## **Introduction**

The 3ds max Software Development Kit (SDK) is an object-oriented programming library for creating plug-in applications for 3ds max. The SDK provides a comprehensive set of classes that developers can combine and extend to create seamlessly integrated plug-in applications.

Using the SDK one can create a great variety of plug-ins. In fact, much of 3ds max itself is written as plug-in applications.

## How to Use the Documentation

The documentation for the SDK is an on-line help file. This format provides easy hypertext jumping between related topics. The on-line format also allows developers to copy source code from the documentation to paste into plug-ins. This is especially handy in the Reference sections.

### **The on-line help is broken into three modules: Orientation, Guidance, and Reference.**

The **Orientation** module gives you an overview of how to get started with the SDK. It lists what hardware and software is needed to develop 3ds max plug-in applications. This module discusses what technical expertise is required. There is a section on recommended reading in C++, CG and Windows programming.

This module also provides an introduction to the types of plug-ins developers may create using the SDK. Most of the descriptions in this section allow hyperlink jumps to the main classes these plug-ins are derived from. Additionally, relevant sample code available in the SDK is listed here.

The **Guidance** module is intended to enable you to learn to accomplish a specific task. It begins with a description of the 3ds max plug-in architecture that provides a diagram of the principal classes. There is a section describing information common to all plug-in development.

There is a section for experienced 3D Studio IPAS programmers making the transition to MAX. This section discusses the similarities and differences in the IPAS and 3ds max programming architectures. The changes in development environment, plug-in/system control flow, user interface, and graphics programming support are reviewed. This section also discusses the six types of IPAS routines possible under 3D Studio DOS and how analogous plug-ins may be implemented under the 3ds max architecture.

The General Terminology section defines terms used throughout the SDK documentation. These terms also appear as popup help in other parts of the documentation.

The Advanced Topics section presents detailed information about key concepts in using the APIs. The topics presented in this section cross class boundaries, and are instead based on specific implementation issues developers need to understand when designing plug-ins for MAX. Developers getting started with the SDK should take a look through the various Advanced Topics sections. This will help in becoming familiar with what information is available.

The **Reference** module delivers comprehensive reference information about each class used in the API. At the beginning of each class description is an overview of the purpose of the class. All the methods and operators used by each class are documented.

This section also has a class list organized by category. This provides an organized way to jump to the many classes in the SDK. These categories are: Main Plug-In Classes, Interface Classes, Geometry Classes, User Interface Classes, and Miscellaneous Utility Classes.

## What You Need to Get Started

See Also: [Recommended Reading](#).

## **Technical Expertise**

In order to use the SDK you need to know how to program in C++. You should also be familiar with object-oriented programming concepts. This document can get you started, but it does not teach C++ or object-oriented programming. It also assumes a basic understanding of the use of 3ds max and the terminology of its user interface. This is required to understand the way the plug-in applications relate to the entire 3ds max user environment. The documents also refers to specific 3ds max plug-ins present in the core program. Familiarity with these plug-ins from a users perspective will help you understand the example source code.

It is also assumed you are familiar with the Microsoft Visual C++ compiler and development tools.

## **Software**

Microsoft Windows NT version 4.0 or greater, including Windows 2000, XP.

Microsoft Visual C++ version 6.0 (3ds max versions 5.1 and lower).

Microsoft Visual C++ version 7.0 (3ds max 6).

## **Hardware**

The same as required for 3ds max itself.

## **Recommended Reading**

This section lists several C++, Computer Graphics and Windows books you may find helpful.

## **C++ and Object Oriented Programming:**

Bjarne Stroustrup, *The C++ Programming Language* (Second edition, Reading, Massachusetts: Addison-Wesley Publishing Company, 1994), ISBN: 0-201-53992-6.

Bruce Eckel, *Thinking in C++* (Englewood Cliffs, New Jersey: Prentice Hall, Inc., 1995), ISBN: 0-13-917709-4.

Al Stevens, *Teach Yourself... C++* (Fourth edition, New York, New York: MIS:Press). ISBN 1-55828-406-0.

## **Computer Graphics Programming:**

James D. Foley, Andries van Dam, Steven K. Feiner, and John F. Hughes, Richard L. Phillips, Introduction to Computer Graphics (Reading, Massachusetts: Addison-Wesley Publishing Company, 1993). ISBN: 0-201-60921-5.

John Vince, 3-D Computer Animation (Reading, Massachusetts: Addison-Wesley Publishing Company, 1993). ISBN: 0-201-62756-6.

Alan Watt and Mark Watt, Advanced Animation and Rendering Techniques (Reading, Massachusetts: Addison-Wesley, 1992). ISBN: 0-201-54412-1

James D. Foley, Andries van Dam, Steven K. Feiner, and John F. Hughes, Computer Graphics Principles and Practice (Second edition in C, Reading, Massachusetts: Addison-Wesley Publishing Company, 1995). ISBN: 0-201-84840-6.

Kenton Musgrave, Darwyn Peachey, Ken Perlin, Steven Worley, Texturing and Modeling A Procedural Approach (Cambridge, MA: Academic Press, Inc., 1994). ISBN: 0-12-228760-6. This book is very applicable to 3ds max texture plug-in creation.

Les Piegl, Wayne Tiller, The NURBS Book (Berlin Heidelberg New York: Springer-Verlag, 1995). ISBN: 3-540-55069-0. This book provides a great deal of information on B-spline curves and surfaces (NURBS).

Gerald Farin, Curves and Surfaces for Computer Aided Geometric Design : A Practical Guide (San Diego, CA, 1993). ISBN: 0-12-249052-5. This book provides information applicable to the creation of spline and patch plug-ins.

James D. Murray and William vanRyper, Encyclopedia of Graphics File Formats (Second Edition, O'Reilly & Associates, Inc., 1996, 1994). ISBN: 1-56592-161-5. This book provides information about various graphic file formats that are applicable to the creation of image loader / saver plug-ins.

## **Windows Programming:**

Charles Petzold, Programming Windows 95 (Redmond, Washington: Microsoft Press, 1996). ISBN: 1-55615-676-6.

Jeffrey Richter, Advanced Windows The Developer's Guide to the Win32 API for Windows NT 3.5 and Windows 95 (Microsoft Press, 1995). ISBN: 1-55615-677-4.

## Plug-In Types Overview

See Also: [Plug-In Architecture Overview](#).

The following is a brief description of the categories of plug-ins one may create using the 3ds max Software Development Kit.

Sample code in the SDK is available to demonstrate techniques for programming many of these plug-in types. Additional sample code is available to [Sparks Developers](#). Also see the section on [Debugging](#).

The 3ds max 4.0 SDK comes provided with an SDK appwizard that can be used with Microsoft Visual C++. This appwizard allows you to quickly generate skeleton source code for a variety of different plugin types and essentially replaced the previous R3\_SKELETON projects included in the previous release of the software.

The generated code from the appwizard provides a quick way to start building plugins. Each project follows a standard structure with regard to headers and code files. Developers should find it easy to take this generated code and can start creating plugins without manually setting up the entire project from scratch.

## **Procedural Objects**

Procedural Objects are the general class of developer-defined objects that can be used in 3ds max.

## Geometric Objects

These are the only procedural objects that actually get rendered.

### Primitives

Primitive objects such as boxes, spheres, cones, cylinders, and tubes are implemented as procedural geometric objects. These are derived from class [GeomObject](#) or [SimpleObject](#). Example code may be found in **\MAXSDK\SAMPLES\OBJECTS\BOX.CPP, SPHERE.CPP, CONE.CPP**, etc.

### Particles

Developers may create procedural object particle system plug-ins. Some examples are particles that depend upon procedural motion like fireworks, explosions, and water, or particles that track the surface of objects like electrical fields or flame. Applications can be derived from [ParticleObject](#) or [SimpleParticle](#). Example code is available in **\MAXSDK\SAMPLES\OBJECTS\RAIN.CPP** and **\MAXSDK\SAMPLES\MODIFIERS\GRAVITY.CPP**.

### Loft Objects

The 3ds max Loftter is implemented as a procedural object plug-in. Developers may define other modeling modules that fit this form.

### Compound Objects

Compound objects take several objects and combine them together to produce a new object. Examples are Booleans (which produce a new object using operations Union, Intersection and Difference) and Morph objects. Sample code for the boolean object can be found in **\MAXSDK\SAMPLES\OBJECTS\BOOLOBJ.CPP**.

### Patches

Developers can create patch modeling systems that work inside MAX. The TriPatch and Patch Grid are examples of patch objects. These plug-ins are derived from [PatchObject](#). See **\MAXSDK\SAMPLES\OBJECTS\PATCHGRD.CPP**, and **TRIPATCH.CPP** for sample code.

### NURBS

The NURBS API provides an interface into the NURBS objects used by

MAX. Using the API developer can create new NURBS objects or modify existing ones. See the Advanced Topics section [Working with NURBS](#) for more information.

## Helper Objects

Helper objects are items such as dummy objects, grids, tape measurers and point objects. These objects may be derived from classes **HelperObject** or **ConstObject**. Sample code may be found in **\MAXSDK\SAMPLES\OBJECTS\HELPERS\GRIDHELP.CPP**, and **PHELP.CPP**. [See Class HelperObject](#) and [Class ConstObject](#).

## Shape Objects

These are shapes such as Circles, Arcs, Rectangles, Donuts, etc. New splines may be subclassed off [SimpleSpline](#). Sample code may be found in **\MAXSDK\SAMPLES\OBJECTS\CIRCLE.CPP, ELLIPSE.CPP, ARC.CPP**, etc.

## Procedural Shapes

These are shapes that are defined procedurally. An example procedural shape, Helix, may be found in **\MAXSDK\SAMPLES\OBJECTS\HELIX.CPP**. When an edit spline modifier is applied to a procedural shape it is converted to splines with segments that provide vertices in a linear approximation of the shape. This allows the procedural shape to be edited. Procedural shapes may be derived from class [SimpleShape](#). Other examples include Procedural lines, and Text.

Any of these objects can be edited with an edit spline modifier or extruded or surfrev'd.

## Lights

Developers may create custom plug-in lights. There are several classes from which light plug-ins may be derived. These are [LightObject](#), and [GenLight](#).

Example code may be found in

**\MAXSDK\SAMPLES\OBJECTS\LIGHT.CPP.**

## Cameras

Developers may create custom cameras. The two classes from which cameras may be derived are [CameraObject](#) and [GenCamera](#). An example of a plug-in camera may be found in

**`\MAXSDK\SAMPLES\OBJECTS\CAMERA.CPP.`**

## Object Modifiers

Object modifiers are applied to objects in their own local transform space to modify them in some way. Deformations like Bend, Taper, and Twist are examples of Object Modifier plug-ins. Example code may be found in **\MAXSDK\SAMPLES\MODIFIERS\BEND.CPP, TAPER.CPP**, etc. Extrude and Surfrev are also object modifier plug-ins. Sample code for Extrude can be found in **\MAXSDK\SAMPLES\MODIFIERS\EXTRUDE.CPP**. Developers may also create surface modifier plug-ins to alter smoothing groups, texture coordinates, and material assignments. See [Class Modifier](#) or [Class SimpleMod](#).

## **Edit Modifiers**

These plug-ins allow specific object types to be edited. For example, an Edit Mesh modifier allows objects that can convert themselves into triangle meshes to be edited, while an Edit Patch modifier allows objects that can convert themselves into patches to be edited. Edit modifiers typically allow the user to select sub-object elements of the object (vertices faces and edges in the case of the Edit Mesh modifier) and perform at least the standard move/rotate/scale transformations to them. They may also support additional operations (such as the extrude option of the Edit Mesh modifier). Example code may be found in **\MAXSDK\SAMPLES\MODIFIERS\EDITMESH.CPP**.

## Space Warps

Space Warps are basically object modifiers that affect objects in world space instead of in the object's local space (they were originally called 'world space modifiers'). Space Warps are non-rendering objects that affect other objects in the scene based on the position and orientation of the other objects that are bound to the Space Warp object. For example, the Ripple Space Warp applies a sine wave deformation to objects bound to it. Other examples of Space Warps include things like explosions, wind fields, and gravity. Sample code may be found in **\MAXSDK\SAMPLES\MODIFIERS\SINWAVE.CPP**.

Space warps are created in the Creation branch of the command panel, which makes them slightly different from regular modifiers (because they are combinations of space warp objects and space warp modifiers).

Space warps may also affect particle systems. For example, a force field can be applied to a particle system by a space warp. The force field provides a function of position in space, velocity and time that gives a force. The force is then used to compute an acceleration on a particle which modifies its velocity. For details see **\MAXSDK\INCLUDE\OBJECT.H**,

**\MAXSDK\SAMPLES\MODIFIERS\GRAVITY.CPP**, and  
**\MAXSDK\SAMPLES\OBJECTS\RAIN.CPP**.

A collision object can also be applied to a particle system by a space warp. The collision object checks a particle's position and velocity and determines if the particle will collide with it in the next period of time. If so, it modifies the position and velocity.

## Controllers

Controller plug-ins are the objects in 3ds max that control animation. Controllers come in different types based on the data they control. The most common controllers are interpolating or keyframe controllers. Other controller types are position/rotate/scale, mathematical expressions and fractal noise. Example controller code may be found in

**\MAXSDK\SAMPLES\HOWTO\PCONTROL\PCONTROL.CPP**,  
and **NOIZCTRL.CPP** etc. Controllers may be derived from [Class Control](#) or [Class StdControl](#).

## **Systems**

Systems are basically combinations of more than one type of procedural object, along with optional controllers, or modifiers, or space warps all working together. These plug-ins can provide high-order parametric control over very complex systems. An example system is Biped which uses procedural objects and master/slave controllers.

## **File Import**

These plug-ins allows 3D geometry and other scene data to be imported and exported to file formats other than the 3ds max format. An example file import plug-in may be found in `\MAXSDK\SAMPLES\IMPEXP\3DSIMP.CPP`. These plug-ins are derived from [Class SceneImport](#).

## **File Export**

These plug-ins allows 3D geometry and other scene data to be exported to file formats other than the 3ds max format. Sample code may be found in **\MAXSDK\SAMPLES\IMPEXP\3DSEXP.CPP**. These plug-ins are derived from [Class SceneExport](#).

## Atmospheric Plug-Ins

These plug-ins are used for atmospheric effects. MAX's Fog, and Volume Fog are two atmospheric plug-ins. Certain particle system-ish effects can be accomplished via atmospherics more efficiently. For example, a fire effect that is not done with particles but rather as a function in 3D space (the Combustion plug-in is a good example of this). Instead of rendering particles you traverse a ray and evaluate a function. These plug-ins typically use very little memory relative to a particle system equivalent. Atmospheric plug-ins also have the ability to reference items in the scene. (For example, MAX's Volume Lights reference lights in the scene.) These plug-ins are derived from [Class Atmospheric](#).

## Plug-In Materials

These are additional developer-defined material types. Examples are Standard, Mix, and Multi/Sub-Object materials. New materials are subclassed from [Class Mtl](#). Also see the section [Working with Materials and Textures](#). The sample code for these plug-ins is in **\MAXSDK\SAMPLES\MATERIALS**.

## Plug-In Textures

Procedural Texture plug-ins define 2- or 3-dimensional functions which can be assigned as maps within the shader tree architecture of the Materials Editor. Maps may be assigned as ambient, diffuse, specular, shininess, shininess strength, self-illumination, opacity, filter (transmission) color, bump, reflection and refraction maps. These functions may vary over time to produce animated effects. There are both 2D and 3D procedural textures, compositors and color modifiers. These plug-ins are derived from [Class Texmap](#). Also see the section [Working with Materials and Textures](#). The sample code for these plug-ins is in `\MAXSDK\SAMPLES\MATERIALS`.

## **2D Procedural**

Examples of 2D texture are **BITMAP.CPP** and **CHECKER.CPP**.

## **3D Procedural**

Examples of 3D textures are **MARBLE.CPP** and **NOISE.CPP**.

## **Compositor**

Some examples of compositors are **MASK.CPP** and **MIX.CPP**.

## **Color Modifier**

An example color modifier is RGB **TINT.CPP**.

Developers that have created a 3D Studio/DOS SXP and a corresponding 3ds max texture plug-in may want to have a look at [Class Tex3D](#). It provides a way to have an instance of your 3ds max texture plug-in created automatically when the corresponding SXP is found in a 3DS file being imported.

## Image Processing Plug-Ins

### Filters

Filters may be used to alter images in the video post data stream. Filters may operate on a single image or may combine two images together to create a new composite image. These plug-ins are derived from [Class ImageFilter](#). Also see the section [Working with Bitmaps](#).

### One Pass Filter

This plug-in type allows a single image in the video post data stream to be adjusted in some manner. An example plug-in of this type is

**\MAXSDK\SAMPLES\POSTFILTERS\NEGATIVE\NEGATIVE**

### Layer Filter

This plug-in allows two images to be composited to create a single new image. An example of this type of plug-in is

**\MAXSDK\SAMPLES\POSTFILTERS\ADD\ADD.CPP** or  
**\MAXSDK\SAMPLES\POSTFILTERS\ALPHA\ALPHA.CPP.**

## **G Buffer**

A G-buffer is used to store, at every pixel, information about the geometry at that pixel. All plug-ins in video post can request various components of the G-buffer. When video post calls the renderer it takes the sum of all the requests and asks the renderer to produce the G-buffer. Developers can use this information to create visual effects that are impossible to achieve without access to a G-buffer. See [Class GBuffer](#).

## Rendering Effects

This plug-in type is available in release 3.0 and later only.

There is a new item under the Rendering menu which displays the Rendering Effects dialog. From this modeless dialog, the user can select and assign a new class of plug-in, called a "Rendering Effect," which is a post-rendering image-processing effect. This lets the user apply image processing **without** using Video Post, and has the added advantage of allowing animated parameters and references to scene objects. The base class for these plug-ins is [Class Effect](#).

Sample code is available in the directory

**\MAXSDK\SAMPLES\RENDER\RENDEREFFECT.**

## Snap Plug-Ins

This plug-in type is available in release 2.0 and later only.

This plug-in type allows custom points to be provided to the 3ds max snapping system. For example a door plug-in could provide a custom snap for the hinge center. See [Class Osnap](#) for details. For sample code see **`\MAXSDK\SAMPLES\SNAPS\SPHERE\SPHERE.CPP`**.

## **Image Loading and Saving Plug-Ins**

Image loading and saving plug-ins allow the image file formats loaded and saved by 3ds max to be extended. An example is the JPEG loader / saver. Sample code may be found in the sub-directories of **\MAXSDK\SAMPLES\IO**. These plug-in types are derived from [Class BitmapIO](#). Device drivers are also derived from this class. See the sample code in **\MAXSDK\SAMPLES\IO\WSD\WSD.CPP**.

## Utility Plug-Ins

These plug-ins are useful for implementing modal procedures such as 3D paint, dynamics, etc. These plug-ins are accessed from the Utility page of the command panel. Example code may be found in the subdirectory **\MAXSDK\SAMPLES\UTILITIES**. These plug-ins are sub-classes of [Class UtilityObj](#).

## **Global Utility Plug-Ins**

This plug-in type is available in release 3.0 and later only.

These simple utility plug-ins are loaded at boot time, after initialization, but before the message loop starts, and remain loaded. This is how the new 3ds max COM/DCOM interface is implemented. For details see [Class GUP](#).

## Track View Utility Plug-Ins

These plug-ins are launched via the 'Track View Utility' icon just to the left of the track view name field in the toolbar. Clicking on this button brings up a dialog of all the track view utilities currently installed in the system. Most utilities will probably be modeless floating dialogs, however modal utilities may be created as well. These can provide general utility functions that operate on keys, time or function curves in Track View. Sample code is available in **\MAXSDK\SAMPLES\UTILITIES\RANDKEYS.CPP**, **ORTKEYS.CPP** and **SELKEYS.CPP**. These plug-ins are sub-classes off [Class TrackViewUtility](#).

## Plug-In Renderers

Plug-In renderers are derived from the class **Renderer**. The standard 3ds max scanline renderer is itself derived from this class. In a trivial sense, there are only a few methods to implement to create a renderer: **Open()**, **Render()**, **Close()**, **ResetParams()** and **CreateParamDlg()**. See [Class Renderer](#) for more details on this plug-in type.

## Shader Plug-Ins

This plug-in type is available in release 3.0 and later only.

This plug-in type works with the new Standard material. It allows plug-in developers to add additional shading algorithms to the drop down list of available options (previously Constant, Phong, Blinn, Metal). This was only possible previously by writing an entire Material plug-in (which could be a major undertaking). See the base class for this plug-in type [Class Shader](#) for details.

## Sampler Plug-Ins

This plug-in type is available in release 3.0 and later only.

This plug-in type works with the Standard material of release 3. A Sampler is a plug-in that determines where inside a single pixel the shading and texture samples are computed. The user interface of Samplers appears in the Super Sampling rollout in the Sampler dropdown. See [Class Sampler](#) for details.

## **Anti-Aliasing Filter Plug-Ins**

This plug-in type is available in release 3.0 and later only.

This plug-in type is used for filtering and anti-aliasing the image. Documentation for the base class for these filters is in [Class FilterKernel](#). Sample Code is available in the subdirectory

**\MAXSDK\SAMPLES\RENDER\AAFILTERS.**

## Shadow Generator Plug-Ins

This plug-in type is available in release 3.0 and later only.

The generation of shadows is accessible via this plug-in type. The standard 3ds max mapped and raytraced shadows have are plug-ins of this form. See [Class ShadowType](#) and [ShadowGenerator](#) for details. There is also a handy class for creating shadow map buffers. See [Class ShadBufRenderer](#).

## **Sound Plug-In**

A sound plug-in can take control of sound/music production in MAX. These plug-ins control not only the sounds they generate but also the system clock. They can thus coordinate the timing of external sound input / output devices with the animation. Sound plug-ins can provide their user interface as part of the 3ds max Track View.

Sound plug-ins are derived from [Class SoundObj](#).

## **Color Selector Plug-In**

This plug-in type is available in release 3.0 and later only.

This plug-in type provides the user with a custom color picker that appears whenever a standard 3ds max color swatch control is clicked. These plug-ins are selected in the General tab of the Preferences dialog. The color picker chosen is saved in the 3DSMAX.INI file in the "ColorPicker" section so that the choice is maintained between sessions. If the DLL for the selected color picker is not available, it will always default back to the "Default" color picker. See [Class ColPick](#) for details.

## **Front End Controllers**

These plug-ins allow a developer to completely take over the 3ds max user interface. This includes the toolbar, pulldown menus, and command panel. See [Class FrontEndController](#) for details.

## **Motion Capture Input Devices**

Motion Capture Input Device plug-ins can now be written that plug-in to the 3ds max motion capture system. See [Class IMCInputDevice](#) for details. Sample code is available in the subdirectory **\MAXSDK\SAMPLES\MOCAP**.

## **Image Viewer Plug-In**

An image viewer is available from the 3ds max File menu under View File. A developer may replace the viewer DLL launched by this command to provide enhanced functionality for image browsing. The source code for this viewer is in **\MAXSDK\SAMPLES\VIEWFILE\VIEWFILE.CPP**. This plug-in is derived from [Class ViewFile](#).

## Notification Program

There is a program whose source code is in `\MAXSDK\SAMPLES\UTILITIES\notify\notify.cpp`. This program gets invoked by the network manager to handle network progress notifications.

A developer may write another "Notify" program in order to do any proprietary type of notifications. Note that "Notify" can be either a "\*.exe", a "\*.bat", or a "\*.cmd" executable. This allows a user to create a simple script file to do something without having to resort to writing a binary program.

The current **Notify.exe** is very simple as it is used simply as a demonstration. It plays a different wave file for each of the event types. If invoked with no command line, it will bring up a dialog box asking the user to define each of the three wave files. The dialog has "Browse" buttons next to each wave file field which puts the user right into the Windows' "Media" directory where wave files are saved. There are also "play" buttons next to each sound so they can be tested.

## Guidance Introduction

This module of the documentation is intended to enable a developer to learn to accomplish a specific task in programming 3ds max. There is a section on the 3ds max plug-in architecture that provides a diagram of the principal classes. There is a section describing information common to all plug-in development. This module provides How To sections for several of the plug-in types including procedural objects, object space modifiers, space warps, controllers and system plug-ins. These sections include commented source code and descriptions of categories of methods developers must implement to create each plug-in type. There is a section for experienced 3D Studio IPAS programmers making the transition to MAX. This section discusses the similarities and difference in the IPAS and 3ds max programming architectures. The changes in development environment, plug-in/system control flow, user interface, and graphics programming support are reviewed. This section also discusses the six types of IPAS routines possible under 3D Studio DOS and how they may be implemented under the 3ds max plug-in architecture.

The General Terminology section defines terms used throughout the SDK documentation. These terms also appear as popup help in other parts of the documentation.

The Advanced Topics section presents detailed information about key concepts in using the APIs. The topics presented in this section cross class boundaries, and are instead based on specific implementation issues developers need to understand when designing plug-ins for MAX. Developers getting started with the SDK should take a look through the various Advanced Topics sections to become familiar with what information is available.

There is also a section on commonly-encountered problems and solutions.

## Plug-In Directory Search Mechanism

See Also: [DLL Functions and Class Descriptors](#).

This section discusses the system 3ds max uses to search for plug-in DLLs. This includes path searching and the standard file name extensions required by plug-ins.

## **DLL Path Search**

In the root directory with the 3ds max executable is a file **PLUGIN.INI**. This file contains a one-line entry for each plug-in search location. When 3ds max begins execution it searches each path listed in this file looking for plug-in DLLs. When a plug-in DLL is found it is loaded. This system allows developers to store their plug-ins in whatever sub-directory structure they wish. The format for the **PLUGIN.INI** file is:

### **Descriptive Text=Search Path**

Here's what a sample **PLUGIN.INI** might look like:

**Standard MAX plug-ins=C:\3DSMAX\STDPLUGS**

**Miscellaneous free plug-ins=C:\3DSMAX\MISCPLUG**

From the 3ds max File menu is a choice Configure Paths... The dialog page for Plug Ins lists the paths defined in **PLUGIN.INI**. The user may use the interactive tools in this page to edit **PLUGIN.INI** and add or remove search paths. Manual maintenance shouldn't be required often, however, since a plug-in's install routine can automatically write a string to the **PLUGIN.INI** file that contains all the information required after creating the sub-directory and copying its files into it. Mostly, manual maintenance will be used to create directories for freebie plug-ins, and to de-install directories for plug-ins that are no longer used.

## Standard File Name Extensions

There are certain file name extensions that plug-in DLLs must use. 3ds max uses these standard extensions as part of its search algorithm to determine which files it will attempt to load. Below is a list of the extensions and the plug-in types associated with each one:

- BMI** - Bitmap Manager IO DLLs.
- BMF** - Bitmap Manager Filter Plug-Ins.
- BMS** - Bitmap Manager Storage DLLs.
- DLB** - Shader Plug-Ins.
- DLC** - Controllers.
- DLE** - Scene Export Plug-Ins.
- DLF** - Font Loaders.
- DLH** - Sampler Plug-Ins
- DLI** - Scene Import Plug-Ins.
- DLK** - Filter Kernels (Anti-aliasing filters)
- DLM** - Modifiers.
- DLO** - Procedural Objects.
- DLR** - Renderers.
- DLS** - Object Snap Plug-Ins.
- DLT** - Materials and Textures.
- DLU** - Utility Plug-Ins.
- DLV** - Rendering Effects
- FLT** - Image Filter Plug-Ins.
- GUP** - Global Utility Plug-Ins.

Note that it is acceptable to have several different plug-in types present in a single DLL. As long as the DLL uses one of the file name extensions listed above, 3ds max will load ALL the plug-ins present. For example, if a developer created a system plug-in using both a procedural object and a controller, he or she could place them both in the same DLL. 3ds max would load them all (provided the file name extension matched one of those above).

## Plug-In Help System

Plug-In developers may add on-line help for their applications and make this available to users via the 3ds max Help menu.

From the 3ds max Help menu is a choice Plug-in Help... When selected, this brings up a dialog with a list of installed help systems. The user may select one (by double-clicking or selecting and clicking on Display Help) and that help system's main menu will be activated.

Help files for plug-ins are specified in a separate **[Help]** section of the **PLUGIN.INI** file. The syntax is:

**Description of the helpfile=C:\PATH\TO\FIND\THE\HELPPFILE.HLP**

The description is the string that will appear in the list that pops up when you select Plug-in Help, and the specified .HLP file will be loaded when the user asks to see the help.

For example, the following lines added to **PLUGIN.INI** would add the SDK Help file to the list of choices.

**[Help]**

**SDK Help=C:\MAXSDK\HELP\SDK.HLP**

Note: For 3ds max 2.5 and later, developers may use help files in either .HLP (WinHelp) or .CHM (HTMLHelp) formats.

## Plug-In Configuration System

Developers often need to store configuration files for use with their plug-in applications. There is a standard location defined for these files. This allows a 3ds max user to have all their configuration files stored together and not spread around different hard-to-find locations.

The standard location is the **PlugCFG** directory off the 3ds max root directory. This location may be changed by a user using the Files / Configure Paths... menu command. The developer should retrieve the location of this directory using the **GetDir(APP\_PLUGCFG\_DIR)** method of the **BitmapManager** class or the **Interface** class.

The following samples code from `\MAXSDK\SAMPLES\IO\WSD\WSD.CPP` demonstrates one approach a developer may use to read and write configuration files:

```
#define WSDCONFIGNAME _T("wsd.ini")
#define WSDSECTION _T("Default State")
#define WSDHOSTKEY _T("Hostname")
#define WSDSYSKEY _T("System")
#define WSDDEFAULT _T("accom")
#define WSDDEFSYS _T("ntsc")
// GetCfgFilename()
void BitmapIO_WSD::GetCfgFilename( TCHAR *filename ) {
    _tcscopy(filename,TheManager->GetDir(APP_PLUGCFG_DIR));
    int len = _tcslen(filename);
    if (len) {
        if (_tcscmp(&filename[len-1],_T("\\")))
            _tcscat(filename,_T("\\"));
    }
    _tcscat(filename,WSDCONFIGNAME);
}
```

Note: The **GetPrivateProfileString** function retrieves a string from the specified section in an initialization file. This function is part of the Windows API. See the Windows API on-line help for more details.

```
// ReadCfg()
```

```

int BitmapIO_WSD::ReadCfg() {
    TCHAR filename[MAX_PATH];
    TCHAR system[64];
    GetCfgFilename(filename);
    int res =
    GetPrivateProfileString(WSDSECTION,WSDHOSTKEY,WSDDEFA
        hostname,MAX_PATH,filename);
    if (res) {

    GetPrivateProfileString(WSDSECTION,WSDSYSKEY,WSDDEFSY
        system,64,filename);
    } else {
        _tcscpy(system,WSDDEFSYS);
    }
    if (!_tcscmp(system,WSDDEFSYS)) {
        ntsc = TRUE;
        height = 486;
    } else {
        ntsc = FALSE;
        height = 576;
    }
    return (res);
}

```

Note: The **WritePrivateProfileString** function copies a string into the specified section of the specified initialization file. This function is part of the Windows API. See Windows API on-line help for more details.

```

// WriteCfg()
void BitmapIO_WSD::WriteCfg() {
    TCHAR filename[MAX_PATH];
    TCHAR system[64];
    if (ntsc)
        _tcscpy(system,WSDDEFSYS);
    else
        _tcscpy(system,_T("pal"));
}

```

```
GetCfgFilename(filename);  
WritePrivateProfileString(WSDSECTION,WSDHOSTKEY,hostnam  
WritePrivateProfileString(WSDSECTION,WSDSYSKEY,system,file  
}
```

## Plug-In Architecture Overview

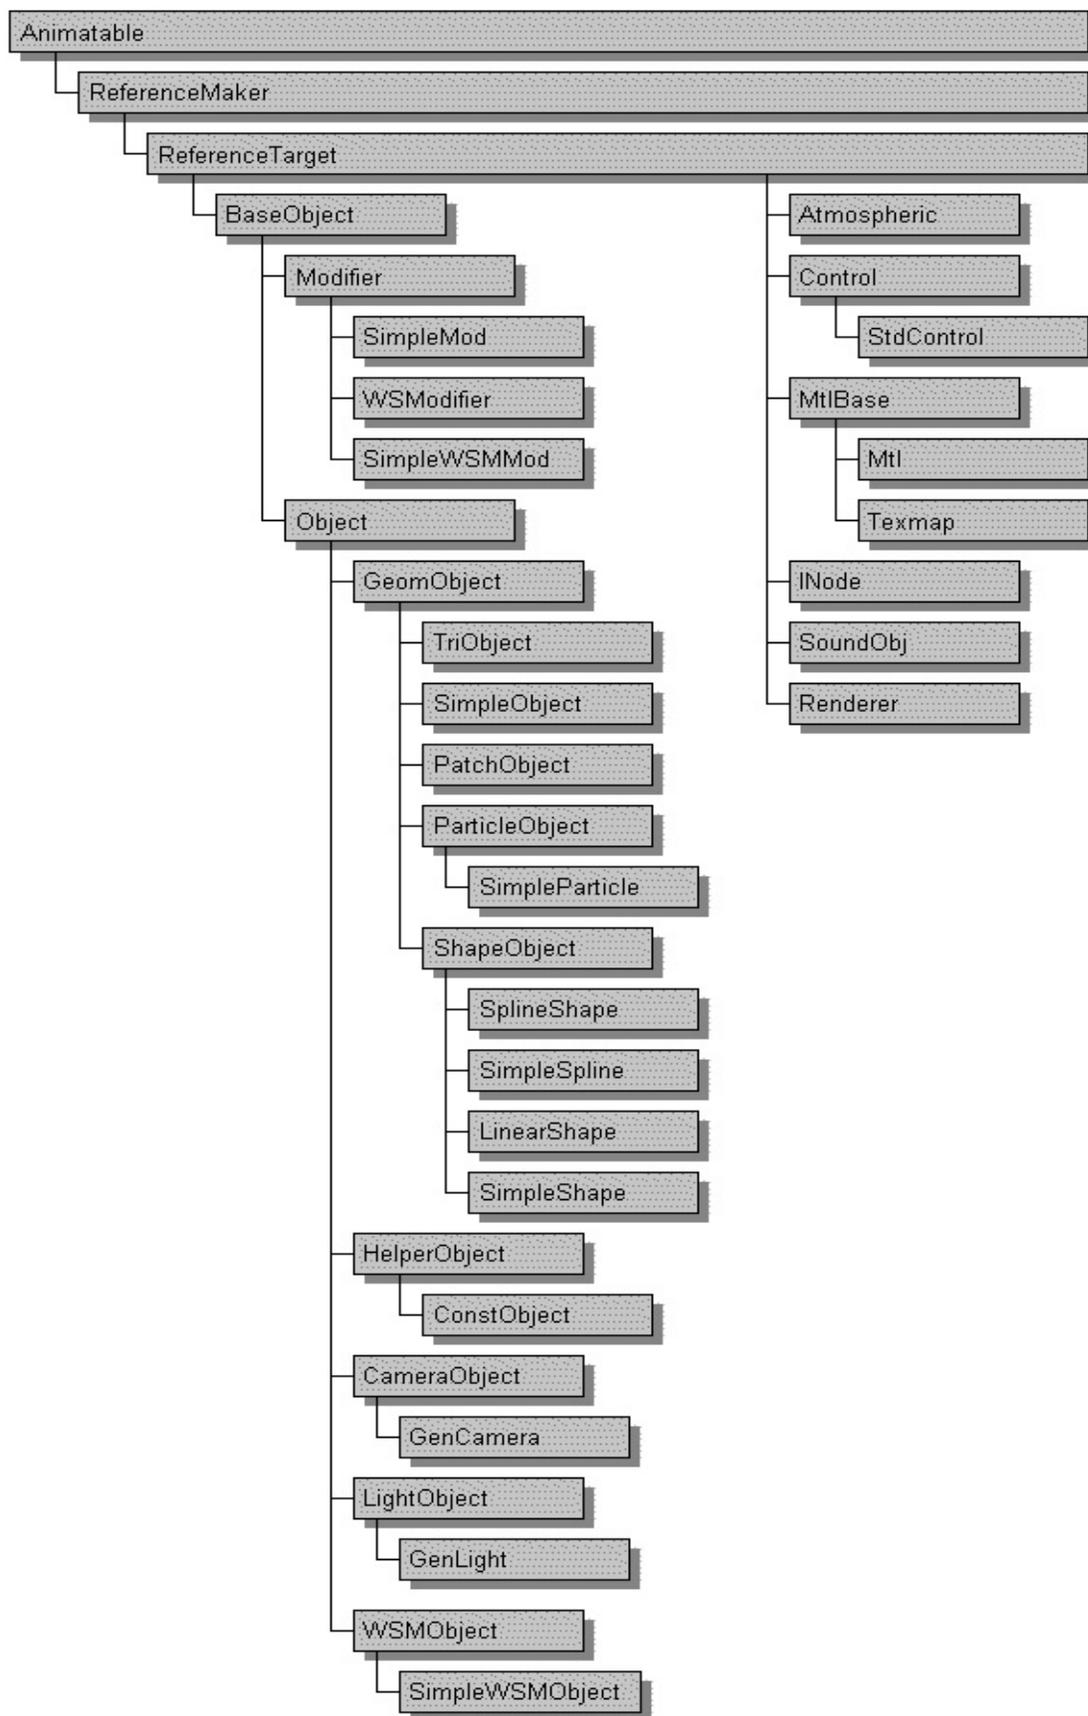

See Also: [Overview of the Principal Classes](#)

The SDK is a set of C++ classes and related routines. Writing a plug-in involves creating objects from the classes and implementing methods to allow communication between the plug-in and the system. In addition to using the provided SDK classes, you can integrate new classes seamlessly into the SDK framework.

Most of the SDK classes inherit from three [= 4\) BSPSPopupOnMouseOver\(event\);">abstract base classes](#). The root class of these three is called Animatable. It defines most of the animation and track view-related methods. Derived from Animatable is ReferenceMaker. This class allows you to make references to other objects. Derived from ReferenceMaker is ReferenceTarget. A reference is a two-way link between objects in the scene. It creates an official record of the dependencies between the ReferenceMaker and the ReferenceTarget. Its primary function is to allow a reference target to inform its dependent reference maker that it has changed in some way.

Classes that don't inherit from Animatable are primarily those that don't deal with animation. For example, the Interface class provides a mechanism for plug-ins to call functions in 3ds max itself. The Interface class is not derived from Animatable.

The following diagram shows the inheritance tree of the principal public classes in the SDK. The base classes (classes that do not have parents) are shown at the top, and the inheritance hierarchy proceeds toward the bottom and to the right.

## **Class Hierarchy**

# Writing Plug-In Applications

See Also: [Main Plug-In Classes](#).

This section presents information common to developing all 3ds max plug-in applications. It discusses the sample files, the plug-in directory search mechanism, the plug-in help system, the configuration file system, the standard DLL functions, and creating thread-safe plug-ins.

Included with the SDK are sample programs that provide many examples of how to write plug-in applications. These sample programs are found in the sub-directories of **\MAXSDK\SAMPLE**. You'll find it very instructive to examine the source code of these examples. The section on [Building the Sample Files](#) has more detailed information on the sample programs available.

3ds max plug-ins are implemented as dynamic link libraries (DLLs). DLLs are object code libraries that let multiple programs share code, data, and resources. Dynamic linking allows an executable module to include only the information needed at run time to locate the executable code for a DLL function. This type of linking differs from the more familiar static linking, which requires a copy of a library function's executable code in the executable module of each application using it.

The development tool for creating these DLLs is Microsoft Visual C++. For a description of how to create a new project file see the Advanced Topics section [Creating a New Plug-In Project](#).

Developers may store their plug-in DLLs in any location they wish. Developers need to let 3ds max know where to search for the DLLs. How this is done is discussed in the section [Plug-In Directory Search Mechanism](#).

Plug-In developers may add on-line help for their applications and make this available to users via the 3ds max Help menu. See the section [Plug-In Help System](#) for more details.

There is a standard location for developers to save any configuration files required by their plug-in application. These may be .INI files, binary configuration files or whatever is needed. See the section [Plug-In Configuration System](#) for details.

## Standard DLL Functions

There are a standard set of functions that ALL plug-in DLLs must implement. These functions are:

**DLLMain()**

**LibDescription()**

**LibNumberClasses()**

**LibClassDesc()**

**LibVersion()**

These functions allow 3ds max to access, work with, and maintain the plug-ins inside the DLL. To review the full details of these functions, see the Advanced Topics section [DLL Functions and Class Descriptors](#)

## **Reentrant and Thread Safe Plug-Ins**

3ds max plug-ins must be 'Reentrant' and 'Thread Safe'. See the Advanced Topics section [Thread Safe Plug-Ins](#) for more information.

## Building the Sample Files

See Also: [Main Plug-In Classes](#).

## Overview

The SDK provides sample code for many of the plug-in types. This section discusses the procedure to build and run the sample plug-ins included in the SDK. All the sample code is located in the sub-directories of **\MAXSDK\SAMPLES**. A MAK file is provided to build each sample.

Each MAK file has several configurations within it. There is a Release configuration, and a Hybrid configuration. In the *special* developer SDK available to registered developers ([See Debugging](#)) there is an extra Debug configuration. Developers may use any of these. Developers using the standard SDK should use the Hybrid configuration for source level debugging and the Release configuration for distribution code. The plug-ins that ship with 3ds max were created using the Release configuration.

These configurations differ based on their optimization of the code, their inclusion of debug symbols, and their use of runtime libraries.

The Release configuration creates optimized code while the other configurations do not.

Both the Hybrid and the Debug configurations contain debug symbols useful in source level debugging. The Release configuration does not include debug symbols.

The Release and Hybrid configurations both use the same runtime libraries. These are called **Multithreaded DLL** in VC++. The Debug configuration uses a different one, the **Debug Multithreaded DLL** library. The difference is the Debug configuration uses a different heap to track memory. The non debug libraries use the same heap as regular release code. The issue is that heaps cannot be mixed and matched. This is why a special Debug version of 3ds max is required to use the special Debug configuration.

Developers using the standard SDK should use the Hybrid configuration for debugging and the Release configuration for distribution code.

## Building the Samples

The MAK files assume the SDK is installed in the \MAXSDK directory off the root of the drive.

The MAK files also assume that the directory to store the 3ds max plug-ins is \MAXSDK\PLUGIN. If this is not where you wish to put them you will need to change the output file directory. Load the MAK file by choosing **File / Open Workspace...** changing the **List File of Type...** to **\*.MAK** and selecting the MAK file.

**1** From the **Build** pull down menu choose **Settings...**

**2** From the Project Settings dialog box choose the **Link** Tab.

**3** Under **Output File Name:** Enter the path to the desired plug-in directory and the output file name.

To build one of the sample projects:

**1** Load the MAK file into VC++.

**2** From the **Build** menu choose **Rebuild All**. This will compile and link the plug-ins in the MAK file. Note that this process will overwrite any plug-in DLLs with the same name in the destination directory.

## Running The Sample Programs

**Important Note:** The SDK plug-ins are the same as the standard 3ds max plug-ins. If you want to run the samples you should copy the plug-in from the `\MAXSDK\PLUGIN` directory to your `\3DSMAX\STDPLUGS` directory. This will replace the standard 3ds max plug-in with the SDK version. If you try to load them both (i.e. put them in separate directories and tell 3ds max to load plug-ins from each of these directories) you'll have a Class\_ID conflict. 3ds max will not load two plug-ins that have the same Class\_ID. It will only load the first one and put up a warning about the second one.

