```
virtual void EmitScript()=0;
```

**Remarks:**

This signals the completion of an accumulating script, causing it to be frozen in the recorder pane and any new calls that might have been folded into the current script will cause a new one to be started. For example, when you drag the time slider, the sliderTime assignment script accumulates the changes, but when you let go of the mouse button, an EmitScript() is called, so that subsequent drags will start a separate script fragment. Same with interactive transforms and node creation.

**Prototype:**

**virtual TSTR GetSubMtlPropName(Mtl\* m, int i)=0;**

**Remarks:**

Returns the property name of the 'i-th' sub-material of the specified material.

**Parameters:**

**Mtl\* m**

The material whose 'i-th' sub-material property name is returned.

**int i**

The zero based index of the sub-material.

**Prototype:**

**virtual TSTR GetSubTexmapPropName(MtlBase\* m, int i)=0;**

**Remarks:**

Returns the property name of the 'i-th' sub-texmap of the specified material.

**Parameters:**

**MtlBase\* m**

The material or texmap whose 'i-th' sub-texmap property name is returned.

**int i**

The zero based index of the sub-texmap.

**Prototype:**

**virtual void Enable()=0;**

**Remarks:**

Enables the Macro Recorder. This call is 'nestable', i.e. it uses a use counter internally so recursive or nested code can manage local enables and disable

states.

**Prototype:**

**virtual void Disable()=0;**

**Remarks:**

Disables the Macro Recorder. This allows the developer to disable the automatic macro recording.

**Prototype:**

**virtual BOOL Enabled()=0;**

**Remarks:**

Returns TRUE if the Macro Recorder is enabled (via **Enable()** above); otherwise FALSE.

**Prototype:**

**virtual BOOL MasterEnable()=0;**

**Remarks:**

In the MAXScript Listener Window Macro Recorder pulldown menu choice is an option to enable or disable the Macro Recorder. This method corresponds to that state. It returns TRUE if enabled; FALSE if disabled.

**Prototype:**

**virtual void MasterEnable(BOOL onOff)=0;**

**Remarks:**

In the MAXScript Listener Window Macro Recorder pulldown menu choice is an option to enable or disable the Macro Recorder. This method sets this state.

**Parameters:**

**BOOL onOff**

TRUE for enabled; FALSE for disabled.

**Prototype:**

**virtual BOOL ShowCommandPanelSwitch()=0;**

**Remarks:**

Returns TRUE if code is emitted when command panels are changed; FALSE if code is not emitted.

**Prototype:**

**virtual void ShowCommandPanelSwitch(BOOL onOff)=0;**

**Remarks:**

Determines if the macro recorder will emit script for command panel mode changes.

**Parameters:**

**BOOL onOff**

TRUE to record command panel changes; FALSE to ignore them.

**Prototype:**

**virtual BOOL ShowToolSelections()=0;**

**Remarks:**

Returns TRUE if the macro recorder will emit script for 3ds max toolbar tool selections; otherwise FALSE.

**Prototype:**

**virtual void ShowToolSelections(BOOL onOff)=0;**

**Remarks:**

Determines if the macro recorder will emit script for 3ds max toolbar selections.

**Parameters:**

**BOOL onOff**

TRUE to record toolbar selections; FALSE to ignore them.

**Prototype:**

**virtual BOOL ShowMenuSelections()=0;**

**Remarks:**

Returns TRUE if the macro recorder will emit script for 3ds max menu

selections; otherwise FALSE.

**Prototype:**

**virtual void ShowMenuSelections(BOOL onOff)=0;**

**Remarks:**

Determines if the macro recorder will emit script for 3ds max menu selections.

**Parameters:**

**BOOL onOff**

TRUE to record menu selections; FALSE to ignore them.

**Prototype:**

**virtual BOOL EmitAbsoluteSceneNames()=0;**

**Remarks:**

Returns TRUE if specific node names are used in the generated code; FALSE if the current selection is used.

**Prototype:**

**virtual void EmitAbsoluteSceneNames(BOOL onOff)=0;**

**Remarks:**

This controls whether the code generated refers to the exact node names being operated on or simply the current selection.

**Parameters:**

**BOOL onOff**

TRUE to record absolute scene names; FALSE to use the selection set.

**Prototype:**

**virtual BOOL EmitAbsoluteSubObjects()=0;**

**Remarks:**

Returns TRUE if recording absolute sub-object numbers; FALSE if using the selection set.

**Prototype:**

**virtual void EmitAbsoluteSubObjects(BOOL onOff)=0;**

**Remarks:**

Determines if code generated is relative to the current sub-object selection state or if explicit sub-object numbers are generated.

**Parameters:**

**BOOL onOff**

TRUE to record explicit, absolute sub-object numbers; FALSE to use the selection set.

**Prototype:**

**virtual BOOL EmitAbsoluteTransforms()=0;**

**Remarks:**

Returns TRUE if code is generated using absolute transform assignments; FALSE if relative transforms operations are generated.

**Prototype:**

**virtual void EmitAbsoluteTransforms(BOOL onOff)=0;**

**Remarks:**

Sets if code is generated using absolute transform assignments.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL EmitExplicitCoordinates()=0;**

**Remarks:**

Returns TRUE if the macro recorder emits explicit coordinate contexts; otherwise FALSE. This determines whether explicit coordinate contexts are emitted in the generated script. For example, when you do a move() call or a .pos assign in MAXScript, the coordinates are interpreted with respect to the current active coordinate system, in a way similar to interactive transforms in the 3ds max UI. You set up the current system using a coordsys context, like this:

**coordsys parent move \$foo [10,0,0]**

which would move the object 'foo' [10,0,0] in its parent's coordinate system. If you just say

**move \$foo [10,0,0]**

it will work relative to the current active coordinate system. So, when this method returns TRUE 3ds max always sticks the coordsys context prefix onto a generated transform script, as set by the user in the coordinate system dropdown.

**Prototype:**

**virtual void EmitExplicitCoordinates(BOOL onOff)=0;**

**Remarks:**

Sets if the code is generated using explicit coordinate contexts. See **EmitExplicitCoordinates()** above.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL BeginCreate(ClassDesc\* cd, int flags=0)=0;**

**Remarks:**

You would use this method if implementing a custom creation manager. This method starts a special accumulation 'mode' in which certain other Macro Recorder calls are treated specially until the next **EmitScript()**.

**BeginCreate()** effectively signals the start of a scene node creation and enters a mode in which calls to **SetNodeTM()**, **SetProperty()**,

**ParamBlockXSetValue()** and **SetSelProperty()** all generate keyword parameters to the current constructor, rather than emitting stand-alone property assignment scripts. Outside the 'create' mode, a call to **SetNodeTM()** would generate something like:

**move \$foo [10,0,0]**

but when in the mode would add a pos: argument to the constructor:

**sphere radius:20 pos:[10,0,0]**

**Parameters:****ClassDesc\* cd**

Points to the class descriptor for the plug-in.

**Return Value:**

This tells you whether MAXScript successfully entered the BeginCreate mode. It will fail if MAXScript can't create the object described by the ClassDesc, so you might use it in some generic situations to decided whether to call the closing EmitScript().

**Prototype:****virtual void SetNodeTM(INode\* n, Matrix3 m)=0;****Remarks:**

This method is for internal use only.

**Prototype:****virtual void ParamBlockSetValue(ParamBlock\* pb, int i, BYTE type, ...)=0;****Remarks:**

This method is for internal use only.

**Prototype:****virtual void ParamBlock2SetValue(ParamBlock2\* pb, int i, int tabIndex, ...)=0;****Remarks:**

This method is for internal use only.

**Prototype:****virtual void ParamBlock2SetCount(IParamBlock2\* pb, int i, int n)=0;****Remarks:**

This method is for internal use only.

**Prototype:**

**virtual BOOL BeginSelectNode()=0;**

**Remarks:**

This method is for internal use only.

**Prototype:**

**virtual void Select(INode\*)=0;**

**Remarks:**

This method is for internal use only.

**Prototype:**

**virtual void DeSelect(INode\*)=0;**

**Remarks:**

This method is for internal use only.

**Prototype:**

**virtual void MAXCommand(int com)=0;**

**Remarks:**

This method is for internal use only.

**The following global function is not a part of this class:**

**Function:**

**void InitMacroRecorder();**

**Remarks:**

This global function is used internally to initialize the macro recorder and should not be called by plug-in developers.

## Class ILayerManager

See Also: [Class ReferenceTarget](#), [Class ILayer](#).

class ILayerManager : public ReferenceTarget

### Description:

This class is available in release 3.0 and later only.

This class is an interface to the layer manager. Note that some methods of this class are not functional in 3ds max (only in 3D Studio VIZ).

### Data Members:

public:

**static const SClass\_ID kLayerManagerSuperClassID;**

The super class ID of the layer manager interface.

### Methods:

public:

### Prototype:

**virtual bool AddLayer(ILayer \*layer)=0;**

### Remarks:

Adds the specified layer.

### Parameters:

**ILayer \*layer**

Points to the layer to add.

### Return Value:

Returns true if the layer was added; false if not.

### Prototype:

**virtual ILayer \* CreateLayer(void) = 0;**

### Remarks:

Creates a layer. The name is based on the incremented layer count.

### Prototype:

**virtual BOOL DeleteLayer(const TSTR & name) = 0;**

**Remarks:**

Deletes the layer whose name is passed. Note: This method does nothing in 3ds max.

**Parameters:**

**const TSTR &name**

The name for the layer.

**Return Value:**

TRUE if the layer was deleted, otherwise FALSE.

**Prototype:**

**virtual void SetCurrentLayer(const TSTR &name)=0;**

**Remarks:**

Sets the layer whose name is passed as current.

**Parameters:**

**const TSTR &name**

The name for the new current layer.

**Prototype:**

**virtual void SetCurrentLayer()=0;**

**Remarks:**

Sets the current layer based on the selection set (the common layer).

**Prototype:**

**virtual ILayer \*GetCurrentLayer() const=0;**

**Remarks:**

Returns an interface to the current layer.

**Prototype:**

**virtual void EditLayer(const TSTR &name)=0;**

**Remarks:**

Edits the layer whose name is passed. Note: This method does nothing in 3ds max.

**Parameters:**

**const TSTR &name**

The name of the layer to edit.

**Prototype:**

**virtual void DoLayerPropDialog(HWND hWnd)=0;**

**Remarks:**

Brings up the layer property dialog. Note: This method does nothing in 3ds max.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual LayerIterator \*MakeIterator()=0;**

**Remarks:**

This method is for internal use in VIZ.

**Prototype:**

**virtual ConstLayerIterator \*MakeConstIterator() const=0;**

**Remarks:**

This method is for internal use in VIZ.

**Prototype:**

**virtual int GetLayerCount()=0;**

**Remarks:**

Returns the number of layers.

**Prototype:**

**virtual ILayer \*GetLayer(const TSTR &name) const=0;**

**Remarks:**

Returns a pointer to a layer interface for the named layer.

**Parameters:**

**const TSTR &name**

The name of the layer to get.

**Prototype:**

**virtual void DoLayerSelDialog(HWND hWnd)=0;**

**Remarks:**

Brings up the select layer dialog. Note: This method does nothing in 3ds max.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual void SetupToolList(HWND hWnd)=0;**

**Remarks:**

Sets up the toolbar list. Note: This method does nothing in 3ds max.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual void ExtendMenu(HMENU hMenu, bool geometry = true, bool grid = false)=0;**

**Remarks:**

Extends the right click menu. Note: This method does nothing in 3ds max.

**Parameters:**

**HMENU hMenu**

The handle of the menu to append to.

**bool geometry = true**

Use true to add the geometry commands; false to not add them.

**bool grid = false**

Use true to add the grid commands; false to not add them.

**Prototype:**

**virtual ILayer \*GetRootLayer() const=0;**

**Remarks:**

Returns an interface to the 0 layer.

**Prototype:**

**virtual void Reset(BOOL fileReset = FALSE)=0;**

**Remarks:**

Resets the layer manager.

**Parameters:**

**BOOL fileReset = FALSE**

This parameter is ignored.

**Prototype:**

**virtual void SelectObjectsByLayer(HWND hWnd) = 0;**

**Remarks:**

This method will bring up the select objects by layer dialog.

**Parameters:**

**HWND hWnd**

The handle to the parent window.

# Class IKMasterControl

See Also: [Class ReferenceTarget](#), [Class IKSlaveControl](#), [Class Control](#).

```
class IKMasterControl : public ReferenceTarget
```

## Description:

This class is available in release 2.0 and later only.

The IK Controller requires that you use the Bones system. When you create the bones, a slave IK controller is assigned to each bone. All of the slave IK controllers in a single hierarchy are, in turn, controlled by a master IK controller. This class provides two methods to work with the master controller. To get an interface to this class call **GetInterface(I\_MASTER);** on the controller in question. If the return value is non-NULL you can cast the pointer to an instance of this class.

For an example the use of this class see

**\\MAXSDK\\SAMPLES\\OBJECTS\\BONES.CPP.**

## Methods:

### Prototype:

```
virtual void AddSlaveNode(INode *node)=0;
```

### Remarks:

Adds the specified node to the list of slave nodes maintained.

### Parameters:

**INode \*node**

The node to add.

### Prototype:

```
virtual void *GetMasterBase()=0;
```

### Remarks:

Returns a pointer to the IK master object.

### Prototype:

```
virtual void SetPosThresh(float t)=0;
```

### Remarks:

This method is available in release 3.0 and later only.

Sets the position threshold. If the UI for the master controller is not visible while this method is called, the screen is not redrawn to reflect the changes. After calling this method you should therefore call

**Interface::RedrawViews()**.

**Parameters:**

**float t**

The value to set.

**Prototype:**

**virtual void SetRotThresh(float t)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the rotation threshold. If the UI for the master controller is not visible while this method is called, the screen is not redrawn to reflect the changes. After calling this method you should therefore call

**Interface::RedrawViews()**.

**Parameters:**

**float t**

The value to set.

**Prototype:**

**virtual void SetIterations(int i)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the iterations value. If the UI for the master controller is not visible while this method is called, the screen is not redrawn to reflect the changes. After calling this method you should therefore call **Interface::RedrawViews()**.

**Parameters:**

**int i**

The value to set.

**Prototype:**

**virtual void SetStartTime(TimeValue s)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the start time. If the UI for the master controller is not visible while this method is called, the screen is not redrawn to reflect the changes. After calling this method you should therefore call **Interface::RedrawViews()**.

**Parameters:**

**TimeValue s**

The time to set.

**Prototype:**

**virtual void SetEndTime(TimeValue e)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the end time. If the UI for the master controller is not visible while this method is called, the screen is not redrawn to reflect the changes. After calling this method you should therefore call **Interface::RedrawViews()**.

**Parameters:**

**TimeValue e**

The time to set.

**Prototype:**

**virtual float GetPosThresh()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the position threshold.

**Prototype:**

**virtual float GetRotThresh()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the rotation threshold.

**Prototype:**

**virtual int GetIterations()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the iterations setting.

**Prototype:**

**virtual TimeValue GetStartTime()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the start time.

**Prototype:**

**virtual TimeValue GetEndTime()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the end time.

**The following function is not part of this class but is available for use:**

**Function:**

**IKMasterControl \*CreateIKMasterControl();**

**Remarks:**

This global function creates a new IK master controller.

## Class MeshDelta

See Also: [Class Mesh](#), [Class FaceChange](#), [Class FaceRemap](#), [Class FaceSmooth](#), [Class VertMove](#), [Class UVVertSet](#), [Class MapDelta](#), [Class VDataDelta](#), [Class AdjEdgeList](#), [Class AdjFaceList](#), [Class MeshChamferData](#), [Template Class Tab](#), [Class BitArray](#).

```
class MeshDelta : public BaseInterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This class represents the notion of a mesh edit.

This is an SDK class that represent some kind of change to a mesh. This "delta" can include topological, geometric, map, and/or selection changes. Most standard mesh "edits" available in the Editable Mesh or Edit Mesh interface are available through the MeshDelta SDK, giving developers a powerful way to manipulate meshes while not having to "sweat the details" of maintaining maps to match the mesh changes, updating edge selections, etc.

The MeshDelta members and methods make use of a number of mesh-related classes, including [Class FaceChange](#), [Class FaceRemap](#), [Class FaceSmooth](#), [Class VertMove](#), [Class UVVertSet](#), [Class MapDelta](#), [Class VDataDelta](#), [Class AdjEdgeList](#), [Class AdjFaceList](#), [Class MeshChamferData](#).

While we often talk about the characteristics of the "input mesh" that a MeshDelta is based on, all MeshDeltas should be able to cope with any mesh.

Note: You must **#include "MESHDLIB.H"** to use this class as it's not included by default by **MAX.H**.

### Methods Groups:

The hyperlinks below take you to the start of groups of related methods within the class:

[Initialization & Cleanup](#)

[Mesh Interaction](#)

[Composition and operators](#)

[Characteristics](#)

[Lookup Table Methods](#)

[Basic Operations](#)

[Advanced additive operations](#)

[Advanced operations](#)  
[I/O, Debugging](#)

**Data Members:**

public:

**DWORD vnum**

The expected number of vertices in the input mesh.

**DWORD fnum;**

The expected number of faces in the input mesh.

**Tab<VertMove> vMove;**

This data member stores movements of input vertices. Each VertMove consists of a vertex ID indicating which vertex should be moved and a Point3 offset in object space. VertMoves are stored in vertex ID order, and there is never more than one VertMove per original vertex.

**Tab<VertMove> vClone;**

If the vClone[i] record has a vid of UNDEFINED, it's considered a "create", and the coordinates of vClone[i].p are considered to be in object space. If vClone[i].vid is not undefined, it's the index of a vertex "original" in the input mesh, and vClone[i].p is treated as an offset from that vertex. If the vertex is not present in the input mesh, i.e. vClone[i].vid >= mesh::numVerts, the clone will not be created in the output. All creates and clones are stored in the order created..

**BitArray vDelete;**

This data member stores deletions of vertices in the input mesh. vDelete's size is vnum.

**Tab<FaceCreate> fCreate;**

This data member stores faces newly created as part of the MeshDelta. These are stored in the order created.

**Tab<FaceRemap> fRemap;**

This data member stores changes in which vertices are used by existing faces. See class FaceRemap for more information. These are stored in original face order, and there is never more than one per original face.

**Tab<FaceChange> fChange;**

This data member stores changes in input face characteristics, such as material ID, edge visibility, and face hiding. See class FaceChange for more

information. These are stored in original face order, and there is never more than one per original face.

**Tab<FaceSmooth> fSmooth;**

This data member stores changes in input face smoothing groups. See class FaceSmooth for more information. These are stored in original face order, and there is never more than one per original face.

**BitArray fDelete;**

This data member stores deletions of faces in the input mesh. The size of this BitArray is fnum.

**BitArray vsel;**

This data member stores the vertex selection of the output mesh.

**BitArray esel;**

This data member stores the edge selection of the output mesh. As with class Mesh's edgeSel data member, this information is indexed by side of face: esel[ff\*3+k] is the edge selection for face ff, side k.

**BitArray fsel;**

This data member stores the face selection of the output mesh.

**BitArray vhide;**

This data member stores the vertex hide information of the output mesh.

**MapDelta \*map;**

Points to an array of MapDeltas which maintain any relevant changes to the various map channels. The size of this array is always equal to mapSupport.GetSize().

**BitArray mapSupport;**

Indicates which maps are supported by this MeshDelta.

**VDataDelta \*vd;**

Points to an array of VDataDeltas which maintain any relevant changes to the various vertex data channels. The size of this array is always equal to vdSupport.GetSize().

**BitArray vdSupport;**

Indicates which vertex data channels are supported by this MeshDelta.

**Methods:**

public:

## Initialization & Cleanup

### Prototype:

**MeshDelta();**

### Remarks:

Constructor. Initializes the MeshDelta with NULL pointers and 0's for input mesh size.

### Prototype:

**MeshDelta(const Mesh &m);**

### Remarks:

Constructor. Initializes the MeshDelta to be based on the mesh given. MapDeltas and VDataDeltas are allocated as appropriate, and vnum and fnum are set.

### Prototype:

**~MeshDelta();**

### Remarks:

Destructor. Frees all allocated memory, including the MapDeltas.

### Prototype:

**void InitToMesh(const Mesh &m);**

### Remarks:

Initializes the MeshDelta to the mesh given, setting map and vdata support as appropriate. Does NOT clear out existing changes.

### Parameters:

**const Mesh &m**

The mesh to init from.

### Prototype:

**void ClearAllOps();**

### Remarks:

Clears out all existing mesh changes. Zeroes all the vCreate, vMove, etc

arrays, as well as those in the active MapDeltas. Does not clear memory.

**Prototype:**

**void SetInFNum(int nface);**

**Remarks:**

Sets the number of faces in the input mesh. NOTE that if nface is less than the current fnum, the data relating to the extra faces will be lost. (That is, if one of your face remaps is applied to face 32, and you SetInFNum to 30, that face remap will be lost, and will not be recovered if you later SetInFNum to 35.) It is NOT necessary to call this method before applying this MeshDelta to a smaller than expected Mesh.

**Parameters:**

**int nface**

The number of faces expected from the input mesh.

**Prototype:**

**void SetInVNum(int nv);**

**Remarks:**

Sets the number of vertices in the input mesh. NOTE that if nv is less than the current vnum, the data relating to the extra vertices will be lost. (That is, if one of your vertex moves is applied to vertex 32, and you SetInVNum to 30, that vertex move will be lost, and will not be recovered if you later SetInVNum to 35.) It is NOT necessary to call this method before applying this MeshDelta to a smaller than expected Mesh.

**Parameters:**

**int nv**

The number of vertices expected from the input mesh.

**Prototype:**

**void SetMapNum(int num, bool keep=TRUE);**

**Remarks:**

Sets the number of map channels used by the MeshDelta – allocates the "map" array.

**Parameters:****int num**

The number of maps to allocate.

**bool keep=TRUE**

If TRUE any previous maps are kept; otherwise they are discarded.

**Prototype:****int GetMapNum();****Remarks:**

Gets the number of map channels in the MeshDelta – equivalent to mapSupport.GetSize().

**Prototype:****MapDelta & Map(int mp);****Remarks:**

Data accessor - gets the MapDelta for the specified map channel. Since in 4.0 we now have "hidden map channels" which are accessed by negative indices (-1 for MAP\_SHADING, for example), data accessor methods like this one should be used instead of the actual arrays. (Hidden map channels are stored in a new private data member, not as part of the public map array.)

**Prototype:****bool getMapSupport (int mp);****Remarks:**

Indicates whether the specified map channel is supported by this MeshDelta. Since in 4.0 we now have "hidden map channels" which are accessed by negative indices (-1 for MAP\_SHADING, for example), data accessor methods like this one should be used instead of the actual data members. (Hidden map channel support information is stored in a new private data member, not as part of the public mapSupport BitArray.)

**Prototype:****void setMapSupport (int mp, bool val=true);**

**Remarks:**

Sets map support in this MeshDelta for the specified map channel. Since in 4.0 we now have "hidden map channels" which are accessed by negative indices (-1 for MAP\_SHADING, for example), data accessor methods like this one should be used instead of the actual data members. (Hidden map channel support information is stored in a new private data member, not as part of the public mapSupport BitArray.)

**Prototype:**

```
bool hasMapSupport ();
```

**Remarks:**

Indicates whether any map channel is supported by this MeshDelta.

**Prototype:**

```
void SetVDataNum(int num, bool keep=TRUE);
```

**Remarks:**

Sets the number of vertex data channels used by the MeshDelta – allocates the "vd" array.

**Parameters:**

**int num**

The number of vertex data channels to allocate.

**bool keep=TRUE**

If TRUE any previous vertex data channels are kept; otherwise they are discarded.

**Prototype:**

```
int GetVDataNum();
```

**Remarks:**

Gets the number of vertex data channels in the MeshDelta – equivalent to vdSupport.GetSize().

**Prototype:**

```
void AddVertexColors();
```

**Remarks:**

Activates the vertex color MapDelta, adding whatever new map verts or faces are needed to match the current MeshDelta. After calling this method, applying this MeshDelta to a mesh without vertex colors will result in a vertex color map with all white vertices and a topology identical to the mesh.

**Prototype:**

**void AddMap(int mapID);**

**Remarks:**

Activates the specified MapDelta, adding whatever new map verts or faces are needed to match the current MeshDelta. If mapID is 0, the standard vertex colors (white) will be applied (see AddVertexColors). Otherwise, after calling this method, applying this MeshDelta to a mesh without the specified map active will result in a map with the same topology as the mesh and UVVerts that are copies of the mesh vertices.

**Parameters:**

**int mapID**

The map channel to add. 0 represents vertex colors, 1 is the original map channel (referred to in class Mesh by tVerts and tvFaces), and 2-99 are the new map channels (stored in meshes in the MeshMap class).

**Prototype:**

**void AddVertexData(int vdChan, Mesh \*m=NULL);**

**Remarks:**

Activates the specified vertex data channel, creating a default set of vertex data to match the output of the current MeshDelta. ("Default" values of vertex data depend on the channel, and are given by VDataDefault (vdChan).)

**Parameters:**

**int vdChan**

The vertex data channel

**Mesh \*m=NULL**

A pointer to the Mesh object.

## Mesh Interaction

### Prototype:

**void FillInFaces(Mesh & m);**

### Remarks:

To make things easy for developers, it's possible to create or remap mapping faces to use UNDEFINED mapping verts. This routine, which is called by Apply below, fills in those UNDEFINED mapping values with the mapping vertices used by neighboring faces, or, if necessary, by new mapping vertices. (These new mapping vertices are always (.5,.5,0) for regular map channels or (1,1,1) for the vertex color channel.)

This process does not produce very good maps, but it allows a sort of minimal mapping support that prevents maps from being lost before the user can make their manual corrections.

### Prototype:

**void Apply(Mesh & m);**

### Remarks:

Changes the given mesh by this MeshDelta, in the following manner:

First, any maps that are supported by the MeshDelta but not by the mesh are assigned to the mesh in their default form. (Vertex color channels are white, and other maps are copies of the mesh vertices. All have the same topology as the mesh.)

Next, any UNDEFINED mapping verts in the MeshDelta are filled in by FillInFaces.

Then the new vertices are added, creates first, followed by clones. The original vertices are then moved.

The faces are then modified, by applying all the FaceRemaps, FaceChanges, and FaceSmooths to the appropriate faces. New faces (in fCreate) are appended to the end of the face list.

Map changes are applied to all active maps, and map channels not supported by this MeshDelta are removed.

After all that is done, the vertices and faces marked in the vDelete and fDelete arrays are deleted.

Finally, the vertex data, vertex hide, and selections kept in the MeshDelta are

applied to the result.

**Prototype:**

**DWORD PartsChanged();**

**Remarks:**

Indicates what data channels of a mesh would be changed by this MeshDelta. For instance, a MeshDelta with vertex moves but no other changes would return PART\_GEOM|PART\_SELECT. PART\_GEOM represents the moves, and PART\_SELECT represents the fact that MeshDeltas always overwrite selection info. Most of the changes in a MeshDelta will alter PART\_TOPO. PART\_VERTCOLOR and PART\_TEXMAP may also be returned.

This is especially useful for knowing what parts of a mesh to back up in a restore object for an undo/redo. (See the SDK implementation of Editable Mesh for an example of this.) Also, it can be used for invalidating temporary data, as in both Edit and Editable Mesh.

## **Composition & Operators**

MeshDeltas can be multiplied together like Transforms before being applied to a mesh. This is especially useful in Edit Mesh, where a single MeshDelta is used to store the current "state" of the Edit Mesh, and extra MeshDeltas are created for each operation and added on to the main MeshDelta.

An example of this is as follows: given a Mesh m that we want to divide a face on, then we want to break the vertex created in the face divide. These operations are adequately handled by the DivideFace and BreakVerts methods independently, but to combine the two into one operation, we must compose two MeshDeltas.

```
MeshDelta DivideThenBreak (const Mesh & m, int ff) {  
MeshDelta md1, md2;  
Mesh mcopy = m;  
md1.DivideFace (mcopy, ff);  
int nvid = md1.vnum; // since DivideFace creates exactly one vertex,  
this must be its index in the result.  
md1.Apply (mcopy);  
md2.InitToMesh (mcopy); // second MeshDelta must be based on
```

```

first MeshDelta result.
BitArray vset;
vset.SetSize (mcopy.numVerts);
vset.Set (nvid);
md2.BreakVerts (mcopy, vset); // breaks the new vertex into a
separate vert for each face.
md1.Compose (md2); // Adds the second MeshDelta into the first.
return md1;
}

```

If all we wanted was to perform these operations on the mesh given, we could have done so without making the composition. The point here is to be able to construct complex MeshDeltas representing a series of user operations while remaining flexible enough to respond to changes in the actual mesh given as input. This is a central feature of the Edit Mesh modifier, completely rewritten for 3.0, found in **MAXSDK\SAMPLES\MODIFIERS**.

**Prototype:**

**DWORD Compose(MeshDelta & td);**

**Remarks:**

Appends the given MeshDelta to the current one.

**Parameters:**

**MeshDelta & td**

The MeshDelta to append. This MeshDelta may be modified to make it suitable, ie the vnum and fnum values will be set to the expected output of the current MeshDelta if they don't already match. (This may result in the loss of some data – see "SetInVNum" and "SetInFNum" for more information.)

**Prototype:**

**MeshDelta & operator\*=(MeshDelta & td);**

**Remarks:**

Appends the given MeshDelta to the current one.

**Parameters:**

**MeshDelta & td**

The MeshDelta to append. This MeshDelta may be modified to make it suitable, ie the vnum and fnum values will be set to the expected output of the current MeshDelta if they don't already match. (This may result in the loss of some data – see "SetInVNum" and "SetInFNum" for more information.)

**Prototype:**

**MeshDelta & operator=(MeshDelta & td);**

**Remarks:**

Assignment operator – makes this MeshDelta just like the one given.

**Prototype:**

**DWORD ChangeFlags(Tab<DWORD> \*mChannels=NULL);**

**Remarks:**

Indicates what parts of a MeshDelta could be changed if this MeshDelta were appended to it. This is useful when backing up MeshDelta for Restore Objects. For instance, if you had a MeshDelta with lots of face smoothing changes, and you wanted to compose it with one that only moved vertices, there would be no reason to back up the smoothing changes for an undo.

**Parameters:**

**Tab<DWORD> \*mChannels=NULL**

If non-NULL, this points to a table that should be filled with change flags for the various map channels. The table is set to the number of map channels, and each DWORD in it is filled in by calling MapDelta::ChangeFlags on the appropriate map channel (or left at zero if the map channel is inactive.)

**Return Value:**

Returns some combination of the following flags, corresponding to the data members that would be changed:

**MDELTA\_VMOVE**

**MDELTA\_VCREATE**

**MDELTA\_VCLONE**

**MDELTA\_VDELETE**

**MDELTA\_VDATA**

**MDELTA\_FREMAP**

**MDELTA\_FCHANGE**  
**MDELTA\_FCREATE**  
**MDELTA\_FDELETE**  
**MDELTA\_FDATA**  
**MDELTA\_NUMBERS**  
**MDELTA\_FSMOOTH**

Note that in 4.0 and thereafter, the **MDELTA\_VCREATE** and **MDELTA\_VCLONE** flags are identical and represent the same information. (This was not true in 3.0 or 3.1.)

**Prototype:**

**void CopyMDChannels(MeshDelta & from, DWORD channels, Tab<DWORD> \*mChannels=NULL);**

**Remarks:**

Copies the specified parts of the MeshDelta. (Useful in combination with ChangeFlags to create efficient Restore objects.)

**Parameters:**

**MeshDelta & from**

The MeshDelta to copy into this.

**DWORD channels**

Indicates the parts to copy – some combination of the following flags:

**MDELTA\_VMOVE**  
**MDELTA\_VCREATE**  
**MDELTA\_VCLONE**  
**MDELTA\_VDELETE**  
**MDELTA\_VDATA**  
**MDELTA\_FREMAP**  
**MDELTA\_FCHANGE**  
**MDELTA\_FCREATE**  
**MDELTA\_FDELETE**  
**MDELTA\_FDATA**

## **MDELTA\_NUMBERS**

## **MDELTA\_FSMOOTH**

Note that in 4.0 and thereafter, the **MDELTA\_VCREATE** and **MDELTA\_VCLONE** flags are identical and represent the same information. (This was not true in 3.0 or 3.1.)

### **Tab<DWORD> \*mChannels=NULL**

If non-NULL, this points to a table that contains channels to copy in the various map channels. The table should be of the size of the number of map channels. For each active map channel in from, the corresponding DWORD in this table is passed in MapDelta::CopyMDChannels to copy the relevant parts of the map.

## **Characteristics**

The following methods give useful information about the MeshDelta.

### **Prototype:**

**DWORD NumVMove(DWORD inVNum);**

### **Remarks:**

Returns the number of vertex moves that would be applied to a mesh with the specified number of vertices. If that number equals this MeshDelta's vnum, this is simply vMove.Count().

### **Parameters:**

**DWORD inVNum**

The number of vertices in the input mesh we're inquiring about.

### **Prototype:**

**DWORD NumVClone(DWORD inVNum);**

### **Remarks:**

Returns the number of vertex clones & creates that would be applied to a mesh with the specified number of vertices. If that number equals this MeshDelta's vnum, this is simply vClone.Count(). If, however, inVNum is lower than the expected vnum, some of the clones might be eliminated, reducing this number.

### **Parameters:**

**DWORD inVNum**

The number of vertices in the input mesh we're inquiring about.

**Prototype:****DWORD NumVDelete(DWORD inVNum);****Remarks:**

Returns the number of vertex deletes that would be applied to a mesh with the specified number of vertices. If that number equals this MeshDelta's vnum, this is simply vDelete.NumberSet ().

**Parameters:****DWORD inVNum**

The number of vertices in the input mesh we're inquiring about.

**Prototype:****DWORD NumFDelete(DWORD inFNum);****Remarks:**

Returns the number of face deletes that would be applied to a mesh with the specified number of faces. If inFNum equals this MeshDelta's fnum, this is simply fDelete.NumberSet ().

**Parameters:****DWORD inFNum**

The number of faces in the input mesh we're inquiring about.

**Prototype:****int NumFCreate ();****Remarks:**

Returns the number of face creates in this MeshDelta.

**Prototype:****DWORD outVNum();****Remarks:**

Returns the number of vertices in the output mesh, assuming that the input

mesh is of the expected (vnum) size.

**Prototype:**

**DWORD outVNum(int inVNum);**

**Remarks:**

Returns the number of vertices in the output mesh, assuming that the input mesh has the specified number of vertices.

**Parameters:**

**DWORD inVNum**

The number of vertices expected in the input mesh.

**Prototype:**

**DWORD outFNum();**

**Remarks:**

Returns the number of faces in the output mesh, assuming that the input mesh is of the expected (fnum) size.

**Prototype:**

**DWORD outFNum(int inFNum);**

**Remarks:**

Returns the number of faces in the output mesh, assuming that the input mesh has the specified number of faces.

**Parameters:**

**DWORD inFNum**

The number of faces expected in the input mesh.

**Prototype:**

**Point3 outVert(Mesh & m, DWORD v);**

**Remarks:**

Returns the expected location in the output mesh of the specified vertex.

**Parameters:**

**Mesh & m**

The input mesh.

**DWORD v**

The vertex you want the output location of. This index is input-based – the vertex index in **m**, not in the output mesh.

**Prototype:**

**Face outFace(Mesh & m, DWORD f);**

**Remarks:**

Returns the specified face as it would appear in the MeshDelta output. Face Changes, Smooths, and Remaps are applied.

**Parameters:**

**Mesh & m**

The input mesh.

**DWORD f**

The index of the face you want the output version of. This index is input-based – the face index in **m**, not in the output mesh.

**Prototype:**

**DWORD RemapID(DWORD ff);**

**Remarks:**

Obtains the index of the fRemap entry that relates to this face.

**Parameters:**

**DWORD ff**

The input-based face index.

**Return Value:**

If there is such an entry, the index is returned, so fRemap[RemapID(ff)].fid == ff. If there is no remap record for this face, the method returns UNDEFINED.

**Prototype:**

**DWORD IsRemapped(DWORD ff, DWORD vid);**

**Remarks:**

Tells whether the specified corner of the specified face has been remapped in

this MeshDelta.

**Parameters:**

**DWORD ff**

The input-based face index.

**DWORD vid**

The corner of the face – 0, 1, or 2.

**Return Value:**

If this corner has been remapped, it returns the vertex it's been remapped to. Otherwise, it returns UNDEFINED.

**Prototype:**

**DWORD MoveID(DWORD i);**

**Remarks:**

Obtains the index of the vMove entry that relates to this vertex.

**Parameters:**

**DWORD i**

The input-based vertex index.

**Return Value:**

The index in the vMove array of the vertex move corresponding to this vertex, or UNDEFINED if this vertex has no move associated with it.

**Prototype:**

**bool IsVCreate(DWORD i);**

**Remarks:**

No longer used.

This method was used in 3.0 and 3.1 to indicate whether the specified vertex was created as a create, not a clone in this MeshDelta. In 4.0, we integrated the clone and create records together, and this method is now set to always return FALSE.

**Parameters:**

**DWORD i**

The output-based vertex index.

**Prototype:****bool IsVClone(DWORD i);****Remarks:**

Indicates whether or not the specified vertex is created in this MeshDelta.

**Parameters:****DWORD i**

The output-based vertex index.

**Prototype:****DWORD VCloneOf(DWORD i);****Remarks:**

Tells you what input vertex the specified output vertex is a clone of.

**Parameters:****DWORD i**

The output-based vertex index.

**Return Value:**

The index in the input mesh of the original vertex this one's a clone of. If this vertex is not a clone, UNDEFINED is returned.

**Prototype:****bool IsFCreate(DWORD i);****Remarks:**

Indicated whether the specified face was created in this MeshDelta.

**Parameters:****DWORD i**

The face index in the output mesh.

**Lookup Table Methods****Prototype:****void UpdateLUTs(int extraV=0, int extraF=0);****Remarks:**

Updates the MeshDelta's internal lookup tables, which make use of all delete and create records to set up a correspondence between output and input vertices and faces.

**Parameters:**

**int extraV**

If nonzero, this indicates the number of extra spaces that should be added to the lookup table. This is useful for example if you want the lookup table to still be valid after the next <extraV> vertex creates or clones.

**int extraF**

If nonzero, this indicates the number of extra spaces that should be added to the lookup table. This is useful for example if you want the lookup table to still be valid after the next <extraF> face creates.

**Prototype:**

**void ClearLUTs();**

**Remarks:**

Invalidates and clears the lookup tables. This usually only needs to be called internally.

**Prototype:**

**DWORD VLut(DWORD i);**

**Remarks:**

Finds the input mesh index of the vertex with the specified output mesh index. Note that these indices are the same if there are no vertex deletes.

**Parameters:**

**DWORD i**

The output mesh index.

**Return Value:**

The input mesh index of the same vertex. If the vertex specified is actually created by this MeshDelta, the return value would be vnum+i for vClone[i].

**Prototype:**

**DWORD FLut(DWORD i);**

**Remarks:**

Finds the input mesh index of the face with the specified output mesh index.  
Note that these indices are the same if there are no face deletes.

**Parameters:****DWORD i**

The output mesh index.

**Return Value:**

The input mesh index of the same face. If the face specified is actually created by this MeshDelta, the return value would be fnum+i for fCreate[i].

**Prototype:**

**DWORD PostVIndex(DWORD i);**

**Remarks:**

Returns the index in the output mesh of the specified input vertex.  
Note that these indices are the same if there are no vertex deletes.

**Parameters:****DWORD i**

The index of the vertex in the input mesh.

**Return Value:**

The output mesh index of the same vertex. If the vertex was deleted in this MeshDelta, UNDEFINED is returned.

**Prototype:**

**DWORD PostFIndex(DWORD i);**

**Remarks:**

Returns the index in the output mesh of the specified input face.  
Note that these indices are the same if there are no face deletes.

**Parameters:****DWORD i**

The index of the face in the input mesh.

**Return Value:**

The output mesh index of the same face. If the face was deleted in this

MeshDelta, UNDEFINED is returned.

## Basic Operations

These operations are the "building blocks" of MeshDeltas. All of them may be safely performed on MeshDeltas that are already quite complex. Those that accept DWORD indices require **output** mesh indices, as all operations are appended to the end of the existing delta.

### Prototype:

```
void Move(int i, const Point3 & p);
```

### Remarks:

Moves a single vertex. (Note that if the same vertex is moved twice, the new move is simply added to the old one – there is never more than one VertMove in the vMove array for a single input vertex.)

### Parameters:

**int i**

The index of the vertex in the output mesh.

**const Point3 & p**

The vector to move the vertex by.

### Prototype:

```
void Move(BitArray & sel, const Point3 & p);
```

### Remarks:

Moves the specified vertices. (Note that if the same vertex is moved twice, the new move is simply added to the old one – there is never more than one VertMove in the vMove array for a single input vertex.)

### Parameters:

**BitArray & sel**

Indicates which vertices should be moved. Vertices are indexed based on the output mesh.

**const Point3 & p**

The vector to move the vertices by.

**Prototype:**

```
void Move(VertMove *vm, int num);
```

**Remarks:**

Adds in the specified vertex moves. (Note that if the same vertex is moved twice, the new move is simply added to the old one – there is never more than one VertMove in the vMove array for a single input vertex.)

**Parameters:**

**VertMove \*vm**

A pointer to an array of VertMoves to apply to this MeshDelta. Vertices are indexed based on the output mesh.

**int num**

The size of the VertMove array.

**Prototype:**

```
DWORD VCreate(Point3 *p, int num=1, BitArray *sel=NULL,  
BitArray *hide=NULL);
```

**Remarks:**

Creates new vertices.

**Parameters:**

**Point3 \*p**

A pointer to an array of points representing the new vertices.

**int num**

The size of the point array.

**BitArray \*sel=NULL**

If non-NULL, this points to a BitArray of size num that indicates which of these new vertices should be selected. (If NULL, none of the new vertices are selected.)

**BitArray \*hide=NULL**

If non-NULL, this points to a BitArray of size num that indicates which of these new vertices should be hidden. (If NULL, none of the new vertices are hidden.)

**Return Value:**

The index (in the output mesh) of the first of these new vertices.

**Prototype:**

**DWORD VClone(DWORD \*v, int num=1);**

**Remarks:**

Clones some vertices.

**Parameters:**

**DWORD \*v**

A pointer to an array of indices of verts that should be cloned.

**int num**

The size of the array.

**Return Value:**

The index (in the output mesh) of the first of the clones.

**Prototype:**

**DWORD VClone(DWORD \*v, Point3 \*off, int num=1);**

**Remarks:**

Clones some vertices.

**Parameters:**

**DWORD \*v**

A pointer to an array of ids of vertices that should be cloned.

**Point3 \*off**

A pointer to an array of offsets for the clones.

**int num**

The size of the arrays.

**Return Value:**

The index (in the output mesh) of the first of the clones.

**Prototype:**

**DWORD VClone(VertMove \*vm, int num=1);**

**Remarks:**

Clones some vertices.

**Parameters:**

**VertMove \*vm**

A pointer to an array of VertMoves indicating which vertices should be cloned and what offsets the clones should use.

**int num**

The size of the vm array.

**Return Value:**

The index (in the output mesh) of the first of the clones.

**Prototype:**

**DWORD VClone(DWORD v);**

**Remarks:**

Clones a single vertex.

**Parameters:**

**DWORD v**

The index (in the output mesh) of the vertex you wish to clone.

**Return Value:**

The index (in the output mesh) of the clone.

**Prototype:**

**DWORD VClone(DWORD v, Point3 off);**

**Remarks:**

Clones and offsets a single vertex.

**Parameters:**

**DWORD v**

The index (in the output mesh) of the vertex you wish to clone.

**Point3 off**

The desired offset from the original vertex.

**Return Value:**

The index (in the output mesh) of the clone.

**Prototype:**

**void VDelete(DWORD \*v, int num=1);**

**Remarks:**

Deletes the specified vertices.

**Parameters:****DWORD \*v**

A pointer to an array of (output-based) ids of the vertices that should be deleted.

**int num**

The number of vertices to delete (the size of the v array).

**Prototype:**

```
void VDelete(BitArray & vdel);
```

**Remarks:**

Deletes the specified vertices.

**Parameters:****BitArray & vdel**

A BitArray, of size OutVNum, indicating which of the vertices should be deleted. Vertices in this array are indexed by output mesh order.

**Prototype:**

```
DWORD FCreate(Face *f, int num=1);
```

**Remarks:**

Creates new faces.

Note: MapDeltas must be kept up to date with all new face creations – see CreateDefaultMapFaces.

**Parameters:****Face \*f**

A pointer to an array of faces to be added to the MeshDelta.

**int num**

The size of the face array.

**Return Value:**

The index (in the output mesh) of the first of these new faces.

**Prototype:**

**DWORD FCreate(FaceCreate \*f, int num=1);**

**Remarks:**

Creates new faces. This is what's used to add in face creations in the all-important Compose method. It assumes that the "originals" in the array of FaceCreates are post-indexed, and uses FLut and extracts originals for creates-of-creates as appropriate.

Note: MapDeltas must be kept up to date with all new face creations – see CreateDefaultMapFaces.

**Parameters:**

**FaceCreate \*f**

A pointer to an array of face create records to be added to the MeshDelta.

**int num**

The size of the face create array.

**Return Value:**

The index (in the output mesh) of the first of these new faces.

**Prototype:**

**DWORD FCreateQuad(DWORD \*v, DWORD smG=0, MtlID matID=0, int orig=UNDEFINED);**

**Remarks:**

Creates 2 new faces, forming a quad.

Note: MapDeltas must be kept up to date with all new face creations – see CreateDefaultMapFaces.

**Parameters:**

**DWORD \*v**

A pointer to an array of 4 vertices to be used as corners of the quad.

**DWORD smG=0**

The smoothing group desired for the new faces.

**MtlID matID=0**

The material ID desired for the new faces.

**int orig=UNDEFINED**

This optional parameter sets the map faces to undefined.

**Return Value:**

The index (in the output mesh) of the first of these 2 new faces.

**Prototype:**

```
DWORD FClone(Face & f, DWORD ff, DWORD remapFlags=0,  
DWORD *v=NULL);
```

**Remarks:**

Creates a new face by copying an existing face. The result is put into the fCreate array and treated thereafter like a face create – this is different from vertex clones, which are maintained separately from vertex creates.

Note: MapDeltas must be kept up to date with all new face creations – see CreateDefaultMapFaces.

**Parameters:****Face & f**

The face we wish to clone. (This is typically generated by the outFace method.)

**DWORD ff**

The (output-based) index of the face we're cloning. (This is used to copy face and edge selection.)

**DWORD remapFlags=0****DWORD \*v=NULL**

If we wish to remap any of the corners of this face while cloning, the appropriate flags and vertices should be passed in these last two arguments. v should point to an array of 3 vertex (output) indices, although the ones not marked as used by the remapFlags need not be set to anything in particular. See class FaceRemap for more information about face remapping.

**Return Value:**

The index (in the output mesh) of the new face.

**Prototype:**

```
DWORD CreateDefaultMapFaces(int num=1);
```

**Remarks:**

MapDeltas must **always** keep their faces in sync with the parent MeshDelta. If

the developer creates new faces, but doesn't want to go through the bother of figuring out exactly how the related map faces should look, this method may be used to create map faces with UNDEFINED verts. These can then be filled in automatically later. (See the MeshDelta FillInFaces method for details.)

For **every** face created in the MeshDelta, either CreateDefaultMapFaces should be called, or map faces should be created in every active map channel, using MapDelta::FCreate and related methods.

**Parameters:**

**int num=1**

The number of default faces we wish to create in each active map channel.

**Prototype:**

**void FRemap(FaceRemap \*f, int num=1);**

**Remarks:**

Adds face remaps to this MeshDelta. If the face specified in each FaceRemap already has a remap record, the two are combined. If the face specified is a face created by this MeshDelta, the remap is applied directly to the fCreate entry instead of being stored in fRemap.

**Parameters:**

**FaceRemap \*f**

A pointer to an array of FaceRemap that should be appended to this MeshDelta.

Note that the faces and vertices in each FaceRemap must be indexed by their positions after all of the current MeshDelta's creates, clones, etc, but before any vertex or face deletes. Vertex index values of 0 through vnum-1 are considered to be the original mesh's vertices; values above this are cloned or created vertices. Likewise, face index values of 0 through fnum-1 are considered to be the original mesh faces, while fnum through fnum+fCreate.Count()-1 are this MeshDelta's face creates.

**int num=1**

The number of elements in the FaceRemap array.

**Prototype:**

**void FRemap(DWORD f, DWORD flags, DWORD \*v);**

**Remarks:**

Adds a face remap to this MeshDelta. If the face specified already has a remap record, the two are combined. If the face specified is a face created by this MeshDelta, the remap is applied directly to the fCreate entry instead of being stored in fRemap.

**Parameters:****DWORD f**

The face to remap.

Note that this face must be indexed by its position after all of the current MeshDelta's face creates, but before any face deletes. Face index values of 0 through fnum-1 are considered to be the original mesh faces, while fnum through fnum+fCreate.Count()-1 are this MeshDelta's face creates.

**DWORD flags**

Face Remap flags – these indicate which vertices should be remapped. The possibilities are FR\_V0 (1), FR\_V1 (2), and FR\_V2 (4). (See class FaceRemap for more information.)

**DWORD \*v**

A pointer to the vertices to remap the face to use. Only the positions indicated in the remap flags need contain meaningful data.

Note that the vertices indicated here must be indexed by their positions after all of the current MeshDelta's creates and clones, but before any vertex deletes – essentially input-based indexing. Vertex index values of 0 through vnum-1 are considered to be the original mesh's vertices; values of vnum through vnum+vCreate.Count()-1 are considered to be this MeshDelta's newly created vertices; and values above this are cloned vertices.

**Prototype:**

```
void FChange(FaceChange *f, int num=1);
```

**Remarks:**

Appends some face changes to the current MeshDelta. Face changes can encompass changes to face material IDs, edge visibility, or face hiding. See class FaceChange for more information.

**Parameters:**

**FaceChange \*f**

A pointer to an array of new face changes for this MeshDelta.

**int num=1**

The number of elements in the FaceChange array.

**Prototype:**

**void FChange(DWORD f, DWORD flags, DWORD dat);**

**Remarks:**

Changes the characteristics of one face.

**Parameters:**

**DWORD f**

The output-indexed face to change.

**DWORD flags**

**DWORD dat**

These two parameters describe the change desired. See class FaceChange for a description of these flags. flags indicates which characteristics should be set, and dat includes the on-or-off state of each flag we're setting. So for example FChange (26, ATTRIB\_EDGE\_A| ATTRIB\_EDGE\_B, ATTRIB\_EDGE\_A) would set face 26 to have the first edge visible and the second invisible, without changing the existing visibility for the third edge.

**Prototype:**

**void SetMatID(DWORD f, MtlID mt);**

**Remarks:**

Sets the material ID for the specified face. If the face is created by this MeshDelta, the fCreate record is amended. If it's an input face, a FaceChange record is created or amended.

**Parameters:**

**DWORD f**

The output-indexed face to change.

**MtlID mt**

The desired material ID.

**Prototype:**

**void SetEdgeVis(DWORD f, DWORD ed, BOOL vis=TRUE);**

**Remarks:**

Sets the edge visibility for the specified side of the specified face. If the face is created by this MeshDelta, the fCreate record is amended. If it's an input face, a FaceChange record is created or amended.

**Parameters:**

**DWORD f**

The output-indexed face to change.

**DWORD ed**

The side of the face to change (0, 1, or 2).

**BOOL vis=TRUE**

The desired visibility.

**Prototype:**

**void FSmooth(FaceSmooth \*f, int num=1);**

**Remarks:**

Adds smoothing group changes to this MeshDelta. See class FaceSmooth for more information.

**Parameters:**

**FaceSmooth \*f**

A pointer to an array of smoothing change records. The face IDs in these records should be output-indexed.

**int num=1**

The number of elements in the FaceSmooth array.

**Prototype:**

**void FSmooth(DWORD f, DWORD mask, DWORD val);**

**Remarks:**

Changes the smoothing groups on the specified face.

**Parameters:**

**DWORD f**

The output-based index of the face to change.

### **DWORD mask**

The smoothing groups to change.

### **DWORD val**

The smoothing group values. For instance, FSmooth (32, 7, 2) would set smoothing group 2 and clear groups 1 and 3 for face 32, since mask has bits 0, 1, and 2 set but val only has bit 1 set.

### **Prototype:**

```
void SetSmGroup(DWORD f, DWORD smG);
```

### **Remarks:**

Sets the smoothing groups on the specified face.

### **Parameters:**

#### **DWORD f**

The output-based index of the face to change.

#### **DWORD smG**

The smoothing groups to set. All bits not set in this parameter are cleared.

### **Prototype:**

```
void FDelete(DWORD *f, int num=1);
```

### **Remarks:**

Deletes the specified faces.

### **Parameters:**

#### **DWORD \*f**

A pointer to an array of output-based indices of faces we wish to delete. Note that all the elements should be based on the output before any deletions occur. So if you wanted to delete what are currently faces 3 and 5, you could pass an array with 3 and 5, you would **not** have to think, "Ah, 3 will be deleted, so I should use 4 instead of 5."

#### **int num=1**

The size of the array.

### **Prototype:**

```
void FDelete(BitArray & fdel);
```

**Remarks:**

Deletes the specified faces.

**Parameters:****BitArray & fdel**

The faces to delete. The faces are indexed by their output mesh positions.

**Advanced additive operations**

The following are more complex operations, built out of the simple operations above. The mesh given is expected to be result of the current MeshDelta. They should all work no matter how complex the current MeshDelta is, but they have not been extensively tested on complex MeshDeltas. To see how most of these work, look at Editable Mesh or Edit Mesh, both of which have source in **MAXSDK\SAMPLES**.

**Prototype:**

```
void AutoSmooth(Mesh & m, BitArray sel, float angle,  
AdjFaceList *af=NULL, AdjEdgeList *ae=NULL);
```

**Remarks:**

Automatically generates smoothing groups for the selected faces. Existing smoothing groups are ignored. See the AutoSmooth feature in Edit Mesh for an example.

**Parameters:****Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The faces to AutoSmooth.

**float angle**

The maximum angle between faces that should be smoothed together.

**AdjFaceList \*af=NULL**

A pointer to the adjacent face list for this mesh. If NULL, the method constructs its own AdjFaceList.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method

constructs its own AdjEdgeList.

**Prototype:**

```
void Bevel(Mesh & m, BitArray vset, float outline, Tab<Point3>  
*odir, float height, Tab<Point3> *hdir);
```

**Remarks:**

Moves the selected vertices along the directions given to produce the movement corresponding to the mouse drags of a Bevel operation in Editable Mesh. Note that this method only changes geometry.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray vset**

The set of vertices to move.

**float outline**

The amount of outlining to do in this Bevel move.

**Tab<Point3> \*odir**

The outline direction for each vertex. This should be given by MeshTempData::OutlineDir. See the Edit Mesh source for details.

**float height**

The amount of extrusion to do in this Bevel move.

**Tab<Point3> \*hdir**

The extrusion direction for each vertex. This should be given by MeshTempData::EdgeExtDir or FaceExtDir. See the Edit Mesh source for examples.

**Prototype:**

```
DWORD CreatePolygon(Mesh & m, int deg, int *v, DWORD  
smG=0, MtlID matID=0);
```

**Remarks:**

Create a polygon of any size. The polygon may be nonconvex, but should be (roughly) coplanar.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**int deg**

The number of vertices used by this polygon (its degree).

**int \*v**

The indices of the vertices in **Mesh m** that this polygon should use.

**DWORD smG=0**

The desired smoothing group for the new polygon.

**MtlID matID=0**

The desired material ID for the new polygon.

**Prototype:**

**void DeleteVertSet(Mesh & m, BitArray sel);**

**Remarks:**

Deletes the specified vertices, along with any faces that used them.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The vertices to delete. Any face that uses any of the vertices selected here will also be deleted.

**Prototype:**

**void DeleteEdgeSet(Mesh & m, BitArray sel);**

**Remarks:**

Deletes all faces using the specified edges. (Doesn't delete any verts.)

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that

should be affected.

**BitArray sel**

The edges to delete the faces of. Edges are indexed by  $\text{face} \times 3 + \text{side}$ .

**Prototype:**

**void DeleteFaceSet(Mesh & m, BitArray sel);**

**Remarks:**

Deletes the specified faces. (Doesn't delete any verts.)

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The faces to delete.

**Prototype:**

**void DeleteSelected(Mesh & m);**

**Remarks:**

Deletes the current subobject selection. If  $\text{m.selLevel}$  is `MESH_OBJECT`, nothing is deleted. If it's `MESH_VERTEX`, the faces using the selected vertices are also deleted.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**Prototype:**

**void DeleteIsoVerts(Mesh & m);**

**Remarks:**

Deletes the vertices not in use by any faces.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**Prototype:**

**void FlipNormal(Mesh & m, DWORD face);**

**Remarks:**

Flips the normal of the specified face (by switching the face's v[0] and v[1]). (Related map faces are also flipped.)

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**DWORD face**

The face to flip.

**Prototype:**

**void MakeSelFacesPlanar(Mesh & m, BitArray sel);**

**Remarks:**

Flattens the faces indicated into the same plane. The target plane is determined by the average of all the face centers and the average of all the face normals.

**Parameters:**

**Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The faces to make coplanar.

**Prototype:**

**void MakeSelVertsPlanar(Mesh & m, BitArray sel);**

**Remarks:**

Flattens the vertices indicated into the same plane. The target plane is determined by the average position and normal of the vertices.

**Parameters:****Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The vertices to make coplanar.

**Prototype:**