Another option is to change the Class\_ID used in the sample code before it is compiled. 3ds max may then load both plug-ins. For more information on Class\_IDs see the section [DLL Functions and Class Descriptors](#).

## **Ready To Build Plug-In Projects**

The 3ds max 4.0 SDK comes provided with an SDK appwizard that can be used with Microsoft Visual C++. This appwizard allows you to quickly generate skeleton source code for a variety of different plugin types and essentially replaced the previous R3\_SKELETON projects included in the previous release of the software.

The generated code from the appwizard provides a quick way to start building plugins. Each project follows a standard structure with regard to headers and code files. Developers should find it easy to take this generated code and can start creating plugins without manually setting up the entire project from scratch.

# Must Read Sections for All Developers

See Also: [Must Read Sections by Plug-In Type](#), [Advanced Topics](#).

The following sections in the help file should be read by all developers. These are fundamental issues every programmer needs to understand to write plug-ins for MAX.

## [DLL/Lib Functions and Class Descriptors](#)

All 3ds max Plug-Ins must implement these DLL and Library functions.

## [Memory Allocation](#)

This section discusses how plug-ins are allocated and deallocated in memory.

## [Intervals](#)

Intervals are an object in 3ds max that describe a range of time. They are a key concept in understanding animation in MAX.

## [Geometry Pipeline System](#)

The Geometry Pipeline is a system used by all plug-ins that deal with geometry.

## [Sub-Anims](#)

The hierarchy of animatable items that appears in Track View is referred to as the sub-anim hierarchy. This section documents how a plug-in provides access to it's sub-anims.

## [References](#)

The concept of a reference is what allows parts of 3ds max that relate to one another to communicate to manage the relationship. This section presents information on how this works.

## [Nodes](#)

Nodes are the items in the 3ds max that have a one to one correspondence with objects in the scene. This section provides information on nodes.

## [Custom User Interface Controls](#)

This section describes the custom controls developers may use in their user interface design.

## [Parameter Blocks](#)

Parameter Blocks are the objects in 3ds max that help to manage the variables that a plug-in uses to store animated values.

## [Parameter Maps](#)

Parameter Maps are used to simplify the programming effort required to manage the user interface of a plug-ins parameters.

### [Matrix Representations of 3D Transformations](#)

Matrices are used in 3ds max to represent various transformation. This section explain how they work.

### [Rotation Concepts](#)

This section provides information on some of the classes that deal with rotation.

# Must Read Sections by Plug-In Type

See Also: [Must Read Section for All Developers](#), [Plug-In Types Overview](#).

The following sections in the help file are those that should be read by developers creating a certain plug-in type. This is simply an aide to point you at the relevent sections that must be understood to create a specific kind of plug-in.

# Fundamental Concepts of the MAX SDK

See Also: [Must Read Section for All Developers](#), [Advanced Topics](#).

## **Overview**

This section provides an overview of the fundamental concepts involved in using the SDK. It provides an explanation of many of the basic issues that developers deal with while creating plug-in applications.

The SDK provides tremendous control over almost all aspects of MAX. For this reason, there is a lot of information. However, broken down into smaller parts, things aren't complex. This section will discuss most of the basic issues in simple terms, and has hyperlinks to the sections in the SDK that contain more detailed information.

## The Object Oriented Philosophy of MAX

3ds max can be thought of as an operating system for 3D graphics. What a user is doing when running MAX, for the most part, is using plug-ins. Almost all areas of 3ds max are open to developers, and the 3ds max programmers use the same SDK and tools as third-party developers.

Instances of the plug-in classes developer create are called **Objects**. The way that they can be built independent of one another, yet work together to function as a system, is what makes the 3ds max plug-in architecture so powerful. The biggest impact this object oriented design has on developers is that one can develop plug-ins independently, without having to know or worry about how the other plug-ins are going about their tasks. Developers do have to understand the 3ds max Reference Architecture, however. The Reference Architecture (discussed later in this topic) is the system that allows all the plug-ins to communicate.

## **Plug-In Types**

All of the following areas of 3ds max are implemented as plug-ins: shapes and splines, patch objects, particle systems, modifiers, space warps, lights, cameras, bitmaps, texture maps, materials, image filters and compositors, animation controllers, file import/export utilities, atmospheric effects, renderers, and sound support.

For a list of all the plug-in types that can be developed with the SDK see the topic [Plug-In Types Overview](#).

## MAX Plug-Ins and the Tools for Creating Them

This section describes the type of executable used for 3ds max plug-ins and the tools used to create them.

Plug-Ins for 3ds max are developed with Microsoft Visual C++. Plug-ins are implemented as Windows Dynamic Link Libraries (DLLs). A dynamic-link library (DLL) is an executable file that acts as a shared library of functions. Dynamic linking provides a way for a process to call a function that is not part of its executable code. The executable code for the function is located in a DLL, which contains one or more functions that are compiled, linked, and stored separately from the processes that use them.

For step by step information on how to set up a new plug-in project using Visual C++ see the section [Creating a New Plug-In Project](#) (this includes information on the AppWizard that's available to quickly create projects). For information on debugging plug-ins using the Visual C++ debugger see the topic [Debugging](#). Once your plug-in is working you can optimize it for speed. See the section on [Profiling Plug-in Performance](#) for this information.

An additional tool that is helpful in searching for information on specific methods in the C++ source code is `\MAXSDK\HELP\SDKLINK.ZIP`. This tool launches the SDK online help and jumps directly to the reference information on the selected method. To use this program unzip it and review the installation and use instructions in the **README.DOC** file.

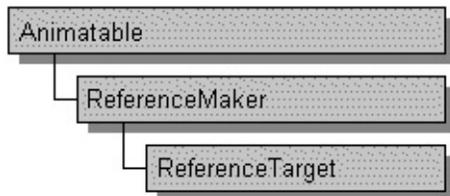

There is also a file, **USERTYPE.DAT**, which can be used to enable syntax highlighting of user defined keywords in VC++ 6.0 IDE. This can make browsing and writing code that much more enjoyable. This file lets you get all the 3ds max methods and definitions highlighted in a custom color inside of Visual C++ (like the colored C/C++ keyword you have now).

To put this tool in place, copy the file `\MAXSDK\HELP\USERTYPE.DAT` into the `\DevStudio6\Common\MSDev98\Bin` directory. After restarting VC++, you can then change the color of 3ds max keywords by modifying the color under Tools/Options/Format/Colors/User Defined Keywords. It is recommended that you choose a different color than the color assigned to Tools/Options/Format/Colors/Keywords, which are specific to C++. Having two different color patterns aids in your understanding of the code.

## The C++ Class Hierarchy

This section describes the hierarchy of C++ classes used to develop plug-ins. C++ classes are used by 3ds max because of their efficiency. When a plug-in is linked directly into the parent program, as it is with Windows DLLs, program flow can proceed directly from 3ds max into the plug-in. The plug-in and 3ds max share memory and can directly access one another's data.

The majority of 3ds max plug-ins are related to modeling, animation and rendering. These plug-ins are generally derived from a series of base classes that provide common characteristics such as the ability to appear in Track View and the ability of the plug-ins to communicate with one another as they are modified and changed.

### Three Base Classes of the MAX Class Hierarchy

At the base level of this hierarchy is the animation related class named **Animatable**. The primary methods of this class relate to appearing in Track View and dealing with memory management. Derived from **Animatable** are two classes used in the communication between different parts of MAX.

These are **ReferenceMaker** and **ReferenceTarget**. These two classes are used to facilitate communication between dependent objects in MAX. This inter-object communication is described later in this topic.

There are other plug-ins that are not derived from these classes. Generally, these are items that don't directly relate to animation. For instance, import / export plug-ins simply get data in and out of MAX. They don't appear in Track View, and function independently of other plug-ins.

For a more complete look at the class hierarchy see the section [Plug-In Architecture Overview](#). For a summary of the main methods of these classes see [Overview of the Principal Classes](#).

## How Plug-Ins Interact with MAX

This section discusses the ways 3ds max calls functions provided by the plug-in, and how plug-ins can call functions provided by MAX.

Plug-ins are derived from a base class provided by MAX. For example, if you wanted to develop a geometric object plug-in you might derive your class from class **SimpleObject** as shown below.

```
class MyGeomObject : public SimpleObject {  
// ...  
};
```

The 3ds max header files include the definition of the **SimpleObject** class. It is your responsibility as the programmer to provide implementations of some of the required methods of **SimpleObject** in your plug-in. Said another way, your plug-in implements (provides the code for) certain methods of the base class. 3ds max can then call these methods on your plug-in. For example, **SimpleObject** has a method **BuildMesh()**. This method is called by 3ds max when it needs to get a triangle mesh representation of your geometric object. In the code for your implementation of **SimpleObject::BuildMesh()** you generate the mesh you need. When 3ds max needs this mesh representation it calls your **BuildMesh()** method.

In other cases, methods are provided by the base class (by MAX). That is, the base class itself provides the implementation. These methods may be called by the plug-in. These methods are inherited from the base class from which the plug-in is derived. For example, a geometric object primitive may be derived from class **GeomObject**. This geometric primitive can call **NotifyDependents()**. This is a method of **ReferenceTarget** that the primitive inherited via the base class hierarchy (**GeomObject->Object->BaseObject->ReferenceTarget**).

In the SDK documentation, methods that the plug-in implements are labeled 'Implemented by the Plug-in'. Those that 3ds max provides the implementation for are labeled 'Implemented by the System'.

There are other ways that plug-ins can call methods provided by MAX. This is done through a pointer to an **Interface Class**. An interface class is simply a class without data members and only pure virtual methods. Classes such as these are essentially just a table of function pointers. Interface classes are used quite often

in 3ds max programming. The most general interface class is named, logically enough, **Interface**. A pointer to this class is passed into a great many methods and plug-ins use it to perform common operations provided by MAX. For example, when a modifier plug-in wants to show its user interface in the command panel it calls a method of **Interface** named **AddRollupPage()** to take care of it. Or when a plug-in wants to retrieve the current time as specified by the frame slider in MAX, the **Interface** method **GetTime()** is called. See the Advanced Topics section [Overview of Interface Classes](#) for more details.

## How Plug-Ins Interact with Each Other -- The Reference Architecture

In the object oriented paradigm of MAX, where independent plug-in objects work together to facilitate the overall functioning of the system, some form of inter-object communication is required. The Reference Architecture is the mechanism 3ds max uses to handle this communication. Consider the following example to understand why it is needed.

One of the 3ds max animation controller plug-ins is called the Look At Controller. This is a transform controller, meaning it controls the position, rotation and scale of an item in the scene. The Look At controller rotates the item it's assigned to so that it is always pointed towards (or "looking at") another object. For example, say you create a Free Camera and assign the Look At controller as the camera's transform controller. You then pick a Box in the scene as the target of the Look At controller. This will cause the Free Camera to rotate such that its direction of view is pointing right at the Box. Whenever the Box is moved, the controller will readjust itself so that the camera remains pointing towards it. Also, if the Box is deleted from the scene, the camera will recognize this and simply remain stationary.

Now consider that each of these items (the Camera, the Look At Controller, and the Box) are all plug-ins. And each is written without any specific knowledge about the other objects. How then can these objects communicate so they are aware of one another? For example, how does the Camera know that its direction of view changes when the Box moves? Or how does the Look At controller know that the Box has been deleted from the scene? The answers are that these objects communicate via what are called **References**.

A Reference is a way to associate two items. One item is considered dependent upon the other. In the example above, the Look At Controller is dependent on the Box. And the Camera is dependent on the Look At Controller. That is to say, if the Box changes in some way it needs to let other objects that might depend on it know it has changed. The controller, via the Reference, gets notified that the Box has changed. And the controller needs to do the same for those items which depend on it. When the controller has changed, it lets those items which may depend on it know. Thus the camera gets notified.

An object sets up this record of dependency by creating a Reference. When an object makes a reference, it is called a Reference Maker. The object that is referenced (that it depends on) is called a Reference Target. In the example above, the Camera is a Reference Maker. It references the Look At Controller.

The Look At Controller is the Reference Target of the Camera. The Look At Controller is also a Reference Maker -- it references the Box. The Box is the Reference Target of the controller. The Box, in fact, has its own references, for example, its transform controller.

The inter-dependencies created through References exist all over MAX. In a simple scene, dozens of references exist (many that 3ds max is using internally). In a complex scene, hundreds may exist.

For additional details on how References are used for inter-object communication see the Advanced Topics section [References](#). Also see the sub-topic in that section called **Viewing Reference Messages**. It discusses a utility plug-in called the Reference Watcher. This plug-in may be used to help understand the reference structure of a chosen item and to monitor the reference messages it sends. This provides a quick, visual way to examine the use of references in MAX.

## **The Parametric Nature of MAX Objects and the Impact on Plug-Ins**

The geometric objects provided by 3ds max are parametric objects. This means they are defined by their user interface parameters, rather than directly by the vertices and faces which make up a mesh surface. For example, a Sphere primitive is defined by its Radius, Segments count, Hemisphere setting, etc. These are what are stored in memory, and saved by 3ds max when the sphere object is written to disk. A triangle mesh representation of the Sphere is required for rendering, but it is computed 'on the fly' from the parameters. Contrast this with the older 3D Studio for DOS. Its objects were not parametric and existed only as the vertices and faces that described the surface. If a user wanted to go back and modify the sphere's segment count she would have to delete and re-create a new sphere object with the setting changed. In 3ds max one can simply change the segment count at any time and the surface is regenerated.

Geometric objects must eventually be converted to triangle meshes for rendering, however. The 3ds max renderer works with mesh objects **only**, so primitives, booleans, loft objects, particles, patches and NURBS surfaces all are converted to triangle meshes.

In addition to procedural objects, 3ds max provides an extensive collection of Modifiers. Many of these are applied to objects to provide some form of modification, deformation, manipulation or editing of the underlying object. Users can also apply Space Warp plug-ins to alter geometry based on world space positions. The implication of all this for plug-in developers is that they need to understand the conversion process from parametric object to modified triangle mesh.

The **Geometry Pipeline System** of 3ds max is used to handle this processing and conversion. The geometry pipeline is the system used to allow parametric objects to be operated on by modifiers, with the eventual generation of a triangle mesh suitable for rendering and display in the viewports. For the full details see the Advanced Topic section [Geometry Pipeline System](#). For information regarding how procedural objects and modifiers work together to facilitate the modification see the section [Object Modification](#).

Plug-in developers may find helpful to study the code for the Collapse Utility. This utility lets a user collapse the Stack of one or more selected objects into an Editable Mesh and, optionally, perform a Boolean operation on them at the same time. See the code in

**\MAXSDK\SAMPLES\UTILITIES\COLLAPSE.CPP.**

## The Scene -- Nodes

The 3ds max Scene, that is the objects, lights, cameras, space warps, particles, etc., are each associated with a **Node**. There is a one to one correspondence between each item in the scene and a node. A node is simply the item that manages the information needed to allow its associated object to exist in the scene. These are things such as the transform controller, the material used, data about parent-child hierarchies, and grouping information.

The transform controller of the node controls the position, rotation and scale of the object in the scene. The material assigned to the node is used by the renderer to give the object its surface characteristics such as color, texture, bumpiness. The hierarchy information is used to handle the linked / unlined state of objects for forward and inverse kinematics.

For more detailed information see the Advanced Topics section [Nodes](#), [Working With Materials and Textures](#), and [Working with Controllers](#).

## Time and Intervals

Developers dealing with animation need to specify certain points in time, and also certain periods of time. This section discusses each of these.

The basic unit of time in 3ds max and the SDK is equal to 1/4800th of a second. This length of time is a data type called a **TimeValue**. TimeValues are used throughout the class methods in the SDK when a specific instant in time needs to be specified. For example, if your plug-in needed to know the current system time (position of the 3ds max frame slider) it would call the methods **Interface::GetTime()**. This methods returns a **TimeValue** that indicates the current time (in 1/4800ths of a second).

In MAX, intervals are commonly used to define the time period in which an object is unchanging. To be as fast as possible 3ds max avoids re-computing objects whenever it can. If an animated plug-in can specify how long a period it is unchanged 3ds max can know it doesn't have to re-evaluate the object over that time. For example, 3ds max needs to know over what length of time the Modification done by a modifier is valid for. Consider a Bend modifier where the user has animated the bend angle over time (say un-bent from frame 0 to frame 50, and then bent 45 degrees at frame 100.) So that 3ds max doesn't need to re-evaluate the modifier every frame (after all, its not bending from frame 0 to 50) the modifier provides 3ds max with a **Validity Interval** that tells it how long the deformation is valid for. This validity interval is relative to a certain time. For instance, say 3ds max asks the modifier how long the modification is valid for at frame 0. The modification is valid from frame 0 to frame 50. If 3ds max asked how long the modification was valid for after frame 50, say at frame 75, then the answer is only for a single instant of time. That's because the modifier is animated from frame 50 to 100. At each frame it is different (bent more towards the final 45 degrees). Therefore the validity interval is only a single point in time (or **TimeValue**).

Intervals of time are specified in the SDK using an **Interval** object. This object has a start and end time and various methods to work with the interval. There are numerous methods that a plug-in implements to specify validity intervals in MAX. The modifier example above would do so in the method **Modifier::LocalValidity()**. For more information on Time in the SDK see the Advanced Topics section [Time](#). More information on intervals can be found in the topic [Intervals](#).

## Animation Controllers

All animation in 3ds max is managed by a plug-in type called an animation controller (or controller for short). Some controllers are keyframe based. This means the user sets the value of the controller at important (key) points in time and the controller provides all the values at other times by interpolating between the key values. Others are procedural, meaning the value is computed at a certain time based on a pre-programmed effect (for instance, the Noise controller uses a fractal function to compute the value).

There are six basic controller types based on the data type they control: floating point values (**float**), three float values (**Point3**), Position (**Matrix3**), Rotation (**Quat**), Scale (**ScaleValue**), and Transform (**Matrix3**). Using the SDK developers can create new controller types, or work with the properties of existing types. See the topic [Working With Controllers](#) for more information.

Many plug-ins use animated parameters, for instance the animated radius parameter of a procedural Sphere. 3ds max provides tools for developers wanting to use animated parameters that make them very easy to manage. Two of these are **Parameter Blocks** and **Parameter Maps**. Parameter Blocks provide a mechanism for storing values for a plug-ins parameters and managing the controller which handle the interpolation or generation of values. Parameter Maps are used to associated a control in the user interface of the plug-in with an animated value. See the Advanced Topics sections [Parameter Blocks and Maps in Release 3 and Later](#), [Parameter Maps](#) and [Parameter Blocks](#) for details.

## User Interface Issues

The user interacts with 3ds max mainly via the command panel rollups/dialogs, the mouse (or tablet), the keyboard, and the 3D viewports. The SDK provides developers with the ability to control each of these areas of user interaction.

Plug-Ins generally provide their user interface controls in one of three ways: In one or more of the Command Panel branches, in rollups which appear in the Materials Editor, Environment, or Render dialogs, or as modal or modeless floating dialogs. Many of the buttons, spinners, edit fields, etc. that appear in these dialogs/rollups are from the set of the 3ds max provided **Custom Controls**. These are used to make the UI of plug-ins consistent in appearance from one to another. For more information on these controls and how to work with them see [Custom User Interface Controls](#).

In addition to the custom controls, the mouse is used to interact with MAX. The way this type of interaction is handled in the SDK is through what are called **Command Modes**. For more information see the section [Command Modes and Mouse Procs](#).

Plug-ins can also make use of the keyboard to speed user interaction with their plug-in. This is done by registering what are called **Keyboard Accelerators**. These allow the user to execute some of their plug-in's functions by assigning them to keystrokes. For information on how this is done see the Advanced Topics section [Keyboard Accelerators and Dialog Messages](#).

Finally, plug-ins often need to draw in the 3D viewports to show themselves or their 'gizmos'. This is accomplished using the methods provided by the interactive renderer class GraphicsWindow. For information on the way to work with this renderer see [Interactive Renderer: Graphics Window](#).

## Functions Every Plug-In Must Provide

This section describes a set of five functions required by every plug-in DLL. It also outlines an object developers need to provide for each plug-in class.

Every plug-in developer needs to provide the code for the DllMain function and four Lib functions. Each is described briefly below:

### Function Called to Handle Initialization

**DllMain()** -- This function is the hook used by Windows to initialize the DLL. 3ds max plug-ins use it to initialize the common controls library and MAX's custom controls.

### Functions Used by MAX to Inventory and Categorize the Plug-ins in a DLL

These four functions describe the number and properties of the plug-ins provided by the DLL.

**LibNumberClasses()** -- This function returns the number of plug-in classes contained in the DLL.

**LibVersion()** -- This is a function that allows the system to deal with obsolete versions of plug-in DLLs.

**LibDescription()** -- This function returns a text string to present to the user if the DLL is unavailable.

**LibClassDesc()** -- This function returns a pointer to an object called a **Class Descriptor** for each plug-in class in the DLL. This Class Descriptor object describes the properties of each plug-in class and a way to allocate an instance of the class in memory. The next section describes these Class Descriptors.

### Creating and Classifying Instances of Plug-In Classes

The **Class Descriptor** described above is an object derived from class **ClassDesc**. It has several important purposes. The two main ones relate to classifying the type of object the plug-in is, and allocating the memory for instances of the plug-in objects. The full details of Class Descriptors are described elsewhere but three important methods are described below.

Plug-ins of all types create 3ds max system objects. These are not the 3D objects that appear in a scene, but objects in the C++ sense. There are two IDs associated with each plug-in system object. These are the Super Class ID and the Class ID. The Super Class ID specifies what super-class of 3ds max

the plug-in class is a sub-class of. The Class ID differentiates between the various plug-ins for a super-class. For example, a Sphere object has a Class ID, **unique** to it. This is simply an ID generated using a program provided by the SDK that uniquely identifies the plug-in class (it is in `\MAXSDK\HELP\GENCID.EXE` -- [Click Here to Try It](#)). Its Super Class ID, which is shared by all geometric primitives, is **GEOMOBJECT\_CLASS\_ID**. The Super Class IDs are defined by MAX, and each plug-in falls into one of these predefined categories. For instance, all Texture Map plug-ins share the same Super Class ID of **TEXMAP\_CLASS\_ID**. Each individual texture map plug-in has its own unique Class ID however. Thus, the Super Class ID defines which kind of object it is, the Class ID uniquely identifies a specific plug-in class.

The Class Descriptor method **ClassDesc::SuperClassID()** returns the Super Class ID. The method **ClassDesc::ClassID()** returns the Class ID. Another function of the class descriptor is to allocate instances of the plug-in class. For example, when a 3ds max file is loaded which contains a procedural Sphere, 3ds max needs a way to create an instance of the Sphere plug-in. It calls a method of the Sphere's class descriptor (**ClassDesc::Create()**). See the next section for more on this method.

The functions outlined above are described in greater detail in the Advanced Topics section [DLL/Lib Functions and Class Descriptors](#).

### **The Memory Allocation and Deallocation of Plug-In Classes**

As discussed above, instances of plug-in classes are created by calling Class Descriptor's Create method (**ClassDesc::Create()**). This applies to all plug-in classes in the SDK.

The way this memory is freed varies based on the class the plug-in is derived from. Usually it is done by calling a method named **DeleteThis()** on the plug-in. In the classes that are part of the **Animatable** class hierarchy this is a method of **Animatable**. So for these plug-ins, the memory is allocated by **ClassDesc::Create()** and deallocated by **Animatable::DeleteThis()**.

For other plug-ins that are not derived from **Animatable**, the plug-in class itself may provide a **DeleteThis()** method. For example, the **Bitmap** class is not derived from **Animatable**. It however provides its own **DeleteThis()** method to deallocate the memory created by **ClassDesc::Create()**.

In other cases, memory is freed automatically by 3ds max itself when it is done with the plug-in. For example, the **ImageFilter** class used to create image processing effects for use in Video Post has its memory freed by 3ds max itself (by using the **delete** operator).

See the Advanced Topics section [Memory Allocation](#) for more details.

## Summary

This topic has provided a look at some of the fundamental issues developers need to understand to create 3ds max plug-ins. The Advanced Topics sections in the SDK provide detailed information about many different aspects of the API. To review the relevant parts of the SDK that relate to a certain plug-in type see the section [Must Read Sections by Plug-In Type](#).

# Moving from IPAS to MAX Plug-In Development

See Also: [Plug-In Types Overview](#), [Plug-In Architecture Overview](#).

## **Overview**

This topic is provided as an aide to IPAS programmers making the transition to 3ds max plug-in development. This section discusses the similarities and differences in the IPAS and 3ds max programming architectures. The changes in development environment, plug-in/system control flow, user interface, and graphics programming support are reviewed. This section also discusses the six types of IPAS routines possible under 3D Studio DOS and how they may be implemented under the 3ds max plug-in architecture.

## **Development Environment**

IPAS routines were developed in 3D Studio DOS using the C programming language with the MetaWare or Watcom compilers. In MAX, development is done using the C++ programming language with Microsoft Visual C++ 5.0 under Windows NT. The 3ds max architecture is an object-oriented system that provides a comprehensive set of classes that developers can combine and extend to create seamlessly integrated plug-in applications. See the section [Writing Plug-In Applications](#) for more information on the basics of 3ds max development.

## **Control Flow**

IPAS plug-ins would completely take over control of 3D Studio DOS. When the IPAS routine started it had exclusive control and maintained this control until the user exited the routine. This forced the user to leave the familiar program interface and work with a separate and different interface with each IPAS routine. This is not the case in 3ds max. Most 3ds max plug-ins are modeless in operation. This means their operation comes in and out of focus as the system requires processing on their part. The user is free to operate the remainder of the standard 3ds max interface even as the plug-in has its user interface up. In this way the user never leaves their familiar working environment.

## User Interface

3ds max provides a set of custom controls that provide a consistent user interface between the plug-in and the system. This provides a level of familiarity for users who often use many different plug-ins. See the Advanced Topics section [Custom Controls](#) for more details on user interface implementation in MAX.

IPAS provided a set of graphic functions that let developers access the screen directly and use standard dialogs. These were the GFX calls such as **gfx\_xorline**, **gfx\_c\_blitput**, and **gfx\_file\_selector**. Most of these functions were low level (get/put pixel, draw line, etc.), but there are also a number of higher-level interface routines, such as standard 3D Studio file selectors, material selectors and other commonly used dialogs. These capabilities are provided by 3ds max as well. Review the section [Interactive Renderer: Graphics Window](#) for details on the low level graphics routines supplied by MAX. For higher level interface routines such as access to standard 3ds max dialog boxes see the methods of the [Interface class](#). The Windows API is also often employed in graphics work in MAX.

IPAS also provided routines to access the mouse and change the cursor form. 3ds max provides mouse and cursor control using the **CommandMode** class. See the section [Command Modes and Mouse Procs](#) for more details on working with the mouse.

There were also GFX routines to access 3D Studio bitmap services (load / save bitmaps, re-size bitmaps, color-cut bitmaps, etc.). 3ds max provides a comprehensive set of bitmap management tools. For details see the section [Working with Bitmaps](#).

Many interfaces built in IPAS were created using the 3DE utility. This simplified the creation of dialog boxes and custom user interfaces. 3ds max uses the Visual C++ tools for creating its dialog boxes. These tools are more comprehensive and robust than 3DE. The section on [Custom Controls](#) provides an general introduction to this tool although you will want to consult the VC++ on-line help for more detail.

## Graphics Programming Functions

IPAS routines could make use of some SDK-supplied include files that provided utility functions such as linear algebra, quaternion algebra, and other common graphics programming functions. The 3ds max architecture provides a very comprehensive set of these tools as well. These standard classes are used throughout 3ds max programming. The following list of classes all provide various graphic / geometric programming support: [Class Point2](#), [Class Point3](#), [Class Matrix3](#), [Class Quat](#), [Class Color](#).

## **IPAS Plug-In Types as MAX Plug-Ins**

The following sections discuss how each of the six IPAS types may be implemented as a 3ds max plug-in. In many cases there is not an exact one-to-one correspondence due to the differences in the two architectures. On the whole however, IPAS developers will find the 3ds max APIs much more powerful, comprehensive and better integrated with the core program.

## **IXP - Image Processing Modules**

IXPs were used to create new images or modify existing ones in the video post data stream. They were also used to create special effects such as image blur, star filters and glows. In 3ds max these types of effects are achieved using Filter plug-ins. These plug-ins are derived from class [ImageFilter](#). Filters may be used as image modifiers, image compositors or as transition effects. The 3ds max capabilities for image processing plug-ins are much greater than their IPAS counterparts. Sample code may be found in the sub directories of **\MAXSDK\SAMPLES\POSTFILTERS** for example **ADD.CPP**.

## **PXP - Procedural Objects Modules**

This type of IPAS routine was usually used to create an object from an algorithm or to modify an existing object. In 3ds max this type of plug-in translates into a procedural object, or an object modifier, or a utility plug-in.

In 3ds max a procedural object is best suited to create an object defined by an algorithm. Geometric procedural objects are derived from [SimpleObject](#), or [GeomObject](#). Sample code for this plug-in type may be found in

**\\MAXSDK\SAMPLES\OBJECTS\SPHERE.CPP.**

To modify an existing object, the object space modifier plug-in type is appropriate. Sample code for an object space modifier may be found in

**\\MAXSDK\SAMPLES\MODIFIERS\BEND.CPP.**

Certain utility IPAS routines were created as PXPs. 3ds max also supports these utility plug-ins. Utility plug-ins are derived from [Class UtilityObj](#).

Sample code for this plug-in type may be found in

**\\MAXSDK\SAMPLES\UTILITIES\ASCIOUT.CPP.**

## **AXP - Animated Procedural Objects**

These plug-ins were used to create hard-to-animate objects such as particle systems and real world data. These procedures animated at render-time on a frame by frame basis.

Certain AXP types could be implemented in 3ds max as procedural objects (particles systems), atmospheric plug-ins (some types of smoke, vapor, and fog), or space warps.

Particle systems may be derived from classes [ParticleObject](#), and [SimpleParticle](#). Sample code may be found in **\MAXSDK\SAMPLES\OBJECTS\RAIN.CPP**. Particle-system type effects may also be created using the [Atmospheric](#) class.

Geometric procedural objects are derived from [SimpleObject](#), or [GeomObject](#).

Space warp plug-ins may be used to modify existing geometry in world space. These plug-ins are derived from [Modifier](#) or [WSMModifier](#).

## **SXP - Solid Texture Procedures**

The IPAS SXP routines were 3D functions that could be assigned as maps in the 3D Studio Material Editor. 3ds max provides similar but more-extensive capabilities for both 2D and 3D procedural textures, compositors and color modifiers. 3ds max also provides APIs to develop complete plug-in materials. The sample code for these plug-ins can be found in the directory **\MAXSDK\SAMPLES\MATERIALS.**

## **KXP - Keyframe Procedures**

These IPAS routines were typically used to create or modify keyframe data of objects in the keyframer. In MAX, controller plug-ins are used to manage animation. See classes [Control](#) and [StdControl](#). Sample controller code is available in

**\MAXSDK\SAMPLES\HOWTO\PCONTROL\PCONTROL.CPP.**

There is also an interface into the Linear, TCB, or Bezier key frame controllers that allows a developer to add, delete, retrieve and store the keys of the controller. See [Class IKeyControl](#).

## **BXP - Bitmap Loading / Saving Procedures**

BXP plug-ins were used to provide extended image file loading and saving support. These image loader / saver plug-ins are called IO modules in MAX. These plug-ins are derived from class [BitmapIO](#). Sample code for these plug-in may be found in the sub-directories of `\MAXSDK\SAMPLES\IO`, for example `\MAXSDK\SAMPLES\IO\BMP.CPP`.

## Summary

This section presented an overview of the similarities and differences between the IPAS and 3ds max plug-in architectures. 3ds max provides a powerful development system for creating plug-ins that are tightly integration with the core program. IPAS developers are encouraged to implement their plug-ins using the standard 3ds max types in order to provide the best integration with the system. For those plug-ins that simply don't fit within the 3ds max architecture, the Utility API is provided to allow these plug-ins to work in MAX.

You may find it helpful to review the section [Plug-In Types Overview](#) to see a summary of the general categories of 3ds max plug-in applications.

## Updating MAX 1.0 Plug-Ins to Work with MAX 2.x

See Also: [What's New in the MAX 2.0 and 2.5 SDKs.](#)

## Overview

This section discusses some changes in the SDK APIs from 3ds max 1.0 to 2.0 or 2.5. Developers need to be aware of these changes as old plug-ins won't compile or operate properly unless they are made. The changes are broken down into specific areas that have changed. Some general notes related to all plug-ins appear at the beginning of this topic. For a brief overview of the API additions and changes for r2 see the section [What's New in the MAX 2.0 and 2.5 SDKs](#). Note that this section does not present all the areas of change -- only those where the change will prevent the plug-in from compiling/linking/executing under 3ds max 2.0.

## Recompilation

Plug-Ins that were developed for use with 3ds max 1.0 will need to be recompiled using the 3ds max 2.0 SDK in order to run. The **LibVersion()** function will prevent older plug-ins from running in 3ds max 2.0. These plug-ins will display the message:

**DLL <full pathname> is an obsolete version - not loading.**

In some cases a simple recompilation is all that is required. In other cases changes must be made. Developers need to be aware of the following changes to the API that affects their ability to run in 3ds max version 2.

Note: The **LibVersion()** method has been expanded to include information about the current version of MAX, the SDK, and the API. See the Advanced Topics section on [DLL Functions and Class Descriptors](#) for details.

**Also Note:** Generally, plug-ins developed for 3ds max 2.0 will run without recompilation on 3ds max 2.5. The only exception to this are those that use the NURBS API. Significant changes have taken place in the NURBS API and thus a recompile is required. If your plug-in **#includes** either **SURF\_API.H** or **TESSINT.H** (and you're using them, of course) you'll need to recompile. If you don't include these files, your plug-in developed for 3ds max 2.0 will run without problems on 3ds max 2.5 without recompilation.

## Development Environment

To use the 3ds max SDK you need to use the same version of the same compiler that is used to compile MAX. There are several reasons for this. The first reason is name mangling. Developers need a compiler with an identical name mangling scheme. The second reason is memory management. The plug-ins need to use the same memory manager as MAX.

Developers need to use Visual C++ Version 5.0 for developing plug-ins for 3ds max 2.0. The use of **any** previous version of VC++ is not supported.

Loading an existing project into VC++ 5.0 will attempt to convert it to the new format. If this process fails for some reason, or to build a new project from scratch, see the section [Creating a New Plug-In Project](#) for the proper settings.

## Checking the Current Version of MAX at Runtime

Developers should be aware that they cannot call methods provided in later versions of the 3ds max API from an earlier version of MAX. This can happen, for example, if a user tries to run a 3ds max 2.5 plug-in on 3ds max 2.0. The plug-in will load just fine, but the 2.5 specific functions would not exist. Developers can do something like the following to check the running version of MAX:

```
DWORD v = Get3DSMAXVersion();  
int r = GET_MAX_RELEASE(v);  
if (r >= 2500) {  
// Code that requires 2.5 API here  
}
```

## **New Parameters of Existing Methods**

Developers should watch out for the case where existing virtual methods have had new parameters added to them. This results in the compiler not seeing the new methods as being implemented. Rather the existing implementation of the method is just seen as a method of the sub-class. Instances of this are rare, however cases where new parameter have been added to existing methods are noted in the documentation for the methods.

## Passing Along Mouse Messages in Dialog Procs

In 3ds max 2.0 a change was made in the rollup window message handling so that the right mouse button menu works in all rollups. Developers can now remove the code from their dialog procs that passes the mouse button and move messages into **Interface::RollupMouseMove()**. For example, in 3ds max 1.x developers needed to pass along **WM\_LBUTTONDOWN**, **WM\_LBUTTONUP**, and **WM\_MOUSEMOVE** messages to MAX. This is no longer required. So, code such as the following can be removed from any dialog procedures.

```
case WM_LBUTTONDOWN: case WM_LBUTTONUP: case
WM_MOUSEMOVE:
    theUtility.ip->RollupMouseMove(hWnd, msg, wParam,
lParam);
    break;
```

To implement the change the **DWL\_USER** slot was used in the RollupPanel's window to store a pointer to the RollupPanel. This works fine with most plug-ins, which use **GWL\_USERDATA** to store a pointer to their context. Developers must be aware that if they are developing any code that uses **DWL\_USER** for a RollupPanel dialog proc to store its context, change it to use **GWL\_USERDATA**. There is a test in place to detect this which will put up an alert when the rollup is initialized, saying "Rollup Window Procs must use GWL\_USERDATA, not DWL\_USER", so developers breaking this rule will be informed pretty quickly.

## Working with the New Object Snap System

Developers who implement creation procedures for their plug-in that call **ViewExp::SnapPoint()** should add a call to **ViewExp::SnapPreview()** to their code where the **MOUSE\_FREEMOVE** message is processed. This allows the user to get proper visual feedback about object snaps that are in effect. See the Advanced Topics section on [Snapping](#), specifically the section 'Handling Snap Preview and Point Snap in Creation Procedures' for more details. Developers who don't do this will get snapping to occur in their plug-ins but won't get the visual feedback.

## Bitmap Memory Management

Previously bitmaps were deleted using the delete operator. This has changed. The bitmap class now has a **DeleteThis()** method that must be used to delete all bitmaps. For example, previously code to create a bitmap and delete it that looked like this:

```
Bitmap *bmap = TheManager->Create(&bi);  
// Do something...  
delete bmap
```

This is now written as follows:

```
Bitmap *bmap = TheManager->Create(&bi);  
// Do something...  
bmap->DeleteThis();
```

If you attempt to do it the old way you'll get a error message during compilation similar to **'Bitmap::~~Bitmap' : cannot access private member declared in class 'Bitmap'**.

## Space Warp Plug-Ins

It is important to note that source code examples in the 1.x SDK had the **space warp helper object** returning 1 from the **ClassDesc::IsPublic()** method. This indicated that the helper was available for use not just by the plug-in itself but by anyone. This was incorrect. However there was no user interface available to allow the user to choose and run these plug-ins independently so it was never caught as an error. With the new space warp architecture there is. Thus, the **ClassDesc::IsPublic()** method must return 0 instead of 1 for space warp helper objects to prevent the user from creating them without the space warp itself.

## Automatically Turning On Mapping Coordinates in Procedural Objects

The 3ds max renderer and plug-in procedural objects now support the ability to automatically turn on mapping coordinates when they are needed but aren't available. In 3ds max 1.x, if the renderer needed mapping coordinates for an object, and the 'Generate Mapping Coordinates' check box wasn't on, or a mapping modifier was not applied, an error message was presented to the user. In 3ds max 2.0 the renderer can request that the object turn on mapping coordinates itself and thus avoid having to put up the error message.

Procedural object plug-ins need to implement a few methods (**Object::HasUVW()** and **Object::SetGenUVW()**) to provide this capability. See the documentation for these methods in [Class Object](#) for more details.

## Supporting the Second Mapping Channel

In 3ds max 2.0 and later there are now two channels of mapping coordinates that can be assigned and carried by a mesh. This lets the user have two different sets of mapping coordinates, simultaneously, on the same face. Developers of plugins that provide mapping coordinate support should now also support the new second mapping channel.

The second mapping channel is stored in the mesh in the same arrays as the color per vertex information. Thus, the second mapping channel vertex array is stored in the **Mesh** data member **VertColor \*vertCol**, and the face array is **TVFace \*vcFace**. The number of texture verts is **int numCVerts**.

For additional details see [Class Mesh](#).

## Supporting the Drag and Drop System

Drag and drop functionality has been expanded to include all map and material buttons -- including those in plug-in materials and texmaps. As a result, a 3ds max user can drag the button over a like button to display the Swap/Copy/Cancel dialog. Developers creating plug-in materials and texmaps, as well as plug-ins with UI controls with a bitmap or material/texmap need to implement code to work with drag and drop. There are several new or revised classes to support this system. For additional details see [Class DADMgr](#), [Class TexDADMgr](#), [Class MtlDADMgr](#), [Class DADBitmapCarrier](#), [Class ICustButton](#), [Class IDADWindow](#).

## Splines

Three methods have been removed from [Class Spline3D](#) and replaced with six others. The **InVec()** and **OutVec()** methods were giving direct access to the spline data via a reference. The way the spline vectors are stored inside the class has been revised and this could no longer be allowed. Instead, there are new **GetInVec()**, **GetOutVec()**, **SetInVec()** and **SetOutVec()** methods. Also, all the data has been moved into the **private:** section to prevent improper access.

Developers using the **InVec()** methods will either be using it on the left side of the = or the right side. The changes that must be made are as follows:

Left Side of = (lvalue)

Example:

```
InVec(i) = Point3(0,0,0);
```

Change To:

```
SetInVec(i, Point3(0,0,0));
```

Right Side of = (rvalue)

Example:

```
Point3 p = InVec(0);
```

Change To:

```
Point3 p = GetInVec(0);
```

Also, the **KnotPoint()** method has been replaced. This is part of a larger series of changes which have made working with spline shapes much faster. By removing the direct access of the reference-returning methods, the **Spline3D** class will be able to control caching of various data within itself, preventing time-wasting repeated operations computing bezier control points. The **KnotPoint()** method has been replaced by two new methods:

```
Point3 GetKnotPoint(int i);
```

```
void SetKnotPoint(int i, Point3& p);
```

## ShapeObjects

**ShapeObjects** are now renderable. In order to accomplish this, they are now subclassed off of **GeomObject** rather than **Object**, as they were in previous versions. They are still **SHAPE\_CLASS\_ID** objects, though.

This has introduced a couple of important ramifications. See the remarks at the top of [Class ShapeObject](#) for the details.

## PatchMesh

The **PatchMesh** class has been updated so that it can contain multiple texture mapping channels, like the **Mesh** class. Unlike the **Mesh** class, however, the second texture mapping channel is stored in a new, second array member of the **PatchMesh** members, which are now defined as:

```
int numTVerts[PATCH_TEXTURE_CHANNELS];  
UVVert *tVerts[PATCH_TEXTURE_CHANNELS];  
TVPatch *tvPatches[PATCH_TEXTURE_CHANNELS];
```

At present, **PATCH\_TEXTURE\_CHANNELS** is defined as **2**, specifying the two texture mapping channels available. This could be extended in future versions, so keep this in mind.

Operations remapping texture patch information should perform the operations on all texture channels. See the file

**\MAXSDK\SAMPLES\MODIFIERS\EDITPAT.CPP** for examples.

All texture-mapping-related methods within the **PatchMesh** class have been adapted to deal with the new mapping channel. The old methods all access channel 0, to retain backwards compatibility. To access channels other than zero, new methods with "Channel" at the end of their names have been added:

## **NURBS**

The original 3ds max 1.x NURBS classes have been replaced in the SDK. Developers can get an overview of the new NURBS API by reading the section [Working with NURBS](#).

## Particle Systems

Several new methods have been added to class **ParticleObject** in 3ds max 2.0. These methods have default implementations but in order for the particle system to participate in Motion Blur when rendering these methods need to be implemented. These methods are: **ParticlePosition()**, **ParticleVelocity()**, **ParticleSize()**, **ParticleCenter()**, **ParticleAge()**, and **ParticleLife()**. See [Class ParticleObject](#) for details.