```
void MoveVertsToPlane(Mesh & m, BitArray sel, Point3 & N,  
float offset);
```

**Remarks:**

Moves the vertices indicated into the specified plane. (The target plane is defined as all points which, when DotProd'd with N, return offset.) All vertices are moved along the normal vector N.

**Parameters:****Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

**BitArray sel**

The vertices to move into the plane.

**Point3 & N**

The unit normal to the plane.

**float offset**

The offset of the plane (also its distance from the origin).

**Prototype:**

```
void RestrictMatIDs(Mesh & m, int numMats);
```

**Remarks:**

Like the old standalone method "FitMeshIDsToMaterial", this method limits the material IDs to values between 0 and numMats-1. This is useful eg in matching the number of material Ids to the number of materials used on this node.

**Parameters:**

## **Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

## **int numMats**

The number of material ids allowed.

## **Prototype:**

```
void SelectFacesByFlags(Mesh & m, BOOL onoff, DWORD  
flagmask, DWORD flags);
```

## **Remarks:**

Sets or clears face selection depending on whether they match a pattern of flags. This is pretty much only useful for selecting or deselecting hidden faces:

```
mdelta.SelectFacesByFlags(*mesh, FALSE, FACE_HIDDEN,  
FACE_HIDDEN); // deselects hidden faces.
```

## **Parameters:**

### **Mesh & m**

The mesh, which should match the output of the current MeshDelta, that should be affected.

### **BOOL onoff**

Indicates whether faces should be selected or deselected if they match the flag pattern.

### **DWORD flagmask**

Indicates whether faces should be selected or deselected if they match the flag pattern.

### **DWORD flags**

Indicates whether faces should be selected or deselected if they match the flag pattern.

## **Advanced operations**

The following will initialize to the mesh given: they can't be used to "add" ops to an existing MeshDelta. (To add these ops, make a new MeshDelta, call one of the following, and append it to your previous one with Compose.) To see how most of these work, look at Editable Mesh or Edit Mesh, both of which have

source in **MAXSDK\SAMPLES**.

**Prototype:**

**void AttachMesh(Mesh & m, Mesh & attachment, Matrix3 & relativeTransform, int matOffset);**

**Remarks:**

Attaches another mesh to this one.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**Mesh & attachment**

The mesh this MeshDelta should attach.

**Matrix3 & relativeTransform**

The transform taking the attachment mesh from its object space to ours.

**int matOffset**

The offset that should be applied to all the material IDs in the attachment.

**Prototype:**

**void BreakVerts(Mesh & m, BitArray vset);**

**Remarks:**

Splits the selected vertices into a separate vertex for every face that uses them.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be broken.

**Prototype:**

**void ChamferEdges(Mesh & m, BitArray eset, MeshChamferData & mcd, AdjEdgeList \*ae=NULL);**

**Remarks:**

Performs the topological changes needed for an edge chamfer, and creates the information necessary to do the geometric changes.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray eset**

The edges to chamfer.

**MeshChamferData & mcd**

A class in which the directions and limits of movement for all the vertices involved in the chamfer should be stored. See class MeshChamferData.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

```
void ChamferMove(Mesh & m, MeshChamferData & mcd, float amount, AdjEdgeList *ae=NULL);
```

**Remarks:**

Moves the relevant vertices to a specified chamfer value.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**MeshChamferData & mcd**

A class in which the directions and limits of movement for all the vertices involved in the chamfer have been stored by a previous ChamferVertices or ChamferEdges call. See class MeshChamferData.

**float amount**

The amount (in object space units) of chamfering to do. For vertex chamfers, this indicates how far along the edges each point should move. For edge chamfers, it represents how far along each face each edge should move.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

**void ChamferVertices(Mesh & m, BitArray vset,  
MeshChamferData & mcd, AdjEdgeList \*ae=NULL);**

**Remarks:**

Performs the topological changes needed for a vertex chamfer, and creates the information necessary to do the geometric changes.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be chamfered.

**MeshChamferData & mcd**

A class in which the directions and limits of movement for all the vertices involved in the chamfer should be stored. See class MeshChamferData.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

**void CloneFaces(Mesh & m, BitArray fset);**

**Remarks:**

Clones the specified faces, along with the vertices and mapping vertices they use.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces that should be cloned.

**Prototype:**

**void CloneVerts(Mesh & m, BitArray vset);**

**Remarks:**

Clones the specified vertices. More efficient on an initialized MeshDelta than

VClone, which has to be able to cope with existing complex MeshDeltas.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be cloned.

**Prototype:**

```
void CollapseEdges(Mesh & m, BitArray ecol, AdjEdgeList  
*ae=NULL);
```

**Remarks:**

Collapses the edges indicated down to a point.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray ecol**

The edges to collapse.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

```
DWORD Cut(Mesh & m, DWORD ed1, float prop1, DWORD ed2,  
float prop2, Point3 &norm, bool fixNeighbors=TRUE, bool  
split=FALSE);
```

**Remarks:**

Cuts the mesh from a point on one edge to a point on another, along a line drawn by looking at the mesh from a particular viewpoint. (See Edit Mesh's Cut feature for an illustration.)

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**DWORD ed1**

The edge that the cut starts on. The edge is indexed by  $\text{face} \cdot 3 + \text{side}$ , so the start vertex is  $\text{m.faces}[\text{ed1}/3].\text{v}[\text{ed1}\%3]$ , and the end vertex is  $\text{m.faces}[\text{ed1}/3].\text{v}[(\text{ed1}+1)\%3]$ .

**float prop1**

The position on the edge to start the cut from. 0 means the start vertex of the edge, and 1 means the end vertex.

**DWORD ed2**

The edge that the cut should end on.

**float prop2**

The position on the edge to finish the cut on. 0 means the start vertex of the edge, and 1 means the end vertex.

**Point3 &norm**

The direction of view. The cut will take place on this "side" of the mesh, in the plane formed by this vector and the direction from the start to the end.

**bool fixNeighbors=TRUE**

Indicates whether the faces on the other side of each end of the cut should be split to prevent splits at the ends.

**bool split=FALSE**

Indicates whether the cut should actually split the mesh apart or just refine it by adding geometry.

**Prototype:**

```
void Detach(Mesh & m, Mesh *out, BitArray fset, BOOL faces,  
            BOOL del, BOOL elem);
```

**Remarks:**

Detaches a subset of the geometry from the mesh given, either separating it as a new element or creating a new mesh with it.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**Mesh \*out**

The new mesh into which the detached portion can be put. (If elem is TRUE, this is not used and may be NULL.)

### **BitArray fset**

The selection to detach. If faces is TRUE, this is a face selection. Otherwise, it's a vertex selection.

### **BOOL faces**

If TRUE, we should detach the selected faces; otherwise, we should detach the selected vertices.

### **BOOL del**

Indicates whether the detached portion should be deleted from the original mesh.

### **BOOL elem**

If TRUE, we're actually just detaching to an element, and the out mesh will not be used.

### **Prototype:**

```
void DivideEdge(Mesh & m, DWORD ed, float prop=.5f,  
AdjEdgeList *el=NULL, bool visDiag1=FALSE, bool  
fixNeighbors=TRUE, bool visDiag2=FALSE, bool split=FALSE);
```

### **Remarks:**

Divides the specified edge, adding a point and dividing faces to match.

### **Parameters:**

#### **Mesh & m**

The mesh this MeshDelta should be based on.

#### **DWORD ed**

The edge to divide, indexed as face\*3+side.

#### **float prop=.5f**

The proportion along the edge where the division should occur. 0 is the start vertex, m.faces[ed/3].v[ed%3], and 1 is the end vertex, m.faces[ed/3].v[(ed+1)%3].

#### **AdjEdgeList \*el=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList if needed.

#### **bool visDiag1=FALSE**

Indicates whether the diagonal connecting the new point on this edge with the far corner of face ed/3 should be visible.

**bool fixNeighbors=TRUE**

Indicates whether the face on the other side of this edge, that is, the face using this edge that isn't ed/3, should be divided as well to prevent the introduction of a seam.

**bool visDiag2=FALSE**

Indicates whether the diagonal connecting the new point on this edge with the far corner of the face on the other side of the edge should be visible. (Not used if fixNeighbors is FALSE.)

**bool split=FALSE**

Indicates whether the method should create separate vertices for the two halves of the edge, splitting the mesh open along the diagonal(s).

**Prototype:**

```
void DivideEdges(Mesh & m, BitArray eset, AdjEdgeList  
*el=NULL);
```

**Remarks:**

Divides all the selected edges in half, creating new points and subdividing faces.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray eset**

The edges to divide.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

```
void DivideFace(Mesh & m, DWORD f, float *bary=NULL);
```

**Remarks:**

Divides the selected face into 3, by introducing a new point on the face and splitting the original face along lines from the corners to the new point.

**Parameters:**

## **Mesh & m**

The mesh this MeshDelta should be based on.

## **DWORD f**

The face to divide.

## **float \*bary=NULL**

A pointer to the barycentric coordinates of the new point on the face. If NULL, the center of the face is used.

Barycentric coordinates on a triangle are a set of three numbers between 0 and 1 that add up to 1. Any point on a triangle can be uniquely described by a set of these. The point corresponding to barycentric coordinates (a,b,c) on a face with corners A,B,C is  $a*A + b*B + c*C$ .

## **Prototype:**

```
void DivideFaces(Mesh & m, BitArray fset, MeshOpProgress *mop=NULL);
```

## **Remarks:**

Divides the selected faces into 3, by creating their center points and splitting the original faces along lines from the corners to the center.

## **Parameters:**

### **Mesh & m**

The mesh this MeshDelta should be based on.

### **BitArray fset**

The faces to divide.

### **MeshOpProgress \*mop=NULL**

If non-NULL, this points to an implementation of class MeshOpProgress which can be used to interrupt the algorithm if it's taking too long. See class MeshOpProgress for details.

## **Prototype:**

```
void EdgeTessellate(Mesh & m, BitArray fset, float tens, AdjEdgeList *ae=NULL, AdjFaceList *af=NULL, MeshOpProgress *mop=NULL);
```

## **Remarks:**

Tessellates the mesh. This algorithm is exactly the one used in the Tessellate modifier, when operating on "Faces" (triangle icon) and in "Edge" type.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces to tessellate.

**float tens**

The tension for the edge tessellation. This value should be fairly small, between 0 and .5, and corresponds to the value in the Tessellate, Edit Mesh, or Editable Mesh UI's divided by 400.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**AdjFaceList \*af=NULL**

A pointer to the adjacent face list for this mesh. If NULL, the method constructs its own AdjFaceList.

**MeshOpProgress \*mop=NULL**

If non-NULL, this points to an implementation of class MeshOpProgress which can be used to interrupt the algorithm if it's taking too long. See class MeshOpProgress for details.

**Prototype:**

**void ExplodeFaces(Mesh & m, float thresh, bool useFaceSel=FALSE, AdjFaceList \*af=NULL);**

**Remarks:**

"Explodes" the mesh into separate elements.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**float thresh**

The threshold angle between faces that indicates whether they should be in the same or different element.

**bool useFaceSel=FALSE**

Indicates whether the mesh's current face selection should be used or if the whole mesh should be exploded.

**AdjFaceList \*af=NULL**

A pointer to the adjacent face list for this mesh. If NULL, the method constructs its own AdjFaceList.

**Prototype:**

```
void ExtrudeEdges(Mesh & m, BitArray eset, Tab<Point3>  
*edir=NULL);
```

**Remarks:**

Performs the topological changes necessary to extrude the indicated edges. (The geometric component is handled later by the Bevel method.)

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray eset**

The edges to extrude.

**Tab<Point3> \*edir=NULL**

Fills in the directions for moving all the relevant vertices to handle the geometric part of the extrusion. See the Edit Mesh or Editable Mesh source in **MAXSDK\SAMPLES\MODIFIERS** and **MAXSDK\SAMPLES\MESH\EDITABLEMESH** to see how this is used.

**Prototype:**

```
void ExtrudeFaces(Mesh & m, BitArray fset, AdjEdgeList  
*el=NULL);
```

**Remarks:**

Performs the topological changes necessary to extrude the indicated faces. (The geometric component is handled later by the Bevel method.)

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces that should be extruded.

**AdjEdgeList \*el=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

**void ResetVertWeights(Mesh & m);**

**Remarks:**

Resets all the vertex weights to 1.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**Prototype:**

**void SetFaceColors(Mesh & m, BitArray fset, VertColor vc , int mp=0);**

**Remarks:**

Sets the indicated faces to have vertex colors all equal to the color value specified. (This often involves creating new vertex color map vertices, so faces that neighbor the indicated faces are not affected.)

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces that should be affected.

**VertColor vc**

The desired color.

**int mp=0**

The map channel. Use 0 for normal vertex colors, MAP\_SHADING for the illumination channel, and MAP\_ALPHA for the alpha channel.

**Prototype:**

```
void SetVertColors(Mesh & m, BitArray vset, VertColor vc , int mp=0);
```

**Remarks:**

Sets all vertex color map vertices associated with the indicated vertices to the specified color.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be affected. If more than one map vertex is used at this vertex, all of them have their colors set.

**VertColor vc**

The desired color.

**int mp=0**

The map channel. Use 0 for normal vertex colors, MAP\_SHADING for the illumination channel, and MAP\_ALPHA for the alpha channel.

**Prototype:**

```
void SetFaceAlpha (Mesh &m, BitArray fset, float alpha, int mp=MAP_ALPHA);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the indicated faces to have face alpha.

**Parameters:****Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces that should be affected.

**float alpha**

The amount of alpha

**int mp=MAP\_ALPHA**

The map channel. Use 0 for normal vertex colors, MAP\_SHADING for the

illumination channel, and MAP\_ALPHA for the alpha channel.

**Prototype:**

```
void SetVertAlpha (Mesh &m, BitArray vset, float alpha, int  
mp=MAP_ALPHA);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the indicated vertices to have face alpha.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be affected.

**float alpha**

The amount of alpha

**int mp=MAP\_ALPHA**

The map channel. Use 0 for normal vertex colors, MAP\_SHADING for the illumination channel, and MAP\_ALPHA for the alpha channel.

**Prototype:**

```
void ResetVertCorners (Mesh & m);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method resets the vertex corners.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**Prototype:**

```
void SetVertWeights(Mesh & m, BitArray vset, float weight);
```

**Remarks:**

Sets the weights of the specified vertices. (These weight values are only used

in MeshSmooth NURMS mode as of 3ds max 3.0.)

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should have their weights set.

**float weight**

The weight to set.

**Prototype:**

```
void Slice(Mesh & m, Point3 N, float off, bool sep=FALSE, bool  
remove=FALSE, BitArray *fslice=NULL, AdjEdgeList  
*ae=NULL);
```

**Remarks:**

Slices the mesh along the specified slicing plane.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**Point3 N**

The normal of the slice plane.

**float off**

These parameters define the slicing plane as all points  $p$  satisfying the equation  $\text{DotProd}(p,N) = \text{off}$ .  $N$  should be normalized.

**bool sep=FALSE**

Indicates whether the slice should separate the mesh into two separate elements (if TRUE) or just refine the existing mesh by splitting faces (if FALSE).

**bool remove=FALSE**

Indicates whether the slice should remove the portion of the mesh "below" the slicing plane, where "below" is defined as the area where  $\text{DotProd}(p,N) - \text{off} < 0$ . If remove is TRUE, sep is ignored.

**BitArray \*fslice=NULL**

A bit array containing the list of faces to slice.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

**void TurnEdge(Mesh & m, DWORD ed, AdjEdgeList \*el=NULL);**

**Remarks:**

"Turns" the specified edge. Only works on edges that have a face on both sides. These two faces are considered as a quad, where this edge is the diagonal, and remapped so that the diagonal flows the other way, between the vertices that were opposite this edge on each face.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**DWORD ed**

The edge to turn, indexed as face\*3+side.

**AdjEdgeList \*ae=NULL**

A pointer to the adjacent edge list for this mesh. If NULL, the method constructs its own AdjEdgeList.

**Prototype:**

**BOOL WeldByThreshold(Mesh & m, BitArray vset, float thresh);**

**Remarks:**

Welds all vertices that are sufficiently close together.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that are candidates for being welded.

**float thresh**

The maximum distance (in object space units) between two vertices that will allow them to be welded.

**Return Value:**

Returns TRUE if any vertices were welded, FALSE if none were within threshold.

**Prototype:**

```
void WeldVertSet(Mesh & m, BitArray vset, Point3  
*weldPoint=NULL);
```

**Remarks:**

Welds the specified vertices together into one vertex, no matter how far apart they are.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray vset**

The vertices that should be welded.

**Point3 \*weldPoint=NULL**

If non-NULL, this points to the location we'd like to put the weld result. (If NULL, the result is put at the average location of the selected vertices.)

**Prototype:**

```
void PropagateFacing(Mesh & m, BitArray & fset, int face,  
AdjFaceList & af, BitArray & done, BOOL bias=1);
```

**Remarks:**

This method is designed for internal use, in UnifyNormals, but may also be called directly.

**Parameters:**

**Mesh & m**

The mesh this MeshDelta should be based on.

**BitArray fset**

The faces that should be affected.

**int face**

The starting face to propagate normal directions from.

**AdjFaceList & af**

The adjacent face list corresponding to the mesh. Required, can't be made

locally, for efficiency's sake.

### **BitArray & done**

Keeps track of which faces have had their normals unified. Faces that are set here when the call is made will not be processed, and will not be crossed to reach other faces. Faces that are still clear upon completion were not processed, probably because they were on a separate element from "face".

### **BOOL bias=1**

Used to keep track of whether the current face has been oriented correctly. For example, if the starting face was not selected in fset, and therefore doesn't have the right orientation, but you still want selected faces in the same element to be corrected, you would submit FALSE here.

### **Prototype:**

```
void UnifyNormals(Mesh & m, BitArray fset, AdjFaceList  
*af=NULL);
```

### **Remarks:**

Unifies normals on selected faces, making the normals consistent from face to face.

### **Parameters:**

#### **Mesh & m**

The mesh this MeshDelta should be based on.

#### **BitArray fset**

The faces that should be affected. Nonselected faces can be traversed by the algorithm, but they will not be corrected if their normals are pointing the "wrong" way.

#### **AdjFaceList \*af=NULL**

A pointer to the adjacent face list corresponding to the mesh. If NULL, an adjacent face list is computed by the method.

## **I/O, Debugging**

### **Prototype:**

```
IOResult Save(ISave *save);
```

### **Remarks:**

Saves the MeshDelta to a 3ds max file.

**Prototype:**

**IOResult Load(ILoad \*load);**

**Remarks:**

Loads the MeshDelta from a 3ds max file.

**Prototype:**

**void MyDebugPrint(bool lut=FALSE, bool mp=FALSE);**

**Remarks:**

Prints out the MeshDelta to the DebugPrint window in Developer Studio.

**Parameters:**

**bool lut=FALSE**

If TRUE, the vertex and face lookup tables are printed out.

**bool mp=FALSE**

Active map deltas are also printed out if this is TRUE.

## Class VertMove

See Also: [Class Mesh](#), [Class Point3](#).

class VertMove

### Description:

This class is available in release 3.0 and later only.

This class represents the notion of a mesh edit vertex move. The public data members provide the index of the vertex moved as well as the amount of the move in X, Y, Z.

### Data Members:

public:

**DWORD vid;**

The id of the vertex moved.

**Point3 dv;**

The amount of the move.

### Methods:

public:

### Prototype:

**VertMove();**

### Remarks:

Constructor.

### Prototype:

**VertMove(DWORD i, Point3 p);**

### Remarks:

Constructor. The data members are initialized to the values passed.

### Prototype:

**~VertMove();**

### Remarks:

Destructor.

**Prototype:**

**VertMove &operator=(VertMove & from);**

**Remarks:**

Assignment operator.

## Class UVVertSet

See Also: [Class Mesh](#), [Class Point3](#).

class UVVertSet

### Description:

This class is available in release 3.0 and later only.

This class represents the notion of a mesh edit UVW vertex assignment. The public data members provide the index of the vertex as well as the UVWVert.

### Data Members:

public:

**DWORD vid;**

The index of the vertex.

**UVVert v;**

The UVW vertex.

### Methods:

public:

### Prototype:

**UVVertSet();**

### Remarks:

Constructor.

### Prototype:

**UVVertSet(DWORD i, UVVert p);**

### Remarks:

Constructor. The data members are initialized to the values passed.

### Prototype:

**~UVVertSet();**

### Remarks:

Destructor.

**Prototype:**

**UVVertSet & operator=(UVVertSet & from);**

**Remarks:**

Assignment operator.

## Class FaceRemap

See Also: [Class Mesh](#), [Class Face](#), [Class Point3](#).

class FaceRemap

### Description:

This class is available in release 3.0 and later only.

This class represents the notion of a mesh edit Face Remap, which changes one or more of the vertices a face uses. It can also alter the visibility of the face's edge, its hidden state and its material ID.

### Data Members:

public:

**DWORD f,**

Face being remapped. This is a zero based index into the Mesh's **faces** array.

**DWORD flags**

Specifies which vertices to remap. One or more of the following values:

**FR\_V0** - Remap the 0th vertex.

**FR\_V1** - Remap the 1st vertex.

**FR\_V2** - Remap the 2nd vertex.

**FR\_ALL** - Remap all the vertices.

**DWORD v[3];**

Array of vertex indices. These indicate which vertex is used by each specified corner of the face being remapped.

### Methods:

public:

### Prototype:

**FaceRemap();**

### Remarks:

Constructor. The **flags** and **f** are set to 0.

### Prototype:

**FaceRemap(DWORD ff, DWORD fl, DWORD \*vv);**

**Remarks:**

Constructor.

**Parameters:**

**DWORD ff**

The face to remap.

**DWORD fl**

The flags to set.

**DWORD \*vv**

The array of vertex indicies.

**Prototype:**

**void Apply(Face &ff);**

**Remarks:**

Applies the vertex remapping to the given face based on the flags of this FaceRemap object.

**Parameters:**

**Face &ff**

The face whose vertices are remapped.

**Prototype:**

**void Apply(TVFace &tf);**

**Remarks:**

Applies the vertex remapping to the given map face based on the flags of this FaceRemap object.

**Parameters:**

**TVFace &tf**

The texture face whose tVerts are remapped by the verts of this FaceRemap object. The **v** data member used contains indices into the mesh object's **tVerts** array.

**Prototype:**

**void Apply(FaceRemap &fr);**

**Remarks:**

Assigns the flags and verts of this FaceRemap object to the FaceRemap passed.

**Parameters:****FaceRemap &fr**

The FaceRemap whose flags and verts are assigned.

**Prototype:**

**Face operator\*(Face &ff);**

**Remarks:**

Returns a new Face with the FaceRemap applied.

**Prototype:**

**TVFace operator\*(TVFace & ff);**

**Remarks:**

Returns a new TVFace with the FaceRemap applied.

# Class FaceChange

See Also: [Class Mesh](#), [Class Face](#), [Class Point3](#).

class FaceChange

## Description:

This class is available in release 3.0 and later only.

This class represents the notion of a mesh edit Face Change, which changes the visibility of the face's edges, its hidden state and/or its material ID.

## Data Members:

public:

### DWORD f

The face to change. This is a zero based index into the Mesh's **faces** array.

### DWORD flags

Specifies which attributes to change. One or more of the following values:

**ATTRIB\_EDGE\_A** - Alter edge between v0 and v1

**ATTRIB\_EDGE\_B** - Alter edge between v1 and v2

**ATTRIB\_EDGE\_C** - Alter edge between v2 and v0

**ATTRIB\_EDGE\_ALL** - Alter all the edges.

**ATTRIB\_HIDE\_FACE** - Alter the face hidden state.

**ATTRIB\_MATID** - Alter the material ID.

### DWORD val;

The value containing the face change information. Bits 0, 1, 2 hold the edge visibility, bit 3 holds the hidden state, and bits 5-21 hold the material ID.

## Methods:

public:

## Prototype:

**FaceChange();**

## Remarks:

Constructor. The **flags** and **f** are set to 0.

## Prototype:

**FaceChange(DWORD ff, DWORD fl, DWORD v);**

**Remarks:**

Constructor. The data members are initialized to the values passed.

**Parameters:**

**DWORD ff**

The index of the face to change. This is a zero based index into the Mesh's **faces** array.

**DWORD fl**

The flags to set.

**DWORD v**

The value to set.

**Prototype:**

**void Apply(Face &ff);**

**Remarks:**

Applies the face change to the Face passed using the flags of this FaceChange object to control what's altered.

**Parameters:**

**Face &ff**

The face to change.

**Prototype:**

**void Apply(FaceChange &fa);**

**Remarks:**

Updates the flags and val to the FaceChange passed using this FaceChange and its flags.

**Parameters:**

**FaceChange &fa**

The FaceChange object to alter.

## Class FaceSmooth

See Also: [Class Mesh](#), [Class Face](#), [Class Point3](#).

class FaceSmooth

### Description:

This class is available in release 3.0 and later only.

This class represents the notion of the edit mesh Face Smooth operation. This updates the smoothing group information in the face.

### Data Members:

public:

#### **DWORD f**

The face to change. This is a zero based index into the Mesh's **faces** array.

#### **DWORD mask**

The mask into the face of the smoothing groups.

#### **DWORD val;**

The smoothing group information to store.

### Methods:

public:

### Prototype:

**FaceSmooth();**

### Remarks:

Constructor. The **flags** and **f** are set to 0.

### Prototype:

**FaceSmooth(DWORD ff, DWORD mk, DWORD vl);**

### Remarks:

Constructor. The data members are initialized to the values passed.

### Prototype:

**void Apply(Face &ff);**

### Remarks:

Applies this smoothing change to the given face.

**Parameters:**

**Face &ff**

The face to update.

**Prototype:**

**void Apply(FaceSmooth &fs);**

**Remarks:**

Assigns the flags and val to the given FaceSmooth object from this one.

**Parameters:**

**FaceSmooth &fs**

The FaceSmooth object to alter.

## Class MeshDeltaUser

See Also: [Class Mesh](#), [Class MeshDelta](#).

class MeshDeltaUser : public InterfaceServer

### Description:

This class is available in release 3.0 and later only.

This is a virtual class which both Editable Mesh (class EditTriObject) and Edit Mesh (class EditMeshMod) subclass off of. It contains interface methods for editable meshes, much like the IMeshSelect class contains interface methods for modifiers and objects that can select sub-object parts of meshes.

### Methods:

public:

### Prototype:

**virtual void LocalDataChanged(DWORD parts)=0;**

### Remarks:

This method is used to notify the **MeshDeltaUser** that at least one of its associated **MeshDeltaUserDatas** has changed.

### Parameters:

#### **DWORD parts**

This represents the parts of the local data that have changed. One or more of the following values:

**PART\_TOPO, PART\_GEOM, PART\_TEXMAP, PART\_MTL,  
PART\_SELECT, PART\_SUBSEL\_TYPE, PART\_DISPLAY,  
PART\_VERTCOLOR, PART\_GFX\_DATA**

### Prototype:

**virtual void ToggleCommandMode(meshCommandMode mode)=0;**

### Remarks:

This method is used to start up one of the interactive command modes of the editable mesh.

### Parameters:

## **meshCommandMode mode**

The mode to start. One of the following values:

**McmCreate, McmAttach, McmExtrude, McmBevel,  
McmChamfer, McmSlicePlane, McmCut, McmWeldTarget,  
McmFlipNormalMode, McmDivide, McmTurnEdge**

### **Prototype:**

**virtual void ButtonOp(meshButtonOp opcode)=0;**

### **Remarks:**

This method performs the equivalent operation as a button press in the editable mesh UI.

### **Parameters:**

**meshButtonOp opcode**

One of the following values:

**MopHide, MopUnhideAll, MopDelete, MopDetach, MopBreak,  
MopViewAlign, MopGridAlign, MopMakePlanar, MopCollapse,  
MopTessellate, MopExplode, MopSlice, MopWeld,  
MopShowNormal, MopAutoSmooth, MopRemoveIsolatedVerts,  
MopSelectOpenEdges, MopCreateShapeFromEdges,  
MopFlipNormal, MopUnifyNormal, MopVisibleEdge,  
MopInvisibleEdge, MopAutoEdge, MopAttachList,  
MopSelectByID, MopSelectBySG, MopClearAllSG,  
MopSelectByColor**

### **Prototype:**

**virtual void GetUIParam(meshUIParam uiCode, int &ret);**

### **Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

### **Parameters:**

**meshUIParam uiCode**

One of the following values;

**MuiSelByVert, MuiIgBack, MuiIgnoreVis, MuiSoftSel,  
MuiSSUseEDist, MuiSSEDist, MuiSSBack, MuiWeldBoxSize,  
MuiExtrudeType, MuiShowVNormals, MuiShowFNormals,  
MuiPolyThresh, MuiFalloff, MuiPinch, MuiBubble,  
MuiWeldDist, MuiNormalSize**

**int &ret**

The returned value.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void SetUIParam(meshUIParam uiCode, int val);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:**

**meshUIParam uiCode**

One of the following values;

**MuiSelByVert, MuiIgBack, MuiIgnoreVis, MuiSoftSel,  
MuiSSUseEDist, MuiSSEDist, MuiSSBack, MuiWeldBoxSize,  
MuiExtrudeType, MuiShowVNormals, MuiShowFNormals,  
MuiPolyThresh, MuiFalloff, MuiPinch, MuiBubble,  
MuiWeldDist, MuiNormalSize**

**int val**

The value to set.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void GetUIParam(meshUIParam uiCode, float &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit spline parameters from the command panel. Currently not in use.

**Parameters:****meshUIParam uiCode**

One of the following values;

**MuiSelByVert, MuiIgBack, MuiIgnoreVis, MuiSoftSel,  
MuiSSUseEDist, MuiSSEDist, MuiSSBack, MuiWeldBoxSize,  
MuiExtrudeType, MuiShowVNormals, MuiShowFNormals,  
MuiPolyThresh, MuiFalloff, MuiPinch, MuiBubble,  
MuiWeldDist, MuiNormalSize**

**float &ret**

The returned value.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetUIParam(meshUIParam uiCode, float val);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit spline parameters from the command panel. Currently not in use.

**Parameters:****meshUIParam uiCode**

One of the following values;

**MuiSelByVert, MuiIgBack, MuiIgnoreVis, MuiSoftSel,  
MuiSSUseEDist, MuiSSEDist, MuiSSBack, MuiWeldBoxSize,  
MuiExtrudeType, MuiShowVNormals, MuiShowFNormals,  
MuiPolyThresh, MuiFalloff, MuiPinch, MuiBubble,  
MuiWeldDist, MuiNormalSize**

**float val**

The value to set.

**Default Implementation:**

**{ }**

## Class MeshDeltaUserData

See Also: [Class Mesh](#), [Class MeshDelta](#), [Class MeshDeltaUser](#), [Class LocalModData](#), [Class Matrix3](#), [Class Point3](#), [Class Quat](#), [Class BitArray](#).

class MeshDeltaUserData

### Description:

This class is available in release 3.0 and later only.

This class provides a standard interface for modifiers and objects that use mesh deltas -- specifically Edit Mesh and Editable Mesh.

Both Edit Mesh and Editable Mesh have a current "state", which can be modified by MeshDeltas. In Editable Mesh, this "state" is an actual mesh, while in Edit Mesh, this is one **MeshDelta** per **LocalModData**. This class provides a standard interface to these: "MeshDeltaUser" and "MeshDeltaUserData".

### Methods:

public:

### Prototype:

```
virtual void ApplyMeshDelta(MeshDelta &md, MeshDeltaUser *mdu, TimeValue t)=0;
```

### Remarks:

This method applies the MeshDelta. Everything that happens in Edit Mesh and Editable Mesh goes through this method. Note that in Edit Mesh, the MeshDeltaUserData (EditMeshData) is separate from the MeshDeltaUser (EditMeshMod), though in Editable Mesh, EditTriObject subclasses from both of them.

There's essentially one mesh that can be edited per **MeshDeltaUserData**, so **ApplyMeshDelta** is the way to edit that mesh. ApplyMeshDelta typically handles adding Restore objects (if theHold.Holding()), clearing out any temporary local caches that are invalidated, and notifying the pipeline that the mesh has changed.

### Parameters:

**MeshDelta &md**

The mesh delta to apply.

**MeshDeltaUser \*mdu**

Points to the mesh delta user.

**TimeValue t**

The time to apply the mesh delta.

**Prototype:**

**virtual MeshDelta \*GetCurrentMDState();**

**Remarks:**

Returns a pointer to the MeshDelta object for this application of the Edit Mesh modifier. This is only non-NULL in Edit Mesh.

**Default Implementation:**

**{ return NULL; }**

**The following global function is not part of this class but is available for use:**

**Function:**

**void FindTriangulation(Mesh & m, int deg, int \*vv, int \*tri);**

**Remarks:**

This global function is available in release 3.0 and later only.

Finds a triangulation of an n-sided polygon using vertices in the specified mesh. As long as the vertices are coplanar, this algorithm will find a proper triangulation, even for nonconvex polygons.

**Parameters:**

**Mesh &m**

The mesh containing the vertices used in the polygon.

**int deg**

The size of the polygon.

**int \*vv**

The vertex indices of the polygon, in order around the perimeter. For instance, if deg is 5 and w points to an array containing (3, 6, 8, 0, 7), the polygon is presumed to have the outline described by m.verts[3], m.verts[6], m.verts[8], m.verts[0], and m.verts[7].

**int \*tri**

This is where the output is placed. Note that this should point to an array of size at least  $(deg-2)*3$ , to hold all the triangles. The values placed in this array are indices into the  $w$  array -- that is, given a 5-sided polygon, one triangle in this list might be (0,2,3), indicating you should use the 0th, 2nd, and 3rd elements of  $w$  to form the triangle. Put another way, to make a face from the  $n$ 'th triangle given by this array, you would set:

**$f.v[0] = w[tri[n*3+0]];$**

**$f.v[1] = w[tri[n*3+1]];$**

**$f.v[2] = w[tri[n*3+2]];$**

## Class VDataDelta

See Also: [Class Mesh](#), [Class PerData](#), [Class MeshDelta](#).

class VDataDelta

### Description:

This class is available in release 3.0 and later only.

VDataDelta is a way for a MeshDelta to keep track of per-vertex information. Like vertex selection, this information is explicitly set after all topological changes performed by the MeshDelta, so any active vertex data channels are always set to the size **outVNum()** for the related **MeshDelta**.

An example of this being used is in Edit Mesh, where you can assign or modify vertex weights. All these changes and assignments are stored in the Edit Mesh's main MeshDelta.

### Data Members:

public:

**PerData \*out;**

This is where the output vertex data is kept, if the given vertex data channel has been activated.

### Methods:

public:

### Prototype:

**VDataDelta();**

### Remarks:

Constructor. The data member **out** is set to NULL.

### Prototype:

**~VDataDelta();**

### Remarks:

Destructor. If **out** is allocated it is deleted.

### Prototype:

**void SetVNum(int nv, BOOL keep=FALSE);**

**Remarks:**

Sets the size of the output vertex data to the value specified.

**Parameters:**

**int nv**

The number of elements to allocate.

**BOOL keep=FALSE**

If TRUE previous values are kept (copied to the new storage); otherwise they are discarded.

**Prototype:**

**void Activate(int vnum, int vdID);**

**Remarks:**

If the output vertex data has not been allocated this method allocates it with the specified number of elements.

**Parameters:**

**int vnum**

The number of elements to allocate.

**int vdID**

The channel to allocate. One of the following values:

**VDATA\_SELECT**

**VDATA\_WEIGHT**

**Prototype:**

**void Set(int where, void \*data, int num=1);**

**Remarks:**

Sets the specified number of elements of vertex data at the location passed.

**Parameters:**

**int where**

The zero based index of the destination in the **out** array.

**void \*data**

The source data.

**int num=1**

The number of elements to set.

# Class MapDelta

See Also: [Class Mesh](#), [Class MeshDelta](#), [Template Class Tab](#).

class MapDelta

## Description:

This class is available in release 3.0 and later only.

This is an SDK class that represents some kind of change to a mesh map. This "delta" can include changes in map vertices and/or faces. It is always a subordinate part of a MeshDelta. Most of the time, the programmer does not need to worry about this class directly, but can let the parent MeshDelta do most of the work.

Note: You must **#include "MESHDLIB.H"** to use this class as it's not included by default by **MAX.H**.

## Methods Groups:

The hyperlinks below take you to the start of groups of related methods within the class:

[Initialization & Cleanup](#)

[Mesh Map Interaction](#)

[Composition and Operators](#)

[Characteristics](#)

[Basic Operations](#)

[Debugging](#)

## Data Members:

public:

**DWORD vnum**

The expected number of vertices in the input mesh

**DWORD fnum;**

The expected number of faces in the input mesh

**Tab<UVVertSet> vSet;**

This data member stores changes in the mapping vertices given as input. See class UVVertSet for more information. UVVertSets are stored in original map vertex ID order, and there is never more than one UVVertSet per original map vertex.

**Tab<Point3> vCreate;**

This data member stores mapping vertices newly created as part of the MapDelta. These are stored in the order created.

**Tab<TVFace> fCreate;**

This data member stores map faces newly created as part of the MapDelta. These are stored in the order created.

**Tab<FaceRemap> fRemap;**

This data member stores changes in which map vertices are used by existing map faces. See [Class FaceRemap](#) for more information. These are stored in original face order, and there is never more than one per original face.

**Methods:**

public:

**Initialization & Cleanup****Prototype:****MapDelta();****Remarks:**

Constructor. Initializes the MapDelta with empty tables and 0's for input mesh map size.

**Prototype:****void ClearAllOps(const Mesh & m);****Remarks:**

Clears out all existing map changes. Zeroes all the vCreate, vSet, etc tables.

**Prototype:****void SetInFNum(DWORD n);****Remarks:**

Sets the number of map faces in the input map. NOTE that if n is less than the current fnum, the data relating to the extra faces will be lost. (That is, if one of your face remaps is applied to face 32, and you SetInFNum to 30, that face remap will be lost, and will not be recovered if you later SetInFNum to 35.) It

is NOT necessary to call this method before applying this MapDelta to a smaller than expected Map.

**Parameters:**

**DWORD n**

The number of faces expected from the input mesh.

**Prototype:**

**void SetInVNum(DWORD n);**

**Remarks:**

Sets the number of map vertices in the input map. NOTE that if n is less than the current vnum, the data relating to the extra vertices will be lost. (That is, if one of your map vertex sets is applied to map vertex 32, and you SetInVNum to 30, that vertex set will be lost, and will not be recovered if you later SetInVNum to 35.) It is NOT necessary to call this method before applying this MapDelta to a smaller than expected Map.

**Parameters:**

**DWORD n**

The number of vertices expected from the input mesh.

## **Mesh Map Interaction**

**Prototype:**

**void Apply(UVVert \*tv, TVFace \*tf, DWORD inVNum, DWORD inFNum);**

**Remarks:**

Changes the given map by this MapDelta, in the following manner:

First, any maps that are supported by the MeshDelta but not by the mesh are assigned to the mesh in their default form. (Vertex colors are white, other maps are copies of the mesh vertices, and all have the same topology as the mesh.)

Next, any UNDEFINED mapping verts in the MeshDelta are filled in by FillInFaces.

Then the new vertices are added, creates first, followed by clones. The original vertices are then moved.

The faces are then modified, by applying all the FaceRemaps, FaceChanges, and FaceSmooths to the appropriate faces. New faces (in fCreate) are appended to the end of the face list.

Map changes are applied to all active maps, and map channels not supported by this MeshDelta are removed.

After all that is done, the vertices and faces marked in the vDelete and fDelete arrays are deleted.

Finally, the vertex data, vertex hide, and selections kept in the MeshDelta are applied to the result.

**Parameters:**

**UVVert \*tv**

The map vertex array to change. This should be allocated to handle all the new map vertices in the vCreate array.

**TVFace \*tf**

The map face array to change. This should be allocated to handle all the new map faces in the fCreate array.

**DWORD inVNum**

The actual number of map vertices (which doesn't have to match this MapDelta's vnum) in the input map.

**DWORD inFNum**

The actual number of map faces (which doesn't have to match this MapDelta's fnum) in the input map.

## **Composition & Operators**

See the class MeshDelta section on composition and operators for more information.

**Prototype:**

**MapDelta & operator\*=(MapDelta & from);**

**Remarks:**

Appends the given MapDelta to the current one.

**Parameters:**

**MapDelta & td**

The MapDelta to append. This MapDelta may be modified to make it suitable,

ie the vnum and fnum values will be set to the expected output of the current MapDelta if they don't already match. (This may result in the loss of some data – see "SetInVNum" and "SetInFNum" for more information.)

**Prototype:**

**MapDelta & operator=(MapDelta & td);**

**Remarks:**

Equality operator – makes this MapDelta just like the one given.

**Prototype:**

**DWORD ChangeFlags();**

**Remarks:**

Indicates what parts of a MapDelta could be changed if this MapDelta were appended to it. This is useful when backing up the MapDelta for Restore Objects. For instance, if you had a MapDelta with lots of face remaps, and you wanted to compose it with one that only added map vertices, there would be no reason to back up the remaps for an undo.

**Return Value:**

Returns some combination of the following flags, corresponding to the data members that would be changed:

**MDELTA\_VMOVE:** Indicates that the vSet array will be altered by this MapDelta.

**MDELTA\_VCREATE:** Indicates that the vCreate array will be altered by this MapDelta.

**MDELTA\_FREMAP:** Indicates that the fRemap array will be altered by this MapDelta.

**MDELTA\_FCREATE:** Indicates that the fCreate array will be altered by this MapDelta.

**Prototype:**

**void CopyMDChannels(MapDelta & from, DWORD channels);**

**Remarks:**

Copies the specified parts of the MapDelta. (Useful in combination with

ChangeFlags to create efficient Restore objects.)

**Parameters:**

**MapDelta & from**

The MapDelta to copy into this.

**DWORD channels**

Indicates the parts to copy – some combination of the following flags:

**MDELTA\_VMOVE:** Copy the vSet array.

**MDELTA\_VCREATE:** Copy the vCreate array.

**MDELTA\_FREMAP:** Copy the fRemap array.

**MDELTA\_FCREATE:** Copy the fCreate array.

**Characteristics**

The following methods give useful information about the MeshDelta.

**Prototype:**

**DWORD NumVSet(DWORD inVNum);**

**Remarks:**

Returns the number of map vertex sets that would be applied to a map with the specified number of map vertices. (If that number equals this MapDelta's vnum, this is simply vSet.Count().)

**Parameters:**

**DWORD inVNum**

The number of vertices in the input map we're inquiring about.

**Prototype:**

**DWORD outVNum();**

**Remarks:**

Returns the number of vertices in the output map, assuming that the input map is of the expected (vnum) size.

**Prototype:**

**DWORD outVNum(int inVNum);**

**Remarks:**

Returns the number of vertices in the output map, assuming that the input map has the specified number of map vertices.

**Parameters:**

**DWORD inVNum**

The number of map vertices expected in the input map.

**Prototype:**

**TVFace OutFace(TVFace \*mf, DWORD ff);**

**Remarks:**

Returns the specified map face as it would appear in the MapDelta output, taking into account any remaps.

**Parameters:**

**TVFace \*mf**

The input map face array.

**DWORD f**

The index of the face you want the output version of.

**Prototype:**

**DWORD RemapID(DWORD ff);**

**Remarks:**

Obtains the index of the fRemap entry that relates to this face.

**Parameters:**

**DWORD ff**

The map face index.

**Return Value:**

If there is such an entry, the index is returned, so fRemap[RemapID(ff)].fid == ff. If there is no remap record for this map face, the method returns UNDEFINED.

**Prototype:**

**DWORD IsRemapped(DWORD ff, DWORD vid);**

**Remarks:**

Tells whether the specified corner of the specified face has been remapped in this MapDelta.

**Parameters:****DWORD ff**

The map face index.

**DWORD vid**

The corner of the face – 0, 1, or 2.

**Return Value:**

If this corner has been remapped, it returns the vertex it's been remapped to. Otherwise, it returns UNDEFINED.

**Prototype:**

**DWORD SetID(DWORD i);**

**Remarks:**

Obtains the index of the vSet entry that relates to this vertex.

**Parameters:****DWORD i**

The map vertex index.

**Return Value:**

The index in the vSet array of the map vertex set corresponding to this vertex, or UNDEFINED if this map vertex has not been modified.

**Prototype:**

**bool IsCreate(DWORD i);**

**Remarks:**

Indicates whether the specified map vertex was created in this MapDelta.

**Parameters:****DWORD i**

The index in the output of the map vertex.

**Basic Operations**

These operations are the "building blocks" of MeshDeltas. All of them may be safely performed on MeshDeltas that are already quite complex. Those that accept DWORD indices require **output** mesh indices, as all operations are appended to the end of the existing delta.

**Prototype:**

**void Set(DWORD i, const UVVert & p);**

**Remarks:**

Sets an existing map vertex to the value given. (Note that if the same map vertex is set twice, the new set simply replaces the old one – there is never more than one UVVertSet in the vSet array for a single input map vertex.)

**Parameters:**

**int i**

The index of the map vertex to set.

**const UVVert & p**

The value to set the map vertex to.

**Prototype:**

**void Move(BitArray & sel, const UVVert & p);**

**Remarks:**

Sets the specified vertices to the value given. (Note that if the same map vertex is set twice, the new set simply replaces the old one – there is never more than one UVVertSet in the vSet array for a single input map vertex.)

**Parameters:**

**BitArray & sel**

Indicates which map vertices should be set.

**const UVVert & p**

The value to set the map vertex to.

**Prototype:**

**DWORD VCreate(UVVert \*v, int num=1);**

**Remarks:**

Creates new map vertices.

**Parameters:****UVVert \*v**

A pointer to an array of UVVerts representing the new map vertices.

**int num**

The size of the UVVert array.

**Return Value:**

The index (in the output map) of the first of these new map vertices.

**Prototype:****void FCreate(TVFace \*f, int num=1);****Remarks:**

Creates new map faces.

Note: MapDeltas must be kept up to date with the parent MeshDelta in all new face creations. See the MeshDelta method CreateDefaultMapFaces for details.

**Parameters:****TVFace \*f**

A pointer to an array of map faces to be added to the MapDelta.

**int num**

The size of the map face array.

**Prototype:****void FCreateDefault(int num=1);****Remarks:**

Creates new "default" map faces, where all the corners are UNDEFINED. (These are later filled in by a call to the parent MeshDelta's FillInFaces method.)

Note: MapDeltas must be kept up to date with the parent MeshDelta in all new face creations. See the MeshDelta method CreateDefaultMapFaces for details.

**Parameters:****int num**

The number of default faces to create.

**Prototype:**

```
void FCreateQuad(DWORD *t);
```

**Remarks:**

Creates 2 new faces, forming a quad.

Note: MapDeltas must be kept up to date with the parent MeshDelta in all new face creations. See the MeshDelta method CreateDefaultMapFaces for details.

**Parameters:**

```
DWORD *t
```

A pointer to an array of 4 map vertices to be used as corners of the quad.

**Prototype:**

```
DWORD FClone(TVFace & tf, DWORD remapFlags=0, DWORD *v=NULL);
```

**Remarks:**

Creates a new map face by copying (and optionally remapping) the face given.

Note: MapDeltas must be kept up to date with the parent MeshDelta in all new face creations. See the MeshDelta method CreateDefaultMapFaces for details.

**Parameters:**

```
TVFace & tf
```

The map face we wish to clone. (This is typically generated by the OutFace method.)

```
DWORD remapFlags=0
```

```
DWORD *v=NULL
```

If we wish to remap any of the corners of this map face while cloning, the appropriate flags and vertices should be passed in these last two arguments. v should point to an array of 3 map vertex indices, although the ones not marked as used by the remapFlags need not be set to anything in particular. See class FaceRemap for more information about face remapping.

**Prototype:**

```
void FRemap(FaceRemap & fr);
```

**Remarks:**

Adds a face remap to this MapDelta. If the face specified in the FaceRemap

already has a remap record, the two are combined. If the face specified is a face created by this MapDelta, the remap is applied directly to the fCreate entry instead of being stored in fRemap.

**Parameters:**

**FaceRemap & fr**

A FaceRemap that should be appended to this MapDelta.

**Prototype:**

**void FRemap(DWORD f, DWORD flags, DWORD \*v);**

**Remarks:**

Adds a face remap to this MapDelta. If the face specified already has a remap record, the two are combined. If the face specified is a face created by this MapDelta, the remap is applied directly to the fCreate entry instead of being stored in fRemap.

**Parameters:**

**DWORD f**

The face to remap.

**DWORD flags**

Face Remap flags – these indicate which vertices should be remapped. The possibilities are FR\_V0 (1), FR\_V1 (2), and FR\_V2 (4). (See class FaceRemap for more information.)

**DWORD \*v**

A pointer to the vertices to remap the face to use. Only the positions indicated in the remap flags need contain meaningful data.

Note that the vertices indicated here must be indexed by their positions after all of the current MeshDelta's creates and clones, but before any vertex deletes – essentially input-based indexing. Vertex index values of 0 through vnum-1 are considered to be the original mesh's vertices; values of vnum through vnum+vCreate.Count()-1 are considered to be this MeshDelta's newly created vertices; and values above this are cloned vertices.

**Prototype:**

**void FDelete(int offset, BitArray & fdel);**

**Remarks:**

Deletes the specified faces. This only affects the fCreate array, and should generally only be called by the parent MeshDelta's FDelete method to keep the face create arrays in sync.

**Parameters:****int offset**

Indicates what position in the fdel array corresponds to the first created face. (This is necessary since the BitArrays handed to MeshDelta::FDelete generally are based on the indexing after the previous MeshDelta::fDelete is applied. So this value is less than fnum if there was some previous deletion of original faces in the MeshDelta.)

**BitArray & fdel**

The faces to delete. The faces are indexed by their output mesh positions.

**Debugging****Prototype:**

```
void MyDebugPrint();
```

**Remarks:**

Prints out all the changes in this MapDelta to the DebugPrint window in Developer Studio.