Also, the methods **CollisionObject::CheckCollision()** and **ForceField::Force()** both have a new parameter (**int index**), which is the index of the particle being forced or collided. See [Class CollisionObject](#) and [Class ForceField](#).

## Plug-Ins With an Interface in Track View

Plug-Ins that provide a user interface in Track View themselves will need to implement several new methods of [Class Animatable](#). These methods are all marked 'This method is available in release 2.0 and later only', and the methods themselves discuss the changes.

Track View has changed a bit. It now remembers the open/close state of the hierarchy as well as the selected/deselected state of the animatables. This information is saved with each Animatable in the data members maintained by the class:

**DWORD tvflags1, tvflags2;**

For example, several methods now have an additional parameter that specifies which Track View the method deals with.

There are other new methods that deal with the increased copy/paste functionality in R2 as well.

## Custom Creation Plug-Ins

In 3ds max 2.0 when a new object is created, if the hide by category flag for that object type is set to hidden, it is reset to visible before the object is created. In order to unhide a category (object, lights, particle systems, etc.) when an entity of that type is created, code was added to the creation routines of entities that don't use the default creation methods.

Making the required changes is simple. Just add the following statement during the first mouse down during creation:

```
GetCOREInterface()->SetHideByCategoryFlags(  
    GetCOREInterface()->GetHideByCategoryFlags() &  
    ~HIDE_X));
```

Where, **\_X** is **\_OBJECTS**, **\_LIGHTS**, etc. (or ~

**(HIDE\_OBJECTS|HIDE\_PARTICLES)** for particle systems.

Anyone moving custom-creation plug-ins from 3ds max 1.x to 2.x should add this functionality.

## Scaling Parameter Values

There is a new virtual method of **ReferenceMaker** named **RescaleWorldUnits(float f)**. Its purpose is principally to allow conversion of units between different unit scales (for instance centimeters to inches) when merging files.

What it is meant to do is to multiply any parameter that is expressed in world units by the scale factor **f**. This applies to things like a sphere's radius, a cylinder's radius and height, a control point position, etc.

To make this method work everywhere in 3ds max is going to require all plug-in developers to make sure it is implemented for their classes. In many cases the default implementations will work without change.

To detect if an object (or modifier) is rescaling correctly is simple:

- (1) Create the object and create a camera looking at it.
- (2) Render the camera view of the object.
- (3) In the Utility panel, bring up Rescale World Units utility, click "Rescale..." and set a scale factor to say 10. The "Affect" should be set to "Scene". Click OK. This will call **RescaleWorldUnits(10.0)** on the entire scene.
- (4) The camera view should have remained unchanged. Render it again to check.

Developers should check if your object/modifiers/space warp/whatever is rescaling correctly. If not, follow the steps below to make them do so.

The default **ReferenceMaker** implementation of **RescaleWorldUnits()** simply recursively calls **RescaleWorldUnits()** on the sub-references. (To avoid rescaling multiple instances more than once, a flag **A\_WORK1** is cleared before the whole process begins and is used to flag entities that have been rescaled.)

```
void ReferenceMaker::RescaleWorldUnits(float f) {  
    // This code should appear at the beginning of any  
    // RescaleWorldUnits implementation:  
    if (TestAFlag(A_WORK1))  
        return;  
    SetAFlag(A_WORK1);
```

```

// This code will be replaced in particular implementations
for (int i=0; i<NumRefs(); i++) {
    ReferenceMaker *srm = GetReference(i);
    if (srm)
        srm->RescaleWorldUnits(f);
}
}

```

The basic controllers have the method **RescaleWorldUnits()** implemented. Parameter blocks also have an implementation of **RescaleWorldUnits()** that will only rescale parameters for which the Param Dimension is **stdWorldDim**. (This is the value returned by **NotifyRefChanged()** in response to the **REFMSG\_GET\_PARAM\_DIM** message.) So if an object's parameters are all managed by a parameter block, making sure that **stdWorldDim** is returned only for those parameters which represent world units is all that need to be done. If some parameters are not handled by the parameter block, or there are some sub-references that you know need not be rescaled, you can implement **RescaleWorldUnits()**.

In certain cases, the default implementation for **ParamBlock::RedrawWorldUnits()** is not sufficient, or there may be conflict between your use of **stdWorldDim** and world unit rescaling. In this case, you will need to implement your object's **RescaleWorldUnits()** and use the method:

```

void IParamBlk::RescaleParam(int paramNum, float f)=0;

```

to rescale world unit parameters one at a time. For example, here is the **RescaleWorldUnits()** for the Fog atmosphere:

```

void FogAtmos::RescaleWorldUnits(float f) {
    if (TestAFlag(A_WORK1))
        return;
    SetAFlag(A_WORK1);
    pblock->RescaleParam(PB_TOP,f);
    pblock->RescaleParam(PB_BOTTOM,f);
}

```

In general it's pretty simple to get things scaling correctly. There can be some easy-to-miss subtleties, however. For instance, during 3ds max development

there appeared some anomalies in the shadows of scenes scaled by a large factor, and the fix involved scaling the shadow bias distance, which was overlooked. It's very important for plug-in developers to get this working across all entities so all developers should be careful in implementing this concept.

## Import / Export Plug-Ins

A change was made internally in 3ds max 2.0 that causes a bug in Export plug-ins. This bug will be addressed in a maintenance release, but for now, developers will need to make the following change in order for their description string to appear properly. Usually, this string is retrieved from a string table as in:

```
const TCHAR * AsciiExp::Ext(int n)
{
    switch(n) {
        case 0:
            return GetString(IDS_EXTENSION1);
        }
    return _T("");
}
```

This will be a problem in 3ds max 2.0 due to an internal change in the **ImpExp** code. The corrected code should just return the literal string, as in:

```
const TCHAR * AsciiExp::Ext(int n)
{
    switch(n) {
        case 0:
            return _T("ASE");
        }
    return _T("");
}
```

Developers should also be aware of one other change to these plug-in types.

There is a new parameter to the **SceneImport::DoImport()** and **SceneExport::DoExport()** methods. This is **suppressPrompts**. Developers of Import / Export plug-in may wish to respect this parameter to allow other 3ds max developers to use their plug-in for file IO (using **Interface::ImportFromFile()** and **ExportToFile()**). See [Class SceneImport](#) and [Class SceneExport](#) for details.

## Overview of the Principal Classes

This section lists the main classes of the SDK. The Overview hyperlinks take you to a brief summary of the methods of the class. The Reference hyperlinks jump to the full details on every method of the class.

## Overview Reference

[Animatable Class Animatable](#)  
[BaseObject Class BaseObject](#)  
[CameraObject Class CameraObject](#)  
[ConstObject Class ConstObject](#)  
[Control Class Control](#)

## Main Plug-In Classes

See Also: [Plug-In Types Overview](#), [Overview of the Principal Classes](#).

The following is a list of plug-in types and the classes from which they may be derived:

Atmosphere: [Class Atmospheric](#).

Cameras: [CameraObject](#), [GenCamera](#).

Construction Grid Objects: [Class ConstObject](#).

Controllers: [Class Control](#), [Class StdControl](#).

File Import: [Class SceneImport](#).

File Export: [Class SceneExport](#).

Image Filter / Compositor: [Class ImageFilter](#).

Image Loader / Saver: [Class BitmapIO](#).

Helper Objects: [Class HelperObject](#).

Lights: [Class LightObject](#), [GenLight](#).

Materials: [Class Mtl](#).

Modifiers: [Class Modifier](#), [Class SimpleMod](#).

Particle Systems / Effects: [Class SimpleParticle](#), [Class Atmospheric](#).

Patch Objects [Class PatchObject](#).

Procedural Objects: [Class GeomObject](#), [Class SimpleObject](#).

Renderer [Class Renderer](#).

Spline Shapes: [Class SimpleSpline](#), [Class SplineShape](#).

Sound Plug-Ins: [Class SoundObj](#).

Space Warps: [Class WSMObject](#), [Class WSMModifier](#).

Textures: [Class Texmap](#).

Utility: [Class UtilityObj](#).

# Interface Classes

See Also: [Overview of the Principal Classes](#), [Interface Classes Overview](#).

The following classes provides interfaces into 3ds max:

General Interface into MAX: [Class Interface](#), [Class IObjParam](#), [Class IObjCreate](#).

Access node properties: [Class INode](#)

Viewport related methods: [Class ViewExp](#)

Loading and Saving data: [Class ILoad](#), [Class ISave](#).

Enumeration of nodes in the scene: [Class IScene](#).

Interface passed to materials and textures: [Class IMtlParams](#).

Access to the 3ds max Track Bar: [Class ITrackBar](#).

Access to XRef objects: [Class IXRefObject](#).

Access to the Layers functionality provided by 3D Studio VIZ. [Class ILayer](#).

Interfaces into the standard 3ds max plug-ins:

Access to Procedural Object and Space Warps parameters - See the methods in [Class BaseObject](#):

```
virtual IParamArray *GetParamBlock();  
virtual int GetParamBlockIndex(int id);
```

For an overview of this process see [Object Creation Methods](#).

Access to derived objects: [Class IDerivedObject](#).

Access to the standard 3ds max controllers: [Class IKeyControl](#).

Access to the standard 3ds max text object: [Class ITextObject](#).

Access to 3ds max Standard material properties: [Class StdMat](#).

Access to the 3ds max Bitmap texture properties: [Class BitmapTex](#).

Access into MAX's default WAV sound object. [Class IWaveSound](#).

Access to the Spline Select Modifier: [Class ISplineSelect](#), [Class ISplineSelectData](#).

Access to the Editable Spline Object: [Class ISplineOps](#).

Access to the Patch Select Modifier: [Class IPatchSelect](#), [Class IPatchSelectData](#).

Access to the Editable Patch Object: [Class IPatchOps](#).

Access to the FFD Modifier and World Space Modifier: [Template Class](#)

[IFFDMod.](#)

Interfaces into the parameter blocks and maps:

Access to parameter blocks: [Class IParamBlock](#), [Class IParamBlock2](#).

Access to parameter maps: [Class IParamMap](#), [Class IParamMap2](#).

## Geometry / Bitmap Classes

See Also: [Overview of the Principal Classes](#).

Mesh / Face: [Class Mesh](#), [Class Face](#), [Class TVFace](#), [Class TriObject](#).

Bitmap Images: [Class BitmapInfo](#), [Class Bitmap](#), [Class BitmapIO](#), [Class BitmapManager](#).

2D and 3D Points: [Class IPoint2](#), [Class Point2](#), [Class IPoint3](#), [Class Point3](#)

2D and 3D Boxes: [Class Box2](#), [Class Box3](#).

Matrices: [Class Matrix2](#), [Class Matrix3](#), [Structure AffineParts](#).

Angles / Quaternions: [Class AngAxis](#), [Class Quat](#), [Class ScaleValue](#).

## User Interface Classes

See Also: [Overview of the Principal Classes](#), [The Interactive Renderer](#).

Access the interactive renderer: [Class GraphicsWindow](#)

Create custom mouse modes: [Class CommandMode](#), [Class MouseCallBack](#)

Parameter Blocks / Maps: [Class IParamMap](#), [Class IParamBlock](#), [IParamArray](#).

Custom Controls: , [Class ICustomControl](#), [Class ICustEdit](#), [Class ISpinnerControl](#), [Class ICustImage](#), , [Class ICustStatus](#), [Class IColorSwatch](#), [Class ICustButton](#), [Class ICustToolbar](#), [Class IRollupWindow](#), [Class IOffScreenBuf](#).

## Miscellaneous Utility Classes

See Also: [Overview of the Principal Classes](#).

Bit flags using array access [Class BitArray](#)

Unique plug-in Class\_ID [Class Class\\_ID](#)

Class Descriptor [Class ClassDesc](#)

Gamma / de-gamma conversion [Class GammaMgr](#)

Palette computation [Class Quantizer](#)

Packing colors into a palette [Class ColorPacker](#)

Simple character string class [Class CStr](#)

Wide character string class [Class WStr](#)

Table of names [Class NameTab](#)

Table template class [Class Tab](#)

Color picker dialog [Class ColorPicker](#)

## Reference Introduction

This module of the documentation is a reference to the classes provided in the SDK.

There are sections on typographic conventions, data types, and a structured class list organized by category.

At the beginning of each class is an overview of the purpose of the class. All the data members, methods and operators used by each class are documented.

## Typeface Conventions

This documentation uses the following typographic conventions:

### **Typeface Use**

**Sans Serif** Used for most text.

**Sans Serif Bold** Used for titles and headings.

**Monospace bold** Program text, variables, classes, types and other program constructs.

## Data Types

This section lists the data types most commonly used in the SDK. Some of these data types are defined by 3ds max while others are part of the Win32 API.

### **BOOL**

A boolean value, either TRUE or FALSE.

### **BYTE**

An 8-bit unsigned value.

### **CIRCLE**

The CIRCLE structure defines the x and y coordinates of the circle center and radius value. A CIRCLE data structure has the following form (defined in **GFX.H**):

```
typedef struct tagCIRCLE
{
    LONG x;
    LONG y;
    LONG r;
} CIRCLE;
```

### **COLORREF**

A 32-bit value used as a color value. See [COLORREF](#).

### **DWORD**

A 32-bit unsigned integer or the address of a segment and its associated offset.

### **HFONT**

The handle of a font.

### **HCURSOR**

The handle of a cursor.

### **HDC**

The handle of a device context (DC).

### **HIMAGELIST**

The handle to an image list.

### **HINSTANCE**

The handle of an instance.

### **HMENU**

The handle of a menu.

## **HPALETTE**

The handle of a palette.

## **LONG**

A 32-bit signed integer.

## **LPARAM**

A 32-bit value passed as a parameter to a window procedure or a callback function.

## **LPSTR**

A 32-bit pointer to a character string.

## **LRESULT**

A 32-bit value returned from a window procedure or callback function.

## **POINT**

The POINT structure defines the x and y coordinates of a point. A POINT data structure has the following form:

```
typedef struct tagPOINT {  
    int x;  
    int y;  
} POINT;
```

## **RECT**

The RECT structure defines the coordinates of the upper-left and lower-right corners of a rectangle. A RECT data structure has the following form:

```
typedef struct tagRECT {  
    int left;  
    int top;  
    int right;  
    int bottom;  
} RECT;
```

## **USHORT**

A 16-bit unsigned short integer.

## **SIZE**

This structure specifies the width and height of a rectangle. The rectangle dimensions stored in this structure can correspond to viewport extents, window extents, text extents, bitmap dimensions, or the aspect-ratio filter for some extended functions.

**typedef struct tagSIZE {**

**int cx;**

**int cy;**

**} SIZE;**

**ULONG**

A 32-bit unsigned long integer.

**WNDPROC**

A 32-bit pointer to a window procedure.

**WORD**

A 16-bit unsigned integer.

**LPARAM**

A 32-bit value passed as a parameter to a window procedure or callback function.

Other various typedefs and structures used in the SDK:

**typedef unsigned long ulong;**

**typedef unsigned char uchar;**

**typedef uchar UBYTE;**

**typedef unsigned short USHORT;**

**typedef unsigned short UWORD;**

**typedef int TimeValue;**

**typedef unsigned short BMMRES;**

**typedef ulong SClass\_ID;**

**typedef unsigned int RefMessage;**

**typedef unsigned short MtlID;**

**typedef unsigned long ChannelMask;**

**struct Color24 {**

**uchar r,g,b;**

**};**

**struct Color48 {**

**UWORD r,g,b;**

**};**

**struct Color64 {**

**UWORD r,g,b,a;**

```
};
typedef Point3 UVVert;
typedef Point3 VertColor;
typedef AColor RGBA;

typedef enum {IO_OK=0, IO_END=1, IO_ERROR=2} IOResult;
typedef enum {NEW_CHUNK=0, CONTAINER_CHUNK=1,
DATA_CHUNK=2} ChunkType;
enum RefResult {
    REF_FAIL,
    REF_SUCCEED,
    REF_DONTCARE,
    REF_STOP,
    REF_INVALID
};
enum LightType { OMNI_LGT, SPOT_LGT, DIRECT_LGT,
    AMBIENT_LGT };
typedef enum {IOTYPE_MAX=0, IOTYPE_MATLIB=1} FileIOType;

typedef unsigned long NURBSId;
typedef Tab<NURBSId> NURBSIdTab;
typedef Tab<BOOL> BoolTab;

typedef Tab<WVert *> WVertTab;
typedef Tab<WEdge *> WEdgeTab;
typedef Tab<WFace *> WFaceTab;

typedef DWORD HJOB;
typedef INT_PTR_MSVC70 StringResID;
typedef INT_PTR_MSVC70 ResID;
typedef Animatable* AnimatablePtr;
typedef DWORD ActionTableId;
typedef DWORD ActionContextId;
typedef DWORD HJOB;
typedef INT_PTR_MSVC70 StringResID;
typedef INT_PTR_MSVC70 ResID;
```

```
typedef Animatable* AnimatablePtr;  
typedef DWORD ActionTableId;  
typedef DWORD ActionContextId;
```

## General Terminology

This section defines various terms used throughout the SDK documentation.

## **What's New in the MAX 2.0 and 2.5 SDKs**

See Also: [Updating MAX 1.0 Plug-Ins to work with MAX 2.x.](#)

## Overview

This section provides a general overview of the new capabilities of the 3ds max R2 API. New classes have been added, new methods to existing classes have been added, and new parameters to existing methods have been added as well. Any new classes in the SDK begin their Description section with the line:

**This class is available in release 2.0 and later only** or

**This class is available in release 2.5 and later only.**

Any new methods in a class begin:

**This method is available in release 2.0 and later only** or

**This method is available in release 2.5 and later only.**

Newly added parameters to existing methods begin:

**This parameter is available in release 2.0 and later only** or

**This parameter is available in release 2.5 and later only.**

Newly added data members begin:

**This data member is available in release 2.0 and later only** or

**This data member is available in release 2.5 and later only.**

The sub-sections below list some of the major areas of improvement or new capabilities in the SDK. This includes new plug-in types available, some animation capabilities for ImageFilter plug-ins, and the G-buffer system. This section does not discuss all the changes -- only the major ones. Developers of existing 1.x plug-ins can look at the reference information for their plug-in class to review any new capabilities. Note that there is a separate section in the SDK which discusses how to get existing 3ds max R1 plug-ins to work with R2. See [Updating MAX 1.0 Plug-Ins to work with MAX 2.x](#) for details.

## New in the MAX 2.5 SDK

The major change to the 2.5 API is related to NURBS. The additional capabilities of NURBS system (such as projected curves, trimmed surfaces, etc.) have been made available via the SDK. Developers will need to recompile plug-ins that use the NURBS API to run on 3ds max 2.5 because of these significant changes. If your plug-in **#includes** either **SURF\_API.H** or **TESSINT.H** you'll need to recompile. If you don't include these files, your plug-in developed for 3ds max 2.0 will run without problems on 3ds max 2.5 without recompilation. See the Advanced Topics section [Working With NURBS](#) for information on the new classes available in 2.5.

Also enhanced for 3ds max 2.5 are the Minnesota Mesh and related classes. See [Class MNMesh](#) for details.

There are two new callbacks available via [Structure NotifyInfo](#) for pre-save and post-save notification.

## New Plug-In Types in MAX 2.0

### World Space Modifiers Without Helper Objects.

There is a new type of space warp plug-in that doesn't require a helper object to operate in world space. This was done because some plug-in modifiers needed to operate in world space, and thus needed to be space warps, but didn't require being bound to the dummy helper object. The new WSMs are available to be assigned like OSMs via buttons in the Modify branch of the command panel. They don't need to be specifically bound to a helper object to be created and assigned. 3ds max uses the **ClassDesc::IsPublic()** method to determine if they may be directly assigned. If **IsPublic()** returns nonzero they may be assigned by the user. If it returns zero then they depend on the helper object and can only be created when bound to the helper.

### Easily created WSM versions of OSMs

Modifiers derived **SimpleMod** may also be used to easily create a Space Warp version as well. See [Class SimpleOSMToWSMObject](#) for details on how this is done.

### Track View Utilities

There is a new type of utility plug-in that operate inside of Track View. These are accessed by pressing the Track View Utilities icon in the Track View toolbar. Samples of this type of utility are the 'Randomize Keys', 'Create Out of Range Keys' and 'Select Keys by Time'. These plug-ins are derived from [Class TrackViewUtility](#). See that class for more details on their creation.

### Front End Controllers

These new plug-ins allow a developer to completely take over the 3ds max user interface. This includes the toolbar, pulldown menus, and command panel. See [Class FrontEndController](#) for details.

### Motion Capture Input Devices

Motion Capture Input Device plug-ins can now be written that plug-in to the 3ds max motion capture system. See [Class IMCInputDevice](#) for details. Sample code is available in the subdirectory **\MAXSDK\SAMPLES\MOCAP**.

### Notification Program

There is a new program whose source code is in **\MAXSDK\SAMPLES\UTILTIES\nOTIFY\nOTIFY.CPP**. This program gets invoked by the network manager to handle network progress

notifications. The network manager calls it with two command line arguments as follows:

### **Notify.exe datafile type**

Where:

#### **datafile**

This is the fully qualified path and filename of the actual notification notice. This is the text that may be sent out as email, fax or whatever the notification program wants to do.

#### **type**

This is a numeric value indicating what type of notification this is. The types are defined in `\MAXSDK\INCLUDE\ALERTS.H`. The options are:

**NOTIFY\_FAILURE**

**NOTIFY\_PROGRESS**

**NOTIFY\_COMPLETION**

A developer may write another "Notify" program in order to do any proprietary type of notifications. Note that "Notify" can be either a "\*.exe", a "\*.bat", or a "\*.cmd" executable. This allows a user to create a simple script file to do something without having to resort to writing a binary program.

The current **Notify.exe** is very simple as it is used simply as a demonstration. It plays a different wave file for each of the event types. If invoked with no command line, it will bring up a dialog box asking the user to define each of the three wave files. The dialog has "Browse" buttons next to each wave file field which puts the user right into the Windows' "Media" directory where wave files are saved. There are also "play" buttons next to each sound so they can be tested.

## Animated Parameter in ImageFilter Plug-Ins

A new system has been provided to allow Filter plug-ins to use animated parameters. These parameters are just like the other parameters in 3ds max that are controlled by an animation controller. These parameters appear in Track View as a separate branch under 'World' labeled 'Video Post'. In order for this to work a developer must create something called a Track View Node. Controllers may then be added to this node. Using the **SetValue()** and **GetValue()** methods of the controller allow for values to be stored and retrieved.

Also, Filters may have interactive dialog boxes that may be open and operated at the same time as 3ds max and Track View. This allows a user to press the Animate button and adjust the properties of the filters parameters to animate the value. See [Class ImageFilter](#), [Class ImageFilterInfo](#) and [Class ITrackViewNode](#) for the new methods available.

## The G-Buffer System

Three new channels has been added to the G-buffer. These are **BMM\_CHAN\_COVERAGE**, **BMM\_CHAN\_BG**, and **BMM\_CHAN\_NODE\_RENDER\_ID**. See [List of Image Channels](#) for more details.

## **New Notifications (Callbacks)**

3ds max 2.0 supports a system where a plug-in can ask to receive a callback when events such as the system unit settings change, system time settings change, or the user executes File/Reset or File/New. The documentation for [Structure NotifyInfo](#) describes how this system works.

## New Mesh Related Classes

The **MNMesh** class is provided in 3ds max 2.0 for temporary use by plug-ins, to help with complex topology-based modifications to Meshes. It has capabilities, such as the ability to recognize faces with more than 3 sides, that are useful in certain applications. See [Class MNMesh](#) for details.

## **New NURBS API**

The NURBS API from 3ds max 1.0 has been replaced in 3ds max 2.0 and extended in 3ds max 2.5. Developers now have a more complete API for developing with NURBS. See the Advanced Topics section [Working With NURBS](#) for details.

## **New Pre and Post Save Callbacks**

For use with 3ds max 2.5 and later, two new options have been added for use with [Structure NotifyInfo](#). These allow plug-ins to get called before and after a 3ds max file is saved.

## **Network Rendering Manager Access**

There is a new Advanced Topics section that documents the protocol used to communicate with the network rendering manager. This is for developers who want to write their own Queue Manager and/or submit net render jobs on their own. This is not an SDK and there is no code -- it is just a detailed description of the TCP/IP protocol used to communicate with the manager. See the Advanced Topics section on [Network Rendering](#) for information.

## **Plug-In Project AppWizard**

New to the 3ds max 2.0 SDK is an AppWizard which may be used to easily create new plug-in projects. See the Advanced Topics section on [Creating a New Plug-In Project](#) for details on using the AppWizard.

## **On-Line Help Inside the Visual C++ IDE**

A program is provided in `\MAXSDK\HELP\SDKLINK.ZIP` to allow developers to launch the SDK help file and jump to a specific class or method from within VC++. See the **README.DOC** file inside that ZIP for a description for how to set this up inside the Developer Studio IDE.

# What's New in the MAX 3.0 SDK

See Also: [Required Changes to MAX 2.x Plug-Ins for MAX 3.0](#), [What's New in the MAX 2.0 and 2.5 SDKs](#), [Updating MAX 1.0 Plug-Ins to work with MAX 2.x](#).

## Overview

This section provides a general overview of the new capabilities of the 3ds max 3.0 API. New plug-in types, new classes, and new methods to existing classes have been added. In some cases new parameters to existing methods have been added as well.

Any new classes in the SDK begin their Description section with the line:

**This class is available in release 3.0 and later only**

Any new methods in a class begin:

**This method is available in release 3.0 and later only**

Newly added parameters to existing methods begin:

**This parameter is available in release 3.0 and later only**

Newly added data members begin:

**This data member is available in release 3.0 and later only**

The sub-sections below list some of the major areas of improvement or new capabilities in the SDK. This includes new plug-in types, new parameter map system, new texture map architecture, new keyboard accelerator system, as well as numerous other changes.

## New Plug-In Types

The following are the new plug-in types introduced in the 3ds max 3.0 SDK. Each has link to the base class for the creation of that plug-in type.

### Rendering Effects

There is a new item under the Rendering menu which displays the Rendering Effects dialog. From this modeless dialog, the user can select and assign a new class of plug-in, called a “Rendering Effect,” which is a post-rendering image-processing effect. This lets the user apply image processing **without** using Video Post, and has the added advantage of allowing animated parameters and references to scene objects. The base

class for these plug-ins is [Class Effect](#). Sample code is available in the directory `\MAXSDK\SAMPLES\RENDER\RENDEREEFFECT`.

### **Anti-Aliasing Filters**

There is a new plug-in type for filtering and anti-aliasing the image. Documentation for the base class for these filters is in [Class FilterKernel](#). Sample Code is available in the subdirectory `\MAXSDK\SAMPLES\RENDER\AAFILTERS`.

### **Shader Plug-Ins**

This new plug-in type works with the new Standard material. It allows plug-in developers to add additional shading algorithms to the drop down list of available options (previously Constant, Phong, Blinn, Metal). This was only possible previously by writing an entire Material plug-in (which could be a major undertaking). See the base class for this plug-in type [Class Shader](#) for details.

### **Sampler Plug-Ins**

This plug-in type works with the Standard material of release 3. A Sampler is a plug-in that determines where inside a single pixel the shading and texture samples are computed. The user interface of Samplers appears in the Super Sampling rollout in the Sampler dropdown. See [Class Sampler](#) for details.

### **Shadow Generator Plug-Ins**

The generation of shadows is now accessible via this new plug-in type. The standard 3ds max mapped and raytraced shadows have been revised to be plug-ins of this form. See [Class Class ShadowType](#) and [Class ShadowGenerator](#) for details. There is also a handy class for creating shadow map buffers. See [Class ShadBufRenderer](#).

### **Color Selector Plug-Ins**

This new plug-in type provides the user with a custom color picker that appears whenever a standard 3ds max color swatch control is clicked. These plug-ins are selected in the General tab of the Preferences dialog. The color picker chosen is saved in the 3DSMAX.INI file in the "ColorPicker" section so that the choice is maintained between sessions. If the DLL for the selected color picker is not available, it will always default back to the "Default" color picker. See [Class ColPick](#) for details.

### **Global Utility Plug-Ins**

These simple utility plug-ins are loaded at boot time, after initialization, but before the message loop starts, and remain loaded. This is how the new 3ds max COM/DCOM interface is implemented. For details see [Class GUP](#).

## Ready To Build Plug-In Projects

The 3ds max 4.0 SDK comes provided with an SDK appwizard that can be used with Microsoft Visual C++. This appwizard allows you to quickly generate skeleton source code for a variety of different plugin types and essentially replaced the previous R3\_SKELETON projects included in the previous release of the software.

The generated code from the appwizard provides a quick way to start building plugins. Each project follows a standard structure with regard to headers and code files. Developers should find it easy to take this generated code and can start creating plugins without manually setting up the entire project from scratch.

## New Example Code for R3 Programming Concepts

The SDK has sample code for demonstrating several programming concepts and exposed APIs introduced in R3. This code can be found in the sub-directories of **\MAXSDK\SAMPLESHOWTO\EXAMPLES**. The API exposed by the Morpher modifier is demonstrated in **MORPHERAPI**. In the directory **SCRIPTPLUGIN** is a utility that demonstrates SDK access to a scripted plugin's parameters. Code which demonstrates using the Custom User Interface APIs is in **CUI-TEST**.

## MAXScript SDK

The MAXScript SDK is a set of Visual C++ headers and import libraries that programmers can use to extend MAXScript. The MAXScript SDK source is now a part of the main 3ds max SDK source tree. It is available in the directory **\MAXSDK\INCLUDE\MAXSCRIPT**. In order to use the MAXScript SDK, you'll need to add **\MAXSDK\LIB\MAXSCRIPT.LIB** to your project and add **\MAXSDK\INCLUDE\MAXSCRIPT** to your preprocessor include directories. See the Advanced Topics section [MAXScript SDK](#) for documentation on this SDK.

There are two samples programs available in the directory

**\MAXSDK\SAMPLES\HOWTO\MXS\_SAMPLES.** These are **TESTDLX** and **MXSAGNI**. **TESTDLX** shows how to add new types of classes to MAXScript. It also shows how to add custom controls. The other is **MXSAGNI** which shows how to expose globals, struct globals, primitives and struct primitives. It also shows how to add new types of classes like BigMatrix, TrackViewPick, and Physique and Biped interfaces. There is also sample code in the SDK showing how to add a custom function to MAXScript, add a custom UI element, add a system variable and add a class. For this see the projects in **\MAXSDK\HOWTOR3\_SKELETONS\MAXSCRIPTSDK.**

## **COM/DCOM Interface**

The COM/DCOM interface available in 3ds max 3.0 may be used to load and save scenes, import files, and drive the 3ds max renderer. The interface for doing this is discussed in the Advanced Topics section [COM/DCOM Interface](#).

## **Deferred Loading of Plug-Ins**

3ds max 3.0 has introduced the concept of delay-loading plug-ins. In previous releases every plug-in was loaded at 3ds max load time. Now, certain plug-ins are only loaded as needed. This results in a smaller memory footprint for 3ds max and shorter load time at startup. The impact of this on developers is that the method **ClassEntry::CD()** may return a pointer to an instance of class **DataClassDesc** rather than a full **ClassDesc** as it did previously. This derived class implements **Create()** by returning NULL. Developers need to call **ClassEntry::FullCD()** in order to ensure that the class is actually there. See [Class DataClassDesc](#) and [Class ClassEntry](#) for information on these methods. For additional details on delay-loading see the Advanced Topics section [Deferred Loading of Plug-Ins](#).

## **New Parameter Map System**

The existing parameter map system remains for backwards compatibility but a new and improved system is available in the 3ds max 3.0 SDK. This system makes user interface coding even simpler than before and allows plug-ins to properly integrate with 3ds max 3.0's Macro Recorder, 3ds maxScript and Schematic View. For details on this system see the Advanced Topics section

## [Parameter Blocks and Maps in Release 3.](#)

### **Multiple Map Support**

New in 3ds max 3.0 is the ability to use more than two texture maps per face of a mesh. Now users may use up to 100. This has impacted how mapping coordinates are stored by the mesh as well as how the color per vertex data is stored. There are corresponding new methods in [Class Object](#) and [Class Mesh](#). Also see the Advanced Topics section [Working with Meshes](#) (Mapping Channels in Release 3.0 and Later) for additional information.

This has also affect Patches and NURBS. See the sections [Required Changes to Patch Related Plug-Ins](#) and [Required Changes to NURBS](#) for details.

### **Access to Scene XRefs and XRef Objects**

3ds max 3.0 introduces Scene and Object External References (XRefs). Scene XRefs are stored as complete hierarchies with the XRef scene's root node as a child of the client scene's root node. There are new methods in [Class INode](#) to access these Scene XRefs subtrees. There are also two new methods in [Class Interface](#) for controlling the scene node traversal. Object XRefs are derived from [Class IXRefObject](#) and this class provides access to the Object XRef parameters.

### **New G-Buffer Capabilities**

The G-Buffer has been significantly enhanced for R3. The concept of 'layers' has been added as well as four new channels. The multiple layers of the G-Buffer allow image processing effects to do better anti-aliasing and handling of transparency. The new channels are:

#### **BMM\_CHAN\_COLOR**

This is the color returned by the material shader for the fragment.

#### **BMM\_CHAN TRANSP**

This is the transparency returned by the material shader for the fragment.

#### **BMM\_CHAN\_VELOC**

This gives the velocity vector of the fragment relative to the screen, in screen coordinates.

#### **BMM\_CHAN\_WEIGHT**

This is the sub-pixel weight of a fragment.

See [Class GBuffer](#) and [List of Image \(G-Buffer\) Channels](#) for details.

## **New NURBS Related Classes**

The NURBS API has been extended and altered in release 3.0. The primary change has been in the way texture surface are handled. See the sub-topic **Texture Mapping** in the [Working with NURBS](#) topic for an overview of the classes. Also see the section [Required Changes to NURBS Related Plug-Ins](#) for an overview of the other changes. The new classes introduced in release 3.0 are:

[Class NURBSTextureChannelSet.](#)

[Class NURBSTextureChannel.](#)

[Class NURBSTexturePoint.](#)

[Class NURBSSurfaceEdgeCurve.](#)

[Class NURBSFilletSurface.](#)

[Class NURBSProceduralCurve.](#)

[Class NURBSProceduralSurface.](#)

## **Access to the File Properties Data**

The 3ds max File Properties dialog allows a user to enter various information to be stored in the 3ds max file. Developers can access this information via the SDK. Methods of class Interface provide this access (see the [PropertySet methods of Class Interface](#) for details). There is a sample project in the SDK which demonstrates how this is done. See the code in

**\MAXSDK\SAMPLES\UTILITIES\PROPERTYTEST\PROPERTYT**

## **New Notifications (Callbacks)**

The SDK provides a notification system where a plug-in can ask to receive a callback for events such as the user executing File/Reset, changing the viewport layout, rendering the scene, etc. There are several new types of notifications codes that may be registered in R3. The documentation for [Structure NotifyInfo](#) and [List of Notification Codes](#) describes them.

## **Ability For Non-3D Windows to Appear in a 3ds max Viewport**

Programs that want to have their user interface appear in a 3ds max viewport (much like Track View and the Asset Manager do) can now accomplish this. See [Class ViewWindow](#) for details.

## New Keyboard Shortcut System

This new system is used to register keyboard shortcuts in a uniform manner. In 3ds max 3.0 in the Customize / Preference Settings / Keyboard tab dialog there is a section to assign Plug-In shortcuts to commands. For details on how this works see [Keyboard Shortcut System](#). Sample code is available in the directory `\MAXSDK\SAMPLES\MODIFIERS\FFD`.

## New Custom User Interface API

3ds max now allows users to customize the user interface. There is an API that allows developers to do some customization as well. Developers can create their own custom toolbars and tab panels which may be docked or floated. The buttons can run 3ds max keyboard commands and execute 3ds max script commands in addition to the usual custom toolbar functionality (icon buttons, flyoffs, etc.)

There is a sample program in the SDK which demonstrates the use of these API. It's in `\MAXSDK\SAMPLES\HOWTO\EXAMPLES\CUI-TEST`.

Follow the instruction in the comments at the top of the code to build and run this plug-in.

The main classes used in working with the custom UI are:

### [Class ICustToolbar](#)

This existing class has been enhanced to support the new CUI functionality. Toolbars may now support multiple rows, or appear vertically. They may also have macro buttons (added with the **MacroButtonData** class) which may have icons or text.

When a Toolbar is part of a CUI frame it's called a Tool Palette. Tool Palettes can either float or dock (whereas a Toolbar must be placed by the developer in a dialog using the resource editor). When you want to create a Tool Palette you create a Toolbar (as before) and then you create a **CUIFrame** and then link the two using a method of **CUIFrame**.

### [Class MacroButtonData](#)

A Macro Button is a button which can execute either a keyboard macro or a MAXScript macro. This class contains the data and access methods for such a UI button.

### [Class ICUIFrame](#)

This class provides access to the individual windows (frames) that contain the toolbars, menus, etc.

### [Class CUIFrameMgr](#)

There is one instance of the **CUIFrameMgr** and it controls the overall operation of the individual CUI frames. This class has methods for things like docking a tool palette, bringing up the toolbar right click menu, and returns button IDs and window handles.

### [Class CUIFrameMsgHandler](#)

Since the CUI frame is just a window, it needs a window proc. There is one built into the CUI system, but certain frames may need additional information that is specific to how the frame is being used. For example, the command panel is a CUI frame which can't be resized horizontally. To manage this, the application must install a **CUIFrameMsgHandler** object. This class has one method, **ProcessMessage()**.

### [Class CUIPosData](#)

This is the object that provides the position data when the **CUIFrameMsgHandler::ProcessMessage()** method receives a **CUI\_POSDATA\_MSG** message. The developer creates an instance of this class and implements the **GetWidth()** and **GetHeight()** methods which return size information based on the size type and orientation passed.

### [Class ToolMacroItem](#)

This class allows a Macro button control to be added to the toolbar.

### [Class MacroDir](#)

This class provides access to Macro scripts. Macro scripts (or macros) are scripts that live in buttons and menus in the customizable UI. Methods of this class are available to access macros using IDs or category and name strings, methods to edit macro scripts, methods to execute macros, and methods for directory scanning and loading.

### [Class MacroEntry](#)

This class provides access to a single macro entry. There are methods

provided to access the macro ID, name, category, file name, tooltip, UI button text, and the UI button icon. MacroEntries are returned from methods of class **MacroDir**.

## **New Custom Slider and Curve Controls**

There is a new custom horizontal slider control. This control is functionally similar to the custom spinner control with a few handy features. An example of this control can be seen in the Color Balance Render Effect. See [Class ISliderControl](#) for details.

There is also a new custom curve control. An example of this control in the 3ds max user interface can be seen in the Color Map section of the Output rollup of a 2D Texture map. Sample code using these APIs is available in `\MAXSDK\SAMPLES\UTILITIES\CCUTIL\CCUTIL.CPP`. See [Class ICurveCtl](#) for reference information.

## **New RightClickMenuManager Methods**

These new methods let plug-ins add sub-menus to the viewport right-click menu. Developers can call the methods

```
int BeginSubMenu(LPCTSTR name);
```

```
int EndSubMenu();
```

to start and end sub-menus. See [Class RightClickMenuManager](#).

## **Access to the Track Bar**

Directly below the time slider is a new Track Bar, which offers a quick way to manipulate keyframes for selected objects. Keys are displayed on the track bar just like they are in Track View. Developers have access to a class which may be used to manipulate the Track Bar. See [Class ITrackBar](#) for details.

## **New Multiple Viewport Enabled Mouse Proc**

This new mouse proc allows drawing in multiple viewports, offsetting from the construction plane, and orthogonal and angle snapping. This is the mouse proc that NURBS uses for curve creation. This allows developers to support orthogonal snapping and angle snapping on creation like the Bezier Line tool does. Also if the user presses Shift while dragging the mouse, the point is

snapped to the nearest quadrant (ortho snapping). If the Alt key is held, the point is snapped using the setting of the angle snap system.

Users of this mouse proc need to sub-class from the [Class DataEntryMouseProc](#) and implement some virtual methods to use it.

## **Ability to Replace the 3ds max Load and Save File Dialogs**

There are two new classes and two methods of **Interface** that allow developers to replace the load and save file dialogs with custom ones. See the methods:

**virtual void SetMAXFileOpenDlg(MAXFileOpenDialog\* dlg)=0;**

**virtual void SetMAXFileSaveDlg(MAXFileSaveDialog\* dlg)=0;**

in [Class Interface](#) for more information.

## **Schematic View API**

The Schematic View window allows users to review, and perform certain operations on, many of the objects that make up the scene. See the Advanced Topics section on [Schematic View](#) for an overview of the API. Developers have access to method for working with Schematic View as part of the following classes:

### [Class IGraphObjectManager](#)

This class represents an instance of a schematic view window and provides methods for adding nodes and node pointers, refreshing the schematic view, accessing filter bits and updating and controlling the various editors within 3ds max.

### [Class IGraphNode](#)

This represents a node in the schematic view graph and provides a few methods for querying information about the node.

### [Class IGraphRef](#)

IGraphRef represents a node pointer in Schematic View.

### [Class Animatable](#)

There is a set of methods in Animatable that can be overridden, all or in part, to specialize the behavior of the schematic view node(s) which represents the Animatable object.

### [Class SubClassList](#)

This existing class also has some Schematic View drawing related methods (**GetUIInfo()** and **SetUIInfo()**).

## **Random Number Generator**

There is a new class that may be used to generate pseudo-random number in either floating point or integer format within a specified range. Each instantiation of this class is independent, permitting several uncoupled random number generators to be present in the system at once. See [Class Random](#).

## **Macro Recorder API**

3ds max R3 introduced the concept of macro recording. The macro recorder generates MAXScript code for operations the user performs when running 3ds max. These scripts can then be played back to automate operations inside 3ds max. Since 3ds max is made up of plug-ins there needs to be a way that the plug-ins can record their own changes as the user operates them. This is the purpose of the Macro Recorder API.

Most common operations performed by a plug-in are handled automatically. For example the getting and setting of parameter block values automatically generates script for the Macro Recorder. In such cases a plug-in developer doesn't need to do anything. There are other operations that can't be handled automatically, however. For example a plug-in may have a button in its user interface that internally results in some looping. To generate code to record a loop the methods of **MacroRecorder** would be used. See [Class MacroRecorder](#).

## **Access To 3D Studio VIZ Layers**

For use with the layer capabilities of 3D Studio VIZ several classes have been added to the 3ds max API. See [Class ILayer](#) and [Class ILayerManager](#) for details.

## **New Methods for the IK Master Controller**

The new methods provide additional access to the controls. See [Class IKMasterControl](#).

## New and Revised Mesh Related Classes

The following classes track various aspects of an edit operation to a mesh. They are the principal means of keeping track of what's going on in the Edit Mesh modifier, and have many standard mesh edits available for use by other plug-ins.

### [Class MeshDelta](#)

This is a class that represent some kind of change to a mesh. This “delta” can include topological, geometric, map, and/or selection changes. Most standard mesh “edits” available in the Editable Mesh or Edit Mesh interface are available through the MeshDelta SDK, giving developers a powerful way to manipulate meshes while not having to “sweat the details” of maintaining maps to match the mesh changes, updating edge selections, etc.