## Class MeshTempData

See Also: [Class Mesh](#), [Class AdjEdgeList](#), [Class FaceClusterList](#), [Template Class Tab](#).

```
class MeshTempData : public BaseInterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This is a class for caching winged edge lists, face adjacency lists, face and edge clusters, vertex normals, and other derived data about a mesh.

There is a **SetMesh()** method to set the current mesh that the TempData is based on, then there's a series of methods to update the cache and return some sort of derived data. All of these methods follow the form:

### **DerivedData \*MeshTempData::DData (parameters);**

DerivedData is the container for the derived data requested (often a simple table, though there are some specialized classes returned from some methods). If the data has already been computed, the parameters are ignored and the cached data is returned. Otherwise, the data is computed from the parameters and the current mesh.

There are no procedures in place to detect changes in parameters or the mesh since the last time a method was called, so it's the calling routine's responsibility to free invalid structures. If you know that only certain pipeline channel, such as **GEOM\_CHANNEL**, have changed, you can use the **Invalidate(DWORD partsChanged)** method. (**GEOM\_CHANNEL** would free the distances-to-selected-vertices, for example, but not the **Adjacent Edge List**.)

In particular, there is no way for the **MeshTempData** to know when its mesh pointer is no longer valid, so it's vital that the calling routine clear the mesh (with **SetMesh(NULL)**) or stop using the **MeshTempData** when this happens.

All data members are private. They basically consist of a series of pointers which are initialized to NULL and then filled with allocated derived data as requested. There is also a NULL-initialized, private mesh pointer which is set with **SetMesh()**.

Editable Mesh and Edit Mesh both use this class to hold all the varieties of temporary, cached data they create -- examples are vertex normals and face clusters. This is called "ETTempData" in Editable Mesh and "EMTempData" in

Edit Mesh.

To use MeshTempData, just set it to your mesh and start asking for stuff:

```
MyAlgorithm (Mesh *m) {  
  MeshTempData mtd(m);  
  // Get Adjacent Edge List.  
  AdjEdgeList ae = mtd.AdjEList ();  
}
```

### **Methods Groups:**

The hyperlinks below take you to the start of groups of related methods within the class:

[Initialization and Class methods](#)

[Methods to Get Data](#)

[Data invalidation methods](#)

### **Data Members:**

public:

### **Initialization and Class methods**

#### **Prototype:**

```
MeshTempData();
```

#### **Remarks:**

Constructor. Sets all data members to NULL.

#### **Prototype:**

```
MeshTempData(Mesh *m);
```

#### **Remarks:**

Constructor. Sets the internal mesh pointer to the mesh passed.

#### **Parameters:**

```
Mesh *m
```

The mesh to set.

#### **Prototype:**

**~MeshTempData();**

**Remarks:**

Destructor. Frees all cached data.

**Prototype:**

**void SetMesh(Mesh \*m);**

**Remarks:**

Sets the internal mesh pointer to **m**.

**Parameters:**

**Mesh \*m**

Points to the mesh to set.

## **Methods to Get Data**

**Prototype:**

**AdjEdgeList \*AdjEList();**

**Remarks:**

Returns an adjacent edge list. See class **AdjEdgeList** for more information. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh.

**Prototype:**

**AdjFaceList \*AdjFList();**

**Remarks:**

Returns an adjacent face list. See class **AdjFaceList** for more information. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh.

**Prototype:**

**FaceClusterList \*FaceClusters();**

**Remarks:**

Returns a face cluster list, which groups selected faces into "clusters" for

transformation. See class **FaceClusterList** for more information. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh.

**Prototype:**

**EdgeClusterList \*EdgeClusters();**

**Remarks:**

Returns an edge cluster list, which groups selected edges into "clusters" for transformation. See class **EdgeClusterList** for more information. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh.

**Prototype:**

**Tab<DWORD> \*VertexClusters(DWORD sl);**

**Remarks:**

Returns an index of which cluster, if any, each vertex is in. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameter.

**Parameters:**

**DWORD sl**

Selection level. This should be either **MESH\_EDGE** or **MESH\_FACE**, to indicate whether the vertex cluster information should be based on edge or face clusters. Note that this parameter is ignored if there's already a vertex cluster cache.

**Return Value:**

A table of DWORD's is returned, one for each vertex. If (**\*VertexClusters(sl)**) [i] is UNDEFINED, vertex i is not in any cluster. Otherwise, the value for vertex i is the cluster index.

**Prototype:**

**Tab<Point3> \*ClusterNormals(DWORD sl);**

**Remarks:**

Returns average normals for each cluster. If cached, the cache is returned.

Otherwise a cache is allocated and computed from the current mesh and the parameter. Note that cluster centers and normals are computed and cached at the same time, when you call either method.

**Parameters:**

**DWORD sl**

Selection level. This should be either MESH\_EDGE or MESH\_FACE, to indicate whether the clusters we're talking about are the edge or face clusters. Note that this parameter is ignored if there's already a cluster normal cache.

**Return Value:**

A table of Point3's is returned, one for each cluster. The values are already normalized to length 1.

**Prototype:**

**Tab<Point3> \*ClusterCenters(DWORD sl);**

**Remarks:**

Returns mean centers for each cluster. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameter. Note that cluster centers and normals are computed and cached at the same time, when you call either method.

**Parameters:**

**DWORD sl**

Selection level. This should be either MESH\_EDGE or MESH\_FACE, to indicate whether the clusters we're talking about are the edge or face clusters. Note that this parameter is ignored if there's already a cluster center cache.

**Return Value:**

A table of Point3's is returned, one for each cluster.

**Prototype:**

**Matrix3 ClusterTM(int clust);**

**Remarks:**

Uses the current cluster center and normal caches to return the "objectspace to clusterspace" transform. This is the transform of the "local" axis in moving edge or face clusters in Edit(able) Mesh. If the cluster centers & normals have

not been cached, the identity matrix is returned; thus the control over whether this is an edge or face cluster is handled by the last call to ClusterCenters or ClusterNormals.

**Parameters:**

**int clust**

The cluster you want the transform for.

**Prototype:**

**Tab<Point3> \*VertexNormals();**

**Remarks:**

Returns a table of local average normals for vertices. This is equivalent to the average normals computed by the standalone function:

**void AverageVertexNormals(Mesh & mesh, Tab<Point3> & vnormals)**

If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh.

**Prototype:**

**Tab<float> \*VSWeight(BOOL useEdgeDist, int edgeIts, BOOL ignoreBack, float falloff, float pinch, float bubble);**

**Remarks:**

Returns Vertex Selection weights (for affect region). If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters. Weights are based on an Affect Region type falloff from the current selection.

**Parameters:**

**BOOL useEdgeDist**

If useEdgeDist is TRUE, the distance between vertices is computed along edges. If FALSE, it's computed directly through space.

**int edgeIts**

This indicates the maximum number of edges the algorithm may travel along in finding the distance between vertices. (Maximum path length.)

WARNING: If useEdgeDist is FALSE, this is an n-squared algorithm: it

compares every vertex not in the cluster with every vertex in it. If `useEdgeDist` is `TRUE`, the time it takes is proportional to the number of verts in the cluster times `edgeIts`.

### **BOOL ignoreBack**

If `TRUE`, vertices with a normal (as computed in `VertexNormals`) that points more than 90 degrees away from the average normal of the selection are not given any partial selections. They're either 1 if selected or 0 otherwise.

### **float falloff**

The limit distance of the effect. If `distance > falloff`, the function will always return 0.

### **float pinch**

Use this to affect the tangency of the curve near `distance=0`. Positive values produce a pointed tip, with a negative slope at 0, while negative values produce a dimple, with positive slope.

### **float bubble**

Use this to change the curvature of the function. A value of 1.0 produces a half-dome. As you reduce this value, the sides of the dome slope more steeply. Negative values lower the base of the curve below 0.

### **Return Value:**

Returns a table of float values, one per vertex, that are 1.0 if the vertex is in the current selection, 0.0 if it's more than `falloff` distance (or more than `edgeIts` edges, if (`useEdgeDist`)), and **`AffectRegionFunction(*SelectionDist(useEdgeDist, edgeIts), falloff, pinch, bubble)`** otherwise.

### **Prototype:**

```
Tab<float> *SelectionDist(BOOL useEdgeDist, int edgeIts);
```

### **Remarks:**

Computes the current distance of each vertex from the current selection. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters. The term "Selected verts" below refers to the vertices that are selected in the mesh's current selection level. (See the **Mesh** method **GetTempSel** for details.)

### **Parameters:**

### **BOOL useEdgeDist**

If TRUE, the distance between vertices is computed along edges. If FALSE, it's computed directly through space.

### **int edgeIts**

This indicates the maximum number of edges the algorithm may travel along in finding the distance between vertices. (Maximum path length.).

WARNING: If **useEdgeDist** is FALSE, this is an n-squared algorithm: it compares every nonselected vertex with every selected one. If **useEdgeDist** is TRUE, the time it takes is proportional to the number of selected vertices times edgeIts.

### **Return Value:**

A table consisting of one float value per vertex. If this value is 0, the vertex is either selected or on top of a selected vertex. Otherwise it represents the distance to the closest selected vertex. If **useEdgeDist** is TRUE, values of -1.0 are returned for vertices with no edgeIts-length path to a selected vertex.

### **Prototype:**

```
Tab<float> *ClusterDist(DWORD sl, int clustId, BOOL useEdgeDist, int edgeIts);
```

### **Remarks:**

Computes the current distance of each vertex from the specified cluster. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters.

### **Parameters:**

#### **DWORD sl**

Indicates whether we should use edges (MESH\_EDGE) or faces (MESH\_FACE) to construct the clusters, if needed.

#### **int clustId**

The index of the cluster we're measuring distance from.

#### **BOOL useEdgeDist**

If useEdgeDist is TRUE, the distance between vertices is computed along edges. If FALSE, it's computed directly through space.

#### **int edgeIts**

This indicates the maximum number of edges the algorithm may travel along

in finding the distance between vertices. (Maximum path length.)

**WARNING:** If **useEdgeDist** is FALSE, this is an n-squared algorithm: it compares every vertex not in the cluster with every vertex in it. If useEdgeDist is TRUE, the time it takes is proportional to the number of verts in the cluster times edgeIts.

**Return Value:**

A table consisting of one float value per vertex. If this value is 0, the vertex is either selected or on top of a vertex in the cluster. Otherwise it represents the distance to the closest selected vertex. If **useEdgeDist** is TRUE, values of -1.0 are returned for vertices with no edgeIts-length path to a vertex in the cluster.

**Prototype:**

**Tab<Point3> \*EdgeExtDir(Tab<Point3> \*edir, int extrusionType);**

**Remarks:**

Returns the direction each vertex should be going, after a topological edge extrusion, to handle the geometric extrusion. This should be obtained after applying a **MeshDelta::ExtrudeEdges()** to the mesh to obtain valid results. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters.

**Parameters:**

**Tab<Point3> \*edir**

This should be the edge direction table filled out by MeshDelta::ExtrudeEdges. It is necessary.

**int extrusionType**

This is one of **MESH\_EXTRUDE\_CLUSTER** or **MESH\_EXTRUDE\_LOCAL**, to indicate whether vertices should move according to cluster or local face normals.

**Return Value:**

A table of Point3's, one per vertex, representing the direction each vertex should move for further extrusion. The size of each nonzero entry is set to 1.

**Prototype:**

**Tab<Point3> \*FaceExtDir(int extrusionType);**

**Remarks:**

Returns the direction each vertex should be going, after a topological face extrusion, to handle the geometric extrusion. This should be obtained after applying a MeshDelta::ExtrudeFaces to the mesh to obtain valid results. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters.

**Parameters:**

**int extrusionType**

This is one of **MESH\_EXTRUDE\_CLUSTER** or **MESH\_EXTRUDE\_LOCAL**, to indicate whether vertices should move according to cluster or local face normals.

**Return Value:**

A table of Point3's, one per vertex, representing the direction each vertex should move for further extrusion. The size of each nonzero entry is set to 1.

**Prototype:**

**Tab<Point3> \*CurrentExtDir();**

**Remarks:**

This computes nothing; it merely returns the current extrusion direction cache, if any. The extrusion direction is controlled by the first call to EdgeExtDir or FaceExtDir since the last invalidation. If cached, the cache is returned. Otherwise a cache is allocated and computed from the current mesh and the parameters.

**Prototype:**

**Tab<Point3> \*OutlineDir(int extrusionType);**

**Remarks:**

This produces the "Outline" direction of all vertices, based on the current face selection. "Outlining" is the direction vertices move to move edges of the current face selection outward at a constant rate. They are not set to length 1, but rather to whatever "rate" best makes the outline edges movemost consistently, without changing their angles.

**Parameters:****int extrusionType**

This is one of MESH\_EXTRUDE\_CLUSTER or MESH\_EXTRUDE\_LOCAL, to indicate whether vertices should move according to cluster or local face normals.

**Prototype:**

**MeshChamferData \*ChamferData();**

**Remarks:**

Returns the cache of a ChamferData for use in the MeshDelta methods,

**void ChamferEdges (Mesh & m, BitArray eset, MeshChamferData &mcd, AdjEdgeList \*ae=NULL);**

**void ChamferMove (Mesh & m, MeshChamferData &mcd, float amount, AdjEdgeList \*ae=NULL);**

**void ChamferVertices (Mesh & m, BitArray vset, MeshChamferData &mcd, AdjEdgeList \*ae=NULL);**

Unlike other MeshTempData methods, this method makes no calculations based on the current mesh, but merely supplies a memory cache.

**Data Invalidation Methods:****Prototype:**

**void Invalidate(DWORD part);**

**Remarks:**

Invalidates all data based on the specified part of the mesh. In the following chart, the columns represent the channels GEOM\_CHANNEL (G), TOPO\_CHANNEL (T), SELECT\_CHANNEL (S), and SUBSEL\_TYPE\_CHANNEL (U).

X's indicate dependency of the specified data cache on the given channel.

**Method to get cache G T S U**

**AdjEList X**

**AdjFList X**

**FaceClusters X X**

**EdgeClusters X X**  
**VertexClusters X X X**  
**ClusterCenters X X X X**  
**ClusterNormals X X X X**  
**VertexNormals X X**  
**SelectionDist X X X X**  
**ClusterDist X X X X**  
**VSWeight X X X X**

The extrusion direction methods could also be said to be dependent on all four channels, but is currently handled separately in freeBevelInfo. ChamferData is handled in freeChamferData, and is not based on the cached mesh.

Sample use: Suppose you use a MeshDelta to modify a mesh, twice:

```
DoStuffToMesh (Mesh & m) {  
MeshTempData foo;  
foo.SetMesh (&m);  
MeshDelta md(m);  
md.Op1 (m, foo.AdjEList()); // insert op of choice here  
md.Apply (m);  
foo.Invalidate (md.PartsChanged ());  
md.ClearAllOps ();  
md.Op2 (m, foo.VSWeights ());  
md.Apply (m);  
foo.Invalidate (md.PartsChanged ());  
}
```

Only the parts of foo that are dependent on what was changed by the first meshdelta are freed. The other parts, if any, remain cached for further operations.

**Parameters:**

**DWORD part**

One or more of the following channels:

**GEOM\_CHANNEL, TOPO\_CHANNEL, SELECT\_CHANNEL,  
SUBSEL\_TYPE\_CHANNEL**

**Prototype:**

**void InvalidateDistances();**

**Remarks:**

Uncaches (frees) the distance dependent data returned by VSWeight, SelectionDist, and ClusterDist.

**Prototype:**

**void InvalidateAffectRegion();**

**Remarks:**

Frees the VSWeight data. This is useful, e.g., if the mesh has not changed, but you wish to change the falloff, pinch, or bubble parameters to get new vertex selection weights.

**Prototype:**

**void freeClusterDist();**

**Remarks:**

Mainly for internal use, this frees just the cluster distance data.

**Prototype:**

**void freeBevelInfo();**

**Remarks:**

Frees only the extrusion direction data.

**Prototype:**

**void freeChamferData();**

**Remarks:**

Frees only the chamfer data structure.

**Prototype:**

**void freeAll();**

**Remarks:**

Frees all cached data.

## Class MeshChamferData

See Also: [Class Mesh](#), [Class MeshDelta](#), [Template Class Tab](#).

class MeshChamferData

### Description:

This class is available in release 3.0 and later only.

This class contains all the data needed to move points as the user drags a chamfer. It's created by the topological change that happens at the start of the chamfer. It is used to maintain chamfer information between several **MeshDelta** methods. The strategy is this: The chamfer operation is divided into two parts, the topological change and a later geometric change. (This works well for EditableMesh, where the topology change is completed first, then apply a series of geometry changes as the user spins a spinner or drags a mouse. Each geometry change is undone before the next is applied, but the topology change only happens once.)

This class is filled in by the topological change with the "directions" for all the geometric and mapping vert changes:

### Data Members:

public:

**Tab<Point3> vdir;**

This table contains the directions of movement for each vertex, scaled in such a manner to produce a consistent chamfer.

**Tab<float> vmax;**

This table contains the limits of motion for each vertex - stopping the vertices at these limits will prevent them from crossing each other or over far edges.

**Tab<UVVert> \*mdir;**

For each active map channel **mp**, **mdir[mp]** represents the directions of movement of the map verts for that channel. (Map verts need to be moved as well, otherwise the maps get distorted.)

### Methods:

public:

### Prototype:

**MeshChamferData();**

**Remarks:**

Constructor. This sets **mdir** to NULL.

**Prototype:**

**MeshChamferData(const Mesh &m);**

**Remarks:**

Constructor.

**Parameters:**

**const Mesh &m**

The mesh to init this MeshChamferData object from, allocating the vertex and mapping vertex tables as appropriate.

**Prototype:**

**~MeshChamferData();**

**Remarks:**

Destructor. If **mdir** is allocated it is seleted.

**Prototype:**

**void InitToMesh(const Mesh &m);**

**Remarks:**

This method sets up a **MeshChamferData** based on a given mesh, allocating the vertex and mapping vertex tables as appropriate.

**Parameters:**

**const Mesh &m**

The Mesh to init from.

**Prototype:**

**void setNumVerts(int nv, bool keep=TRUE, int resizer=0);**

**Remarks:**

This method simply allocates the vdir and vmax tables, and initializes the new members of vmax to 0. This method can be applied to an existing **MeshChamferData** to reflect an increase in vertices by VClone or VCreate

operations.

**Parameters:**

**int nv**

The number of verts

**bool keep=TRUE**

TRUE to keep if resized; FALSE to discard.

**int resizer=0**

The number of elements the vdir and vmax tables are resized beyond their current size.

**The following methods are not part of the class, but are useful for debugging**

**Prototype:**

**DllExport void MeshChamferDataDebugPrint (MeshChamferData & mcd, int mapNum);**

**Description**

This function uses calls to DebugPrint() to output all the data in the specified MeshChamferData to the DebugPrint buffer during debug runs. It is available for programmers' use, providing easy access to MeshChamferData during development. It ought to be removed for release builds.

**Parameters:**

**MeshChamferData & mcd**

The MeshChamferData we want to investigate.

**int mapNum**

The number of map channels in the Mesh associated with this MeshChamferData. (For historical reasons, this information is not kept in the MeshChamferData class.) Generally this is retrieved with a call to Mesh::getNumMaps().

## Class EdgeClusterList

See Also: [Class Mesh](#).

class EdgeClusterList

### Description:

This class is available in release 3.0 and later only.

This is a list of edge "clusters" for a given mesh. A typical application would be in Edit(able) Mesh, where the user has selected a two separate groups of edges on different parts of the mesh and wants to extrude them both, or rotate both around their local centers. Each "cluster" is a contiguous group of selected edges. Like AdjEdgeLists and AdjFaceLists, this class is only defined in relation to some mesh.

Note: for construction of this list, an edge is considered selected on both sides if it's selected on either. If you select the diagonal on top of a box, you probably only selected one of (face 2, edge 2 = 8) or (face 3, edge 2 = 11). But edges 8 and 11 will both be in the same cluster.

### Data Members:

public:

#### **DWORDTab clust;**

The cluster IDs of all the edges -- this table has size mesh::numFaces\*3. clust[i] is UNDEFINED if edge i is not in any cluster (ie is totally unselected).

#### **DWORD count;**

The number of clusters.

### Methods:

public:

### Prototype:

**EdgeClusterList(Mesh &mesh, BitArray &esel, AdjEdgeList &adj);**

### Remarks:

Constructor.

Creates an edge cluster list from the current selection. All adjacent selected edges are grouped into the same cluster.

**Parameters:**

**Mesh &mesh**

The mesh associated with this EdgeClusterList.

**BitArray &esel**

The bit array containing the edge selection data for the mesh.

**AdjEdgeList &adj**

The adjacent edge list for the mesh.

**Prototype:**

**DWORD ID(int f, int e) {return clust[f\*3+e];};**

**Remarks:**

Returns the cluster ID for face f, edge e.

**Parameters:**

**int f**

The index of the face in the mesh.

**int e**

The index of the edge in the mesh.

**Prototype:**

**void MakeVertCluster(Mesh &mesh, Tab<DWORD> &vclust);**

**Remarks:**

Creates a list of cluster IDs for vertices.

**Parameters:**

**Mesh &mesh**

The mesh associated with this EdgeClusterList.

**Tab<DWORD> & vclust**

This is where the output goes: vclust is set to size mesh.numVerts, and the value of each entry in this table tells which cluster the vertex has been assigned to, based on the edges it's on. If vertex "v" is not in any clusters (ie none of the edges that use it are in any clusters), vclust[v] is UNDEFINED.

**Prototype:**

```
void GetNormalsCenters(Mesh &mesh, Tab<Point3> & norm,  
Tab<Point3> & ctr);
```

**Remarks:**

This method extracts normal and center information for the various clusters of the mesh.

**Parameters:**

**Mesh &mesh**

The mesh to evaluate.

**Tab<Point3> & norm**

This table has its sizes set to the number of clusters in the cluster list. Normals are computed as the normalized average of the area-normal vectors of all faces in the cluster.

**Tab<Point3> & ctr**

This table has its sizes set to the number of clusters in the cluster list. Centers are the average location of the face centers or edge centers -- thus a point on three faces or edges in the same cluster has more weight than a point on one face in the cluster.

**Prototype:**

```
DWORD operator[](int i);
```

**Remarks:**

Access operator. Returns the cluster ID for edge i (indexed as 3\*face+edge).

**The following functions are not part of a class but are available for use:**

**Function:**

```
float AffectRegionFunction(float dist, float falloff, float pinch, float  
bubble);
```

**Remarks:**

This function is available in release 3.0 and later only.

This is the standard affect region function, based on a distance and the three affect region parameters (same as the editable mesh).

This function is a cubic curve which returns 1 at distance 0, 0 if distance is greater than falloff, and other values for distance between 0 and falloff. To "see" this function graphed, look at the curve in the Soft Selection parameters in Edit Mesh, Editable Mesh, Mesh Select, or Volume Select. This function currently is constructed as follows:

```
float u = ((falloff - dist)/falloff);  
float u2 = u*u, s = 1.0f-u;  
return (3*u*bubble*s + 3*u2*(1.0f-pinch))*s + u*u2;"
```

#### **Parameters:**

##### **float dist**

The distance to the selection. The method for computing this distance is up to the developer; for example in Mesh Select, it's the distance to the nearest selected vertex, while in Volume Select (with a box or sphere selection region) it's the distance to the selection volume.

##### **float falloff**

The limit distance of the effect. If distance > falloff, the function will always return 0.

##### **float pinch**

Use this to affect the tangency of the curve near distance=0. Positive values produce a pointed tip, with a negative slope at 0, while negative values produce a dimple, with positive slope.

##### **float bubble**

Use this to change the curvature of the function. A value of 1.0 produces a half-dome. As you reduce this value, the sides of the dome slope more steeply. Negative values lower the base of the curve below 0.

#### **Return Value:**

Returns the strength of the Affect Region function at the given distance. (In selection modifiers, this is the "soft selection" amount, the amount it's considered selected. A vertex at a distance with a return value of .25, for instance, will be affected 1/4 as strongly in a deformation as a fully selected vertex.)

#### **Function:**

```
void MatrixFromNormal(Point3& normal, Matrix3& mat);
```

**Remarks:**

This function is available in release 3.0 and later only.

This function creates a matrix with the normal as a Z-axis. The X and Y axes are chosen arbitrarily.

**Parameters:****Point3& normal**

The input normal is specified here.

**Matrix3& mat**

The output matrix.

**Function:**

```
void AverageVertexNormals(Mesh & mesh, Tab<Point3> & vnormals);
```

**Remarks:**

This function is available in release 3.0 and later only.

This function creates vertex normals that are weighted averages of faces using each vertexSmoothing groups are not used in these computations -- the normals are those you would expect with a totally smooth mesh.

**Parameters:****Mesh & mesh**

The mesh whose average vertex normals are computed.

**Tab<Point3> & vnormals**

The output vertex normals. . This will be set to size **mesh.numVerts**.

**Function:**

```
Point3 AverageSelVertNormal(Mesh& mesh);
```

**Remarks:**

This function is available in release 3.0 and later only.

This function computes and returns the average normal of a group of selected vertices.

**Parameters:****Mesh& mesh**

The mesh to check. The function uses **mesh.vertSel** to check for selected verts.

**Function:**

**Point3 AverageSelVertCenter(Mesh& mesh);**

**Remarks:**

This function is available in release 3.0 and later only.

This function computes and returns the average center of a group of selected vertices.

**Parameters:**

**Mesh& mesh**

The mesh to check. The function uses **mesh.vertSel** to check for selected verts.

**Function:**

**void DeselectHiddenFaces(Mesh &mesh);**

**Remarks:**

This function is available in release 3.0 and later only.

Removes hidden faces from the **mesh.faceSel** selection array.

**Parameters:**

**Mesh& mesh**

The mesh to check.

**Function:**

**void DeselectHiddenEdges(Mesh &mesh);**

**Remarks:**

This function is available in release 3.0 and later only.

This function removes edges on hidden faces from the **mesh.edgeSel** selection array.

**Parameters:**

**Mesh& mesh**

The mesh to check.

**Function:**

**void HiddenFacesToVerts(Mesh &mesh, BitArray &alsoHide);**

**Remarks:**

This function is available in release 3.0 and later only.

This function hides vertices that are only used by hidden faces. If **alsoHide** has size **mesh.numVerts**, it is used to indicate other vertices that should also be hidden. Note that passing **mesh.vertHide** as **alsoHide** will NOT WORK, as mesh.vertHide is overwritten before alsoHide is read.

**Parameters:****Mesh &mesh**

The mesh to check.

**BitArray &alsoHide**

If specified, this is used to indicate other vertices that should also be hidden.

**Function:**

**void SelectionDistance(Mesh & mesh, float \*selDist);**

**Remarks:**

This function is available in release 3.0 and later only.

This function computes distances from selected vertices (as indicated by **mesh.VertexTempSel()**) to non-selected ones.

NOTE: This is an order-of-n-squared algorithm. Each unselected vert is compared with each selected vert. So, if you have a mesh with 1000 sel verts and 1000 unsel verts, this involves a million compares.

**Parameters:****Mesh & mesh**

The mesh to check.

**float \*selDist**

This is assumed to be a float array of size **mesh.numVerts**. It is set to -1 for all verts if there is no selection. Otherwise, selected vertices have a value of 0, and nonselected vertices have the distance to the nearest selected vertex.

**Function:**

```
void SelectionDistance(Mesh & mesh, float *selDist, int iters,  
AdjEdgeList *ae=NULL);
```

**Remarks:**

This function is available in release 3.0 and later only.

This function computes distances from selected vertices (as indicated by **mesh.VertexTempSel()**) to non-selected ones along edge paths. **selDist** is assumed to be a float array of size **mesh.numVerts**. **selDist** is set to -1 for all verts if there is no selection. Otherwise, selected vertices have **selDist** value 0; non-selected vertices that are "iters" or fewer edges away from a selected vertex are assigned the shortest edge-path distance to a selected vertex; and non-selected vertices that are more than **iters** edges away are set to -1. The **AdjEdgeList** is computed by the algorithm if the one passed is NULL; otherwise you can save time by passing a cached one in.

This is NOT an n-squared algorithm like the one above. It's more a sort of order-of-n-times-(iters-squared).

**Parameters:**

**Mesh & mesh**

The mesh to check.

**float \*selDist**

An array of floats of size **mesh.numVerts**.

**int iters**

If 0, Selection Distance is computed from each vertex to the nearest selected vertex, regardless of topology. This is a VERY EXPENSIVE ALGORITHM, which takes almost 4 times as long for twice as many vertices. If iters is non-zero, it represents the number of edges one should "travel" in trying to find the nearest selected vertex -- this means that it only takes twice as long for twice as many verts. (This is like the Edge Distance parameter in EMesh's Soft Selection dialog.) If iters is 0, ae is irrelevant and may be left as NULL. If iters is nonzero, an Adjacent Edge List is required, and will be computed internally from the mesh if ae is NULL. (If you've got an AdjEdgeList for this mesh handy, pass it in, otherwise don't worry about it.)

Note also that if iters is nonzero, the distance is computed along the edges, not directly through space. If there is no selected vertex within an iters-length path, a vertex is assigned a 0 selection value.

**AdjEdgeList \*ae=NULL**

The optional adjacent edge list.

**Function:**

**void ClustDistances(Mesh & mesh, DWORD numClusts, DWORD \*vclust, Tab<float> \*\*clustDist);**

**Remarks:**

This function is available in release 3.0 and later only.

Computes distances from nonselected vertices in the mesh to each of the vertex clusters. This is a VERY EXPENSIVE ALGORITHM, which takes almost 4 times as long for twice as many vertices.

Preparation for this method would typically look like:

```
// given Mesh msh, FaceClusterList fclust:  
Tab<DWORD> vclust;  
fclust.MakeVertCluster (msh, vclust);  
Tab<float> ** clustDist;  
clustDist = new (Tab<float> *)[fclust.count];  
for (int i=0; i<fclust.count; i++) clustDist[i] = new Tab<float>;  
ClustDistances (mesh, fclust.count, vclust.Addr(0), clustDist);
```

Then (\*clustDist[c])[v] would give the distance from vertex v in the mesh to the vertices of cluster c.

**Parameters:**

**Mesh &mesh**

The mesh the clusters are based on.

**DWORD numClusts**

The number of clusters in this mesh.

**DWORD \*vclust**

A pointer to an array of vertex cluster IDs. Typically this is a pointer to the data in the table created by EdgeClusterList::GetVertClusters or FaceClusterList::GetVertClusters.

**Tab<float> \*\*clustDist**

This is an array of <numClusts> pointers to tables that will be used to store distances from various clusters. Each table will be set to the size of

mesh.numVerts and filled with distances to the cluster that table represents.

**Function:**

```
void ClustDistances(Mesh & mesh, DWORD numClusts, DWORD  
*vclust, Tab<float> **clustDist, int iters, AdjEdgeList  
*ae=NULL);
```

**Remarks:**

This function is available in release 3.0 and later only.

Computes distances from nonselected vertices in the mesh to each of the vertex clusters. Unlike the other version which doesn't have an iters or ae parameter, this is a linear algorithm which computes distance along a finite number of edges.

Preparation for this method would typically look like:

```
// given Mesh msh, FaceClusterList fclust:  
Tab<DWORD> vclust;  
fclust.MakeVertCluster (msh, vclust);  
Tab<float> ** clustDist;  
clustDist = new (Tab<float> *)[fclust.count];  
for (int i=0; i<fclust.count; i++) clustDist[i] = new Tab<float>;  
ClustDistances(mesh, fclust.count, vclust.Addr(0), clustDist);
```

Then (\*clustDist[c])[v] would give the distance from vertex v in the mesh to the vertices of cluster c.

**Parameters:**

**Mesh & mesh**

The mesh the clusters are based on.

**DWORD numClusts**

The number of clusters in this mesh.

**DWORD \*vclust**

A pointer to an array of vertex cluster IDs. Typically this is a pointer to the data in the table created by EdgeClusterList::GetVertClusters or FaceClusterList::GetVertClusters.

**Tab<float> \*\*clustDist**

This is an array of <numClusts> pointers to tables that will be used to store

distances from various clusters. Each table will be set to the size of mesh.numVerts and filled with distances to the cluster that table represents.

**int iters**

The maximum number of edges to travel along looking for a vertex in the given cluster.

**AdjEdgeList \*ae=NULL**

Edge length computations require an adjacent edge list. If you don't pass one in this parameter, it'll have to construct its own from the mesh.

## Class UVWMapper

See Also: [Class Mesh](#), [Class Matrix3](#), [Class Point3](#).

class UVWMapper

### Description:

This class is available in release 3.0 and later only.

Prior to release 3.0, developers could implement **Object::ApplyUVWMap()** in their objects, but didn't have access to the algorithm 3ds max uses internally to turn the mapping types (MAP\_BOX, MAP\_PLANE, etc) into an actual vertex-to-mapping-coordinate function. This class now makes this available.

The constructors for the class initialize the data members with information about the mapping desired. The main method, **MapPoint()**, maps a point in object space into the UVW map defined by this mapper.

Note: **typedef Point3 UVVert;**

### Data Members:

public:

#### **int type;**

The mapping type. One of the following values:

**MAP\_PLANAR**

**MAP\_CYLINDRICAL**

**MAP\_SPHERICAL**

**MAP\_BALL**

**MAP\_BOX**

**MAP\_FACE**

#### **int cap;**

This is used with **MAP\_CYLINDRICAL**. If nonzero, then any face normal that is pointing more vertically than horizontally will be mapped using planar coordinates.

#### **float utile;**

Number of tiles in the U direction.

#### **float vtile;**

Number of tiles in the V direction.

**float wtile;**

Number of tiles in the W direction.

**int uflip;**

If nonzero the U values are mirrored.

**int vflip**

If nonzero the V values are mirrored.

**int wflip;**

If nonzero the W values are mirrored.

**Matrix3 tm;**

This defines the mapping space. As each point is mapped, it is multiplied by this matrix, and then it is mapped.

**Methods:**

public:

**Prototype:**

**UVWMapper();**

**Remarks:**

Constructor. The data members are initialized as follows:

**type = MAP\_BOX;**

**utile = 1.0f;**

**vtile = 1.0f;**

**wtile = 1.0f;**

**uflip = 0;**

**vflip = 0;**

**wflip = 0;**

**cap = 0;**

**tm.IdentityMatrix();**

**Prototype:**

**UVWMapper(int type, const Matrix3 &tm, int cap=FALSE, float  
utile=1.0f, float vtile=1.0f, float wtile=1.0f,int uflip=FALSE, int  
vflip=FALSE, int wflip=FALSE);**

**Remarks:**

Constructor. The data members are initialized to the values passed.

**Prototype:**

**UVWMapper(UVWMapper& m);**

**Remarks:**

Constructor. The data members are initialized from the UVWMapper passed.

**Prototype:**

**UVVert MapPoint(Point3 p, const Point3 & norm, int \*nan=NULL);**

**Remarks:**

This method maps a point in object space into the UVW map defined by this mapper. This gives the UVW coordinates for the specified point according to this mapper's mapping scheme.

**Parameters:****Point3 p**

The location of a vertex, i.e. the point being mapped. This point should NOT be transformed by the UVWMapper's tm, as this happens internally.

**const Point3 & norm**

The direction of the surface normal at p. This information is only required for types MAP\_BOX or MAP\_CYLINDRICAL. See the method **NormalMatters()** below.

**int \*nan=NULL**

If non-NULL, this points to an int which should be set to FALSE if this mapping is good for all faces using this vertex, or TRUE if different faces should have different mapping coordinates. This is generally set to TRUE more often than absolutely necessary to make sure nothing is missed.

**Return Value:**

The mapped point.

**Prototype:**

**UVVert TileFlip(UVVert uvw);**

**Remarks:**

Applies the UVWMap's tile and flip parameters to the given UVVert, and returns the result..

**Parameters:**

**UVVert uvw**

The input UVVert.

**Return Value:**

The modified UVVert.

**Prototype:**

**int MainAxis(const Point3 & n);**

**Remarks:**

This method indicates which direction the given vector "chiefly points", after vector transformation by the UVWMapper's transform.

**Parameters:**

**const Point3 & n**

The input vector whose main axis is determined.

**Return Value:**

One of the following values:

**0:** tm.VectorTransform(n) points mainly in the +x direction.

**1:** tm.VectorTransform(n) points mainly in the +y direction.

**2:** tm.VectorTransform(n) points mainly in the +z direction.

**3:** tm.VectorTransform(n) points mainly in the -x direction.

**4:** tm.VectorTransform(n) points mainly in the -y direction.

**5:** tm.VectorTransform(n) points mainly in the -z direction.

**Prototype:**

**bool NormalMatters();**

**Remarks:**

This method lets you know whether the current mapping type uses the normal information. If FALSE, it doesn't matter what value you pass as a normal to MapPoint. If TRUE, the MainAxis of the normal is used to determine the

mapping.

# Class IMeshSelect

See Also: [Class Mesh](#), [Class LocalModData](#), [Class IMeshSelectData](#).

class IMeshSelect

## Description:

This class is available in release 2.0 and later only.

This class provides access to selection data for the Mesh Select Modifier, Editable Mesh and Edit Mesh modifier.

To get a pointer to this interface given a pointer to a modifier or editable mesh object, use the following macro (defined in **ANIMTBL.H**). Using this macro, given any Animatable, it is easy to ask for the interface.

```
#define GetMeshSelectInterface(anim) ((IMeshSelect*)anim->GetInterface(I_MESHSELECT))
```

A plug-in developer may use this macro as follows:

```
IMeshSelect *ims = GetMeshSelectInterface(anim);
```

This return value will either be NULL or a pointer to a valid Mesh Select interface.

## Methods:

### Prototype:

```
virtual DWORD GetSelLevel()=0;
```

### Remarks:

Returns the current level of selection for the modifier.

### Return Value:

One of the following values:

**IMESHSEL\_OBJECT**: Object level.

**IMESHSEL\_VERTEX**: Vertex level.

**IMESHSEL\_FACE**: Face level.

**IMESHSEL\_EDGE**: Edge level.

### Prototype:

```
virtual void SetSelLevel(DWORD level)=0;
```

**Remarks:**

Sets the selection level of the modifier.

**Parameters:****DWORD level**

One of the following values:

**IMESHSEL\_OBJECT**: Object level.

**IMESHSEL\_VERTEX**: Vertex level.

**IMESHSEL\_FACE**: Face level.

**IMESHSEL\_EDGE**: Edge level.

**Prototype:**

**virtual void LocalDataChanged()=0;**

**Remarks:**

This method must be called when the **LocalModData** of the modifier is changed. Developers can use the methods of **IMeshSelectData** to get and set the actual selection for vertex, face and edge. When a developers does set any of these selection sets this method must be called when done.

**Prototype:**

**virtual BOOL HasWeightedVertSel();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if this modifier or object has weighted vertex selection data (Soft Selection data), FALSE if not.

**Default Implementation:**

**{ return FALSE; }**

**Prototype:**

**virtual BOOL CanAssignWeightedVertSel();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if this modifier or object can assign weighted vertex selection

data; FALSE if it cannot.

**Default Implementation:**

```
{ return FALSE; }
```

## Class IMeshSelectData

See Also: [Class ModContext](#), [Class BitArray](#), [Class IMeshSelect](#), [Class Interface](#), [Class GenericNamedSelSetList](#).

class IMeshSelectData

### Description:

This class is available in release 2.0 and later only.

When a developer gets the **LocalModData** from the **ModContext** of the Mesh Select Modifier or Edit Mesh Modifier, they may cast it to this class and use these methods. They may be used to get/set the vert/face/edge selection state of the modifier. This class also provides access to the named sub-object selection sets.

To get a pointer to this interface given a pointer to a modifier use the following macro (defined in **ANIMTBL.H** ). Using this macro, given any Animatable, it is easy to ask for the interface.

```
#define GetMeshSelectDataInterface(anim)  
((IMeshSelectData*)anim->GetInterface(I_MESHSELECTDATA))
```

A plug-in developer may use this macro as follows:

```
IMeshSelectData *imsd = GetMeshSelectDataInterface(anim);
```

This return value will either be NULL or a pointer to a valid Mesh Select Data interface.

### Methods:

#### Prototype:

```
virtual BitArray GetVertSel()=0;
```

#### Remarks:

Returns a **BitArray** that reflects the current vertex selection. There is one bit for each vertex. Bits that are 1 indicate the vertex is selected.

#### Prototype:

```
virtual BitArray GetFaceSel()=0;
```

#### Remarks:

Returns a **BitArray** that reflects the current face selection. There is one bit

for each face. Bits that are 1 indicate the face is selected.

**Prototype:**

**virtual BitArray GetEdgeSel()=0;**

**Remarks:**

Returns a **BitArray** that reflects the current edge selection. There is one bit for each edge. Bits that are 1 indicate the edge is selected.

**Prototype:**

**virtual void SetVertSel(BitArray &set, IMeshSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the vertex selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each vertex. Bits that are 1 indicate the vertex is selected.

**IMeshSelect \*imod**

This parameter is available in release 3.0 and later only.

Points to the IMeshSelect instance (generally this is a modifier).

**TimeValue t**

This parameter is available in release 3.0 and later only.

The current time at which the call is made.

**Prototype:**

**virtual void SetFaceSel(BitArray &set, IMeshSelect \*imod, TimeValue t)=0;**

**Remarks:**

Sets the face selection of the modifier.

**Parameters:**

**BitArray &set**

There is one bit for each face. Bits that are 1 indicate the face is selected.

### **IMeshSelect \*imod**

This parameter is available in release 3.0 and later only.

Points to the IMeshSelect instance (generally this is a modifier).

### **TimeValue t**

This parameter is available in release 3.0 and later only.

The current time at which the call is made.

### **Prototype:**

```
virtual void SetEdgeSel(BitArray &set, IMeshSelect *imod,  
TimeValue t)=0;
```

### **Remarks:**

Sets the edge selection of the modifier.

### **Parameters:**

#### **BitArray &set**

There is one bit for each edge. Bits that are 1 indicate the edge is selected.

#### **IMeshSelect \*imod**

This parameter is available in release 3.0 and later only.

Points to the IMeshSelect instance (generally this is a modifier).

#### **TimeValue t**

This parameter is available in release 3.0 and later only.

The current time at which the call is made.

### **Prototype:**

```
virtual GenericNamedSelSetList &GetNamedVertSelList()=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to an instance of **GenericNamedSelSetList** used for storing vertex level named selection sets. This class provides access to and the ability to manipulate a list of named selection sets.

### **Prototype:**

```
virtual GenericNamedSelSetList &GetNamedEdgeSelList()=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to an instance of **GenericNamedSelSetList** used for storing edge level named selection sets. This class provides access to and the ability to manipulate a list of named selection sets.

**Prototype:**

```
virtual GenericNamedSelSetList &GetNamedFaceSelList()=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to an instance of **GenericNamedSelSetList** used for storing face level named selection sets. This class provides access to and the ability to manipulate a list of named selection sets.

**Prototype:**

```
virtual void GetWeightedVertSel(int nv, float *sel) {};
```

**Remarks:**

This method is available in release 3.0 and later only.

Retrieves the weighted vertex selections data (Soft Selection data).

**Parameters:**

**int nv**

The number of vertices.

**float \*sel**

An array of floats to store the results.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetWeightedVertSel(int nv, float *sel, IMeshSelect *imod, TimeValue t);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the weighted vertex selection data (Soft Selection data) to the values passed.

**Parameters:**

**int nv**

The number of vertices.

**float \*sel**

An array of floats with the data.

**IMeshSelect \*imod**

Points to the IMeshSelect object.

**TimeValue t**

The time at which to set the data.

**Default Implementation:**

```
{}
```

## Class View

See Also: [Class GeomObject](#), [Class Interface](#), [Class Control](#), [Class Matrix3](#), [Class Point3](#).

```
class View : public InterfaceServer
```

### Description:

This class is passed in to **GeomObject::GetRenderMesh()** to allow objects to do view dependent rendering. It is also passed to **Control::EvalVisibility()**. For example particle systems use this to have the particles exactly face the camera (if this option is enabled). If **GetRenderMesh()** is called by the renderer, the methods of this class are implemented by the system. If a plug-in is calling this method, they must implement these methods. The sample code below shown a null implementation that may be used if a viewport is not involved:

```
class NullView : public View {
public:
    Point2 ViewToScreen(Point3 p)
        { return Point2(p.x,p.y); }
    NullView() {
        worldToView.IdentityMatrix();
        screenW=640.0f; screenH = 480.0f;
    }
};
```

### Data Members:

```
public:
```

```
float screenW, screenH;
```

These hold the screen dimensions in pixels for width and height.

```
Matrix3 worldToView;
```

A transformation matrix from world into view space. This is into the camera's space.

```
int projType;
```

This data member is available in release 2.0 and later only.

The view projection type: **0** is perspective, **1** is parallel.

**float fov;**

This data member is available in release 2.0 and later only.

The field of view in radians.

**float pixelSize;**

This data member is available in release 2.0 and later only.

The pixel size setting.

**Matrix3 affineTM;**

This data member is available in release 2.0 and later only.

This is the world to camera transformation matrix.

**DWORD flags;**

This data member is available in release 3.0 and later only.

The following flag is defined.

**RENDER\_MESH\_DISPLACEMENT\_MAP**

Indicates that Displacement Mapping is enabled. Note that this flag should be tested, and not **Interface::GetRendDisplacement()**, because the values may not be the same (for instance when rendering in the Materials Editor).

**Methods:****Prototype:****virtual Point2 ViewToScreen(Point3 p)=0;****Remarks:**

This method is used to convert a point in view space to screen space. This includes any perspective projection.

**Parameters:****Point3 p**

The point in view space.

**Return Value:**

The point in screen space (in pixel coordinates).

**Prototype:****virtual BOOL CheckForRenderAbort();**

**Remarks:**

This method is available in release 3.0 and later only.

This method should be used by **GetRenderMesh()** implementations that require a lot of processing time. This allows these processes to be interrupted by the user. An example of this in use is the extensive computations done for displacement mapping. These may be interrupted by the user during a render.

So, any implementation of **GetRenderMesh()** which takes a long time should periodically call this method to see if the user has canceled the render

**Return Value:**

Returns TRUE iff user has cancelled; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

## Class SpecialFX

See Also: [Class ReferenceTarget](#), [Class SFXParamDlg](#), [Class IRendParams](#), [Class Atmospheric](#), [Class Effect](#), [Class AppendGizmoRestore](#), [Class DeleteGizmoRestore](#).

```
class SpecialFX : public ReferenceTarget
```

### Description:

This class is available in release 3.0 and later only.

This is the base class for Atmospheric, Renderer Effect, and Shader Plug-Ins. It contains a few methods common to each of those plug-in classes.

### Data Members:

public:

**TSTR name;**

This is the name which appears in Track View.

### Methods:

public:

### Prototype:

**virtual BOOL Active(TimeValue t);**

### Remarks:

Implemented by the Plug-In.

Returns TRUE if the effect is active; otherwise FALSE.

### Parameters:

**TimeValue t**

The time at which to check.

### Default Implementation:

```
{ return FALSE; }
```

### Prototype:

**virtual TSTR GetName();**

### Remarks:

Implemented by the Plug-In.

This method is used to retrieve the name for the plug-in. This name will appear in the track view and the list of current atmospheric or rendering effects.

**Prototype:**

**virtual void Update(TimeValue t, Interval& valid);**

**Remarks:**

Implemented by the Plug-In.

This method is called once per frame when the renderer begins. This gives the atmospheric or rendering effect the chance to cache any values it uses internally so they don't have to be computed on every frame.

**Parameters:**

**TimeValue t**

The current time of the call.

**Interval& valid**

The validity interval of the cache created by the plug-in. The plug-in may set this for its own use. The plug-in can then check if the cache is up to date and update it if not.

**Prototype:**

**virtual SFXParamDlg \*CreateParamDialog(IRendParams \*ip);**

**Remarks:**

This method is available in release 4.0 and later only.

This method creates and returns a new instance of a class derived from **SFXParamDlg** to manage the user interface. This put up a modal dialog that lets the user edit the plug-ins parameters.

**Parameters:**

**IRendParams \*ip**

This is the interface given to the plug-in so it may display its parameters.

**Default Implementation:**

**{ return NULL; }**

**Prototype:**

```
virtual BOOL SetDlgThing(SFXParamDlg* dlg);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implement this if you are using the ParamMap2 AUTO\_UI system and the effect has secondary dialogs that don't have the effect as their 'thing'. Called once for each secondary dialog for you to install the correct thing.

Note: Developers needing more information on this method can see the remarks for [MtlBase::CreateParamDlg\(\)](#) which describes a similar example of this method in use (in that case it's for use by a texture map plug-in).

**Parameters:**

```
SFXParamDlg* dlg
```

Points to the ParamDlg.

**Return Value:**

Return TRUE if you process the dialog; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual int NumGizmos();
```

**Remarks:**

Implemented by the Plug-In.

If an atmospheric or rendering effect has references to gizmos or other objects in the scene it can optionally provide access to the object list. This method returns the number of gizmos or objects the plug-in has.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual INode *GetGizmo(int i);
```

**Remarks:**

Implemented by the Plug-In.

Returns a pointer to the 'i-th' gizmo or object node.

**Parameters:**

**int i**

The index of the gizmo to return.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void DeleteGizmo(int i);
```

**Remarks:**

Implemented by the Plug-In.

Deletes the 'i-th' gizmo or object from those used by the plug-in.

**Parameters:**

**int i**

The index of the gizmo to delete.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void AppendGizmo(INode *node);
```

**Remarks:**

Implemented by the Plug-In.

Adds the specified node to the end of the list of gizmos used by the plug-in.

**Parameters:**

**INode \*node**

Points to the node to append.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL OKGizmo(INode *node);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to approve a node for possible use as gizmo. Return TRUE if the node is okay; otherwise FALSE.

**Parameters:**

**INode \*node**

The node to check.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void EditGizmo(INode *node);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to select the specified gizmo and displays parameters for it (if any).

In the Special Effects section of the light dialog there is a button labelled 'Setup'. The Setup button brings up the Environment dialog (for Atmospherics) or the Render Effects dialog (for Render Effects) and selects the chosen effect. It also selects the "gizmo" within that effect, so if there are particular parameters for each gizmo the user will see them. Pressing that button causes this method to be called.

**Parameters:**

**INode \*node**

The gizmo node.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void InsertGizmo(int i, INode *node);
```

**Remarks:**

Implemented by the Plug-In.

Inserts the specified gizmo node into the list of gizmos. This method must be defined to use the **DeleteGizmoRestore** class.

**Parameters:**

**int i**

The zero based index of the position in the list of where the insertion should take place.

**INode \*node**

The gizmo node to insert.

**Default Implementation:**

```
{ assert(0); }
```

**Prototype:**

```
IOResult Save(ISave *isave);
```

**Remarks:**

Implemented by the System.

To facilitate naming atmospheric or rendering effects, a 'name' string has been added to the base class. This method should be called from the developers sub-classed Atmospheric or Effects plug-in to save the name.

**Prototype:**

```
IOResult Load(ILoad *iload);
```

**Remarks:**

Implemented by the System.

To facilitate naming atmospheric or rendering effects, a 'name' string has been added to the base class. This method should be called from the developers sub-classed Atmospheric or Effects plug-in to load the name.

## Class AppendGizmoRestore

See Also: [Class RestoreObj](#), [Class Atmospheric](#), [Class Effect](#), [Class SpecialFX](#), [Class INode](#).

```
class AppendGizmoRestore: public RestoreObj
```

### Description:

This class is available in release 3.0 and later only.

This class enables implementing undo of Gizmo assignment in Atmosphere and Effects classes. This class provides implementations of the **RestoreObj** methods. An instance of this class can be put on the Hold stack when a Gizmo is appended. For example:

```
if (theHold.Holding())
```

```
theHold.Put(new AppendGizmoRestore(this,node));
```

All methods of this class are implemented by the System.

### Data Members:

public:

```
SpecialFX *fx;
```

Points to the Atmosphere of Effect.

```
INode *node;
```

Points to the gizmo node.

### Methods:

public:

### Prototype:

```
AppendGizmoRestore(SpecialFX *f, INode *n);
```

### Remarks:

Constructor. The data members are initialized to the values passed.

## Class DeleteGizmoRestore

See Also: [Class RestoreObj](#), [Class Atmospheric](#), [Class Effect](#), [Class SpecialFX](#), [Class INode](#).

```
class DeleteGizmoRestore: public RestoreObj
```

### Description:

This class is available in release 3.0 and later only.

This class enables implementing undo of Gizmo deletion in Atmosphere and Effects classes. This class provides implementations of the **RestoreObj** methods. An instance of this class can be put on the Hold when a Gizmo is deleted. For example:

```
if (theHold.Holding())
```

```
theHold.Put(new DeleteGizmoRestore(this,nodes[i],i));
```

All methods of this class are implemented by the System.

### Data Members:

public:

```
SpecialFX *fx;
```

Points to the Atmosphere of Effect.

```
INode *node;
```

Points to the gizmo node.

```
int num;
```

The index of the gizmo which is being deleted.

### Methods:

public:

### Prototype:

```
DeleteGizmoRestore(SpecialFX *a, INode *n, int i);
```

### Remarks:

Constructor. The data members are initialized to the parameter passed.

## Class RenderGlobalContext

See Also: [Class ShadeContext](#), [Class Renderer](#), [Class RenderInstance](#), [Class Texmap](#), [Class Atmospheric](#), [Class Matrix3](#), [Class Point2](#), [Class Point3](#), [Class AColor](#), [Class Color](#), [Class IRenderElementMgr](#), [Class IRenderElement](#).

```
class RenderGlobalContext : public BaseInterfaceServer
```

### Description:

A pointer to an instance of this class is a data member of the ShadeContext (**RenderGlobalContext \*globContext;**). This can be used by materials, texmaps, etc. to retrieve information about the global rendering environment. This is information such as the renderer in use, the project type for rendering, the output device width and height, several matrices for transforming between camera and world coordinates, the environment map, the atmospheric effects, the current time, field rendering information, and motion blur information.

Note that raytracing (and all shading calculations in the default renderer) take place in camera space.

When a ray intersects on the face edge it can happen that no intersection is returned. One way to handle this situation is to perturb the ray minimally so it will point in a slightly different direction. This presumes that you are fairly sure that the no intersection is probably not what you're looking for. **IntersectRay()** is linear in the number of faces so **NUM\_ATTEMPTS** should be kept small.

```
for (perturb=0; perturb < NUM_ATTEMPTS; perturb++)
{
    Matrix3 ptb;
    float prop = ((float)rand()) / ((float) RAND_MAX);
    // gets random rotation of up to half a degree.
    float ang = PI*prop/360.0f;
    switch (perturb%3) {
        case 0: ptb = RotateXMatrix (ang); break;
        case 1: ptb = RotateYMatrix (ang); break;
        case 2: ptb = RotateZMatrix (ang); break;
    }
    ray.dir = ptb*ray.dir;
```

```
// try IntersectRay() again, see if you get a hit.  
}
```

### Data Members:

public:

**Renderer \*renderer;**

A pointer to the active renderer.

**int projType;**

Returns the type of projection used during rendering. One of the following values:

**PROJ\_PERSPECTIVE**

**PROJ\_PARALLEL**

**int devWidth;**

The width in pixels of the output device.

**int devHeight;**

The height in pixels of the output device.

**float xscale;**

The X scale factor for mapping from world space to screen space.

**float yscale;**

The Y scale factor for mapping from world space to screen space.

**float xc;**

The X center point used in mapping from world space to screen space.

**float yc;**

The Y center point used in mapping from world space to screen space.

**BOOL antialias;**

TRUE if antialiasing is enabled; otherwise FALSE.

**Matrix3 camToWorld;**

This matrix may be used to transform coordinates from camera space to world space.

**Matrix3 worldToCam;**

This matrix may be used to transform coordinates from world space to camera space.

**float nearRange;**

The near range setting of the camera.

**float farRange;**

The far range setting of the camera.

**float devAspect;**

The **pixel** aspect ratio of a device pixel. This is the height / width.

**float frameDur;**

This defines the duration of one frame in floating point units. This is used, for example, by video post rendering where the user can stretch time. A video post frame might be 1/2 a frame long for instance.

**Texmap \*envMap;**

The environment map (which may be NULL).

**Color globalLightLevel;**

This parameter is available in release 3.0 and later only.

This is the global light level.

**Atmospheric \*atmos;**

The atmosphere effects (which may be NULL).

**ToneOperator\* pToneOp;**

This data member is available in release 4.0 and later only.

The tone operator, may be NULL

**TimeValue time;**

The current time.

**BOOL wireMode;**

This parameter is available in release 3.0 and later only.

TRUE if rendering in wire frame mode; otherwise FALSE.

**float wire\_thick;**

This parameter is available in release 3.0 and later only.

The global wire thickness.

**BOOL force2Side;**

TRUE if force two-sided rendering enabled; otherwise FALSE.

**BOOL inMtlEdit;**

TRUE if the rendering is being done in the materials editor; otherwise FALSE.

**BOOL fieldRender;**

TRUE if field rendering is being done; otherwise FALSE.

**BOOL first\_field;**

TRUE if this is the first field; FALSE if it's the second.

**BOOL field\_order;**

Determines which field is first. 0 if the even first; 1 if odd first.

**BOOL objMotBlur;**

This is used for handling object motion blur in ray-trace maps and materials. TRUE if object motion blur is enabled; FALSE if it's disabled.

**int nBlurFrames;**

This is used for handling object motion blur in ray-trace maps and materials. The number of object motion blur time slices. See [Class RenderInstance](#).

**Methods:**

**Prototype:**

**IRenderElementMgr \*GetRenderElementMgr();**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the Render Element Manager. See [Class IRenderElementMgr](#).

**Prototype:**

**void SetRenderElementMgr(IRenderElementMgr \*pIRenderElementMgr);**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the render element manager being used.

**Parameters:**

**IRenderElementMgr \*pIRenderElementMgr**

Points to the render element manager to set.

**Prototype:**

**int NRenderElements();**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the number of render elements.

**Prototype:**

**IRenderElement\* GetRenderElement(int n);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the specified render element (or NULL if not found).

**Parameters:**

**int n**

The zero based index of the render element.

**Prototype:**

**Point2 MapToScreen(Point3 p);**

**Remarks:**

Computes the screen space coordinates of the point passed in world coordinates. This is implemented as:

**Parameters:**

**Point3 p**

The point to map to screen space.

**Prototype:**

**virtual FilterKernel\* GetAAFilterKernel();**

**Remarks:**

Returns a pointer to the current anti-aliasing filter from the renderer. See [Class FilterKernel](#).

**Prototype:**

**virtual float GetAAFilterSize();**

**Remarks:**

Returns the filter size of the current anti-aliasing filter.

**Prototype:**

**virtual int NumRenderInstances();**

**Remarks:**

Returns the number of **RenderInstances**.

**Prototype:**

```
virtual RenderInstance* GetRenderInstance(int i);
```

**Remarks:**

Returns a pointer to the 'i-th' **RenderInstance**.

**Parameters:**

**int i**

Specifies which **RenderInstance** to return (**0** through **NumRenderInstances()-1**).

**Prototype:**

```
virtual AColor EvalGlobalEnvironMap(ShadeContext &sc, Ray  
&r, BOOL applyAtmos);
```

**Remarks:**

This method evaluates the global environment map using the specified ray as a point of view, and returns the resulting color.

**Parameters:**

**ShadeContext &sc**

The shade context.

**Ray &r**

Defines the direction of view of the environment. See [Class Ray](#).

**BOOL applyAtmos**

TRUE if atmospheric effects should be considered; otherwise FALSE.

**Default Implementation:**

```
{ return AColor(0.0f,0.0f,0.0f,1.0f); }
```

**Prototype:**

```
virtual void IntersectRay(RenderInstance *inst, Ray& ray, ISect  
&isct, ISectList &xpList, BOOL findExit);
```

**Remarks:**

This method takes the specified **ray** and intersects it with the single RenderInstance **inst**.

**Parameters:****RenderInstance \*inst**

The render instance to intersect. The Mesh may be retrieved via **Mesh& m = \*(inst->mesh);**

**Ray& ray**

Defines the direction to check. This is the point to look from, and a normal vector specifying the direction to look. See [Class Ray](#).

**ISect &isct**

The information about the first opaque object hit by the ray is returned here. See [Structure ISect](#).

**ISectList &xplist**

The list of transparent objects that are intersected on the way to the opaque one are returned here. See [Class ISectList](#).

**BOOL findExit**

TRUE to compute the exit point; FALSE to not compute it. Once a ray has been intersected with a transparent object and you want to find out where the refracted ray leaves the object, this parameter may be set to TRUE. This allows the ray to look at the inside faces of the object and compute the intersection point at exit.

**Prototype:**

```
virtual BOOL IntersectWorld(Ray &ray, int skipID, ISect &hit,  
ISectList &xplist, int blurFrame = NO_MOTBLUR);
```

**Remarks:**

This method takes the specified **ray** and intersects it with the entire 3ds max scene.

**Parameters:****Ray &ray**

Defines the direction to check. This is the point to look from, and a normal vector specifying the direction to look. See [Class Ray](#).

## **int skipID**

This specifies an ID (from **RenderInstance::nodeID**) that is skipped in the intersection computations. This is used to prevent self intersection.

## **ISect &hit**

The information about the first opaque object hit by the ray is returned here. See [Structure ISect](#).

## **ISectList &xplist**

The list of transparent objects that are intersected on the way to the opaque one are returned here. See [Class ISectList](#).

## **int blurFrame = NO\_MOTBLUR**

**NO\_MOTBLUR** is used for non-motion blurred objects. If this is not equal to **NO\_MOTBLUR**, it should be in the range **0** to **nBlurFrames-1**. In that case, this method will only consider blur objects corresponding to that blur sub-frame.

When object motion blur is turned on, for each object, several objects are generated. Each of these objects is given a number. This corresponds to the value **RenderInstance::objMotBlurFrame**.

This method will always intersect objects that aren't motion blurred. However, if this is set to a number other than **NO\_MOTBLUR**, then when it comes to a motion blurred object, it will only look at the sub-object corresponding to the specified slice in time.

This may be used to do a kind of dither where for each of the sub-samples, this number is randomly selected. In this way the different motion blur slices will basically blur together and give a motion blurred ray trace result.

## **Prototype:**

```
virtual ViewParams *GetViewParams();
```

## **Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to a class which describes the properties of a view being rendered.. See [Class ViewParams](#).

## **Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);**

**Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

**Parameters:**

**int cmd**

The index of the command to execute.

**ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

**Default Implementation:**

**{ return 0; }**

**Prototype:**

**virtual FILE\* DebugFile();**

**Remarks:**

This method is used internally.

**Default Implementation:**

**{ return NULL; }**

## Class ShadeContext

See Also: [Working with Materials](#), [Class LightDesc](#), [Class RenderGlobalContext](#), [Class Color](#), [Class ShadeOutput](#), [Class AColor](#), [Class UVGen](#), [Class Box3](#), [Class IPoint2](#), [Class Point2](#), [Class IRenderElement](#), [Class Point3](#), [Class Class\\_ID](#).

```
class ShadeContext : public InterfaceServer
```

### Description:

This class is passed to materials and texture maps. It contains all the information necessary for shading the surface at a pixel.

Normally, the **ShadeContext** is provided by the 3ds max renderer. However developers that need to create their own **ShadeContext** for use in passing to the texture and material evaluation functions can do so by deriving a class from **ShadeContext** and providing implementations of the virtual methods. Some sample code is available demonstrating how this is done in `\MAXSDK\SAMPLES\OBJECTS\LIGHT.CPP` (see the code for **class SCLight : public ShadeContext**). The default implementations of these methods are shown for developers that need to create their own **ShadeContext**. Note that raytracing (and all shading calculations in the default renderer) takes place in camera space.

For additional information on the methods **DP()**, **Curve()**, **DUVW()** and **DPdUVW()** see [Additional Notes](#).

All methods are implemented by the system unless noted otherwise.

### Data Members:

public:

#### **ULONG mode;**

One of the following values:

#### **SCMODE\_NORMAL**

In normal mode, the material should do the entire illumination including transparency, refraction, etc.

#### **SCMODE\_SHADOW**

In shadow mode, you are just trying to find out what color the shadow is that is falling on an object. In this case, all you care about is transmitted

color.

### **BOOL doMaps**

Indicates if texture maps should be applied.

### **BOOL filterMaps;**

Indicates if textures should be filtered.

### **BOOL shadow**

Indicates if shadows should be applied.

### **BOOL backFace;**

Indicates if we are on the back side of a 2-sided face.

### **int mtlNum**

The material number of the face being shaded. This is the sub-material number for multi-materials.

### **Color ambientLight**

This is the color of the ambient light.

### **int nLights;**

This is the number of lights being used in a render, which is the number of active lights in the scene, or if there are none, 2 for the default lights. For example, this is used in the Standard material in a loop like this:

```
LightDesc *l;  
for (int i=0; i<sc.nLights; i++) {  
l = sc.Light(i);  
..etc  
}
```

### **int rayLevel;**

This data member is available in release 2.0 and later only.

This is used to limit the number of reflections for raytracing. For instance, if you're rendering a hall of mirrors, and the ray is reflecting back and forth, you don't want the raytracing to go forever. Every time **Texmap::EvalColor()** gets called again on a ray you create a new **ShadeContext** and bump up the **rayLevel** one. This allows you to test this value and see if it has reached the limit of how deep to go (if it reaches a maximum level, you can return black for example).

Note that it is conceivable that more than one raytrace material can be in effect

at a time (from different developers). In such a case, where one surface might have one raytracer and another surface a different one, and a ray was bouncing back and forth between them, each needs to be aware of the other. This is why this value is here -- the two texmaps each modify and check it.

### **int xshadeID;**

This data member is available in release 2.0 and later only.

This is currently not used.

### **RenderGlobalContext \*globContext;**

This data member is available in release 2.0 and later only.

Points to an instance of **RenderGlobalContext**. This class describes the properties of the global rendering environment. This provides information such as the renderer in use, the project type for rendering, the output device width and height, several matrices for transforming between camera and world coordinates, the environment map, the atmospheric effects, the current time, field rendering information, and motion blur information.

### **LightDesc \*atmosSkipLight;**

The light description of lights to prevent self shadowing by volumetric lights.

### **RenderGlobalContext \*globContext;**

A pointer to the rendering global context.

### **ShadeOutput out;**

This is where the material should leave its results.

The following is a discussion of blending the ShadeContext.out.c and ShadeContext.out.t together to get the final color:

The (c,t) returned by shaders is interpreted as follows: t.r is the (premultiplied) alpha for the r-channel, etc.

So if you want to composite (c,t) over a background b,

color = b\*t + c ( where the multiplication of b and t multiplies the individual components ).

When you want to convert a (c,t) to a simple R,G,B,Alpha, just average together the components of t to get Alpha. (and use the r,g,b components of c directly).

### **Methods:**

### **Prototype:**

## **ShadeContext()**

### **Remarks:**

Constructor. The data members are initialized as follows:

```
mode = SCMODE_NORMAL; nLights = 0; shadow = TRUE;  
rayLevel = 0; globContext = NULL; atmosSkipLight = NULL;
```

### **Prototype:**

```
void ResetOutput(int n = -1)
```

### **Remarks:**

Sets the surface color output and surface transparency output to Black.

### **Parameters:**

```
int n = -1
```

By supplying a negative value this method will clear elements but leave the number of elements unchanged.

### **Prototype:**

```
Class_ID ClassID();
```

### **Remarks:**

This method is available in release 2.0 and later only.

Returns the Class\_ID of this ShadeContext. This is used to distinguish different ShadeContexts.

### **Default Implementation:**

```
{ return Class_ID(0,0); }
```

### **Prototype:**

```
virtual BOOL InMtlEditor()=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if this rendering is for the material editor sample sphere (geometry); otherwise FALSE.

### **Prototype:**

**virtual int Antialias();**

**Remarks:**

Returns the state of the antialiasing switch in the renderer dialog - TRUE if on; FALSE if off.

**Default Implementation:**

**{return 0;}**

**Prototype:**

**virtual int ProjType();**

**Remarks:**

This method returns the projection type.

**Return Value:**

A value of 0 indicates perspective projection; a value of 1 indicates parallel projection.

**Default Implementation:**

**{return 0;}**

**Prototype:**

**virtual LightDesc\* Light(int n)=0;**

**Remarks:**

This method returns the 'i-th' light. Use data member **nLights** to get the total number of lights.

**Parameters:**

**int n**

Specifies the light to return.

**Prototype:**

**virtual TimeValue CurTime()=0;**

**Remarks:**

Returns the current time value (the position of the frame slider).

**Return Value:**

The current time.

**Prototype:**

```
virtual int NodeID();
```

**Remarks:**

Returns the node ID for the item being rendered or -1 if not set. This ID is assigned when the scene is being rendered - each node is simply given an ID - 0, 1, 2, 3, etc.

**Default Implementation:**

```
{return -1;}
```

**Prototype:**

```
virtual INode *Node();
```

**Remarks:**

Returns the INode pointer of the node being rendered. This pointer allows a developer to access the properties of the node. See [Class INode](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual Object *GetEvalObject();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the evaluated object for this node. When rendering, usually one calls **GetRenderMesh()** to get the mesh to render. However, at certain times you might want to get the object itself from the node. For example, you could then call **ClassID()** on the object and determine its type. Then the object could be operated on procedurally (for instance you could recognize it as a true sphere, cylinder or torus). Note that this method will return NULL if object is motion blurred.

For example, here is how you can check if the object is a particle system:

```
// ...
```

```
Object *ob = sc.GetEvalObject();  
if (ob && ob->IsParticleSystem()) {
```

```
// ...
```

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual Point3 BarycentricCoords()
```

**Remarks:**

The coordinates relative to triangular face. The barycentric coordinates of a point **p** relative to a triangle describe that point as a weighted sum of the vertices of the triangle. If the barycentric coordinates are **b0**, **b1**, and **b2**, then:

$$\mathbf{p} = \mathbf{b0} * \mathbf{p0} + \mathbf{b1} * \mathbf{p1} + \mathbf{b2} * \mathbf{p2};$$

where **p0**, **p1**, and **p2** are the vertices of the triangle. The Point3 returned by this method has the barycentric coordinates stored in the its three coordinates. These coordinates are relative to the current triangular face being rendered. These barycentric coordinates can be used to interpolate **any** quantity whose value is known at the vertices of the triangle. For example, if a radiosity shader had available the illumination values at each of the three vertices, it could determine the illumination at the current point using the barycentric coordinates.

**Default Implementation:**

```
{ return Point3(0,0,0);}
```

**Prototype:**

```
virtual int FaceNumber()=0;
```

**Remarks:**

Returns the index of the face being rendered. For the scan-line renderer, which renders only triangle meshes, this is the index of the face in the Mesh data structure. This is meant for use in plug-in utilities such as a radiosity renderer, which stores a table of data, indexed on face number, in the Nodes's AppData, for use in a companion material.

**Prototype:**

**virtual Point3 Normal()=0;**

**Remarks:**

Returns the interpolated normal (in camera space). This is the value of the face normal facing towards the camera. This is affected by **SetNormal()** below.

**Prototype:**

**virtual void SetNormal(Point3 p)**

**Remarks:**

This method will set the value of the face normal facing towards the camera. This may be used to temporarily perturb the normal. The Standard material uses this for example because it implements bump mapping. It changes the normal and then calls other lighting functions, etc. These other method then see this changed normal value. When it is done it puts back the previous value.

**Parameters:**

**Point3 p**

The normal to set.

**Prototype:**

**virtual Point3 OrigNormal();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the original surface normal (not affected by **SetNormal()** above.)

**Default Implementation:**

```
{ return Normal(); }
```

**Prototype:**

**virtual float Curve();**

**Remarks:**

This is an estimate of how fast the normal is varying. For example if you are doing environment mapping this value may be used to determine how big an area of the environment to sample. If the normal is changing very fast a large area must be sampled otherwise you'll get aliasing. This is an estimate of

$dN/dsx$ ,  $dN/dsy$  put into a single value.

**Prototype:**

**virtual Point3 Gnormal()=0**

**Remarks:**

This returns the geometric normal. For triangular mesh objects this means the face normal. Normals are unit vectors.

**Prototype:**

**virtual Point3 ReflectVector()=0;**

**Remarks:**

This takes the current view vector and the current normal vector and calculates a vector that would result from reflecting the view vector in the surface. This returns the reflection vector.

**Prototype:**

**virtual Point3 RefractVector(float ior)=0;**

**Remarks:**

This is similar to the method above however it calculates the view vector being refracted in the surface. This returns the refraction vector.

**Parameters:**

**float ior**

The relative index of refraction between the air and the material.

**Prototype:**

**virtual void SetIOR(float ior);**

**Remarks:**

This method is available in release 2.0 and later only.

Set index of refraction.

**Parameters:**

**float ior**

The index of refraction to set. This value can be any positive (non-zero) value.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual float GetIOR();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the index of refraction.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual Point3 CamPos()=0;
```

**Remarks:**

Returns the camera position in camera space. For the 3ds max renderer this will always be 0,0,0.

**Prototype:**

```
virtual Point3 V()=0
```

**Remarks:**

This method returns the unit view vector, from the camera towards P, in camera space.

**Prototype:**

```
virtual void SetView(Point3 p)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the view vector as returned by **V()**.

**Parameters:**

**Point3 p**

The view vector set.

**Prototype:**

**virtual Point3 OrigView();**

**Remarks:**

This method is available in release 2.0 and later only.

This is the original view vector that was not affected by **ShadeContext::SetView()**.

**Default Implementation:**

**{ return V(); }**

**Prototype:**

**virtual Point3 P()=0**

**Remarks:**

Returns the point to be shaded in camera space.

**Prototype:**

**virtual Point3 DP()=0**

**Remarks:**

This returns the derivative of P, relative to the pixel. This gives the renderer or shader information about how fast the position is changing relative to the screen.

**Prototype:**

**virtual void DP(Point3& dpdx, Point3& dpdy);**

**Remarks:**

This returns the derivative of P, relative to the pixel - same as above. This method just breaks it down into x and y.

**Prototype:**

**virtual Point3 PObj()=0**

**Remarks:**

Returns the point to be shaded in object coordinates.

**Prototype:**

**virtual Point3 DPObj()=0**

**Remarks:**

Returns the derivative of **PObj()**, relative to the pixel.

**Prototype:**

**virtual Box3 ObjectBox()=0**

**Remarks:**

Returns the object extents bounding box in object coordinates.

**Prototype:**

**virtual Point3 PObjRelBox()=0**

**Remarks:**

Returns the point to be shaded relative to the object box where each component is in the range of -1 to +1.

**Prototype:**

**virtual Point3 DPObjRelBox()=0**

**Remarks:**

Returns the derivative of **PObjRelBox()**. This is the derivative of the point relative to the object box where each component is in the range of -1 to +1.

**Prototype:**

**virtual void ScreenUV(Point2& uv, Point2 &duv)=0;**

**Remarks:**

Retrieves the point relative to the screen where the lower left corner is 0,0 and the upper right corner is 1,1.

**Parameters:**

**Point2& uv**

The point.

**Point2 &duv**

The derivative of the point.

**Prototype:**

```
virtual IPoint2 ScreenCoord()=0;
```

**Remarks:**

Returns the integer screen coordinate (from the upper left).

**Prototype:**

```
virtual Point2 SurfacePtScreen();
```

**Remarks:**

This method is available in release 3.0 and later only.

Return the surface point at the center of the fragment in floating point screen coordinates. See the documentation for **Sampler::DoSample()** for an explanation of the use of this method. See [Class Sampler](#).

**Default Implementation:**

```
{ return Point2(0.0,0.0); }
```

**Prototype:**

```
virtual Point3 UVW(int channel=0)=0;
```

**Remarks:**

Returns the UVW coordinates for the point.

**Parameters:**

```
int channel=0;
```

Specifies the channel for the values. One of the following:

**0**: Vertex Color Channel.

**1** through **99**: Mapping Channels.

**Prototype:**

```
virtual Point3 DUVW(int channel=0)=0
```

**Remarks:**

This method returns the UVW derivatives for the point. This is used for filtering texture maps and antialiasing procedurals that are using UVW. Note that in standard 3ds max textures, the **UVGen** class is used, and it calls this method itself. See the methods **UVGen::GetBumpDP()** for more details

for using **UVGen**. If you are not using **UVGen** then you can use this method and **UVW()**. **UVW()** gets the UVW coordinates of the point and **DUVW()** gets the change in the UVWs for the point. This tells you a maximum change for each of UVW. This tells you how much of the area of the map to sample. So when you call the **Bitmap** method **GetFiltered(float u, float v, float du, float dv, BMM\_Color\_64 \*ptr)** this tells you how big the sample should be. This lets you filter or average over this area to keep the map from aliasing.

**Parameters:**

**int channel=0;**

Specifies the channel for the values. One of the following:

**0**: Vertex Color Channel.

**1** through **99**: Mapping Channels.

**Prototype:**

**virtual void DPdUVW(Point3 dP[3], int channel=0)=0**

**Remarks:**

This returns the bump basis vectors for UVW in camera space. Note that if you want to retrieve these bump basis vectors that are altered by the UVGen instance use the method **UVGen::GetBumpDP()**. Also see the Advanced Topics section [Working with Materials and Textures](#) for more details on bump mapping.

**Parameters:**

**Point3 dP[3]**

The bump basic vectors. **dP[0]** is a vector corresponding to the U direction. **dp[1]** corresponds to V, and **dP[2]** corresponds to W.

**int channel=0;**

Specifies the channel for the values. One of the following:

**0**: Vertex Color Channel.

**1** through **99**: Mapping Channels.

**Prototype:**

**virtual int BumpBasisVectors(Point3 dP[2], int axis, int channel=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This method should replace DpDUVW over time but is left in place as not to break 3<sup>rd</sup> party plugins. If this method returns 1, that is assumed to mean it is implemented, and it will be used instead of DpDUVW.

**Parameters:**

**Point3 dP[2]**

The bump basic vectors. **dP[0]** is a vector corresponding to the U direction. **dp[1]** corresponds to V, and **dP[2]** corresponds to W.

**int axis**

Specified the 2D cases for: **AXIS\_UV**, **AXIS\_VW**, or **AXIS\_WU**.

**int channel=0;**

Specifies the channel for the values. One of the following:

**0**: Vertex Color Channel.

**1** through **99**: Mapping Channels.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

**virtual Point3 UVWNormal(int channel=0);**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns a vector in UVW space normal to the face in UVW space. This can be  $\text{CrossProd}(U[1]-U[0], U[2]-U[1])$ , where  $U[i]$  is the texture coordinate at the  $i$ -th vertex of the current face. This may be used for hiding textures on back side of objects.

**Parameters:**

**int channel=0;**

Specifies the channel for the values. One of the following:

**0**: Vertex Color Channel.

1 through 99: Mapping Channels.

**Default Implementation:**

```
{ return Point3(0,0,1); }
```

**Prototype:**

```
virtual float RayConeAngle();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the angle of a ray cone hitting this point. It gets increased/decreased by curvature on reflection.

Visualize a small pyramid, with the top at the eye point, and its sides running through each corner of the pixel to be rendered, then onto the scene. Then visualize a small cone fitting inside this pyramid. This method returns the angle of that cone. When rendering, if the ray cone goes out and hits a flat surface, the angle of reflection will always be constant for each pixel.

However, if the ray cone hits a curved surface, the angle will change between pixels. This change in value give some indication of how fast the sample size is getting bigger.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

```
virtual float RayDiam();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the diameter of the ray cone at the pixel point (the point it intersects the surface being shaded). This is a dimension in world units. As a ray is propogated it is updated for each new surface that is encountered.

**Default Implementation:**

```
{ return Length(DP()); }
```

**Prototype:**

```
virtual AColor EvalEnvironMap(Texture *map, Point3 view)
```

**Remarks:**

This is used by the Standard material to do the reflection maps and the refraction maps. Given the map, and a direction from which you want to view it, this method changes the view vector to be the specified vector and evaluates the function.

**Parameters:**

**Texmap \*map**

The map to evaluate.

**Point3 view**

The view direction.

**Return Value:**

The color of the map, in r, g, b, alpha.

**Prototype:**

**virtual void GetBGColor(class Color &bgCol, class Color &transp, int fogBG=TRUE)=0**

**Remarks:**

Retrieves the background color and the background transparency.

**Parameters:**

**class Color &bgCol**

The returned background color.

**class Color &transp**

The returned transparency.

**int fogBG**

Specifies you want the current atmospheric shaders to be applied to the background color. If TRUE the shaders are applied; if FALSE they are not.

**Prototype:**

**virtual float CamNearRange()**

**Remarks:**

Returns the camera near range set by the user in the camera's user interface.

**Prototype:**

## **virtual float CamFarRange()**

### **Remarks:**

Returns the camera far range set by the user in the camera's user interface.

### **Prototype:**

**virtual Point3 PointTo(const Point3& p, RefFrame ito)=0;**

### **Remarks:**

Transforms the specified point from internal camera space to the specified space.

### **Parameters:**

**const Point3& p**

The point to transform.

**RefFrame ito**

The space to transform the point to. One of the following values:

**REF\_CAMERA**

**REF\_WORLD**

**REF\_OBJECT**

### **Return Value:**

The transformed point, in the specified space.

### **Prototype:**

**virtual Point3 PointFrom(const Point3& p, RefFrame ifrom)=0;**

### **Remarks:**

Transforms the specified point from the specified coordinate system to internal camera space.

### **Parameters:**

**const Point3& p**

The point to transform.

**RefFrame ifrom**

The space to transform the point from. One of the following values:

**REF\_CAMERA**

**REF\_WORLD**

## **REF\_OBJECT**

### **Return Value:**

The transformed point in camera space.

### **Prototype:**

**virtual Point3 VectorTo(const Point3& p, RefFrame ito)=0;**

### **Remarks:**

Transform the vector from internal camera space to the specified space.

### **Parameters:**

**const Point3& p**

The vector to transform.

**RefFrame ito**

The space to transform the vector to. One of the following values:

**REF\_CAMERA**

**REF\_WORLD**

**REF\_OBJECT**

### **Prototype:**

**virtual Point3 VectorFrom(const Point3& p, RefFrame ifrom)=0;**

### **Remarks:**

Transform the vector from the specified space to internal camera space.

### **Parameters:**

**const Point3& p**

The vector to transform.

**RefFrame ifrom**

The space to transform the vector from. One of the following values:

**REF\_CAMERA**

**REF\_WORLD**

**REF\_OBJECT**

### **Prototype:**

**virtual Point3 VectorToNoScale(const Point3& p, RefFrame ito);**

**Remarks:**

This method is available in release 3.0 and later only.

Transform the vector from internal camera space to the specified space without scaling.

**Parameters:**

**const Point3& p**

The vector to transform.

**RefFrame ito**

The space to transform the vector to. One of the following values:

**REF\_CAMERA**

**REF\_WORLD**

**REF\_OBJECT**

**Prototype:**

**virtual Point3 VectorFromNoScale(const Point3& p, RefFrame ifrom);**

**Remarks:**

This method is available in release 3.0 and later only.

Transform the vector from the specified space to internal camera space without scaling.

Note: This method was added to correct a problem that was occurring in 3D Textures when the bump perturbation vectors were transformed from object space to camera space, so they are oriented correctly as the object rotates. If the object has been scaled, this transformation causes the perturbation vectors to be scale also, which amplifies the bump effect. This method is used to rotate the perturbation vectors so they are correctly oriented in space, without scaling them.

**Parameters:**

**const Point3& p**

The vector to transform.

**RefFrame ifrom**

**RefFrame ifrom**

The space to transform the vector from. One of the following values:

**REF\_CAMERA**  
**REF\_WORLD**  
**REF\_OBJECT**

**Prototype:**

**virtual void SetGBufferID(int gbid);**

**Remarks:**

When a map or material is evaluated (in **Shade()**, **EvalColor()** or **EvalMono()**), if it has a non-zero **gbufID**, it should call this routine to store the **gbid** into the shade context.

Note: Normally a texmap calls this method so the index would be set for all of the area covered by the texture. There is no reason that this has to be done for every pixel however. A texture could just set the ID for particular pixels. This could allow post processing routines (for example a glow) to only process part of a texture and not the entire thing. For example, at the beginning of texmap's **EvalColor()** one typically has code that does:

**if (gbufid) sc.SetGBufferID(gbufid);**

This takes the **gbufid** (which is in **MtlBase**) and (if it is non-zero) stores it into the shade context. The renderer, after evaluating the **Shade()** function for the material at a pixel, looks at the gbufferID left in the shade context, and stores it into the gbuffer at that pixel. So if the texmap adds another condition like

**if (inHotPortion)**

**if (gbufid) sc.SetGBufferID(gbufid);**

It will do it for just the chosen pixels.

**Parameters:**

**int gbid**

The ID to store.

**Prototype:**

**virtual AColor EvalGlobalEnvironMap(Point3 dir);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the color of the global environment map from the given view direction.

**Parameters:**

**Point3 dir**

Specifies the direction of view.

**Default Implementation:**

```
{ return AColor(0,0,0,0); }
```

**Prototype:**

```
LightDesc *GetAtmosSkipLight();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method, along with **SetAtmosSkipLight()** below, are used by the lights to avoid self-shadowing when applying atmospheric shadows. This method returns a pointer to the **LightDesc** instance currently calling the **Atmosphere::Shade()** method when computing atmospheric shadows.

Here's how they are used:

(1) When computing the atmospheric shadows:(somewhere in **::LightDesc::Illuminate()**) do the following:

```
sc.SetAtmosSkipLight(this);
```

```
sc.globContext->atmos->Shade(sc, lightPos, sc.P(), col, trans);
```

```
sc.SetAtmosSkipLight(NULL);
```

(2) In **LightDesc::TraverseVolume()** do the following:

```
if (sc.GetAtmosSkipLight()==this)
```

```
return;
```

**Default Implementation:**

```
{ return atmosSkipLight; }
```

**Prototype:**

```
void SetAtmosSkipLight(LightDesc *It);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method sets the **LightDesc** instance currently calling the **Atmosphere::Shade()** method. See **GetAtmosSkipLight()** above.

**Parameters:**

**LightDesc \*lt**

Points to the LightDesc to set.

**Default Implementation:**

```
{ atmosSkipLight = lt; }
```

**Prototype:**

```
virtual BOOL GetCache(Texture *map, AColor &c);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is used with texture maps only. If a map is multiply instanced within the same material, say on the diffuse channel and on the shininess channel, it will return the same value each time its evaluated. Its a waste of processor time to reevaluate the map twice. This method allows you to cache the value so it won't need to be computed more than once.

Note that the cache is automatically cleared after each ShadeContext call. This is used within one evaluation of a material hierarchy.

**Parameters:**

**Texture \*map**

Points to the texture storing the cache (usually the plug-ins **this** pointer).

**AColor &c**

The color to store.

**Return Value:**

TRUE if the color was returned; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Sample Code:**

This code from `\MAXSDK\SAMPLES\MATERIALS\NOISE.CPP`

and shows how the cache is retrieved and stored:

```
RGBA Noise::EvalColor(ShadeContext& sc) {  
  Point3 p,dp;  
  if (!sc.doMaps) return black;  
  
  AColor c;  
  // If the cache exists, return the color  
  if (sc.GetCache(this,c))  
    return c;  
  // Otherwise compute the color  
  ...  
  // At the end of the eval the cache is stored  
  sc.PutCache(this,c);
```

**Prototype:**

```
virtual BOOL GetCache(Texmap *map, float &f);
```

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves a floating point value from the cache. See the AColor version above for details.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**float &f**

The value to store.

**Return Value:**

TRUE if the value was returned; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual BOOL GetCache(Texmap *map, Point3 &p);
```

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves a Point3 value from the cache. See the AColor version above for details.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**Point3 &p**

The point to store.

**Return Value:**

TRUE if the value was returned; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void PutCache(Texmap *map, const AColor &c);
```

**Remarks:**

This method is available in release 2.0 and later only.

Puts a color to the cache. See the method **GetCache(Texmap \*map, const AColor &c)** above for details.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**const AColor &c**

The color to store.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void PutCache(Texmap *map, const float f);
```

**Remarks:**

This method is available in release 2.0 and later only.

Puts a floatint point value to the cache. See the method **GetCache(Texmap \*map, const AColor &c)** above for details.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**const float f**

The floating point value to store.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void PutCache(Texmap *map, const Point3 &p);
```

**Remarks:**

This method is available in release 2.0 and later only.

Puts a floatint point value to the cache. See the method **GetCache(Texmap \*map, const AColor &c)** above for details.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**const Point3 &p**

The Point3 value to store.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void TossCache(Texmap *map);
```

**Remarks:**

This method is available in release 2.0 and later only.

Removes the specified cache.

**Parameters:**

**Texmap \*map**

Points to the texmap storing the cache (usually the plug-ins **this** pointer).

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual FILE* DebugFile();
```

**Remarks:**

This method is used internally.

**Prototype:**

```
virtual INT_PTR Execute(int cmd, ULONG arg1=0, ULONG  
arg2=0, ULONG arg3=0);
```

**Remarks:**

This method is available in release 3.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

This is reserved for future use.

**Parameters:**

**int cmd**

The command to execute.

**ULONG arg1=0**

Optional argument 1 (defined uniquely for each **cmd**).

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value (defined uniquely for each **cmd**).

**Default Implementation:**

```
{ return 0; }
```

**Prototype:****bool IsPhysicalSpace() const;****Remarks:**

This method is available in release 4.0 and later only.

This method returns TRUE if the operator really maps physical values to RGB, otherwise FALSE. This method is provided so shaders can determine whether the shading calculations are in physical or RGB space.

**Prototype:****void ScaledToRGB(T& energy) const;****Remarks:**

This method is available in release 4.0 and later only.

This method will map a scaled energy value into RGB. This converts a color value which will be stored in energy.

**Parameters:****T& energy**

The converted color value.

**Prototype:****float ScaledToRGB(float energy) const;****Remarks:**

This method is available in release 4.0 and later only.

This method will map a scaled energy value into RGB. This converts a monochrome value which will be returned.

**Parameters:****float energy**

The scaled energy value.

**Prototype:****void ScaledToRGB();****Remarks:**

This method is available in release 4.0 and later only.

This method will map an energy value into **out.c** into RGB. The converted value is stored in **out.c**.

**Prototype:**

**void ScalePhysical(T& energy) const;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will scale physical values so they can be used in the renderer.

This converts a color value which will be stored in energy.

**Parameters:**

**T& energy**

The converted color value.

**Prototype:**

**float ScalePhysical(float energy) const;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will scale physical values so they can be used in the renderer.

This converts a monochrome value which will be returned.

**Parameters:**

**float energy**

The energy value.

**Prototype:**

**void ScaleRGB(T& energy) const;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will scale RGB values, just supplied to invert ScalePhysical. This converts a color value which will be stored in energy.

**Parameters:**

**T& energy**

The converted color value.

**Prototype:**

**float ScaleRGB(float energy) const;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will scale RGB values, just supplied to invert ScalePhysical. This converts a monochrome value which will be returned.

**Parameters:**

**float energy**

The energy value.

**Prototype:**

**LightDesc \*GetAtmosSkipLight();**

**Remarks:**

This method is available in release 4.0 and later only.

This method can be used to determine from within the ShadeContext if a volumetric light should be prevented from generating self-shadows.

**Default Implementation:**

```
{ return atmosSkipLight; }
```

**Prototype:**

**void SetAtmosSkipLight(LightDesc \*lt);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the volumetric light that should be prevented from generating self-shadows.

**Parameters:**

**LightDesc \*lt**

A pointer to the light to set.

**Default Implementation:**

```
{ atmosSkipLight = lt; }
```

**Prototype:**

```
virtual int NRenderElements();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns the number of render elements.

**Default Implementation:**

```
{ return globContext->NRenderElements(); }
```

**Prototype:**

```
virtual IRenderElement *GetRenderElement(int n);
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns an interface to the 'i-th' render element.

**Parameters:**

**int n**

The zero based index of the render element to return.

**Default Implementation:**

```
{ return globContext->GetRenderElement(n); }
```

**Prototype:**

```
virtual Color DiffuseIllum();
```

**Remarks:**

This method is available in release 4.0 and later only.  
Computes and returns the incoming diffuse illumination color (for matte/shadow).

**Notes on the functions DP(), Curve(), DUVW() and DPdUVW()**

The functions DP(), Curve(), and DUVW() are all for the purposes of antialiasing. They give the amount of variation of various quantities across the pixel. DPdUVW() is for the purposes of bump mapping. This section describes the method that 3ds max's renderer uses for computing them.

(1) Point3 DP();

This gives the approximate dimension of a 3D box which bounds the surface fragment cut out of the surface by the current pixel being rendered. It can be used for antialiasing 3D textures.

First calculate (where  $U = \{u,v,w\}$  )

$dP/dx$ : the derivative of a point on the surface relative to the screen x-coordinate.

$dP/dy$ : the derivative of a point on the surface relative to the screen y-coordinate.

Then take the sum of the absolute values of these:

$DP = \text{abs}(dP/dx) + \text{abs}(dP/dy)$ .

(2) Point3 DUVW();

This is similar to DP(), but bounds the change in UVW space. It is used for texture filtering.

First calculate (where  $U = \{u,v,w\}$  )

$dU/dx$ : the derivative of  $\{u,v,w\}$  relative to the screen x-coordinate.

$dU/dy$ : the derivative of  $\{u,v,w\}$  relative to the screen y-coordinate.

Then take the sum of the absolute values of these:

$DUVW = DU = \text{abs}(dU/dx) + \text{abs}(dU/dy)$ .

(3) float Curve();

This gives an approximation of the amount of curvature of the surface. It is basically a measure of the length of a vector representing the rate of change of the surface normal across the pixel. It is used to scale the sample size in reflection mapping. (high curvature==>big sample).

Here is our implementation:

```

float SContext::Curve() {
    calc_derivs(); // calculate dxdx, etc.
    Point3 nv0 = actf->GetVertexNormal(0); // surface normal at vertex 0
    Point3 nv1 = actf->GetVertexNormal(1); // surface normal at vertex 1
    Point3 nv2 = actf->GetVertexNormal(2); // surface normal at vertex 2
    nv1 -= nv0;
    nv2 -= nv0;
    float dx2 = LengthSquared(dsdX*nv1 + dtdx*nv2);
    float dy2 = LengthSquared(dsdY*nv1 + dtdy*nv2);
    return (float)sqrt(0.5*(dx2+dy2));
}

```

Notes:

calc\_derivs() calculates the terms dsdx,dsdy, dtdx, dtdy.

(s,t) are skew coordinates of the current point in the face relative to the face vertices (V0,V1,V2):

(i.e. the current point  $P = V0 + s*(V1-V0) + t*(V2-V0)$ ;) )

dsdx is derivative of s relative to screen x.

dsdy is derivative of s relative to screen y.

dtdx is derivative of t relative to screen x.

dtdy is derivative of t relative to screen y.

dx2 is the length squared of the change in normal relative to screen x.

dy2 is the length squared of the change in normal relative to screen y.

(4) void DPdUVW(Point3 dP[3]);

This method returns the 3 basis vectors that describe U,V,and W axes in XYZ space.

The following function computes the U and V bump basis vectors for a triangle given the texture coordinates at the three vertices of the triangle ( tv[] ) and the 3D coordinates at the vertices ( v[] ). It is simply a solution using

linear algebra for the U and V axes in terms of the XYZ coordinates. It returns

$$b[0] = DP/DU$$

$$b[1] = DP/DV$$

This function does not compute DP/DW, which at present is a shortcoming of the scanline renderer. It also makes the assumption that the bump basis vectors are constant over a given face, which has worked out successfully.

```
void ComputeBumpVectors(const Point3 tv[3], const Point3 v[3], Point3  
bvec[3]) {
```

```
float uva,uvb,unc,uvd,uvk;
```

```
Point3 v1,v2;
```

```
uva = tv[1].x-tv[0].x;
```

```
uvb = tv[2].x-tv[0].x;
```

```
unc = tv[1].y-tv[0].y;
```

```
uvd = tv[2].y-tv[0].y;
```

```
uvk = uvb*unc - uva*uvd;
```

```
v1 = v[1]-v[0];
```

```
v2 = v[2]-v[0];
```

```
if (uvk!=0) {
```

```
  bvec[0] = (unc*v2-uvd*v1)/uvk;
```

```
  bvec[1] = (uva*v2-uvb*v1)/uvk;
```

```
}
```

```
else {
```

```
  if (uva!=0)
```

```
    bvec[0] = v1/uva;
```

```
  else if (uvb!=0)
```

```
bvec[0] = v2/uvb;  
else  
bvec[0] = Point3(0.0f,0.0f,0.0f);  
if (uvc!=0)  
bvec[1] = v1/uvc;  
else if (uvd!=0)  
bvec[1] = v2/uvd;  
else  
bvec[1] = Point3(0.0f,0.0f,0.0f);  
}  
bvec[2] = Point3(0,0,1);  
}
```

# Class NURBSExtrudeSurface

See Also: [Class NURBSSurface](#).

```
class NURBSExtrudeSurface : public NURBSSurface
```

## Description:

This class is available in release 2.0 and later only.

This class defines a dependent extrude surface. An extrude surface is extruded from a curve sub-object. It is similar to a surface created with the Extrude modifier. The advantage is that an extrude sub-object is part of the NURBS model, so you can use it to construct other curve and surface sub-objects. Methods are available to get/set the parent index and id, get/set the extrusion vector and get/set the extrusion distance.

All methods of this class are implemented by the system.

## Friend Classes:

```
friend class NURBSSet
```

## Methods:

protected:

## Prototype:

```
void Clean(NURBSIdTab ids);
```

## Remarks:

This method is available in release 3.0 and later only.

This methods breaks the relation between this **NURBSObject** and a **NURBSSet**.

## Parameters:

**NURBSIdTab ids**

A table with the IDs of each object in the **NURBSSet**.

public:

## Prototype:

```
NURBSExtrudeSurface();
```

## Remarks:

Constructor. The data members are initialized as follows:

```
mType = kNExtrudeSurface;  
mpObject = NULL;  
mpNSet = NULL;  
mParentId = 0;  
mParentIndex = -1;  
mXForm.IdentityMatrix();  
mDistance = 0.0;  
mCurveStartParam = 0.0;
```

**Prototype:**

```
virtual ~NURBSExtrudeSurface();
```

**Remarks:**

Destructor.

**Prototype:**

```
void SetParent(int index);
```

**Remarks:**

Sets the index in the **NURBSSet** of the parent object.

**Parameters:**

**int index**

The index into the **NURBSSet** of the parent surface.

**Prototype:**

```
void SetParentId(NURBSId id);
```

**Remarks:**

Sets the **NURBSId** of the parent.

**Parameters:**

**NURBSId id**

The id to set.

**Prototype:**

**int GetParent();**

**Remarks:**

Returns the index in the **NURBSSet** of the parent object.

**Prototype:**

**NURBSId GetParentId();**

**Remarks:**

Returns the **NURBSId** of the parent. Note that a **NURBSId** won't be valid until the object has been instantiated in the scene.

**Prototype:**

**void SetAxis(TimeValue t, Matrix3& ray);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the extrusion axis at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the axis system.

**Matrix3& ray**

The extrusion axis.

**Prototype:**

**Matrix3& GetAxis(TimeValue t);**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the extrusion axis at the specified time.

**Parameters:**

**TimeValue t**

The time at which to get the axis.

**Prototype:**

**void SetDistance(TimeValue t, double d);**

**Remarks:**

Sets the length of the extrusion at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the distance.

**double d**

The distance to set.

**Prototype:**

**double GetDistance(TimeValue t);**

**Remarks:**

Returns the length of the extrusion at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the distance.

**Prototype:**

**void SetCurveStartPoint(TimeValue t, double startpoint);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the start point at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the start point.

**double startpoint**

The start point in the range 0.0 to 1.0.

**Prototype:**

**double GetCurveStartPoint(TimeValue t);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the start point at the specified time.

**Parameters:**

**TimeValue t**

The time at which to get the start point.

**Operators:**

**Prototype:**

**NURBSExtrudeSurface & operator=(const  
NURBSExtrudeSurface& surf);**

**Remarks:**

Assignment operator.

**Parameters:**

**const NURBSExtrudeSurface& surf**

The surface to assign.

## Class NURBSSet

See Also: [Class NURBSObject](#), [Class NURBSDisplay](#), [Class TessApprox](#), [Class NURBSFuseSurfaceCV](#), [Class NURBSFuseCurveCV](#), [Template Class Tab](#).

```
class NURBSSet : public NURBSObject
```

### Description:

This class is available in release 2.0 and later only.

This class contains a table of **NURBSObject** entities used to make up the set. Additionally it has two fuse tables: one for fuse curves and one for fuse surfaces. These are used to allow the CVs in the curves or surfaces to be 'stitched' together so if one curve or surface moves the other moves with it. This class also has information required to tessellate the objects to triangle meshes for use in the viewports and the production renderer.

All methods of this class are implemented by the system.

### Data Members:

protected:

**TessApprox \*mpVTess;**

This object describes the properties of a tessellation approximation to the mathematical surface for representation in the viewports.

**TessApprox \*mpRTess;**

This object describes the properties of a tessellation approximation to the mathematical surface for the production renderer.

**TessApprox \*mpRTessDisp;**

This object describes the tessellation properties for displacement mapping in the production renderer.

**TessApprox \*mpVTessCurve;**

This object describes the properties of a tessellation approximation to the mathematical curve for representation in the viewports.

**TessApprox \*mpRTessCurve;**

This object describes the properties of a tessellation approximation to the mathematical curve for the production renderer.

**float mTessMerge;**

Controls the tessellation of surface sub-objects whose edges are joined or very

nearly joined. When input to a modifier -- such as Mesh Select -- requires a mesh, and when NURBS surfaces are tessellated for production rendering, by default 3ds max adjusts the tessellation of adjoining surfaces to match each other, in terms of the number of faces along the edges. The Merge parameter controls how this is done. If Merge is zero, adjoining faces are unchanged. Increasing the value of Merge increases the distance 3ds max uses to calculate how edges should match, guaranteeing no gaps between the surfaces when they are rendered.

**Tab<NURBSObject\*> mObjects;**

A table of pointers to the **NURBSObjects** in the set.

**Object \*mpObject;**

The instantiated object in the scene associated with this **NURBSSet**. This is NULL if there isn't one.

**NURBSDisplay mDisplay;**

Controls the display of the object in the viewport..

public:

**Tab<NURBSFuseSurfaceCV> mSurfFuse;**

A table of objects used to allow surfaces in the set to relate to on another.

**Tab<NURBSFuseCurveCV> mCurveFuse;**

A table of objects used to allow curves in the set to relate to on another.

**Methods:**

**Prototype:**

**NURBSSet();**

**Remarks:**

Constructor. The data members are initialized as follows:

**mpObject = NULL;**

**mpVTess = NULL;**

**mpRTess = NULL;**

**mpRTessDisp = NULL;**

**mpVTessCurve = NULL;**

**mpRTessCurve = NULL;**

**mTessMerge = 0.01f;**

```
mDisplay.mDisplayCurves = TRUE;  
mDisplay.mDisplaySurfaces = TRUE;  
mDisplay.mDisplayLattices = FALSE;  
mDisplay.mDisplayShadedLattice = FALSE;  
mDisplay.mDisplaySurfCVLattices = TRUE;  
mDisplay.mDisplayCurveCVLattices = TRUE;  
mDisplay.mDisplayDependents = TRUE;  
mDisplay.mDisplayTrimming = TRUE;  
mDisplay.mDegradeOnMove = TRUE;
```

**Prototype:**

```
~NURBSSet();
```

**Remarks:**

Destructor. Any tessellation objects are deleted.

**Prototype:**

```
void Clean();
```

**Remarks:**

This method is available in release 3.0 and later only.

This removes the NURBS Set connection to a live NURBS object. One use of this is so you can call **CreateNURBSObject()** twice with the same **NURBSSet**. You call **Clean()** in between the calls. Another use is if you want to use the API to copy a NURBS object. You could call **GetNURBSSet()** followed by a **Clea()** followed by a **CreateNURBSObject()**.

**Prototype:**

```
int GetNumObjects();
```

**Remarks:**

Returns the number of objects in the set.

**Prototype:**

**void SetObject(int index, NURBSObject\* obj);**

**Remarks:**

This method sets an object in the table of objects maintained by the set. If the **index** is to an existing object in the set this will replace that object. If it is a new index, all the objects which follow this one in the set are set to NULL and the one passed is set.

**Parameters:**

**int index**

If the index is an existing object in the set this will replace the object. If it is a new index, all the objects which follow this one are set to NULL and the one passed is set.

**NURBSObject\* obj**

Points to the object to add to the table.

**Prototype:**

**NURBSObject\* GetNURBSObject(int index);**

**Remarks:**

Returns a pointer to the specified object in the table.

**Parameters:**

**int index**

The zero based index of the object to return.

**Prototype:**

**NURBSObject\* GetNURBSObject(NURBSId id);**

**Remarks:**

Returns a pointer to the specified object in the table.

**Parameters:**

**NURBSId id**

The Id of the object to return.

**Prototype:**

**void SetObject(int index, NURBSObject\* obj);**

**Remarks:**

Sets the specified NURBSObject pointer in the table to the specified pointer. If the value of index is greater than the number of items in the table, the table is resized and any non-initialized pointers are set to NULL.

**Parameters:**

**int index**

The zero based index of the object to set.

**NURBSObject\* obj**

Points to the object to set.

**Prototype:**

**int AppendObject(NURBSObject\* obj);**

**Remarks:**

Adds the specified object pointer to the end of the table of object pointers.

Note: This method is ONLY used for adding an object to a **NURBSSet** that is not yet in the scene. To add an object to an existing scene use the global function **AddNURBSObjects()**.

**Parameters:**

**NURBSObject\* obj**

The pointer to the object to append.

**Return Value:**

Returns the number of objects in the table prior to appending.

**Prototype:**

**void RemoveObject(int index);**

**Remarks:**

Removes the specified object pointer from the table.

**Parameters:**

**int index**

The zero based index of the object to remove.

**Prototype:**

```
void DeleteObjects();
```

**Remarks:**

Deletes all the objects that are in the table.

This method frees all the **NURBSObjects** in a **NURBSSet**. A developer using a **NURBSSet** must call this method to free all the memory when done.

**Prototype:**

```
TessApprox* GetProdTess(NURBSTessType  
type=kNTessSurface);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the TessApprox object for the production renderer for the specified tessellation operation.

**Parameters:**

```
NURBSTessType type=kNTessSurface
```

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

```
TessApprox* GetViewTess(NURBSTessType  
type=kNTessSurface);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the TessApprox object for the viewport renderer for the specified tessellation operation.

**Parameters:**

```
NURBSTessType type=kNTessSurface
```

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

```
void SetProdTess(TessApprox& tess, NURBSTessType  
type=kNTessSurface);
```

**Remarks:**

Sets the TessApprox object for the production renderer for the specified tessellation operation.

**Parameters:****TessApprox& tess**

The tessellation object.

**NURBSTessType type=kNTessSurface**

This parameter is available in release 3.0 and later only.

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

```
void SetViewTess(TessApprox& tess, NURBSTessType  
type=kNTessSurface);
```

**Remarks:**

Sets the TessApprox object for the viewport renderer for the specified tessellation operation.

**Parameters:****TessApprox& tess**

The tessellation object.

**NURBSTessType type=kNTessSurface**

This parameter is available in release 3.0 and later only.

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

```
void ClearViewTess(NURBSTessType type=kNTessSurface);
```

**Remarks:**

This method is available in release 3.0 and later only.

Clears (deletes) the specified tessellation object used for viewport rendering.

**Parameters:****NURBSTessType type=kNTessSurface**

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

**void ClearProdTess(NURBSTessType type=kNTessSurface);**

**Remarks:**

This method is available in release 3.0 and later only.

Clears (deletes) the specified tessellation object used for production rendering.

**Parameters:**

**NURBSTessType type=kNTessSurface**

The type of tessellation. See [List of NURBSTessTypes](#).

**Prototype:**

**void GetTessMerge();**

**Remarks:**

Returns the tessellation merge value.

**Prototype:**

**void SetTessMerge(float merge);**

**Remarks:**

Sets the tessellation merge value.

**Parameters:**

**float merge**

The tessellation merge value. Controls the tessellation of surface sub-objects whose edges are joined or very nearly joined. When input to a modifier -- such as Mesh Select -- requires a mesh, and when NURBS surfaces are tessellated for production rendering, by default 3ds max adjusts the tessellation of adjoining surfaces to match each other, in terms of the number of faces along the edges. The Merge parameter controls how this is done. If Merge is zero, adjoining faces are unchanged. Increasing the value of Merge increases the distance 3ds max uses to calculate how edges should match, guaranteeing no gaps between the surfaces when they are rendered.

**Prototype:**

**Object\* GetMAXObject();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the instantiated object in the scene associated with this **NURBSSet**. This is NULL if there isn't one.

**Prototype:**

**NURBSDisplay GetDisplaySettings();**

**Remarks:**

This method is available in release 2.5 and later only.

Returns the display settings for this **NURBSSet**.

**Prototype:**

**void SetDisplaySettings(NURBSDisplay& disp);**

**Remarks:**

This method is available in release 2.5 and later only.

Sets the display settings used by this **NURBSSet**.

**Parameters:**

**NURBSDisplay& disp**

The settings to use.

# Class TessApprox

See Also: [Class NURBSSet](#).

class TessApprox

## Description:

This class is available in release 2.0 and later only.

This class describes the properties of a tessellation approximation to the mathematical surface.

All methods of this class are implemented by the system.

## Data Members:

public:

### TessType type;

These are the types of tessellation (one of which is obsolete). One of the following values:

#### TESS\_SET

This is the old form of tessellation for Bezier Patches. This is also the default for these patches. For instance, if you create a Quad Patch and apply an Edit Patch modifier, then exit sub-object mode, you'll see a panel in the rollup for 'Tessellation'. The top choice is 'Fixed (original)'. This is the same type of tessellation done in 3ds max 1.x.

#### TESS\_PARAM

Specifies parametric tessellation. This provides for a fixed number of **u** by **v** tessellations. There are **u** times **v** quadrilaterals and each one is split up into two triangles.

#### TESS\_SPATIAL

Specifies spatial tessellation. This uses **edge** as its parameter. This specifies that the size of the tessellation will be the **edge** length (see below). In view dependent tessellation **edge** is specified in pixels.

#### TESS\_CURVE

Specifies view dependent tessellation. This uses the **ang** and **dist** data members described below.

#### TESS\_LDA

This option is available in release 3.0 and later only.

Specifies a method which combines the spatial (edge-length) method and the curvature (distance and angle) methods. This uses the **ang**, **dist** and **edge** data members below.

### **TESS\_REGULAR**

This option is available in release 3.0 and later only.

Generates a fixed, regular tessellation across the surface. There are no additional parameters.

### **TESS\_ISO**

Obsolete -- Do Not Use.

## **ViewConfig vpt\_cfg;**

This determines what is displayed in the interactive renderer. These correspond to the controls in the user interface (under Surface/Approximation/Viewports). This is not available for bezier patches. One of the following values:

### **ISO\_ONLY**

Only Iso lines. Iso(parametric) lines are similar to contour lines. The lines show where the NURBS surface has a constant U value or V value or both. Iso line representations can be less crowded and easier to visualize than wire mesh representations..

### **ISO\_AND\_MESH**

Iso lines and the mesh. When chosen, wireframe viewports display iso line representations of the surface, and shaded viewports display the shaded surface.

### **MESH\_ONLY**

Just the mesh. When chosen, wireframe viewports display the surface as a wire mesh, and shaded viewports display the shaded surface. In wireframe viewports, this option lets you see the curve approximation used for viewports.

## **TessSubdivStyle subdiv;**

This data member is available in release 3.0 and later only.

The type of subdivision. One of the following values:

### **SUBDIV\_TREE**

Subdivides the surface using a binary tree.

### **SUBDIV\_GRID**

Subdivides the surface using a regular grid.

### **SUBDIV\_DELAUNAY**

Subdivides the surface using nearly equilateral triangles.

### **BOOL view;**

Specifies if this is view dependent tessellation. If TRUE this will tessellate less finely the farther away from the camera the object is. If FALSE the tessellation does not change based on distance from the camera.

### **int u;**

This is used for parametric tessellation. This is the number of tessellations in u. This is the number of sub-divisions for a knot span for the surface.

### **int v;**

This is used for parametric tessellation. This is the number of tessellations in v.

### **int u\_iso;**

This is used with the ISO line display. This is the number of additional **interior** iso lines in u (there are always lines along the outer edges).

### **int v\_iso;**

This is used with the ISO line display. This is the number of additional **interior** iso lines in v (there are always lines along the outer edges).

### **float ang;**

This is used in curvature dependent tessellation (**TESS\_CURVE**). If 0.0 is specified this is ignored. If specified this ensure that no two adjacent face normals exceed this angle between them. This value is specified in radians.

### **float dist;**

This is used in curvature dependent tessellation (**TESS\_CURVE**). If 0.0 is specified this is ignored. This specifies a distance that cannot be exceeded between a vertex on the mesh and the mathematical surface. This is defined as a percentage of the diagonal of the bounding box of the individual surface in object space. For instance if this was set to 1.0, the allowable error in generating a tessellation would be 1% of the bounding box diagonal distance of the surface. This would be 1/100 (1 %) of the diagonal distance of the bounding box. In this way if an object is scaled the tessellation remains the same. Additionally, if you have an object with a big surface and a little surface, the smaller surface will get tessellated more finely because its own bounding box is used. This prevents the smaller surface from just becoming a single triangle for example.

**float edge;**

This is the length of an edge to use in spatial (**TESS\_SPATIAL**) tessellation. In view dependent tessellation this is specified in pixels. If not in view dependent tessellation this is a percentage of the bounding box diagonal length.

**int minSub;**

This data member is available in release 3.0 and later only.

For Grid or Tree subdivisions, this limit controls the number of recursive decompositions that are performed during tessellation. This is the minimum number of recursions.

**int maxSub;**

This data member is available in release 3.0 and later only.

For Grid or Tree subdivisions, this limit controls the number of recursive decompositions that are performed during tessellation. This is the maximum number of recursions.

**int maxTris;**

This data member is available in release 3.0 and later only.

For Delaunay subdivision, this specifies the maximum number of triangles into which the surface will be divided.

**Methods:****Prototype:****TessApprox();****Remarks:**

Constructor. The data members are initialized as follows:

**type = TESS\_SET;****u = v = 2;****u\_iso = 2;****v\_iso = 3;****view = FALSE;****ang = 20.0f;****dist = 10.0f;****edge = 10.0f;****vpt\_cfg = ISO\_AND\_MESH;**

```
merge = 0.0f;  
minSub = 0;  
maxSub = 5;  
maxTris = 20000;  
subdiv = SUBDIV_TREE;  
showInteriorFaces = FALSE;
```

**Prototype:**

```
TessApprox(TessType type, float distance, float edge, float angle,  
TessSubdivStyle subdivStyle, int minSub, int maxSub, float m =  
0.0f);
```

**Remarks:**

This method is available in release 3.0 and later only.

Constructor. The data members are initialized to the values passed.

**Prototype:**

```
TessApprox(const TessApprox &tess);
```

**Remarks:**

Constructor. The data members are initialized from the object passed.

**Operators:**

**Prototype:**

```
TessApprox & operator=(const TessApprox& tess);
```

**Remarks:**

Assignment operator.

**Parameters:**

```
const TessApprox &tess
```

The object to assign.

**Prototype:**

```
int operator==(const TessApprox &tess) const;
```

**Remarks:**

Equality operator. Returns nonzero if they are equal; otherwise zero.

**Parameters:**

**const TessApprox &tess**

The object to compare.

## Class NURBSCurve

See Also: [Class NURBSObject](#), [Class NURBSTrimPoint](#).