### [Class VertMove](#)

This class represents the notion of a mesh edit vertex move. The public data members provide the index of the vertex moved as well as the amount of the move in X, Y, and Z.

### [Class UVVertSet](#)

This class represents the notion of a mesh edit UVW vertex assignment. The public data members provide the index of the vertex as well as the UVWVert.

### [Class FaceRemap](#)

This class represents the notion of a mesh edit Face Remap, which changes one or more of the verticies a face uses. It can also alter the visibiliy of the face's edge, its hidden state and its material ID.

### [Class FaceChange](#)

This class represents the notion of a mesh edit Face Change, which changes the visibiliy of the face's edges, its hidden state and/or its material ID.

### [Class FaceSmooth](#)

This class represents the notion of the edit mesh Face Smooth operation. This updates the smoothing group infomation in the face.

Similar to the above classes, but used for topological operations in the Edit Mesh modifier and Editable mesh are the classes below:

### [Class MeshDeltaUser](#) and [Class MeshDeltaUserData](#)

Both Edit Mesh and Editable Mesh have a current "state", which can be modified by MeshDelta objects. In Editable Mesh, this "state" is an actual

mesh, while in Edit Mesh, this is one MeshDelta per LocalModData. These are the two new classes which provide a standard interface to these.

#### [Class VDataDelta](#)

VDataDelta is simply a way for a MeshDelta to keep track of per-vertex information.

#### [Class MapDelta](#)

This class that represents some kind of change to a mesh map. This “delta” can include changes in map vertices and/or faces.

#### [Class MeshTempData](#)

This is a class for caching winged edge lists, face adjacency lists, face and edge clusters, vertex normals, and other derived data about a mesh.

#### [Class MeshChamferData](#)

This is a class to maintain chamfer information between several **MeshDelta** methods.

#### [Class EdgeClusterList](#)

This is a list of edge "clusters" for a given mesh. A typical application would be in Edit(able) Mesh, where the user has selected a two separate groups of edges on different parts of the mesh and wants to extrude them both, or rotate both around their local centers. Each "cluster" is a contiguous group of selected edges.

#### [Class UVWMapper](#)

Prior to release 3.0, developers could implement the **Object::ApplyUVWMap()** in their objects, but they haven't had access to the algorithm 3ds max uses to turn the mapping types (MAP\_BOX, MAP\_PLANE, etc) into an actual vertex-to-mapping-coordinate function. Now this is available as a class, **UVWMapper**. The mesh **ApplyUVWMap()** method has been changed to take advantage of this.

The **IMeshSelect** and **IMeshSelectData** classes have been extended to support the Editable Mesh and Edit Mesh modifier (not just the Mesh Select modifier).

#### [Class IMeshSelect](#)

This class provides access to the Editable Mesh object, Edit Mesh modifier and Mesh Select modifier selection-level data as well as a selection-change-notification method.

### [Class IMeshSelectData](#)

This class may be used to get and set the vertex, face, and edge selection state of the Edit Mesh or Mesh Select modifier.

## **New Interface Classes**

The following new interface classes provide access to various objects, modifiers, controllers etc.

[Class ISplineSelect.](#)

[Class ISplineSelectData.](#)

[Class ISplineOps.](#)

[Class IPatchSelect.](#)

[Class IPatchSelectData.](#)

[Class IPatchOps.](#)

[Template Class IFFDMod.](#)

# Required Changes To Geometric Objects

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

## Overview

This section discusses the changes to Geometric Objects. Note that not all these changes are required of every object. It depends on the type of object and whether the default behavior is undesirable. A brief description of the new or changed methods is provided here. Please refer to the reference section for the method for details.

## Mapping Methods

The new multiple mapping methods are for object which support mapping channels. These methods describe how many mapping channels are available and how many are currently used. Both are from [Class Object](#).

```
virtual int NumMapChannels();
```

```
virtual int NumMapsUsed();
```

## Counting Face and Vertex Quantities

There are many places in 3ds max that compute face and vertex counts of objects in the scene. For instance the object properties dialog, summary info, the polygon counter utility, and on file saving to write that info into the file. This was previously done by doing a **ConvertToType()** to a **TriObject** representation and counting up the faces and vertices. For certain object types, for instance NURBS, this could be very expensive since the code would need to re-tessellate the whole object. This would also consume a great deal of memory. There is now a new method in the **Object** class used to compute the number of faces and vertices in the mesh representation of the **Object**. This is:

```
virtual BOOL PolygonCount(TimeValue t, int& numFaces, int& numVerts);
```

Rather than doing a **ConvertToType()** many objects can simply iterate over their cached mesh to compute this. Geometric objects that represent themselves as a Mesh can also compute this quickly. Therefore developers of Geometric

objects that are mesh-based should implement this method. See [Class Object](#) for the details.

There is also a global function developers can call to get this information from any geometric object. It is:

```
void GetPolygonCount(TimeValue t, Object* pObj, int& numFaces, int& numVerts);
```

## Multiple Parametric Surface Access

Methods have been added for accessing multiple parametric surfaces within an object. Previously, only one surface within each object could be accessed. The new methods are:

```
virtual int NumSurfaces(TimeValue t);
```

```
virtual Point3 GetSurfacePoint(TimeValue t, int surface, float u, float v, Interval &iv);
```

```
virtual void SurfaceClosed(TimeValue t, int surface, BOOL &uClosed, BOOL &vClosed);
```

Please see [Class Object](#) for details.

## Access to Selected Point Information

Geometric Object which support the selection of points (verticies, control points, etc) can make the selection data available to other plug-ins via two new methods of [Class Object](#). These are:

```
virtual BOOL IsPointSelected(int i);
```

```
virtual float PointSelection(int i);
```

## Aborting Generating a Mesh

Geometric Object which implement **GeomObject::GetRenderMesh()** may wish to check for aborted renderings while they generate the render mesh. Some plug-ins do extensive calculations inside this method and to allow 3ds max to respond more rapidly to user abort requests these calculations should be stopped as soon as possible. By calling a methods of the **View** class,

**CheckForRenderAbort()**, inside of **GetRenderMesh()**, 3ds max can be made to feel all the more responsive. See [Class GeomObject](#) and [Class View](#) for

details.

## **IMeshSelectData Change**

The return types of the **GetVertSel()**, **GetFaceSel()** and **GetEdgeSel()** methods of the [Class IMeshSelectData](#) class have changed. They no longer return a reference to a **BitArray** but rather a **BitArray** itself.

## **Supporting AutoGrid**

AutoGrid allows for on-the-fly creation of a construction plane during another object's creation mode. This results in objects aligning to one another during creation. Objects which handle their own creation will need to add some code to their creation proc. To make it work you can do the following in the creation proc.

```
...  
case MOUSE_FREEMOVE:  
    vpt->TrackImplicitGrid(m);  
...  
case MOUSE_POINT:  
    if (point == 0)  
        vpt>CommitImplicitGrid(m, flag );  
...  
if( "returning" CREATE_STOP)  
    vpt>ReleaseImplicitGrid();
```

See [AutoGrid Related Methods](#) in class **ViewExp** for information on these methods.

## Required Changes To Particles

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### New Particle Methods

New methods have been added to the [SimpleParticle](#) class to set the position, velocity and age for an individual particle:

```
void SetParticlePosition(TimeValue t, int i, Point3 pos);
```

```
void SetParticleVelocity(TimeValue t, int i, Point3 vel);
```

```
void SetParticleAge(TimeValue t, int i, TimeValue age);
```

### Inter-Particle Collision

The 3ds max 3.0 SUPRPRTS particle systems support Inter Particle Collision (IPC). IPC is not built into the 3ds max core, or even into PARTICLE.DLL.

Rather, it's implemented at a relatively high level in SUPRPRTS. Developers of particle systems that want to support IPC will have to implement their own IPC system using the 3ds max code as an example. Also, see the

**CheckCollision()** method of [Class CollisionObject](#) which has two new parameter for IPC support.. The source code for SUPRPTRS is in the directory **\MAXSDK\SAMPLES\OBJECTS\PARTICLES**.

## Required Changes To Helper Objects

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

Any **ConstObject**-based classes will need to have their **GetSnaps()** method changed to return a **Point3**, not a **Point3&**.

## Required Changes To Light Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Atmospheres and Effects Rollup Support

Light plug-ins should use the new 'Atmospheres & Effects' rollup in their user interface. This is a new rollout that lets you assign Atmosphere and Render Effects to a selected light from the command panel. Note that you can do the same thing from within the Environment dialog or the Render Effects dialog, but this provides the controls for the light you're working on, and lets you easily see, just by selecting a light in the scene, if that light has an effect assigned to it.. See [Class Interface](#) and [Class Atmospheric](#) for details.

### Several New Methods of LightObject

There are a number of new light methods. See [Class LightObject](#) to review them.

### New Shadow Generator Plug-Ins

Lights may now have a corresponding shadow generator if desired. See the [What's New in the MAX 3.0 SDK](#) section discussing the new Shadow Generator Plug-in type or see [Class ShadowType](#).

## Required Changes To Atmospheric Plug-ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Atmospheric Gizmos

Developers may want to use the Atmospheres & Effects rollup which appears in some of the core 3ds max plug-ins. This is a new rollout that appears only in the Modify panel. (It does not appear when you create the atmosphere gizmo.) The items in the new rollout let you assign Atmosphere and Render Effects to a selected atmosphere gizmo from the command panel. Note that you can do the same thing from within the Environment dialog or the Render Effects dialog, but this provides the controls for the gizmo you're working on and lets you easily see, just by selecting a gizmo in the scene, if that gizmo has an effect assigned to it.

See [Class Interface](#) and [Class Atmospheric](#) for the required methods.

### Handling Undo for Adding and Deleting Gizmo References

Atmosphere plug-ins need to implement undo for the adding and deleting of gizmo references.

Below is a summary of what needs to be done:

Implement the **SpecialFX** methods **AppendGizmo()** and **DeleteGizmo()** to handle the undo. See [Class SpecialFX](#). There are helper classes for this purpose. See [Class AppendGizmoRestore](#) and [Class DeleteGizmoRestore](#).

Anywhere in the plug-in where a gizmo is deleted, it should call **DeleteGizmo()** so the undo will work uniformly. The **DeleteGizmo()** calls should be surrounded with **theHold.Begin** and **theHold.Accept**.

**AppendGizmo()** calls (for instance inside pick procs) should be surrounded by **theHold.Begin** and **theHold.Accept**.

Use code in **NotifyRefChanged()** to update any list box controls, where changes can happen due to an Undo. For example:

```
case REFMSG_SUBANIM_STRUCTURE_CHANGED:
case REFMSG_NODE_NAMECHANGE:
if (dlg) dlg->UpdateNames();
break;
```

## Required Changes To Snap Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

Snap plug-ins are now required to implement a **Osnap::Category()** method. Previously, if this method returned NULL, the snap was loaded into the default category. This is no longer true. Snaps which return NULL from this method will not be registered with the system. See [Class Osnap](#).

## Required Changes To Space Warps

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

There is a new method used as a way of identifying the 'parent' Deflector for a CollisionObject available to a particle system. This must be implemented by all Deflectors. It returns the object pointer to the Deflector from which the Collision object is derived. See **GetSWObject()** in [Class CollisionObject](#).

## Required Changes To File Import Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

File Import Plug-Ins have a single new method used to control how Zoom Extents is handled after a scene import takes place. See the method **ZoomExtents()** in [Class SceneImport](#).

## Required Changes To File Export Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

File Export Plug-Ins have a new parameter in the method **DoExport()** to support the export of only the selected nodes. There is also a related new method called **SupportsOptions()**. See [Class SceneExport](#).

Developers should also consider the implications of the new multiple texture mapping channels present in 3ds max 3.0. These will have an impact on what needs to be done to export a faithful visual representation of the scene. For more information see the Advanced Topics section on [Working with Meshes](#) as well as the section on **Multiple Mapping Channels** in the [What's New in the MAX 3.0 SDK](#) section.

## Required Changes To Plug-In Materials

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Change to BuildMaps

The method **MtlBase::BuildMaps()** has had its return value behaviour altered. If this method now returns zero the render is cancelled (previously rendering would continue).

### Maximum Pixel Size

The maximum pixel size preference has been removed from the UI and thus the following methods were removed from the **Interface** class.

**virtual float GetRendMaxPixelSize()=0;**

**virtual void SetRendMaxPixelSize(float s)=0;**

There are new methods in [Class RenderGlobalContext](#) to retrieve the filter and the filter size. These are **GetAAFilterKernel()** and **GetAAFilterSize()**.

### New Return Value from MapSlotType

There is a new value to be returned by the method **MtlBase::MapSlotType()** to identify slots that hold displacement maps. This is **MAPSLOT\_DISPLACEMENT**. Developers should modify their **MapSlotType()** method to return this new value for the displacement channel.

### API Modifications to Handle 3D Bump Maps

The following changes are needed to correct a problem with 3D bump maps when objects in the scene are scaled. This scaling results in a very noticeable inappropriate change in the bumping effect.

The problem is occurring when the bump perturbation vectors must be transformed from object space to camera space, so they are oriented correctly as the object rotates. If the object has been scaled, this transformation causes the perturbation vectors to be scale also, which amplifies the bump effect. What is needed is a way to rotate the perturbation vectors so they are correctly oriented

in space, without scaling them. To do a new method has been added to [Class ShadeContext](#).

**ShadeContext::VectorFromNoScale(const Point3& p, RefFrame ifrom);**

There is also a complimentary new method **VectorToNoScale()** added for completeness.

**ShadeContext::VectorToNoScale(const Point3& p, RefFrame ito);**

The coding ramifications of this are as follows:

- Any plug-in that creates a shade context in which materials are evaluated needs to implement these two new functions (**VectorFromNoScale()** and **VectorToNoScale()**). This applies to plug-in renderers and materials.
- A change is required related to loading old files by plug-in materials which support bump maps. This change is required since if nothing is done to modify old files, bump maps on scaled objects will not render as they did previously (the bump amount for scaled-up objects will become much less). When loading old files, the Standard material uses a post-load callback that looks to see if the node that references the material is scaled up, and if so, multiplies the bump amount by a similar factor. Note that if the material is used by more than one node, there's nothing that can be done to make them all render the same if they have different scales. The same is true if a node is scaled non-uniformly. A postload callback similar to the one the Standard material uses will have to be used by plug-in materials which support the use of bump maps.

# Required Changes To NURBS Related Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

## Overview

This section discusses the changes to the NURBS API that affects plug-ins. Note that not all these changes are required of every NURBS related plug-in. A brief description of the new or changed methods is provided here. Please refer to the reference section for the methods for details.

## New NURBS Texture Surface API

The API for NURBS Texture Surfaces has changes significantly to reflect the underlying change. This reflects a significant architectural change and will mean that users of the API will need to rebuild this functionality. See the subsection **Texture Mapping** in [Working with NURBS](#) for a list of the new or revised classes.

## Replaced or Eliminated Methods

Two methods have been removed from [Class NURBSExtrudeSurface](#). These are:

**void SetEVec(TimeValue t, Point3& evec);**

**Point3& GetEVec(TimeValue t);**

They are replaced by the methods:

**void SetAxis(TimeValue t, Matrix3& ray);**

**Matrix3& GetAxis(TimeValue t);**

## Tessellation Related Changes

The tessellation methods have changed in this release. This impacts several areas such as [Class NURBSSet](#) and [Class TessApprox](#). There are also some new tessellation related global functions available. See [Working with NURBS](#) to review these.

## Material IDs

Material IDs have been added to NURBS curves. [Class NURBSCurve](#) now has a new data member **int mMatID**.

## Required Changes To Textures Plug-In

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Using an XYZGen or UVGen

All 2D textures that use UVGen or otherwise select mapping channels need to implement the method **MtlBase::LocalMappingsRequired()**

Here is a typical implementation:

```
void LocalMappingsRequired(int subMtlNum, BitArray &  
mapreq, BitArray &bumpreq) {  
    uvGen->MappingsRequired(subMtlNum,mapreq,bumpreq);  
}
```

All 3D Textures that use the XYZGen to put up a coordinates rollup must now implement the new **MtlBase::LocalMappingsRequired()** method

An example is shown below:

```
void LocalMappingsRequired(int subMtlNum, BitArray &  
mapreq,BitArray &bumpreq) {  
    xyzGen->MappingsRequired(subMtlNum,mapreq,bumpreq);  
}
```

Materials that need bump mapping for certain channels also need to implement this function so they can set the bits in **bumpreq** for those channels.

### GetUVWSource Return Values

The method **Texmap::GetUVWSource()** returns a value indicating where to get the texture vertices. One of the options has changed meaning. The value **UVWSRC\_EXPLICIT2** has been changed to always mean the vertex color channel.

### New GetMapChannel Method

There is a new method in Texmap related to the new mapping channels, **GetMapChannel()**. This method returns the map channel being used when

**GetUVWSource()** returns **UVWSRC\_EXPLICIT**.

## List of Material Requirement Flags

The old material requirement flags returned from the **MtlBase::Requirements()** method **MTLREQ\_UV**, **MTLREQ\_UV2**, **MTLREQ\_BUMPUV**, and **MTLREQ\_BUMPUV2** are still recognized by the renderer for backwards compatibility, but they will probably go away at some time. See [Class MtlBase](#) for details.

## Maximum Pixel Size

The maximum pixel size preference has been removed from the UI and thus the following methods were removed from the **Interface** class.

**virtual float GetRendMaxPixelSize()=0;**

**virtual void SetRendMaxPixelSize(float s)=0;**

There are new methods in [Class RenderGlobalContext](#) to retrieve the filter and the filter size. These are **GetAAFilterKernel()** and **GetAAFilterSize()**.

## API Modifications to Handle 3D Bump Maps

The following changes are needed to correct a problem with 3D bump maps when objects in the scene are scaled. This scaling results in a very noticeable inappropriate change in the bumping effect.

The problem is occurring when the bump perturbation vectors must be transformed from object space to camera space, so they are oriented correctly as the object rotates. If the object has been scaled, this transformation causes the perturbation vectors to be scale also, which amplifies the bump effect. What is needed is a way to rotate the perturbation vectors so they are correctly oriented in space, without scaling them. To do a new method has been added to [Class ShadeContext](#).

**ShadeContext::VectorFromNoScale(const Point3& p, RefFrame ifrom);**

There is also a complimentary new method **VectorToNoScale()** added for completeness.

**ShadeContext::VectorToNoScale(const Point3& p, RefFrame ito);**

The coding ramifications of this are as follows:

All 3D Textures need to replace calls to **ShadeContext::VectorFrom()** with calls to **ShadeContext::VectorFromNoScale()**.

Here's an example of the use of **VectorFromNoScale()** in an **EvalNormalPerturb()** function:

```
Point3 Marble::EvalNormalPerturb(ShadeContext& sc) {  
  float del,d;  
  Point3 p,dp;  
  if (!sc.doMaps) return Point3(0,0,0);  
  if (gbufID) sc.SetGBufferID(gbufID);  
  xyzGen->GetXYZ(sc,p,dp);  
  if (size==0.0f) size=.0001f;  
  p *= FACT/size;  
  
  d = MarbleFunc(p);  
  del = 20.0f;  
  Point3 np;  
  
  Point3 M[3];  
  xyzGen->GetBumpDP(sc,M);  
  np.x = (MarbleFunc(p+del*M[0]) - d)/del;  
  np.y = (MarbleFunc(p+del*M[1]) - d)/del;  
  np.z = (MarbleFunc(p+del*M[2]) - d)/del;  
  
  np *= 100.0f;  
  return sc.VectorFromNoScale(np,REF_OBJECT);  
  }
```

## Required Changes To Renderer Plug-In

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Render Change to Allow View-Oriented Lights

The 3ds max renderer has been modified so that if a `DefaultLight` is passed into **Renderer::Open** with a transformation matrix that is all zeros, the renderer will interpret this to mean that on each frame it should create a light located at the view point, pointing in the view direction. This allows the implementation of the new viewport 1-light option so that it tracks the camera during an animated camera move. See [Class Renderer](#).

### Class, Parameter and Data Member Changes Affecting Renderers

The **ShadowBuffer** and **ShadowQuadTree** classes have been removed. Shadows are a new plug-in type in release 3.0. See [Class ShadowType](#).

The following parameters were moved from [Class RendParams](#) to [Class FrameRendParams](#), so they can be varied frame to frame.

**int regxmin,regxmax;**

**int regymin,regymax;**

Added these data members to [Class FrameRendParams](#):

**Point2 blowupCenter;**

**Point2 blowupFactor;**

Thus you can now control the horizontal and vertical blowup factors independently.

Added the following method to `RenderInstace`.

**CastsShadowsFrom(ObjLightDesc &lt)**

Added several new data members to [RenderGlobalContext](#).

**BOOL force2Side;**

**float wire\_thick;**

**Color globalLightLevel;**

Added a new data member to the [ObjLightDesc](#) class.

**int renderNumber;**

Added a parameter to the **ObjLightDesc::Update()** method:

**RenderGlobalContext \*rgc**

Two methods from [RenderInstance](#) have been removed:

**virtual int NumShadLights()=0;**

**virtual LightDesc \*ShadLight(int n)=0;**

These methods from [RendContext](#) have been removed.

**virtual ShadowBuffer\* NewShadowBuffer() const=0;**

**virtual ShadowQuadTree\* NewShadowQuadTree() const=0;**

## Default Light Changes

The default lights passed to the renderer no longer have the global light level included. This must be multiplied in in the implementation of the **::Update()** method of the default light in the renderer (using the **RendContext::GlobalLightLevel()** method passed in).

## API Modifications to Handle 3D Bump Maps

The following changes are needed to correct a problem with 3D bump maps when objects in the scene are scaled. This scaling results in a very noticeable inappropriate change in the bumping effect.

The problem is occurring when the bump perturbation vectors must be transformed from object space to camera space, so they are oriented correctly as the object rotates. If the object has been scaled, this transformation causes the perturbation vectors to be scale also, which amplifies the bump effect. What is needed is a way to rotate the perturbation vectors so they are correctly oriented in space, without scaling them. To do a new method has been added to [Class ShadeContext](#).

**ShadeContext::VectorFromNoScale(const Point3& p, RefFrame ifrom);**

There is also a complimentary new method **VectorToNoScale()** added for completeness.

**ShadeContext::VectorToNoScale(const Point3& p, RefFrame ito);**

The coding ramifications of this are as follows: Any plug-in that creates a shade

context in which materials are evaluated needs to implement these two new functions (**VectorFromNoScale()** and **VectorToNoScale()**). This applies to plug-in renderers and materials.

## Required Changes To Bitmap Loader/Saver Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

BitmapIO plug-in have two changed methods. The methods

**BitmapIO::GetOutputPixels()** and

**BitmapIO::GetDitheredOutputPixels()** now have a new parameter

**BOOL preMultAlpha** which defaults to TRUE. Setting it to FALSE will

cause pixels with non-premultiplied alpha to be returned. See [Class BitmapIO](#).

## Required Changes To Controller Plug-Ins

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Deleting Controllers

A new "Delete Controller" button has been added to the Track View toolbar that is enabled when one or more delete-able tracks are selected. This method allows a plug-in to indicate to the Track View that one or more of its sub-controllers are delete-able. This provides a way for the user to delete node sub-controllers such as the visibility track, "Image Motion Blur Multiplier", "Object Motion Blur On/Off", etc.

There are two new methods of the **Control** class to support this. Each has a default implementation so overriding it is optional but developers may wish to do so.

These methods are **CanDeleteSubAnim()** and **DeleteSubAnim()**. See [Class Control](#) for details.

## Required Changes To Shape Objects

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Material IDs in Shape Related Classes

New in the 3ds max 3.0 SDK is material ID access to various shape-related classes. This results in various methods being added as shown below:

ShapeObject:

```
virtual MtlID GetMatID(TimeValue t, int curve, int piece) { return 0; }
```

SimpleShape:

```
virtual MtlID GetMatID(TimeValue t, int curve, int piece);
```

SimpleSpline:

```
MtlID GetMatID(TimeValue t, int curve, int piece);
```

BezierShape:

```
MtlID GetMatID(int poly, int piece);
```

PolyShape:

```
MtlID GetMatID(int poly, int piece);
```

PolyLine:

```
MtlID GetMatID(int segment);
```

SplineShape:

```
MtlID GetMatID(TimeValue t, int curve, int piece);
```

LinearShape:

```
MtlID GetMatID(TimeValue t, int curve, int piece);
```

Note that ShapeObject has a default implementation so it is not necessary to implement it if the shape class does not support material IDs.

### Number of Vertices in ShapeObjects

There is a new method of **ShapeObject** called **NumberOfVertices()**. This method is used by the Summary Info and Object Properties dialogs to inform the user how many vertices or CVs are in the object. Developers may wish to

implement this method.

## **Attach Shape Method**

Developers implementing the **ShapeObject::AttachShape()** method need to add the **weldEnds** and **weldThreshold** parameters. If any endpoints of the curves in the shape being attached are within the threshold distance to endpoints of an existing curve, and the weld flag is TRUE, they should be welded.

## **RescaleWorldUnits Implementations**

Objects derived from the **ShapeObject** class which have **RescaleWorldUnits** methods implemented need to call the **ShapeObject::RescaleWorldUnits** method. See [Class ShapeObject](#).

## Required Changes To Patches

See Also: [What's New in the MAX 3.0 SDK](#), [Required Changes to MAX 2.0 Plug-Ins for MAX 3.0](#).

### Overview

This section discusses some of the changes to the patch related classes in the SDK. The main changes relate to the fact that Patch objects became editable Patches objects and that patches now support more than two mapping channels.

### Mapping Channel Changes

**PatchMesh** objects no longer use a hard coded **PATCH\_TEXTURE\_CHANNELS** number of maps, but rather a dynamically allocated amount up to **MAX\_MESHMAPS** (100). The following data members have been changed from fixed-size arrays to tables:

// **Texture Coord assignment**

**Tab<int> numTVerts;**

**Tab<UVVert \*> tVerts;**

**Tab<TVPatch \*> tvPatches;**

As before, the patch is considered to have a map on channel 'i' if **tvPatches[i]** is not NULL. There are **PatchMesh::numPatches** elements in each tvPatches array, and **numTVerts[i]** UVVerts in array **tVerts[i]**.

**IMPORTANT NOTE:** previously, developers could only have 2 map channels. Map channel 0 represented traditional texture verts and map channel 1 represented vertex colors. As with meshes, this has been reversed for R3: channel 0 in these tables and methods is the Vertex Color channel, and channels 1-99 are map channels 1-99.

To maintain the number of maps, the following method has been introduced:

**void setNumMaps(int ct, BOOL keep=TRUE);**

If keep is FALSE, all the existing maps will be freed; otherwise, only those over 'ct' will be freed. New map channels are initialized with NULL arrays and 0 numTVerts. (**numTVerts**, **tVerts**, and **tvPatches** are all set to a size of 'ct'.)

However, most developers won't have to worry about calling this method, since it's called by **setNumTVertsChannel()**, which has been used to set the number of mapping verts in each channel.

There are now two versions of most methods handling maps in patches, to cope with a necessary change in map indexing between 3ds max 2.5 and 3.0 (This problem comes up in patches, but not meshes, since patches already had a channel indexing scheme in methods like **setNumTVertsChannel()**. Mesh only had methods like **setNumTVerts()**, with no channel argument.)

Old TV/VC methods are given with "TV" in the name. For these methods, channel 0 is the original map channel, while any nonzero channel is vertex colors. If no index is given, the original map channel is assumed. This is all consistent with usage in the 2.5 SDK.

New methods are given with "Map" in the name. For these methods, channel 0 is the VC channel, as it is now in Object. Channel 1 is the original map channel, while 2-99 are the new channels. The plan here is that the "Map" methods will be used in future, the "TV" methods will be considered obsolete.

There is one incompatibility with the 2.5 SDK, in that the public data members numTVerts, tVerts, and tvPatches all now use the new indexing scheme, and are now Tab<> tables instead of simple arrays as noted above.

[Class TVPatch](#)

# What's New in the MAX 4.0 SDK

See Also: [Required Changes to MAX 3.x Plug-Ins for MAX 4.0.](#)

## Overview

This section provides a general overview of the new capabilities of the 3ds max 4.0 API. New plug-in types, new classes, and new methods to existing classes have been added. In some cases new parameters to existing methods have been added as well.

Any new classes in the SDK begin their Description section with the line:

**This class is available in release 4.0 and later only**

Any new methods in a class begin:

**This method is available in release 4.0 and later only**

Newly added parameters to existing methods begin:

**This parameter is available in release 4.0 and later only**

Newly added data members begin:

**This data member is available in release 4.0 and later only**

## New Plug-In Types

The following are the new plug-in types introduced in the 3ds max 4.0 SDK. Each has a link to the base class for the creation of that plug-in type.

### Manipulator Plug-Ins

One of the new UI features for R4 is a system of direct manipulation plug-ins called manipulators. These plug-ins are a special kind of helper object that can be used to modify parameters of Objects, Modifiers, INodes and Controllers by using gizmos in the 3D viewports. See [Class Manipulator](#) or [Class SimpleManipulator](#) for more details.

The relevant classes are located in

**\MAXSDK\INCLUDE\MANIPULATOR.H**

A sample on how to write these plugins is located in

**\MAXSDK\SAMPLES\HOWTO\BENDMANIP**

### Tone Operator Plug-Ins

In order to provide better quality images a tone operator plug-in has been

added to 3ds max and the SDK. This is used to convert lighting energy values to RGB values for rendering and display after shading is performed. See [Class ToneOperator](#) for more information on this topic.

The relevant classes are located in `\MAXSDK\INCLUDE\TONEOP.H`

### **Render Element Plug-Ins**

A new plug-in type called Render Elements has been added. A render element isolates a component of a rendering like specular, diffuse, emission, etc. and outputs it to either a separate bitmap or a multi-channel RPF or RLA file. The new plug-in type communicates with the ShadeContext, retrieving color data stored there by the shaders, compositing and saving the resulting image to file. See [Render Elements](#) for more details.

The relevant classes are located in

`\MAXSDK\INCLUDE\RENDERELEMENTS.H`

### **Multi-Pass Render Camera Effect**

The multipass camera effect allows modification of viewpoints & view directions or time for each pass of a multipass rendering. Algorithms such as Depth of Field, Scene motion blur can be implemented using multipass techniques. See [Class ImultiPassCameraEffect for more details](#).

The relevant classes are located in `\MAXSDK\INCLUDE\OBJECT.H`

### **Inverse Kinematics, Solver Plugins.**

IK solvers are now plug-able. The IK system will recognize a plug-in solver by putting it in the solver list wherever it appears. For more information refer to the section on [Inverse Kinematics](#).

The API of the IK solver is defined in

`\MAXSDK\INCLUDE\IKSOLVER.H, IKHIERARCHY.H,`

`IIKSYS.H, and IKCTRL.H.` For an example, please look at

`\MAXSDK\SAMPLES\IKSOLVERS\IKLIMB`

## **New Features By Category**

### **Rendering**

#### **Interactive Reshading**

The relevant classes are located in `\MAXSDK\INCLUDE\MTL.H`. See [Class IReshading](#).

## Interactive Rendering

With the likelihood of evolving rendering and shading techniques which are going to be markedly different from what is being used now, the 3ds max SDK provides the infrastructure to support interactive rendering. Since renderers are a plugin to 3ds max and since each renderer has a different set of resources and capabilities the interactive rendering and shading API is made into as much a general API and independent as possible. See [Class InteractiveRender](#).

## Image Motion Blur

The new motion blur effect plug-in, MotionBlur.dlv, now contains code that used to be part of the renderer, and uses function publishing to allow the renderer to call functions to do image blur. For details on how this is done see [Class IMBOps](#). Sample code is available in

**\MAXSDK\SAMPLES\RENDER\RENDEREFFECT\MOTIONBLUI**

Also, Image Motion Blur has been improved so that objects that are moving behind transparent object will blur fairly realistically. See [Class GBuffer](#) for details. The relevant classes are located in **\MAXSDK\INCLUDE\GBUF.H, IMBLUR.H**

## Vertex Colors from a Non-Internal Color Array

A new method of the Mesh class allows the source data for vertex colors to come from other than the default, internal vertex color array (also known as map channel 0). [Class Mesh \(Color Per Vertex Methods\)](#) . An overview of this can be found in the Advanced Topics section [Working With Meshes](#). The relevant classes are located in **\MAXSDK\INCLUDE\MESH.H**.

## Material Surface Evaluation

Material surface evaluation allows extraction of more precise color information from a material. The material interface now exports a set of functions in order to enable "interactive display" to show the material correctly in the viewport. Note that these functions do not take into consideration texture maps and other shading parameters. Relevant changes were made to [Class Mtl](#) and [Class Texmap](#).

## Multiple Map Display in the Viewports

The code in the Mesh class and associated classes has been modified so that multiple textures are available for display in the interactive viewport. See [Class Mesh](#). Plug-In Materials have several new methods to implement related to this. These are **SetupGfxMultiMaps** and **SupportsMultiMapsInViewport** from [Class MtlBase](#). The relevant classes are located in `\MAXSDK\INCLUDE\MESH.H, IMTL.H`.

## New Material Handlers for New Particle Systems

This interface allows particle systems to support material per face and particle ID per face. This class may also be used by plug-ins that want to support this capability. See [Class IChkMtlAPI](#). The relevant classes are located in `\MAXSDK\INCLUDE\CHKMTLAPI.H`

## New Network Rendering API

This is the new API for network rendering. The relevant classes are located in `\MAXSDK\INCLUDE\MAXNET_MANAGER.H`. See the Advanced Topics section [Network Rendering](#) for details.

## A New Interface to Allow Multiple Image Viewers (VFBs)

Up until this point, the VFB has been tightly coupled with the 3ds max Bitmap implementation. This new abstract interface will let multiple image viewer implementations be used to view Bitmaps.

See [Class IImageViewer](#) for details.

The relevant classes are located in

`\MAXSDK\INCLUDE\IIMAGEVIEWER.H`

## User Interface

### Action Tables

New in R4 is a class called ActionTable that is a generalization of the ShortcutTable class added for R3. ActionTable contains operations that can be tied to various UI elements in 3ds max including toolbar buttons, keyboard

shortcuts and menu items. See the Advanced Topics section [UI Customization](#) for details. The relevant classes are located in **\MAXSDK\INCLUDE\ACTIONABLE.H, MAXAPI.H, PLUGAPI.H.**

## **Function Publishing**

See the Advanced Topics section on [Function Publishing System](#) for details.

## **Track Bar Update**

The Track Bar API has been updated to support the new functionality provided in R4. See [Class ITrackBar](#). The relevant classes are located in **\MAXSDK\INCLUDE\MAXAPI.H**

## **Menu Manager**

This is an interface to the menu customization system. See [Class IMenuManager](#). The relevant classes are located in **\MAXSDK\INCLUDE\IMENUMAN.H**

## **Color Manager**

The color manager allows plug-ins to register colors that can be customized and saves / restores them from a file. See [Class IColorManager](#). The relevant classes are located in **\MAXSDK\INCLUDE\ICOLORMAN.H**

## **OLE DragAndDrop Manager**

The DragAndDrop manager is a new component in R4 that provides a general framework for handling OLE-based drag-and-drop in 3ds max. The prime motivations for adding this new component were to accommodate the new iDrop™ tool for dragging 3ds max content from the web and to provide a general way to implement drop targets for the new dropScript capability in 3ds max.

The new manager is a generalization of the VIZ R3 OLE-based DragAndDrop manager that has been ported into 3ds max 4. It is exposed through a public API in the 3ds max SDK and the Function Publishing system, supports an extensible

set of clipboard formats and drop types and permits individual 3ds max windows to specialize drop handling. This allows you to support new iDrop™ file types, such as dropScripts, fold the 3ds max internal drag-and-drop into the same system that handles external drag-and-drop, and allows custom drops to various interesting windows in 3ds max, such as the material editor, schematic view, the new modifier stack, etc. or other 3rd-party windows. See [Class IDragAndDropMgr](#) for more details.

The relevant classes are located in  
**\MAXSDK\INCLUDE\IDRAGANDDROP.H**

## **Dialog Position / Size Manager API**

This feature may be used to increase UI consistency by having all major floating dialogs remember their previous position and size, like Track View and Medit do now. This is done by calling methods to save the size / position to the CUI file.

## **R4 Parameter Wiring System**

The parameter wiring features are encapsulated in an interface class that allows you to directly control the various parameter wiring operations. See [Class IParamWireMgr](#) for more information.

The relevant classes are located in **\MAXSDK\INCLUDE\IPARAMWIRE.H**

## **New Mouse Manager Functionality**

Newly added to the mouse manager is the ability to add a callback function that lets a command mode get all the raw mouse windows messages from a viewport. This way developers can avoid using the **MouseCallBack::proc()** method, which does a lot of filtering on the messages that it sends.

The relevant classes are located in  
**\MAXSDK\INCLUDE\MOUSEMAN.H**

## **Modeling**

### **Node Handles**

This is a new unique ID for each node in the scene. See [Class INode](#) and [Class Interface](#), in particular the methods **Interface::GetINodeByHandle()** and **INode::GetHandle()**. The relevant classes are located in **\MAXSDK\INCLUDE\INODE.H** and **MAXAPI.H**

## Node Display Callback

The feature enables a plug-in developer to register a callback function that gets called whenever a node needs to be drawn. The developer can hide the standard mesh and display their own image for the node. This allows one to control a node's display without being part of the modifier stack. See [Class NodeDisplayCallback](#).

The relevant classes are located in **\MAXSDK\INCLUDE\NODEDISP.H**

## New Callback Classes

Two new callbacks are available. One is used to filter the display of nodes in the scene by category. See [Class DisplayFilterCallback](#). The other is to filter the selection of nodes. See [Class SelectFilterCallback](#). Also see the methods in **Class Interface** associated with activating these callbacks ([Interface callback methods](#)).

## Extension Object -- New Extension Channel

This feature enhances the geometry pipeline by allowing a developer to add a custom object to the pipeline object. This object will get notified whenever something in the pipeline changes. This extends the flexibility of the Modifier Stack by being able to implement a combination of a custom data notification system. An example of this in use is a game developer who wants to indicate when a certain object becomes invalid for export to their game engine. By inserting an Extension Object into the pipeline they can accomplish this, by constantly checking the structure of the object and displaying wrong faces/vertices etc. in the viewport. See [Class XTObject](#).

Sample code is available in:

**\MAXSDK\SAMPLES\EXTENSIONCHANNELOBJECTS\XMODII**

The relevant classes are located in **\MAXSDK\INCLUDE\CHANNELS.H**, **XTOBJECT.H**

## Geometry Pipeline Enumeration

There is a new class and several new global functions that can be used to enumerate the geometry pipeline.

For details see [Class GeomPipelineEnumProc](#).

## Vertex Alpha

This feature adds map channels to support "Vertex Alpha" and "Vertex Illumination" in all object types and gives the user editing controls for these channels in Editable Objects and Edit Modifiers. See [Class Mesh](#). The relevant prototypes are located in: `\INCLUDE\MESH.H`

## Custom Face Data Storage

This feature allows a Mesh object to support up to 100 custom data channels for Faces. Each channel provides an array to store data as defined by the developer. The types of data will often be standard items such as floats and ints, however, pointers to more sophisticated objects may be stored as well. The number of elements in the array for each channel will correspond to the number of faces in the Mesh.

The main advantages and differences over the current per-vertex-data support are: face-data channels are identified by a `Class_ID` rather than an integer; face-data channels can store objects of a user defined type, not just float; 3rd party developers can derive their own face-data channel from **Class**

**IFaceDataChannel**. The Mesh notifies all its face-data channel objects of events and operations related to faces, so 3rd parties can really manage their per-face data the way they want, they have a lot of flexibility. This is different from the current per-vertex-data because the vertex data channels are entirely exposed to and managed by the Mesh. Note that only Meshes support the **IFaceDataMgr** interface. See [Class IFaceDataChannel](#), [Class IFaceDataMgr](#).

## Object Conversion Between Types

There is a new class that allows developers to convert between their object types and the native 3ds max types. See [Class ObjectConverter](#) for details.

## Conversion Modifiers

There are now modifiers to perform explicit object type conversions in the pipeline. Specifically, modifiers which will operate on all object types:

Turn to Mesh

Turn to Patch

Turn to Poly

There are new global functions for doing this conversion. See the [Explicit Conversion Functions](#).

The relevant prototypes are located in **\MAXSDK\INCLUDE\PATCH.H** and **POLYOBJ.H**

## **SubObjType API**

There is a new API for working with Sub-Objects. The new Stack View in the command panel uses this API. There are several new classes related to it. See [Class BaseObject](#) [the Class BaseObject page has the wrong font on its title], [Class ISubObjType](#), [Class GenSubObjType](#), [Class MaxIcon](#). The relevant classes are located in **\MAXSDK\INCLUDE\OBJECT.H**.

## **Polymesh Object**

See [Class PolyObject](#).

The relevant classes are located in **\MAXSDK\INCLUDE\POLYOBJ.H**

## **Editable Poly**

See [Class EPoly](#).

The relevant classes are located in **\MAXSDK\INCLUDE\IEPOLY.H**

## **Patches**

A large number of new methods and data members have been added to the various classes relating to patches. Details on these new methods and data members can be found by browsing through the classes listed below and looking for the R4 specific availability notes. In this section a shortlist of general additions and changes will be listed.

Class **PatchMesh** has gained a number of methods dealing with unifying and flipping normals, welding and cloning, vertex weights, and linear and curved

mapping.

Class **PatchObject** has gained a number of methods dealing with setting the Show End Results option and handling the status thereof, getting and setting vertex and patch colors, selecting vertices by color and illumination, creating shapes from edges, welding and breaking, flipping and unifying normals, deleting selected patches, and changing the mapping type of patches.

Class **Patch** has gained a few methods dealing with linear and curved mapping, finding edges and vertices based on vertex indices.

Class **TVPatch** has gained some extra data members and methods dealing with patch handles and interiors.

Class **PatchVert** will now deal with an array of edges used by a vertex.

See [Class PatchMesh](#), [Class PatchObject](#), [Class Patch](#), [Class PatchEdge](#), [Class TVPatch](#), [Class PatchVert](#)

See [Required Changed from R3.x to R4](#).

The relevant classes are located in `\MAXSDK\INCLUDE\PATCH.H` and `PATCHOBJ.H`

## Animation

### New Interface Classes for Various Controllers

There are several new classes for accessing the parameters of new or modified controllers in R4. These are listed below. The relevant classes are located in `\MAXSDK\INCLUDE\ISTDPLUG.H`

#### **LookAt Constraint**

This is the new Look At Controller (rotation only as opposed to the previous LookAt Transform controller). An interface to its parameters is available in [Class ILookAtConstRotation](#).

#### **Orientation Constraint**

The Orientation Constraint matches the orientation of an object to its target without affecting its position. See [Class IOrientConstRotation](#) for the interface details.

#### **Position Constraint**

A 3ds max user can use the Position Constraint to make an object move to

and be coincident with another target object. The Position Constraint can also move an object to the position of the weighted average of several different targets. See [Class IPosConstPosition](#) for access to this controller.

### **Path Constraint**

The old path controller has been modified and renamed the Path Constraint. For an interface to the parameters of this controller see [Class IPathPosition](#).