```
class NURBSCurve : public NURBSObject
```

### Description:

This class is available in release 2.0 and later only.

This class describes the properties of a NURBS curve. This includes its number of trim points and its open/closed state. The **Evaluate()** method is used to compute points on the curve.

All methods of this class are implemented by the system.

### Data Members:

protected:

**int mMatID;**

This data member is available in release 3.0 and later only.

The material ID for the curve.

### Friend Classes:

**friend class NURBSCVCurve;**

**friend class NURBSPointCurve;**

**friend class NURBSBlendCurve;**

**friend class NURBSOffsetCurve;**

**friend class NURBSXFormCurve;**

```
friend class NURBSExtrudeSurface;  
friend class NURBSLatheSurface;  
friend class NURBSCapSurface;  
friend class NURBS1RailSweepSurface;  
friend class NURBS2RailSweepSurface;  
friend class NURBSMultiCurveTrimSurface;
```

**Methods:**

public:

**Prototype:**

```
NURBSCurve();
```

**Remarks:**

Constructor. The data members are initialized as follows:

```
mKind = kNURBSCurve;
```

```
mMatID = 1;
```

**Prototype:**

```
~NURBSCurve();
```

**Remarks:**

Destructor.

**Prototype:**

```
BOOL IsClosed();
```

**Remarks:**

Returns TRUE if the curve is closed; otherwise FALSE.

**Prototype:**

```
int NumTrimPoints();
```

**Remarks:**

Returns the number of trim points in the curve.

**Prototype:**

**NURBSTrimPoint GetTrimPoint(TimeValue t, int i);**

**Remarks:**

Returns the 'i-th' trim point.

**Parameters:**

**TimeValue t**

The time to retrieve the trim point.

**int i**

The zero based index of the trim point to return.

**Prototype:**

**BOOL Evaluate(TimeValue t, double u, Point3& pt, Point3& tangent);**

**Remarks:**

Retrieves the point along the curve at the specified point and the tangent at that point.

**Parameters:**

**TimeValue t**

The time to evaluate the curve.

**double u**

Specifies the point along the curve to evaluate. This value must be between the **uMin** and **uMax** as returned from **GetParameterRange()**.

**Point3& pt**

The point along the curve is returned here.

**Point3& tangent**

The tangent at the specified point is returned here.

**Return Value:**

TRUE if the method was able to evaluate the curve; otherwise FALSE.

**Prototype:**

**void GetParameterRange(TimeValue t, double& uMin, double& uMax);**

**Remarks:**

Retrieves the minimum and maximum valid values for **u** as passed to **Evaluate()**.

**Parameters:**

**TimeValue t**

The time to get the parameter range of the curve.

**double& uMin**

The minimum value is returned here.

**double& uMax**

The maximum value is returned here.

**Prototype:**

**BOOL GetNURBSData(TimeValue t, int& degree, int& numCVs, NURBSCVTab& cvs, int& numKnots, NURBSKnotTab knots);**

**Remarks:**

This method is available in release 2.5 and later only.

Retrieves data about the NURBSCurve at the specified time.

**Parameters:**

**TimeValue t**

The time at which to get the NURBS information.

**int& degree**

The degree of the curve.

**int& numCVs**

The number of CVs.

**NURBSCVTab& cvs**

The table of CVs. Note: **typedef Tab<NURBSControlVertex>**

**NURBSCVTab;**

**int& numKnots**

The number of knots.

**NURBSKnotTab knots**

A table of knots in U. Note: **typedef Tab<double> NURBSKnotTab;**

**Return Value:**

TRUE if the data was retrieved; otherwise FALSE.

**Prototype:**

**int MatID();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the material ID for the curve.

**Prototype:**

**void MatID(int id);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the material ID for the curve.

**Parameters:**

**int id**

The ID to set.

**Operators:**

**Prototype:**

**NURBSCurve & operator=(const NURBSCurve& curve);**

**Remarks:**

Assignment operator.

**Parameters:**

**const NURBSCurve& curve**

The curve to assign.

## Class RendParams

See Also: [Class Atmospheric](#), [Class Effect](#), [Class IRenderElementMgr](#), [Class ToneOperator](#).

class RendParams

### Description:

This class has a set of data members, and these parameters are passed to the renderer when the renderer is opened. All methods of this class are implemented by the system.

### Data Members:

public:

#### **RendType rendType;**

The type of rendering to perform. See the [List of Render Types](#) for more information.

#### **BOOL isNetRender;**

Determines if this is a render on a network slave.

#### **BOOL fieldRender;**

If TRUE the image will be field rendered; otherwise frame rendered.

#### **int fieldOrder;**

The field order used. One of the following values:

**0** specifies even.

**1** specifies odd.

#### **TimeValue frameDur;**

This is used, for example, by video post. In video post you can stretch time. A video post frame might be 1/2 frame long for example. This data member defines the duration of one frame in TimeValue units.

#### **BOOL colorCheck;**

Determines if the color is ranged checked.

#### **int vidCorrectMethod;**

Video correction method. One of the following values:

**0** specifies FLAG (with black).

**1** specifies SCALE\_LUMA (scale luminance).

**2** specifies SCALE\_SAT (scale saturation).

**int ntscPAL;**

Determines if the color is range checked using NTSC or PAL standards. One of the following values:

**0** specifies NTSC.

**1** specifies PAL.

**BOOL superBlack;**

If TRUE Super Black is used.

**int sbThresh;**

Specifies the Super Black threshold.

**BOOL rendHidden;**

If TRUE hidden objects are rendered.

**BOOL force2Side;**

If TRUE two sided materials are used for all items in the scene.

**BOOL inMtlEdit;**

If TRUE the rendering is taking place in the material editor.

**float mtlEditTile;**

If rendering is taking place in the material editor, scale tiling.

**BOOL mtlEditAA;**

If TRUE antialiasing should be done in the material editor.

**BOOL multiThread;**

This is used internally.

**BOOL useEnvironAlpha;**

If TRUE one should use alpha from the environment map.

**BOOL dontAntialiasBG;**

If the low-order bit is set don't antialias against the background (this is often used for 'sprites' in video games). For 3ds max 1.1 and 1.2 (in 2.0 and later see **scanBandHeight** below), this parameter may also be used to access the height of the abuffer in scan lines. This may be obtained using the following syntax:

**abufBandHeight = rendpar.dontAntialiasBG>>8**

**BOOL useDisplacement;**

The apply displacement mapping setting.

**bool useRadiosity;**

This data member is available in release 4.0 and later only.  
Indicates if radiosity should be included in rendering.

**bool computeRadiosity;**

This data member is available in release 4.0 and later only.  
Indicates if radiosity should be computed before rendering.

**Texmap \*envMap;**

The environment map. This may be NULL.

**Atmospheric \*atmos;**

The atmosphere effects. This may be NULL. To the renderer it looks like there is only one atmosphere. You can use this atmosphere and it will go ahead and call all the individual atmospheric effects for you.

**Effect \*effect;**

This data member is available in release 3.0 and later only.  
The post-processing effects. This may be NULL if there aren't any.

**RadiosityEffect\* pRadiosity;**

This data member is available in release 4.0 and later only.  
Points to the radiosity effect.

**ToneOperator\* pToneOp;**

This data member is available in release 4.0 and later only.  
Points to the tone operator if present. This may be NULL

**TCHAR biFileName[MAX\_PATH];**

This data member is available in release 4.0 and later only.  
The bitmap output file name.

**TimeValue firstFrame;**

This data member is available in release 2.0 and later only.  
This is the first frame that will be rendered. This lets **Open()** know the first frame that will be rendered, so it will not have to evaluate at frame 0 when building.

**int scanBandHeight;**

This data member is available in release 2.0 and later only.  
This is the height of a scan band (for the default 3ds max scanline renderer).

**ULONG extraFlags;**

This data member is available in release 2.0 and later only.

## **RENDER\_HIDE\_FROZEN**

This option is available in release 4.0 and later only.

Instruct the renderer to hide frozen objects

### **int width;**

The image height.

### **int height;**

The image width.

### **BOOL filterBG;**

The filter background.

### **Methods:**

#### **Prototype:**

**RendParams();**

#### **Remarks:**

Constructor. The initialization can be seen in the header file RENDER.H.

#### **Prototype:**

**RenderMode GetRenderMode();**

#### **Remarks:**

This method is available in release 4.0 and later only.

Returns the rendering mode. One of the following values:

#### **RM\_Default**

This is being used for a normal rendering.

#### **RM\_IReshade**

The render is being used for interactive reshading.

#### **Prototype:**

**void SetRenderElementMgr(IRenderElementMgr  
\*pIRenderElementMgr);**

#### **Remarks:**

This method is available in release 4.0 and later only.

Sets the render element manager used.

**Parameters:****IRenderElementMgr \*pIRenderElementMgr**

Points to the render element manager to set.

**Prototype:****IRenderElementMgr \*GetRenderElementMgr();****Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the render element manager interface.

**Prototype:****virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);****Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.**Parameters:****int cmd**

The index of the command to execute.

**ULONG arg1=0**Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

# Class FrameRenderParams

See Also: [Class RenderParams](#), [Class Color](#), [Class Point2](#).

```
class FrameRenderParams : public BaseInterfaceServer
```

## Description:

This is passed to the renderer on every frame. This provides information about the ambient light color, the background color, the duration of one frame, etc.

## Data Members:

public:

### **Color ambient;**

The ambient light color.

### **Color background;**

The background color.

### **Color globalLightLevel;**

This data member is available in release 2.0 and later only.

This is a multiplier that scales the brightness of all scene lights: it doesn't affect the ambient light level.

### **float frameDuration;**

The duration of one frame in units of current frames. This describes how much scene time is used by one (video) frame time. For instance, in Video Post, you can scale time so it's stretched out or compressed. In this case, you may be rendering one frame to video, but because the scene is being run at a faster speed than normal, you in fact see say 2.5 frames of the scene. Things such as field rendering or motion blur must know about this so they know how long a frame is in terms of the time of the scene.

### **float relSubFrameDuration;**

This data member is available in release 2.0 and later only.

This is the relative fraction of **frameDuration** used by a subframe. Within the **frameDuration**, if you're sub-dividing the rendering up into multiple frames for scene motion blur, this may be used.

For instance, say the duration (frames) is set to 0.5 and the duration subdivisions is 5, then this data member would be 0.1. This means that each subframe is effectively covering only 1/10th of the frame duration.

This value is always less than 1.0.

**int regxmin, regxmax;**

These values were members of Class RendParams prior to release 3.

The x min and max boundary values for render region or render blowup in device coordinates.

**int regymin, regymax;**

These values were members of Class RendParams prior to release 3.

The y min and max boundary values for render region or render blowup in device coordinates.

**Point2 blowupCenter;**

This parameter is available in release 3.0 and later only.

The 2D point at the center of the render blowup region.

**Point2 blowupFactor;**

This parameter is available in release 3.0 and later only.

The X and Y scale factors for render blowup.

**Methods:**

**Prototype:**

**FrameRendParams();**

**Remarks:**

Constructor. The **frameDuration** is set to 1.0 and **relSubFrameDuration = 1.0f**.

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);**

**Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

**Parameters:**

**int cmd**

The index of the command to execute.

**ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

## Class ObjLightDesc

See Also: [Class LightDesc](#), [Class LightRayTraversal](#), [Class INode](#), [Class Point3](#), [Class Matrix3](#), [Class Ray](#), [Class RendContext](#), [Class ShadeContext](#), [Class RenderInstance](#).

```
class ObjLightDesc : public LightDesc
```

### Description:

A light must be able to create one of these objects to give to the renderer. As the renderer is getting ready to render, it will ask for one of these from each of the lights. The **Illuminate()** method (inherited from **LightDesc**) is called by the renderer to illuminate a surface point.

There is an **ObjLightDesc** for every instance of the light. The renderer will ask each light object to produce one of these **ObjLightDescs**. It will then set this data up in the node's render data (See [Class RenderData](#)). For example in 3ds max's volume light implementation of **Atmospheric::Update()** it goes through its node references to lights and calls **GetRenderData()**. It then casts this as an **ObjLightDesc**. This is how a atmosphere effect can get access to these descriptors at render time.

### Data Members:

This data will be set up by the default implementation of **Update()**.

#### **public:**

#### **LightState ls;**

The light state structure. See [Structure LightState](#).

#### **INode \*inode;**

This parameter is the **INode** pointer of the instance of the light that created this **ObjLightDesc**.

#### **BOOL uniformScale;**

This indicates if the light's scale is uniform. TRUE if uniform; otherwise FALSE. This saves some steps in the renderer if the scale is uniform.

#### **Point3 lightPos;**

The position of the light in camera space.

#### **Matrix3 lightToWorld;**

This is effectively the light node's object TM. This matrix will transform

points from light space to world space.

**Matrix3 worldToLight;**

This matrix will transform points from world space to light space. This is the inverse of above.

**Matrix3 lightToCam;**

This matrix will transform points from light space to camera space. This is updated in **UpdateViewDepParams()**.

**Matrix3 camToLight;**

This matrix will transform points from camera space to light space. This is updated in **UpdateViewDepParams()**. For example, the renderer would have points in camera space. To figure out if a point was in shadow it would transform the point from camera space to light space using this matrix. It could then look in the shadow buffer to see if the point was in shadow.

**int renderNumber;**

This data member is available in release 3.0 and later only.

This is set by the renderer. It is used in

**RenderInstance::CastsShadowsFrom()**. This is a number used by the renderer to identify the lights so it can quickly determine if a given light casts shadows from a given object. It is for use by the renderer.

**Methods:**

**Prototype:**

**ObjLightDesc(INode \*n);**

**Remarks:**

Constructor. The **inode** data member is initialized to **n**.

**Prototype:**

**virtual ~ObjLightDesc();**

**Remarks:**

Destructor.

**Prototype:**

**virtual ExclList\* GetExclList()**

**Remarks:**

Implemented by the Plug-In.  
Retrieves the light's exclusion list.

**Return Value:**

See [Class NameTab](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual int Update(TimeValue t, const RendContext &rc,  
RenderGlobalContext *rgc, BOOL shadows, BOOL  
shadowGeomChanged);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method is called once per render to update the light state for things that depend on the position of objects and lights in world space. A plug-in light could update any data it would need to here. The default implementation is shown below.

**Parameters:****TimeValue t**

The time of the render.

**const RendContext &rc**

See [Class RendContext](#).

**RenderGlobalContext \*rgc**

This pointer may be used to retrieve information about the global rendering environment.

**BOOL shadows**

TRUE if shadows are turned on (in the render parameters, not the light parameters); otherwise FALSE.

**BOOL shadowGeomChanged**

This tells the Update procedure that the geometry of the objects that are shadowed by the light has changed (TRUE) or not (FALSE). If it is a shadow

buffer, **shadowGeomChanged == TRUE** means it has to re-render the shadow buffer, **shadowGeomChanged == FALSE** means it can use the shadow buffer from the previous frame.

**Return Value:**

The value return should normally be 1. A returned value of 0 means an error has occurred (such as out of memory) and the render will be halted.

**Default Implementation:**

```
int ObjLightDesc::Update(TimeValue t, const RendContext& rc,
RenderGlobalContext *rgc, BOOL shadows, BOOL
shadowGeomChanged) {
  if (inode) {
    Interval valid;
    ObjectState os = inode->EvalWorldState(t);
    assert(os.obj->SuperClassID()==LIGHT_CLASS_ID);
    LightObject* lob = (LightObject *)os.obj;
    lob->EvalLightState(t, valid, &ls);
    lightToWorld = inode->GetObjTMAfterWSM(t);
    worldToLight = Inverse(lightToWorld);
    uniformScale = IsUniformScale(lightToWorld);
    affectDiffuse = ls.affectDiffuse;
    affectSpecular = ls.affectSpecular;
    ambientOnly = ls.ambientOnly;
  } else {
    uniformScale = TRUE;
    lightToWorld.IdentityMatrix();
    worldToLight.IdentityMatrix();
  }
  return 1;
}
```

**Prototype:**

```
virtual void UpdateGlobalLightLevel(Color globLightLevel);
```

**Remarks:**

This method is available in release 3.0 and later only.

Implemented by the Plug-In.

This method is called to update the light state that depends on the global light level.

**Parameters:**

**Color globLightLevel**

The global light level.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual int UpdateViewDepParams(const Matrix3& worldToCam);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to update the light state that depends on the view matrix. This is used to cache certain computed quantities that are dependent on where you are looking from. In a given scene at a given time, the system may render from several viewpoints. This is because of things like reflection maps and mirrors that need to get rendered. This method is called for each of these different viewpoints.

**Parameters:**

**const Matrix3& worldToCam**

The world space to camera space transformation matrix.

**Prototype:**

```
virtual Point3 LightPosition();
```

**Remarks:**

This method is from **LightDesc**. Here it provides a default implementation returning the **lightPos** data member.

**Default Implementation:**

```
{ return lightPos; }
```

**Prototype:**

```
virtual void TraverseVolume(ShadeContext& sc, const Ray &ray,  
int samples, float tStop, float attenStart, float attenEnd, DWORD  
flags, LightRayTraversal *proc);
```

**Remarks:**

Implemented by the Plug-In.

This function traverses a ray through the light volume. This method is implemented by plug-in lights.

Consider how the 3ds max atmospheric effects like the volume lights use this information. For each light the atmospheric effect is bound to, it calls the this method (**TraverseVolume()**) on the light. The volume light atmospheric effect passes a callback to this method (**proc**). The light then calls the **Step()** method of the callback for each partial segment of the ray. Given the illumination on the segment it computes the fog density over that segment.

The density may be constant if noise is not turned on, or it may change if noise is turned on. Using the fog density and the illumination it computes the light reflected off the atmosphere for the segment.

**Parameters:****ShadeContext& sc**

This is the **ShadeContext** passed into the **Shade()** method of the Atmospheric effect. The shade context passed in should only be used for state (like are shadows globally disabled). The position, normal, etc. serve no purpose.

**const Ray &ray**

Defines the world space ray that will be traversed.

**int samples**

The number of samples to sample along the ray. A reasonable range is from 25-100. This is more or less the suggested number of times the **proc->Step()** callback will be called. It is not precisely however because the system may take greater or fewer steps than specified as it needs to.

**float tStop**

This is the end of the **ray**. This is the point at which the traversal will stop (**ray.p+tStop\*ray.dir**). Note that the traversal can terminate earlier if the callback returns FALSE.

### **float attenStart**

Specifies a percent of the light attenuation distances that should be used for lighting during the traversal. This is used so a light can have an attenuation set to a certain percent, and then have the volume light be attenuated at a different point.

### **float attenEnd**

This specifies the ending percent of the light attenuation distances that should be used for lighting during the traversal.

### **DWORD flags**

There are three ways the shadow maps can be sampled. If none of these flags are set, the shadow map is sampled directly (this is the fastest). One of the following values:

#### **TRAVERSE\_LOWFILTSHADOWS**

This is a simple filtering where the system samples a point in the shadow map and then some of the neighboring points. This corresponds to 'Medium' in the Volume Light user interface (a value of 0 for flags is 'Low' -- just sampling the shadow map with no filtering at all).

#### **TRAVERSE\_HIFILTSHADOWS**

This is a higher resolution sampling. This corresponds to 'High' in the Volume Light user interface.

#### **TRAVERSE\_USESAMPLESIZE**

This produces the highest quality. This corresponds to 'Use Light Sample Range' in the Volume Light user interface. This is like a box filter, but also takes into consideration the position of the point within the pixel to do additional weighting.

### **LightRayTraversal \*proc**

A developer derives a class from **LightRayTraversal** and implements the **Step()** method. A pointer to it is passed here as the callback object.

### **Default Implementation:**

```
{}
```

# Class RenderInstance

See Also: [Class Mtl](#), [Class LightDesc](#), [Class INode](#), [Class Object](#), [Class Mesh](#), [Class Matrix3](#), [Class Box3](#), [Class Point3](#), [Class Interval](#).

class RenderInstance

## Description:

This class is available in release 2.0 and later only.

This class provides information about a single node being rendered. This includes information such as the mesh of the object, its material, unique node ID, object space bounding extents, number of lights affecting it, material requirements, and normals and vertex coordinates in various spaces (object and camera).

## Data Members:

public:

### **ULONG flags;**

The flags that describe the properties of this instance. See [List of Render Instance Flags](#).

### **Mtl \*mtl;**

This is the material from the node.

### **float wireSize;**

The wireframe size.

### **Mesh \*mesh;**

The mesh to be rendered. This is the result of **GeomObject::GetRenderMesh()**.

### **float vis;**

Object visibility (between 0.0 and 1.0). This is the value the visibility track evaluates to at a particular time.

### **int nodeID;**

A unique ID associated with the node. It's unique within the scene during a render.

### **int objMotBlurFrame;**

This will be equal to **NO\_MOTBLUR** for all non-blurred objects. For blurred objects, it takes on the values (**0..nBlurFrames-1**) for the successive

blur-instances.

**int objBlurID;**

The purpose of this is to differentiate blur-instances generated from different nodes. All the blur-instances for an object-motion-blurred object will have the same **objBlurID**. This is as distinct from **nodeID**, which is different for every instance. This makes it possible to easily avoid intersecting a ray with all blur-instances for an object. If

**RenderGlobalContext::IntersectWorld()** is being used, then passing in the **objBlurID** for the parameter **skipID** will have this effect.

The basic technique is this: When reflecting or refracting rays, and object motion blur is enabled, choose sub-frame times randomly for the different rays (effectively giving a coarse stochastic sampling of time).

**Matrix3 objToWorld;**

This matrix can be used to transform object coordinates to world coordinates.

**Matrix3 objToCam;**

This matrix can be used to transform object coordinates to camera coordinates.

**Matrix3 normalObjToCam;**

This matrix can be used for transforming surface normals from object space to camera space.

**Matrix3 camToObj;**

This matrix can be used to transform camera coordinates to object coordinates.

**Box3 obBox;**

The object space extents of the object being rendered.

**Point3 center;**

The object bounding sphere center (in camera coordinates)

**float radsq;**

The square of the bounding sphere's radius.

**Methods:**

**Prototype:**

**void SetFlag(ULONG f, BOOL b);**

**Remarks:**

Sets the specified flag(s) to the state passed.

**Parameters:**

## **ULONG f**

The flags to set. See [List of Render Instance Flags](#).

## **BOOL b**

The state to set; TRUE for on; FALSE for off.

### **Prototype:**

```
void SetFlag(ULONG f);
```

### **Remarks:**

Sets the specified flag(s) to on.

### **Parameters:**

**ULONG f**

The flags to set. See [List of Render Instance Flags](#).

### **Prototype:**

```
void ClearFlag(ULONG f);
```

### **Remarks:**

Clears the specified flag(s).

### **Parameters:**

**ULONG f**

The flags to set to zero. See [List of Render Instance Flags](#).

### **Prototype:**

```
BOOL TestFlag(ULONG f);
```

### **Remarks:**

Returns TRUE if the specified flag(s) are set; otherwise FALSE.

### **Parameters:**

**ULONG f**

The flags to set to zero. See [List of Render Instance Flags](#).

### **Prototype:**

```
virtual RenderInstance *Next()=0;
```

**Remarks:**

Returns a pointer to the next in **RenderInstance** in the list. A pointer to the first element in the list may be retrieved from **RenderGlobalContext::InstanceList()**.

**Prototype:**

**virtual Interval MeshValidity()=0;**

**Remarks:**

Returns the validity interval of the mesh of this render instance.

**Prototype:**

**virtual int NumLights()=0;**

**Remarks:**

Returns the number of lights affecting the node.

**Prototype:**

**virtual LightDesc \*Light(int n)=0;**

**Remarks:**

Returns a pointer to the LightDesc for the 'i-th' light affecting the node.

**Parameters:**

**int n**

Specifies which light.

**Prototype:**

**virtual BOOL CastsShadowsFrom(const ObjLightDesc& lt)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if this particular instance will cast shadows from the particular light based on the light's Exclusion/Inclusion list; FALSE if it won't cast shadows.

**Parameters:**

**const ObjLightDesc& lt**

Describes the light. See [Class ObjLightDesc](#).

**Prototype:**

**virtual INode \*GetINode()=0;**

**Remarks:**

Returns the INode pointer for the instance.

**Prototype:**

**virtual Object \*GetEvalObject()=0;**

**Remarks:**

Returns a pointer to the evaluated object for the instance. You can use this to get more information about the type of object being rendered. For instance you could look at the **Class\_ID** and recognize it as a sphere, a box, a torus, etc.

**Prototype:**

**virtual ULONG MtlRequirements(int mtlNum, int faceNum)=0;**

**Remarks:**

Returns the material requirements of the material assigned to the node. See [List of Material Requirement Flags](#).

**Parameters:**

**int mtlNum**

Specifies the number of the sub-material whose requirements should be returned. A value of **-1** may be passed to return a value generated by looping over all the sub-materials and ORing together the requirements.

**int faceNum**

This parameter is available in release 4.0 and later only.

This is the integer face number for objects which support material per face (if flag **INST\_MTL\_BYFACE** is set). See [Class IChkMtlAPI](#).

**Prototype:**

**virtual Point3 GetFaceNormal(int faceNum)=0;**

**Remarks:**

Returns the geometric normal of the specified face in object space.

**Parameters:**

**int faceNum**

Zero based index of the face whose normal is returned.

**Prototype:**

**virtual Point3 GetFaceVertNormal(int faceNum, int vertNum)=0;**

**Remarks:**

Returns the vertex normal of the specified face in camera coordinates.

**Parameters:**

**int faceNum**

Zero based index of the face in the mesh.

**int vertNum**

Zero based index of the vertex in the face.

**Prototype:**

**virtual void GetFaceVertNormals(int faceNum, Point3 n[3])=0;**

**Remarks:**

Returns the three vertex normals of the specified face in camera coordinates.

**Parameters:**

**int faceNum**

Zero based index of the face in the mesh.

**Point3 n[3]**

The normals are returned here.

**Prototype:**

**virtual Point3 GetCamVert(int vertnum)=0;**

**Remarks:**

Returns the coordinate for the specified vertex in camera coordinates

**Parameters:**

**int vertnum**

The zero based index of the vertex in the mesh.

**Prototype:**

**virtual void GetObjVerts(int fnum, Point3 obp[3])=0;**

**Remarks:**

Returns the vertices of the specified face in object coordinates.

**Parameters:**

**int fnum**

Zero based index of the face in the mesh.

**Point3 obp[3]**

The three vertices of the face in object coordinates.

**Prototype:**

**virtual void GetCamVerts(int fnum, Point3 cp[3])=0;**

**Remarks:**

Returns the vertices of the specified face in camera (view) coordinates.

**Parameters:**

**int fnum**

Zero based index of the face in the mesh.

**Point3 cp[3]**

The three vertices of the face in camera coordinates.

**Prototype:**

**virtual Mtl \*GetMtl(int faceNum)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Objects can provide a material as a function of face number via the interface provided by [Class IChkMtlAPI](#). This method will return

**RenderInstance::mtl** if flag **INST\_MTL\_BYFACE** is not set. If

**INST\_MTL\_BYFACE** is set it will return the proper by-face material. See

[List of Render Instance Flags](#).

**Parameters:**

## **int faceNum**

The zero based index of the face in the mesh.

Objects can provide a material as a function of face number via the IChkMtlAPI interface (chkmtlapi.h).

### **Prototype:**

```
virtual INT_PTR Execute(int cmd, ULONG arg1=0, ULONG  
arg2=0, ULONG arg3=0)=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

### **Parameters:**

#### **int cmd**

The index of the command to execute.

#### **ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

#### **ULONG arg2=0**

Optional argument 2.

#### **ULONG arg3=0**

Optional argument 3.

### **Return Value:**

An integer return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

### **Default Implementation:**

```
{ return 0; }
```

## Class RendContext

See Also: [Class ObjLightDesc](#).

class RendContext

### Description:

This class is passed into the method **ObjLightDesc::Update()**. The methods of this class are implemented by the 3ds max scanline renderer. Developer creating other renderer plug-ins may choose to implement the methods of this class if they wish to use the same architecture. Developers who wish to take advantage of the 3ds max volumetric light effects should implement the methods of this class. The volumetric lights are set up to work with this mechanism.

### Methods:

#### Prototype:

**virtual int Progress(int done, int total) const;**

#### Remarks:

Implemented by the Plug-In.

This method is used to update the progress bar and check the keyboard and mouse for user cancellation. A plug-in renderer should implement this method by calling the **RendProgressCallback::Progress()** method on the **RendProgressCallback** passed in to the **Renderer::Render()** method.

#### Parameters:

**int done**

This is the number completed so far.

**int total**

This is the total number of things to complete.

#### Return Value:

Nonzero to continue; zero if the user has canceled.

#### Default Implementation:

```
{ return 1; }
```

#### Prototype:

**virtual Color GlobalLightLevel() const = 0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is a multiplier that scales the brightness of all scene lights: it doesn't affect the ambient light level. It is included in **RenderContext** so the lights can use it to multiply times the light's color.

# Class PatchMesh

See Also: [Class Patch](#), [Class PatchVec](#), [Class PatchEdge](#), [Class PatchVert](#), [Class BitArray](#), [Class TessApprox](#), [Class PatchTVert](#), [Working with Patches](#).

```
class PatchMesh : public BaseInterfaceServer
```

## Description:

A patch mesh can be made up of any number of patches. Each of these patches can be three or four sided. Each edge of a patch can only be used by either one patch (which makes it an open edge) or two patches (which makes it a transitional edge between the two).

All methods of this class are implemented by the system.

## Friend Classes:

## Data Members:

```
public:
```

## Topology:

**int numVerts;**

The number of vertices.

**int numVecs;**

The number of vectors.

**int numPatches;**

The number of patches.

**int numEdges;**

The number of edges.

**Patch \*patches;**

The list of patches.

**PatchVec \*vecs;**

The list of PatchVecs.

**PatchEdge \*edges;**

The list of PatchEdges.

**Tab<HookPoint> hooks;**

This data member is available in release 3.0 and later only.

This table is used internally

**Geometry:**

**PatchVert \*verts;**

The list of PatchVerts.

**Texture coordinate assignment:**

**Tab<int> numTVerts;**

This data member is available in release 3.0 and later only.

A table containing the number of texture vertices for each channel.

**Tab<PatchTVert \*> tVerts;**

This data member is available in release 3.0 and later only.

A table containing pointers to the texture vertices for each channel.

Previous to R4.0 this was a Tab<UVVert \*>.

**Tab<TVPatch \*> tvPatches;**

This data member is available in release 3.0 and later only.

A table containing pointers to the texture vertex patches for each channel.

## **Material assignment**

**DWORD mtlIndex;**

The object level material.

## Selection

**BitArray vertSel;**

The selected vertices.

**BitArray edgeSel;**

The selected edges.

**BitArray patchSel;**

The selected patches.

**int bezVecVert;**

This is used internally.

**DWORD dispFlags;**

The display attribute flags. See [List of Patch Display Flags](#).

**DWORD selLevel;**

The current selection level. One of the following values:

**PATCH\_OBJECT** - Object level.

**PATCH\_VERTEX** - Vertex level.

**PATCH\_PATCH** - Patch level.

**PATCH\_EDGE** - Edge level.

**int cacheSteps;**

This data member is available in release 3.0 and later only.

The meshSteps used for the cache.

**BOOL cacheAdaptive;**

This data member is available in release 3.0 and later only.

The adaptive switch used for the mesh cache.

**Tab<Point3> extrudeDeltas;**

This data member is available in release 3.0 and later only.

This data member is for internal use only.

**Tab<ExtrudeData> extrudeData;**

This data member is available in release 3.0 and later only.

This data member is for internal use only.

**BitArray bevelEdges;**

This data member is available in release 3.0 and later only.

This data member is for internal use only.

## **Tab<float> edgeDistances;**

This data member is available in release 3.0 and later only.

This data member is for internal use only.

## **Methods:**

## **Constructors / Destructor**

### **Prototype:**

**PatchMesh();**

### **Remarks:**

Constructor. Initializes data members (see **Init()** below).

### **Prototype:**

**PatchMesh(PatchMesh& fromPatch);**

### **Remarks:**

Constructor. This **PatchMesh** is initialized from the specified **PatchMesh**.

### **Prototype:**

**void Init();**

### **Remarks:**

Initializes the data members to default values:

```
meshSteps = 5;  
adaptive = FALSE;  
rVerts = NULL;  
cacheGW = NULL;  
numVerts = 0;  
numVecs = 0;  
numPatches = 0;  
numEdges = 0;  
patches = NULL;  
edges = NULL;  
numTVerts.ZeroCount();
```

```
tvPatches.ZeroCount();
tVerts.ZeroCount();
vecs = NULL;
verts = NULL;
mtlIndex = 0;
flags = 0;
snapVCt = 0;
snapPCt = 0;
snapV = NULL;
snapP = NULL;
dispFlags = DISP_LATTICE;
selLevel = PATCH_OBJECT;
bezVecVert = -1;
bdgBox.Init();
cacheSteps = -9999;
cacheAdaptive = -9999;
prodTess.u = 5;
prodTess.v = 5;

dispTess.view = TRUE;
viewTess.u = 5;
viewTess.v = 5;
viewTess.view = FALSE;
viewTess.ang = 20.0f;
viewTess.dist = 10.0f;
viewTess.edge = 10.0f;
```

**Prototype:**

**~PatchMesh();**

**Remarks:**

Destructor. Frees up allocated arrays.

**Prototype:**

**void CopyPatchDataFrom(PatchMesh &fromPatchMesh);**

**Remarks:**

This method is available in release 3.0 and later only.

The following is similar to operator=, but just takes the major components, not the display flags, selection level, etc.

**Parameters:**

**PatchMesh &fromPatchMesh**

The patch mesh to copy from.

**Vert Access****Prototype:**

**BOOL setNumVerts(int ct, BOOL keep = FALSE);**

**Remarks:**

Sets the number of vertices in the patch mesh.

**Parameters:**

**int ct**

The new number of vertices.

**BOOL keep = FALSE**

If TRUE any old vertices are copied to the new array; otherwise they are freed.

**Return Value:**

TRUE if the number of vertices was allocated; otherwise FALSE.

**Prototype:**

**int getNumVerts();**

**Remarks:**

Returns the number of vertices in the patch mesh.

**Prototype:**

```
void setVert(int i, const Point3 &xyz)
```

**Remarks:**

Sets the 'i-th' vertex.

**Parameters:**

**int i**

The index of the vertex to set.

**const Point3 &xyz**

The vertex location.

**Prototype:**

```
void setVert(int i, float x, float y, float z)
```

**Remarks:**

Sets the 'i-th' vertex.

**Parameters:**

**int i**

The index of the vertex to set.

**float x, float y, float z**

The vertex location.

**Prototype:**

```
PatchVert &getVert(int i)
```

**Remarks:**

Returns the 'i-th' vertex.

**Parameters:**

**int i**

The index of the vertex to retrieve.

**Prototype:**

**PatchVert \*getVertPtr(int i)**

**Remarks:**

Returns the address of the 'i-th' vertex.

**Parameters:**

**int i**

The index of the vertex.

## **TVert Access**

**Prototype:**

**BOOL setNumTVerts(int ct, BOOL keep=FALSE);**

**Remarks:**

Sets the number of mapping verts in the original mapping channel (channel 1).

**Parameters:**

**int ct**

The number of map vertices desired.

**BOOL keep = FALSE**

If TRUE, any existing mapping verts are copied over into the new array.

**Return Value:**

TRUE if successful, FALSE if unsuccessful.

**Prototype:**

**int getNumTVerts() const;**

**Remarks:**

Returns the number of mapping vertices in the original mapping channel (channel 1).

**Prototype:**

**BOOL setNumTVertsChannel(int mp, int ct, BOOL keep=FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the number of mapping vertices in the original TV map or vertex color channel.

**Parameters:**

**int mp**

Specifies the channel. If 0, the number of vertices in the original mapping channel (map channel 1) is set. If nonzero, the number of vertices in the vertex color channel (map channel 0) is set.

**int ct**

The number of map vertices desired.

**BOOL keep=FALSE**

If TRUE, any existing mapping verts are copied over into the new array.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**int getNumTVertsChannel(int mp);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of mapping verts in the original map or vertex colors.

**Parameters:**

**int mp**

If 0, the number of vertices in the original mapping channel (map channel 1) is returned. If nonzero, the number of vertices in the vertex color channel (map channel 0) is returned.

**Prototype:**

**PatchTVert \*mapVerts(int mp);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the list of PatchTVerts for the specified channel of this patch.

**Parameters:**

**int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**Prototype:**

**BOOL setNumMapVerts(int mp, int ct, BOOL keep = FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of mapping verts in the specified mapping channel.

**Parameters:****int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int ct**

The number of mapping verts desired.

**BOOL keep=FALSE**

If TRUE any old vertices are copied to the new array; otherwise they are freed.

**Return Value:**

TRUE if the number of vertices was allocated; otherwise FALSE.

**Prototype:**

**int getNumMapVerts(int mp);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of mapping verts in the specified mapping channel.

**Parameters:****int mp**

In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**Prototype:**

**void setTVert(int i, const UVVert &xyz)**

**Remarks:**

Sets the 'i-th' map vertex.

**Parameters:**

**int i**

The index of the map vertex to set.

**const UVVert &xyz**

The value to set.

**Prototype:**

**void setTVert(int i, float x, float y, float z)**

**Remarks:**

Sets the 'i-th' map vertex.

**Parameters:**

**int i**

The index of the map vertex to set.

**float x, float y, float z**

The values to set.

**Prototype:**

**void setTVertChannel(int channel, int i, const UVVert &xyz);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the 'i-th' map vertex of the specified channel.

**Parameters:**

**int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the map vertex to set.

**const UVVert &xyz**

The value to set.

**Prototype:**

**void setTVertChannel(int channel, int i, float x, float y, float z);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the 'i-th' map vertex of the specified channel.

**Parameters:**

**int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the map vertex to set.

**float x, float y, float z**

The values to set.

**Prototype:**

**void setTVPatchChannel(int channel, int i, TVPatch &tvpatch);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the 'i-th' map patch.

**Parameters:**

**int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the map vertex to set.

**TVPatch &tvpatch**

The map patch to set.

**Prototype:**

**void setTVPatch(int i, TVPatch &tvpatch);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified map patch.

**Parameters:**

**int i**

The zero based index of the texture patch to set.

**TVPatch &tv**

The map patch to set.

**Prototype:**

**void setMapVert(int mp, int i, const UVVert &xyz);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified mapping vertex in the channel passed.

**Parameters:**

**int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the vert to set.

**const UVVert &xyz**

The vert to set.

**Prototype:**

**void setMapVert(int mp, int i, float x, float y, float z);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified mapping vertex in the channel passed.

**Parameters:**

**int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the vert to set.

**float x**

The x coordinate of the vert to set.

**float y**

The y coordinate of the vert to set.

**float z**

The z coordinate of the vert to set.

**Prototype:**

```
void setMapPatch(int mp, int i, const TVPatch &ttp);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified mapping patch in the channel passed.

**Parameters:****int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the TVPatch to set.

**const TVPatch &ttp**

The map patch to set.

**Prototype:**

```
PatchTVert &getMapVert(int mp, int i);
```

**Remarks:**

This method is available in release 3.0 and later only.

Previous to R4, this method returned an UVVert&.

Returns a reference to the specified mapping vert from the specified channel.

**Parameters:****int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the vert to get.

**Prototype:**

**PatchTVert \*getMapVertPtr(int mp, int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Previous to R4, this method returned an UVVert\*.

Returns a pointer to the specified mapping vert from the specified channel.

**Parameters:**

**int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the vert to get.

**Prototype:**

**TVPatch &getMapPatch(int mp, int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a reference to the specified map patch from the specified channel.

**Parameters:**

**int mp**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The zero based index of the map patch to get.

**Prototype:**

**PatchTVert &getTVert(int i)**

**Remarks:**

Previous to R4, this method returned an UVVert&.

Returns the 'i-th' map vertex.

**Parameters:****int i**

The index of the map vertex to retrieve.

**Prototype:****PatchTVert \*getTVertPtr(int i)****Remarks:**

Previous to R4, this method returned an UVVert\*.

Returns a pointer to the 'i-th' map vertex.

**Parameters:****int i**

The index of the map vertex.

**Prototype:****PatchTVert &getTVertChannel(int channel, int i);****Remarks:**

This method is available in release 2.0 and later only.

Previous to R4, this method returned an UVVert&.

Returns the 'i-th' map vertex of the specified channel.

**Parameters:****int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the map vertex to retrieve.

**Prototype:****PatchTVert \*getTVertPtrChannel(int channel, int i);****Remarks:**

This method is available in release 2.0 and later only.

Previous to R4, this method returned an UVVert\*.

Returns a pointer to the 'i-th' map vertex of the specified channel.

**Parameters:****int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the texture vertex.

**TVPatch Access****Prototype:****BOOL setNumTVPatches(int ct, BOOL keep=FALSE, int oldCt=0);****Remarks:**

Sets the number of map patches in the original TV channel. (Note that **setNumMapPatches()** is called from **setNumPatches()**, so this doesn't need to be called separately once a map channel is active.)

Note:

If the map patches are NULL and keep = TRUE they stay NULL.

If the map patches are NULL and keep = FALSE they are allocated, and map verts also init themselves from the main vert array.

If the map patches are non-NULL and ct = 0 they are set to NULL (and freed)

**Parameters:****int ct**

The number of map patches desired -- should match the number of patches.

**BOOL keep=FALSE**

If TRUE, existing map patches are copied into the new map patch array. oldCt should specify how many patches were around previously.

**int oldCt=0**

The old number of patches. This is important for determining how much to copy over when keep is TRUE.

**Return Value:**

TRUE if storage has been allocated and the number is set; otherwise FALSE.

**Prototype:**

```
BOOL setNumTVPatchesChannel(int channel, int ct, BOOL  
keep=FALSE, int oldCt=0);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the number of map patches in the original TV or vertex color channels. (Note that **setNumMapPatches()** is called from **setNumPatches()**, so this doesn't need to be called separately once a map channel is active.)

**Note:**

If the map patches are NULL and keep = TRUE they stay NULL.

If the map patches are NULL and keep = FALSE they are allocated, and map verts also init themselves from the main vert array.

If the map patches are non-NULL and ct = 0 they are set to NULL (and freed)

**Parameters:****int channel**

If 0, the number of map patches in the original map channel are set. If nonzero, the number of map patches in the vertex color channel is set.

**int ct**

The number of map patches desired -- should match the number of patches.

**BOOL keep=FALSE**

The keep flag. See above.

**int oldCt=0**

The old number of patches. This is important for determining how much to copy over when keep is TRUE.

**Return Value:**

TRUE if storage has been allocated and the number is set; otherwise FALSE.

**Prototype:**

```
BOOL setNumMapPatches(int channel, int ct, BOOL keep=FALSE, int  
oldCt=0);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the number of map patches in the specified map channel. (Note that this is called from **setNumPatches()**, so it doesn't need to be called separately once a map channel is active.)

Note:

If the map patches are NULL and keep = TRUE they stay NULL.

If the map patches are NULL and keep = FALSE they are allocated, and map verts also init themselves from the main vert array.

If the map patches are non-NULL and ct = 0 they are set to NULL (and freed).

**Parameters:**

**int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int ct**

The number of map patches desired -- should match the number of patches.

**BOOL keep=FALSE**

If TRUE, existing map patches are copied into the new map patch array. oldCt should specify how many patches were around previously.

**int oldCt=0**

The old number of patches. This is important for determining how much to copy over when keep is TRUE.

**Return Value:**

TRUE if storage has been allocated and the number is set; otherwise FALSE.

**Prototype:**

**TVPatch &getTVPatchChannel(int channel, int i);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the 'i-th' texture patch structure of the specified channel.

**Parameters:**

**int channel**

The mapping channel. In this method, 0 is the vertex color channel, and channels 1 through MAX\_MESHMAPS-1 are the map channels.

**int i**

The index of the TVPatch.

**Prototype:**

**TVPatch &getTVPatch(int i);**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the 'i-th' texture patch from map channel 1.

**Parameters:**

**int i**

The index of the TVPatch.

## **Vec Access**

**Prototype:**

**BOOL setNumVecs(int ct, BOOL keep = FALSE);**

**Remarks:**

Sets the number of vectors.

**Parameters:**

**int ct**

The new vector count.

**BOOL keep = FALSE**

If TRUE any previous vectors are copied; otherwise they are freed.

**Return Value:**

TRUE if the number was allocated and set; otherwise FALSE.

**Prototype:**

**int getNumVecs();**

**Remarks:**

Returns the number of vectors.

**Prototype:**

**void setVec(int i, const Point3 &xyz)**

**Remarks:**

Sets the 'i-th' vector.

**Parameters:**

**int i**

The index of the vector to set.

**const Point3 &xyz**

The vector to set.

**Prototype:**

**void setVec(int i, float x, float y, float z)**

**Remarks:**

Sets the 'i-th' vector.

**Parameters:**

**int i**

The index of the vector to set.

**float x, float y, float z**

The vector values to set.

**Prototype:**

**PatchVec &getVec(int i)**

**Remarks:**

Returns the 'i-th' vector.

**Parameters:**

**int i**

The index of the vector to retrieve.

**Prototype:**

**PatchVec \*getVecPtr(int i)**

**Remarks:**

Returns the address of the 'i-th' vector.

**Parameters:****int i**

The index of the vector.

**Patch Access****Prototype:****BOOL setNumPatches(int ct, BOOL keep = FALSE);****Remarks:**

Sets the number of patches.

**Parameters:****int ct**

The new patch count.

**BOOL keep = FALSE**

If TRUE any previous patches are copied; otherwise they are freed.

**Return Value:**

TRUE if the number was allocated and set; otherwise FALSE.

**Prototype:****int getNumPatches();****Remarks:**

Returns the number of patches.

**Edge Access****Prototype:****BOOL setNumEdges(int ct, BOOL keep = FALSE);****Remarks:**

Sets the number of edges.

**Parameters:****int ct**

The new edge count.

**BOOL keep = FALSE**

If TRUE any previous edges are copied; otherwise they are freed.

**Return Value:**

TRUE if the number was allocated and set; otherwise FALSE.

**Prototype:**

**int getNumEdges();**

**Remarks:**

Returns the number of edges.

**RVert Access**

**Prototype:**

**PRVertex &getRVert(int i)**

**Remarks:**

This method is not currently used.

**Prototype:**

**PRVertex \*getRVertPtr(int i)**

**Remarks:**

This method is not currently used.

**Material / Mapping Access**

**Prototype:**

**void setMtlIndex(DWORD i)**

**Remarks:**

This method is no longer used.

**Prototype:**

**DWORD getMtlIndex()**

**Remarks:**

This method is no longer used.

**Prototype:**

**void setNumMaps(int ct, BOOL keep=TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Set the number of texture maps used by this PatchMesh.

**Parameters:**

**int ct**

The number to use. This is a value between 2 and **MAX\_MESHMAPS-1**.

**BOOL keep=TRUE**

TRUE to keep the old mapping information after the resize; FALSE to discard it.

**Prototype:**

**void setMapSupport(int chan, BOOL init=TRUE);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will allocate mapping channels as needed. If the map channel is already present, no action is taken. Otherwise, the additional channels are created.

**Parameters:**

**int chan**

Specifies which channel. See [List of Mapping Channel Index Values](#). If zero (special vertex color channel) and **init** is TRUE, all vertex colors are initialized to white (1,1,1).

**BOOL init=TRUE**

If TRUE, the channel is initialized to match the PatchMesh's structure.

**Prototype:**

**int getNumMaps();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the number of mapping channels in use.

**Prototype:**

**BOOL getMapSupport(int mp);**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns TRUE if the specified mapping channel is supported; otherwise FALSE.

**Parameters:**

**int mp**

Specifies which channel. See [List of Mapping Channel Index Values](#).

**Prototype:**

**int NumMapChannels();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the maximum number of possible mapping channels.

**Prototype:**

**void ApplyUVWMap(int type,  
float utile, float vtile, float wtile,  
int uflip, int vflip, int wflip, int cap,  
const Matrix3 &tm, int channel=1);**

**Remarks:**

This method may be called to map this **PatchMesh** with UVW mapping coordinates.

**Parameters:**

**int type**

The mapping type. One of the following values:

**MAP\_PLANAR**

**MAP\_CYLINDRICAL**

**MAP\_SPHERICAL**

**MAP\_BALL**

**MAP\_BOX**

**float utile**

Number of tiles in the U direction.

**float vtile**

Number of tiles in the V direction.

**float wtile**

Number of tiles in the W direction.

**int uflip**

If nonzero the U values are mirrored.

**int vflip**

If nonzero the V values are mirrored.

**int wflip**

If nonzero the W values are mirrored.

**int cap**

This is used with **MAP\_CYLINDRICAL**. If nonzero, then any patch normal that is pointing more vertically than horizontally will be mapped using planar coordinates.

**const Matrix3 &tm**

This defines the mapping space. As each point is mapped, it is multiplied by this matrix, and then it is mapped.

**int channel=1**

This parameter is available in release 2.0 and later only.

This indicates which channel the mapping is applied to -- **channel==1** corresponds to the original texture channel. Note that this is a change from what it meant before release 3.0. Previously channel 1 referred to the color per vertex channel (and this parameter defaulted to 0).

**Prototype:**

**void ChangePatchToLinearMapping(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

This method changes the mapping of a patch or all selected patches to linear.

**Parameters:**

**int index**

The index of the patch for which to change the mapping to linear. A value < 0 indicates all selected patches are to be changed to linear mapping.

**Prototype:**

**void ChangePatchToCurvedMapping(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

This method changes the mapping of a patch or all selected patches to curved.

**Parameters:**

**int index**

The index of the patch for which to change the mapping to curved. A value < 0 indicates all selected patches are to be changed to curved mapping.

**Prototype:**

**BOOL ArePatchesLinearMapped(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will check if one or all selected patches have linear mapping applied.

**Parameters:**

**int index**

The index of the patch for which to check if mapping is linear. A value < 0 indicates all selected patches are checked for linear mapping.

**Return Value:**

TRUE if the specified patch or selected patches have linear mapping applied, otherwise FALSE.

**Prototype:**

**BOOL ArePatchesCurvedMapped(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will check if one or all selected patches have curved mapping applied.

**Parameters:****int index**

The index of the patch for which to check if mapping is curved. A value < 0 indicates all selected patches are checked for curved mapping.

**Return Value:**

TRUE if the specified patch or selected patches have curved mapping applied, otherwise FALSE.

**Prototype:**

**BOOL RecordTopologyTags();**

**Remarks:**

This method tags the points in the patch components to record our topology (this stores identifying values in the various aux2 fields in the Patch). This information can be used after topology-changing operations to remap information tied to vertices, edges and patches.

**Return Value:**

Returns TRUE if tagged successfully; otherwise FALSE.

**Prototype:**

**void Transform(Matrix3 &tm);**

**Remarks:**

This method is available in release 3.0 and later only.

Transforms the vertices and vectors of the patch mesh, re-computes the interior bezier points for each patch in the mesh and invalidates the geometry cache.

**Parameters:****Matrix3 &tm**

The matrix to transform with.

**Prototype:**

**BOOL Weld(float thresh, BOOL weldIdentical=FALSE, int startVert=0);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**void DeletePatchParts(BitArray &delVerts, BitArray &delPatches);**

**Remarks:**

This method is available in release 3.0 and later only.

This is a method which may be used to delete sets of verts or patches.

**Parameters:**

**BitArray &delVerts**

A bit array with bits set for verts to delete.

**BitArray &delPatches**

A bit array with bits set for patches set to delete.

**Prototype:**

**void Subdivide(int type, BOOL propagate);**

**Remarks:**

This method is available in release 3.0 and later only.

Subdivides the selected edge or patch.

**Parameters:**

**int type**

One of the following values:

**SUBDIV\_EDGES**

Subdivides an edge.

**SUBDIV\_PATCHES**

Subdivides an entire patch

**BOOL propagate**

TRUE to propagate; FALSE to not propagate.

**Prototype:**

**void AddPatch(int type);**

**Remarks:**

This method is available in release 3.0 and later only.

Add a patch of the desired type to each selected edge that doesn't have two patches attached.

**Parameters:**

**int type**

One of the following values:

**PATCH\_TRI**

**PATCH\_QUAD**

**Prototype:**

**int AddHook();**

**Remarks:**

This method is available in release 3.0 and later only.

This method is obsolete and should not be used.

**Prototype:**

**int AddHook(int index);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is obsolete and should not be used.

**Prototype:**

**int AddHook(int vertIndex, int segIndex);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is obsolete and should not be used.

**Prototype:**

**int RemoveHook();**

**Remarks:**

This method is available in release 3.0 and later only.

This method is obsolete and should not be used.

**Prototype:**

**int UpdateHooks();**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**void CreateExtrusion(int type = PATCH\_PATCH, BOOL  
edgeClone=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

This method will create all the necessary geometry for an extrusion operation.

**Parameters:**

**int type**

This option is available in release 4.0 and later only.

Specifies the extrusion type, either **PATCH\_PATCH** or **PATCH\_EDGE**.

If the extrusion type is set to **PATCH\_EDGE**, then the **edgeClone** parameter will tell the function to clone the selected edges prior to creating the extrusion geometry.

**BOOL edgeClone**

This option is available in release 4.0 and later only.

The edge clone flag. If set to **TRUE** the function will clone the selected edges prior to creating the extrusion geometry.

**Prototype:**

**Point3 AverageNormals(int type = PATCH\_PATCH);**

**Remarks:**

This method is available in release 3.0 and later only.

This method will allow you to obtain the average normal of all selected patches or edges.

**Parameters:****int type**

This option is available in release 4.0 and later only.

Specifies if the average normal return is based on all selected patches, using **PATCH\_PATCH**, or all selected edges using **PATCH\_EDGE**.

**Prototype:**

**Point3 PatchNormal(int index);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**void MoveNormal(float amount, BOOL useLocalNorms, int type);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**void FlipPatchNormal(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

This method flips the normal of the specified patch. This is done by reordering the vertices. If the PatchMesh has textures assigned to it then the texture patches are processed as well.

**Parameters:****int index**

The index of the patch for which you want to flip the normal.

**Prototype:****void UnifyNormals(BOOL useSel);****Remarks:**

This method is available in release 4.0 and later only.

This method makes sure the patches in the operation set are all facing the same direction. This is determined by the vertex order around the edges of the patch.

**Parameters:****BOOL useSel**

If this parameter is set to TRUE, the operation set is the set of selected patches as indicated by the **patchSel** BitArray. If this parameter is set to FALSE, all patches are processed.

**Prototype:****void AutoSmooth(float angle, BOOL useSel, BOOL preventIndirectSmoothing);****Remarks:**

This method is available in release 4.0 and later only.

This method will perform automatic smoothing on the patch mesh. The smoothing angle is determined for each patch by computing the normals at each corner of the patch (using the corner vertex and the two edge vectors connected to that vertex), then averaging the normals of the two corners of each edge to arrive at a normal for that edge. These normals are used to determine whether adjacent patches are within the auto-smooth threshold angle.

**Parameters:****float angle**

The minimum angle between surface normals for smoothing to be applied, in radians.

**BOOL useSel**

If this parameter is set to TRUE then only the selected patches are smoothed.

**BOOL preventIndirectSmoothing**

TRUE to turn on; FALSE to leave it off. This matches the option in the

Smooth Modifier UI -- use this to prevent smoothing "leaks" when using this method. If you use this method, and portions of the patch mesh that should not be smoothed become smoothed, then try this option to see if it will correct the problem. Note that the problem it corrects is rare, and that checking this slows the automatic smoothing process.

**Prototype:**

**void CreateBevel();**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**void Bevel(float amount, int smoothStart, int smoothEnd);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used internally.

**Prototype:**

**Point3 GetBevelDir(int patchVertID);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use.

**buildLinkages() / computeInteriors() / ApplyConstraints() /  
GetEdge()**

**Prototype:**

**BOOL buildLinkages(int patch = -1);**

**Remarks:**

This is an important method to call after putting together a **PatchMesh**. This method does the work to figure out how the **PatchMesh** is connected together, one patch to another. It determines which edges are used by which

patches and so on.

**Parameters:**

**int patch**

This option is available in release 4.0 and later only.

This optional parameter allows you to only update adjacency information for a single new patch. If the plugin code is adding new patches and not removing any others then you can call this method with the new patch index and the various adjacency information in vertices, vectors, and edges will be built. If you call this method for the entire object (no parameter or **patch** < 0) it will destroy all adjacency information and rebuild it from scratch.

**Return Value:**

TRUE if the patch mesh is valid, FALSE if it is not.

**Prototype:**

**void computeInteriors();**

**Remarks:**

This method computes the interior bezier points for each patch in the mesh. This method should be called after any modifications have been made to alter the **PatchMesh** (for example changes to point positions). If there are any automatic patches this will compute the interior vectors.

**Prototype:**

**void ApplyConstraints(BOOL selOnly = FALSE);**

**Remarks:**

This method may be called to apply the coplanar constraints to the patch mesh. The constraints may optionally only apply to selected vertices. There is a flag that may be set for a patch vertex (**PVERT\_COPLANAR**). For example, you can set this flag to make a vertex coplanar with its vectors. If this is done, then when this method is called, the patch code will then go through the **PatchMesh** and find the average plane that is used by the vertex and all the vectors associated with it. It will then constrain all the vectors to lie in this plane (by rotating them so that they lie on the plane). In this way there will be a consistent transition between the patches sharing the vertex.

**Parameters:**

**BOOL selOnly = FALSE**

If TRUE the constraints are only applied to the selected vertices; otherwise all vertices.

**Prototype:**

**int GetEdge(int v1, int v12, int v21, int v2, int p);**

**Remarks:**

This method is used internally.

**ClonePatchParts() / SingleEdgesOnly() / GetElement() / WeldEdges()**

**Prototype:**

**void ClonePatchParts(BitArray \*patches = NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will copy the patches specified by the BitArray, or by the patch selection set if the BitArray **patches** pointer is NULL. This method is used by Editable Patch and Edit Patch to facilitate the shift-copy operations.

**Parameters:**

**BitArray \*patches**

The array containing the series of selected patches.

**Prototype:**

**BOOL SingleEdgesOnly();**

**Remarks:**

This method is available in release 4.0 and later only.

This method examines the selected edges and will return TRUE if all selected edges are used by only one single patch. If the method returns FALSE, there are no edges selected or any of the selected edges are used by more than one single patch.

**Prototype:****BitArray& GetElement(int index);****Remarks:**

This method is available in release 4.0 and later only.

This method will return a BitArray that defines the group of patches defining an element that contains the patch indicated by the specified index. A PatchMesh element is any set of patches sharing common vertices.

**Parameters:****int index**

The patch index for which to return the element.

**Prototype:****BOOL WeldEdges();****Remarks:**

This method is available in release 4.0 and later only.

This method will weld any edges which are selected and have the same endpoints.

**Return Value:**

TRUE if any welding took place, otherwise FALSE.

## Selection Weights

**Prototype:****float \*GetVSelectionWeights();****Remarks:**

This method is available in release 4.0 and later only.

This method provides direct access to the vertex weights array and is included to match a similar function in the Mesh class.

**Return Value:**

A pointer to the vertex weights array.

**Default Implementation:****{ return mpVertexWeights; }**

**Prototype:****void SupportVSelectionWeights();****Remarks:**

This method is available in release 4.0 and later only.

This method allocates a vertex weights array, if none is currently allocated.

This method is included to match a similar function in the Mesh class.

**Conversion to Mesh****Prototype:****void ComputeMesh(Mesh& msh, DWORD convertFlags);****Remarks:**

This method is available in release 4.0 and later only.

This method will produce the mesh version of the PatchMesh.

**Parameters:****Mesh& msh**

The mesh in which the resulting mesh should be stored.

**DWORD convertFlags**

The flags modifying the mesh process.

**PATCH\_CONVERT\_KEEPESEL**

This flag indicates that the subobject vertex and patch selections in the PatchMesh should be converted to subobject vertex and face selections in the mesh.

**PATCH\_CONVERT\_USESOFTSEL**

This flag indicates that soft selections should be used in the mesh to interpolate between selected and nonselected vertices. (Soft Selections cannot be based on edge or patch selection in the PatchMesh, only vertex selection.)

**Render / Snap / Hit Test****Prototype:****void render(GraphicsWindow \*gw, Material \*ma, RECT \*rp, int**

**compFlags, int numMat=1);**

**Remarks:**

Renders a patch mesh using the specified graphics window and array of materials.

**Parameters:**

**GraphicsWindow \*gw**

Points to the graphics window to render to.

**Material \*ma**

The list of materials to use to render the patch.

**RECT \*rp**

Specifies the rectangular region to render. If the patch mesh should be rendered to the entire viewport pass NULL.

**int compFlags**

One or more of the following flags:

**COMP\_TRANSFORM**

Forces recalculation of the model to screen transformation; otherwise attempt to use the cache.

**COMP\_IGN\_RECT**

Forces all polygons to be rendered; otherwise only those intersecting the box will be rendered.

**COMP\_LIGHTING**

Forces re-lighting of all vertices (as when a light moves); otherwise only re-light moved vertices

**COMP\_ALL**

All of the above flags.

**COMP\_OBJSELECTED**

If this bit is set then the node being displayed by this mesh is selected. Certain display flags only activate when this bit is set.

**COMP\_OBJFROZEN**

If this bit is set then the node being displayed by this mesh is frozen.

**int numMat=1**

The number of materials supported.

**Prototype:**

```
BOOL select(GraphicsWindow *gw, Material *ma, HitRegion *hr,  
int abortOnHit = FALSE, int numMat=1);
```

**Remarks:**

Checks the given HitRecord **hr** to see if it intersects the patch mesh object.

**Parameters:**

**GraphicsWindow \*gw**

Points to the graphics window to check.

**Material \*ma**

The list of materials for the patch mesh.

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**int abortOnHit = FALSE**

If nonzero, the hit testing is complete after any hit; otherwise all hits are checked.

**int numMat=1**

The number of materials supported.

**Return Value:**

TRUE if the item was hit; otherwise FALSE.

**Prototype:**

```
void snap(GraphicsWindow *gw, SnapInfo *snap, IPoint2 *p,  
Matrix3 &tm);
```

**Remarks:**

Checks to see if there is a snap point near the given mouse point.

**Parameters:**

**GraphicsWindow \*gw**

The graphics window in which to check.

**SnapInfo \*snap**

This structure describes the snap settings used, and the results of the snap test. See [Structure SnapInfo](#).

**IPoint2 \*p**

The mouse point to check.

**Matrix3 &tm**

The object transformation matrix. This is the transformation to place the object into the world coordinate system.

**Prototype:**

```
BOOL SubObjectHitTest(GraphicsWindow *gw, Material *ma,  
HitRegion *hr,  
DWORD flags, SubPatchHitList& hitList, int numMat=1);
```

**Remarks:**

This method may be called to perform sub-object hit testing of the patch mesh.

**Parameters:****GraphicsWindow \*gw**

The graphics window associated with the viewport the patch mesh is being hit tested in.

**Material \*ma**

The list of materials for the patch mesh.

**HitRegion \*hr**

This describes the properties of a region used for the hit testing. See [Class HitRegion](#).

**DWORD flags**

Flags for sub object hit testing. One or more of the following values:

**SUBHIT\_PATCH\_SELOONLY**

Selected only.

**SUBHIT\_PATCH\_UNSELOONLY**

Unselected only.

**SUBHIT\_PATCH\_ABORTONHIT**

Abort hit testing on the first hit found.

**SUBHIT\_PATCH\_SELSSOLID**

This treats selected items as solid and unselected items as not solid. Treating an item as solid means the patch will be hit if the mouse is anywhere inside the patch region and not just over a visible edge.

## **SUBHIT\_PATCH\_VERTS**

Hit test vertices.

## **SUBHIT\_PATCH\_VECS**

Hit test vectors.

## **SUBHIT\_PATCH\_PATCHES**

Hit test patches.

## **SUBHIT\_PATCH\_EDGES**

Hit test edges.

## **SubPatchHitList& hitList**

See [Class SubPatchHitList](#).

## **int numMat=1**

The number of materials for the mesh.

### **Return Value:**

TRUE if the item was hit; otherwise FALSE.

## **Bounding Box Methods**

### **Prototype:**

**void buildBoundingBox();**

### **Remarks:**

Computes the bounding box of the patch mesh. The bounding box is stored with the patch mesh object, use **getBoundingBox()** to retrieve it.

### **Prototype:**

**Box3 getBoundingBox(Matrix3 \*tm=NULL);**

### **Remarks:**

Retrieves the bounding box of the patch mesh object.

### **Parameters:**

**Matrix3 \*tm=NULL**

The optional TM allows the box to be calculated in any space.

### **Prototype:**

**void renderGizmo(GraphicsWindow \*gw);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will render a gizmo version of the PatchMesh and is used primarily by Editable Patch and Edit Patch to facilitate the Show End Result feature.

**Parameters:**

**GraphicsWindow \*gw**

The graphics window associated with the viewport the patch mesh gizmo should be shown in.

## Data Flow Evaluation

**Prototype:**

**void InvalidateGeomCache();**

**Remarks:**

This method should be called when the **PatchMesh** changes. It invalidates the caches of the patch mesh.

**Prototype:**

**void FreeAll();**

**Remarks:**

Frees everything from the patch mesh.

**Prototype:**

**void ShallowCopy(PatchMesh \*amesh, ULONG\_PTR channels);**

**Remarks:**

This method is used internally in data flow evaluation.

**Prototype:**

**void DeepCopy(PatchMesh \*amesh, ULONG\_PTR channels);**

**Remarks:**

This method is used internally in data flow evaluation.

**Prototype:**

**void NewAndCopyChannels(ULONG\_PTR channels);**

**Remarks:**

This method is used internally in data flow evaluation.

**Prototype:**

**void FreeChannels(ULONG\_PTR channels, int zeroOthers=1);**

**Remarks:**

This method is used internally in data flow evaluation.

## Display Flags Access

**Prototype:**

**void SetDispFlag(DWORD f);**

**Remarks:**

Sets the state of the specified display flags.

**Parameters:**

**DWORD f**

The flags to set. See [List of Patch Display Flags](#).

**Prototype:**

**DWORD GetDispFlag(DWORD f);**

**Remarks:**

Returns the state of the specified display flags.

**Parameters:**

**DWORD f**

The flags to get. See [List of Patch Display Flags](#).

**Prototype:**

**void ClearDispFlag(DWORD f);**

**Remarks:**

Clears the specified display flags.

**Parameters:**

**DWORD f**

The flags to clear. See [List of Patch Display Flags](#).

**Selection Access****Prototype:**

**BitArray& VertSel();**

**Remarks:**

Returns the bits representing the vertex selection status. See the Data Members above. See [Class BitArray](#).

**Prototype:**

**BitArray& PatchSel();**

**Remarks:**

Returns the bits representing the patch selection status. See the Data Members above. See [Class BitArray](#).

**Prototype:**

**BitArray& EdgeSel();**

**Remarks:**

Returns the bits representing the edge selection status. See the Data Members above. See [Class BitArray](#).

**Prototype:**

**BitArray VertexTempSel();**

**Remarks:**

Constructs a vertex selection list based on the current selection level. For example if the selection level is at object level all the bits are set. If the selection level is at vertex level only the selected vertex bits are set. See [Class BitArray](#).

## Tri / Quad Patch Creation

### Prototype:

```
BOOL MakeQuadPatch(int index, int va, int vab, int vba,  
int vb, int vbc, int vcb, int vc, int vcd, int vdc,  
int vd, int vda, int vad, int i1, int i2, int i3,  
int i4, DWORD sm);
```

### Remarks:

Create a quadrilateral patch given a patch index and a list of all the vertices, vectors, interiors, and a smoothing group.

### Parameters:

**int index** - The index of the patch to create ( $0 \leq \text{index} < \text{numPatches}$ ).

**int va** - The first vertex.

**int vab** - Vector ab.

**int vba** - Vector ba.

**int vb** - The second vertex.

**int vbc** - Vector bc.

**int vcb** - Vector cb.

**int vc** - The third vertex.

**int vcd** - Vector cd.

**int vdc** - Vector dc.

**int vd** - The fourth vertex.

**int vda** - Vector da.

**int vad** - Vector ad.

**int i1** - Interior 1.

**int i2** - Interior 2.

**int i3** - Interior 3.

**int i4** - Interior 4.

**DWORD sm** - The smoothing group.

### Return Value:

TRUE if the patch was created; otherwise FALSE.

### Prototype:

```
BOOL MakeTriPatch(int index, int va, int vab, int vba, int vb,
```

**int vbc, int vcb, int vc, int vca, int vac, int i1, int i2,  
int i3, DWORD sm);**

**Remarks:**

Create a triangular patch given a patch index and a list of all the vertices, vectors, interiors, and a smoothing group.

**Parameters:**

**int index** - The index of the patch to create ( $0 \leq \text{index} < \text{numPatches}$ ).

**int va** - The first vertex.

**int vab** - Vector ab.

**int vba** - Vector ba.

**int vb** - The second vertex.

**int vbc** - Vector bc.

**int vcb** - Vector cb.

**int vc** - The third vertex.

**int vca** - Vector ca.

**int vac** - Vector ac.

**int i1** - Interior 1.

**int i2** - Interior 2.

**int i3** - Interior 3.

**DWORD sm** - The smoothing group.

**Returns:**

TRUE if the patch was created; otherwise FALSE.

## **Get/Set Mesh Steps and Adaptive Switch/TessApprox**

**Prototype:**

**void SetMeshSteps(int steps);**

**Remarks:**

Sets the number of steps along each edge that determines how fine the mesh is generated off the patch.

**Parameters:**

**int steps**

The number of steps to set.

**Prototype:**

**int GetMeshSteps();**

**Remarks:**

Returns the number of mesh steps.

**Prototype:**

**void SetMeshStepsRender(int steps);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the Surface Render Steps setting.

**Parameters:**

**int steps**

The value to set.

**Prototype:**

**int GetMeshStepsRender();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the Surface Render Steps setting.

**Prototype:**

**void SetShowInterior(BOOL si);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the 'Show Interior Edges' value.

**Parameters:**

**BOOL si**

TRUE for on; FALSE for off.

**Prototype:**

**BOOL GetShowInterior();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the 'Show Interior Edge' setting; TRUE if on; FALSE if off.

**Prototype:**

```
void SetAdaptive(BOOL sw);
```

**Remarks:**

This is currently not used. Reserved for future use.

**Prototype:**

```
BOOL GetAdaptive();
```

**Remarks:**

This is currently not used. Reserved for future use.

**Prototype:**

```
void SetViewTess(TessApprox tess);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the tessellation approximation object used for viewport rendering.

**Parameters:**

```
TessApprox tess
```

The tessellation approximation object to be used for viewport rendering.

**Prototype:**

```
TessApprox GetViewTess();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the tessellation approximation object used for rendering in the viewports.

**Prototype:**

```
void SetProdTess(TessApprox tess);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the tessellation approximation object used for production rendering.

**Parameters:**

**TessApprox tess**

The tessellation approximation object to be used for production rendering.

**Prototype:**

**TessApprox GetProdTess();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the tessellation approximation object used for production rendering.

**Prototype:**

**void SetDispTess(TessApprox tess);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the tessellation approximation object used for display in the viewports.

**Parameters:**

**TessApprox tess**

The tessellation approximation object to be used for the viewports.

**Prototype:**

**TessApprox GetDispTess();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the tessellation approximation object used for display in the viewports.

**Prototype:**

**BOOL GetViewTessNormals();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if normals are used from the viewport tesselator; otherwise FALSE.

**Prototype:**

**void SetViewTessNormals(BOOL use);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets if normals are used from the viewport tesselator.

**Parameters:**

**BOOL use**

TRUE to use normals; FALSE to not use them.

**Prototype:**

**BOOL GetProdTessNormals();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns TRUE if normals are used from the production renderer tesselator; otherwise FALSE.

**Prototype:**

**void SetProdTessNormals(BOOL use);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets if normals are used from the production renderer tesselator.

**Prototype:**

**BOOL GetViewTessWeld();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns TRUE if the viewport mesh is welded after tessellation; otherwise FALSE.

**Prototype:**

**void SetViewTessWeld(BOOL weld);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the viewport mesh is welded after tessellation; otherwise FALSE.

**Parameters:**

**BOOL weld**

TRUE to weld; FALSE to not weld.

**Prototype:**

**BOOL GetProdTessWeld();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the production renderer mesh is welded after tessellation; otherwise FALSE.

**Prototype:**

**void SetProdTessWeld(BOOL weld);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the production renderer mesh is welded after tessellation; otherwise FALSE.

**Parameters:**

**BOOL weld**

TRUE to weld; FALSE to not weld.

**Dump()**

**Prototype:**

**void Dump();**

**Remarks:**

This method may be called to dump the patch mesh structure via

**DebugPrint()**. See [Debugging](#).

**Prototype:**

**int IntersectRay(Ray& ray, float& at, Point3& norm);**

**Remarks:**

This method is available in release 3.0 and later only.

Calculates the intersection of the specified ray with this patch mesh object.

This method calls the method of the same name on the Mesh cache.

**Parameters:**

**Ray& ray**

Specifies the origin and direction of the ray to intersect with the patch mesh.

See [Class Ray](#).

**float& at**

The computed point of intersection on the surface of the patch mesh.

**Point3& norm**

The face normal at the point of intersection (**at**).

**Return Value:**

Nonzero if the ray intersected the mesh object; otherwise 0. Note that this method ignores backfaces when computing the result.

**Operators:**

**Prototype:**

**PatchMesh& operator=(PatchMesh& fromPatchMesh);**

**Remarks:**

Assignment operator from another **PatchMesh**.

**Prototype:**

**PatchMesh& operator=(Mesh& fromMesh);**

**Remarks:**

Assignment operator. This operator will do the conversion from a **Mesh** to a **PatchMesh**. Note that this can get very slow if there are a lot of faces in the

mesh. When the system does the conversion it must do a fair amount of work with its interior connection lists. It builds a data base of what is connected to what and makes sure that the **PatchMesh** doesn't have any places where an edge is used by more than two patches. Also, for every face in the mesh it generates a triangular patch. Therefore use this method with some caution as it can create some very complex **PatchMesh** objects.

# Class Patch

See Also: [Class PatchMesh](#), [Class TVPatch](#), [Working with Patches](#).

```
class Patch : public BaseInterfaceServer
```

## Description:

A **PatchMesh** is made up of a series of **Patch** objects derived from this class. This is similar to the way faces relate to a mesh. All methods of this class are implemented by the system.

## Data Members:

public:

**int type;**

The patch type. One of the following values:

**PATCH\_UNDEF**

Undefined.

**PATCH\_TRI**

Triangular patch.

**PATCH\_QUAD**

Quadrilateral patch.

**int v[4];**

A patch can have three or four vertices based on the **type**. The corner vertices on a patch are referred to as **a**, **b**, **c**, (and if it's a quad patch **d**). These are ordered **a**, **b**, **c**, **d** going counter-clockwise around the patch.

**int vec[8];**

A patch can have six or eight vector points. The vectors are referred to as follows: **ab** is the vector coming out of vertex **a** towards **b**. **ba** is the one coming out of **b** towards **a**. **bc** is the vector coming out of **b** towards **c**. **cb** is the one coming out of **c** towards **b**, and so on.

**int interior[4];**

A patch can have three or four interior vertices.

**Point3 aux[9];**

This is used internally for triangular patches only (degree 4 control points).

**int edge[4];**

Pointers into the edge list. There can be three or four depending on the patch

**type.**

**DWORD smGroup;**

The smoothing group. This defaults to 1. All patches are smoothed in a **PatchMesh**.

**DWORD flags;**

Patch Flags. The following value may be set.

**PATCH\_AUTO**

Interior vertices are computed automatically if this flag is set (and normally it is set). An example of when this flag would not be set is if you were creating a primitive using patches that needed to make special interior control points to create the shape. In this case you'd clear this flag and then put whatever values you needed into the **vec** array.

**PATCH\_HIDDEN**

The patch is hidden.

**PATCH\_LINEAR Mapping**

This option is available in release 4.0 and later only.

The patch is using the old linear mapping scheme.

**PATCH\_USE\_CRUVED\_MAPPING\_ON\_VERTEX\_COLOR**

This option is available in release 4.0 and later only.

The patch is using the new curved mapping for vertex colors also.

**int aux1;**

This data member is available in release 3.0 and later only.

This is used to track topology changes during editing (Edit Patch).

**int aux2;**

This data member is available in release 3.0 and later only.

This is used to track topology changes during editing (PatchMesh).

**Methods:**

**Prototype:**

**Patch();**

**Remarks:**

Constructor. The type is set to undefined, the smooth group is set to 1, and the flags indicate automatic interior points. Note: This constructor does not

allocate arrays. Use **SetType(type)**.

**Prototype:**

**Patch(Patch& fromPatch);**

**Remarks:**

Constructor. The **this** pointer is set to the **fromPatch**.

**Prototype:**

**~Patch();**

**Remarks:**

Destructor.

**Prototype:**

**void Init();**

**Remarks:**

This method is used by the constructors internally. Developers should not call this method.

**Prototype:**

**void setVerts(int \*vrt);**

**Remarks:**

The vertices are copied from the array passed. Based on the patch type either three or four vertices are copied.

**Parameters:**

**int \*vrt**

The vertices are set to these values. These values are indices into the **v** array.

**Prototype:**

**void setVerts(int a, int b, int c);**

**Remarks:**

Sets the vertices for Tri Patch to those passed.

**Parameters:**

**int a, int b, int c**

The vertices to set. **v[0]=a; v[1]=b; v[2]=c**; These values are indices into the **v** array.

**Prototype:**

**void setVerts(int a, int b, int c, int d)**

**Remarks:**

Sets the vertices for a Quad Patch to those passed.

**Parameters:**

**int a, int b, int c, int d**

The vertices to set. **v[0]=a; v[1]=b; v[2]=c; v[3] = d**; These values are indices into the **v** array.

**Prototype:**

**void setVecs(int ab, int ba, int bc, int cb, int ca, int ac)**

**Remarks:**

Sets the vectors for a Tri Patch to those passed.

**Parameters:**

**int ab, int ba, int bc, int cb, int ca, int ac;**

The vectors to set. **vec[0]=ab; vec[1]=ba; vec[2]=bc;**

**vec[3]=cb; vec[4]=ca; vec[5]=ac**; These values are indices into the **vec** array.

**Prototype:**

**void setVecs(int ab, int ba, int bc, int cb, int cd,  
int dc, int da, int ad)**

**Remarks:**

Sets the vectors for a Quad patch to those passed.

**Parameters:**

**int ab, int ba, int bc, int cb,**

**int cd, int dc, int da, int ad ;**

The vectors to set. **vec[0]=ab; vec[1]=ba; vec[2]=bc; vec[3]=cb; vec[4]=cd; vec[5]=dc; vec[6]=da, vec[7]=ad;** These values are indices into the **vec** array.

**Prototype:**

**void setInteriors(int a, int b, int c)**

**Remarks:**

Sets the interior vertex values for a Tri Patch.

**Parameters:**

The interior values to set: **interior[0]=a; interior[1]=b; interior[2]=c;** These values are indices into the **interior** array.

**Prototype:**

**void setInteriors(int a, int b, int c, int d)**

**Remarks:**

Sets the interior vertex values for a Tri Patch.

**Parameters:**

**int a, int b, int c, int d**

The interior values to set: **interior[0]=a; interior[1]=b; interior[2]=c; interior[3]=d;** These values are indices into the **interior** array.

**Prototype:**

**int getVert(int index);**

**Remarks:**

Returns the vertex specified by the index.

**Parameters:**

**int index**

The vertex to retrieve. This value may be 0, 1, 2 (or 3 if it's a quad patch).

**Prototype:**

**int \*getAllVerts(void);**

**Remarks:**

Returns a pointer to the vertex array.

**Prototype:**

**int WhichEdge(int v1, int v2);**

**Remarks:**

This method is available in release 4.0 and later only.

This method provides an easy way to find out which edge of a patch uses two vertices. Simply supply the two vertices of the desired edge and call this method.

**Parameters:**

**int v1, int v2**

The index of the two vertices.

**Return Value:**

The index of the edge within the patch (0 - 2 for triangular patches, 0 - 3 for quad patches).

CAUTION: Be sure to check the return value before using it for an index – If the two vertices supplied are not used as an edge on this patch, -1 is returned.

**Prototype:**

**int WhichVert(int v);**

**Remarks:**

This method is available in release 4.0 and later only.

This method provides an easy way to find out which corner of a patch uses a given vertex. Simply supply the vertex index and call this method.

**Parameters:**

**int v**

The index of the vertex.

**Return Value:**

The corner index of the given vertex within the patch (0 - 2 for triangular patches, 0 - 3 for quad patches).

CAUTION: Be sure to check the return value before using it for an index – If the vertex supplied is not used as a corner on this patch, -1 is returned.

**Prototype:**

**Point3 interp(PatchMesh \*pMesh, float u, float v);**

**Remarks:**

Quadrilateral patch interpolator. This method returns a point on the surface of the patch based on the specified u and v values.

**Parameters:**

**PatchMesh \*pMesh**

Points to the **PatchMesh** to interpolate.

**float u**

The u value in the range 0.0 to 1.0. This defines the distance along one axis of the patch.

**float v**

The v value in the range 0.0 to 1.0. This defines the distance along the other axis of the patch.

**Return Value:**

A point on the surface of the patch.

**Prototype:**

**Point3 interp(PatchMesh \*pMesh, float u, float v, float w);**

**Remarks:**

Triangle patch interpolator. This method returns a point on the surface of the patch based on the specified u, v and w values. The u, v, w values are barycentric coordinates.  $u+v+w = 1.0$ . If u is 1, and v and w are 0, the point is at the first vertex. If u is 0, v is 1, and w is 0, then the point is at the second vertex. If u and v are 0 and w is 1 then the point is at the third vertex. Varying positions between these values represent different positions on the patch.

**Parameters:**

**PatchMesh \*pMesh**

Points to the **PatchMesh** to interpolate.

**float u, float v, float w**

The barycentric coordinates.

**Return Value:**

A point on the surface of the patch.

**Prototype:**

**void ComputeAux(PatchMesh \*pMesh, int index);**

**Remarks:**

This method is used internally. It compute the degree-4 alias control points.

**Prototype:**

**void computeInteriors(PatchMesh\* pMesh);**

**Remarks:**

Whenever you are done working on a **PatchMesh**, this method should be called. If the interior vertices of the patch are automatic it will update them to correctly match the changes to the other vectors. This computes interior vertices considering this patch only.

**Parameters:**

**PatchMesh\* pMesh**

Points to the **PatchMesh** to compute the interior vertices of.

**Prototype:**

**void SetType(int type, BOOL init = FALSE);**

**Remarks:**

Sets the type of the patch to either Tri or Quad and optionally resets the arrays.

**Parameters:**

**int type**

The patch type. One of the following values:

**PATCH\_TRI** - Triangular Patch

**PATCH\_QUAD** - Quadrilateral Patch

**BOOL init = FALSE**

If TRUE the arrays are reset to undefined; otherwise they are left unchanged. Normally this is set to FALSE.

**Prototype:**

**void SetAuto(BOOL sw = TRUE);**

**Remarks:**

Sets the flag controlling if interior vertices are computed automatically.

**Parameters:**

**BOOL sw = TRUE**

TRUE to set; FALSE to clear.

**Prototype:**

**BOOL IsAuto();**

**Remarks:**

Returns TRUE if the **PATCH\_AUTO** flag is set; otherwise FALSE.

**Prototype:**

**void SetHidden(BOOL sw = TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the hidden state of the patch.

**Parameters:**

**BOOL sw = TRUE**

TRUE to hide; FALSE to unhide.

**Prototype:**

**BOOL IsHidden();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the patch is hidden; otherwise FALSE.

**Prototype:**

**void Dump();**

**Remarks:**

This may be called to dump the patch mesh structure via **DebugPrint()**. See [Debugging](#).

**Operators:**

**Prototype:**

**Patch& operator=(Patch& from);**

**Remarks:**

Assignment operator.

**Parameters:**

**Patch& from**

The patch to copy from.

# Class PatchVec

See Also: [Class PatchMesh](#), [Working with Patches](#).

class PatchVec

## Description:

This class represents a patch vector. This can be either an interior vector or an edge vector. All methods of this class are implemented by the system.

## Data Members:

public:

### **Point3 p;**

The vertex location.

### **int vert;**

The vertex which owns this vector.

### **IntTab patches;**

These are the patches that share this vector. If the edge is open there will only be one patch. In this case **patches[0]** will be used and **patches[1]** will be -1. Note: As of R4.0 the previous array of [2] has been replaced with the IntTab because vectors can now be used by more than two patches.

### **DWORD flags;**

The patch vector flag:

#### **PVEC\_INTERIOR**

This indicates the vector is an interior vector. These are the three vectors inside a tri patch or the four inside a quad patch.

### **int aux1;**

This data member is available in release 3.0 and later only.

Used to track topology changes during editing (Edit Patch).

### **int aux2;**

This data member is available in release 3.0 and later only.

Used to track topology changes during editing (PatchMesh).

## Methods:

## Prototype:

**PatchVec();**

**Remarks:**

Constructor. The location is set to 0,0,0. The vertex owner is set to undefined. The patches using the vector is set to undefined. The flags are set to 0.

**Prototype:**

**PatchVec(PatchVec &from);**

**Remarks:**

Constructor. The data members are initialized to those of the **from** patch vector.

**Parameters:**

**PatchVec &from**

The vector to copy from.

**Prototype:**

**void ResetData();**

**Remarks:**

Resets the data members. The vertex owner is set to undefined. The patches using the vector is set to undefined.

**Prototype:**

**BOOL AddPatch(int index);**

**Remarks:**

Adds the specified patch to this vector table.

**Parameters:**

**int index**

The index in the **PatchMesh** class patches table (**patches**) of the patch to add.

**Return Value:**

Returns TRUE if the patch was added; otherwise FALSE.

**Prototype:**

**void Transform(Matrix3 &tm);**

**Remarks:**

This method is available in release 3.0 and later only.  
Transforms the vertex location p by the specified matrix.

**Parameters:****Matrix3 &tm**

The matrix to transform the vertex.

**Prototype:**

**IOResult Save(ISave\* isave);**

**Remarks:**

This is used internally to save the data to the .MAX file.

**Prototype:**

**IOResult Load(ILoad\* iload);**

**Remarks:**

This is used internally to load the data from the .MAX file.

**Operators:****Prototype:**

**PatchVec& operator=(PatchVec& from);**

**Remarks:**

Assignment operator.

**Parameters:****PatchVec& from**

The patch vector to copy from.

## Class PatchVert

See Also: [Class PatchMesh](#), [Template Class Tab](#), [Working with Patches](#).

### Description:

This class stores the information associated with a patch vertex and provides methods to access the data associated with this vertex. All methods of this class are implemented by the system.

### Data Members:

public:

#### **Point3 p;**

The vertex location.

#### **IntTab vectors;**

The list of vectors attached to this vertex. There can be any number of vectors attached to a vertex. For example consider the north pole of a sphere made from a set of triangular patches. If there were 16 patches meeting at this point there would be 16 vectors. The table contains the indices of these vectors. This is set up automatically when a developer calls **buildLinkages()**.

#### Note: **typedef Tab<int> IntTab;**

Note that the methods below allow a developer to manipulate the tables of this class. Developers must be careful when doing so as it is easy to corrupt the patch data structures. It may be easier for developers to manipulate the patches, delete vertices, etc., by manipulating them in the **PatchMesh** and then call **buildLinkages()** again. The methods below do work however and may be used.

#### **IntTab patches;**

The list of patches using this vertex.

#### **IntTab edges;**

This data member is available in release 4.0 and later only.

The list of edges using this vertex. This table will be set up automatically when a developer calls **buildLinkages()**.

#### **DWORD flags;**

The patch vertex flags

**PVERT\_COPLANAR**

This constrains things such that this vertex and all the vectors that are attached to it are coplanar. If this is set, and you call **ApplyConstraints()**, the system will adjust the vectors to the average plane that they are in and then constrain them to it.

**PVERT\_CORNER**

The vertex is a corner.

**PVERT\_HIDDEN**

The vertex is hidden.

**int aux1;**

Used to track topo changes during editing (Edit Patch).

**int aux2;**

Used to track topology changes during editing (PatchMesh).

**Methods:**

**Prototype:**

**PatchVert();**

**Remarks:**

Constructor. The location is set to 0,0,0. The flags are set to 0.

**Prototype:**

**PatchVert(PatchVert &from);**

**Remarks:**

Constructor. The data members are copied from the from **PatchVert**.

**Parameters:**

**PatchVert &from**

The source PatchVert.

**Prototype:**

**~PatchVert();**

**Remarks:**

Destructor. Deletes the elements from the **vectors** table and **patches** table.

**Prototype:**

**void ResetData();**

**Remarks:**

This method deletes the elements from the **vectors** table and **patches** table.

**Prototype:**

**int FindVector(int index);**

**Remarks:**

Returns the index in this classes **vectors** table of the vector whose index is passed. If not found, -1 is returned.

**Parameters:**

**int index**

The index in the **PatchMesh** class vectors table (**vecs**) of the vector to find.

**Prototype:**

**void AddVector(int index);**

**Remarks:**

Adds the specified vector to this vector table.

**Parameters:**

**int index**

The index in the **PatchMesh** class vectors table (**vecs**) of the vector to add.

**Prototype:**

**void DeleteVector(int index);**

**Remarks:**

Deletes the specified vector from this vector table.

**Parameters:**

**int index**

The index in the **PatchMesh** class vectors table (**vecs**) of the vector to delete.

**Prototype:**

**int FindPatch(int index);**

**Remarks:**

Returns the index in this classes **patches** table of the patch whose index is passed. If not found, -1 is returned.

**Parameters:**

**int index**

The index in the **PatchMesh** class patches table (**patches**) of the patch to find.

**Prototype:**

**void AddPatch(int index);**

**Remarks:**

Adds the specified patch to this vector table.

**Parameters:**

**int index**

The index in the **PatchMesh** class patches table (**patches**) of the patch to add.

**Prototype:**

**void DeletePatch(int index);**

**Remarks:**

Deletes the patch specified by the index.

**Parameters:**

**int index**

The index in the **PatchMesh** class patches table (**patches**) of the patch to delete.

**Prototype:**

**int FindEdge(int index);**

**Remarks:**

Returns the index in this classes **edges** table of the patch whose index is

passed. If not found, -1 is returned.

**Parameters:**

**int index**

The index in the **PatchMesh** class edges table (**edges**) of the edge to find.

**Prototype:**

**void AddEdge(int index);**

**Remarks:**

Adds the specified edge to this vector table.

**Parameters:**

**int index**

The index in the **PatchMesh** class edges table (**edges**) of the edge to add.

**Prototype:**

**void DeleteEdge(int index);**

**Remarks:**

Deletes the edge specified by the index.

**Parameters:**

**int index**

The index in the **PatchMesh** class edges table (**edges**) of the edge to delete.

**Prototype:**

**void Transform(Matrix3 &tm);**

**Remarks:**

This method is available in release 3.0 and later only.

Transform the vertex by the specified matrix.

**Parameters:**

**Matrix3 &tm**

The matrix which transforms the point.

**Prototype:**

**void setHidden(BOOL sw = TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the hidden state of the vertex.

**Parameters:**

**BOOL sw = TRUE**

TRUE to set to hidden; FALSE for visible.

**Prototype:**

**BOOL IsHidden();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns TRUE if the vertex is hidden; otherwise FALSE.

**Prototype:**

**IOResult Save(ISave\* isave);**

**Remarks:**

This method is used internally to save the class data to disk storage.

**Prototype:**

**IOResult Load(ILoad\* iload);**

**Remarks:**

This method is used internally to load the class data from disk storage.

**Operators:**

**Prototype:**

**PatchVert& operator=(PatchVert& from);**

**Remarks:**

Assignment operator.

**Parameters:**

**PatchVert& from**

The patch vertex to copy from.

## Class PatchEdge

See Also: [Class PatchMesh](#), [Working with Patches](#).

class PatchEdge

### Description:

This class describes a patch edge using the vertices at the edge ends, and the indices of the patches sharing the edge. All methods of this class are implemented by the system.

### Data Members:

public:

**int v1;**

Index of the first vertex.

**int vec12;**

Vector from **v1** to **v2**.

**int vec21;**

Vector from **v2** to **v1**.

**int v2;**

Index of second vertex.

**IntTab patches;**

Index of the patches using this edge. If the edge is only used by one patch, patches[1] will be less than zero. Note: Previous to R4.0 two separate integer variables (**patch1** and **patch2**) were used.

**int aux1;**

This is used to track topology changes during editing (Edit Patch).

**int aux2;**

This is used to track topology changes during editing (PatchMesh).

### Methods:

### Prototype:

**PatchEdge();**

### Remarks:

Constructor. The data members are initialized as undefined.

**Prototype:**

**PatchEdge(PatchEdge &from);**

**Remarks:**

Constructor. The data members are initialized from the **PatchEdge** passed.

**Prototype:**

**PatchEdge(int v1, int vec12, int vec21, int v2, int p1, int p2, int  
aux1=-1, int aux2=-1);**

**Remarks:**

Constructor. The data members are initialized to the values passed.

**Prototype:**

**IOResult Save(ISave\* isave);**

**Remarks:**

This is used internally to save the data to the .MAX file.

**Prototype:**

**IOResult Load(ILoad\* iload);**

**Remarks:**

This is used internally to load the data from the .MAX file.

**Prototype:**

**void Dump();**

**Remarks:**

You may call this method to dump the patch edge structure via **DebugPrint()**. See [Debugging](#).

## Class TVPatch

See Also: [Class Patch](#), [Class PatchMesh](#), [Working with Patches](#).

class TVPatch

### Description:

This is a texture vertex patch structure. This is similar to the **TVFace** class used with a **Mesh**. All methods of this class are implemented by the system.

### Data Members:

public:

**int tv[4];**

Texture vertices. There are always four here, even for Tri Patches. These are indices in the PatchMesh's **tVerts** array.

**int handles[8];**

The UVW vertices for the handles.

**int interiors[4];**

The UVW interior handles.

### Methods:

#### Prototype:

**TVPatch();**

#### Remarks:

Constructor.

#### Prototype:

**TVPatch(TVPatch& fromPatch);**

#### Remarks:

Constructor. The **this** pointer is set to the **fromPatch**.

#### Prototype:

**void Init();**

#### Remarks:

Performs initialization by setting the texture vertices to 0.

**Prototype:**

```
void setTVerts(int *vrt, int count);
```

**Remarks:**

Sets the specified number of texture vertices.

**Parameters:**

**int \*vrt**

The array of verts to set.

**int count**

The number to set.

**Prototype:**

```
void setTVerts(int a, int b, int c, int d = 0);
```

**Remarks:**

Sets the texture vertices for a Quad Patch.

**Parameters:**

**int a, int b, int c, int d = 0**

The vertices to set: **tv[0]=a; tv[1]=b; tv[2]=c; tv[3]=d;**

**Prototype:**

```
int getTVert(int index);
```

**Remarks:**

Returns the texture vertex specified by the index.

**Parameters:**

**int index**

The index of the texture vertex to return.

**Prototype:**

```
int *getAllTVerts();
```

**Remarks:**

Returns a pointer to the array of texture vertices.

**Prototype:**

```
void setTHandles(int *vrt, int count);
```

**Remarks:**

Sets the specified number of texture (UVW) handles.

**Parameters:**

**int \*vrt**

The array of handles to set.

**int count**

The number to set.

**Prototype:**

```
void setTHandles(int a, int b, int c, int d, int e, int f, int g = 0, int h = 0);
```

**Remarks:**

Sets the texture (UVW) handles for a Quad Patch.

**Parameters:**

**int a, int b, int c, int d, int e, int f, int g = 0, int h = 0**

The handles to set: **handles[0]=a; handles[1]=b; handles[2]=c;**

**handles[3]=d; handles[4]=e; handles[5]=f; handles[6]=g;**

**handles[7]=h;**

**Prototype:**

```
void setTInteriors(int *vrt, int count);
```

**Remarks:**

Sets the specified number of interior texture (UVW) handles.

**Parameters:**

**int \*vrt**

The array of interior handles to set.

**int count**

The number to set.

**Prototype:**

**void setTInteriors(int a, int b, int c, int d = 0);**

**Remarks:**

Sets the interior texture (UVW) handles for a Quad Patch.

**Parameters:**

**int a, int b, int c, int d = 0**

The interior handles to set: **interiors[0]=a; interiors[1]=b;  
interiors[2]=c; interiors[3]=d;**

**Prototype:**

**IOResult Save(ISave \*isave);**

**Remarks:**

This method is used internally in saving to the MAX file.

**Prototype:**

**IOResult Load(ILoad \*iload);**

**Remarks:**

This method is used internally in loading from the MAX file.

**Operators:**

**Prototype:**

**TVPatch& operator=(const TVPatch& from);**

**Remarks:**

Assignment operator.

**Parameters:**

**TVPatch& from**

The texture vertex patch to copy from.

## Class Manipulator

See Also: [Class HelperObject](#), [Class SimpleManipulator](#), [Class IManipulatorMgr](#), [Class INode](#), [Class ViewExp](#), [Class IPoint2](#), [Class Box3](#)

```
class Manipulator : public HelperObject
```

### Description:

This class is available in release 4.0 and later only.

This is the base class for the development of Manipulator plug-ins. Shown are the methods that need to be implemented by the plug-in. Most of these methods are implemented by the **SimpleManipulator** class so most developers will not need to use these unless **SimpleManipulator** is not sufficient.

### Data Members:

protected:

**INode\* mpINode;**

The node being manipulated

### Methods:

public:

### Prototype:

**Manipulator(INode\* pINode);**

### Remarks:

Constructor. The node data member is initialized to the node passed.

### Prototype:

**virtual int HitTest(TimeValue t, INode\* pNode, int type, int crossing, int flags, IPoint2 \*pScreenPoint, ViewExp \*pVpt) = 0;**

### Remarks:

This method is called to determine if the specified screen point intersects the manipulator. The method returns nonzero if the item was hit; otherwise 0. This is like the normal **HitTest()** method in the **BaseObject** class. The difference is that it needs to log it hits in the viewport SubObjectHitList. It does this using the **ManipHitData** class defined in **Manipulator.h**.

**Parameters:****TimeValue t**

The time to perform the hit test.

**INode\* pNode**

A pointer to the node to test.

**int type**

The type of hit testing to perform. See [Hit Test Types](#) for details.

**int crossing**

The state of the crossing setting. If TRUE crossing selection is on.

**int flags**

The hit test flags. See [Hit Test Flags](#) for details.

**IPoint2 \*pScreenPoint**

Points to the screen point to test.

**ViewExp \*pVpt**

An interface that may be used to call methods associated with the viewports.

**Return Value:**

Nonzero if the item was hit; otherwise 0.

**Prototype:**

```
virtual int Display(TimeValue t, INode* pNode, ViewExp *pVpt,  
int flags) = 0;
```

**Remarks:**

This method lines the **BaseObject::Display()** method and displays the manipulator object.

**Parameters:****TimeValue t**

The time to display the object.

**INode\* pNode**

Points to the node that is being manipulated by the manipulator.

**ViewExp \*pVpt**

An interface that may be used to call methods associated with the viewports.

**int flags**

See [List of Display Flags](#).

**Return Value:**

The return value is not currently used.

**Prototype:**

```
virtual void GetLocalBoundingBox(TimeValue t, INode* inode,  
ViewExp* vp, Box3& box) = 0;
```

**Remarks:**

Used Internally.

Returns the object space bounding box of the manipulator in the object's local coordinates.

**Parameters:****TimeValue t**

The time to retrieve the bounding box.

**INode\* inode**

The node that is being manipulated by the manipulator.

**ViewExp\* vp**

An interface that may be used to call methods associated with the viewports.

**Box3& box**

The bounding box is returned here.

**Prototype:**

```
virtual bool AlwaysActive();
```

**Remarks:**

This method can be used to tell the manipulator management system that this manipulator is always active.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual TSTR& GetManipName() = 0;
```

**Remarks:**

This method returns the manipulator name string. The **SimpleManipulator**

class uses this method for the tooltip in the viewport.

**Prototype:**

**virtual DisplayState MouseEntersObject(TimeValue t, ViewExp\* pVpt, IPoint2& m, ManipHitData\* pHitData);**

**Remarks:**

This method gets called when the mouse first passes over a manipulator object. The return value is used to determine whether a redraw is needed or not. Normally manipulators display in a different color when the mouse is over them, so this should return **kFullRedrawNeeded**.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Return Value:**

The display state indicating whether no redraw, a full redraw, or a post redraw is needed.

**Default Implementation:**

**{return kNoRedrawNeeded; }**

**Prototype:**

**virtual DisplayState MouseLeavesObject(TimeValue t, ViewExp\* pVpt, IPoint2& m, ManipHitData\* pHitData);**

**Remarks:**

This method gets called when the mouse leaves the manipulator object. The return value is used to determine whether a redraw is needed or not. Normally manipulators display in a different color when the mouse is over them, so this should return **kFullRedrawNeeded**.

**Parameters:****TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Return Value:**

The display state indicating whether no redraw, a full redraw, or a post redraw is needed.

**Default Implementation:**

```
{return kNoRedrawNeeded; }
```

**Prototype:**

```
virtual void OnMouseMove(TimeValue t, ViewExp* pVpt,  
IPoint2& m, DWORD flags, ManipHitData* pHitData);
```

**Remarks:**

This method gets called when the mouse is pressed down and moves within the manipulator context. It is the method that does the actual manipulator. It is up to the manipulator code to turn the mouse position into a new value for the parameter(s) being manipulated.

**Parameters:****TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**DWORD flags**

Not used, should be set to 0.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void OnButtonDown(TimeValue t, ViewExp* pVpt,  
IPoint2& m, DWORD flags, ManipHitData* pHitData);
```

**Remarks:**

This method gets called when the mouse buttons is first pressed down within the manipulator context.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**DWORD flags**

Not used, should be set to 0.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void OnButtonUp(TimeValue t, ViewExp* pVpt, IPoint2&  
m, DWORD flags, ManipHitData* pHitData);
```

**Remarks:**

This method gets called when the mouse buttons is released within the manipulator context, and thus signals the end of the manipulation.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**DWORD flags**

Not used, should be set to 0.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual INode* GetINode();
```

**Remarks:**

This method returns a pointer to the INode that is currently being manipulated.

**Default Implementation:**

```
{ return mpINode; }
```

**Prototype:**

```
virtual void DeleteThis();
```

**Remarks:**

This method deletes the manipulator instance.

**Default Implementation:**

```
{ delete this; }
```

## Class SimpleManipulator

See Also: [Class Manipulator](#), [Class ISimpleManipulator](#), [Class PolyShape](#), [Class GizmoShape](#), [Class ReferenceTarget](#), [Class IParamBlock2](#), [Class INode](#), [Class Mesh](#), [Class Point3](#), [Class Point2](#), [Class ViewExp](#), [Class IColorManager](#), [Class Ray](#), [Class ManipHitData](#), [List of Marker Types](#)

```
class SimpleManipulator: public Manipulator, public ISimpleManipulator
```

### Description:

This class is available in release 4.0 and later only.

The SimpleManipulator class provides a framework for implementing many common manipulators. It provides the following services:

- It supports an arbitrary number of gizmos made from PolyShape and/or Mesh objects.
- It creates and maintains tool tips in the viewport.
- It does hit testing, display and bounding box computations of the gizmos.
- It maintains an IParamBlock2 for the parameters of the Manipulator.

This class maintains a pointer to a parameter block. If the client of **SimpleManipulator** uses a single parameter block then **SimpleManipulator** can manage all the methods associated with SubAnims and References for the client.

If the client of **SimpleManipulator** maintains several parameter blocks then the client must implement the methods **NumSubs()**, **SubAnim(i)**, **SubAnimName(i)**, **NumRefs()**, **GetReference(i)** and **SetReference(i)** and call the **SimpleManipulator** methods when 'i' refers to the parameters maintained by **SimpleManipulator**.

Samples of Manipulators can be found in the SDK,  
**\MAXSDK\SAMPLES\MANIPULATORS.**

The Function Publishing interface to SimpleManipulators is defined as:  
**#define SIMPLE\_MANIP\_INTERFACE Interface\_ID(0x617c41d4, 0x6af06a5f)**

The following functions are not part of this class but are available for use with it

in the making of gizmo objects:

**Function:**

**Mesh\* MakeSphere(Point3& pos, float radius, int segments);**

**Remarks:**

This global function is available in release 4.0 and later only.

Creates a new mesh sphere at the given center position with the specified radius and segments count.

**Parameters:**

**Point3& pos**

The center point for the sphere in object space.

**float radius**

The radius for the sphere.

**int segments**

The number of segments for the sphere mesh.

**Return Value:**

A pointer to the sphere mesh. Developers are responsible for deleting this mesh when done.

**Function:**

**Mesh\* MakeTorus(Point3& pos, float radius, float radius2, int segs, int sides);**

**Remarks:**

This global function is available in release 4.0 and later only.

Create a mesh torus with the given center point, outer radius, inner radius, and segment counts along the two circular dimensions of the torus.

**Parameters:**

**Point3& pos**

The center point in object space.

**float radius**

The first radius.

**float radius2**

The second radius.

**int segs**

The segment count along the vertical circular dimension.

**int sides**

The segment count along the horizontal circular dimension.

**Return Value:**

A pointer to the torus mesh created. Developers are responsible for deleting this mesh when done with it.

**Function:**

**Mesh\* MakeBox(Point3& pos, float l, float w, float h, int lsegs, int wsegs, int hsegs);**

**Remarks:**

This global function is available in release 4.0 and later only.

Creates a mesh box with the given center point, length, width and height as well as segment parameters.

**Parameters:****Point3& pos**

The box is built from this position in size along +X, +Y and +Z. This coordinate is in object space.

**float l**

The length of the box.

**float w**

The width of the box.

**float h**

The height of the box.

**int lsegs**

The number of segments in the length dimension.

**int wsegs**

The number of segments in the width dimension.

**int hsegs**

The number of segments in the height dimension.

**Return Value:**

A pointer to the box mesh. Developers are responsible for deleting this mesh

when done.

**Function:**

**void AddCubeShape(PolyShape& shape, Point3& pos, float size);**

**Remarks:**

This global function is available in release 4.0 and later only.

Creates a new series of lines in the form of a cube and adds it to the specified PolyShape with the given position and side length size.

**Parameters:**

**PolyShape& shape**

The PolyShape to add the box shape to.

**Point3& pos**

The position for the center of the cube shape in object space.

**float size**

The size of one side of the cube in object space.

**Data Members:**

protected:

**int mDispSelectedIndex;**

The Index of manipulator that the mouse is over, for display.

**TSTR mToolTip;**

The tooltip text.

**float mGizmoScale;**

The scaling factor of the gizmo.

**IParamBlock2 \*mpPblock;**

The Parameter Block 2 for the manipulator.

**RefTargetHandle mhTarget;**

The handle to the manipulator reference target.

**MouseState mState;**

The state of the mouse, which is one of the following:

**kMouseIdle**

The mouse is idle, manipulator not active and the mouse is not over it.

**kMouseDragging**

The mouse is currently dragging the manipulator.

**kMouseOverManip**

The mouse is over the manipulator, but it is not being dragged.

**BOOL mActiveViewOnly;**

This flag defines whether the manipulator is shown in the active viewport only.

**Interval mValid;**

The validity interval of the reference.

**Methods:**

public:

**Prototype:**

**SimpleManipulator();**

**Remarks:**

Constructor.

**Prototype:**

**SimpleManipulator(INode\* pNode);**

**Remarks:**

Constructor.

**Prototype:**

**~SimpleManipulator();**

**Remarks:**

Destructor.

**Prototype:**

**void ClearPolyShapes();**

**Remarks:**

Implemented by the system.

Removes all of the current gizmos in the manipulator. This is normally called at the top of **UpdateShapes()** to clear out any previous gizmos before

creating new ones.

**Prototype:**

```
void AppendPolyShape(PolyShape* pPolyShape, DWORD flags = 0, Point3& unselColor = GetUIColor(COLOR_SEL_GIZMOS), Point3& selColor = GetSubSelColor());
```

**Remarks:**

Implemented by the system.

This method adds a new PolyShape gizmo to the manipulator. The shape is defined in the local coordinates of the node that owns the manipulator.

**Parameters:**

**PolyShape\* pPolyShape**

A pointer to the poly shape to add.

**DWORD flags = 0**

The flags can have one or more of the following values:

**kGizmoDontDisplay;**

Tells the gizmo not to display. It will still hit test it.

**kGizmoDontHitTest;**

Tells the gizmo not to hit test. It will still display.

**kGizmoScaleToViewport;**

Tells the gizmo to scale itself to have a constant size in the viewport. In this case, the system uses the **ManipulatorGizmo::mGizmoSize** to determine how big the manipulator should be. It interprets **mGizmoSize** as pixels in this case. This flag only applies to mesh gizmo currently.

**Point3& unselColor = GetUIColor(COLOR\_SEL\_GIZMOS)**

The color of the gizmo when unselected.

**Point3& selColor = GetSubSelColor()**

The color of the gizmo when selected.

**Prototype:**

```
void AppendGizmo(GizmoShape* pGizmoShape, DWORD flags = 0, Point3& unselColor = GetUIColor(COLOR_SEL_GIZMOS), Point3& selColor = GetSubSelColor());
```

**Remarks:**

Implemented by the system.

This method adds a new GizmoShape to the manipulator. The shape is defined in the local coordinates of the node that owns the manipulator.

**Parameters:**

**GizmoShape\* pGizmoShape**

A pointer to the gizmo shape to add.

**DWORD flags = 0**

The flags can have one or more of the following values:

**kGizmoDontDisplay;**

Tells the gizmo not to display. It will still hit test it.

**kGizmoDontHitTest;**

Tells the gizmo not to hit test. It will still display.

**kGizmoScaleToViewport;**

Tells the gizmo to scale itself to have a constant size in the viewport. In this case, the system uses the **ManipulatorGizmo::mGizmoSize** to determine how big the manipulator should be. It interprets **mGizmoSize** as pixels in this case. This flag only applies to mesh gizmo currently.

**Point3& unselColor = GetUIColor(COLOR\_SEL\_GIZMOS)**

The color of the gizmo when unselected.

**Point3& selColor = GetSubSelColor()**

The color of the gizmo when selected.

**Prototype:**

```
void AppendMesh(Mesh* pMesh, DWORD flags = 0, Point3&  
unselColor = GetUIColor(COLOR_SEL_GIZMOS), Point3&  
selColor = GetSubSelColor());
```

**Remarks:**

Implemented by the system.

This method adds a new Mesh to the manipulator. The shape is defined in the local coordinates of the node that owns the manipulator.

**Parameters:**

**Mesh\* pMesh**

A pointer to the mesh to add.

**DWORD flags = 0**

The flags can have one or more of the following values:

**kGizmoDontDisplay;**

Tells the gizmo not to display. It will still hit test it.

**kGizmoDontHitTest;**

Tells the gizmo not to hit test. It will still display.

**kGizmoScaleToViewport;**

Tells the gizmo to scale itself to have a constant size in the viewport. In this case, the system uses the **ManipulatorGizmo::mGizmoSize** to determine how big the manipulator should be. It interprets **mGizmoSize** as pixels in this case. This flag only applies to mesh gizmo currently.

**Point3& unselColor = GetUIColor(COLOR\_SEL\_GIZMOS)**

The color of the gizmo when unselected.

**Point3& selColor = GetSubSelColor()**

The color of the gizmo when selected.

**Prototype:**

```
void AppendMarker(MarkerType markerType, Point3& position,  
DWORD flags = 0, Point3& unselColor =  
GetUIColor(COLOR_SEL_GIZMOS), Point3& selColor =  
GetSubSelColor());
```

**Remarks:**

Implemented by the system.

This method adds a new Marker to the manipulator. The shape is defined in the local coordinates of the node that owns the manipulator.

**Parameters:**

**MarkerType markerType**

The marker type for marker gizmos. See the [List of Marker Types](#)

**Point3& position**

The position of the marker.

**DWORD flags = 0**

The flags can have one or more of the following values:

**kGizmoDontDisplay;**

Tells the gizmo not to display. It will still hit test it.

**kGizmoDontHitTest;**

Tells the gizmo not to hit test. It will still display.

**kGizmoScaleToViewport;**

Tells the gizmo to scale itself to have a constant size in the viewport. In this case, the system uses the **ManipulatorGizmo::mGizmoSize** to determine how big the manipulator should be. It interprets **mGizmoSize** as pixels in this case. This flag only applies to mesh gizmo currently.

**Point3& unselColor = GetUIColor(COLOR\_SEL\_GIZMOS)**

The color of the gizmo when unselected.

**Point3& selColor = GetSubSelColor()**

The color of the gizmo when selected.

**Prototype:**

```
void AppendText(TCHAR* pText, Point3& position, DWORD  
flags = 0, Point3& unselColor =  
GetUIColor(COLOR_SEL_GIZMOS), Point3& selColor =  
GetSubSelColor());
```

**Remarks:**

Implemented by the system.

This method adds a new Text to the manipulator. The shape is defined in the local coordinates of the node that owns the manipulator.

**Parameters:****TCHAR\* pText**

The text string to add.

**Point3& position**

The position of the text.

**DWORD flags = 0**

The flags can have one or more of the following values:

**kGizmoDontDisplay;**

Tells the gizmo not to display. It will still hit test it.

**kGizmoDontHitTest;**

Tells the gizmo not to hit test. It will still display.

**kGizmoScaleToViewport;**

Tells the gizmo to scale itself to have a constant size in the viewport. In this case, the system uses the **ManipulatorGizmo::mGizmoSize** to determine how big the manipulator should be. It interprets **mGizmoSize** as pixels in this case. This flag only applies to mesh gizmo currently.

**Point3& unselColor = GetUIColor(COLOR\_SEL\_GIZMOS)**

The color of the gizmo when unselected.

**Point3& selColor = GetSubSelColor()**

The color of the gizmo when selected.

**Prototype:**

**TSTR& GetManipName();**

**Remarks:**

Implemented by the system.

This method returns the manipulator name.

**Prototype:**

**void SetGizmoScale(float gizmoScale);**

**Remarks:**

Implemented by the system.

This method allows you to set the scale of the gizmo.

**Parameters:**

**float gizmoScale**

The scale factor.

**Prototype:**

**TSTR& GetToolTip();**

**Remarks:**

Implemented by the system.

This method returns the tooltip string. Used internally.

**Default Implementation:**

```
{ return mToolTip; }
```

**Prototype:**

```
void SetToolTipWnd(HWND hWnd);
```

**Remarks:**

Implemented by the system.

Used internally.

**Prototype:**

```
void SetToolTipTimer(UINT timer);
```

**Remarks:**

Implemented by the system.

Used internally.

**Prototype:**

```
UINT GetToolTipTimer();
```

**Remarks:**

Implemented by the system.

Used internally.

**Prototype:**

```
HWND GetToolTipWnd();
```

**Remarks:**

Implemented by the system.

Used internally.

**Prototype:**

```
IParamBlock2* GetPBlock();
```

**Remarks:**

Implemented by the system.

This method returns a pointer to the parameter block.

**Default Implementation:**

```
{ return mpPblock; }
```

These must be implemented in the sub-class of SimpleManipulator

**Prototype:**

```
virtual void UpdateShapes(TimeValue t, TSTR& toolTip) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method gets called whenever the manipulator needs to update its gizmos.

This is implemented by the manipulator to create the gizmos based on the current state of the node being manipulated.

**Parameters:**

**TimeValue t**

The time at which to update the shape.

**TSTR& toolTip**

The tool tip text to update.

**Prototype:**

```
virtual void ManipulatorSelected();
```

**Remarks:**

Implemented by the system.

Used internally.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
void SetManipTarget(RefTargetHandle hTarg);
```

**Remarks:**

Implemented by the system.

This tells the SimpleManipulator to make a reference to hTarg. This is normally called in the constructor of a manipulator to set a reference to whatever is being manipulated.

**Parameters:**

**RefTargetHandle hTarg**

The handle to the reference target.

**Prototype:**

**RefTargetHandle GetManipTarget();**

**Remarks:**

This method returns the handle to the manipulator reference target.

**Default Implementation:**

```
{ return mhTarget; }
```

**Prototype:**

**void SetMouseState(MouseState state);**

**Remarks:**

This method sets the state of the mouse.

**Parameters:**

**MouseState state**

One of the following values:

**kMouseIdle**

The mouse is idle, manipulator not active and the mouse is not over it.

**kMouseDragging**

The mouse is currently dragging the manipulator.

**kMouseOverManip**

The mouse is over the manipulator, but it is not being dragged.

**Default Implementation:**

```
{ mState = state; }
```

**Prototype:**

## **MouseState GetMouseState();**

### **Remarks:**

Implemented by the system.

This method returns the state of the mouse, which is one of the following values: **kMouseIdle**, **kMouseDragging**, or **kMouseOverManip**.