## **New System Utilities**

### **New Notification Codes**

Numerous new notification codes have been added for R4. See [Structure NotifyInfo](#).

The relevant structure is located in `\MAXSDK\INCLUDE\notify.h`

### **New Reference Messages**

There are a few new reference message that may be used. See [List of Reference Messages](#).

The relevant defines are located in `\MAXSDK\INCLUDE\ref.h`

### **Scanline Pager template**

This new template is used to minimize memory usage when rendering. Bitmaps (for instance textures and the frame buffer) are normally accessed on a scanline basis when rendering. Currently they are fully loaded into memory when rendering starts. This class is used to try to keep only the active block of scanlines in memory and the rest of the bitmap on disk – making the extra RAM available for geometry and other memory buffers.

The relevant classes are located in

`\MAXSDK\INCLUDE\scanlinepagemgr.h`

### **New Miscellaneous Global Functions**

See [List of Miscellaneous Utility Functions](#) for a few new global functions related to checking the number of processors in the system, determining the version of Windows running, and checking the screen width and height.

## **Custom Attributes**

An unlimited number of custom attributes (e.g. parameters) can be added dynamically to individual objects. These can be very useful for game developers and/or other project specific data. The SDK provides a way to define and add these custom attributes to objects in the scene.

A sample on how to write these plugins is located in  
`\MAXSDK\SAMPLESHOWTO\CUSTATTRIBUTIL`

See [Class CustAttrib](#) for details on custom attributes.

## **Particle Collision Encapsulation**

The SDK adds new support for particle collision detection whereby other systems such as Flex and MaxScript can also benefit from this more open architecture. These collision API's provide an interface to determine if a particle hits a surface. Three basic collision detection classes are provided, a planar, spherical, and a mesh deflection class.

See [Class ICollision](#) for more information.

## **Random Number Generator**

A new and improved random number generator class has been provided in order to deal with the shortcomings of the standard random number generation functions.

See [Class RandGenerator](#) for more information.

## **Support for Hardware Shaders**

3ds max 4.0 supports custom hardware vertex shaders and pixel shaders using Direct-3D, right in the graphics viewports. The primary aim of this support is to enable a 1:1 relation between what users see in the viewport and the content they are creating for other Direct-3D enabled applications.

See [Class ID3DGraphicsWindow](#), [Class IDX8PixelShader](#), and [Class IDX8VertexShader](#) for more information.

# What's New in the MAX 4.0 SDK

See Also: [What's New in the MAX 4.0 SDK](#).

## Overview

This section provides general information on the changes required to all plug-ins to get them running in 3ds max 4.0. It also provides links to topics that discuss the specific changes for many affected plug-in types. Some of these changes are required while others are optional but advantageous.

## Microsoft Platform SDK

It is recommended to obtain and install the Microsoft Platform SDK which many of the examples depend on and require in order to compile properly. In order to ensure proper compilation of plugins and voiding any linker errors, please make note of the following;

- · When compiling plugins using the command line, ensure that the path environment variables for library and include files precede the paths set by Microsoft Visual Studio.
- · When compiling plugins using the Visual Studio IDE, ensure that the path configuration (options menu-> directories) for library and include files are listed as the top entries.

Note: The Microsoft Platform SDK can be obtained through the MSDN web site.

## Patches

As of R4.0 a vector can now be used by more than two patches. Previously the [Class PatchVec](#) kept an index to two patches sharing the vector as an integer array of 2 elements. This has changed to an IntTab. While this would most likely not invalidate any code it is advisable to keep in mind that there could now be more than 2 patches sharing a vector.

Some structural changes have been made to the [Class PatchEdge](#) that will

require some changes in the plugin code. Previous to R4.0 the patches that used an edge were kept in **int patch1** and **int patch2**. These two integers have been replaced with an integer table, **IntTab patches** because edges can now be used by more than two patches. The plugin code should be changed to reflect these changes.

In order to facilitate the new topology tracking code for the Edit Patch modifier a new class has been introduced, [Class PatchTVert](#). This new class has been integrated with the class **PatchMesh** and brings with it a number of changes. The previous table of **UVVerts** has been replaced with a table of **PatchTVert's**. And a number of methods in [Class PatchMesh](#) have been altered to take advantage of this new class. These are; **mapVerts()**, **getTVertChannel()**, **getTVert()**, **getTVertPtrChannel()**, **getTVertPtr()**, **getMapVert()**, and **getMapVertPtr()**.

Slight changes have been made to the **PatchObject::DoBevel()** and **PatchObject::DoExtrude()** methods. Both now take a **Timevalue** as a parameter. Please make sure you adapt your code according to this new behavior if you are using these methods.

## Splines

A few changes were made to the [Class ShapeObject](#) methods in order to support the new animated renderable shapes. These changes should be observed and adjusted in the plugin's code. **ShapeObject::SetThickness(float t)** now accepts a TimeValue prior to the thickness parameter, and was changed to; **SetThickness(TimeValue t, float thick)**. The **ShapeObject::GetThickness()** method now accepts a TimeValue and an Interval parameter, and was changed to; **SetThickness(TimeValue t)**. Currently the previous syntax of these methods will get or set the thickness at frame 0, however Sparks Developers who are using the debug build should take note of the fact that the debug build will raise an assertion to indicate that the old syntax is obsolete and that the new syntax should be used.

## User Interface Notes

Developers should no longer use the Win32 calls **GetSysColor()** and **GetSysColorBrush()**. Due to the new customizable color schemes in 3ds max 4 developers should now use the encapsulated functions provided by the SDK; **GetCustSysColor()** and **GetCustSysColorBrush()**. These will take the same parameters as the Win32 functions but will retrieve the color information from the custom color database.

## Keyboard Shortcuts

The previous keyboard shortcut system has been replaced by an enhanced system. The new system uses what are called Action Tables. These tables unify all the actions that can be assigned to keyboard shortcuts, CUI buttons, right-click menus and main menu. See [Class ActionTable](#) for more information.

Some of these methods have the same name as ActionItem methods, and a more complete

## Sending WM\_COMMAND messages to 3ds max

If you are sending WM\_COMMAND messages to 3ds max' main window you will now need to make sure that **HIWORD(wParam)** is 1, not 0. If you ever get an assertion failure in **MenuManager::ExecuteAction()**, then it is probably because a WM\_COMMAND message was sent with a 0 HIWORD.

## Registering window classes for custom controls.

Previously every DLL had to initialize the window classes through a call to **InitCustomControls()** in DllMain. This caused a substantial hit on the available system resources in Windows 9x for every plug-in that was loaded. The classes are now globally registered for the whole process. Plug-ins no longer have to call **InitCustomControls()** at startup - but it doesn't hurt since once the classes have been registered they will not be registered again.

## Additions to Class BaseObject

Objects and modifiers, that support subobjects have to overload the two new methods **NumSubObjTypes()** and **GetSubObjType()**. and return a class derived from **ISubObjType** in **GetSubObjType()**. Developers can use the **GenSubObjType** for convenience. If the parameter passed into

**GetSubObjType** is -1, the system requests a **ISubObjType**, for the current SubObjectLevel that flows up the modifier stack. If the subobject selection of the modifier or base object does not affect the subobj selection that flows up the stack, the method must return NULL.

Note that this replaces the way subobjects were handled prior to this release. RegisterSubObjectLevel() is obsolete and should no longer be used. Instead the **NumSubObjTypes()** and **GetSubObjType()** methods should be used. For more information see [Class ISubObjType](#) and [Class BaseObject](#).

## Rendering

Plugin renderers should implement **ShadeContext::BumpBasisVectors()**.

**Interface::DoExclusionListDialog()** accepts an ExclList instead of a NameTab. This will cause the compile to break for plugin renders, which need to be modified to use the new node lists. There is a method

**Interface::GetINodeByHandle(handle)** which can be used to get the node from the handles in the ExclList. Additionally

**Interface::ConvertNameTabToExclList()** allows you to convert name tables to the new exclusion lists. A number of methods now return an ExclList instead of a NameTab, these are; **ObjLightDesc::GetExclList()**, **LightObject::GetExclList()**, **GenLight::GetExclusionList()**, **GenLight::SetExclusionList()**.

In Class IllumParams a few members were replaced; **ULONG shFlags** and **mtlFlags**, and **Point3 N**, and **V**. The class now contains pointers to the shader and material from which flags and other information can be retrieved. The shading normal **N** was a copy of the normal in the shadeContext, which is now provided to shaders and renderElements as well as IllumParams, thus **sc.Normal()** should be used to get the bumped shading normal.

## Programmatically collapsing the stack

Developers, who are collapsing the stack programmatically, should pay attention to the new Extension Channel ([Class XTCObject](#)) and the [Class BaseObject](#) methods **NotifyPreCollapse()** and **NotifyPostCollapse()**. These methods will be called by the collapse code. It will give the modifier (or BaseObject); that adds an XTC object to the stack the possibility to apply a modifier, that inserts

these XTC objects onto the stack after the collapse. Through this mechanism, the XTC will survive a stack collapse. In case these method are not called, the Extension Channel Objects will by default be copied as well, since they are part of the object in the wsCache. However, they won't survive a save/load operation. Please see the [Class XTCObject](#) for more details.

## **Parameter change in Animatable::GetSystemNodes()**

The method Animatable:GetSystemNodes() has its signature changed from previous versions and could potentially require an adjustment of plugin code. If you use the previous signature while having it overridden, the compiler will let this pass unnoticed because it assumes this is a new function (while the actual method itself is empty and hidden in the super class). As a result 3ds max will call the method with the new signature and, because it wasn't overridden, it will call the default implementation as defined

## **Trivial changes to samplers**

Samplers had to be generalized for use with Render Effects. All samplers had to be rewritten slightly, as will other plug-in samplers. The change is quite trivial, however.

## **Bump vectors in ShadeContext**

A problem in the way bump basis vectors were being calculated has been dealt with.

The code was trying to deduce a single set of 3 vectors for U,V,and W, and this led to problems. Since the bump vectors are only used in pairs ( UV,VW, WU) a better approach turns out to be to compute 2 vectors for the specific pair of axes. This required some new API calls. There is a new method in [Class ShadeContext](#), **BumpBasisVectors()**, which should replace **DpDUVW()** over time. **DpDUVW()** is left in so as not to break a lot of plugins.If **BumpBasisVectors()** returns 1, that is assumed to mean it is implemented, and it will be used instead of **DpDUVW()**.

## **Systemwide Clone implementation change**

A call to **BaseClone(this, newob,remap)** has been added to all plugins in 3ds

max, that implement the **Clone** method. **BaseClone** is a virtual member function of [Class ReferenceTarget](#). This method allows base classes to copy their data into a new object created by clone. All overwrites of **BaseClone** must call their base classes implementation. The implementation in [Class ReferenceTarget](#) is copying the CustAttrib objects into the newly created object.

All plugins that implement a **Clone** method have to call **BaseClone** with the old and the new object as parameters. The ordering in regards to when this method is called is unimportant. It obviously has to be called after the cloned object is created. The **BaseClone** method has to check for the cases of from, or to to be NULL and from and to to be equal. It is important to mention for **BaseClone**, that all overrides have to call their BaseClass' implementation. With **ReferenceTarget::BaseClone** we have a central method, that gets called for all clone operations. This allows us to add notifications etc. for cloning.

## Code Cleaning for 64 bit

**INT\_PTR**, **DWORD\_PTR** and other **\_PTR** types are new types defined by Microsoft to support UDM (Unified Data Model), These are polymorphic types that are defined to be of the type they indicate but large enough to hold a pointer. For example an int is 32 bits on both Win32 and Win64, so if you cast a pointer to an int it will loose the high bits. To solve this they added the **\_PTR** types so if you need to do pointer arithmetic (with int types) you need to have the type **INT\_PTR** type and the type will be large enough to hold a pointer (i.e. 32 bits on Win32 and 64 bits on Win64). Mesh methods, which dealt with the geometry pipeline had their channel parameters revised from unsigned along to **ULONG\_PTR**.

## Changed to GetLocalTMComponents

The API of the **GetLocalTMComponents()** method has been changed. In the current version, the parent matrix is not given as a pointer to the parent node, but as an indirect matrix representation.

## Changed support for multi-meshes in the renderer

Two important methods are added to the [Class GeomObject](#). These are

**GetMultipleRenderMesh()** and **GetMultipleRenderMeshTM()**. Please refer to the class documentation for more information.

## Changes to **GBufReader** to allow writing and bug fix

Two new methods have been added to [Class GBufReader](#):

**ModifyChannelData()** and **ModifyAllData()**. These methods allow values in the current layer to be written. This may seem strange, writing data from the reader, but developers asked for the capability of writing to the already created gbuffer, and it is much simpler to add this capability to the **GBufReader** than to **GBufWriter**, which is designed to construct gbuffers from scratch, not modify existing ones.

## Transparency and opacity maps in viewports

For the purposes of implementing transparency and opacity maps in the viewports, a new flag has been defined that indicates if transparency is required in the viewport: **MTLREQ\_TRANSP\_IN\_VP**. See the [List of Material Requirement Flags](#) for more details.

## Removal of hidden vertices

MNMeshes used to support "hidden vertices". These would be vertices that exist "in the middle" of faces, taking part in their triangulation but considered more a feature of the face than vertices in their own right. These vertices were useful in the past, when MNMeshes were constantly being converted to and from Meshes. We needed to remove them for PolyMeshes to be an efficient pipeline object; keeping track of them was drastically increasing the size of every face, whether it had such vertices or not.

## Changes in Class **MeshDelta**

In class **MeshDelta**, the data member **fCreate** was switched from **Tab<Face>** to **Tab<FaceCreate>**. In conjunction with this a new method **FCreate()** was added. More information can be found in [Class MeshDelta](#) and [Class FaceCreate](#).

## Changes in Class MNMapFace

Data members **hdeg**, and **hvtx** have been removed. The constructor **MNMapFace()** now only accepts one argument, **SetAlloc()** and **SetSize()** also accept only one argument, **HInsert()** and **HDelete()** have been removed, and **MNDebugPrint()** no longer accepts any arguments. More details can be found in [Class MNMapFace](#).

## Changes in Class MNFace

Data members **hdeg** and **hvtx** have been removed. The constructor **MNFace()** no longer accepts a second argument. **SetAlloc()** no longer accepts a second argument, **HInsert()** and **HDelete()** have been removed and **MNDebugPrint()** now only accepts one argument. The "**tri**" array was replaced by the new "**diag**" array. The diag array's allocated size is always  $(dalloc-3)*2$ . If  $dalloc==3$  (triangle), this pointer is NULL. The method "**TriVert**" was removed. Use **GetTriangles()** to access this sort of information. More information can be found in [Class MNFace](#).

## Changes in Class MNMesh

The methods **HVNum()** and **KillUnusedHiddenVerts()** have been removed. There is no longer an **MNM\_SL\_TRI** selection level. Methods **FindExternalTriangulation()** and **BestConvexTriangulation()** were changed to **FindDiagonals()** and **BestConvexDiagonals()**, respectively.

The [Class MNMap](#) data member, "**m**", became private. The accessor method, **M**, remains public, and now takes values of -1 (**MAP\_SHADING**) and -2 (**MAP\_ALPHA**) as well as 0-99. **SetMapSeamFlags()**, which previously took an argument of (mp=-1), where -1 meant "set map seam flags based on all maps", had to be split into two methods as follows: void **SetMapSeamFlags()** and **SetMapSeamFlags(int mp)**;

Several methods that accept a selection level as an argument were changed to take an MNMesh selection level (such as **MNM\_SL\_VERTEX**) instead of the old Mesh selection levels they used to take (such as **MESH\_VERTEX**). This has affected the following methods in class MNMesh; **GetBorder()**, **TargetVertsBySelection()**, **TargetEdgesBySelection()**,

**TargetFacesBySelection(), Slice(), PropagateComponentFlags(), SabinDoo(), SabinDooVert(), and AndersonDo().**

## **Change internal triangulation storage from triangles to diagonals for Class MNMesh**

This is another space-saving measure. We always store a particular triangulation, or way to convert the polygon into triangles, in each MNFace. This is necessary to preserve face orientation when converting to and from regular meshes, or to allow users to explicitly edit the triangulation in R4. We used to store this info as triangles, based on the face's "internal" indices. For instance, if we're dealing with an octagon, the vertices would be numbered 0,1,...7, corresponding to the order in the "vtx" array. However, this was very inefficient, as it required 3 int's to store the triangulation of a triangle (0,1,2), or 6 int's for a quad (0,1,2,2,3,0), even though there's only 1 way to "triangulate" a triangle, and only 2 possibilities for a quad. (The other would be (0,1,3,1,2,3).) Now we're storing diagonals.

For instance, in a quad, we really only need to know whether the diagonal goes from 0 to 2 or from 1 to 3. We can list all the diagonals of an n-sided polygon with  $(n-3)*2$  ints - 0 for a triangle, 2 for a quad, 4 for a pentagon, etc. (The old scheme took  $(n-2)*3$  ints - 3 for a triangle, 6 for a quad, 9 for a pentagon.) This is probably not totally optimized, but it strikes a nice balance between memory usage and ease of use.

## **CUI Image Lists**

CUI Image lists are no longer used. Everything now goes through the icon manager and as such the **GetDefaultImageList()** and **AddToImageList()** methods were removed from the Class CUIFrameMgr.

## **Modifier Sets and Categories**

The categories shown in the modifiers drop-down list are modifier sets which you can configure using the Configure Modifier Sets dialog. Modifier Set information is stored in the 3dsmax.ini file. In order to add your own custom Modifier Set to have your plugin showing under its own heading you can create the heading with the appropriate class ID in the 3dsmax.ini file.

## **Note about member alignment**

Please make sure that when you save data from your plugin you save individual data members using a chunk ID instead of saving the image of a class. Saving (and loading) a class image puts you at risk of running into member alignment problems and as such could potentially corrupt saved files. File IO would be put further at risk when you keep Intel's IA-64 architecture in mind which depends on member alignment. What you should not do is outlined in the following example when loading a class image;

**iload->Read(&myclass, sizeof(MyClass), &ab);**

Once you change the class in such a way that it affects the data size you run the risk of having to support different versions, file IO incompatibility, and member alignment issues.

## What's New in the MAX 5.0 SDK

See Also [Required Changes to Certain MAX 4.0 Plug-Ins](#), [New and Unsupported Changes](#)

### Overview

This section provides general descriptions and links to the associated classes/interfaces of new feature functionality in 3ds max 5.0.

## Global Illumination

**Description:** 3ds MAX 5.0 currently has two solutions for global illumination: Radiosity, and Light Tracer.

**Documentation:** [Class RadiosityEffect](#), [Class ISpecularCompositeShader](#), [Class IEmissionColor](#), [Class INodeGIProperties](#)

## Spline IK

**Description:** Refers to the new modifier which, when assigned to a spline (or a NURBS) curve, generates a certain number of helper objects attached to the knots of the curve. This interface provides access to most of this new functionality

**Documentation:** [Class ISplineIKControl](#)

## Texture Baking

**Description:** Provides the interfaces for creating Texture Baking plugins in 3ds max. The texture baking plugins are controlled through the Maxscript “Render To Texture”. There are methods available in this class that provide the ability to produce a dynamic UI in Maxscript.

**Documentation:** [Class MaxBakeElement](#)

## Viewport Shaders

**Description:** These interfaces give you the opportunity for you to write your own DX Hardware Shaders and have a mechanism for displaying them in the MAX viewports

**Documentation:** [Class IViewportShaderManager](#) , [Class IDXDataBridge](#) , [Class IHardwareMaterial](#)

## Skin Posing

**Description:** This interface provides access for getting and setting a special,non-animated, transformation pose.

**Documentation:** [Class RotationValue](#) , [Class ISkinPose](#)

## UVUnwrap

**Description:** This new interface allows for Normal, Flatten, and Unfold mapping. You can bring them up through a dialog or through a script command.

**Documentation:** [Class IUnwrapMod2](#)

## Node Exposure

**Description:** This interface provides the ability for a node to define whether it is visible in any of max's dialog boxes. This interface will be extended and used by more of 3ds max's core utilities, but **currently ONLY TrackView and the Select Object/HideObject dialog box use this interface.** By default this interface is not available through the default nodes, it needs to be added.

**Documentation:** [Class INodeExposure](#)

## Node Layer Properties

**Description:** This class defines an interface for accessing a node's global illumination properties.

**Documentation:** [Class INodeLayerProperties](#)

## Assemblies

**Description:** Assemblies combine the collective nature of a group with the programmability of a system. These interface classes allow control over which nodes belong to an assembly and which is the head. Methods are also provided to control the accessibility of members.

**Documentation:** [Class IAssembly](#) , [Class IAssembly2](#)

## Edit Normals Modifier

**Description:** This interface provides access to the functionality in the Edit Normals modifier, which allows you to edit three categories of normals: Unspecified, Specified, and Explicit. Please see the associated documentation for a full description of this modifier's functionality.

**Documentation:** [Class IEditNormalsMod](#)

## New and Unsupported SDK Changes for MAX 5.0

See Also: [What's New in the MAX 5.0 SDK](#) , [Required Changes to Certain MAX 4.0 Plug-Ins](#)

### Overview

This section provides general information on the SDK additions which are accessible yet unsupported in 3ds max 5.0.

## **Set Key**

**Discreet will not be supporting Set Key functionality for 3<sup>rd</sup> party plugins.**

## Painter Interface

**Discreet will not be supporting Painter Interface functionality for 3<sup>rd</sup> party plugins.** However, you may view extensive comments by the developer of this feature in the IPainterInterface header file located here:  
**[/samples/painterinterface/include/ipainterinterface.h](#)**

## **BackBurner2 – Network Rendering**

**Backburner is the new Network rendering system for 3dsmax r5. It provides a unified model for both 3dsmax and Combustion rendering.**

Although the API for backburner has not changed from the API available in 3dsmax 4, some changes have been introduced with the way backburner interacts with the 3dsmax application. Some DLLs required for the API have a very close connection to Backburner, so if backburner is not present or is not loaded these DLLs may fail to load, causing plugin failure.

## Required Changes to Certain MAX 4.x Plug-ins for MAX 5.0

See Also: [What's New in the MAX 5.0 SDK](#), [New and Unsupported Changes](#)

### Overview

This section provides general information on the changes required to a small list of plug-in types to get them running in 3ds max 5.0.

## **IK Solver**

**All plug-ins implementing IK Solver functionality will require a recompile to run in 3ds MAX 5.0.**

## **TrackView Utilities**

**All TrackView Utility plug-ins will require a recompile to run in 3ds MAX 5.0.**

## What's New in the MAX 6.0 SDK

### Overview

In an effort to provide the 3ds max SDK development community with up-to-date SDK changes and documentation updates, we're moving our SDK updates presentation to a more dynamic, online location. With this move, we can assure the development community that all changes and updates will be reflected as soon as they occur, without the requirement of downloading a new 3ds max SDK documentation build.

Please click the link below to view the current SDK and documentation updates page online:

**Internet Address**

[http://sparks.discreet.com/knowledgebase/techdocs/sdk\\_change\\_update](http://sparks.discreet.com/knowledgebase/techdocs/sdk_change_update)

# Game Export Interface

## Overview

The Game Export Interface has been developed to greatly simplify data export from 3ds max. The following is a list of associated components and materials for this plugin:

1. The .lib file is located in /maxsdk/lib/IGame.lib.
2. The help documentation is located as IGame.chm in the /maxsdk/help/ directory.
3. The sample exporter can be found through /samples/impexp/IGameExporter/ directory.

## Internet Address

More Game Exporter related materials can be located online through the Sparks developer website: <http://sparks.discreet.com/downloads/>

# **VC7 memory wrapper for 3ds max**

## Overview

To accommodate for development of 3ds max 5.1 plug-ins using the VC7 development environment, Discreet has developed a system to address the incompatibility between the VC7 memory subsystem and 3ds max, which is VC6 native. Developers can employ this solution by including the `MAX_Mem.h` header in their plug-in project, which serves as a replacement for `malloc.h`, `new.h` and `crtDBG.h`. The result is to redirect memory allocation and de-allocation functions into equivalents implemented in the 3ds max core, operating on a VC6 native heap.

You can find this header in the `maxsdk/include` directory.

## Limitations

The memory wrapper is necessary only in situations where memory allocated by a plug-in is later deallocated by 3ds max, or vice versa. In these cases, both operations must occur on the same VC6 heap. Any other memory used by a plug-in may reside on a VC7 heap, and in those cases the use of MAX\_Mem is not necessary.

A limited set of memory allocation functions is supported under MAX\_Mem. These include malloc(), free(), new, delete (including array forms) and heap inspector functions like \_heapchk(). Functions which implicitly allocate memory, such as strcpy(), are not generally supported.

## **Expanding Memory Wrapper**

Developers wishing to expand upon the memory wrapper may create their own VC6-compiled DLL which provides access to the necessary functions. The functions could be accessed using a preprocessor macro, which defines the original function name as a call to the VC6 exported function, or, in the case of `new()` and `delete()`, by using a function overload. These are only suggestions, and other schemes are possible at the developer's discretion.

## Further Information

For more information regarding VC7 compatibility with 3ds max, see the document “VC7 plugins for 3dsmax 5 and 5.1” in the Sparks Knowledgebase:

[http://sparks.discreet.com/search/index.cfm?url=/knowledgebase/techdocs/searchable/Techdoc\\_3dsmaxVC7/3dsmax](http://sparks.discreet.com/search/index.cfm?url=/knowledgebase/techdocs/searchable/Techdoc_3dsmaxVC7/3dsmax)

# Sparks Developer Program

## Introduction

[sparks.discreet.com](http://sparks.discreet.com) is the Discreet developer portal for 3ds MAX 4.0 and above. Join sparks to receive the highest level of 3ds MAX SDK support!

## How to Join Sparks

Apply for sparks directing your browser to the following internet address: <http://sparks.discreet.com/app/appmain.cfm>. For more information, either read on or go here: <http://sparks.discreet.com/info/fohome.cfm>

## Sparks Membership Tiers

**The sparks program provides three levels of access to 3ds MAX SDK developers. These tiers are Public, Standard, and Premium.**

**Public** users of sparks.discreet.com have access to the [Sparks Developer Knowledgebase](#), the [Sparks Webboard](#), and public [Sparks Downloads](#). There is no cost for access to these support channels.

**Standard** users of sparks.discreet.com have access to everything public, as well as additional downloads in the form of the latest 3ds MAX Debug Builds, and other private samples. *The cost for this membership is \$400 US.*

**Premium** users of sparks.discreet.com are entitled to everything public and standard, as well as access to the Sparks Incident Reporting system which allows direct, web-based, contact with the Discreet Sparks SDK Support Team. *The cost for this membership is \$1200 US.*

*Please note that all prices are subject to change.*

## Sparks Developer Support Channels

**The following methods of support are available through the sparks.discreet.com domain. Please follow the links below for brief description of each topic, as well as its associated internet address.**

[Sparks Developer Knowledgebase](#)

[Sparks Message Archives](#)

[Sparks Documentation Updates](#)

[Sparks Webboard](#)

[Sparks Downloads](#)

[Sparks Incident Reporting](#)

## **Further Information**

For more information regarding the sparks program, please direct your browser to the following internet address:

<http://sparks.discreet.com/info/infohome.cfm> .

# Sparks Developer Knowledgebase

See Also: [Sparks Developer Program](#)

## Overview

### **See Also:**

The sparks developer knowledgebase offers search-engine access to a plethora of 3ds MAX SDK support materials, including techdocs/labs, solutions, support threads, and the documentation contained in this help file. *Please note that additional support materials are available for Premium members.*

**The Sparks Developer Knowledgebase is available to the public, with additional support materials provided to Premium sparks members only.**

## Internet Address

<http://sparks.discreet.com/search>

# Sparks Message Archives

See Also: [Sparks Developer Program](#)

## Overview

The sparks message archives provide an offline archive of all threads in the Sparks Webboard. You can download the most recent archive from the public downloads or you can find a less recent version of the file (sparks\_archive.chm) in the help directory in the maxsdk directory. Note that as long as that file resides in that directory, all searches in this this file (sdk.chm) will have access to those threads.

**The Sparks Message Archive is available to the public.**

## Internet Address

[http://sparks.discreet.com/downloads/downloadshome.cfm?  
f=2&wf;\\_id=56](http://sparks.discreet.com/downloads/downloadshome.cfm?f=2&wf;_id=56)

# Sparks Documentation Updates

See Also: [Sparks Developer Program](#)

## Overview

The sparks team is constantly updating the help documentation for the MAX development community. To access the latest compiled help file, please follow the go the [Sparks Downloads Area](http://sparks.discreet.com/downloads/) (<http://sparks.discreet.com/downloads/>) or visit the [Sparks Developer Knowledgebase](http://sparks.discreet.com/search) (<http://sparks.discreet.com/search>) and click the “knowledgebase” link in the upper-left of the site.

**New for 3ds max 6, we are offering an online SDK and documentation update list.** To view this list, please go here: [http://sparks.discreet.com/knowledgebase/techdocs/sdk\\_change\\_update](http://sparks.discreet.com/knowledgebase/techdocs/sdk_change_update).  
[to](#)

**All Sparks Documentation Updates are available to the public.**

# Sparks Webboard

See Also: [Sparks Developer Program](#)

## Overview

The sparks developer webboard offers a community source for all items related to the MAX SDK. Join the forum and participate in discussions with fellow MAX SDK developers

**The Sparks Developer Knowledgebase is available to the public.**

## Internet Address

<http://sparks.discreet.com/webboard/wbpx.dll/~maxsdk>

# Sparks Downloads

See Also: [Sparks Developer Program](#)

## Overview

The sparks downloads area provides the latest samples, documentation, debug builds (for members only), and other support materials for the MAX development community.

**The Sparks Downloads area is available to the public, with additional downloads such as MAX Debug Builds provided for sparks members only.**

## Internet Address

**Public Downloads:**

<http://sparks.discreet.com/downloads/downloadshome.cfm>

**Private Downloads:** You must be logged in to the sparks members area and click 'downloads' on the left menu to access additional downloads such as 3ds MAX Debug Build(s) and private samples.

# Sparks Incident Reporting

See Also: [Sparks Developer Program](#)

## Overview

The sparks incident reporting system allows direct correspondence with the Sparks SDK Support Team. As a Premium member, you'll be able to file questions and receive professional responses to your development queries straight from the experts at Discreet.

**The Sparks Incident Reporting system is available Premium sparks members only.**

## **Internet Address**

**You must be logged in to the sparks members area and click “SDK Support’ on the left menu to access this resource.**

## Advanced Topics

See Also: [Must Read Sections by Plug-In Type](#), [Must Read Sections for All Developers](#).

This section presents detailed information about key concepts in using the 3ds max APIs. This section contains more explanation than is available in the reference section. The topics presented here cross class boundaries and are instead based on specific concepts developers need to understand when creating 3ds max plug-ins.

For a list of these topics important to read when creating a specific plug-in type see [Must Read Sections by Plug-In Type](#). For those sections which should be read by everyone see [Must Read Sections for All Developers](#).

## Anti-Piracy Protection

See Also: [Read Only Plug-Ins](#).

Developers may wish to implement an anti-piracy protection scheme for their plug-ins. The 3ds max SDK provides a function developers may use as part of their copy protection strategy. This function retrieves the unique hardware lock ID attached to a particular machine. 3ds max itself requires the machine to have a hardware lock, and every hardware lock used with 3ds max has a unique ID associated with it. The function **HardwareLockID()** returns this ID as an unsigned integer. A developer can call this function using the code shown below:

### Prototype:

```
unsigned int HardwareLockID();
```

### Remarks:

This function returns 0 if no lock is found and the lock ID if one is found, regardless if 3ds max is in slave mode or not.

### Sample Code:

```
unsigned int hLockID = HardwareLockID()
```

Developers may key off this ID in numerous ways to authorize a plug-in to run on only a particular machine. The actual copy protection strategy employed using this lock ID is the developers responsibility. 3ds max is only responsible for insuring the integrity of the **HardwareLockID()** function. Internally, 3ds max checks the integrity of this function to prevent tampering that attempts to affect the values returned from the function.

Developers are, of course, free to implement any additional copy protection schemes as they see fit. The two basic suggested methods are to either be "tricky" about what they do to the plug-in code / functionality once it has been detected that the lock check has been tampered with or they can go to the extreme of providing an additional hardware lock for use with their own plug-ins.

In any anti-piracy / authorization strategy employed, developers should be careful how their code affects users. For example, putting up an authorization dialog when 3ds max is performing a network render is very destructive and mustn't be done. Also, plug-ins that pop up dialogs when the command panel branch is changed are also far too inconvenient for the user. Anti-Piracy dialogs should not be implemented where they will pop up from any calls within the

Class Descriptor. It may be appropriate to put lock checking code inside ClassDesc methods, but putting up dialogs that interrupts the users work flow should not be done there. The best places to show dialogs are within methods such as **CreateParamDialog()** or **BeginEditParams()**. If you have a rendering related plug-in (renderer, material, texmap, atmospheric effect, etc.) that you want licensed per CPU, it's better to use a watermark or to disable functionality, but don't disrupt the user's workflow.

Sample code using an authorization scheme can be found in **\MAXSDK\SAMPLES\MODIFIERS\TWIST.CPP**.

# Character Strings

See Also: [Class CStr](#), [Class WStr](#), [Class FilterList](#).

This section presents information developers need to know when using character strings in MAX. It discusses the meaning of the **TSTR**, **\_T**, and **TCHAR** macros that are commonly seen in the source code examples. This section also covers important substitutes for the standard C **str\*** functions, and some general functions that are available for use with character strings.

## The TSTR, \_T and TCHAR Macros

When 3ds max was designed there was originally the possibility of using UNICODE for the storage of character strings. During development it was decided that 3ds max would use MBCS (multi-byte character sets) instead. To provide the flexibility to switch between the two (perhaps some day to make it possible to also support UNICODE once it's fully supported under Windows NT), a macro is used to substitute either wide character strings (UNICODE) or single character strings (MBCS). This macro is **TSTR**. Its definition is shown below:

```
#ifndef _UNICODE  
#define TSTR WStr  
#else  
#define TSTR CStr  
#endif
```

If UNICODE is in use, the macro is defined to mean **Class WStr**. If UNICODE is not in use, **Class CStr** is used. As mentioned above, the decision was made to not go with UNICODE, and thus **TSTR** is equivalent to **CStr**.

**Class WStr** is used for wide character strings (16 bits per character). **Class CStr** is for single and double-byte character sets. DBCS **may** need 2 bytes to represent a single character, whereas UNICODE **always** uses two bytes per character. Note: Windows code often refers to "MBCS", but in reality, the only multi-byte type supported is "double-byte". I.e. Windows doesn't support any character sets that need 3 bytes for some characters.

Both **Cstr** and **WStr** provide methods and operators for calculating lengths, concatenation, sub-string operations, character searching, case conversion, comparison, and formatted writing. For additional information on these classes see [Class CStr](#) and [Class WStr](#).

Developers are encouraged to use the **TSTR** macro for string definitions, rather than going straight to **CStr**. In this way if a future version of 3ds max is developed that uses UNICODE, the text definitions will convert with a simple re-compile.

Developers will also encounter the **\_T** macro in the source code examples. Literal string definitions use **\_T** preceding the string, for example

**\_T("Parameters")**). This macro is defined in a Microsoft include file **\MSDEV\INCLUDE\TCHAR.H**. This macro will convert a string to the proper form for either UNICODE or non-UNICODE. In general, any code that is written for internationalization should use the **\_T** macro for literal string definitions.

A developer may also encounter the **TCHAR** macro in the source code. This macro will be either a **char** (8 bit) or a **wchar\_t** (16 bit UNICODE char) depending if UNICODE is in use.

## Standard String Functions from C

The proper way to deal with strings (other than the methods of the **CStr** and **WStr** classes) is to use the **\_t** version of the standard string functions. Because 3ds max uses MCBS (multi-byte character sets), the **\_t** versions sometimes map to functions other than the traditional **str\*** ones (which are only guaranteed to work with single-byte character sets). Below is a list of several common mappings from the standard Microsoft VC++ include file (usually **\MSDEV\INCLUDE\TCHAR.H**).

**strcat** maps to **\_tcscat**

**strcpy** maps to **\_tcscopy**

**strlen** maps to **\_tcslen**

**sprintf** maps to **\_stprintf**

**scanf** maps to **\_stscanf**

For example, instead of using the standard C **strcpy** function, use the one shown below:

```
TCHAR buf[64];  
_tcscopy(buf, _T("[ 0, 0, 0 ]"));
```

Developers who need to use the standard C string functions in their 3ds max code should refer to **\MSDEV\INCLUDE\TCHAR.H** to see if there is a **\_t** version of the string function defined for use.

## The GetString() Function

Developers may also see the **GetString()** functions used in the sample source code. This function is simply used to return a string from a resource library. It is defined as follows:

```
TCHAR *GetString(int id) {  
    static TCHAR buf[256];  
  
    if (hInstance)  
        return LoadString(hInstance, id, buf, sizeof(buf)) ? buf : NULL;  
    return NULL;  
}
```

This function is used so that the 3ds max program can be easily translated into other non-English languages. By loading the strings from a resource table, only the resource string table has to be updated to allow the user interface of 3ds max to appear translated into another language. For more details on using resource libraries, see the Advanced Topics section [Globalization](#).

## Summary of Rules for Using Strings

The following rules summarize what developers need to be aware of when working with characters strings.

- Use the **TSTR** string class as much as possible, since these strings automatically allocate the right amount of memory for their storage. (As an added bonus, they're also a lot easier to use than standard strings, because a lot of functionality is built into the string class.)
- If you have to use static character arrays, make sure the array allocation is adequate. Also, make sure that system limits (like 259 for path+filename) are always met or exceeded.
- Don't use **char** or **w\_char** arrays: instead use **TCHAR** as the character type.
- Don't use any standard string manipulation functions (like **strcat**, **strcpy**, **sprintf**, etc.) directly. Rather, use the character-set independent versions found in **\MSDEV\INCLUDE\TCHAR.H**. For example, use **\_tcscat** instead of **strcat**. Note that even routines like **fopen()** that take a string have character-set independent versions in **TCHAR.H**.
- Put all literal strings inside the **\_T** macro, as in **\_T("This is literal")**. The **\_T** macro will convert strings to Unicode automatically if we ever choose to compile with that enabled.
- When comparing characters, use the same macro as for strings but with single quotes. Also, if for any reason you are comparing with a slash for directory separation, make sure to also check for forward slashes as they are valid in NT and used when mounting Unix drives. For example:

```
if (my_path[x] == _T('/') || my_path[x] == _T('\\')) {  
    // do something...  
}
```

For internationalization / localization consider the following when working with strings:

- Try to avoid any string-specific manipulation (like keying off of the first letter in a string, or concatenating strings to form a longer token), since much of this won't translate easily into other languages.
- Keep all literal strings in a resource string table. If all goes well, the internationalization/localization process will consist of only editing resources, not code. In fact, the French, Italian, Spanish, German, and Kanji

versions of 3ds max all use the same code.

## Miscellaneous String Functions

The following two functions are part of the 3ds max API and are useful for breaking up filenames.

### Prototype:

```
void SplitFilename(TSTR& name,TSTR* p, TSTR* f, TSTR* e);
```

### Remarks:

Splits filename **name** into its path, filename, and extension.

### Parameters:

**TSTR& name**

The filename to split apart.

**TSTR\* p**

The path portion.

**TSTR\* f**

The filename portion.

**TSTR\* e**

The filename extension portion.

### Prototype:

```
void SplitPathFile(TSTR& name,TSTR* p, TSTR* f);
```

### Remarks:

Splits filename **name** into its path and a filename.extension.

### Parameters:

**TSTR& name**

The filename to split apart.

**TSTR\* p**

The path portion.

**TSTR\* f**

The filename AND extension portion.

### Prototype:

```
BOOL MatchPattern(TSTR &s, TSTR &ptrn, BOOL  
ignoreCase=TRUE);
```

**Remarks:**

This function is available in release 2.0 and later only.

This method is used to check if a string matches a wildcard pattern.

**Parameters:****TSTR &s**

The string to check.

**TSTR &ptrn**

The wildcard pattern. The \* character matches 1 more characters. The ? character matches a single character.

**BOOL ignoreCase=TRUE**

If TRUE the check is not case sensitive; otherwise it is case sensitive.

**Return Value:**

TRUE if the string matches the pattern; otherwise FALSE.

**Prototype:****int MaxAlphaNumComp(TCHAR \*a, TCHAR \*b);****Remarks:**

This function is available in release 2.0 and later only.

A "smart" alphanumeric compare that sorts things so that numerical suffixes come out in numerical order. This version is case sensitive.

**Parameters:****TCHAR \*a**

The first string to compare.

**TCHAR \*b**

The second string to compare.

**Return Value:**

< 0 means string **a** is less than string **b**.

= 0 means that string **a** is identical to string **b**.

> 0 means that string **a** is greater than string **b**.

**Prototype:**

**int MaxAlphaNumCompI(TCHAR \*a, TCHAR \*b);**

**Remarks:**

This function is available in release 2.0 and later only.

A "smart" alphanumeric compare that sorts things so that numerical suffixes come out in numerical order. This version is case insensitive.

**Parameters:**

**TCHAR \*a**

The first string to compare.

**TCHAR \*b**

The second string to compare.

**Return Value:**

**< 0** means string **a** is less than string **b**.

**= 0** means that string **a** is identical to string **b**.

**> 0** means that string **a** is greater than string **b**.

# Creating a New Plug-In Project

See Also: [Plug-In Directory Search Mechanism](#), [Building the Sample Files](#).

## Overview

This topic presents step by step instructions on how to create a project file for a 3ds max plug-in.

Note: The 3ds max 2.0 SDK now includes a set of AppWizards to create projects for many of the standard plug-ins. Currently it supports: Atmosphere, Anti-Aliasing Filters, Color Selector, File Import, Front End Controllers, Global Utility Plug-Ins, Image Filter / Compositor, Materials, Modifiers, Procedural Objects, Rendering Effects, Textures 2D, Samplers, Shaders, Shadow Generator, Textures 2D, Textures 3D, Track View Utility, and Utility plug-ins.

Using these wizards makes it much easier to create new projects. In addition to setting up most of the compiler / link settings they create CPP files containing the basic class methods that need to be implemented.

To install the AppWizard, copy the **\MAXSDK\HELP\SDKAPWZ.ZIP** file to the Developer Studio Template directory. For example, copy it to the **\Microsoft Visual Studio\Common\MSDev98\Template** directory. Then simply unzip the file. The next time you start VC++, from the **File / New ...** menu, you may choose **3ds max Plugin AppWizard** and follow the onscreen prompts. The AppWizard has online help available but the steps are very self explanatory.

If you want to create a plug-in project 'by hand', the process is described next.

## Beginning a New Project

To create a new 3ds max plug-in project from within Microsoft Developers Studio follow the steps below:

- 1 From the File pulldown menu choose **New...**
- 2 From the **New** dialog make sure the **Projects** tab is selected.
- 3 Select **Win32 Dynamic Link Library** from the list of project types.
- 4 In the **Location:** box enter the path to where you want the project directory created (for example **C:\MYPLUGS**).
- 5 In the **Project Name:** box enter the name for the directory and plug-in project (for example **PRJNAME**). A new directory with this name will be created as

a **sub-directory** of the directory entered in the **Location:** box. The starter project files will also use this name.