### **Default Implementation:**

```
{ return mState; }
```

### **Prototype:**

```
void OnButtonDown(TimeValue t, ViewExp* pVpt, IPoint2& m,  
DWORD flags, ManipHitData* pHitData);
```

### **Remarks:**

Implemented by the system.

This method gets called when the mouse buttons is pressed within the manipulator context. Used internally.

### **Parameters:**

#### **TimeValue t**

The time to display the object.

#### **ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

#### **IPoint2& m**

The location of the tooltip.

#### **DWORD flags**

Not used, should be set to 0.

#### **ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

### **Prototype:**

```
void OnMouseMove(TimeValue t, ViewExp* pVpt, IPoint2& m,  
DWORD flags, ManipHitData* pHitData);
```

### **Remarks:**

This method gets called when the mouse is pressed down and moves within

the manipulator context. It is the method that does the actual manipulator. It is up to the manipulator code to turn the mouse position into a new value for the parameter(s) being manipulated. It also updates the tooltip with the current value of the parameter.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**DWORD flags**

Not used, should be set to 0.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Prototype:**

**void OnButtonUp(TimeValue t, ViewExp\* pVpt, IPoint2& m, DWORD flags, ManipHitData\* pHitData);**

**Remarks:**

Implemented by the system.

This method gets called when the mouse buttons is released within the manipulator context. Used internally.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**DWORD flags**

Not used, should be set to 0.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Prototype:**

**DisplayState MouseEntersObject(TimeValue t, ViewExp\* pVpt, IPoint2& m, ManipHitData\* pHitData);**

**Remarks:**

Implemented by the system.

This method gets called when the mouse enters the manipulator object. Used internally.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Return Value:**

The display state indicating whether no redraw, a full redraw, or a post redraw is needed.

**Prototype:**

**DisplayState MouseLeavesObject(TimeValue t, ViewExp\* pVpt, IPoint2& m, ManipHitData\* pHitData);**

**Remarks:**

Implemented by the system.

This method gets called when the mouse leaves the manipulator object. Used internally.

**Parameters:**

**TimeValue t**

The time to display the object.

**ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The location of the tooltip.

**ManipHitData\* pHitData**

A pointer to the hitdata containing information on which manipulator was hit.

**Return Value:**

The display state indicating whether no redraw, a full redraw, or a post redraw is needed.

**Prototype:**

```
IPoint2& GetTipPos();
```

**Remarks:**

Implemented by the system.

This method returns the position of the tooltip. Used internally.

**Default Implementation:**

```
{ return mToolTipPos; }
```

**Prototype:**

```
void GetLocalViewRay(ViewExp* pVpt, IPoint2& m, Ray&  
viewRay);
```

**Remarks:**

This method is normally called from a manipulator's OnMouseMove method. It computes a ray that passes through the given mouse point in the given viewport. The result is in the local coordinates of the node owning the manipulator.

**Parameters:****ViewExp\* pVpt**

An interface that may be used to call methods associated with the viewports.

**IPoint2& m**

The screen coordinate.

**Ray& viewRay**

The returned local view ray.

**Prototype:**

**Invalidate();**

**Remarks:**

This method invalidates the validity interval.

**Default Implementation:**

**{ mValid = NEVER; }**

**Prototype:**

**void UnRegisterViewChange();**

**Remarks:**

This method unregister the notifications so changes in the view are no longer registered.

**Prototype:**

**void SetResettingFlag(BOOL val);**

**Remarks:**

Used internally.

**Prototype:**

**BOOL GetResettingFlag();**

**Remarks:**

Used internally.

**Prototype:**

**void KillToolTip();**

**Remarks:**

This method will destroy the tooltip and its timer and cleans up.

**Prototype:**

**Point3 GetUnselectedColor();**

**Remarks:**

This method returns the color of the gizmo when unselected.

## Class ToneOperator

See Also: [Class SpecialFX](#), [Class ToneOperatorInterface](#), [Class IRendParams](#), [Class RendParams](#), [Class RenderGlobalContext](#), [Class RenderMapsContext](#), [Class ShadeContext](#), [Class Interval](#).

```
class ToneOperator : public SpecialFX
```

### Description:

This class is available in release 4.0 and later only.

This is the base class for the creation of Tone Operator plug-ins. A Tone Operator performs two functions:

1. It converts physically based values to RGB for filtering and display. The renderer calls the tone operator immediately after **Mtl::Shade** is called.
2. It balances physical and non-physical lighting.

The tone operator balances the physical and non-physical lighting by providing a scale relationship between them. The scale converts physical candelas to the non-physical value 1.0. Physically based objects in the 3ds max scene use this scale to convert their values for use by the renderer and materials. The tone operator then converts the scaled value to RGB for display.

An example of this is the tone operator for a radiosity plug-in. 3ds max works in a lighting space where values run from 0 to 1 and don't have any meaning. Pre-rendered Reflection maps, Refraction maps and self-illumination maps also use a 0 to 1 scale without any meaning. A radiosity plug-in introduces physical values to 3ds max that range from 0 to 90000 for the sun.

So the question is "How do we mix these values with physical values?" One solution is to use a scale. Physical values are scaled to "3ds max" values. Then they are processed by the shaders and materials, and then the scaled values are converted to RGB by ScaledToRGB.

So the PhysicalUnits, ScalePhysical and ScaleRGB are used to convert from 3ds max lighting values to physical lighting values. We can use this to balance 3ds max lights with physical lights, and to assign physical values to 3ds max lights when we want to use them in a radiosity solution.

The tone operator may include a UI that allows the user to set the scale, or it can set the scale apriori. The scale is also used for reflection maps, which are usually implemented in 32 bit bitmaps. If the scale is set too high, reflection maps can show banding because of rounding errors. If the scale is set too low, reflection

maps can wash out because of clipping values to 0...255.

The tone operator uses the standard Special Effects parameter dialog class for its user interface.

Note: **typedef SFXParamDlg ToneOpParamDlg;**

### **Methods:**

public:

### **Prototype:**

```
virtual ToneOpParamDlg *CreateParamDialog(IRendParams  
*ip);
```

### **Remarks:**

This method creates the rollup pages in the render panel that lets the user edit the tone operator's parameters. You can use

**IRendParams::AddRollupPage** and

**IRendParams::DeleteRollupPage** to manage your rollup pages directly.

Or, if your parameters are stored in a ParamBlock2 object, you can use

**CreateRParamMap2** and **DestroyRParamMap2** to manage the rollups.

You may return NULL, if no UI is required.

### **Parameters:**

**IRendParams \*ip**

Points to the render parameter dialog interface. You may call the methods of that class using this pointer.

### **Return Value:**

Pointer to the tone operator dialog.

### **Default Implementation:**

```
{ return NULL; }
```

### **Prototype:**

```
virtual void SetActive(bool active, TimeValue t);
```

### **Remarks:**

Implemented by the Plug-In.

This method indicates whether the tone operator is active. The default implementation does not use the **TimeValue t**. The result of the default

implementation can be retrieved using **SpecialFX::GetActive**. If you override this method and change the mechanism for storing this state, you should also override **SpecialFX::GetActive** so the correct state is returned.

**Parameters:**

**bool active**

A boolean indicating if the tone operator is active.

**TimeValue t**

The time at which the active check is made.

**Default Implementation:**

```
if (active ^ (TestAFlag(A_ATMOS_DISABLED) == 0)) {  
    if (active) {  
        ClearAFlag(A_ATMOS_DISABLED);  
    }  
    else {  
        SetAFlag(A_ATMOS_DISABLED);  
    }  
    NotifyDependents(FOREVER, PART_ALL,  
REFMSG_CHANGE);  
}
```

**Prototype:**

```
virtual BOOL SetDlgThing(ToneOpParamDlg* dlg);
```

**Remarks:**

Implemented by the Plug-In.

Implement this if you are using the ParamMap2 AUTO\_UI system and the atmosphere has secondary dialogs that don't have the effect as their 'thing'.

Called once for each secondary dialog for you to install the correct thing.

**Parameters:**

**ToneOpParamDlg\* dlg**

Points to the tone operator dialog.

**Return Value:**

Return TRUE if you process the dialog, FALSE otherwise.

**Prototype:**

```
virtual bool IsPhysicalSpace() const;
```

**Remarks:**

Implemented by the Plug-In.

Returns a boolean which indicates if this tone operator really maps physical values to RGB. This method is provided so shaders can determine whether the shading calculations are in physical or RGB space.

**Default Implementation:**

```
{ return true; }
```

**Prototype:**

```
virtual void Update(TimeValue t, Interval& valid);
```

**Remarks:**

This method is called once per frame when the renderer begins. This gives the tone operator the chance to cache any values it uses internally so they don't have to be computed on every pixel. But, this method should **not** be used to perform any very long tasks. This would be the likely method that caches the frames physical scaling value.

**Parameters:****TimeValue t**

The time at which the rendering is beginning.

**Interval& valid**

The validity interval for the update.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual bool BuildMaps(TimeValue t, RenderMapsContext& rmc);
```

**Remarks:**

This method is called for the operator to do any work it needs to do prior to rendering. You may use this method to perform a subrender to sample the

rendered output for histogramming or automatic exposure.

**Parameters:**

**TimeValue t**

The time at which the rendering is taking place.

**RenderMapsContext& rmc**

The context of the map rendering.

**Return Value:**

True means this method succeeded. False means it didn't. This method should return false if it the sub-render fails or if it can't allocate memory or some other error occurs. If BuildMaps returns false, the render is aborted.

**Default Implementation:**

```
{ return true; }
```

**Prototype:**

```
virtual void ScaledToRGB(float energy[3]) = 0;
```

**Remarks:**

This method maps a scaled energy value into RGB. This version converts a color value. The converted color value is stored in **energy**.

This method assumes that **Update()** has been called to cache the various values needed by the tone operator.

Note: By using a float array to pass in color values, we can use the same routine to handle the various classes used to store color information, for example, Color, AColor and Point3.

**Parameters:**

**float energy[3]**

The input energy value to convert. The converted color value is stored here as well. The red, green and blue components are stored in that order in the array. The valid ranges are -infinity to +infinity, but the returned value is clipped by the renderer very quickly to [0,1]. The tone operator can do it's own clipping, but it isn't required.

**Prototype:**

```
virtual float ScaledToRGB(float energy) = 0;
```

**Remarks:**

This method maps a scaled energy value to monochrome. The converted monochrome value is returned. This method assumes that **Update()** has been called to cache the various values needed by the tone operator.

**Parameters:****float energy**

The input energy value to convert.

**Prototype:**

```
virtual float GetPhysicalUnit(TimeValue t,Interval& valid = Interval(0,0)) const = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method returns the physical value that is scaled to 1.

**Parameters:****TimeValue t**

The time at which to return the value.

**Interval& valid = Interval(0,0)**

The validity interval for the value.

**Prototype:**

```
virtual void SetPhysicalUnit(float value, TimeValue t) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method sets the physical value that is scale to 1. This is simply a programatic method to change the physical scaling of the tone operator. Valid values are (0,+infinity).

**Parameters:****TimeValue t**

The time at which to set the value.

**Interval& valid = Interval(0,0)**

The validity interval for the value.

**Prototype:**

```
virtual void ScalePhysical(float energy[3]) const = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is used to scale a physical color value so it may be used in the renderer.

This method assumes that Update has been called to cache the various values needed by the tone operator.

Note: By using a float array to pass in color values, we can use the same routine to handle the various classes used to store color information, for example, Color, AColor and Point3.

**Parameters:**

**float energy[3]**

The input and output (converted) color value. The colors are stored as red=energy[0], green=energy[1], and blue=energy[2].

**Prototype:**

```
virtual float ScalePhysical(float energy) const = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is used to scale a physical monochrome value so it may be used in the renderer.

This method assumes that Update has been called to cache the various values needed by the tone operator.

**Parameters:**

**float energy**

The input value to scale.

**Return Value:**

The scaled output value is returned.

**Prototype:**

```
virtual void ScaleRGB(float color[3]) const = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to scale RGB values (the inverse of ScalePhysical()).

This method assumes that Update has been called to cache the various values needed by the tone operator.

**Parameters:**

**float color[3]**

The input values to scale and storage for the output scaled values as well. The colors are stored as red=energy[0], green=energy[1], and blue=energy[2]. The output values are in the range 0-1.

**Prototype:**

**virtual float ScaleRGB(float color) const = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to scale a monochrome value (the inverse of ScalePhysical()).

**Parameters:**

**float color**

The input value to scale.

**Return Value:**

The scaled output value is returned.

**Prototype:**

**bool GetProcessBackground();**

**Remarks:**

Returns the state of **A\_TONEOP\_PROCESS\_BG**, indicating whether the ToneOperator will be processing the background.

**Prototype:**

**void SetProcessBackground(bool active);**

**Remarks:**

This method allows you to set **A\_TONEOP\_PROCESS\_BG**.

**Parameters:**

**bool active**

TRUE to activate, FALSE to deactivate.

## Class IMultiPassCameraEffect

See Also: [Class ReferenceTarget](#), [Class CameraObject](#).

```
class IMultiPassCameraEffect : public ReferenceTarget
```

### Description:

This class is available in release 4.0 and later only.

The multipass camera effect allows modification of viewpoints & view directions or time for each pass of a multipass rendering. Algorithms such as Depth of Field, Scene motion blur can be implemented using multipass techniques.

Basically, a multipass camera effect is a plug-in to camera objects. It allows the renderer to query the camera for the view params for each pass of the rendering, & provides a dithered combining function to combine the bitmaps produced by each pass into the final bitmap. It also allows time to be manipulated for each rendering pass, providing effects such as motion blur.

### Methods:

public:

### Prototype:

```
virtual bool IsCompatible(CameraObject *pCameraObject) = 0;
```

### Remarks:

Some cameras are not compatible with some render effects, this method allows cameras to list compatible effects in the UI and as such allows the effect to declare its compatibility with the current camera object.

### Parameters:

**CameraObject \*pCameraObject**

A pointer to a camera object.

### Return Value:

TRUE if compatible, otherwise FALSE.

### Prototype:

```
virtual bool DisplayPasses(TimeValue renderTime) = 0;
```

### Remarks:

There is a UI option on multipass effects that indicates whether the renderer should display each pass as it is rendered. Note this is not used by viewport renderer, because of the hardware involvement. This method returns whether to display individual passes as they are computed.

**Parameters:**

**TimeValue renderTime**

The rendertime at which to check the display passes.

**Return Value:**

TRUE if display is on, otherwise FALSE.

**Prototype:**

**virtual int TotalPasses(TimeValue renderTime) = 0;**

**Remarks:**

The multipass effect also has a variable number of passes. This method tells the renderer how many passes to render per final output frame and as such returns the total number of passes to be rendered

**Parameters:**

**TimeValue renderTime**

The rendertime at which to check the display passes.

**Prototype:**

**virtual ViewParams \*Apply(INode \*pCameraNode,  
CameraObject \*pCameraObject, int passNum, TimeValue  
&overrideRenderTime) = 0;**

**Remarks:**

This method will modify the camera, camera node, or time value to affect each pass.

This is the modify function called for each pass of the frame. The effect can alter the camera node, camera object, or override the render time in the course of this call. 3ds max renderers take an optional parameter viewParams\* that when not NULL overrides the normal rendering camera. When this is called the override render time will be set to the current frame time. If the value is changed, this will be the time value used for the pass. Note that at the time that

apply is called, the renderer has not yet been called, hence it is possible, with care, to alter the scene in a general way, not just the camera & time parameters. Apply should return NULL if the normal unmodified camera is to be used.

**Parameters:**

**INode \*pCameraNode**

A pointer to the node of the camera.

**CameraObject \*pCameraObject**

A pointer to the camera object.

**int passNum**

The number of the pass.

**TimeValue &overrideRenderTime**

The time if you wish to override the render time.

**Return Value:**

The viewparams returned by apply which are supplied to the renderer.

**Prototype:**

```
virtual void AccumulateBitmap(Bitmap *pDest, Bitmap *pSrc, int  
passNum, TimeValue renderTime) = 0;
```

**Remarks:**

This method will blend each pass (**src**) into the final accumulator (**dest**).

After each pass is rendered, it needs to be combined into the final output bitmap. The current multipass effects use a dithered combiner, so that hard edges from the passes are more smoothly blended. There are many ways to do this, with varying quality, so this method allows different future implementations. Note that this is not used by the viewport renderer, as there's no way to tell the hardware to do this. Hardware is for fast & edgy, software is for slow & smooth.

**Parameters:**

**Bitmap \*pDest**

The destination bitmap.

**Bitmap \*pSrc**

The source bitmap.

**int passNum**

The number of the pass.

**TimeValue renderTime**

The render time.

**Prototype:**

**virtual void PostRenderFrame() = 0;**

**Remarks:**

This method is called after all passes have been rendered.

After all passes have been rendered & accumulated, this method will be called so that the effect can do any final cleanup. Currently unused, it can be ignored by multipass effects if they wish.

**Prototype:**

**virtual RefResult NotifyRefChanged(Interval changeInt,  
RefTargetHandle hTarget, PartID& partID, RefMessage  
message);**

**Remarks:**

This method is implemented to receive and respond to messages broadcast by all the dependants in the entire system.

**Parameters:**

**Interval changeInt**

This is the interval of time over which the message is active.

**RefTargetHandle hTarget**

This is the handle of the reference target the message was sent by. The reference maker uses this handle to know specifically which reference target sent the message.

**PartID& partID**

This contains information specific to the message passed in. Some messages don't use the partID at all. See the section [List of Reference Messages](#) for more information about the meaning of the partID for some common messages.

**RefMessage message**

The msg parameters passed into this method is the specific message which needs to be handled. See [List of Reference Messages](#).

**Return Value:**

The return value from this method is of type RefResult. This is usually **REF\_SUCCEED** indicating the message was processed. Sometimes, the return value may be **REF\_STOP**. This return value is used to stop the message from being propagated to the dependents of the item.

**Default Implementation:**

```
{ return REF_SUCCEED; }
```

**Prototype:**

```
virtual SClass_ID SuperClassID();
```

**Remarks:**

This method returns the super class ID of the creator of the clip object.

**Default Implementation:**

```
{ return MPASS_CAM_EFFECT_CLASS_ID; }
```

## Class IReshading

See Also: [Class IReshadeFragment](#), [Class ShadeContext](#), [Class IllumParams](#)

class IReshading

### Description:

This class is available in release 4.0 and later only.

This interface class is the interface that must be supported by materials and shaders to support interactive rendering in 3ds max. If this interface is not returned when requested through **GetInterface()** on the mtl or shader, then it is determined they do not support reshading. Any material that does not support reshading is evaluated only at preshading time.

In 3ds max, interactive rendering is implemented as fragment based caching scheme. It's very much like a giant multi-layer g-buffer with enough information stored with each fragment to re-run the material shading process without re-rendering, all stored in a compressed form.

The rendering process is divided into 2 parts: preshading and reshading. Preshading builds the scene and renders fragments to the compressed g-buffer, called the **rsBuffer**. To do this, it saves a minimal amount of information with each fragment, then gives each material and texture the opportunity to pre-shade itself.

Basically, the reshader populates a minimal **ShadeContext**, with the fragment center position in camera space (where shading is done), the shading normal, the sub-pixel mask, the coverage, pointers to the original material and **INode**, light lists, screen bounding box of object, the renderID, and screen integer x and y.

Any other values from the shade context that a material, shader, texture(future), atmosphere(future) or light(future) needs to save, it does so at pre-shade time, and retrieves the data at reshading time. So, for example, the multi-materials save which material is visible, anisotropic shaders save the Anisotropic reference vector.

### Methods:

public:

### Prototype:

**virtual ReshadeRequirements GetReshadeRequirements();**

**Remarks:**

This method is called by the interactive reshader after being notified that the material has changed. The return value indicates if the material is still valid, or needs to be pre-shaded or reshaded. The value should pertain only to the latest change to the material. If a material doesn't support reshading, it doesn't need to override this function -- any change will cause the nodes to which it's attached to be re- preShaded.

**Return Value:**

One of the following values;

**RR\_None**

No actions needs to be taken.

**RR\_NeedPreshade**

A pre-shade is needed.

**RR\_NeedReshade**

A re-shade is needed.

**Default Implementation:**

```
{ return RR_NeedPreshade; }
```

**Prototype:**

```
virtual void PreShade(ShadeContext& sc, IReshadeFragment* pFrag);
```

**Remarks:**

This method will pre-shade the object and cache any needed values in the fragment.

This method is called on the materials/shaders/textures as the reshading buffer is being built at the same point in the rendering process where the materials shade function would normally be called. Note that at this time the shade context is completely valid, as in a normal rendering. Any values the material wishes to cache can be attached to the reshading fragment passed in, and retrieved later at postShade time.

**Parameters:****ShadeContext& sc**

A reference to the shade context.

## **IReshadeFragment\* pFrag**

A pointer to the fragment.

### **Default Implementation:**

```
{ }
```

### **Prototype:**

```
virtual void PostShade(ShadeContext& sc, IReshadeFragment*  
pFrag, int& nextTexIndex, IllumParams* ip = NULL);
```

### **Remarks:**

This method will retrieve cached values and compute shade & transparency for the fragment.

This method is called for the material of each fragment as the reshading buffer is being traversed. Materials retrieve whatever they may have stored to complete the minimal shade context and compute a shade for the fragment.

**PostShade()** calls to shaders contain an additional parameter, the **IllumParams**, filled with the textured/blended but unshaded values for each texture. The shade context passed into **PostShade()** is the minimal shade context outlined above.

### **Parameters:**

#### **ShadeContext& sc**

A reference to the shade context.

#### **IReshadeFragment\* pFrag**

A pointer to the fragment.

#### **int& nextTexIndex**

A reference to the next texture index.

#### **IllumParams\* ip = NULL**

A pointer to the IllumParams containing textured/blended but unshaded values for each texture.

### **Default Implementation:**

```
{ }
```

## Class IInteractiveRender

See Also: [Class InterfaceServer](#), [Class IIRenderMgr](#), [Class INode](#), [Class ViewExp](#), [Class Bitmap](#), [Class DefaultLight](#), [Class IRenderProgressCallback](#), [Class Animatable](#) , [Class ActionTable](#)

```
class IInteractiveRender : public InterfaceServer
```

### Description:

This class is available in release 4.0 and later only.

This is the abstract class (Interface) for a a renderer supporting interactive rendering.

With the likelihood of evolving rendering and shading techniques which are going to be markedly different from what is being used now, the 3ds max SDK provides the infrastructure to support interactive rendering. Since renderers are a plugin to 3ds max and since each renderer has a different set of resources and capabilities the interactive rendering and shading API has been made as general and independent as possible. The independence of the renderer also means that the renderer must do a fair amount of work that could be done by the system for all renderers.

Interactive rendering and shading is a separate interface which can be optionally supported by 3<sup>rd</sup> party renderers and can be obtained by using the

**GetInterface()** method on the renderer. **I\_RENDER\_ID** is passed as the ID parameter to a renderer's implementation of **Animatable::GetInterface()**.

The renderer returns a pointer to a class **IInteractiveRender** instance if it supports interactive rendering, otherwise the default implementation will return NULL, indicating that interactive rendering is not supported. This class,

**IInteractiveRender** is defined in

**\MAXSDK\INCLUDE\interactiveRendering.h.**

As it is, interactive renderers will reference any and all objects, as well as lights and materials in the scene that they can respond to changes from. Via the normal 3ds max notification system the interactive shader will then receive messages whenever one of these referenced objects changes and it must then decide how best to update the scene for the user.

### Methods:

public:

**Prototype:**

```
virtual void BeginSession() = 0;
```

**Remarks:**

This method initiates the interactive rendering and will reference objects in the scene so the renderer receives the proper change notifications. The interactive renderer will automatically update the scene when these changes are received.

This is called when the user first invokes interactive rendering. During the begin session call, the renderer should reference any object in the scene that it can respond to changes from. There are reference manager classes in the SDK to ease this referencing in the file **referenceManager.h**. many of the parameters of interactive reshading are set up prior to the call to **BeginSession()**, here is a code snippet from the interactive rendering manager:

```
mIRenderInterface->SetOwnerWnd(mpIMaxBitmapViewer-  
>GetHDisplayWindow());
```

```
mIRenderInterface->SetIIRenderMgr(this);
```

```
mIRenderInterface->SetBitmap(mpIMaxBitmapViewer-  
>GetBitmap());
```

```
mIRenderInterface->SetSceneINode(mpInterface-  
>GetRootNode());
```

```
mIRenderInterface->SetUseViewINode(false);
```

```
mIRenderInterface->SetViewINode(NULL);
```

```
mIRenderInterface->SetViewExp(mpViewExp);
```

```
mIRenderInterface->SetRegion(mSelectedRegion);
```

```
mIRenderInterface->SetDefaultLights(mDefaultLights,  
mNumDefaultLights);
```

```
mIRenderInterface->SetProgressCallback(  
    dynamic_cast<IRenderProgressCallback *>  
    (&mImageViewerCB)  
);
```

```
mIRenderInterface->BeginSession();
```

Consequently, **BeginSession()** can rely on all these local attributes being

valid.

**Prototype:**

**virtual void EndSession() = 0;**

**Remarks:**

This method will end an interactive rendering session and will remove all references placed on the scene.

**Prototype:**

**virtual void SetOwnerWnd(HWND hOwnerWnd) = 0;**

**Remarks:**

This method allows you to set the owner window, which could come in handy if you want to pass it to the renderer if necessary. The owner HWND is supplied to the interactive renderer so that it may receive window messages for the interactive window, update the window, etc.

**Parameters:**

**HWND hOwnerWnd**

A handle to the owner window.

**Prototype:**

**virtual HWND GetOwnerWnd() const = 0;**

**Remarks:**

This method allows you to retrieve the owner window.

**Prototype:**

**virtual void SetIIRenderMgr(IIRenderMgr \*pIIRenderMgr) = 0;**

**Remarks:**

This method sets a pointer to the controlling renderMgr, so that various states can be queried.

**Parameters:**

**IIRenderMgr \*pIIRenderMgr**

A pointer to the controlling interactive rendering manager.

**Prototype:**

```
virtual IIRenderMgr *GetIIRenderMgr(IIRenderMgr  
*pIIRenderMgr) const = 0;
```

**Remarks:**

This method allows you to retrieve a pointer to the controlling interactive render manager

**Parameters:**

**IIRenderMgr \*pIIRenderMgr**

A pointer to the render manager interface.

Used internally. This should always be set to NULL.

**Prototype:**

```
virtual void SetBitmap(Bitmap *pDestBitmap) = 0;
```

**Remarks:**

This method allows you to set the destination bitmap to be rendered and re-rendered to. This destination bitmap is persistent between update renderings, basically the renderer holds the bitmap and updates the screen while the manager holds the reference to the bitmap and controls its lifetime.

**Parameters:**

**Bitmap \*pDestBitmap**

A pointer to the destination bitmap to set.

**Prototype:**

```
virtual Bitmap *GetBitmap(Bitmap *pDestBitmap) const = 0;
```

**Remarks:**

This method allows you to retrieve the destination bitmap that's being rendered and re-rendered to.

**Parameters:**

**Bitmap \*pDestBitmap**

A pointer to the destination bitmap.

Used internally. This should always be set to NULL.

**Prototype:**

```
virtual void SetSceneINode(INode *pSceneINode) = 0;
```

**Remarks:**

This method allows you to set the scene root node. In general, the idea of interactive rendering is to start with a fixed scene and then respond to changes in that scene. This call sets the scene root node. All items stemming from this scene root that an interactive renderer can respond to changes in should be referenced.

**Parameters:**

```
INode *pSceneINode
```

A pointer to the scene root node.

**Prototype:**

```
virtual INode *GetSceneINode() const = 0;
```

**Remarks:**

This method returns a pointer to the scene's root node.

**Prototype:**

```
virtual void SetUseViewINode(bool bUseViewINode) = 0;
```

**Remarks:**

This method sets whether to use the ViewINode. When a separate camera node is needed instead of ViewExp, the interactive rendering manager will set the viewINode to the interactive renderer and set UseViewINode to TRUE.

**Parameters:**

```
bool bUseViewINode
```

If FALSE, ViewParams obtained from ViewExp should be used.

**Prototype:**

```
virtual bool GetUseViewINode() const = 0;
```

**Remarks:**

This method returns FALSE if the ViewParams obtained from ViewExp should be used. TRUE would indicate that this is not the case.

**Prototype:**

```
virtual void SetViewINode(INode *pViewINode) = 0;
```

**Remarks:**

This method allows you to set the View INode in case a separate camera node is needed instead of ViewExp.

**Parameters:**

**INode \*pViewINode**

A pointer to the view node.

**Prototype:**

```
virtual INode *GetViewINode() const = 0;
```

**Remarks:**

This method returns a pointer to the view node if this is used instead of ViewExp.

**Prototype:**

```
virtual void SetViewExp(ViewExp *pViewExp) = 0;
```

**Remarks:**

This method allows you to set the ViewExp. The ViewExp is the view specification for docked windows. The interactive renderer gets the view params out of the ViewExp.

**Parameters:**

**ViewExp \*pViewExp**

A pointer to the ViewExp.

**Prototype:**

```
virtual ViewExp *GetViewExp() const = 0;
```

**Remarks:**

This method returns a pointer to the ViewExp which is used for the view specification for docked windows.

**Prototype:**

**virtual void SetRegion(const Box2 &region) = 0;**

**Remarks:**

This method allows you to set the region of the bitmap to be rendered.

There are two standard interactive modes that should be supported in all interactive renderers: region rendering and selected object rendering, and these modes should ideally work in consort if at all possible: scenes are often very complex and the plugin renderer must be able to limit complexity to increase interactivity. Note that if **Box2::IsEmpty()** returns TRUE, it indicates to render entire bitmap.

**Parameters:**

**const Box2 &region**

A reference to the rectangular area.

**Prototype:**

**virtual const Box2 &GetRegion() const = 0;**

**Remarks:**

This method returns the region of the bitmap to be rendered. Note that if **Box2::IsEmpty()** returns TRUE, it indicates to render entire bitmap.

**Prototype:**

**virtual void SetDefaultLights(DefaultLight \*pDefLights, int numDefLights) = 0;**

**Remarks:**

This method allows you to set the default lights to be used in absence of scene lights. These lights will be used when no user specified lights are in the scene. This should be noted when the scene is traversed in begin session, and of course altered if new user lights are created.

**Parameters:**

**DefaultLight \*pDefLights**

A pointer to a default light source.

**int numDefLights**

The number of default lights.

**Prototype:**

```
virtual const DefaultLight *GetDefaultLights(int &numDefLights)  
const = 0;
```

**Remarks:**

This method returns a pointer to the default lights and the number of default lights which are used in absence of scene lights.

**Parameters:**

**int &numDefLights**

The number of default lights returned.

**Prototype:**

```
virtual void SetProgressCallback(IRenderProgressCallback  
*pProgCB) = 0;
```

**Remarks:**

This method allows you to set an interactive rendering progress callback object.

The Progress/Abort Callback should be called by the renderer ideally about every 100 milliseconds, but the actual range varies widely. The callback allows the manager to display rendering progress and/or abort a rendering.

**Parameters:**

**IRenderProgressCallback \*pProgCB**

A pointer to the interactive rendering progress callback object.

**Prototype:**

```
virtual const IRenderProgressCallback *GetProgressCallback()  
const = 0;
```

**Remarks:**

This method returns a pointer to the interactive rendering progress callback object.

**Prototype:**

```
virtual void Render(Bitmap *pDestBitmap) = 0;
```

**Remarks:**

This method renders the bitmap using default non-interactive rendering functionality. This is the only actual command to the interactive renderer.

**Parameters:****Bitmap \*pDestBitmap**

The destination bitmap to render to.

**Prototype:**

```
virtual ULONG GetNodeHandle(int x, int y) = 0;
```

**Remarks:**

This method returns the closest node handle for a given bitmap pixel location. This can be implemented with an item buffer, by using ray casting, or some other method and allows the interactive rendering manager to implement object selection.

**Parameters:****int x, int y**

The x and y coordinate of the bitmap pixel.

**Return Value:**

The node handle or 0 if there is no node.

**Prototype:**

```
virtual bool GetScreenBBox(Box2& sBBox, INode *pINode) = 0;
```

**Remarks:**

This method returns the screen bounding box of the corresponding INode, so the selection box corners can be drawn.

**Parameters:****Box2& sBBox**

The screen bounding box.

**INode \*pINode**

The INode for which you wish to retrieve the screen bounding box.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:****virtual ActionTableId GetActionTableId() = 0;****Remarks:**

This method returns the ActionTableId for any action items the renderer may implement. This method will return 0 if none are available. Action tables are used as context sensitive command system to generate quad menus and the like from the various objects in the scene.

**Prototype:****virtual ActionCallback \*GetActionCallback() = 0;****Remarks:**

This method returns a pointer to an ActionCallback for any action items the renderer may implement. This method will return NULL if none are available.

**Prototype:****virtual void \*GetInterface();****Remarks:**

This method provides a general extension mechanism, access to additional method interfaces.

**Default Implementation:****{ return NULL; }****Prototype:****virtual BOOL IsRendering() = 0;****Remarks:**

This method returns TRUE if the renderer is currently rendering, otherwise FALSE.

When the interactive rendering manager gets a message to shut down or abort an interactive rendering, there is a potential race condition between the interactive renderer shutting down and the shutting down of the manager itself, which deletes the renderer. Since it is the renderer itself that decides when, what and how to re-render the image, it's not clear to the manager whether a delete is safe. This method allows the manager to inquire whether

the renderer is recomputing the image. To abort a rendering, the progress/abort callback must be used. When the abort is complete, IsRendering will return FALSE.

## Class IMBOps

See Also: [Class FPStaticInterface](#), [Class Bitmap](#), [Class CheckAbortCallback](#).

class IMBOps: public FPStaticInterface

### Description:

This class is available in release 4.0 and later only.

This class is an interface for Image Motion Blur. This interface is implemented in the Effect plug-in MotionBlur.dlv, which must be present to use it. This interface does NOT support scripting, only direct calling. The sample code below shows how this is done:

### Sample Code:

```
ClassDesc2* mbcd = GET_MBLUR_CD;
if (mbcd) {
    IMBOps* imb = GetIMBInterface(mbcd);
    imb->ApplyMotionBlur(bm, &imbc, 1.2f);
}
```

### Methods:

public:

### Prototype:

```
virtual ULONG ChannelsRequired(ULONG flags=0)=0;
```

### Remarks:

Sets the channels required for the image motion blur.

### Parameters:

**ULONG flags=0**

The following flag may be set:

**IMB\_TRANSP**

Controls whether motion blur works through transparency. Setting it to 0 saves memory, runs faster.

### Prototype:

```
virtual int ApplyMotionBlur(Bitmap *bm, CheckAbortCallback
```

**\*progCallback=NULL, float duration=1.0f, ULONG flags=IMB\_TRANSP, Bitmap\* extraBM=NULL)=0;**

**Remarks:**

Applies the motion blur process to the specified bitmap.

**Parameters:**

**Bitmap \*bm**

The bitmap to apply the motion blur to.

**CheckAbortCallback \*progCallback=NULL**

A pointer to a callback, allowing an abort check during the progress.

**float duration=1.0f**

The motion blur duration.

**ULONG flags=IMB\_TRANSP**

The following flag may be set:

**IMB\_TRANSP**

Controls whether motion blur works through transparency. Setting it to 0 saves memory, runs faster.

**Bitmap\* extraBM=NULL**

If the **extraBM** bitmap is supplied, then that is used as the target color bitmap, but the gbuffer information still comes from the other, main, bitmap. this is used to apply motion blur to render elements.

**Return Value:**

TRUE if success, otherwise FALSE.

## Class IChkMtlAPI

See Also: [Class Mtl](#), [Class RenderInstance](#).

class IChkMtlAPI

### Description:

This class is available in release 4.0 and later only.

This class provides interface methods used to support indirect material referencing and enhanced face / material associations. Generally, these methods will need to be implemented by the plug-in using them and cannot be called from a standard library, since the information required is intimately associated with the geometry of the object.

All methods of this class are implemented by the Plug-In.

### Methods:

public:

### Prototype:

**virtual BOOL SupportsParticleIDbyFace();**

### Remarks:

Returns TRUE if the object can associate a particle number with a face number, and FALSE if not.

### Default Implementation:

**{ return FALSE; }**

### Prototype:

**virtual int GetParticleFromFace(int faceID);**

### Remarks:

Returns the particle to which the face identified by faceID belongs.

### Parameters:

**int faceID**

The ID of the face.

### Default Implementation:

**{ return 0; }**

**Prototype:**

**virtual BOOL SupportsIndirMtlRefs();**

**Remarks:**

Returns TRUE if the object can return a material pointer given a face being rendered, and FALSE if the object will be associated for that render pass with only the material applied to the node.

**Default Implementation:**

**{ return FALSE; }**

**Prototype:**

**virtual int NumberOfMtlsUsed();**

**Remarks:**

Returns the number of different materials used on the object. This number is used in enumerating the different materials via the methods **GetNthMtl()** and **GetNthMaxMtlID()** below.

**Default Implementation:**

**{ return 0; }**

the following methods are meaningful.

**Prototype:**

**virtual Mtl \*GetNthMtl(int n);**

**Remarks:**

If the method **SupportsIndirMtlRefs()** above returns TRUE then this method returns the different materials used on the object.

**Parameters:**

**int n**

The zero based index of the material used on the object.

**Return Value:**

**Default Implementation:**

**{ return NULL; }**

**Prototype:**

```
virtual int GetNthMaxMtlID(int n);
```

**Remarks:**

If the method **SupportsIndirMtlRefs()** above returns TRUE then this method returns the maximum material ID number used with the specified material on the object

**Parameters:**

**int n**

The zero based index of the material.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual Mtl *GetMaterialFromFace(int faceID);
```

**Remarks:**

If the method **SupportsIndirMtlRefs()** above returns TRUE then this method returns a pointer to the material associated with the face identified by faceID.

**Parameters:**

**int faceID**

The ID of the face to check.

**Default Implementation:**

```
{ return NULL; }
```

## Class IImageViewer

See Also: [Class DADMgr](#) , [Class BaseInterface](#), [Class IMaxBitmapViewer](#)

class IImageViewer

### Description:

This class is available in release 4.0 and later only.

This class represents an abstract interface class for an image viewer.

### Methods:

public:

### Prototype:

```
virtual void PostDisplayCallback::PostDisplayCB(HWND hWnd)  
= 0;
```

### Remarks:

The PostDisplayCB method of the PostDisplayCallback class is called after an image is displayed in the image viewer. Developers can use this to do any post-display related work.

### Parameters:

**HWND hWnd**

The handle of the image viewer window.

### Prototype:

```
virtual BaseInterface*  
PostDisplayCallback::GetInterface(Interface_ID id);
```

### Remarks:

This method provides a way to extend the class with interfaces.

### Parameters:

**Interface\_ID id**

The interface ID.

### Default Implementation:

```
{ return NULL; }
```

**Prototype:**

```
virtual LRESULT  
PreEventHandlerCallback::EventHandlerCB(HWND hWnd,  
UINT message, WPARAM wParam, LPARAM lParam, bool  
&propagate) = 0;
```

**Remarks:**

The EventHandlerCB method of the PreEventHandlerCallback class allows you to intercept window events prior to them being passed through.

**Parameters:****HWND hWnd**

The handle of the image viewer window.

**UINT message**

The message identifier.

**WPARAM wParam**

The WPARAM value.

**LPARAM lParam**

The LPARAM value.

**bool &propagate**

TRUE if the message and event are to be propagated, otherwise FALSE.

**Prototype:**

```
virtual BaseInterface*  
PreEventHandlerCallback::GetInterface(Interface_ID id);
```

**Remarks:**

This method provides a way to extend the class with interfaces.

**Parameters:****Interface\_ID id**

The interface ID.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual void Show() = 0;**

**Remarks:**

This method will show the image viewer. In the **IMaxBitmapViewer** class, the **Display()** method must initially be used to display the viewer; this method only displays the viewer after using **Hide()**.

**Prototype:**

**virtual void Hide() = 0;**

**Remarks:**

This method will hide the image viewer. In the **IMaxBitmapViewer** class, the **UnDisplay()** method should be used to close the viewer when done; use **Hide()** to temporarily hide the window.

**Prototype:**

**virtual HWND GetHDisplayWindow() = 0;**

**Remarks:**

This method returns the handle to the display window of the image viewer.

**Prototype:**

**virtual void SetPos(int x, int y, int w, int h) = 0;**

**Remarks:**

This method allows you to set the position of the image viewer window.

**Parameters:**

**int x, y**

The position of the window.

**int w, h**

The width and height of the window.

**Prototype:**

**virtual DisplayStyle GetDisplayStyle() const = 0;**

**Remarks:**

This method will return the display style used by the image viewer window,

which is either **IV\_FLOATING** or **IV\_DOCKED**.

**Prototype:**

**virtual void SetContextHelpId(DWORD helpID) = 0;**

**Remarks:**

This method allows you to set the context help identifier for the image viewer.

**Parameters:**

**DWORD helpID**

The help identifier.

**Prototype:**

**virtual DWORD GetContextHelpId() const = 0;**

**Remarks:**

This method returns the context help identifier.

**Prototype:**

**virtual void SetDADMgr(DADMgr \*pDADMgr) = 0;**

**Remarks:**

This method allows you to set the drag and drop manager which should be used for the image viewer.

**Parameters:**

**DADMgr \*pDADMgr**

A pointer to the drag and drop manager.

**Prototype:**

**virtual void**

**SetPreEventHandlerCallback(PreEventHandlerCallback\*  
pPreEventHandlerCB) = 0;**

**Remarks:**

This method allows you to set the pre-event handler callback method.

**Parameters:**

## **PreEventHandlerCallback\* pPreEventHandlerCB**

A pointer to the callback function.

### **Prototype:**

```
virtual PreEventHandlerCallback*  
GetPreEventHandlerCallback() const = 0;
```

### **Remarks:**

This method returns a pointer to the pre-event handler callback function.

### **Prototype:**

```
virtual void SetPostDisplayCallback(PostDisplayCallback*  
pPostDisplayCB) = 0;
```

### **Remarks:**

This method allows you to set the post display callback function.

### **Parameters:**

```
PostDisplayCallback* pPostDisplayCB  
A pointer to the callback function.
```

### **Prototype:**

```
virtual PostDisplayCallback* GetPostDisplayCallback() const = 0;
```

### **Remarks:**

This method returns a pointer to the post display callback function.

### **Prototype:**

```
virtual BaseInterface* GetInterface(Interface_ID id);
```

### **Remarks:**

This method provides a way to extend the class with interfaces.

### **Parameters:**

```
Interface_ID id  
The interface ID.
```

### **Default Implementation:**

```
{ return NULL; }
```

## Class IMenuManager

See Also: [Class IMenu](#), [Class IMenuBarContext](#), [Class IQuadMenuContext](#), [Class Interface](#).

class IMenuManager

### Description:

This class is available in release 4.0 and later only.

To get an interface for calling the methods of this class use

**Interface::GetMenuManager()**.

### Methods:

public:

### Prototype:

```
virtual bool RegisterMenu(IMenu* pMenu, DWORD flags = 0) = 0;
```

### Remarks:

This method allows you to add a menu to the manager.

### Parameters:

**IMenu\* pMenu**

Points to the menu to register.

**DWORD flags = 0**

Not used.

### Return Value:

Returns false if the menu is already registered; true if not.

### Prototype:

```
virtual bool UnRegisterMenu(IMenu* pMenu) = 0;
```

### Remarks:

This method allows you to remove a menu form the mananger.

### Parameters:

**IMenu\* pMenu**

Points to the menu to unregister.

**Return Value:**

FALSE if the menu was not registered, TRUE if successfully unregistered.

**Prototype:**

```
virtual IMenu* FindMenu(TCHAR* pTitle) = 0;
```

**Remarks:**

This method will return a pointer to a menu based on its name.

**Parameters:**

**TCHAR\* pTitle**

The name of the menu to return.

**Return Value:**

A pointer to the menu or NULL if the menu wasn't found.

**Prototype:**

```
virtual IQuadMenu* FindQuadMenu(TCHAR* pTitle) = 0;
```

**Remarks:**

This method will return a pointer to a quad menu based on its name.

**Parameters:**

**TCHAR\* pTitle**

The name of the menu to return.

**Return Value:**

A pointer to the quad menu or NULL if the menu wasn't found.

**Prototype:**

```
virtual bool RegisterMenuBarContext(MenuContextId contextId,  
TCHAR* pName) = 0;
```

**Remarks:**

This method allows you to register a new menu bar context

**Parameters:**

**MenuContextId contextId**

The menu context ID.

**TCHAR\* pName**

The name of the menu bar.

**Return Value:**

TRUE if the new menu is registered, FALSE if the menu was already registered.

**Prototype:**

```
virtual bool RegisterQuadMenuContext(MenuContextId  
contextId, TCHAR* pName) = 0;
```

**Remarks:**

This method allows you to register a new quad menu context.

**Parameters:**

**MenuContextId contextId**

The menu context ID.

**TCHAR\* pName**

The name of the quad menu.

**Return Value:**

TRUE if the new quad menu is registered, FALSE if the quad menu was already registered.

**Prototype:**

```
virtual int NumContexts() = 0;
```

**Remarks:**

This method returns the number of contexts registered.

**Prototype:**

```
virtual IMenuContext* GetContextByIndex(int index) = 0;
```

**Remarks:**

This method returns a pointer to a menu context by the specified index.

**Parameters:**

**int index**

The index of the menu context to retrieve.

**Prototype:**

```
virtual IMenuContext* GetContext(MenuContextId contextId) = 0;
```

**Remarks:**

This method returns a pointer to a menu context by the specified menu context ID. This method returns NULL if the context does not exist.

**Parameters:**

**MenuContextId contextId**

The menu context ID.

**Prototype:**

```
virtual void UpdateMenuBar() = 0;
```

**Remarks:**

This method can be called to update 3ds max' main menu bar after adding sub-menu's or menu items.

**Prototype:**

```
virtual BOOL LoadMenuFile(TCHAR* pMenuFile) = 0;
```

**Remarks:**

This method allows you to load a menu file from disk and automatically update the UI accordingly.

**Parameters:**

**TCHAR\* pMenuFile**

The path and filename of the menu file to load.

**Return Value:**

TRUE if the menu file was loaded, otherwise FALSE.

**Prototype:**

```
virtual BOOL SaveMenuFile(TCHAR* pMenuFile) = 0;
```

**Remarks:**

This method allows you to save a menu file to disk.

**Parameters:**

## **TCHAR\* pMenuFile**

The path and filename of the menu file to save.

### **Return Value:**

TRUE if the menu file was saved, otherwise FALSE.

### **Prototype:**

```
virtual TCHAR* GetMenuFile() = 0;
```

### **Remarks:**

This method returns the file name of the currently loaded and active menu file.

### **Prototype:**

```
virtual BOOL SetMainMenuBar(IMenu* pMenu) = 0;
```

### **Remarks:**

This method allows you to set the main menu bar.

### **Parameters:**

**IMenu\* pMenu**

A pointer to the menu you wish to set as the main menu bar.

### **Return Value:**

TRUE if it was set successfully.

### **Prototype:**

```
virtual IMenu* GetMainMenuBar() = 0;
```

### **Remarks:**

This method returns a pointer to the main menu bar.

### **Prototype:**

```
virtual BOOL  
SetViewportRightClickMenu(IQuadMenuContext::RightClickCont  
context, IQuadMenu* pQuadMenu) = 0;
```

### **Remarks:**

This method allows you to set the viewport right-click menu to the specified quad menu.

**Parameters:**

**IQuadMenuContext::RightClickContext context**

See the [List of Right-Click Contexts](#).

**IQuadMenu\* pQuadMenu**

A pointer to the quad menu you wish to set.

**Return Value:**

TRUE if it was set successfully.

**Prototype:**

**virtual IQuadMenu\***

**GetViewportRightClickMenu(IQuadMenuContext::RightClickContext context) = 0;**

**Remarks:**

This method returns a pointer to the current viewport right-click quad menu.

**Parameters:**

**IQuadMenuContext::RightClickContext context**

See the [List of Right-Click Contexts](#)..

**Prototype:**

**virtual bool GetShowAllQuads(IQuadMenu\* pQuadMenu) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method checks if the "Show All Quads" flag is set for a specific QuadMenu and will return TRUE if the flag is set or FALSE if the flag is not set.

**Parameters:**

**IQuadMenu\* pQuadMenu**

A pointer to the QuadMenu you wish to check the flag for.

**Prototype:**

**virtual void SetShowAllQuads(IQuadMenu\* pQuadMenu, bool showAll) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method sets the "Show All Quads" flag for a specific QuadMenu.

**Parameters:****IQuadMenu\* pQuadMenu**

A pointer to the QuadMenu you wish to set the flag for.

**bool showAll**

TRUE to set the flag to on, FALSE to set the flag off.

**Prototype:**

```
virtual TCHAR* GetQuadMenuName(IQuadMenu*  
pQuadMenu) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the name given to a specific QuadMenu as a string.

**Parameters:****IQuadMenu\* pQuadMenu**

A pointer to the QuadMenu for which you wish to retrieve the name.

**Prototype:**

```
virtual void SetQuadMenuName(IQuadMenu* pQuadMenu,  
TCHAR* pName) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the name of a specific QuadMenu.

**Parameters:****IQuadMenu\* pQuadMenu**

A pointer to the QuadMenu for which you wish to set the name.

**TCHAR\* pName**

The string containing the name for the QuadMenu.

## Class IColorManager

See Also: [Class FPStaticInterface Class Point3](#), [COLORREF](#), [List of Standard Color IDs](#), [Generate a Class\\_ID](#), [Class GUP](#), [Getting and Setting User Preferences](#).