6 Press the **OK** button to exit the dialog.

7 At the prompt **What kind of DLL would you like to create?** select **A simple DLL project** and press the **Finish** button to exit the dialog. Press **OK** at the next dialog to complete creating the initial files.

Result: Developer Studio creates a new directory and puts starter **OPT, DSP, DSW, MAK,** and **NCB** files in this directory. These files are explained below

**PRJNAME.DSP** -- This is the project file used within the development environment. In previous versions of Visual C++ this file extension was .MAK. It stores the information specific to your project. There will be a separate .DSP file for each project you create. .DSP files are not compatible with NMAKE. You must export a makefile to build with NMAKE.

**PRJNAME.DSW** -- This is the workspace file used within the development environment. It organizes all the projects into a single workspace.

**PRJNAME.NCB** -- This is the No compile Browser file. It contains information generated by the parser which is used by ClassView, WizardBar, and Component Gallery. If the file is accidentally or deliberately deleted, it is automatically regenerated.

**PRJNAME.OPT** -- This is the workspace options file used within the development environment. It stores all the user options you create for your workspace, so that each time you open the project workspace it has the look and feel you want and includes any customizations you have made.

**PRJNAME.MAK** -- The project makefile.

## **Creating and Adding DEF and CPP files to the Project**

When you create a 3ds max project using the Microsoft Developer Studio, you also need the following file types:

**CPP** -- The C++ source code.

**DEF** -- The module-definition file. A module-definition file is an ASCII text file containing one or more module statements that describe various attributes of a DLL. A DLL requires a DEF file to create an import library (LIB) file and an export (EXP) file. The linker uses the import library to build any executable module that uses the DLL and uses the export file to build the DLL file.

You now need to create the **DEF** file and edit the **CPP** file. It is usually most convenient if these files reside in the same directory as the **DSP** file. In the instructions shown below it is assumed your plug-in is called **MYPLUGIN**.

**1** From the File menu choose **New. . .**

**2** From the New dialog choose the **Files** tab, check the **Add to project** checkbox, enter the C++ source code file name in the **File name:** box (for example **MYPLUGIN**) and select **C++ Source File**. This brings up a new text file window where you'll add your source code. You can begin the **CPP** file with the standard 3ds max include file. This is done by adding the following line to the **CPP** file:

```
#include "MAX.H".
```

Next you need to create the **DEF** file.

**1** From the File menu choose **New. . .**

**2** From the New dialog choose the **Files** tab, check the **Add to project** box, enter the DEF file name in the **File name:** box (for example **MYPLUGIN.DEF**), select **Text File** and press **OK**. This brings up a new text file window where you'll edit the **DEF** file text.

**3** Copy the text shown below from this help file into your new text window. This is the basic structure of a **DEF** file.

```
LIBRARY MyPlugIn
```

```
EXPORTS
```

```
LibDescription @1
```

```
LibNumberClasses @2
```

```
LibClassDesc @3
```

```
LibVersion @4
```

```
SECTIONS
```

```
.data READ WRITE
```

**4** You'll need to perform a single edit to this **DEF** file to work with your project. The only thing you need to change is the Library name. Simply change it to the name of your DLL. Do not include a file name extension. As shown above the library name is **MyPlugIn**.

### **Adding a Resource Script to the Project**

You now need to create a Resource file. The resource has an extension of RC.

**RC** -- The resource file. A resource is binary data that a resource compiler adds to an application's executable file. The data in a resource typically describes an icon, cursor, menu, dialog box, bitmap, etc. Any rollup pages or dialogs you create to implement your user interface will be stored in the RC file. The resource compiler will generate an include file which you must include in your source file.

To create the resource file follow these steps:

**1** From the File menu choose **New. . .**

**2** Choose **Resource Script**.

**3** In the **File name:** box enter your resource name (for example **MyPlugIn.RC**).

Result: A resource script window will pop up.

You now need to add a dialog template to this resource script.

**1** From the **Insert** pull down menu choose **Resource. . .**

**2** From the **Insert Resource** dialog choose **Dialog** and press **New**.

Result: A default dialog will pop up.

**1 Right Click** on the dialog box itself, and from the popup menu choose **Properties...**

**2** In the **ID:** field enter the ID for the dialog, for example **IDD\_MYPLUGIN**

If your dialog is for use in the command panel or materials editor (not a floating dialog), follow the steps below:

**3** Click on the **Styles** Tab

**4** From the **Style:** drop down list choose **Child**

**5** From the **Border:** drop down list choose **None**

**6** Close the Properties dialog box and resize the plug-in dialog frame size to a width of **108 units**. This is the standard width for the command panel in 3ds max for use in the United States. You can see the size displayed in the lower right corner of the IDE. If you are creating a material or texmap plug-in whose interface shows up in the materials editor dialog the proper width is **217 units**. If you're doing an atmospheric or renderer plug-in the correct width is **212 units**. If you are creating a dialog that will not be used in the command panel you may, of course, use any size.

Result: You have a dialog template to which you may add controls. For use in the command panel you may wish to delete the **OK** and **Cancel** buttons.

When you compile the RC file an include file is generated. The default name is

**resource.h.** This file will be included in your **CPP** source file to specify the resource ID's. To add the include file to your **CPP** file edit the **CPP** file and add the line:

```
#include "resource.h"
```

## Adding a String Table

Now you need to add a string table to your project. This allows you to put your literal strings into a table for easier translation to other languages. Rather than searching your text for literal strings you can simply change them in the string table. The sample code in the SDK uses this technique to manage strings. To add a string table, do the following:

- 1 From the **Insert** pull down menu choose **Resource...**
- 2 Choose **String Table** and press the **New** button.

Result: You have added the string table to your project.

When you want to add a literal string to your plug-in enter the value into the string table and then use the **GetString()** function to load that string. To enter the value you simply double click on an empty slot in the table and enter an ID (the ID passed to **GetString()**) and a Caption (the text). Consider the **Animatable::GetClassName()** method as an example.

Without the string table, the code would be written:

```
void GetClassName(TSTR& s) { s = _T("Ring Array"); }
```

With the string table, it would be written:

```
void GetClassName(TSTR& s) { s =  
GetString(IDS_DB_RING_ARRAY_CLASS); }
```

The **GetString()** function loads the string from the table and returns a pointer to it. You need to include this function, listed below, in your CPP source file:

```
TCHAR *GetString(int id) {  
    static TCHAR buf[256];  
    if (hInstance)  
        return LoadString(hInstance, id, buf, sizeof(buf)) ? buf : NULL;  
    return NULL;  
}
```

For more information see the Advanced Topics section on [Globalization](#).

## Specifying Output and Include File Settings

You now need to specify the output file name. This is the name of the DLL created. You specify the output file name for your plug-in using the procedure below:

- 1 From the **Project** pull down menu choose **Settings...** Make sure all the configuration are being changed by selecting **All Configurations** from the **Settings For:** dropdown list.

- 2 From the **Project Settings** dialog box choose the **Link** Tab.

- 3 Under **Output file name:** Enter the path to 3ds max plug-ins and your file name. For example **\3DSMAX\STDPLUGS\MYPLUGIN.DLO**

Result: When the project is compiled and linked successfully, the DLL is written to this location.

The example above (**MYPLUGIN.DLO**) is the extension typically used by procedural object plug-ins. For a list of the standard filename extensions for all plug-ins see [Plug-In Directory Search Mechanism](#). Note that 3ds max will only load DLLs that use these standard extensions.

You now need to specify the path of the include files for the SDK:

- 1 From the **Project Settings** dialog box choose the **C/C++** Tab.

- 2 From the **Category:** drop down list box choose **Preprocessor**.

- 3 Under **Additional include directories:** enter the path **\MAXSDK\INCLUDE**.

You also need to add **COMCTL32.LIB** which is not included by default by Visual C++ in the list of libraries to link.

- 1 Still within the **Project Settings** dialog box choose the **Link** Tab (you may need to scroll to see it).

- 2 In the list of Object/library modules add **COMCTL32.LIB** to the list of existing choices.

- 3 Select **OK** to exit the dialog.

## Updating the Project Configurations

A new plug-in project contains two default configurations. These are named **Win32 Release** and **Win32 Debug**. The sample code that comes with the 3ds max SDK has an additional configuration: **Win32 Hybrid**. This section discusses the need for these different configuration.

There are three conditions for plug-ins working with MAX. These are:

- 1) Release 3ds max and Release Mode (non-debug) plug-ins. When you create a plug-in for general distribution you'll compile in **Release** mode.
- 2) Release 3ds max and Debug Mode plug-ins. While developing a plug-in and using source code level debugging you'll compile in **Hybrid** mode.
- 3) Debug 3ds max (only registered developers have access to this special version of MAX) and Debug Mode plug-ins. While using the special Debug SDK, and Debug 3ds max you'd compile in **Debug** Mode.

In Microsoft Developer Studio the Debug and Release C runtime libraries use different heap management. This means that allocating an object in debug mode and de-allocating it in release mode (and vice versa) can cause a crash. Most developers will work with a version of 3ds max compiled in Release mode. Thus it uses the run-time libraries called **Multithreaded DLL**. Plug-Ins that work with this version of 3ds max need to match this run-time library. If they don't crashes will occur.

To prevent this from happening you need to create a new configuration and change some of the settings of the existing configurations.

To create the **Win32 Hybrid** configuration follow these steps:

- 1 From the **Build** menu choose **Configurations...** and then choose **Add...**
- 2 Enter **Hybrid** in the **Configuration** edit box then choose **Win32 Debug** from the **Copy settings from:** list box and press **OK** and then **Close** to exit the **Configurations** dialog. This creates a new Hybrid configuration using the same initial settings as the **Win32 Debug** configuration.
- 3 From the **Project** menu choose **Settings....**
- 4 From the **Settings For:** section choose the **Win32 Hybrid** configuration.
- 5 From the **C/C++** tab, under the **Categories:** drop down list choose **Code Generation**.
- 6 From the **Use run-time library:** drop down list choose **Multithreaded DLL**.
- 7 Choose the **General** tab of the dialog.
- 8 In the edit boxes under both **Intermediate files:** and **Output files:** enter **Hybrid**.
- 9 Select **OK** to exit the dialog.

Now update the **Win32 Release** configuration:

- 1 From the **Project** menu choose **Settings....**
- 2 From the **Settings For:** section choose the **Win32 Release** configuration.

- 3 From the **C/C++** tab, under the **Categories:** drop down list choose **Code Generation**.
- 4 From the **Use run-time library:** drop down list choose **Multithreaded DLL**.
- 5 Select **OK** to exit the dialog.

Now update the **Win32 Debug** configuration:

- 1 From the **Project** menu choose **Settings...**
- 2 From the **Settings For:** section choose the **Win32 Debug** configuration.
- 3 From the **C/C++** tab, under the **Categories:** drop down list choose **Code Generation**.
- 4 From the **Use run-time library:** drop down list choose **Debug Multithreaded DLL**.
- 5 Select **OK** to exit the dialog.

Result: You now have three configurations available, each used for a different purpose. When you create a plug-in for distribution to the public use your **Win32 Release** configuration. During development of the plug-in when you want to use source level debugging use the **Win32 Hybrid** configuration. If you are a registered developer using the special Debug SDK and Debug 3ds max then use the **Win32 Debug** configuration.

## Specifying Library files for the Project

You will also need to add the 3ds max library files (**LIB**) to the project. The **LIB** files required varies depending on the type of plug-in that is being created. Here is the list of the available library files and their use:

### **ACAP.LIB**

The Call Attributed Profiler library. When a plug-in is using the profiler to test performance this library is required. See the Advanced Topics section on [Debugging](#) for more information on profiling.

### **BMM.LIB**

Bitmap manager library. Image loader / saver plug-ins, and those that deal with bitmaps require this library.

### **CLIENT.LIB**

Network rendering client library. This one is used internally for network rendering. A plug-in developer won't use this library.

### **CORE.LIB**

Functions exported from MAX. All plug-ins use this library.

## **EDMODEL.LIB**

The NURBS library. Plug-Ins that want to use the NURBS API require this library.

## **EXPR.LIB**

Expression library. Plug-Ins that use the mathematical expression parser ([Class Expr](#)) require this library.

## **FLILIBD.LIB**

## **FLILIBH.LIB**

## **FLILIBR.LIB**

Flic file (FLI/FLC) libraries (debug, hybrid, and release versions). Plug-ins that work with FLI/FLC files require the appropriate version of this library. Plug-Ins for release (using the Win32 Release configuration) should use FLILIBR.LIB. Plug-Ins used for source level debugging should use FLILIBH.LIB. Registered developers using the special 3ds max Debug SDK should use FLILIBD.LIB.

## **FLT.LIB**

Filters library. Image Filter plug-ins use this library.

## **GCOMM.LIB**

This library is used internally.

## **GEOM.LIB**

Geometry library. Procedural objects, modifiers, controllers, and utility plug-in use this library.

## **GFX.LIB**

Graphics library. Plug-ins that use MAX's GraphicsWindow calls require this library.

## **LVSIO.LIB**

This is a library designed for reading and writing the Lightscape files.

## **MAXSCRIPT.LIB**

Users of the MAXScript SDK require this library.

## **MAXUTIL.LIB**

Utility library. All plug-ins use this library.

## **MESH.LIB**

Mesh library. Plug-Ins that call methods of MAX's Mesh class require this library.

## **MNMATH.LIB**

The 'Minnesota Math' library. Plug-Ins that use the MNMesh and related classes require this library. See [Class MNMesh](#) for details.

## **PARAMBLK2.LIB**

The Parameter Block 2 library. Plug-ins that use the parameter block / map system introduced in R3 require this library.

## **PARTICLE.LIB**

Particles library. Plug-ins that relate to particle systems use this library.

## **PATCH.LIB**

Patch library. Plug-ins that deal with Patch objects use this library.

## **RENDERUTIL.LIB**

Render utilities library. It includes the implementation of Quantizer and ColorPacker methods.

## **TESSINT.LIB**

Tesselation library. Plug-ins that deal with the tessellation of NURBS or patches use this library.

## **VIEWFILE.LIB**

This is the file viewer library used by VIEWFILE.DLL.

To add the library files to the project follow these steps:

- 1** From the **Project** menu choose **Add To Project** then **Files...**
- 2** Change the **Files of type:** drop down list to **Library files (.lib)**.
- 3** Choose the required **LIB** files from the list (from the **\MAXSDK\LIB** directory) (you may **Ctrl** click on them to select more than one). Select **OK** to exit the dialog.

Result: The **LIB** files are added to the project.

Note: You may remove the files **ODBC32.LIB** and **ODBCCP32.LIB** which are included by default but not needed.

## **Finishing Up**

To complete the new project creation follow these steps:

Since you'll likely need to spend time debugging the Hybrid configuration should be your initial choice. When you've finished development and want to create your DLL for distribution change this to Win32 - Release and rebuild. To set your default configuration to Hybrid do the following.

- 1** From the **Build** menu choose **Set Active Configuration...**

2 Choose **Win32 Hybrid** and select **OK** to close the dialog.

Now you need to update the project dependencies and save your work.

1 From the **Build** pull down choose **Update All Dependencies...** and choose the all your configurations using the check boxes and then select **OK**.

2 From the **File** menu choose **Save Workspace** to save your new project.

### **Disabling Exception Handling**

This step is not necessary, but developers may wish to disable exception handling for their plug-ins. This can be done using the **Project Settings** dialog, **C++ Tab**, **C++ Language** category and un-checking the **Enable exception handling** box. This makes the code both smaller and faster.

# COM/DCOM Interface

See Also: [Class GUP](#).

## **Overview**

The idea behind this COM (Component Object Model) object is to expose the core of 3ds max so applications can invoke 3ds max to generate images. The whole implementation of the COM interface was done as a plug-in itself so developers have the option of enhancing it in any manner they wish. Not just by adding interfaces to this object but also by creating entire new objects using this implementation as a code base. The code is extensively documented and the test "Client Application" is also extensively documented in a way where even developers who don't have any experience with COM objects can make use of it. For those with experience, the 3ds max COM interface is implemented entirely using ATL which makes it very simple to add and/or modify any aspect of the code.

COM Interfaces and their types are defined in an "**IDL**" file. They may be found in **\MAXSDK\SAMPLES\GUP\COMSRV\COMSRV.IDL**.

## **Registering 3ds max as a DCOM Server**

The following steps register 3ds max as a DCOM server:

- 1) Build **\MAXSDK\SAMPLES\UTILITIES\COMSRV.MAK** and copy the resulting **COMSRVUI.DLU** to the 3ds max PLUGINS directory.
- 2) Start 3ds max and go the Utility Panel. Choose More and pick COM/DCOM Server Control.
- 3) If the button in the comand panel says "Register" then click it, or if it says "Unregister", then do nothing (as 3ds max is already registered).

Now 3ds max is registered as a DCOM server and an instance of it can be created from any COM client.

It is also possible to register and unregister 3ds max from the command line. There are two command line options that can be passed to MAX:

**3DSMAX -RegisterMAXRenderer**

**3DSMAX -UnregisterMAXRenderer**

## **The MaxRenderer Interface**

This is the main interface exported by this COM object. Through its methods you can load a 3ds max scene, define the parameters for a resulting image, request 3ds max to render any number of frames, collect the resulting images, and so on. The other interfaces defined are support interfaces used by the different methods of the 3ds max Renderer Interface.

## Properties

These properties are the same ones found in the 3ds max API. They are exposed here so applications can query or define the different attributes of a scene to be rendered.

**HRESULT AnimationStart([out, retval] float \*pVal);**

**HRESULT AnimationStart([in] float newVal);**

Sets or returns the frame number defined as the starting frame for the current animation. The frame number argument is a float in order to isolate the foreign application from MAX' frame granularity. A 3ds max frame can be divided into around 4096 time slices. In other words, it is possible to generate animation images with a  $1/(30 * 4096)$  of a second resolution.

**HRESULT AnimationEnd([out, retval] float \*pVal);**

**HRESULT AnimationEnd([in] float newVal);**

Same as above but for the last frame of the current animation.

**HRESULT RenderFieldRender([out, retval] BOOL \*pVal);**

**HRESULT RenderFieldRender([in] BOOL newVal);**

Defines (or gets the current state) if the rendered images will be field rendered.

**HRESULT RenderColorCheck([out, retval] BOOL \*pVal);**

**HRESULT RenderColorCheck([in] BOOL newVal);**

Defines (or gets the current state) if the generated images will be checked for invalid colors.

**HRESULT RenderSuperBlack([out, retval] BOOL \*pVal);**

**HRESULT RenderSuperBlack([in] BOOL newVal);**

Defines (or gets the current state) how pure blacks are generated.

**HRESULT RenderHidden([out, retval] BOOL \*pVal);**

**HRESULT RenderHidden([in] BOOL newVal);**

Defines (or gets the current state) if hidden objects are to be rendered.

**HRESULT RenderForceTwoSide([out, retval] BOOL \*pVal);**

**HRESULT RenderForceTwoSide([in] BOOL newVal);**

Defines (or gets the current state) if both sides of an object are to be rendered. Usually, just the "outside" is rendered.

**HRESULT RenderAtmosphere([out, retval] BOOL \*pVal);**

**HRESULT RenderAtmosphere([in] BOOL newVal);**

Defines (or gets the current state) if atmospheric effects are to be rendered.

**HRESULT RenderFieldOrder([out, retval] long \*pVal);**

**HRESULT RenderFieldOrder([in] long newVal);**

Defines (or gets the current order) the order fields are rendered (if field rendering).

## Methods

These methods are a superset of the methods found in the 3ds max API. They encapsulate some of the API functions (specifically those related to rendering) in order to simplify the process as well as to isolate the foreign applications from classes and data not exposed.

### **HRESULT LoadScene([in] BSTR SceneName);**

Loads the given 3ds max scene. Note that the location of the scene is from the perspective of the computer where the 3ds max instance is being created. The use of physical drive letters should only be used if you know the scene file resides in the same computer. In doubt, use UNC path names.

### **HRESULT SaveScene([in] BSTR SceneName);**

The counterpart of the above to save the given 3ds max scene.

### **HRESULT ImportFile([in] BSTR FileName);**

Same idea as in LoadScene() but it deals with non 3ds max files. This can be used to write a "translator" where scene files are imported and then saved as 3ds max files.

### **HRESULT EnumCameras(void);**

Use this to enumerate all cameras defined in a scene. When you request 3ds max to render a scene, one of the arguments you need to pass is the name of the camera to use. This method will return all cameras defined in the current scene. The returned names are collected through the `_ImaxRendererEvents()` interface defined below.

### **HRESULT OpenRenderer([in] BSTR CameraName, [in] IMaxBitmapInfo \*pBif, [in] BOOL region);**

Opens the renderer and prepares it to render. The first argument is the camera name to use. You can enumerate all cameras defined in a scene using the `EnumCameras()` methods described above. The `pBif` argument is a pointer to a `IMaxBitmapInfo()` interface (defined below). This object will define the parameters of the resulting image to be created. The last argument defines if the render will be a full image or just a region.

### **HRESULT SetRegion([in] short x,[in] short y,[in] short w,[in] short h);**

If you are rendering just a region of the image, use this to define the region to be rendered. Given as an example a scene you want rendered at 640x480. If you

want to render just the first quarter of the image, you would pass a rectangle starting at 0,0, 320 pixels wide, and 240 pixels high.

### **HRESULT RenderFrame([in] float Time, [in] float Duration);**

You've loaded a scene, opened the renderer, now you want to render an image. Use this method to generate the image. The first argument defines the frame you want to render. The second defines the duration of the frame. Render progress is processed through the `_ImaxRendererEvents()` interface defined below. This method returns immediately. You keep track of the progress through the sink event defined above until you receive a `OnRenderDone()` event call.

### **HRESULT CancelRenderer(void);**

Cancels the rendering.

### **HRESULT CloseRenderer(void);**

When done, use this to close the renderer.

### **HRESULT GetLine([in] MAXchannelTypes type, [in] long line, [in] BOOL linear, [out, retval] SAFEARRAY(unsigned char) \*psa);**

Use this method to collect the image you just rendered. The first argument defines the bitmap layout. You can collect the image in many different formats depending on what channels you requested to be rendered in the `ImaxBitmapInfo()` argument passed to `OpenRenderer()`. The second argument defines which line you want to collect. The third argument defines if you want the image to be linear or gamma processing should take place.

### **HRESULT GetPreviewLine([in] long line, [in] long width, [out, retval] SAFEARRAY(unsigned char) \*psa);**

Used to collect sub-sampled lines used to maintain a preview of the render process as it is happening.

### **HRESULT ExecuteMAXScriptString([in] BSTR String);**

### **HRESULT ExecuteMAXScriptFile([in] BSTR Filename);**

These are used if you need to request 3ds max to do something and the method for doing this something is not exposed above, you could issue a 3ds max Script command (or a whole 3ds max Script file) in order to accomplish this "something" task. Note: These two calls are untested, and unfortunately, there is no error control.

### **The `_ImaxRendererEvents()` sink interface**

Use this interface to receive notifications and events from MAX.

#### **HRESULT OnEnumCameras([in] BSTR CameraName);**

When you issue a `ImaxRenderer::EnumCameras()`, `OnEnumCameras()` will be fired for every camera found in the scene.

#### **HRESULT OnRenderProgress([in] long Done,[in] long Total);**

This event will be fired during the render process to update the current progress of the render process.

#### **HRESULT OnRenderMessage([in] BSTR Message);**

Same as in above. This event will be fired with message updates describing the current stage of the render process.

#### **HRESULT OnRenderDone();**

This event is fired when the render is complete.

## **The MaxBitmapInfo Interface**

This interface is used to define the characteristics of the resulting image generated by MAX. There are only properties. The only one that might need explanation is the Channels() property. Use this to define what types of special channels you want generated. These are in addition to the standard RGBA channels.

## Command Modes and Mouse Procs

See Also: [Class CommandMode](#), [Class MouseCallback](#).

## **Overview**

In addition to any user interface that a plug-in may provide in the command panel via rollup pages, a plug-in may want to process mouse interaction in any of the viewports. Command modes allow the plug-in developer to define custom user / mouse interaction procedures. The system uses command modes as well. Examples are the viewport manipulation commands such as zoom and arc-rotate. Move, rotate and scale are implemented as command modes as well.

This section discusses command modes and the methods used to work with them.

## Methods

In MAX, there is always a current command mode. This is the instance of the class **CommandMode** that is currently at the top of the system's command stack. Command modes can either be pushed on the stack or replace the item on the top of the stack.

There are methods in MAX's [Interface class](#) to set and get the current command mode as well as getting the size of the command stack and finding a particular mode by index. See the methods:

```
virtual void PushCommandMode(CommandMode *m)=0;  
virtual void SetCommandMode(CommandMode *m)=0;  
virtual void PopCommandMode()=0;  
virtual CommandMode* GetCommandMode()=0;  
virtual void SetStdCommandMode(int cid)=0;  
virtual void PushStdCommandMode(int cid)=0;  
virtual void RemoveMode(CommandMode *m)=0;  
virtual void DeleteMode(CommandMode *m)=0;  
virtual int GetCommandStackSize();  
virtual GetCommandStackEntry(int entry)
```

Viewport manipulation commands, for instance, are always pushed on the stack so that if the user right clicks while in a viewport mode, the viewport command mode is popped off the stack, restoring the previous command mode in effect before the viewport command was engaged.

A command mode provides the system with two major things:

A callback procedure which flags nodes that belong in the foreground plane.

A mouse proc which handles mouse input in the viewports.

For the first item, plug-ins typically use a standard callback object provided by the system that flags all nodes dependent on the plug-in object. So when the plug-in object changes, any nodes that change as a result will be in the foreground plane, making redraw time faster. For more details see the section [Foreground / Background Planes](#).

The mouse proc is the object that allows plug-ins to process viewport mouse input. The **MouseCallback** class is a pure virtual class with a method named **proc()**. This method is called when a mouse event takes place. It gets passed several parameters:

The window handle of the window the user clicked in. This will be one of the viewports. An interface to the viewport can be obtained from the system, given this window handle.

A message parameter. This describes the type of event such as mouse down, mouse up, mouse move, etc.

The point number. this is 0 for the first click, 1 for the second, etc.

Flags. These specify the state of the Shift, Ctrl, and Alt keys.

The 2D screen point that the user clicked on. Methods in the viewport interface allow this point to be converted into a world space ray or a 3D view space point. A world space ray can be intersected with the active construction plane which results in a point on the active construction plane.

The mouse proc can specify how many points it wants for its specific task. For instance, the move transform needs two points. The first point represents the point where the user clicked down and the second point represents where the user released the mouse. A mouse proc can specify that it needs a large number of points and then return an abort code when it has completed its operation. For instance, the mouse proc that handles the creation of a spline expects to get some arbitrary number of points. When the user completes the spline, the mouse proc signals the system that its operation is completed.

In addition to providing the system with a foreground callback and a mouse proc, a command mode also has some other methods.

When a command mode becomes active its **EnterMode()** method is called. Usually it would respond by changing the state of a control somewhere to reflect to the user that they were in that mode. Typically this means pushing in a tool button. When the mode is finished the button should be returned to normal. The user may have activated the mode by pushing in the tool button, in which case it is redundant for the command mode to also set the button's state to 'in', however the mode could have been entered by right clicking while in a viewport manipulation mode in which case, the tool button would have been in the 'out' state. Note: A developer should use the standard color **GREEN\_WASH** for check buttons that instigate a command mode. While the command mode is active the button should be displayed in **GREEN\_WASH**. See [Class ICustButton](#) (specifically the method **SetHighlightColor()**) for more details.

When the active mode is replaced by a different mode, its **ExitMode()** method is called. Typically, the command mode would respond by setting its corresponding tool button to the 'out' state.

Command modes are identified by a class ID and an ID. The class ID is usually chosen from a pre-defined set of class IDs although developers may create their own. These define the 'type' of mode. The ID is the mode's unique ID.

There are two other methods a developer may find useful. These methods allow a plug-in to receive notification when the command mode has been changed by the user. These methods of class **Interface** are:

```
virtual void RegisterCommandModeChangedCallback(  
    CommandModeChangedCallback *cb)=0;
```

Register a callback object that will get called when the user changes the command mode. See [Class CommandModeChangedCallback](#).

```
virtual void UnRegisterCommandModeChangedCallback(  
    CommandModeChangedCallback *cb)=0;
```

Un-registers the command mode change callback object.

## Display of Messages in Command Modes

Developers cannot put up a message box using the Windows **MessageBox()** API while in the middle of a mouse operation inside a command mode. For example, if the user is dragging the mouse, it will cause problems to put up a message box. The prompt line may be used if a message needs to be sent to the user while in this state. This is done using the methods of class **Interface**. See [Class Interface](#) to review these methods.

## Summary

Command modes allow the plug-in developer to process mouse interaction in any of the viewports. A command mode provides the system with a foreground callback and a mouse proc. See the section [Object Creation Methods](#) for a discussion of how command modes participate in custom object creation procedures.

# Computing Face and Vertex Normals

See Also: [Class Point3](#), [Class Mesh](#), [Template Class Tab](#).

## Overview

Developers often need to compute the face and vertex normals when working with meshes in MAX. This section discusses the process of computing these normals and provides some sample code to do so.

## Face Normals

A face normal is a vector that defines which way a face is pointing. The direction that the normal points represents the front, or outer surface of the face. To compute the face normal of a face in a mesh you simply take the cross product of two edge vectors of the face. The following code shows how this is done using the 3ds max API. It loops through each face in a mesh and stores the computed face normal in a table of **Point3**s named **fnorms**. At the end of the code, the **DebugPrint()** API is used to display each normal in the table to the debug window of the VC++ IDE.

```
void Utility::ComputeFaceNormals(Mesh *mesh) {
    Face *face;;
    Point3 *verts;
    Point3 v0, v1, v2;
    Tab<Point3> fnorms;

    // Compute face (surface) normals for the mesh
    face = mesh->faces;
    verts = mesh->verts;
    fnorms.SetCount(mesh->getNumFaces());
    for (int i = 0; i < mesh->getNumFaces(); i++, face++) {
        v0 = verts[face->v[0]];
        v1 = verts[face->v[1]];
        v2 = verts[face->v[2]];
        fnorms[i] = (v1-v0)^(v2-v1);
        fnorms[i] = Normalize(fnorms[i]);
    }

    // Display the normals in the debug window of the VC++ IDE
    DebugPrint("\n\nFace Normals ---");
    for (i = 0; i < fnorms.Count(); i++) {
        DebugPrint("\nFace Normal[%d]=(%.1f, %.1f, %.1f)",
            i, fnorms[i].x, fnorms[i].y, fnorms[i].z);
    }
    DebugPrint("\n\n");
}
```

As a side note on face normals -- If you take the length of a face normal vector

(for example using the **Point3::Length()** method), you get a quantity equal to twice the surface area of that face.

## Vertex Normals

This section discusses the way vertex normals may be computed. Two algorithms are reviewed. The first ignores smoothing groups and returns an averaged normal at the vertex. The second one looks at the smoothing information and computes multiple normals when there are faces that have different smoothing groups that share a vertex. Sample code to handle the smoothing group aware case is shown.

First, consider the case where smoothing groups are not checked. In this case, there will be a single vertex normal for each vertex of the mesh. The vertex normal is the average of the face normals of each of the faces that share that vertex. The algorithm to compute such vertex normals is as follows:

First, allocate an array of normals, one for each vertex in the mesh, and initialize them to zero (**Point3(0,0,0)**). Then for each face, compute its face normal, and add it into each of the three vertex normals that the face contributes to. For example, if you have a vertex normal shared by five faces, each face will add in its normal to that vertex, and thus the result will be average normal of those five faces. When all the faces in the mesh have been processed, the average normal vector has been computed. As a last step, all the normals in the array can be normalized.

The above algorithm does not take smoothing groups into account. When smoothing groups are involved, you may have multiple normals for each vertex. For example, if you had a sphere that had the top and bottom hemi-spheres smoothed separately (i.e. not smoothed across the equator), then the vertices across the equator would have two normals for each vertex while the other vertices would have one. There may be as many normals as there are smoothing groups colliding at a vertex. However, it is by far the most common case to have one, and anything other than one or two is very rare.

The class used to compute vertex normals considering smoothing is shown below. This class, **VNormal**, is similar to the **RNormal** class used by 3ds max internally. The class contains a **Point3** which is the normal, a **DWORD** for the smoothing groups, and a pointer to the **next** normal -- this class is a linked list. The **init** variable is used as a flag to indicate if the first normal in the list has been initialized.

```
// Linked list of vertex normals
class VNormal {
```

```

public:
    Point3 norm;
    DWORD smooth;
    VNormal *next;
    BOOL init;

    VNormal() {smooth=0;next=NULL;init=FALSE;norm=Point3(0,0,0);}
    VNormal(Point3 &n,DWORD s)
    {next=NULL;init=TRUE;norm=n;smooth=s;}
    ~VNormal() {delete next;}
    void AddNormal(Point3 &n,DWORD s);
    Point3 &GetNormal(DWORD s);
    void Normalize();
};

```

A key method to this class is **AddNormal()**. It is used when a face is going to add its normal to a vertex. This method is passed the normal and the smoothing information for that face. It checks if the normal passed shares smoothing information with the existing normal. If it does, the normal is added in, and the smoothing bits are bitwise OR-ed in. If it does not, a new vertex normal is created. In this way, as normals that share smoothing information are added, they contribute to the overall normal for that smoothing condition at the vertex. If it is a normal whose face does not share smoothing information, a new vertex normal is allocated.

```

// Add a normal to the list if the smoothing group bits overlap,
// otherwise create a new vertex normal in the list
void VNormal::AddNormal(Point3 &n,DWORD s) {
    if (!(s&smooth) && init) {
        if (next) next->AddNormal(n,s);
        else {
            next = new VNormal(n,s);
        }
    }
    else {
        norm += n;
        smooth |= s;
        init = TRUE;
    }
}

```

```

}

// Retrieves a normal if the smoothing groups overlap or there is
// only one in the list
Point3 &VNormal::GetNormal(DWORD s) {
    if (smooth&s || !next) return norm;
    else return next->GetNormal(s);
}

// Normalize each normal in the list
void VNormal::Normalize() {
    VNormal *ptr = next, *prev = this;
    while (ptr) {
        if (ptr->smooth&smooth) {
            norm += ptr->norm;
            prev->next = ptr->next;
            delete ptr;
            ptr = prev->next;
        }
        else {
            prev = ptr;
            ptr = ptr->next;
        }
    }
    norm = ::Normalize(norm);
    if (next) next->Normalize();
}

```

The method **ComputeVertexNormals()** shown below is a demonstration method that uses the **VNormal** class above. The first thing done is to create a table of the vertex normals. Note that since the **Tab** class does not do any initialization (it only allocates the memory), the code loops through each normal and call the constructor to perform the initialization. Then it goes through each face , calculates the surface normal, and adds it into each of the three vertex normals for the face using **AddNormal()**. When all the faces have been processed, it goes through each of the vertex normals and normalizes them. In the code below, the vertex normals are displayed using **DebugPrint()** to the

output window. If there is more than one normal at a vertex, each one is displayed (the **DisplayVertexNormal()** method recursively calls itself to display each one).

```
// Compute the face and vertex normals
void Utility::ComputeVertexNormals(Mesh *mesh) {
    Face *face;
    Point3 *verts;
    Point3 v0, v1, v2;
    Tab<VNormal> vnorms;
    Tab<Point3> fnorms;

    face = mesh->faces;
    verts = mesh->verts;
    vnorms.SetCount(mesh->getNumVerts());
    fnorms.SetCount(mesh->getNumFaces());

    // Compute face and vertex surface normals
    for (int i = 0; i < mesh->getNumVerts(); i++) {
        vnorms[i] = VNormal();
    }
    for (i = 0; i < mesh->getNumFaces(); i++, face++) {
        // Calculate the surface normal
        v0 = verts[face->v[0]];
        v1 = verts[face->v[1]];
        v2 = verts[face->v[2]];
        fnorms[i] = (v1-v0)^(v2-v1);
        for (int j=0; j<3; j++) {
            vnorms[face->v[j]].AddNormal(fnorms[i],face->smGroup);
        }
        fnorms[i] = Normalize(fnorms[i]);
    }
    for (i=0; i < mesh->getNumVerts(); i++) {
        vnorms[i].Normalize();
    }

    // Display the normals in the debug window of the VC++ IDE
    DebugPrint("\n\nVertex Normals ---");
```

```
for (i = 0; i < vnorms.Count(); i++) {  
    DisplayVertexNormal(vnorms.Addr(i), i, 0);  
}  
DebugPrint("\n\n");  
}
```

```
void Utility::DisplayVertexNormal(VNormal *vn, int i, int n) {  
    DebugPrint("\nVertex %d Normal %d=(%.1f, %.1f, %.1f)",  
        i, n, vn->norm.x, vn->norm.y, vn->norm.z);  
    if (vn->next) DisplayVertexNormal(vn->next, i, n+1);  
}
```

## Other Techniques for Computing Vertex Normals

This next section discusses two other techniques that may be used in computing vertex normals. The first technique weights the normals by the vertex angle on each face. The second weights the normal using the area of each face.

### Weighting by Face Angle

To understand why using a weighted normal approach might be used consider the following example:

Create a default Box and convert it to an Editable Mesh. Go into SubObject mode, and find vertex 1 (generally found at the front lower left corner). Display the edges, and go into object properties to unclick "edges only" (so you see the hidden edges). You'll see that vertex 1 is used by bottom faces 1 and 2. (In the SDK, these are vertex 0 and faces 0 and 1.) It's also used by front faces 5 and 6, and left face 11. (4,5,10.)

If we simply averaged the normals of all incident faces, we'd get:

Normalize  $(2*(0,0,-1) + 2*(0,-1,0) + (-1,0,0))$ , which is  $(1/3, 2/3, 2/3)$ .

Because this arrangement of diagonals is haphazard and (inherently) asymmetric, we'd get vertex normals on a box pointing odd, uncoordinated directions.

If we instead weight the normals by the vertex angle on each face, we get:

Normalize  $(\pi/2*(0,0,-1) + \pi/2*(0,-1,0) + \pi/2*(-1,0,0)) = (1,1,1)/\text{Sqrt}(3)$

This is more natural for the user. Each vertex normal points away from all three sides symmetrically. (The individual front and bottom triangles may have varying angles, but the pairs of them always add up to  $\pi/2$ .)

This seems like the right approach in general -- when you divide a face, for example, you don't wind up changing the vertex normal when the surface hasn't essentially changed. If you change vertex angles by dragging neighboring vertices, the normal changes in a natural fashion.

You can compute the vertex angle by using dot products as shown below:

**// Corner is 0, 1, or 2 -- which corner do we want the angle of?**

**float FindVertexAngle(Mesh \*mesh, int face, int corner) {**

**int cnext = (corner+1)%3;**

**int cprev = (corner+2)%3;**

**DWORD \*vv = mesh->faces[face];**

```

// Get edge vectors:
Point3 A = mesh->verts[vv[cnext]] - mesh->verts[vv[corner]];
Point3 B = mesh->verts[vv[corner]] - mesh->verts[vv[cprev]];

// Normalize the edge-vectors, but return 0 if either has 0 length.
float len = Length(A);
if (!len) return len;
A = A/len;
len = Length(B);
if (!len) return len;
B = B/len;

// The dot product gives the cosine of the angle:
float dp = DotProd (A,B);
if (dp>1) dp=1.0f; // shouldn't happen, but might
if (dp<-1) dp=-1.0f; // shouldn't happen, but might
return acos(dp);
}

```

To be efficient when computing all normals, you may want to cache the normalized edge directions (A & B). You can index these by an adjacent edge list for the mesh, where edir[i] is the unit vector pointing from vertex ae->edges[i].v[0] to ae->edges[i].v[1] (AdjEdgeList \*ae).

### Weighting by Face Area

Another possibility is to weight the normals by the area of each face. The area of a face is very easy to compute, it's just half the length of the normal cross product:

```

void GetAreaAndNormal (Mesh *mesh, int face, Point3 & N, float
area) {
    DWORD *vv = mesh->faces[face].v;
    Point3 A = mesh->verts[vv[1]] - mesh->verts[vv[0]];
    Point3 B = mesh->verts[vv[2]] - mesh->verts[vv[0]];
    N = A^B;
    area = Length (N) / 2.0f;
    Normalize (N);
}

```

}

This works using any two edges for A and B.

To weight face normals by area, you can just use the  $N=A \wedge B$  vector directly.

Weighting by area gives an interesting result, but perhaps not as satisfactory as weighting by face angle.

## Custom User Interface Controls

See Also: [Class Interface](#), [Class ICustomControl](#), [Class ICustEdit](#), [Class ISpinnerControl](#), [Class ISliderControl](#), [Class ICustImage](#), [Class ICustStatus](#), [Class IColorSwatch](#), [Class ICustButton](#), [Class ICurveCtl](#), [Class ICustToolbar](#), [Class IRollupWindow](#), [Class IOffScreenBuf](#), [Class TCBGraphParams](#), [Class IDADWindow](#).

## Overview

A set of custom controls are available for use in the user interface design of 3ds max plug-ins. The 3ds max program itself makes extensive use of these custom controls. These controls provide an important element of consistency between the plug-in and the system, making new plug-ins appear fully integrated with MAX. The use of these controls by the majority of developers will provide a level of familiarity for users who often work with many different plug-ins.

This section takes a quick look at all the control types. It then discusses two major aspects of using MAX's custom controls. The first is how the controls are added to a rollup page in the command panel and presented to the user. The second is how the user's operation of these controls is processed by the plug-in.

The sample program **CUSTCTRL.CPP** demonstrates each of the custom controls which may be used in the command column. To run this program, copy the file **\MAXSDK\PLUGIN\CUSTCTRL.DLU** into your stdplugs directory. The program is implemented as a utility plug-in. You can run the program by choosing the Custom Control selection in the Utility branch under How To. This section makes reference to portions of this plug-in.

You can also look at the custom controls' header file in **\MAXSDK\INCLUDE\CUSTCONT.H**.

## Available Custom Controls

### Custom Edit Controls

This control is a simple text input control. The user may type any string into the field and the plug-in is notified when the user presses the ENTER key. There are also methods to parse and return integer and floating point values entered in the control. If the edit control is to be used with numeric values, it is typically used in conjunction with a custom spinner control.

## Spinner Controls

 (Spinner control)

 (Edit control and Spinner control)

The spinner control is used (usually in conjunction with the custom edit control) to provide input of values limited to a fixed type. For example, the control may be limited to the input of only positive integers. The input options are integer, float, universe (world space units), positive integer, positive float, positive universe, and time. This control allows the user to increment or decrement a value by clicking on the up or down arrows. The user may also click and drag on the arrows to interactively adjust the value. The Ctrl key may be held to accelerate the value changing speed, while the Alt key may be held to decrease the value changing speed. The user may also right click on the arrows to reset the value its default.

## Slider Controls

This control is available in release 3.0 and later only.

The custom slider control is functionality similar to the custom spinner control with some additional functionality. The slider control is used (sometimes in conjunction with the custom edit control) to provide input of values limited to a fixed type.