```
class IColorManager : public FPStaticInterface
```

### Description:

This class is available in release 4.0 and later only.

This class is an interface to the Color Manager. Within 3ds max using the Customize pull down menu / Customize User Interface choice / Colors tab a user is able to alter the colors used for various UI elements. They can change the saturation, value and transparency of elements, and load and save color schemes.

Using the methods of this class developers can do the same (the 3ds max color manager uses this class internally). Developers can add their own named custom colors. Developers wanting to do this need to pick a random 32-bit **ColorId** to identify it. (Note: **typedef DWORD ColorId;**). The Class\_ID generator may be used for this where only one of the two DWORDS is used. See [Class Class\\_ID](#) for more details. The low integer ColorIds are reserved for 3ds max internal use. These colors should be registered on startup, so a Global Utility Plug-In (GUP) is the best way to handle this. See [Class GUP](#) for details. Methods that are marked as internal should not be used.

**The following global functions are not part of this class but are available for use:**

### Function:

```
IColorManager* GetColorManager();
```

### Remarks:

This global function is available in release 4.0 and later only.

Returns a pointer to the color manager with which you can call the methods of this class.

Note the following #define which may be used to simplify coding a bit:

```
#define ColorMan() (GetColorManager())
```

### Methods:

public:

**Prototype:**

**virtual bool UseStandardWindowsColors() = 0;**

**Remarks:**

Returns true if the standard windows colors are used and false if custom colors are used.

**Prototype:**

**virtual void SetUseStandardWindowsColors(bool useStandardColors) = 0;**

**Remarks:**

Sets whether standard windows colors are used or not. This allows the developer to tell the system to use standard windows colors, instead of the custom colors. This only affects calls to **CustSysColor()** and not **GetColor()**.

**Parameters:**

**bool useStandardColors**

Pass true to use the standard windows color and false to use the custom colors.

**Prototype:**

**virtual bool RegisterColor(ColorId id, TCHAR\* pName, TCHAR\* pCategory, COLORREF defaultValue) = 0;**

**Remarks:**

This method registers a new color with the system. For plug-in developers this should be done at startup using a Global Utility Plug-in which calls this method. See the Description section above for details. If developers want to add a color of their own, they need to pick a random 32-bit integer ColorId to identify it.

**Parameters:**

**ColorId id**

The ID of the color to register. This should be generated by the developer using a single DWORD from the output of the Class\_ID program. See [Class ID](#) for more details.

**TCHAR\* pName**

The name for the color.

**TCHAR\* pCategory**

The category for the color. If the name passed matches one of the existing 3ds max categories the color will be placed in there, otherwise a new one will be created.

**COLORREF defaultValue**

The default value for the color. This is the value that the color will be reset to when a 3ds max user presses "Reset" in the color customization dialog. See [COLORREF](#).

**Return Value:**

Returns false if the color is already registered; otherwise true.

**Prototype:**

```
virtual BOOL LoadColorFile(TCHAR* pFileName) = 0;
```

**Remarks:**

This method will load the specified color file from the current UI directory.

**Parameters:****TCHAR\* pFileName**

The filename of the color file to load.

**Return Value:**

TRUE if the load was successful, otherwise FALSE.

**Prototype:**

```
virtual BOOL SaveColorFile(TCHAR* pFileName) = 0;
```

**Remarks:**

This method will save the specified color file from the current UI directory.

**Parameters:****TCHAR\* pFileName**

The filename of the color file to save.

**Return Value:**

TRUE if the save process was successful, otherwise FALSE.

**Prototype:**

**virtual TCHAR\* GetColorFile() = 0;**

**Remarks:**

This method returns the file name of the current color file.

**Prototype:**

**virtual bool SetColor(ColorId id, COLORREF color) = 0;**

**Remarks:**

Sets the color value of the previously registered color whose ID is passed.

**Parameters:****ColorId id**

Specifies which color to set.

**COLORREF color**

The color value to set. See [COLORREF](#).

**Return Value:**

Returns true if the color was set and false if the id passed could not be found.

**Prototype:**

**virtual COLORREF GetColor(ColorId id) = 0;**

**Remarks:**

Returns the color value of the color whose ID is passed.

**Parameters:****ColorId id**

Specifies which color to get.

**Return Value:**

The color is returned or black (RGB(0,0,0)) if the ColorId passed was not found.

**Prototype:**

**virtual Point3 GetColorAsPoint3(ColorId id) = 0;**

**Remarks:**

This method returns the color associated with a specified color ID as a Point3.

**Parameters:**

**ColorId id**

The ID of the color you wish to get.

**Prototype:**

**virtual HBRUSH GetBrush(ColorId id) = 0;**

**Remarks:**

Returns a handle to the brush for the color whose id is specified. NULL is returned if the id passed is not found. Note that the color manager does resource management for brushes, so the value returned should not be deleted.

**Parameters:**

**ColorId id**

The color whose brush handle is returned.

**Prototype:**

**virtual TCHAR\* GetName(ColorId id) = 0;**

**Remarks:**

Returns the name of the color whose ID is passed.

**Parameters:**

**ColorId id**

The ID of the color.

**Prototype:**

**virtual TCHAR\* GetCategory(ColorId id) = 0;**

**Remarks:**

Returns the category string of the color whose ID is passed.

**Parameters:**

**ColorId id**

The ID of the color.

**Prototype:**

**virtual COLORREF CustSysColor(int which) = 0;**

**Remarks:**

This method takes the specified windows color definition (for example **COLOR\_BTNHIGHLIGHT**) and returns the 3ds max customized version of that color. Anyone writing a plug-in with custom windows code should use this call (and **CustSysColorBrush()** below) instead of the Win32 **GetSysColor()** and **GetSysColorBrush()** if they want to participate in the 3ds max custom color scheme.

Note the following #define which may be used to simplify coding:

```
#define GetCustSysColor(which) (ColorMan()->CustSysColor(which))
```

**Parameters:****int which**

Specifies the windows color definition. See [List of Standard Color IDs](#). For a full list of windows color definitions, please refer to the Win32 API, in particular the methods **GetSysColor()** and **SetSysColor()**.

**Prototype:**

```
virtual HBRUSH CustSysColorBrush(int which) = 0;
```

**Remarks:**

This method returns a handle identifying a logical brush that corresponds to the specified color index. Note that the color manager does resource management for brushes, so the value returned should not be deleted.

**Parameters:****int which**

Specifies the windows color definition. See [List of Standard Color IDs](#). For a full list of windows color definitions, please refer to the Win32 API, in particular the methods **GetSysColor()** and **SetSysColor()**.

Note the following #define which may be used to simplify coding a bit:

```
#define GetCustSysColorBrush(which) (ColorMan()->CustSysColorBrush(which))
```

**Prototype:**

```
virtual Point3 GetOldUIColor(int which) = 0;
```

**Remarks:**

Returns the specified color value for drawing various items in the viewports. This is the same as the previous GetUIColor() function.

**Parameters:****int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

**Return Value:**

The color as a Point3.

**Prototype:**

```
virtual COLORREF GetOldUIColorCOLORREF(int which) = 0;
```

**Remarks:**

This method returns the color associated with a user interface color as a COLORREF.

**Parameters:****int which**

The UI color index (see gfx.h).

**Prototype:**

```
virtual void SetOldUIColor(int which, Point3 *clr) = 0;
```

**Remarks:**

Sets the specified color value for drawing various items in the viewports. This is the same as the previous SetUIColor() function.

**Parameters:****int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

**Point3 \*clr**

Points to the color value to set.

**Prototype:**

```
virtual Point3 GetOldDefaultUIColor(int which) = 0;
```

**Remarks:**

Returns the default color used for drawing various items in the 3ds max user interface. The values returned are not affected by the user's color selections or those set by SetUIColor(). This is the same as the previous GetDefaultUIColor() function.

**Parameters:**

**int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

**Prototype:**

**virtual float GetIconColorScale(IconType type, IconColorScale which) = 0;**

**Remarks:**

Returns a floating point value (in the range 0.0f to 1.0f) that is one of the scale factors applied to the specified icon type. These scale values used to do image processing on the icons at start-up time.

**Parameters:**

**IconType type**

The icon type. One of the following values:

**kDisabledIcon**

The disabled icons.

**kEnabledIcon**

The enabled icons.

**IconColorScale which**

The icon color scale. One of the following values:

**kSaturationScale**

The saturation scale.

**kValueScale**

The value scale.

**kAlphaScale**

The alpha scale.

**Prototype:**

**virtual void SetIconColorScale(IconType type, IconColorScale**

**which, float value) = 0;**

**Remarks:**

Sets the specified scale factor for the icon type passed. The color manager maintains the values for the 3ds max icon image processing system. Developers can set values to scale the saturation, value and transparency for enabled and disabled icon images using this method.

**Parameters:**

**IconType type**

The icon type. One of the following values:

**kDisabledIcon**

The disabled icons.

**kEnabledIcon**

The enabled icons.

**IconColorScale which**

The icon color scale. One of the following values:

**kSaturationScale**

The saturation scale.

**kValueScale**

The value scale.

**kAlphaScale**

The alpha scale.

**float value**

The value to set (in the range 0.0f to 1.0f).

**Prototype:**

**virtual bool GetIconColorInvert(IconType type) = 0;**

**Remarks:**

Returns true if the invert flag is set for the specified icon type and false if not set.

**Parameters:**

**IconType type**

The icon type. One of the following values:

**kDisabledIcon**

The disabled icons.

**kEnabledIcon**

The enabled icons.

**Prototype:**

**virtual void SetIconColorInvert(IconType type, bool value) = 0;**

**Remarks:**

Sets the invert flag for the specified icon type to on or off.

**Parameters:**

**IconType type**

The icon type. One of the following values:

**kDisabledIcon**

The disabled icons.

**kEnabledIcon**

The enabled icons.

**bool value**

Pass true for inverted; false for not inverted.

**Prototype:**

**virtual BOOL SetIconFolder(TCHAR\* pFolder) = 0;**

**Remarks:**

This method takes the name of a folder that must be in 3ds max "UI" folder. If the folder exists, then it sets 3ds max icon folder to point to it, and redraws the UI with those new icons. Warning: All of the 3ds max standard icon BMP files must exist in that folder. If any of the standard files are missing, icons will appear blank in the UI. All the icons files needed live in the **UIIcons** folder, which is the default icon folder.

**Parameters:**

**TCHAR\* pFolder**

The icon folder to set.

**Prototype:**

**virtual void InitSystemColors() = 0;**

**Remarks:**

This method is used internally to initialize the colors used by the system to their default values. This should not be called by third party developers.

**Prototype:**

**virtual IColorManager\* Copy() = 0;**

**Remarks:**

This method is used internally. It makes a copy of the color database that the UI changes, and then it copies it back to the original to commit the changes. Third party developers won't need to call this.

**Prototype:**

**virtual TCHAR\* GetFileName() = 0;**

**Remarks:**

Returns the file name of the currently loaded color file.

**Prototype:**

**virtual COLORREF GetDefaultColor(ColorId id) = 0;**

**Remarks:**

Returns the default color for the specified ID. The default color is the value passed as **defaultValue** in **RegisterColor()**, regardless if a **SetColor()** has been done subsequently. This is used by the UI when the user presses "Reset" to reset a color to its default value.

**Parameters:**

**ColorId id**

The ID of the color.

**Prototype:**

**virtual COLORREF GetOldUIColorCOLORREF(int which) = 0;**

**Remarks:**

Returns the specified color value for drawing various items in the viewports as

a COLORREF.

**Parameters:**

**int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

**Prototype:**

**virtual void RepaintUI(RepaintType type) = 0;**

**Remarks:**

This method allows you to issue a repaint of the user interface.

**Parameters:**

**RepaintType type**

The type of repaint you wish to issue; **kRepaintAll**, **kRepaintTrackBar**, **kRepaintTimeBar**.

**The following global functions are used internally and should not be called by plug-in developers**

**IColorManager\* CreateColorManager(TCHAR\* pDefaultColorFile);**

**void DeleteColorManager(IColorManager\* pColorMan);**

**void SaveColors();**

## Class IDragAndDropMgr

See Also: [Class FPStaticInterface](#), [Class DragAndDropHandler](#), [Class URLTab](#)

class IDragAndDropMgr : public FPStaticInterface

### Description:

This class is available in release 4.0 and later only.

The Drag and Drop system is managed through a Core FP interface (DND\_MGR\_INTERFACE), defined by this class. It provides control over the DnD system, manages handler registration and exposes some useful utility methods for downloading URL's, simulating drops, etc.

The DragAndDropMgr supports multiple DragAndDropHandlers registered against a single HWND window. This is to allow new components and 3rd-party developers to incrementally add handlers for new dropTypes to common windows such as viewports that the default handlers don't know how to handle.

The **IDragAndDropMgr::EnableDandD(HWND hwnd, BOOL flag, DragAndDropHandler\* handler)** method can be called multiple times on the same window with different handler instances. The DnDMgr keeps track of all the DragAndDropHandlers on each window and will call their DnD event methods as needed, in order of registration, until one of them returns **S\_OK**. For example, on a viewport, the DefaultDragAndDropHandler is registered by default. The event methods (such as DragEnter, DragOver, Drop, etc.) return **E\_FAIL** if the dropping IDataObject or DropType is not recognized by them. Then, if a new component registers its own handler to deal with some new droptype it adds, the default handler will fail to recognize the new droptype and so its handler will be called to process the new drop type.

Note that this means DragAndDropHandler event methods must correctly return **S\_OK** or **E\_FAIL** depending on whether they handle the IDataObject or DropType currently dropping, so that the appropriate handler is found and called by the DnDMgr.

For an example, please refer to

**\\MAXSDK\\SAMPLES\\HOWTO\\DND\_TEST.**

### Function:

**IDragAndDropMgr\* GetDragAndDropMgr();**

### Remarks:

This function, which is not part of the class, allows you to retrieve a pointer to the Drag and Drop Manager interface. This will return a pointer to the DnD manager interface from the core interface.

**Methods:**

public:

**Prototype:**

**virtual void EnableDandD(BOOL flag)=0;**

**Remarks:**

This method allows you to globally enable or disable the DnD interface.

**Parameters:**

**BOOL flag**

TRUE to enable, FALSE to disable.

**Prototype:**

**virtual BOOL IsEnabled()=0;;**

**Remarks:**

This method returns TRUE if the global DnD interface is enabled, otherwise FALSE.

**Prototype:**

**virtual BOOL EnableDandD(HWND hwnd, BOOL flag,  
DragAndDropHandler\* handler = NULL)=0;;**

**Remarks:**

This method allows you to enable DnD for a given window (and its children). If no custom DragAndDropHandler is supplied, a default one is used that will accept dropped scene files for opening and scripts for running.

**Parameters:**

**HWND hwnd**

A handle to the window you wish to enable or disable DnD for.

**BOOL flag**

TRUE to enable, FALSE to disable.

### **DragAndDropHandler\* handler = NULL**

A pointer to a custom DnD handler, or NULL to accept a default one.

### **Return Value:**

TRUE if the method was successful, otherwise FALSE.

### **Prototype:**

**virtual BOOL DropPackage(HWND hwnd, POINT& point, URLTab& package)=0;**

### **Remarks:**

This method allows the simulation of a package of files into a window at a given point. A package of files, specified as a list of URL strings is the common form of **DropType** data from **iDrop** sources and files dragged from the Windows desktop. The entire package is downloaded, as needed, but only the first file in the list is actually dropped into 3ds max. The other files in the package are presumed to be support files, such as texmaps or xref sources, for the main drop file. After the drop, the URL strings in the URLTab are converted to fully-specified path names to local file copies, if any had to be downloaded from the web.

### **Parameters:**

#### **HWND hwnd**

A handle to the window. If this is set to NULL, the default 3ds max window is used.

#### **POINT& point**

The point at which to drop.

#### **URLTab& package**

A reference to the local copies of the URL strings.

### **Return Value:**

TRUE if the drop was successful, otherwise FALSE.

### **Prototype:**

**virtual BOOL DownloadPackage(URLTab& package, TCHAR\* directory, HWND hwnd = NULL, bool showProgress = false)=0;**

### **Remarks:**

This method serves as a utility function that can be used to download a package of URLs to the specified directory. If the **hwnd** argument is supplied, any progress or other messages are centered over that window.

**Parameters:**

**URLTab& package**

A reference to the local copies of the URL strings.

**TCHAR\* directory**

The directory path string to download to.

**HWND hwnd = NULL**

A handle to the window. If this is set to NULL, the default window is used.

**bool showProgress = false**

The download progress dialog can be displayed by passing true.

**Return Value:**

TRUE if the download was successful, otherwise FALSE.

**Prototype:**

**virtual TCHAR\* GetDownloadDirectory()=0;**

**Remarks:**

This method returns the fully-specified path to the directory in which package drops are downloaded.

**Prototype:**

**virtual int NumHandlers(HWND hwnd)=0;**

**Remarks:**

This method returns the number of handlers associated with the given window.

**Parameters:**

**HWND hwnd = NULL**

A handle to the window.

**Prototype:**

**virtual DragAndDropHandler\* GetHandler(HWND hwnd, int i)=0;**

**Remarks:**

This method returns a pointer to a specified DnD handler of a specified window.

**Parameters:**

**HWND hwnd = NULL**

A handle to the window.

**int i**

The I-th handler.

**Prototype:**

**virtual bool DownloadUrlToDisk(HWND hwnd, TCHAR\* url, TCHAR\* fileName, DWORD dlgflags=0)=0;**

**Remarks:**

This method allows you to download the file referenced by the URL to disk.

**Parameters:**

**HWND hwnd = NULL**

A handle to the window.

**TCHAR\* url**

The URL string of the file to download.

**TCHAR\* fileName**

The filename string of the URL to store on disk.

**DWORD dlgflags=0**

Additional controls to the download behavior. Currently only one flag is supported, **DOWNLOADDLG\_NOPLACE**, which hides an option in the progress dialog that allows the user to place (move) a dropped object immediately after being dropped.

**Return Value:**

TRUE if the download was successful, otherwise FALSE.

**Prototype:**

**virtual INode\* ImportContextNode()=0;**

**Remarks:**

This method returns a pointer to the import context node.

## Class IParamWireMgr

See Also: [Class FPStaticInterface](#), [Class Control](#), [Class ReferenceTarget](#)

```
class IParamWireMgr : public FPStaticInterface
```

### Description:

This class is available in release 4.0 and later only.

This class represents the interface that provides general access to the parameter wiring functions. You can obtain a pointer to the Parameter Wire Manager interface using; **IParamWireMgr\* GetParamWireMgr()**. This macro will return

```
(IParamWireMgr*)GetCOREInterface(PARAMWIRE_MGR_INTEI
```

All methods of this class are Implemented by the System.

### Methods:

public:

### Prototype:

```
virtual void StartParamWire()=0;
```

### Remarks:

This method will launch the parameter wiring UI mode.

### Prototype:

```
virtual void OpenEditor()=0;
```

### Remarks:

This method will open up the parameter wiring dialog on the selected objects.

### Prototype:

```
virtual void EditParams(ReferenceTarget* leftParent, int  
leftSubNum, ReferenceTarget* rightParent, int rightSubNum)=0;
```

### Remarks:

This method allows you to edit the left- and right-hand parameters and opens the parameter wiring dialog using the provided parameters.

### Parameters:

**ReferenceTarget\* leftParent**

A pointer to the left-hand reference target.

**int leftSubNum**

The sub-animatable of the left-hand reference target.

**ReferenceTarget\* rightParent**

A pointer to the right-hand reference target.

**int rightSubNum**

The sub-animatable of the right-hand reference target.

**Prototype:**

```
virtual void EditControllers(Control* leftWire, Control*  
rightWire)=0;
```

**Remarks:**

This method allows you to setup the two controllers for the left- and right-hand to edit.

**Parameters:****Control\* leftWire**

A pointer to the controller for the left-hand wire.

**Control\* rightWire**

A pointer to the controller for the right-hand wire.

**Prototype:**

```
virtual void EditController(Control* wire)=0;
```

**Remarks:**

This method is identical to the **EditControllers()** but accepts a single wire controller for the left-hand. This method effectively calls **EditControllers(wire, NULL)**.

**Parameters:****Control\* wire**

A pointer to the controller being edited.

**Prototype:**

```
virtual bool Connect(ReferenceTarget* fromParent, int  
fromSubNum, ReferenceTarget* toParent, int toSubNum,  
TCHAR* toExpr)=0;
```

**Remarks:**

This method allows you to set up a one-way wire.

**Parameters:**

**ReferenceTarget\* fromParent**

A pointer to the reference target to wire from.

**int fromSubNum**

The sub-animatable to wire from.

**ReferenceTarget\* toParent**

A pointer to the reference target to wire to.

**int toSubNum**

The sub-animatable to wire to.

**TCHAR\* toExpr**

A string containing the expression on the "to wire".

**Return Value:**

TRUE if the connection can be made, otherwise FALSE.

**Prototype:**

```
virtual bool Connect2Way(ReferenceTarget* leftParent, int  
leftSubNum, ReferenceTarget* rightParent, int rightSubNum,  
TCHAR* leftExpr, TCHAR* rightExpr=NULL)=0;
```

**Remarks:**

This method allows you to set up a two-way wire.

**Parameters:**

**ReferenceTarget\* leftParent**

A pointer to the left-hand reference target.

**int leftSubNum**

The sub-animatable of the left-hand reference target.

**ReferenceTarget\* rightParent**

A pointer to the right-hand reference target.

**int rightSubNum**

The sub-animatable of the right-hand reference target.

**TCHAR\* leftExpr**

A string containing the expression for the left-hand target.

**TCHAR\* rightExpr = NULL**

A string containing the expression for the right-hand target.

**Return Value:**

TRUE if the connection can be made, otherwise FALSE.

**Prototype:**

```
virtual bool Disconnect(Control* wireController)=0;
```

**Remarks:**

This method allows you to disconnect a one-way wire.

**Parameters:****Control\* wireController**

A pointer to the wire controller you wish to disconnect.

**Return Value:**

TRUE if the disconnect was successful, otherwise FALSE.

**Prototype:**

```
virtual bool Disconnect2Way(Control* wireController1, Control*  
wireController2)=0;
```

**Remarks:**

This method allows you to disconnect a two-way wire.

**Parameters:****Control\* wireController1**

A pointer to the first wire controller you wish to disconnect.

**Control\* wireController2**

A pointer to the second wire controller you wish to disconnect.

**Return Value:**

TRUE if the disconnect was successful, otherwise FALSE.

## Class NodeDisplayCallback

See Also: [Class InterfaceServer](#), [Class INodeDisplayControl](#), [Class INode](#), [Class ViewExp](#), [Class IPoint2](#).

```
class NodeDisplayCallback : public InterfaceServer
```

### Description:

This class is available in release 4.0 and later only.

A callback to allow plug-ins that aren't actually objects (such as utilities) to control a Node's display.

This class enables you to display extra information on top of a node in a viewport. Once activated, a plug-in will control the display (on/off) of a node's world space representation as well as add data in a viewport on a per node basis. This approach allows you to replace the drawing code of every node without adding modifiers on top of each of them.

### Methods:

public:

### Prototype:

```
virtual void StartDisplay(TimeValue t, ViewExp *vpt, int flags)=0;
```

### Remarks:

This method is called just before 3ds max draws the nodes in the scene.

### Parameters:

#### **TimeValue t**

The time at which the nodes are being drawn.

#### **ViewExp \*vpt**

Points to an interface for the viewport the node is being drawn in.

#### **int flags**

These flags are used internally.

### Prototype:

```
virtual void EndDisplay(TimeValue t, ViewExp *vpt, int flags)=0;
```

### Remarks:

This method is called just after 3ds max draws the nodes in the scene.

**Parameters:****TimeValue t**

The time at which the nodes were drawn.

**ViewExp \*vpt**

Points to an interface for the viewport the node is being drawn in.

**int flags**

These flags are used internally.

**Prototype:**

```
virtual bool Display(TimeValue t, ViewExp *vpt, int flags, INode *node)=0;
```

**Remarks:**

This method is called for every node to allow it display itself.

**Parameters:****TimeValue t**

The time at which the node is to be drawn.

**ViewExp \*vpt**

Points to an interface for the viewport in which the node is being drawn in.

**int flags**

The display flags, which are;

**USE\_DAMAGE\_RECT**

If this flag is set, only the damaged area needs to be displayed. The damaged rectangle may be retrieved using **INode::GetDamagedRect()**. See [Class INode](#).

**DISP\_SHOWSUBOBJECT**

This indicates if an item should display its sub-object selection state. The system will set this flag if the item is selected, the user is in the modify branch, and the item is in sub-object selection mode.

**INode \*node**

Points to the node being drawn.

**Return Value:**

TRUE if displayed, otherwise FALSE.

**Prototype:**

```
virtual bool SuspendObjectDisplay(TimeValue t, INode *node)=0;
```

**Remarks:**

This method is called to determine if the node mesh should be displayed. It should return true; otherwise return false.

**Parameters:****TimeValue t**

The time at which to check if the node should be displayed.

**INode \*node**

The node to check.

**Prototype:**

```
virtual void AddNodeCallbackBox(TimeValue t, INode *node,  
ViewExp *vpt, Box3& box)=0;
```

**Remarks:**

This method will ask the callback to participate in the bounding box calculation.

**Parameters:****TimeValue t**

The time at which to calculate the bounding box.

**INode \*node**

The node to calculate the bounding box for.

**ViewExp \*vpt**

Points to an interface for the viewport in which the node is being drawn in.

**Box3& box**

A reference to the bounding box.

**Prototype:**

```
virtual bool HitTest(TimeValue t, INode *node, int type, int  
crossing, int flags, IPoint2 *p, ViewExp* vpt)=0;
```

**Remarks:**

This method hit tests the callback's mesh.

**Parameters:****TimeValue t**

The time at which to hit test.

**INode \*node**

A pointer to the node to test.

**int type**

The type of hit testing to perform. See [Hit Test Types](#) for details.

**int crossing**

The state of the crossing setting. If TRUE crossing selection is on.

**int flags**

The hit test flags. See [Hit Test Flags](#) for details.

**IPoint2 \*p**

The screen point to test.

**ViewExp\* vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Return Value:**

TRUE if the item was hit, otherwise FALSE.

**Prototype:**

```
virtual void Activate()=0;
```

**Remarks:**

This method is called when the callback gets activated. It is up to the callback to invalidate the screen.

**Prototype:**

```
virtual void Deactivate()=0;
```

**Remarks:**

This method is called when the callback is deactivated.

**Prototype:**

```
virtual TSTR GetName() const = 0;
```

**Remarks:**

This method returns the name of the callback which is used for display in the menu. The user must delete the string returned.

## Class XTCTObject

See Also: [Class InterfaceServer](#), [Class Class\\_ID](#), [Class ModContext](#), [Class ObjectState](#), [Class INode](#), [Class Object](#), [Class Modifier](#), [Class GraphicsWindow](#), [Class FPInterface](#), [List of Channel Bits.](#), [Class XTCTContainer](#), [Class IXTCAccess](#)

```
class XTCTObject : public InterfaceServer
```

### Description:

This class is available in release 4.0 and later only.

This is the base class for an Extension Channel plug-in. These plug-ins are used to allow a developer defined object to flow down the geometry pipeline. This class provides an interface to the extension object. This is the virtual base class that developers can derive objects from, that should be inserted into the extension channel of the object flowing up the stack. Extension Channels will expand the geometry pipeline by allowing one to add a custom object to the pipeline object that can flow down the pipeline. This object will get notified whenever something in the pipeline changes. For example, if you want to indicate when a certain object becomes invalid for export to their game engine, invalid skin-vertex assignments, bound patches etc. By inserting an Extension Channel Object (XTCTObject, for short) into the pipeline you can accomplish this, by constantly checking the structure of the object and displaying wrong faces/vertices etc. in the viewport.

You can specify which other channels it depends on using **DependsOn()**. The extension object has callback methods that get called before and after a modifier modifies a channel that the extension object depends on using **PreChanChangedNotify()** and **PostChanChangedNotify()**. The extension object can declare additional channels that it modifies using **ChannelsChanged()**, so that it can make any changes to the mesh before and after the modification by the modifier.

In general, the Extension Channel is a transient data structure that gets recreated on every pipeline evaluation. So the object that adds an extension channel to the modifier stack automatically makes it persistent. However, when the user collapses the stack, the user might want the Extension Channel to be preserved as well. In order to accomplish that, please refer to the [Class BaseObject](#) and the methods **NotifyPreCollapse()** and **NotifyPostCollapse()**. These methods

will be called by the collapse code. It will give the modifier or BaseObject, that adds an XTC object to the stack the possibility to apply a modifier, that inserts these XTC objects onto the stack after the collapse. Through this mechanism, the XTC will survive a stack collapse. The Pre and Post notifications will be called through a pipeline enumeration downstream (for more info see [Class GeomPipelineEnumProc](#)). Developers, who are collapsing the stack programmatically, have to call this method. In case this method is not called, the XTC objects will by default be copied as well, since they are part of the object in the wsCache. However, they won't survive a save/load operation. In addition to all this, XTC objects also have the possibility to display their data in the viewports. Any Extension Channel Object can disable the display of the object itself and take over the entire display itself, by returning true in the method **SuspendObjectDisplay()**.

Note: Modifiers which change the type of object that flows up the stack have to copy the Extension Channel from the old object into the new one using **CopyAdditionalChannels()** (e.g. the extrude modifier has to copy the XTC from the incoming spline to the Mesh, Patch or NURBS object).

Note: Compound objects have to merge the Extension Channel of the branched pipelines into the resulting pipeline. This is in general a simple copy of the Extension Channel Object into the new Extension Channel. When the CompoundObject evaluates its branches it would call **CopyAdditionalChannels(os->obj)**, so that the Extension Channels of the branches are copied over. In the **ConvertToType()** method it then has to copy the Extension Channels from itself to the converted object using **obj->CopyAdditionalChannels(this)**.

Also note that the Extension Channel itself is implemented in Class Object. This means, that it will be available for all pipeline objects that get implemented in 3ds max. For additional methods related to extension objects see the methods in Class Object -> [Extension Channel Access](#).

All methods of this class are implemented by the plug-in. Default implementations are shown.

## **Methods:**

public:

## **Prototype:**

**virtual Class\_ID ExtensionID()=0;**

**Remarks:**

This method returns the unique identifier for the object.

**Prototype:**

**virtual XTCTObject \*Clone()=0;**

**Remarks:**

This method is called to create a cloned copy of the object. The object should create a copy of itself and return a pointer to it.

**Prototype:**

**virtual ChannelMask DependsOn();**

**Remarks:**

This method returns a ChannelMask which specifies the channels that the XTCTObject depends on. If a modifier changes a channel that a XTCTObject depends on, its **PreChanChangedNotify()** and **PostChanChangedNotify()** methods will be called.

**Return Value:**

See the [List of Channel Bits](#).

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

**virtual ChannelMask ChannelsChanged();**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a ChannelMask which specifies the channels that the extension object changes in the **PreChanChangedNotify()** and **PostChanChangedNotify()** methods.

**Return Value:**

See the [List of Channel Bits](#).

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual ChannelMask ChannelsUsed();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a ChannelMask which specifies the channels that the extension object uses in the **PreChanChangedNotify()** and **PostChanChangedNotify()** methods.

**Return Value:**

See the [List of Channel Bits](#).

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual int Display(TimeValue t, INode* inode, ViewExp *vpt, int flags, Object *pObj);
```

**Remarks:**

If an XTCObject wants to display itself in the viewport it can overwrite this method.

**Parameters:**

**TimeValue t**

The time at which the object is to be displayed.

**INode\* inode**

Points to the node for the object.

**ViewExp \*vpt**

Points to the viewport interface for the object.

**int flags**

See [List of Display Flags](#).

**Object \*pObj**

Points to the object that the extension object is a part of.

**Return Value:**

The return value is not currently used.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void PreChanChangedNotify(TimeValue t, ModContext  
&mc, ObjectState* os, INode *node, Modifier *mod, bool  
bEndOfPipeline);
```

**Remarks:**

This method is called before a modifier is applied that changes a channel that the XTCTObject depends on.

**Parameters:**

**TimeValue t**

The time at which the channel will be modified.

**ModContext &mc**

The modifier context.

**ObjectState\* os**

The objectstate of the object.

**INode \*node**

A pointer to the node.

**Modifier \*mod**

A pointer to the modifier being applied.

**bool bEndOfPipeline**

TRUE to indicate that this is the last change before the wsCache.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void PostChanChangedNotify(TimeValue t, ModContext  
&mc, ObjectState* os, INode *node, Modifier *mod, bool  
bEndOfPipeline);
```

**Remarks:**

This method will be called after a modifier is applied that changes a channel that the XTC object depends on.

**Parameters:**

**TimeValue t**

The time at which the channel will be modified.

**ModContext &mc**

The modifier context.

**ObjectState\* os**

The objectstate of the object.

**Inode \*node**

A pointer to the node.

**Modifier \*mod**

A pointer to the modifier being applied.

**bool bEndOfPipeline**

TRUE to indicate that this is the last change before the wsCache.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL SuspendObjectDisplay();
```

**Remarks:**

If the XTCObject returns TRUE from this method the object is not displayed in the viewport; if FALSE is returned the **Display()** method will be called to display the object.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual void DeleteThis()=0;
```

**Remarks:**

This method is called to delete the extension object.

**Prototype:**

```
virtual void MaybeEnlargeViewportRect(GraphicsWindow *gw,  
Rect &rect);
```

**Remarks:**

This method allows the object to enlarge its viewport rectangle if it wants to. The system will call this method for all XTCObjects when calculating the viewport rectangle; the XTCObject can enlarge the rectangle if desired.

**Parameters:**

**GraphicsWindow \*gw**

Points to the GraphicsWindow instance associated with the viewport the object is displayed in.

**Rect &rect**

The viewport rectangle for the object which may be modified.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual bool RemoveXTCObjectOnMergeBranches(Object  
*obFrom, Object *obTo);
```

**Remarks:**

By default the existing XTCObjects will be deleted if a branch updates. In case the XTCObject wants to do more intelligent branching (not simply delete and add), it can return false from this method so that it can later (see **MergeXTCObject()** below) copy the data from this and other branches into an existing XTCObject.

**Parameters:**

**Object \*obFrom**

Points to the source object.

**Object \*obTo**

Points to the destination object.

**Return Value:**

Returns true if the object will be deleted; false to do more processing via MergeXTCObject.

**Default Implementation:**

```
{ return true; }
```

**Prototype:**

```
virtual bool MergeXTCObject(Object *obFrom, Object *obTo, int  
prio, int branchID);
```

**Remarks:**

The default implementation just adds the XTCObject to the to object. In case the XTCObject should do a more intelligent merge with already existing XTCObjects in the obTo, it has to overwrite this method.

**Parameters:**

**Object \*obFrom**

Points to the source object.

**Object \*obTo**

Points to the destination object.

**int prio**

The priority to set.

**int branchID**

The branch identifier to set.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Default Implementation:**

```
{ obTo->AddXTCObject(this,prio,branchID); return true;}
```

**Prototype:**

```
virtual bool RemoveXTCObjectOnBranchDeleted(Object  
*ComObj,int branchID, bool branchWillBeReordered);
```

**Remarks:**

In case a branch of a compound object is deleted the XTCObject will be asked if the XTCObject should be deleted as well. In case the XTCObject represents a merge of all branches the XTCObject might want to return false to this method and reassign itself to another branch, so that the merged information is not lost.

**Parameters:**

**Object \*ComObj**

A pointer to the compound object.

**int branchID**

The branch identifier to set.

**bool branchWillBeReordered**

TRUE if the branch should be reordered, otherwise FALSE.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Default Implementation:**

```
{ return true; }
```

## Class GeomPipelineEnumProc

See Also: [Class InterfaceServer](#), [Class INode](#), [Class Object](#), [Class Modifier](#), [Class IDerivedObject](#), [Class ModContext](#), [Class NotifyCollapseEnumProc](#).

```
class GeomPipelineEnumProc : public InterfaceServer
```

### Description:

This class and its associated global functions are available in release 4.0 and later only.

This is the callback object for the global geometry pipeline enumeration functions. The single **proc()** method of this class is called as the enumeration takes place.

The following functions are not methods of this class but are available for use with it to begin the enumeration:

These all start a pipeline enumeration down the pipeline towards the baseobject and over the baseobjects' branches in case it is a compound object. A pipeline enumeration can be started from a Node, an Object or from a Modifier.

### Function:

```
int EnumGeomPipeline(GeomPipelineEnumProc *gpep, INode  
*start, bool includeEmptyDOs = false);
```

### Remarks:

The global function begins an enumeration of the geometry pipeline using the specified node.

### Parameters:

**GeomPipelineEnumProc \*gpep**

Points to the callback object to process the enumeration.

**INode \*start**

Points to the node to start the enumeration.

**bool includeEmptyDOs = false**

In case the flag includeEmptyDOs is declared as true, the proc will be called even for DerivedObjects, that don't contain any modifiers. In that case the object pointer will be NULL, the derObj pointer will contain the DerivedObject and the index will be -1.

### Return Value:

One of the following values:

**PIPE\_ENUM\_CONTINUE**

**PIPE\_ENUM\_STOP**

**Function:**

```
int EnumGeomPipeline(GeomPipelineEnumProc *gpep, Object  
*start, bool includeEmptyDOs = false);
```

**Remarks:**

The global function begins an enumeration of the geometry pipeline using the specified object.

**Parameters:**

**GeomPipelineEnumProc \*gpep**

Points to the callback object to process the enumeration.

**Object \*start**

Points to the object to start the enumeration.

**bool includeEmptyDOs = false**

In case the flag includeEmptyDOs is declared as true, the proc will be called even for DerivedObjects, that don't contain any modifiers. In that case the object pointer will be NULL, the derObj pointer will contain the DerivedObject and the index will be -1.

**Return Value:**

One of the following values:

**PIPE\_ENUM\_CONTINUE**

**PIPE\_ENUM\_STOP**

**Function:**

```
int EnumGeomPipeline(GeomPipelineEnumProc *gpep,  
IDerivedObject *start, int modIndex = 0, bool includeEmptyDOs  
= false);
```

**Remarks:**

The global function begins an enumeration of the geometry pipeline using the specified derived object and modifier index. The caller of this method has to provide the IDerivedObject the Modifier is applied to and the index of the

Modifier in the IDerivedObject. Developers can use the method **Modifier::GetIDerivedObject()** in order to get the IDerivedObject and the index, given a modifier and a ModContext.

**Parameters:**

**GeomPipelineEnumProc \*gpep**

Points to the callback object to process the enumeration.

**IDerivedObject \*start**

Points to the derived object to start the enumeration.

**int modIndex = 0**

The zero based index of the modifier in the derived object to start with.

**bool includeEmptyDOs = false**

In case the flag includeEmptyDOs is declared as true, the proc will be called even for DerivedObjects, that don't contain any modifiers. In that case the object pointer will be NULL, the derObj pointer will contain the DerivedObject and the index will be -1.

**Return Value:**

One of the following values:

**PIPE\_ENUM\_CONTINUE**

**PIPE\_ENUM\_STOP**

**Methods:**

public:

**Prototype:**

**virtual PipeEnumResult proc(ReferenceTarget \*object, IDerivedObject \*derObj, int index)=0;**

**Remarks:**

This is the callback procedure for pipeline enumeration. The ReferenceTarget passed to the proc can be a Node, Modifier or Object. In case it is a Modifier the parameter **derObj** contains the DerivedObject and the index is the index of this modifier in the DerivedObject. In all other cases **derObj** is NULL and index is 0.

**Parameters:**

**ReferenceTarget \*object**

Points to the item in the geometry pipeline. This can be a Node, Modifier or Object.

**IDerivedObject \*derObj**

If **object** above is a Modifier this points to the derived object.

**int index**

If **object** above is a Modifier this is the index of this modifier in the DerivedObject.

**Return Value:**

One of the following values which determines how the enumeration proceeds:

**PIPE\_ENUM\_CONTINUE**

Specifies to continue the enumeration.

**PIPE\_ENUM\_STOP**

Specifies to halt the enumeration.

## Class IFaceDataChannel

See Also: [Class IDataChannel](#), [Class IFaceDataChannelsEnumCallBack](#) , [Class IFaceDataMgr](#)

```
class IFaceDataChannel : public IDataChannel
```

### Description:

This class is available in release 4.0 and later only.

This class represents the face-data channel interface and as such is an abstraction of a collection of data objects that is associated with faces of 3ds max objects. 3ds max objects that have face-data channels call the methods of this interface when those faces change in some way. The data channels can then react to the changes to the faces. You can use the macro

**GetFaceDataChannelInterface(obj)** to obtain a pointer to this interface.

Currently in version 4.0 only Meshes support face-data channels.

### Methods:

public:

### Face Operations and Events

The face operations and events are called by the owner of face-data channels when its faces change in some way. It's up to the face-data channel to do whatever it wants to do on these notification methods.

### Prototype:

```
virtual BOOL FacesCreated(ULONG at, ULONG num) = 0;
```

### Remarks:

This method is called when **num** new faces are created at the index **at** in the object's list of faces.

### Parameters:

**ULONG at**

The index in the object's array of faces where the new faces are inserted.

**ULONG num**

The number of new faces which are created.

### Return Value:

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL FacesClonedAndAppended(BitArray& set) = 0;**

**Remarks:**

This method is called when the owner object has cloned some of its faces and appended these to its list of faces. The bits in the set array correspond to the cloned faces.

**Parameters:**

**BitArray& set**

The array of bits. Note that this array has as many bits as there are faces in the owner object.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL FacesDeleted(BitArray& set) = 0;**

**Remarks:**

This method is called when faces were deleted in the owner object. The bits in the set array correspond to the deleted faces.

**Parameters:**

**BitArray& set**

The array of bits. Note that this array has as many bits as there are faces in the owner object.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL FacesDeleted(ULONG from, ULONG num) = 0;**

**Remarks:**

This method is called when faces were deleted in the owner object. This method allows for a more efficient deletion of a range of data objects than the

previous BitArray based one.

**Parameters:**

**ULONG from**

The index in the object's array of faces. Faces starting at this index were deleted.

**ULONG num**

The number of faces that were deleted.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual void AllFacesDeleted() = 0;**

**Remarks:**

This method is called when all faces in the owner object are deleted

**Prototype:**

**virtual BOOL FaceCopied(ULONG from, ULONG to) = 0;**

**Remarks:**

This method is called when a face has been copied from index **from** in the owner object's array of faces to the face at index **to**.

**Parameters:**

**ULONG from**

The index of the source face.

**ULONG to**

The index of the destination face.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL FaceInterpolated(ULONG numSrc, ULONG\* srcFaces, float\* coeff, ULONG targetFace) = 0;**

**Remarks:**

This method is called when a new face has been created in the owner object based on data interpolated from other faces.

**Parameters:**

**ULONG numSrc**

The number of faces used in the interpolation.

**ULONG\* srcFaces**

The array of **numSrc** face indices into the owner object's face array. These faces were used when creating the new face.

**float\* coeff**

The array of **numSrc** coefficients used in the interpolation.

**ULONG targetFac**

The index in the owner object's array of faces of the newly created face.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Geometry pipeline (stack) methods**

These methods are called when the owner object is flowing up the pipeline (stack). They must be implemented to ensure that the face-data channel flows up the pipeline correctly. The owner object expects the face-data to do exactly what the names of these methods imply. These can be seen as commands that are given by the owner object to the face-data channel

**Prototype:**

**virtual IFaceDataChannel\* CreateChannel( ) = 0;**

**Remarks:**

This method will allocate an empty data-channel.

**Prototype:**

**virtual IFaceDataChannel\* CloneChannel( ) = 0;**

**Remarks:**

The data-channel needs to allocate a new instance of itself and fill it with copies of all data items it stores. Note: This method makes it more efficient to clone the whole data-channel.

**Prototype:**

```
virtual BOOL AppendChannel(const IFaceDataChannel*  
fromChan) = 0;
```

**Remarks:**

The data-channel needs to append the data objects in the **fromChan** to itself.

**Parameters:**

**const IFaceDataChannel\* fromChan**

The channel containing the data objects to append.

**Return Value:**

TRUE if successful, otherwise FALSE.

## Class IFaceDataMgr

See Also: [Class BaseInterface](#), [Class IDataChannel](#), [Class IFaceDataChannel](#)

```
class IFaceDataMgr : public BaseInterface
```

### Description:

This class is available in release 4.0 and later only.

This class represents an Interface for managing face-data channels. Objects that wish to have face-data channels should implement this interface. If this interface needs to be changed, a new one should be derived from it and changed (IFaceDataMgr2) and ensuring that objects support face-data implementations of both old and new interfaces.

A "naive" extension of Mesh and MNMesh with a GetInterface method are available but there's no support for interface lifetime management. The Mesh and MNMesh have full control over the lifetime of the face-data manager and as such, clients should not cache an IFaceDataMgr interface aquired from Mesh or MNMesh.

Please note that only **Meshes** supports the **IFaceDataMgr** interface. The **MNMesh** (and thus polygons) does not support it. As a consequence, if you write a modifier that applies face data to a meshes, and then the pipeline transforms this mesh into a poly or patch, the face data is lost at the top of the stack.

### Methods:

public:

#### Geometry pipeline (stack) methods

Modifiers and procedural objects should call these methods to add, remove, or retrieve a face-data channel on an object (mesh, patch, poly).

### Prototype:

```
virtual ULONG NumFaceDataChans() const = 0;;
```

### Remarks:

This method returns the number of face-data channels.

### Prototype:

**virtual IFaceDataChannel\* GetFaceDataChan(const Class\_ID& ID) const = 0;**

**Remarks:**

This method returns a pointer to the face-data channel.

**Parameters:**

**const Class\_ID& ID**

The class ID of the channel you wish to retrieve.

**Prototype:**

**virtual BOOL AddFaceDataChan(IFaceDataChannel\* pChan) = 0;**

**Remarks:**

This method adds a face-data channel to the object.

**Parameters:**

**IFaceDataChannel\* pChan**

A pointer to the face-data channel.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL RemoveFaceDataChan(const Class\_ID& ID) = 0;**

**Remarks:**

This method removes a face-data channel from the object.

**Parameters:**

**const Class\_ID& ID**

The class ID of the channel you wish to remove.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Geometry pipeline (stack) methods**

The system (3ds max) should call these methods to manage the face-data channels when the object flows up the stack

**Prototype:**

```
virtual BOOL AppendFaceDataChan(const IFaceDataChannel*  
pChan) = 0;
```

**Remarks:**

This method appends a face-data channel to the object.

**Parameters:**

```
const IFaceDataChannel* pChan  
The face-data channel to append.
```

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

```
virtual BOOL CopyFaceDataChans(const IFaceDataMgr* pFrom)  
= 0;
```

**Remarks:**

This method adds or appends face-data channels from the **from** object, to this object. If the channel already exists on this object, it's appended otherwise it gets added.

**Parameters:**

```
const IFaceDataMgr* pFrom  
The face-data channel to copy from.
```

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

```
virtual void RemoveAllFaceDataChans() = 0;
```

**Remarks:**

This method removes all face-data channels from this object.

**Prototype:**

```
virtual BOOL  
EnumFaceDataChans(IFaceDataChannelsEnumCallBack& cb,
```

**void\* pContext) const = 0;**

**Remarks:**

This method provides a mechanism for executing an operation for all face-data-channels on this object: For all face-data-channels calls **IFaceDataEnumCallBack::proc()** with a pointer to that face-data-channel and a context data

**Parameters:**

**IFaceDataChannelsEnumCallBack& cb**

A pointer to the face-data channel enumerator callback.

**void\* pContext**

A pointer to the context data.

**Return Value:**

FALSE if the callback returns FALSE for any of the face-data channels.

**Prototype:**

**virtual IOResult Save(ISave\* isave) = 0;**

**Remarks:**

Saves the face-data to the max file.

**Return Value:**

See Also: [List of IO Results](#).

**Prototype:**

**virtual IOResult Load(ILoad\* iload) = 0;**

**Remarks:**

Loads the face-data from the max file.

**Return Value:**

See Also: [List of IO Results](#).

**Prototype:**

**Interface\_ID GetID();**

**Remarks:**

This method returns the interface ID of the object.

**Default Implementation:**

```
{ return FACEDATAMGR_INTERFACE; }
```

## Class ObjectConverter

See Also: [Class InterfaceServer](#), [Class Class\\_ID](#), [Class Object](#), [Class TriObject](#), [Class PatchObject](#).

```
class ObjectConverter : public InterfaceServer
```

### Description:

This class is available in release 4.0 and later only.

This virtual class is implemented by applications that want to supply a conversion method from one object type to another. A typical use would be to support conversion of a native 3ds max type (such as TriObject) to a plug-in's object type. There are a set of global functions that can be used with this class. These are documented at the bottom of the topic. One of these is called to register the ObjectConverter with the system.

Note that the registered object converters are called from the methods:

**Object::CanConvertToType** and **Object::ConvertToType**.

So for individual objects to support these, they'll need to add the line

```
if (Object::CanConvertToType(obtype)) return 1;
```

to the end of their CanConvertToType methods and

```
if (Object::CanConvertToType(obtype))
```

```
return Object::ConvertToType(t, obtype);
```

to the end of their ConvertToType methods.

### Methods:

public:

#### Prototype:

```
virtual Class_ID ConvertsFrom()=0;
```

#### Remarks:

This method returns the Class ID of the object this converter converts from.

#### Prototype:

```
virtual Class_ID ConvertsTo()=0;
```

#### Remarks:

This method returns the Class ID of the object this converter converts to.

**Prototype:**

```
virtual Object *Convert(Object *from)=0;
```

**Remarks:**

This method actually performs the conversion, creating and returning a new object with the class ID specified in **ConvertsTo()**.

**Parameters:**

```
Object *from
```

Points to the object to convert.

**Prototype:**

```
virtual void DeleteThis();
```

**Remarks:**

This should delete the ObjectConverter if necessary.

**Default Implementation:**

```
{}
```

**The following global functions are not part of this class but are available for use:**

**Function:**

```
bool RegisterObjectConverter(ObjectConverter *conv);
```

**Remarks:**

This global function is available in release 4.0 and later only.

Registers an object converter with the system.

**Parameters:**

```
ObjectConverter *conv
```

Points to the ObjectConverter instance to register.

**Return Value:**

Returns true if the converter could be added; false if not.

**Function:**

**int CanConvertTriObject(Class\_ID to);**

**Remarks:**

This global function is available in release 4.0 and later only.

Indicates if a TriObject can convert to the specified class ID.

Note: this actually checks if an Editable Mesh object can convert to the specified type, since an Editable Mesh is what you get when you call **CreateNewTriObject ()**.

This method may be used in an object's **CanConvertToType()** and **ConvertToType()** methods. If your object supports conversion to a TriObject, but doesn't support conversion to the given class ID, you can use this method to find out if TriObjects can be used as an "intermediary". If so, you can construct a temporary TriObject, convert it to the given class ID, and call the temporary TriObject's **DeleteThis()** method.

**Parameters:**

**Class\_ID to**

The Class ID to convert to.

**Return Value:**

Nonzero if the TriObject can be converted to the specified objec type; otherwise zero.

**Function:**

**int CanConvertPatchObject(Class\_ID to);**

**Remarks:**

This global function is available in release 4.0 and later only.

Indicates if a PatchObject can convert to the specified class ID.

**Parameters:**

**Class\_ID to**

The Class ID to convert to.

**Return Value:**

Nonzero if the PatchObject can be converted to the specified objec type; otherwise zero.

**Function:**

**int CanConvertSplineShape(Class\_ID to);**

**Remarks:**

This global function is available in release 4.0 and later only.  
Indicates if a SplineObject can convert to the specified class ID.

**Parameters:**

**Class\_ID to**

The Class ID to convert to.

**Return Value:**

Nonzero if the SplineObject can be converted to the specified object type; otherwise zero.

**Function:**

**void RegisterStaticEditTri(Object \*triob);**

**Remarks:**

This global function is available in release 4.0 and later only.  
This method will register the object passed as the editable tri object.

**Parameters:**

**Object \*triob**

The object to register as the editable tri object.

**Function:**

**void RegisterCollapseType(Class\_ID cid, TSTR name, bool canSelfConvert=false);**

**Remarks:**

This global function is available in release 4.0 and later only.  
Registers a class ID of an object that the user can collapse other objects to.  
The type will only appear if the current object returns nonzero from **CanConvertTo(cid)**.

**Parameters:**

**Class\_ID cid**

The class ID the object will collapse to.

**TSTR name**

The name of the collapse-to object type (such as "Editable Poly").

**bool canSelfConvert=false**

Indicates whether an object should be allowed to collapse to itself. (false is generally preferred, so that the collapse-to menu only has relevant entries.)

## Explicit Conversion Functions

See Also: [Class Mesh](#), [Class PatchMesh](#), [Class MNMesh](#) , [Class ObjectConverter](#)

The following functions are available to apply explicit conversions of object types.

### Function:

```
void ConvertMeshToPatch (Mesh &m, PatchMesh &pm, DWORD flags=0);
```

### Remarks:

This method is available in release 4.0 and later only.

This function converts a mesh to a patch mesh.

### Parameters:

#### **Mesh &m**

The mesh to convert.

#### **PatchMesh &pm**

The patchmesh to convert into.

#### **DWORD flags=0**

The conversion flags;

#### **CONVERT\_KEESEL**

Translate subobject selections, so selected vertices, edges, or surface areas (faces or patches) in the input model is still selected in the output.

#### **CONVERT\_USESOFTSEL**

Translate soft selections. Also, in the case of patches turning into meshes with more vertices, soft selections are used to interpolate between selected patch corners and nonselected ones.

#### **CONVERT\_PATCH\_USEQUADS**

When converting to a Patch model, create quad patches for any quads in the input mesh or polymesh. (Otherwise, turns everything into triangle patches).

#### **CONVERT\_NO\_RELAX**

Indicates in patch-to-mesh conversions that the Relax parameters in the patch should be ignored.

**Function:**

```
void ConvertPatchToMesh (PatchMesh &pm, Mesh &m, DWORD  
flags=0);
```

**Remarks:**

This method is available in release 4.0 and later only.

This function converts a patchmesh to a mesh.

**Parameters:****PatchMesh &pm**

The patchmesh to convert.

**Mesh &m**

The mesh to convert into..

**DWORD flags=0**

The conversion flags;

**CONVERT\_KEESEL**

Translate subobject selections, so selected vertices, edges, or surface areas (faces or patches) in the input model is still selected in the output.

**CONVERT\_USESOFTSEL**

Translate soft selections. Also, in the case of patches turning into meshes with more vertices, soft selections are used to interpolate between selected patch corners and nonselected ones.

**CONVERT\_PATCH\_USEQUADS**

When converting to a Patch model, create quad patches for any quads in the input mesh or polymesh. (Otherwise, turns everything into triangle patches).

**CONVERT\_NO\_RELAX**

Indicates in patch-to-mesh conversions that the Relax parameters in the patch should be ignored.

**Function:**

```
void ConvertPolyToPatch (MNMESH & from, PatchMesh & to,  
DWORD flags=0);
```

**Remarks:**

This method is available in release 4.0 and later only.

This function converts a poly object to a patch mesh.

**Parameters:**

**MNMesh & from**

The poly mesh to convert.

**PatchMesh & to**

The patchmesh to convert into.

**DWORD flags=0**

The conversion flags;

**CONVERT\_KEESEL**

Translate subobject selections, so selected vertices, edges, or surface areas (faces or patches) in the input model is still selected in the output.

**CONVERT\_USESOFTSEL**

Translate soft selections. Also, in the case of patches turning into meshes with more vertices, soft selections are used to interpolate between selected patch corners and nonselected ones.

**CONVERT\_PATCH\_USEQUADS**

When converting to a Patch model, create quad patches for any quads in the input mesh or polymesh. (Otherwise, turns everything into triangle patches).

**CONVERT\_NO\_RELAX**

Indicates in patch-to-mesh conversions that the Relax parameters in the patch should be ignored.

**Function:**

**void ConvertPatchToPoly (PatchMesh & from, MNMesh & to, DWORD flags=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This function converts a patch mesh to a poly object.

**Parameters:**

**PatchMesh & to**

The patchmesh to convert into.

**MNMesh & from**

The poly mesh to convert.

**DWORD flags=0**

The conversion flags;

**CONVERT\_KEESEL**

Translate subobject selections, so selected vertices, edges, or surface areas (faces or patches) in the input model is still selected in the output.

**CONVERT\_USESOFTSEL**

Translate soft selections. Also, in the case of patches turning into meshes with more vertices, soft selections are used to interpolate between selected patch corners and nonselected ones.

**CONVERT\_PATCH\_USEQUADS**

When converting to a Patch model, create quad patches for any quads in the input mesh or polymesh. (Otherwise, turns everything into triangle patches).

**CONVERT\_NO\_RELAX**

Indicates in patch-to-mesh conversions that the Relax parameters in the patch should be ignored.

## Class ISubObjType

See Also: [Class InterfaceServer](#), [Class BaseObject](#), [Class MaxIcon](#), [Class GenSubObjType](#).

```
class ISubObjType : public InterfaceServer
```

### Description:

This class is available in release 4.0 and later only.

Developers have to return a class derived from this class with implementations for all the methods when implementing sub-objects for obejcts and modifiers (see **BaseObject::GetSubObjType()**).

### Methods:

public:

### Prototype:

```
virtual MaxIcon *GetIcon()=0;
```

### Remarks:

Returns a pointer to the icon for this sub-object type. This icon appears in the stack view beside the name.

### Prototype:

```
virtual TCHAR *GetName()=0;
```

### Remarks:

Returns the name of this sub-object type that appears in the stack view.

## Class GenSubObjType

See Also: [Class ISubObjType](#), [Class BaseObject](#), [Class MaxIcon](#).

```
class GenSubObjType : public ISubObjType
```

### Description:

This class is available in release 4.0 and later only.

This class provides a generic implementation for sub-object types. Instead of having to create a sub-class of **ISubObjType** the constructors of this class may be used to initialize private data members of the class. Then implementations of the **GetName()** and **GetIcon()** methods of **ISubObjType** are provided which simply return the data members.

This SubObjectType will either use the **subObjectIcons\_16i.bmp** and **SubObjectIcons\_16a.bmp** bitmaps in the **UICONS** directory (for the **GenSubObjType(int idx)** constructor), or any other bmp file that is specified in the **GenSubObjType(TCHAR \*nm, TCHAR\* pFilePrefix, int idx)** constructor. The bitmap files have to reside in the **UICONS** directory.

All methods of this class are implemented by the System.

### Methods:

public:

### Prototype:

```
GenSubObjType(TCHAR *nm, TCHAR* pFilePrefix, int idx) :  
name(nm), mIcon(NULL), mIdx(idx), mFilePrefix(pFilePrefix);
```

### Remarks:

Constructor. The private data members are inialized to the values passed and the corresponding Get methods of this class will return these data members.

### Parameters:

**TCHAR \*nm**

The name for this sub-object type.

**TCHAR\* pFilePrefix**

The BMP imagelist file name prefix for this sub-object type. This is the file name, without the extension, and with the assumption that the file is in the **ui\icons** directory. For example specifying **\_T("SubObjectIcons")** for this

parameter indicates the file **UICONS\SubObjectIcons\_16i.bmp** if the small icons are in use and **SubObjectIcons\_24i.bmp** if the large icons are in use.

**int idx**

This is the one based index into the image list of the icon to use.

**Prototype:**

```
GenSubObjType(int idx) : mIcon(NULL), mIdx(idx),  
mFilePrefix(_T("SubObjectIcons"));
```

**Remarks:**

This constructor assumes that the icons are in either **UICONS\SubObjectIcons\_16i.bmp** or **SubObjectIcons\_24i.bmp** depending on which size icons are in use by the system. In this case only the index into the image list is required.

**Parameters:**

**int idx**

This is the one based index into the image list of the icon to use.

**Prototype:**

```
~GenSubObjType();
```

**Remarks:**

Destructor.

**Prototype:**

```
void SetName(TCHAR *nm);
```

**Remarks:**

Sets the name for this sub-object type.

**Parameters:**

**TCHAR \*nm**

The name to set.

**Prototype:**

**TCHAR \*GetName();**

**Remarks:**

Returns the name for this sub-object type. This is the implementation of the ISubObjType method.

**Prototype:**

**MaxIcon \*GetIcon();**

**Remarks:**

Returns the icon for this sub-object type. This is the implementation of the ISubObjType method.

## Class MaxIcon

See Also: [Class InterfaceServer](#), [Class ICustButton](#), [Class MaxBmpFileIcon](#).

class MaxIcon : public InterfaceServer

### Description:

This class is available in release 4.0 and later only.

This abstract class represents an icon image for toolbar buttons, icons in list boxes, etc. The class is based on Win32 ImageLists. MaxIcons must provide an image list and index into the list for both large (24x24) and small (16x15) icons.

### Methods:

public:

### Prototype:

**virtual HIMAGELIST GetDefaultImageList() = 0;**

### Remarks:

Returns the handle to the image list for the size of icons that the user has chosen.

### Prototype:

**virtual HIMAGELIST GetSmallImageList() = 0;**

### Remarks:

Returns the image list for small icons.

### Prototype:

**virtual HIMAGELIST GetLargeImageList() = 0;**

### Remarks:

Returns the image list for large icons.

### Prototype:

**virtual int GetSmallImageIndex(bool enabledVersion = true,  
COLORREF backgroundColor =  
GetCustSysColor(COLOR\_BTNFACE)) = 0;**

**Remarks:**

Returns the zero based index into the image list for the small version of this particular icon.

**Parameters:**

**bool enabledVersion = true**

Pass true to get the index of the enabled version of the icon; false to get the disabled version.

**COLORREF backgroundColor =  
GetCustSysColor(COLOR\_BTNFACE)**

The background color to use for the icon.

Specifies the windows color definition. See [List of Standard Color IDs](#). For a full list of windows color definitions, please refer to the Win32 API, in particular the methods **GetSysColor()** and **SetSysColor()**.

**Prototype:**

```
virtual int GetLargeImageIndex(bool enabledVersion = true,  
COLORREF backgroundColor =  
GetCustSysColor(COLOR_BTNFACE)) = 0;
```

**Remarks:**

Returns the zero based index into the image list for the large version of this particular icon.

**Parameters:**

**bool enabledVersion = true**

Pass true to get the enabled version of the icon or false to get the disabled version.

**COLORREF backgroundColor =  
GetCustSysColor(COLOR\_BTNFACE)**

The background color to use for the icon.

Specifies the windows color definition. See [List of Standard Color IDs](#). For a full list of windows color definitions, please refer to the Win32 API, in particular the methods **GetSysColor()** and **SetSysColor()**.

**Prototype:**

```
int GetDefaultImageIndex(bool enabledVersion = true,  
COLORREF backgroundColor =  
GetCustSysColor(COLOR_BTNFACE));
```

**Remarks:**

Returns the zero based index into the image list for the default version of this particular icon.

**Parameters:**

**bool enabledVersion = true**

Pass true to get the enabled version of the icon or false to get the disabled version.

**COLORREF backgroundColor =  
GetCustSysColor(COLOR\_BTNFACE)**

The background color to use for the icon.

Specifies the windows color definition. See [List of Standard Color IDs](#). For a full list of windows color definitions, please refer to the Win32 API, in particular the methods **GetSysColor()** and **SetSysColor()**.

**Prototype:**

```
virtual bool UsesAlphaMask() = 0;
```

**Remarks:**

This method returns true if the icons has an alpha mask that needs to be blended with the background color and false if it doesn't use an alpha mask.

## Class PolyObject

See Also: [Class GeomObject.](#), [Class MNMesh](#)

class PolyObject: public GeomObject

### Description:

This class is available in release 4.0 and later only.

3ds max 4 introduces a new type of pipeline object, the polygon-based mesh object, or **PolyObject** for short. This object is based on the **MNMesh** which has been present in the SDK for some time and used for 3ds max effects like MeshSmooth, Boolean, and Connect.