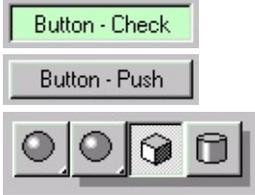

(Slider Control)

('Bracketed' Slider Control)

## Custom Button Controls

Custom Buttons allow the developer to have extra control of the way buttons appear and behave in the dialog box. These custom buttons have the following features:

- The button can be either a check button (which stays pressed in until the user selects it again), or a push button (which pops back out immediately).
- The highlight color of the check button may be specified.
- A button may function as a fly-off. Any number of additional buttons may be specified to fly off. The direction of the fly off may be specified or computed automatically.
- The buttons may be labeled with text or images. Four images may be specified allowing precise control over how the button appears when enabled or disabled and pressed in or released.

## Custom Status Control

(0, 255, 128)

This control provides a recessed area of the dialog which the developer may use as a status prompt area.

## Custom Toolbar Control

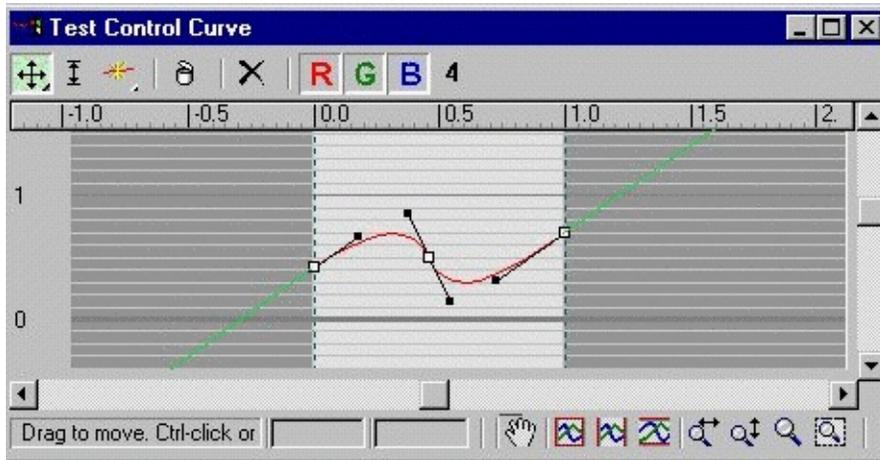

This control allows the creation of toolbars containing buttons (push, check, and fly-offs), status fields, separators (spacers), and other Windows or user defined controls. Note: The standard size for 3ds max toolbar button icons is 16x15.

## Custom Curve Control

This is a spline based control which returns output values from a user adjustable curve. An example of this control in the 3ds max user interface can be seen in the Color Map section of the Output rollup of a 2D Texture map.

Sample code using these APIs is available in

**`\MAXSDK\SAMPLES\UTILITIES\CCUTIL\CCUTIL.CPP.`**

## Custom Image Control

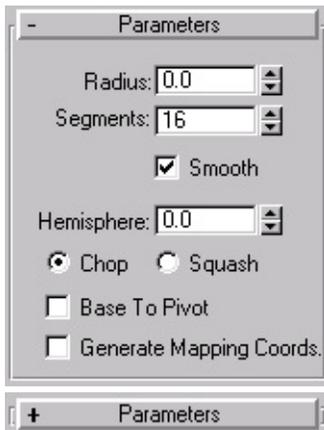

The custom image control provides a recessed area in the dialog to display a bitmap image.

## Color Swatch Control

The Color Swatch control presents the user with the standard 3ds max modeless color selector when the user clicks on the control. The color swatch control displays the currently-selected color and may be continuously updated as the user interactively selects new colors. Color Swatches also handle drag and drop between color swatches.

## Rollup Window Control

This control is used if you are creating a dialog box which will not be used in the command panel. This control adds a container area for rollup pages to be added to the dialog, and provides a scroll bar just like the command panel itself.

Note that this is a special case. Normally, adding rollup pages to the command panel is done using the simple **AddRollupPage()** method of the **Interface** class. This control is only used when you want to have a scrolling region for rollup pages in a dialog box.

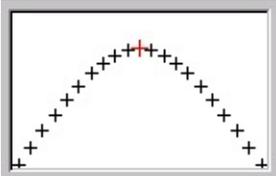

## **Window Thumb Tack Control**

This control installs a thumb tack into a window title bar which allows the user to make the window 'Always On Top'.

## **Off Screen Buffer Control**

This control provides an off-screen buffer which the developer may draw into, then quickly blit onto the actual display for flicker-free image updates.

# TCB Graph

This control displays a tension / continuity / bias graph.

## **Drag and Drop Window Control**

This is a new type of custom control available in 3ds max 2.0 and later. It is used to provide drag and drop to and from things other than Custom Buttons.

## How to a Create a Rollup Page using the Custom Controls

The tool for creating the rollup page portion the user interface of your plug-in is the dialog editor of Visual C++ Developers Studio. You use the dialog editor to create the rollup page, and place and arrange the controls.

The custom controls are positioned in a rollup page like any other control. Each one is created using the Custom Control button. The Custom Control button is the one shown highlighted below.

The control is identified as being custom by filling in the Class field of the Custom Control Properties dialog box with an appropriate string indicating the type of control. To bring up this dialog, double click on the control in the dialog editor window.

These are the values to be used in the Class field of the Custom Control Properties dialog for those custom controls which may appear in a rollup page:

- Custom Edit control - **CustEdit**
- Custom Spinner Control - **SpinnerControl**
- Custom Button control - **CustButton**
- Custom Toolbar control - **CustToolbar**
- Custom Image control - **CustImage**
- Custom Status control - **CustStatus**

Color Swatch control - **ColorSwatch**

Custom Rollup Window - **RollupWindow**

Custom DragAndDrop Window control - **DragDropWindow**

Custom TCB Graph - **TCBGraph**

The other fields in the user control properties dialog are these:

**ID** - This is the resource's identifier. The resource ID is usually a symbol supplied by Visual C++ and defined in the .H file that Visual C++ creates as part of your project. This is where you define the symbolic name for the resource.

**Caption** - This is the text that appears as part of the control to label it. This field is used for Custom Buttons and Status controls.

**Visible** - This determines whether or not the control is visible when the application is first run.

**Disabled** - This determines if the resource is displayed as disabled when the dialog box is created.

**Group** - This specifies the first control of a group of controls in which the user can move from one control to the next by using the arrow keys. All controls in the tab order after the first control with the Group property set to False belong to the same group. The next control in the tab order with Group set to True ends the first group of controls and starts the next group.

**Tabstop** - This specifies that the user can move to this control with the TAB key. This is only appropriate for the edit and button controls.

**Class** - The name of the control's Windows class. This class must be registered before the dialog box containing the control is created. See the class list above.

**Help ID** - Assigns a help ID to the control. The help ID is based on the resource ID. Type: Bool. Default: False.

**Style** - A 32-bit hexadecimal value specifying the control's style, primarily used to edit the lower 16 bits that make up a user control's sub-style.

**ExStyle** - A 32-bit hexadecimal value specifying the control's extended style.

When the rollup page dialog is created, it must be compiled and the resource file it generates must be included in the CPP source file. The default name for this file is **RESOURCE.H**. This may be changed by right clicking on the resource file name from the Resource View list (the top line) and choosing the Resource Includes... option. From this dialog, change the entry under Symbol header file.

Once you create a rollup page layout, there are several ways to present it to the user. The standard way is using a rollup page in the command panel. Typically,

this is called from within **BeginEditParams()** when the user is in the position of editing an items parameters.

There is a method of the interface class to handle adding the rollup. Its called **AddRollupPage()**. The syntax looks like this:

```
hParams = interfacePtr->AddRollupPage(  
    hInstance, // DLL instance handle.  
    MAKEINTRESOURCE(IDD_CUSTCTRL), // ID of the dialog  
    box.  
    DialogProc, // Dialog procedure to process user input.  
    ROLLUP_PAGE_TITLE, // Rollup title text.  
    (LPARAM)this); // Saves the this ptr of the item.
```

The standard width for rollup pages in the command column in the United States is 108 units. When you create dialogs for use in the command panel, always use 108 as the overall width (for use in the United States). Note the width and height are visible in the lower right hand corner of the IDE.

In summary, the custom controls are added to a rollup page layout using the resource editor window of VC++. The Class field of the resource indicates which type of control you are creating. The finished rollup page layout is displayed to the user using the **AddRollupPage()** function.

## How to Process User Input from the Custom Controls

Windows uses a 'Dialog Procedure' created by the developer to handle the users manipulation of the controls in the dialog,. As the user works with the controls, Windows sends messages to the dialog procedure. The developer is responsible for responding to these messages and implementing the logic to process the user input. A full description of this messaging system is beyond the scope of this documentation, but below is a brief overview. If you need more information, see the [Recommended Reading](#) section in the Orientation module.

When you create a dialog box or add a rollup page, you specify the dialog procedure to process the input. The basic structure of this dialog proc is listed below:

```
BOOL CALLBACK DialogProc(HWND hDlg, UINT message,  
WPARAM wParam, LPARAM lParam)  
{  
  switch (message) { // Respond to the message ...  
    case WM_INITDIALOG: // Initialize the Controls here.  
      return TRUE;  
    case WM_DESTROY: // Release the Controls here.  
      return FALSE;  
    case WM_COMMAND: // Various messages come in this way.  
      break;  
    case WM_NOTIFY: // Others this way...  
      break;  
    // Other cases...  
    default:  
      break;  
  }  
  return FALSE;  
}
```

Windows passes in four parameters to the dialog procedure. These are the handle of dialog box, the message, and two parameters which hold message-specific information. Except in response to the **WM\_INITDIALOG** message, the dialog box procedure should return TRUE if it processes the message, and FALSE if it does not.

When the dialog box is initialized, the **WM\_INITDIALOG** message is sent. At this time the custom controls should be initialized. Each control has methods to initialize it. The methods used to initialize the control are discussed in the next section, or you may see the sample program **CUSTCTRL.CPP** for how this is done for each control.

When the user is finished with the dialog box, the **WM\_DESTROY** message is sent. This is where you release the controls. Again, the next section discusses this, or you may take a look at the sample program to see how this is done.

When the user works with any of the custom controls, Windows sends in specific messages to the dialog procedure. For example, when the user changes a spinner control, Windows sends in a **CC\_SPINNER\_CHANGE** message. The developer would add this case to the dialog proc code above and handle the processing required when the spinner changed. The dialog box may have several spinner controls: how does the developer know which spinner changed? The **IParam** and **wParam** arguments to the dialog procedure contain message-specific information. It is here that the ID of the control is provided. (This is the ID entered in the ID field of the user control properties dialog when the control was created). For example, the developer could add a case such as the one below to handle spinner change messages:

```
case CC_SPINNER_CHANGE:
    switch (LOWORD(wParam)) { // Switch on ID
        case IDC_ANGLE_SPINNER: // A specific spinner ID.
            angle = ((ISpinnerControl *)IParam)->GetFVal();
            break;
        case IDC_RADIUS_SPINNER: // A specific spinner ID.
            // Code to handle the Radius spinner...
            break;
    };
    break;
```

This code fragment presents several important concepts. The **LOWORD** macro used above retrieves the low-order word from the given 32-bit value. The spinner control provides the ID of the spinner which changed in the low order word of **wParam**. (Another macro, **HIWORD**, retrieves the high-order word from the given 32-bit value). Splitting the argument into low and high order words allows more information to be packed into the parameter.

A pointer to the spinner control is provided in the **lParam** parameter. This pointer is used to call a method of the spinner to get the new floating point value (**(ISpinnerControl \*)lParam >GetFVal()**).

As another example, let's look at the color change message sent in from the Color Swatch control. When the user is changing the colors in the dialog box, and the developer has asked to be notified on each change, Windows sends the **CC\_COLOR\_CHANGE** message. Again, the developer would add a case to the switch to handle this message. The **LOWORD** of **wParam** contains the ID of the color swatch control. The **HIWORD** of **wParam** contains 0 if the mouse button is down as the user is changing colors, and 1 if the mouse is up. Sometimes, the message sent to the dialog proc is **WM\_COMMAND**, and the programmer must look at both the high and low words of **wParam** to determine the nature of the message and the ID of the control which sent the message. For example, the code below demonstrates how custom button messages may be handled.

```
case WM_COMMAND:
    switch(LOWORD(wParam)) { // Switch on ID
        case IDC_BUTTON: // A specific button's ID.
            switch (HIWORD(wParam)) { // Notification codes
                case BN_BUTTONDOWN: // Button is pressed.
                    break;
                case BN_BUTTONUP: // Button is released.
                    break;
                case BN_RIGHTCLICK: // User right clicked.
                    break;
            };
            break;
        case IDC_FLYOFF: // A specific fly off control ID
            switch (HIWORD(wParam)) { // Notification codes
                case BN_FLYOFF:
                    // This notification code is sent when the
                    // user chooses a new fly off.
                    break;
            };
    };
```

```
break;  
};
```

In summary, when the user works with controls in a dialog, Windows sends messages to the plug-in's dialog proc. The developer responds to these messages to process the user input.

## Overview of Methods of the Custom Control Classes

Before you call any custom control methods, you must initialize the controls by calling the **InitCustomControls()** function (usually from the **DLLMain()** function of the plug-in).

Call **InitCustomControls( hInst )** where **hInst** is the **HINSTANCE** passed into **DLLMain()**.

For each control, there are two functions that you'll always use:

- 1 A function to initialize the pointer to the control so you may call its methods (usually when the dialog is initialized).
- 2 A function to release the control when you are done with it (when the dialog is destroyed).

The sample code below demonstrates this for a spinner control (the other controls are similar):

First, declare a pointer to the control:

```
static ISpinnerControl *radSpin;
```

To initialize the pointer call:

```
radSpin=GetISpinner(GetDlgItem(hDlg, IDC_RAD_SPIN));
```

Each custom control has a Get function to return a handle to the control.

In the example above, two functions are called from a single statement. The **GetDlgItem** function retrieves the handle of a control in the specified dialog box. The parameter **hDlg** is the dialog handle. The **IDC\_RAD\_SPIN** parameter is the ID for the control. This is the name entered in the ID field of the Custom Control Properties dialog box when the control was created.

When you are finished using the control, call:

```
ReleaseISpinner(radSpin);
```

Each control has a Release function to release it.

See [Class ICustomControl](#) for a list of the methods that are available for all the custom controls.

The following functions are not a part of class **ICustomControl** but may also be used in conjunction with the custom controls and UI design in MAX:

This is a bitmap brush where the bitmap is a gray and white checker board.

```
HBRUSH GetLTGrayBrush();
```

```
HBRUSH GetDKGrayBrush();
```

This returns the standard font.

**HFONT GetFixedFont();**

This returns the handle of the hand cursor used for panning.

**HCURSOR GetPanCursor();**

The following section provides links to the custom control classes that document how to use the specific methods of each control.

## Using the Custom Edit Control

See [Class ICustEdit](#).

## Using the Spinner Control

See [Class ISpinnerControl](#).

## Using the Custom Image Control

See [Class ICustImage](#).

## Using the Custom Status Control

See [Class ICustStatus](#).

## Using the Color Swatch Control:

See [Class IColorSwatch](#).

## Using the Custom Button Control

See [Class ICustButton](#).

## Using the Custom Toolbar Control

See [Class ICustToolbar](#).

## Using the Rollup Window Control

See [Class IRollupWindow](#).

## Using the Off Screen Buffer Control

See [Class IOffScreenBuf](#).

## Using the TCB Graph Control

See [Class TCBGraphParams](#).

## Using the Thumb Tack Control

This control installs a thumb tack into a window title bar which allows the user to make the window 'Always On Top'. This control has two functions.

### **void InstallThumbTack(HWND hwnd)**

This function installs a thumb tack in the title bar of a window. NOTE: The window class for the window should have 4 extra bytes in the window structure for **SetWindowLong()**.

### **void RemoveThumbTack(HWND hwnd)**

This function is used to remove the thumb tack from the window title bar.

## Custom Node Properties and App Data

See Also: [Class Interface](#), [Class INode](#), [Class ClassDesc](#), [AppData](#), [AppDataChunk](#).

## **Overview**

A plug-in developer may need to hang arbitrary data off nodes in the scene. 3ds max provides two ways to accomplish this, AppData and User Properties. This section discusses both these approaches. Also discussed is the way a developer can save data associated with their plug-in class to the 3ds max file.

## AppData

AppData is application-specific data that may be attached to any **Animatable** in the scene. With these APIs any 3ds max object (controller, object, node, modifier, material, etc.) can have custom data attached by other objects. These chunks are saved in the .MAX file and can be accessed through the object they are attached to.

The methods used to create AppData are from class **Animatable**. The data is accessed using three owner identifiers: The SuperClassID and the Class\_ID of the owner, and a sub-index.

```
void AddAppDataChunk(Class_ID cid, SClass_ID sid,  
    DWORD sbid, DWORD len, void *d);
```

This method is used to add an AppDataChunk to this Animatable. The chunk is identified using the Class\_ID, and SuperClassID of the owner, and an ID for sub-chunks.

```
AppDataChunk *GetAppDataChunk(Class_ID cid, SClass_ID sid,  
    DWORD sbid);
```

This method is used to retrieve a pointer to an AppDataChunk.

```
BOOL RemoveAppDataChunk(Class_ID cid, SClass_ID sid,  
    DWORD sbid);
```

This method is used to delete an AppDataChunk.

Sample code using these APIs can be found in

**\MAXSDK\SAMPLES\UTILITIES\APPDATA.CPP.**

Developers who have 3D Studio / DOS IPAS AppData associated with nodes being imported into 3ds max have APIs available in 3ds max to help process this imported data. AppData was used by IPAS plug-ins to store special data with nodes. This was used for example by IK and spline patches. These APIs allow a 3ds max plug-in to request incoming app data from an IPAS plug-in and use it. Plug-ins can register a callback that gets called when app data is loaded. The callback can then interpret the data and create a new object that will be used instead of the usual triangle mesh. For more details see [Class ObjectDataReaderCallback](#).

Note: Although it is possible to hang AppData off the scene or the root node, that data won't be saved in the 3ds max file since the scene and the root node are not actually saved.

## Custom Node Properties

Another type of data that may be attached to a node is referred to as a Custom Node Property. This data can be ASCII text, an integer value, a float value, or a Boolean value. These values are stored and retrieved using a 'key' string. This is a string of any length -- the only limitation is the key string must not contain spaces, tabs or the equal sign (=) character.

To get and set specific data values developers may use the following methods of `INode`. These get and set values for ASCII strings, ints, floats, and booleans:

**`GetUserPropString()`, `SetUserPropString()`**

**`GetUserPropInt()`, `SetUserPropInt()`**

**`GetUserPropFloat()`, `SetUserPropFloat()`**

**`GetUserPropBool()`, `SetUserPropBool()`**

An end user may enter this data as well (in the 3ds max user interface it is referred to as a "User Defined Property"). Using the Object Properties dialog a user may enter text in the following format:

**PropertyName=Property Value**

The property name cannot have spaces within it, although a user can use spaces (and any other characters) anywhere outside the property name. The property name must appear at the start of the line (although it can be indented with spaces or tabs) and there can be only one property per line.

A developer may access the entire user-defined property text buffer if they wish to parse it themselves. The methods to do this are **`GetUserPropBuffer()`** and **`SetUserPropBuffer()`**.

For reference information on these methods, see [Class INode](#).

## Saving Class Data

The following three methods of [class ClassDesc](#) may be used to save data associated with a class in a 3ds max file. This is appropriate for preference data and other similar information associated with a class. If you want to save data associated with the class have **NeedsToSave()** return TRUE and implement the **Save()** and **Load()** methods. See the Advanced Topics section on [Loading and Saving](#) for more details on the way data is written to and read from 3ds max files.

### **virtual BOOL NeedsToSave();**

Returns TRUE if there is data associated with the class that needs to be saved in the 3ds max file. If this is so, implement the **Save()** and **Load()** methods below. If there is no class data to save, return FALSE.

### **virtual IOResult Save(ISave \*s);**

If **NeedsToSave()** returns TRUE then this method should be implemented to save the data associated with the class.

### **virtual IOResult Load(ILoad \*l);**

If **NeedsToSave()** returns TRUE then this method should be implemented to load the data associated with the class.

Note: One peculiarity with the loading and saving of the class data is that if the user does a File New or File Reset then the class data is not cleared.

# Debugging

See Also: [Profiling Plug-In Performance](#).

This section presents information on Debugging. This include an introduction to using the VC++ debugger, a useful API for printing debug messages, and information about the [Sparks Developer Program](#).

## Using the Visual C++ IDE to Debug MAX Plug-Ins

### Overview

Developers may use the VC++ IDE to debug 3ds max plug-ins. This provides source code level debugging capabilities while execution is taking place inside the context of the plug-in. One can do things such as set breakpoints (specific lines in the source code where execution stops temporarily so the developer can examine variables, review the call stack, etc.) and establish variables to 'watch'. These variables appear in a separate window and display their current contents as they change.

### Setting Up for Debugging

Developer must use the plug-in project's Hybrid configuration for debugging. The Release build does not contain any source level information and thus cannot be used. For registered developers using the special Debug SDK the Debug configuration should be used (in the description below Hybrid is always referred to however).

To begin, make sure you've compiled the Hybrid configuration so you have the debug information available. You can set the Hybrid configuration as the current one by choosing Build.../Set Active Configuration.... Then choose Build/Rebuild All. This will create a DLL and associated files appropriate for use while debugging.

Next, VC++ needs to know where the 3ds max executable is. You can set this through the IDE by choosing Settings... from the Project pulldown menu. Then go to the Debug Tab, and with the Hybrid configuration selected (highlighted in the 'Settings for:' list), enter the full pathname to 3DSMAX.EXE. For example, under the 'Executable for debug session:' edit field enter 'd:\3dsmax\3dsmax.exe'. In the 'Working directory' field enter 'd:\3dsmax'.

### Executing 3ds max and Your Plug-In

There are several ways to cause execution to halt at a specific spot in your code. One is to set a breakpoint at the spot. This is done by placing the cursor on the line where you want execution to stop and pressing F9. Then, to run the debugger simply press F5. This will launch 3ds max and get things going. 3ds max will run and load your plug-in as usual upon startup. Begin execution of your plug-in as you normally would inside 3ds max (for example, if your plug-in is a modifier apply it to an object). When execution of your plug-in's code reaches the breakpoint, control will return to VC++ and you may use its tool to

examine the state of things (see the section below for more details).

A second way to reach a certain line in your code is to use 'Run to Cursor' option. This is chosen by placing the cursor on the desired line of your source file and selecting 'Build/Start Debug/Run to Cursor' (or by pressing Ctrl+F10). This will begin execution and stop when the point in your source code where the cursor sits.

Once execution is stopped, you can begin again by pressing F5, or pressing F11 to step to the next line of source or into the next function or method. Note that if you attempt to step into MAX's code (not your own) you'll wind up with a window showing the disassembly of the source (since no debugging information is available for MAX's internal code.) If this happens you can simply close this window and set another breakpoint inside your own code.

Note: Before you begin debugging it is often helpful to maximize your (main) source code window. This prevents other tiled windows from overlapping it so you won't have to scroll to see the currently executing line.

### **Examining Variables and the Call Stack**

A Variables Windows is available to examine variables within the program's current context. This window also has a dropdown list for the call stack that shows the hierarchy of functions that are pending completion. This is handy in the case of a program crash since it can often be used to show the sequence of calls made up to the point of the crash.

Also available is a Watch Window. This will display the contents of any variable and updates automatically as the variable changes.

For additional details on these and other debugging tools see the VC++ IDE online help.

### **Summary**

Developers may use the VC++ debugger to help develop 3ds max plug-ins. This section has presented an overview of getting started. Of particular importance is the use of the plug-in project's Hybrid configuration so source code information is available. See the section [Creating a New Plug-In Project](#) for details on setting up such a configuration.

## The DebugPrint() Function

The function **DebugPrint()** may be used to send information to the Debug window in the Developer Studio IDE. This is handy for outputting debug information, as it only appears while debugging. This window is scrollable so a developer can print a lot of information to it, then go back to look it over. The format string works like the standard C **printf()** function.

```
void DebugPrint(const TCHAR *format, ...);
```

## Additional Debugging Tools Available to Sparks Developers

A Debug SDK is available to [registered developers](#). This special version of the SDK provides additional internal source code to 3ds max and is useful to help developers debug their applications deep inside MAX. Also, registered developers are provided with a special build of 3ds max compiled in Debug mode. Using this debug build, registered developers can step into parts of the core of 3ds max as they are debugging.

This special version of 3ds max has a purple animate button to distinguish it from the regular Release build of MAX. There is also a Debug menu available on the toolbar. This menu provides options to review the 3ds max command stack to see what is the current command mode and what modes have been previously pushed.

Also provided is a menu item 'Pipeline...' Each line in the dialog displayed by this command represents the state of the pipeline cache after a particular modifier or derived object.

**TM** refers to the Transform Matrix channel: the number in parenthesis is a zero(0) or one(1) indicating the channel is invalid (0) or valid (1).

**MT** refers to the Material channel, followed by its validity in parenthesis.

**OB** refers to the Object, and is followed by a list in parenthesis of all the object channels. If the channel is listed, it is valid, otherwise only "--" will appear for that channel.

**TO** is the topology channel.

**GE** is the geometry channel.

**TX** is the texture coordinate channel.

**MT** is the sub-object material channel.

**SE** is the sub-object selection channel.

**SU** is the sub-object selection state.

**DI** is the display attributes channel.

An asterisk (\*) following any of these channels indicates that the channel is "locked", meaning that is a shallow copy of a channel that is owned by a cache "upstream" in the pipeline.

The numbers following "t=" and "g=" are the memory addresses of the topology and geometry channel data, respectively, which are useful for debugging

problems related to the shallow copying.

## Deferred Loading of Plug-ins

See Also: [Class DataClassDesc](#), [Class ClassEntry](#).

## **Overview**

It is possible to indicate to 3ds max that certain plug-ins should not be loaded at startup. Each deferred plug-in will be loaded when and if needed, which will happen when one or more of the 3ds max classes implemented by the plug-in is actually created. It might also happen when detailed information about the plug-in is requested. The principal benefit of deferral is that the Windows resources used by the plug-in will not be consumed unless there is some specific use or interrogation of the plug-in. Time taken at startup to load the plug-in, assign its virtual memory, etc. is also saved, or at least deferred.

Deferral is governed by entries in the Windows Registry. These entries contain critical information about each plug-in to be deferred, and about each 3ds max class implemented by each such plug-in. (See details below.) This information must agree with the corresponding values returned by API calls to the plug-in itself. Disagreement can seriously impair the integrity of 3ds max itself.

Typically the Registry entries are created by an installer program or by 3ds max itself if the plug-in supports AutoDefer, but in special cases they could be created by run-time code in a plug-in, or by manual use of a Registry editor.

## AutoDefer

If a plug-in supports deferred loading it can let 3ds max automatically register it. This is done by implementing a new function exported from the DLL itself. This function is called **CanAutoDefer()** and is an addition to the four other required DLL exported functions: **LibNumberClasses()**, **LibVersion()**, **LibDescription()** and **LibClassDesc()**. Example:

```
// Let the plug-in register itself for deferred loading
__declspec( dllexport ) ULONG CanAutoDefer()
{
    return 1;
}
```

You will also need to add this line to the \*.DEF file. Example:

```
CanAutoDefer @5
```

Before adding this function to a plug-in you have to make sure that the plug-in actually supports deferral.

When 3ds max starts up it loads all the plug-in that are not listed as deferred in the registry. If a plug-in is not found in the registry, 3ds max will ask the plug-in if it can be deferred by checking the implementation of **CanAutoDefer()**. If the function is defined, and it returns a non-zero value, then 3ds max continues to load the plug-in and queries it for all the values needed to store in the registry. 3ds max will then write the needed registry information so that next time it starts up, the plug-in will be deferred, i.e. it will not be loaded until it is needed.

When a plug-in is registered by AutoDefer a timestamp is added to the registry. During start-up, if the timestamp of the DLL doesn't match the one in the registry, then the registry information about that plug-in is deleted, the plug-in is loaded, and the plug-in is registered again.

The format of the timestamp is taken from the **lpLastWriteTime** member of the Win32 function **GetFileTime()**. The timestamp is divided into two entries, **TimeStampHigh** and **TimeStampLow**, referencing the **dwLowDateTime** and **dwHighDateTime** members of the **FILETIME** structure.

## Registry Key Structure

The following chain of Registry keys establishes the base for all plug-in descriptions:

**\\HKEY\_LOCAL\_MACHINE\SOFTWARE\Autodesk\3ds  
max\4.0\Plug-ins**

and

**\\HKEY\_LOCAL\_MACHINE\SOFTWARE\Autodesk\3ds  
max\4.0\Plug-ins\Discreet**

Under the 'Plug-ins' key, there can be one key for each supplier of plug-ins; for the internal 3ds max plug-ins, this key is 'Discreet'. Under the key for a supplier there will be one key per deferrable plug-in, with a name that is distinct from all other plug-in key names from that supplier.

This 'plug-in key' has certain mandatory values, and under it there will be one key per 3ds max class implemented by the plug-in. The name of each class key must be distinct, at least within the given plug-in. Each such 'class key' has a set of values, describing certain important properties of the class.

Plug-in Key Values(all must be supplied)

Value Type Example

DLLFile REG\_SZ vrmlimp.dli

LibDescription REG\_SZ VRML Scene Importer

LibVersion REG\_DWORD 0xbb80600

TimeStampHigh REG\_DWORD 0x1be7679 (optional, only supplied for AutoDefer plug-ins)

TimeStampLow REG\_DWORD 0x2d8172f2 (optional, only supplied for AutoDefer plug-ins)

Notes: The DLLFile value gives the name of the DLL file that this key describes; case is disregarded. The name must be unique, and must not match two different files, even if they are in different directories.

Class Key Values

Value Type Example Required for:

ClassIDA REG\_DWORD 0x35da0f0a All

ClassIDB REG\_DWORD 0x10ce4af8 All

ClassName REG\_SZ VrmlImp All

Category REG\_SZ SceneImport All  
SuperClassID REG\_DWORD 0xa10 All  
IsPublic REG\_DWORD 1 All  
OKToCreate REG\_DWORD 1 All  
ShortDesc REG\_SZ VRML Importers, exporters, bitmap loaders  
SupportsOptions REG\_DWORD 0 Exporters  
LongDesc REG\_SZ BMP Image File Bitmap loaders  
Capability REG\_DWORD 0 Bitmap loaders  
ExtCount REG\_DWORD 2 Importers, exporters, bitmap loaders  
Ext REG\_SZ WRL;WRZ Importers, exporters, bitmap loaders  
InputTypeA REG\_DWORD 0x10 Modifiers  
InputTypeB REG\_DWORD 0x00 Modifiers  
InternalName REG\_SZ BitmapTex All plug-ins using  
ParamBlock2/ClassDesc2

Notes: The IsPublic and OKToCreate values should be 0 (no) or 1 (yes). The Ext value consists of upper-case file extensions (without the leading dot); if there are more than one, they are separated by semicolons, with no spaces before or after. The number of extensions given in the Ext value must agree with the ExtCount value. The InternalName value should not be defined if it returns NULL.

## **Deferrable Plug-ins**

To be eligible for deferred loading, a plug-in must meet all of the following criteria.

- All 3ds max classes that it implements must be subclasses of superclasses in the list below.
- All required values must be supplied, and must be constant. Values must not depend on run-time circumstances.
- If values depend on build configurations (e.g. Debug vs. Release), results may be undefined.
- The plug-in must not implement any keyboard accelerators.

Supported Superclasses are: Scene Import, Scene Export, Utility, Bitmap Loader, Helper, Geometric Object, Material/Texture, Image Filter, OSM (Modifiers), WSM/WSMObjects (Space Warps)

A plug-in that does not meet these requirements must not be described for deferral in the Registry.

## **DLL, Library Functions, and Class Descriptors**

See Also: [Class ClassDesc](#), [Generate a Class\\_ID](#), [List of ClassIDs](#), [List of SuperClassIDs](#).

## Overview

The following DLL and Library functions must always be implemented by 3ds max plug-in developers. They are called by 3ds max or Windows at load time and provide information about the DLL being loaded and the plug-in classes provided by DLL. These functions are:

**DllMain(HINSTANCE hinstDLL,ULONG fdwReason,LPVOID  
lpvReserved)**

**LibNumberClasses()**

**LibClassDesc(i)**

**LibDescription()**

**LibVersion()**

This section presents information about each of these functions as well as the details of Class Descriptors. Class Descriptors provide information about plug-in classes and are used by developers in implementing the **LibClassDesc()** function.

## The DllMain() Function

3ds max plug-ins are implemented as DLLs. DLL stands for Dynamic Link Library. DLLs are object code libraries that let multiple programs share code, data, and resources. When developers compile and link their plug-in code, the output is a DLL. The **DllMain()** function is implemented by the developer and called by Windows at startup when the plug-in DLL is loaded.

### DLLMain()

This function is called by Windows when the DLL is loaded (as well as other times, for instance during rendering). Most plug-ins simply make two calls inside this function. These are to initialize the 3ds max custom user interface controls, and to initialize the Win95 common controls. The sample code below, which is typical for most plug-in types, shows how this is done. Developers can see the VC++ help for more details on the **DllMain()** function.

Note that the calls to initialize the controls are made only once. This is done by setting a global variable to TRUE when the controls have been initialized the first time, and checked each time the function is called.

As note above, this function may also be called many times during time critical operations like rendering. Therefore developers need to be careful what they do inside this function. In the code below, note how after the DLL is loaded the first time only a few statements are executed. This function should return TRUE.

```
int controlsInit = FALSE;  
BOOL WINAPI DllMain(HINSTANCE hinstDLL,ULONG  
fdwReason,LPVOID lpvReserved)  
{  
// Hang on to this DLL's instance handle.  
hInstance = hinstDLL;  
if (! controlsInit) {  
    controlsInit = TRUE;  
  
// Initialize MAX's custom controls  
InitCustomControls(hInstance);  
  
// Initialize Win95 controls  
InitCommonControls();  
}
```

```
return(TRUE);  
}
```

## The Library Functions

These functions provide access to, and information about, the classes present inside the plug-in's DLL.

### LibNumberClasses()

When 3ds max is first started, it looks for DLLs to load. When it finds one, it needs a way to determine the number of plug-in classes inside the DLL. The programmer provides this information to 3ds max by defining the

**LibNumberClasses()** function. For example:

```
__declspec(dllexport) int LibNumberClasses() { return 1; }
```

The developer should return the number of plug-in classes inside the DLL.

### LibClassDesc(i)

The plug-in must provide the system with a way to retrieve the Class Descriptors defined by the plug-in. Class descriptors provide the system with information about the plug-in classes in the DLL. The function **LibClassDesc(i)** allows the system to access the class descriptors. A DLL may have several class descriptors, one for each plug-in class. The function should return a pointer to the 'i-th' class descriptor. For example:

```
__declspec(dllexport) ClassDesc *LibClassDesc(int i) {  
switch(i) {  
case 0: return &MeltCD;  
case 1: return &CrumpleCD;  
default: return 0;  
}  
}
```

This example returns a pointer to the Melt plug-in class descriptor, or the Crumple plug-in class descriptor. See the section at the end of this topic for a discussion of the class descriptor returned by **LibClassDesc(i)**.

### LibDescription()

When a 3ds max file is loaded that contains an entity (procedural object, modifier, controller, etc.) that the system does not have access to (i.e. the DLL is not available), a message is presented to the user. The system requires that each DLL return a text string to present to the user if it is unavailable.

As an example, say a user has a Melt modifier. He applies the melt to an object in the scene, and saves the file. He then give this file to a friend who does not have the Melt DLL. When the friend loads the file, the system will put up a message indicating an entity exists in the file that relies upon a DLL that cannot be found. This message could be something like: "Melt Modifier. To obtain a copy, call 1-800-PLUG-INS". To provide this string to the system, the DLL must implement the function **LibDescription()**. This function returns a string to be presented if the DLL is not found. This string is also presented in the dialog presented to the 3ds max user via the File / Summary Info / Plug-In Info... command. Once a plug-in from the DLL has been used in the scene, the system stores the string in the 3ds max file (since it must be presented when the DLL is unavailable).

Note that the scene is still loaded even if the DLL is not present. 3ds max preserves any entities for which the DLL is not found. In this way, if the file is modified and saved, then the user obtains the DLL and loads the modified file, the entity is still present and linked in to the scene. Entities which are loaded without access to their DLL are referred to as orphaned entities.

The orphaned entity will be loaded by a generic 'stand-in' for its SuperClass. The stand in will display a minimal scene representation. For instance, if the entity is a modifier, it will display its name in the modifier list, but no parameters will be presented. Missing object-types have dummy-type representations in the scene. They can be moved, rotated, scaled, linked, grouped, deleted: anything that just involves the node. Missing controllers only provide constant default values, which are not adjustable.

Also see the Advanced Topics section on [Read Only Plug-Ins](#). By allowing your plug-in to function in read-only mode, users can freely distribute the DLL, but unless they are authorized to run based on the ID of a specific hardware lock they will have restricted use until the user purchases their own copy. Below is a sample implementation of this function.

```
__declspec( dllexport ) const TCHAR *LibDescription() {  
    return _T("Melt Modifier. Call 1-800-PLUG-INS to obtain a  
    copy");  
}
```

## **LibVersion()**

Developers must implement a function that allows the system to deal with

obsolete versions of 3ds max plug-in DLLs. Because the 3ds max architecture supports such a close relationship to its plug-ins, the system may at some point need to prevent older plug-in DLLs from being loaded. To allow 3ds max to accomplish this, the DLL must implement a function called **LibVersion()**. This function simply returns a pre-defined constant indicating the version of the system under which it was compiled. Future versions of 3ds max may update this constant, yet the older DLLs will always return the previous value. With this function the system can check if an obsolete DLL is being loaded, and if so put up a message.

```
__declspec( dllexport ) ULONG LibVersion() { return  
VERSION_3DSMAX; }
```

Note: The meaning of **VERSION\_3DSMAX** has been enhanced in R2 to include information about the current 3ds max release as well as the 3ds max API release number and the 3ds max SDK release number.

The upper word now contains the 3ds max release number multiplied by 1000, and the lower word is API number and SDK revision within the API version. 3ds max will only load DLL's with the API number that is current.

The version number is composed as follows:

```
#define VERSION_3DSMAX ((MAX_RELEASE<<16)+  
(MAX_API_NUM<<8)+MAX_SDK_REV)
```

Each part is describes below:

**MAX\_RELEASE**

This is the 3ds max release number multiplied by 1000.

**MAX\_API\_NUM**

This is the 3ds max API number. When a change in the API requires DLLs to be recompiled, this number is incremented and **MAX\_SDK\_REV** is set to 0. This will make all DLLs with the former **MAX\_API\_NUM** unloadable.

**MAX\_SDK\_REV**

This denotes the revision of the SDK for a given API. This is incremented when the SDK functionality changes in some significant way (for instance a new **GetProperty()** query response is added), but the headers have not been changed.

Note: A developer may access this value using the global function:

**Function:**

## **DWORD Get3DSMAXVersion();**

### **Remarks:**

Returns the state of the **VERSION\_3DSMAX** #define from **\MAXSDK\INCLUDE\PLUGAPI.H** when the running version of 3ds max was compiled.

The following macros may be used for extracting parts of **VERSION\_3DSMAX**:

```
#define GET_MAX_RELEASE(x) ((x>>16)&0xffff)
```

```
#define GET_MAX_API_NUM(x) ((x>>8)&0xff)
```

```
#define GET_MAX_SDK_REV(x) (x&0xff)
```

```
#define GET_MAX_SDK_NUMREV(x) (x&0xffff)
```

There is also a function you can call to find out which application your plug-in is running on -- either 3ds max or VIZ.

### **Function:**

## **APPLICATION\_ID GetAppID();**

### **Remarks:**

This function is available in release 2.5 and later only.

This function returns the ApplicationID, either VIZ or MAX. If a plug-in is designed to work only in one product, then it could call this function inside **ClassDesc::IsPublic()** to switch between exposing the plug-in or not.

For example:

```
IsPublic() { return(GetAppID()==kAPP_VIZ?1:0); } // VIZ only
```

### **Return Value:**

One of the following enum values:

**kAPP\_NONE**

**kAPP\_MAX**

**kAPP\_VIZ**

## Library Function Summary

The plug-in must implement these five functions: **DllMain()**, **LibNumberClasses()**, **LibClassDesc(i)**, **LibDescription()**, **LibVersion()**. These functions allow the system to determine information about the plug-ins contained in the DLL.

The section below provides information about the Class Descriptors which must be returned by **LibClassDesc(i)**.

## Class Descriptors

Class descriptors provide the system with information about the plug-in classes in the DLL. A method of the class descriptor is also responsible for allocating new instances of the plug-in class. The developer creates a class descriptor by deriving a class from **ClassDesc** and implementing several of its methods. Below is a sample class descriptor and the declaration of a single static instance.

```
class MeltClassDesc : public ClassDesc {  
public:  
int IsPublic() { return TRUE; }  
void * Create(BOOL loading=FALSE) { return new MeltMod(); }  
const TCHAR * ClassName() { return _T("Melt"); }  
SClass_ID SuperClassID() { return OSM_CLASS_ID; }  
Class_ID ClassID() { return Class_ID(0xA1C8E1D1,  
0xE7AA2BE5); }  
const TCHAR* Category() { return _T(""); }  
};  
static MeltClassDesc MeltCD;
```

The following six methods of the class descriptor are described below:

**IsPublic()**, **Create()**, **ClassName()**, **SuperClassID()**, **ClassID()** and **Category()**. Developers wishing to review the entire set of methods should see [Class ClassDesc](#).

### IsPublic()

This method returns a Boolean value. If the plug-in can be picked and assigned by the user, as is usually the case, return TRUE. Certain plug-ins may be used privately by other plug-ins implemented in the same DLL and should not appear in lists for the user to choose from. These plug-ins would return FALSE.

### Create(BOOL loading=FALSE)

3ds max calls this method when it needs a pointer to a new instance of the plug-in class. For example, if 3ds max is loading a file from disk containing a previously used plug-in (procedural object, modifier, controller, etc.), it will call the plug-in's **Create()** method. The plug-in responds by allocating a new instance of its plug-in class. As the sample implementation above shows, simply use the **new** operator.

The optional parameter passed to **Create()** is a flag indicating if the class being created is going to be loaded from a disk file. If the flag is TRUE, the plug-in may not have to perform any initialization of the object because the loading process will take care of it. See the Advanced Topics section on [Loading and Saving](#) for more information.

When the system needs to delete an instance of a plug-in class, it usually calls a method named **DeleteThis()**. Plug-in developers must implement this method as well. Since a developer uses the **new** operator to allocate memory, he or she should use the **delete** operator to de-allocate it. For instance, the developer would implement **DeleteThis()** as follows:

```
void DeleteThis() { delete this; }
```

See the Advanced Topics section on [Memory Allocation](#) for additional details.

### **ClassName()**

This method returns the name of the class. This name appears in the button for the plug-in in the 3ds max user interface.

### **SuperClassID()**

This method returns a system-defined constant describing the class that this plug-in class was derived from. For example, the Bend modifier returns **OSM\_CLASS\_ID**. This super class ID is used by all object space modifiers. Some other example super class IDs are: **CAMERA\_CLASS\_ID**, **LIGHT\_CLASS\_ID**, **SHAPE\_CLASS\_ID**, **HELPER\_CLASS\_ID**, and **SYSTEM\_CLASS\_ID**. See [List of Super Class IDs](#) for the entire list of available super class IDs.

### **ClassID()**

This method must return the **unique** ID for the plug-in object. A program is provided with the SDK to generate these ClassIDs. It is VERY important you use this program to create the ClassIDs for your plug-ins. **If you use one of the source code examples to create your plug-in, you MUST change the existing Class\_ID**. If you don't, you'll get a conflict. If two ClassIDs conflict, the system will only load the first one it finds (and will post a message when it attempts to load the second one noting that there is a Class\_ID conflict).

A Class\_ID consists of two unsigned 32-bit quantities. The constructor assigns a value to each of these, for example **Class\_ID(0xA1C864D1,**

**0xE7AA2BE5**). See [Class Class\\_ID](#) for reference information.

Note that the sample code plug-ins used in 3ds max use 0 as the second 32-bit quantity of the Class\_ID. **Only the built-in classes (those that ship with MAX) should have the second 32 bits equal to 0.** All plug-in developers should use **both** 32 bit quantities. Again, make sure you use the program provided to create your ClassIDs. This will ensure no conflicts arise between plug-ins. To generate a random Class\_ID and optionally copy it to the clipboard, click [Generate a Class\\_ID](#).

## Category()

The category is selected in the bottom-most drop down list in the create branch of the command panel. If this is set to be an existing category (i.e. "Standard Primitives", "Particle Systems", etc.) then the plug-in will appear in that category. Developers should NOT add to the categories provided by 3ds max (see the note below). If the category doesn't yet exist then it is created. If the plug-in does not need to appear in the list, it may simply return a null string as in `_T("")`. **Category()** is also used for modifiers to classify them in the button sets dialog.

**Important Note: The 3ds max architecture has a limit of 12 plug-ins per category in the Create branch. To prevent a problem with too many plug-ins per category, developers should ALWAYS create a new Category for their plug-ins, rather than using one of the existing ones used by the standard 3ds max plug-ins. Note that versions of 3ds max prior to release 1.2 would crash if there were more than 12 buttons per category.**

# Extending Render To Texture to Support New Materials

## Overview

The render to Texture feature of 3ds max r5 provides the ability to render out various elements from a standard render for example light maps and specular maps. It works in conjunction with the new Unwrap modifier, which can now flatten texture coordinates. Please see the user guide for a more detailed description.

This new feature now creates certain maps that do not fit into any particular material map slot for example, a light map. However 3<sup>rd</sup> party materials may exist that support extended features. **BakeTextureMappings.ini** file allows developers to add support for new materials. This provides the mapping between the different baked elements and the map slots in the material.

An example INI file can be seen below.

**[DeclareFileMappings]**

**DeclareFileMapping1=SaveAll**

**DeclareFileMapping2=CompleteOnly**

**DeclareFileMapping3=**

**DeclareFileMapping4=**

**DeclareFileMapping5=**

**DeclareFileMapping6=**

**DeclareFileMapping7=**

**DeclareFileMapping8=**

**DeclareFileMapping9=**

**DeclareFileMapping10=**

**[CompleteOnly]**

**shaderName = blinn**  
**ambientMap=**  
**diffuseMap = CompleteMap**  
**specularMap=**  
**diffuseLevelMap=**  
**specularLevelMap=**  
**glossinessMap=**  
**selfIllumMap=**  
**opacityMap=**  
**filterMap=**  
**bumpMap=**  
**reflectionMap=**  
**refractionMap=**  
**displacementMap=**  
**diffuseRoughnessMap=**  
**anisotropyMap=**  
**orientationMap=**  
**glossinessMap2=**  
**anisotropyMap2=**  
**orientationMap2=**

**[SaveAll]**

**shaderName= oren-nayar-blinn**  
**ambientMap= CompleteMap**  
**diffuseMap= DiffuseMap**  
**diffuseLevelMap= ShadowsMap**  
**specularLevelMap=SpecularMap**  
**bumpMap= NormalsMap**  
**opacityMap= AlphaMap**  
**selfIllumMap= LightingMap**

## **displacementMap= BlendMap**

The first section of the file is used to populate the drop down list in the RTT dialog box. For each entry there must be a subsequent entry defining the mapping. In the save all section all the supported baked elements are mapped to a standard material. This provides a method of viewing all the maps created, not necessarily to produce the correct rendering

The names, on the left hand side are the supported Maxscript parseable names for the parameters that have been defined in the ParamBlockDesc2 of the material. The name on the right is the actual baked element name used in the RTT. This mapping and naming needs to be accurate as it can cause a run time error in the RTT macro script

The Render To Texture script has been written to use the new ViewportManager to handle new Viewport Shaders, Internally it supports the MetalBump and LightMap shaders. The script can be found at **UI\Macroscripts\Macro\_BakeTextures.mcr**. In the function called **UpdateMaterial**, there is a section that provides additional ViewportShader support. The script lists all available shaders, so all that is needed is for the developer to supply the correct setup for the shader. Examples can be found in the function **setupLightMapShader**.

Script lists all available shaders, so all that is needed is for the developer to supply the correct setup for the shader. Examples can be found in the function **setupLightMapShader**

## Foreground / Background Planes.

See Also: [Class ChangeForegroundCallback](#), [Class IScene](#), [Class ViewExp](#), [Class GraphicsWindow](#), [Class CommandMode](#).

## Overview

In order to allow 3ds max to redraw the viewports as quickly as possible, an option is provided in the 3ds max user interface to allow the user to use Dual Planes. If dual plane mode is enabled, there is an extra buffer in memory that holds what is referred to as The Background. The background contains an entire image buffer and Z buffer (if Z buffering is turned on). Consider the following example to understand how the background buffer is used to speed up screen redraws:

Say there is a scene with two items: a small sphere that the user is interactively moving around, and a 500,000 polygon model that is not changing at all -- simply a static model. The large model could be rendered **once** into the background plane. The sphere that is changing is flagged as being in the foreground. The next time 3ds max needs to redraw the screen, instead of re-rendering both models, it can copy the background image (which has the large model already rendered) into the actual image buffer and only render those nodes that are flagged as being in the foreground (the moving sphere) on top of this background image. This provides the same visual result as rendering both models but is much quicker.

The key to making this system work is to figure out what items need to be in the foreground and what items may be put in the background. The system does this in almost all cases (the plug-in developer does not normally need to worry about this). If the user is moving a selected item in the scene, then the selected items (and all their dependents) go in the foreground. All other items may go in the background. For example, if the user selects a parent node to move, the children nodes must have to go in the foreground as well since they will move along with the parent. However everything else may go to the background. When the user plays back an animation any items that are animated go into the foreground and non-animated items may go in the background. When the user is in the Modify branch, any items that are dependent on the item being edited are put in the foreground, the others go into the background. Also, when a camera is being moved, all objects in the camera's viewport are tagged as being in the foreground, since they all must be redrawn.

## Methods

For specialized plug-ins, APIs are provided to allow the plug-in to control which nodes are put in the foreground when these plug-ins have created their own command mode. There is a method of the **CommandMode** class named **ChangeFGProc()** that can be used to specify a custom callback to process nodes that should be placed in the foreground. For example, if a utility plug-in needs to specify an additional set of nodes to go into the foreground plane along with the one it is currently working on, it could derive a class from **ChangeForegroundCallback** and implement the **callback()** method. In this method it could flag any nodes required (using a method of **INode** named **FlagForeground()**). In almost all cases, however, plug-ins that use a custom command mode can simply specify one of the two predefined values in their implementation of **ChangeFGProc()**. These are **CHANGE\_FG\_SELECTED** and **CHANGE\_FG\_ANIMATED**. See [Class CommandMode](#) for more details.

As a final note, if the user has turned off the Use Dual Plane toggle, there is still a notion of foreground/background objects -- only with dual planes off, some background objects end up being rendered. 3ds max uses a simple bounding box check: If a background object's bounding box intersects the foreground object's bounding box (at either the old or new position), then that background object is re-rendered. Otherwise, it isn't redrawn.

To see this dramatically, consider the example presented above: a small sphere and a large 500K polygon object. If the object is off to the right of the viewport, and the sphere is to the left (all by itself) then the sphere can be moved very quickly. But once it gets near enough to the large object that the bounding boxes intersect, interactivity drops dramatically because the large object must now be redrawn.

# Function Publishing System

[Class FPInterface](#), [Class FPMixinInterface](#), [Class FPInterfaceDesc](#), [Class Interface\\_ID](#), [Class FPFunctionDef](#), [Class FPPropDef](#), [Class FPActionDef](#), [Class FPPParamDef](#), [Class FPPParams](#), [Class FPEnum](#), [Class FPInterfaceCallback](#), [Class FPValue](#), [Class FPPParamOptions](#), [Class FPValidator](#), [Class ClassDesc2](#), [Class ActionTable](#).

## Abstract

### What is Function Publishing?

The Function Publishing System, new to 3ds max R4, is a new system that allows plugins to publish their major functions and operations in such a way that code outside the plugin can discover and make enquiries about these functions and is thus able to call them through a common calling mechanism. The whole system is very similar to Window's COM and OLE Automation systems and share many similar concepts in the architecture. However, the Function Publishing System is not based on COM and OLE but instead is a custom architecture more suited and optimized for MAX. The Function Publishing API serves a number of purposes which allow 3<sup>rd</sup> party developers to open up important portions of their plugins for use by external sources, allowing for users to extend and control these directly. Some of the purposes of the API are:

- • Modularizing plugin code into various "engines" that are able to supply services to other parts of 3ds max and other 3<sup>rd</sup> party plugins and can be delivered to the user through various different user-interfaces.
- • Providing automatic scriptability by exposing the published functions directly to MAXScript.
- • Providing alternate means of invoking plugin functions in the UI, such as via the new manipulator system, scripted menus, quad menus, hot keys, macroScripts, toolbar buttons, etc.
- • Allowing the MAXScript Macro Recorder to automatically generate calls to the published functions, in the event that these are invoked by the expanded ParamMap2 system or other UI mechanisms such as hot keys or

menu items.

- • Facilitate automatic generation of COM interfaces and OLE Type Libraries in such a way that external COM clients can invoke the published functions in the plugin code.

### **What would a plugin publish?**

The various kinds of functions published by a plugin usually fall into the following categories. You can, however, publish anything you want.

- • Important algorithms in the plugin, for example, the Edit Mesh modifier might publish its face extrude and mesh attach functions, or the flex modifier its soft-body dynamics algorithms. In these cases, the functions would be parameterized in the most general way, independent of any current scene state or UI mode in MAX, for example, the face extrude might take a Mesh, a set of faces and a distance.
- • Functions that enquire about or affect the state of one of the plugin's objects in the scene. Usually, these are unnecessary if the plugin stores its state as parameters in ParamBlock2s, which are already accessible externally, but in cases where this is not done or certain kinds of state are not cleanly accessible via the ParamBlock2 system, extra functions may be published by the plugin. These usually take an instance of one of the plugin's objects as one of their parameters, and should be independent of any UI mode, for example, they should not require that the object being manipulated be the current focus in the Command Panel. Prior to R4, plugins that wished to provide scripter access to internal functions would use the MAXScript SDK to provide scripter wrapper functions. In R4, the recommended and much simpler technique, is to use the Function Publishing system, as this not only provides automatic scriptability, but is a general mechanism for any external system to control and use the plugin.
- • UI action functions. These basically provide a programmatic way of "pressing" buttons and keys in the UI for a plugin and are specifically meant to be UI modal. They take no parameters, since these are defined by the current state in the UI. For example, the vertex delete action function for an Editable Mesh object would operate on the current vertex selection

for the current object in the Modify panel. These are not unlike the keyboard ShortcutTables that plugins could publish in R3, but by publishing them as action functions, any external system can effectively control the UI of a plugin. As well as being automatically exposed in the scripter like other published functions, Action functions are automatically entered into the new ActionTable system. This is a generalization of the R3 ShortcutTable system and basically holds all the commands and actions that may be bound to hotkeys or added to menus or put in buttons on a toolbar using the R4 CUI system, so that by publishing your action functions using the FnPub system, you are making them automatically available for binding to hotkeys and placing in menus and toolbar buttons. Action functions are treated specially in the FnPub system, and have extra descriptor data for things like menu item text, tooltip text, enable predicates, etc.

## Introduction to Function Publishing

### The Function Publishing API

The Function Publishing API consists of two main components, a function descriptor system and a function calling mechanism. The descriptor system is used by the publishing component to declare the functions it is publishing and provide necessary descriptive data and may be used by a component's client to enquire about published functions. The calling system is used by a component's client to invoke one of the published functions.

### Interfaces

Functions are published in one or more **Interfaces** by your plugin. If you have a large number of functions to be published, you might organize them functionally into different interfaces to make them more manageable for the user. For example, EditMesh might publish vertex functions, edge functions and face functions in separate interfaces. Action functions must be published in their own (set of) interface(s). Each interface is represented by an instance of a class derived from the base class **FPInterface**. You normally create these instances as static objects using the FPInterface constructor, in much the same way as ParamBlock2 descriptors are created. Each interface contains a list of the functions it publishes and the parameters they take, along with type and name

and other descriptive info for all these things. All the interfaces for a particular plugin class are kept in its ClassDesc object. An external system can find out about the interfaces you publish by calling various query methods on ClassDesc that access these interface definition objects. As well as these enquiry or 'reflection' methods, an FPIInterface also has the calling methods for actually invoking a particular function in the interface, so that if something has hold of one of your interfaces, it can call any of its published functions.

Additionally, a **Mixin** interface is provided which can be multiply-inherited by a plugin's class and returned via its implementation of the above new **GetInterface(Interface\_ID)** method, in the way that most existing object-based interfaces are now implemented.

The FPIInterface class is defined in the header file **maxsdk\include\iFnPub.h**, along with all the other FnPub classes & macros described in these notes.

### **Direct and Indirect Calling**

The FnPub system lets you set up interfaces so that functions in them can be called directly, as virtual member functions of the interface object, or indirectly via a dispatching method that takes a runtime function ID and a table of parameters. This is roughly equivalent to the dual vtable and IDispatch interface schemes in COM. Typically, you provide the virtual interface in a public header file so that it can be compiled against by other plugins and they can call the virtual functions on an interface object directly. The indirect call mechanism is used by MAXScript and other external systems that look for the published interface functions at runtime using the interface metadata.

### **Interface and Function IDs**

Each interface is uniquely identified by an **Interface\_ID**, which is a new class in the R4 SDK. This class is structurally very similar to Class\_ID, containing two randomly-chosen longwords to provide a unique global ID. It is defined in **maxsdk\include\maxtypes.h**

Each function in an interface is identified by an integer ID of type **FunctionID**. This is similar to the BlockID and ParamID's used in the paramblock2 system. This ID is used in the dispatch-based calling mechanism to identify the function

to call.

## Interface Organization

The map is bounded by **BEGIN\_FUNCTION\_MAP** and **END\_FUNCTION\_MAP** and contains one entry for each function in the interface. The map entry macros used come from a set named according to the number of arguments and whether the function is void. In this case, **FN\_2** is used for a 2 argument function returning a value and **VFN\_3** is used for a void function taking 3 arguments. The **FN\_2** macro, for example, takes the function ID, the return type, the virtual interface method name, and the types of the two arguments. **FN\_VA**, **VFN\_VA**, **FNT\_VA**, etc., **FUNCTION\_MAP** entry macro variants have same args as **\_0** macros and specify that the function takes a variable number of arguments (passed directly in **FPParams** instances). There are more details on these macros in the ref section below. There is a separate declaration macro, **DECLARE\_DESCRIPTOR(<class>)** that must be specified in the interface descriptor class. In the implementation class for a static or action or core interface, you provide a single descriptor declarator with the **DECLARE\_DESCRIPTOR()** macro, giving the current class as the macro parameter and a function map using **BEGIN\_FUNCTION\_MAP** and **END\_FUNCTION\_MAP** macros as before. The **DECLARE\_DESCRIPTOR(<class>)** is only required for **FPStaticInterface** subclasses; **FPMixinInterface** subclasses should only have the **FUNCTION\_MAP/END\_FUNCTION\_MAP** map table.

Within your plugin, each interface is usually organized into 3 separate sections of code:

- • The public virtual interface along with the `Interface_ID` and function ID definitions in a public header file.
- • the implementation interface, which inherits from the virtual interface, and contains both the function implementations and a function dispatch map used by the indirect calling methods. The `FnPub` system provides a set of macros to ease the definition of these maps.

- the interface descriptor, usually a static instance of the implementation interface. The constructor for this uses the same varargs technique used by the ParamBlockDesc2 constructor, enabling descriptive info for all the functions in the interface to be supplied in one constructor call.

Here's an (imaginary & simplified) example of an interface on EditMesh called 'FaceOps' with two functions, delete and extrude:

### 1. The public interface (in a public header file)

```
#include "iFnPub.h"
#define EM_FO_INTERFACE Interface_ID(0x434455, 0x65654)
#define GetEMFaceOpsInterface(cd) \
    (EMFaceOps *)(cd)->GetFPInterface(EM_FO_INTERFACE)

enum { em_delete, em_extrude, };

class EMFaceOps : public FPStaticInterface
{
public:
    virtual int Delete (Mesh* m, BitArray* faces)=0;
    virtual void Extrude(Mesh* m, BitArray* faces, float amt)=0;
};
```

This defines the Interface\_ID for the 'FaceOps' interface and provides a helper macro for getting the interface pointer from the plugin's ClassDesc. This is followed by an enum for the two function IDs and then the virtual interface class itself in which each function is declared as a pure virtual function. The return and parameter types of these functions are restricted to a fixed set, defined below. Fixing this set is necessary so that systems that access the interface metadata or use the dispatch form of calling have a known set of types to deal with. External code that wishes to call one of these functions, and has access to this public header can do so as in the following example:

```
EMFaceOps* efi = GetEMFaceOpsInterface(edmeshCD);
```

```
...
```

```
efi->Extrude(mesh, faces, 10.0);
```

To call this function indirectly, you call the `Invoke()` method on the interface, giving it the function ID and an **FPParams** object containing all the parameters, as in the following example:

```
FPParams p (3, TYPE_MESH, mesh,  
            TYPE_BITARRAY, faces,  
            TYPE_FLOAT, 10.0);
```

```
FPValue result;
```

```
FPInterface efi = edmeshCD->GetFPInterface("FaceOps");
```

```
efi->Invoke(em_extrude, result, &p);
```

```
x = result.i;
```

Any function result is passed back in an **FPValue** instance, given as one of the args to `Invoke`, which is a type-tagged variant structure that can hold any one of the FnPub supported types. The **FPParams** class contains a convenience `varargs` constructor for building parameter sets as shown. An **FPParams** instance contains a **Tab<>** of **FPValue** instances, each holding a parameter. This example demonstrates how to look up an interface by name in a `ClassDesc`. The `Invoke()` function has several overloads, for calling functions with and without results and parameters.

## **2. The implementation class (in the .cpp implementation file)**

```
class EMFaceOpsImp : public EMFaceOps  
{  
    DECLARE_DESCRIPTOR(EMFaceOpsImps)  
  
    BEGIN_FUNCTION_MAP
```

```

    FN_2(em_delete, TYPE_INT, Delete, TYPE_MESH,
        TYPE_BITARRAY)
    VFN_3(em_extrude, Extrude, TYPE_MESH, TYPE_BITARRAY,
        TYPE_FLOAT)
    END_FUNCTION_MAP

```

```

int Delete(Mesh* m, BitArray* faces)
{
    //... do the delete
    return face_count;
}
void Extrude(Mesh* m, BitArray* faces, float amt)
{
    //... do the extrude
}
};

```

The interface implementation class specializes the virtual interface class defined in the public header. It can contain any implementation-required data members and utility methods, but must at least contain implementations for each of the virtual methods defined in the virtual interface class.

The key component shown above is the **function map** which generates the indirect call dispatcher used by the Invoke() method. This dispatcher unbundles the parameters from the indirect call parameter structure, forwards them to the correct implementation method and bundles the return value into an **FPValue**. It is specified here using the map macros that come with the FnPub system (in **iFnPub.h**), in a manner somewhat similar to the message maps in MFC. You can implement this dispatcher by hand, but it is advised that you use the map macros.

The map is bounded by **BEGIN\_FUNCTION\_MAP** and **END\_FUNCTION\_MAP** and contains one entry for each function in the interface. The map entry macros used come from a set named according to the

number of arguments and whether the function is void. In this case, **FN\_2** is used for a 2 argument function returning a value and **VFN\_3** is used for a void function taking 3 arguments. The **FN\_2** macro, for example, takes the function ID, the return type, the virtual interface method name, and the types of the two arguments. There are more details on these macros in the ref section below. There is a separate declaration macro,

**DECLARE\_DESCRIPTOR(<class>)** that must be specified in the interface descriptor class. In the implementation class for a static or action or core interface, you provide a single descriptor declarator with the **DECLARE\_DESCRIPTOR()** macro, giving the current class as the macro parameter and a function map using **BEGIN\_FUNCTION\_MAP** and **END\_FUNCTION\_MAP** macros as before. The **DECLARE\_DESCRIPTOR(<class>)** is only required for **FPStaticInterface** subclasses; **FPMixinInterface** subclasses should only have the **FUNCTION\_MAP/END\_FUNCTION\_MAP** map table.

### 3. The interface definition (in the .cpp implementation file)

```
static EMFaceOpsImp emfi (  
    EM_FO_INTERFACE, _T("FaceOps"), IDS_EMFO,  
&edmeshCD, 0,  
    em_delete, _T("delete"), IDS_DELETE, TYPE_INT, 0, 2,  
    _T("mesh"), IDS_MESH, TYPE_MESH,  
    _T("faces"), IDS_FACES, TYPE_BITARRAY,  
    em_extrude, _T("extrude"), IDS_EXTRUDE, TYPE_VOID, 0, 3,  
    _T("mesh"), IDS_MESH, TYPE_MESH,  
    _T("faces"), IDS_FACES, TYPE_BITARRAY,  
    _T("amount"), IDS_AMOUNT, TYPE_FLOAT,  
    end  
);
```

A distinguished instance of the interface implementation class is constructed and registered with the owning ClassDesc. This is the instance given out when the CD is asked for an interface via its **GetFPInterface()** method. The

instance has data members that contain all the metadata for the interface. You normally build this instance as a static in the implementing .cpp file, in a manner similar to ParmBlock2 descriptor instances.

In the example above, the instance 'emii' is statically declared using the FPIInterface's varargs constructor. The initial arguments to this constructor provide the **Interface\_ID**, the internal fixed name, localizable descriptor string resID, owning ClassDesc and flags bits. This is followed by a list of function descriptors which themselves each have lists of parameter descriptors. The **em\_delete** function description, for example, consists of a fixed name, a localizable description string resID, a return type, flag bits and a count of the number of parameters. For each parameter, there is a line giving parameter name, description string resID and type.

### **FnPub Object Based Mixin Interfaces**

A variant of the FPIInterface, known as a Mixin interface, is provided and can be multiply-inherited by a plugin's class and returned via its implementation of the above new **GetInterface(Interface\_ID)** method, in the way that most existing object-based interfaces are now implemented. Here's an example setup. First, the public header that would be used by an SDK-level client of the interface:

```
// interface ID  
#define FOO_INTERFACE Interface_ID(0x342323, 0x55664)  
  
#define GetFooInterface(obj) \  
    ((FooInterface*)obj->GetInterface(FOO_INTERFACE))  
  
// function IDs  
enum { foo_move, foo_setRadius, };  
  
// mixin interface  
class FooInterface : public FPMixinInterface  
{
```

```

BEGIN_FUNCTION_MAP
    VFN_1(foo_move, Move, TYPE_POINT3);
    VFN_1(foo_setRadius, SetRadius, TYPE_FLOAT);
END_FUNCTION_MAP

```

```

FPInterfaceDesc* GetDesc();

virtual void SetRadius(float radius)=0;
virtual void Move(Point3 p)=0;
};

```

This is much the same as existing stand-alone FnPub interfaces, except that the function map is put into the virtual interface class, rather than the implementing interface class. Then, in the plugin class, you inherit the mixin interface (you are "mixing" it into the class). You provide implementations for the interface's virtual methods in the main class and an implementation of **GetInterface()** that returns the object cast to the interface, exactly as you would have done for old-style object-based interfaces:

```

class MyObject : public SimpleObject2, public FooInterface
{
public:
    ...
    void SetRadius(float radius);
    void Move(Point3 p);
    ...
    FPInterface* GetInterface(Interface_ID id) {
        if (id == FOO_INTERFACE)
            return (FooInterface*)this;
        else
            return SimpleObject2::GetInterface(id);
    }
}

```

```
...  
}
```

Note that the **GetInterface()** method needs to cast the 'this' to the mixin interface class so the correct vtable is used (this was the case with old-style object interfaces, as well). It also calls **SimpleObject2::GetInterface()** if the id doesn't match so that other base class interfaces and stand-alone interfaces, if any, are made available to the caller. Finally, you provide a descriptor for the interface, as with stand-alone interfaces, but in this case, you must make it an instance of **FPInterface**, not **FooInterface** or **MyObject**, and must specify the **FN\_MIXIN** flag to denote the interface as mixin:

```
static FPInterfaceDesc foo_mixininterface(FOO_INTERFACE,  
    _T("foo"), 0,  
    &myObjDesc, FP_MIXIN,  
    foo_move, _T("move"), 0, TYPE_VOID, 0, 1,  
    _T("vector"), 0, TYPE_POINT3,  
    foo_setRadius, _T("setRadius"), 0, TYPE_VOID, 0, 1,  
    _T("radius"), 0, TYPE_FLOAT,  
    end  
);  
  
FPInterfaceDesc* FooInterface::GetDesc()  
{  
    return &foo_mixininterface;  
}
```

This static instance provides the interface metadata and is recorded in the **ClassDesc**. To access the interface metadata, you must get this instance directly from the **ClassDesc** via **ClassDesc::GetInterface()**, and not via **Animatable::GetInterface()** on an object.

All this is pretty-much the same work you would do to provide an **Animatable::GetInterface()** interface currently in MAX. The extra stuff is

the **FUNCTION\_MAP** and the interface descriptor. The SDK-level clients use the interface in exactly the same way, but now the scripter and other external systems can find and use these interfaces automatically at runtime.

Mixin object-based interfaces are accessible in the scripter in similar way to stand-alone published interfaces. In particular, the functions are available in a struct function package which is itself accessed as a property on the plugin class object. For example, if the above example plugin class is named 'MyObject' in the scripter, the functions in its 'foo' mixin interface would be accessed as:

**MyObject.foo.move**

**MyObject.foo.setRadius**

The functions are effectively 'generic' functions that require an instance of the plugin as the first argument, resulting in:

**MyObject.foo.move \$baz [10,10,10]**

**MyObject.foo.setRadius \$bar 123.4**

### **Publishing Mixin Interface on Arbitrary Classes**

You can publish FnPub mixin interfaces on any class, not just Animatable subclasses. To do this, you inherit from, **IObject**, a new virtual base class in the FnPub system. This provides an API for querying and iterating FPMixinInterfaces that the class wishes to publish, similar to **Animatable::GetInterface()**. The API that the publishing class must implement is as follows:

```
class IObject  
{  
public:  
    // object/class name  
    virtual TCHAR* GetName()=0;
```

```

// iterate over all interfaces...
virtual int NumInterfaces()=0;
virtual FPInterface* GetInterface(int i)=0;

// get ID'd interface
virtual FPInterface* GetInterface(Interface_ID id)=0;

// IObject ref management (can be implemented by
dynamically-
// allocated IObjects for ref-count based lifetime control)
virtual void Acquire() { };
virtual void Release() { };
};

```

There is a corresponding new ParamType2 type code, TYPE\_IOBJECT, that allows instances of these classes to be passed and returned in **FPInterface** methods, providing a simple form of user-defined type, in the sense that these instance collections are passed as interfaces rather than pointers (similar to COM). MAXScript has been extended to provide wrapper value classes for IObjects and so this mechanism provides a light-weight alternative to the MAXScript SDK facilities for adding new wrapper value classes to the scripter.

MAXScript also calls the **Acquire()** and **Release()** methods on IObjects as it creates and collects these wrappers, so that IObject objects can keep track of MAXScript's extant references to them. For example:

```

class IFoo1 : public FPMixinInterface
{
    virtual void Frabulate(Point3 p)=0;
    ...
};

class IFoo2 : public FPMixinInterface

```

```

{
    ...
};

class Foo : public IObject, public IFoo1, public IFoo2
{
    // Foo methods
    ...
// IObject methods
    TCHAR* GetName() { return _T("Foo"); }
    int NumInterfaces() { return 2; }
    FPIInterface* GetInterface(int i)
    {
        if (i == 0) return (IFoo1*)this;
        if (i == 1) return (IFoo2*)this;
    }
    FPIInterface* GetInterface(Interface_ID id)
    {
        if (id == FOO_INTERFACE_1) return (IFoo1*)this;
        if (id == FOO_INTERFACE_2) return (IFoo2*)this;
    }
// IFoo1 methods
    void Frabulate(Point3 p) { ... }
    ...
// IFoo2 methods
    ...
};

```

Instances of Foo can be passed as parameters and results in FnPub interface descriptors and function maps by declaring them as **TYPE\_IOBJECT** values, and they will get cast to **IObject\*** automatically. For example, in a plugin that

uses the Foo class, a method in one of its FPInterfaces might want to return a Foo instance. The method might be defined as:

```
Foo* GetFoo(INode* object)  
{  
    Foo* x = new Foo (...);  
    ...  
    return x;  
}
```

Since Foo is not a supported base ParamType2 type but is derived from **IObject**, the return value of the above method can be declared using **TYPE\_IOBJECT** in the **FUNCTION\_MAP** as:

```
FN_1(my_getFoo, TYPE_IOBJECT, GetFoo, TYPE_INODE);
```

and in the descriptor constructor as:

```
my_getFoo, _T("getFoo"), 0, TYPE_IOBJECT, 0, 1,  
_T("object"), 0, TYPE_INODE,
```

In MAXScript, calling getFoo() would return an **IObject** value that has two interface properties, ifoo1 and ifoo2, and these in turn would expose their methods as properties:

```
f = getFoo $  
f.ifoo1.frabulate [10,0,0] // call the IFoo1 frabulate method
```

### **Passing FPInterfaces as Parameters & Results**

FPInterfaces themselves can now be passed directly as parameters and results via the new type, **TYPE\_INTERFACE**. These turn up in MAXScript as instances of a new value class, **FPInterface**, with all the interface's methods accessible as properties.

In cases where you have a class publishing a single mixin interface, it is possible to pass instances directly as **TYPE\_INTERFACE** and let the `FPInterface*` type-cast implied by **TYPE\_INTERFACE** extract the mixin interface. This is a useful simple alternative to the **IObject** scheme for publishing a mixin interface on non-Animatables, since you don't actually need to implement the **IObject** protocol in these cases. If the Foo example above had a single mixin, it would publish it in a similar way to the following:

```
class IFoo : public FPMixinInterface
{
    virtual void Frabulate(Point3 p)=0;
    ...
};

class Foo : public OtherBaseClass, public IFoo
{
    // Foo methods
    ...
    // IFoo methods
    void Frabulate(Point3 p) { ... }
    ...
};
```

The same `Foo*`-returning **GetFoo()** method in the previous example would then be declared using **TYPE\_INTERFACE** in the **FUNCTION\_MAP** as:

```
FN_1(my_getFoo, TYPE_INTERFACE, GetFoo, TYPE_INODE);
```

and in the descriptor constructor as:

```
my_getFoo, _T("getFoo"), 0, TYPE_INTERFACE, 0, 1,  
_T("object"), 0, TYPE_INODE,
```

In this case, calling **getFoo()** in MAXScript would return an **FPInterface** value that exposes the **IFoo** methods directly as properties.

```
f = getFoo $  
f.frabulate [10,0,0] // call the Foo1 frabulate method
```

Note again this scheme won't work for class publishing multiple multiple mixins since implied **FPInterface\*** cast becomes ambiguous - you must use the **IObject** mechanism in this case.

### **FP\_CORE Interfaces**

There is an interface descriptor flag, **FP\_CORE**, which must be specified on Core interface descriptors. Static Core interface descriptors are now automatically registered with the Core, so you do not need to explicitly call **RegisterCOREInterface()** on them. The code examples below include a Core interface using this flag. The following example taken from the DragAndDrop manager interface.

#### **1. The public interface definition (in a public header file)**

```
class IDragAndDropMgr : public FPStaticInterface  
{  
public:  
    virtual void EnableDandD(BOOL flag)=0;  
    virtual BOOL IsEnabled()=0;  
    virtual BOOL EnableDandD(HWND hwnd, BOOL flag,  
        DragAndDropHandler* handler = NULL)=0;  
    virtual BOOL DropPackage(HWND hwnd, POINT& point,  
        URLTab& package)=0;  
    virtual BOOL DownloadPackage(URLTab& package,  
        TCHAR* directory,
```

```
    HWND hwnd = NULL)=0;  
    virtual TCHAR* GetStdDownloadDirectory()=0;  
};
```

## 2. The implementation class (in the .cpp implementation file)

Note in this example, a couple of the interface methods use a new type, URLTab, which is not a ParamType2 type. This is a Tab<TCHAR\*> specialization and so provides overloads that take Tab<TCHAR\*>s and convert them to URLTabs, specifically for dispatch-based calls.

```
class DragAndDropMgr : IDragAndDropMgr  
{  
    ...  
public:  
    void EnableDandD(BOOL flag) { global_enable = flag; }  
    BOOL IsEnabled() { return global_enable; }  
    BOOL EnableDandD(HWND hwnd, BOOL flag,  
        DragAndDropHandler* handler = NULL);  
    BOOL DropPackage(HWND hwnd, POINT& point, URLTab&  
package);  
    BOOL DropFiles(HWND hwnd, HDROP hDrop);  
    BOOL DownloadPackage(URLTab& package, TCHAR*  
directory,  
        HWND hwnd = NULL);  
    TCHAR* GetStdDownloadDirectory();  
  
    // variants for FnPub interface that take Tab<TCHAR*>s  
    BOOL DropPackage(HWND hwnd, POINT& point,  
Tab<TCHAR*>& package);  
    BOOL DownloadPackage(Tab<TCHAR*>& package,  
TCHAR* directory);
```

```

DECLARE_DESCRIPTOR(DragAndDropMgr)

// dispatch map
BEGIN_FUNCTION_MAP
    VFN_1(dndmgr_globalEnableDnD, EnableDandD,
TYPE_BOOL);
        FN_0(dndmgr_isEnabled, TYPE_BOOL, IsEnabled);
        FN_2(dndmgr_enableDandD, TYPE_BOOL,
EnableDandD,
            TYPE_HWND, TYPE_BOOL);
        FN_3(dndmgr_dropPackage, TYPE_BOOL,
DropPackage,
            TYPE_HWND, TYPE_POINT_BR,
            TYPE_STRING_TAB_BR);
        FN_2(dndmgr_downloadPackage, TYPE_BOOL,
DownloadPackage,
            TYPE_STRING_TAB_BR, TYPE_STRING);
        FN_0(dndmgr_downloadDirectory, TYPE_STRING,
            GetStdDownloadDirectory);
END_FUNCTION_MAP
    ...
};

```

### 3. The descriptor, note the FP\_CORE flag.

FP\_CORE descriptors are automatically registered with **RegisterCOREInterface()**.

```

DragAndDropMgr dragAndDropMgr(DND_MGR_INTERFACE,
_T("dragAndDrop"),
    IDS_DND_INTERFACE, NULL, FP_CORE,
    dndmgr_globalEnableDnD, _T("globalEnableDragAndDrop"),

```

```

0,
    TYPE_BOOL, 0, 1, _T("onOff"), 0, TYPE_BOOL,
    dndmgr_isEnabled, _T("isEnabled"), 0, TYPE_BOOL, 0, 0,
    dndmgr_enableDandD, _T("enableDragAndDrop"), 0,
TYPE_BOOL, 0, 2,
    _T("window"), 0, TYPE_HWND, _T("onOff"), 0,
    TYPE_BOOL,
    dndmgr_dropPackage, _T("dropPackage"), 0, TYPE_BOOL, 0,
3,
    _T("window"), 0, TYPE_HWND, _T("mousePoint"), 0,
    TYPE_POINT_BR, _T("files"), 0,
    TYPE_STRING_TAB_BR,
    dndmgr_downloadPackage, _T("downloadPackage"), 0,
TYPE_BOOL, 0,
    2, _T("files"), 0, TYPE_STRING_TAB_BR,
    _T("directory"), 0,
    TYPE_STRING,
    dndmgr_downloadDirectory, _T("geStdtdownloadDirectory"), 0,
    TYPE_STRING, 0, 0,
end

```

## Action Interfaces

A special kind of interface is the Action Interface. These interfaces only contain UI Action Functions that provide a programmatic way of "pressing" buttons and keys in the UI for a plugin. As mentioned in the opening section of this doc, these action functions have certain special characteristics and possess additional descriptive metadata, relative to the functions we've described so far. Here's an annotated Action Interface example for the EdMesh system we looked at above.

### 1. The public interface (in a public header file)

```
#include "iFnPub.h"
```

```

#define EM_ACT_INTERFACE Interface_ID(0x65678, 0x123)
#define GetEMAActionsInterface(cd) \
    (EMAActions*)(cd)->GetFPInterface(EM_ACT_INTERFACE)

enum {
    ema_create, ema_create_enabled, ema_create_checked,
    ema_delete, ema_delete_enabled,
};

class EMAActions: public FPInterface
{
public:
    virtual FPStatus Create()=0;
    virtual FPStatus Delete()=0;
    virtual BOOL IsCreateEnabled()=0;
    virtual BOOL IsCreateChecked()=0;
    virtual BOOL IsDeleteEnabled()=0;
};

```

As with normal function interfaces, we we have an **Interface\_ID** defined and interface accessor helpers. There is also a function ID enum, but in this case there are more IDs than published actions. Each action function can have associated with it up to 3 predicate functions that users of the interface can call to determine status for the action. These are the **isEnabled**, **isChecked**, and **isVisible** predicates and they are used mostly by the UI elements that can be bound to an interface action to determine things like whether a button or menu item should greyed or a checkbutton should be highlighted or whether the action should be added to an about-to-be-displayed pop-up menu. The **isEnabled** & **isVisible** predicates are optional and default to always TRUE. The **isChecked** predicate is for actions that toggle a state, for example starting & stopping a mouse command mode. This predicate is also optional and defaults to FALSE, but it is required if the action is bound to **TYPE\_CHECKBUTTON** via the ParamMap2 system.

Declarations for action functions along with any associated predicates are supplied in the virtual interface class. Action functions always take zero arguments and return an **FPStatus** result which indicates whether the action was successfully performed or not (success if **FPS\_OK**, but it may return values such as **FPS\_ACTION\_DISABLED** if the action was not enabled at the time). Predicate functions always take zero arguments and return a **BOOL**.

Here are some action function call examples:

```
EMActions* emai = GetEMActionsInterface(edmeshCD);
```

```
...
```

```
if (emai->IsCreateEnabled()) // direct calls  
    emai->Create();
```

Indirect Calls:

```
if (emai->IsEnabled(ema_delete))  
    emai->Invoke(ema_delete);
```

This indirect example uses one of the predicate helper functions to call the **isEnabled** predicate in the interface for a given function, specified by FunctionID.

## **2. The implementation class (in the .cpp implementation file)**

```
class EMActionsImp : public EMActions  
{  
public:  
    BOOL creating;  
  
DECLARE_DESCRIPTOR(EMActionsImp)  
BEGIN_FUNCTION_MAP
```

```
FN_ACT(ema_create, Create)  
    FN_PRED(ema_create_enabled, IsCreateEnabled)  
    FN_PRED(ema_create_checked, IsCreateChecked)  
FN_ACT(ema_delete, Delete)  
FN_PRED(ema_delete_enabled, IsDeleteEnabled)  
END_FUNCTION_MAP
```

```
void Init()
```

```
{  
    // initialize any state data  
    creating = FALSE;  
}
```

```
    FPStatus Create()
```

```
{  
    //... start or stop the create mode  
    //...  
    creating = !creating; // toggle creating state  
    //...  
    return FPS_OK;  
}
```

```
BOOL IsCreateEnabled()
```

```
{  
    //... determine if create enable, perhaps  
    // vertex subobjlevel test, etc.  
}
```

```
BOOL IsCreateChecked()
```

```
{
```

```

    return creating; // the current create state
}
//...
};

```

The action interface implementation class contains implementations for the actions and predicates, as required by the virtual interface. It also contains a **FUNCTION\_MAP**, but in this case the actions and predicates entries in the map are defined with their own special FN\_ macros, **FN\_ACT** for actions and **FN\_PRED** for predicates.

The Create action in this example corresponds to a vertex create mode start button and so it provides an **isChecked** predicate to tell what state the action is in, in this case checked => in create mode, not checked => not in create mode. The implementation interface contains a data element 'creating' to help keep track of this state. Note that it is initialized in a method called **Init()**. Since the varargs constructor is the normal way the interface instance is created, it guarantees to call this (virtual) init method for you; alternatively, you could make it a static data member and statically initialize it.

### 3. The interface definition (in the .cpp implementation file)

```

static EMActionsImp emai (
    EM_ACT_INTERFACE, _T("Actions"), IDS_EMAI,
    &edmeshCD, FP_ACTIONS,
    ema_create, _T("create"), IDS_CREATE, 0,
    f_predicates, ema_create_enabled, ema_create_checked,
    FP_NO_FUNCTION,
    f_category, _T("creation"), 0,
    f_iconRes, IDI_CREATE_ICON,
    f_toolTip, IDS_VERTEX_CREATE_BY_CLICKIN,
    f_ui, em_params, 0, TYPE_CHECKBUTTON, IDC_CREATE,
    GREEN_WASH,

```

```

    end,
    ema_delete, _T("delete"), IDS_DELETE, 0,
        f_isEnabled, ema_delete_enabled,
        f_ui, em_params, 0, BUTTON, IDC_DELETE,
    end,
end
);

```

The constructor for an Action Interface follows a slightly different syntax to a normal function interface. The header parameters are the same (**Interface\_ID**, internal name, descriptor, CD, flags), the **FP\_ACTIONS** flag must be specified to mark this as an action interface.

Each action function is specified by header parameters giving **FunctionID**, internal name, descriptor **resID** and flag bits. This is followed by one or more tagged action function options, in the same manner as parameter options in a **ParamBlockDesc2** constructor. Each option defines a separate item of metadata for the function. In the case of **ema\_create**, the following are specified:

- • 2 of the 3 possible predicates via their FunctionIDs,
- • a category string, used by the UI customize dialogs to arrange actions into category groups
- • a resID for an Icon resource that will be made available for use in toolbar buttons and other UI locations
- • a toolTip string resID
- • a UI specification that allows the parammap2 system to automatically connect a button to this action. This is described in more detail in the next section.

The possible options include:

**f\_category** category name, as internal TCHAR\* and localizable string resID,

defaults to interface name

**f\_predicates** supply 3 functionIDs for **isEnabled**, **isChecked**, **isVisible**

predicates

**f\_isEnabled** **isEnabled** predicate functionID

**f\_isChecked** **isChecked** predicate functionID

**f\_isVisible** **isVisible** predicate functionID

**f\_iconRes** icon as resource ID

**f\_icon** icon as UI .bmp filename, index pair, as per CUI icon specifications

**f\_buttonText** button text string resID, defaults to function description

**f\_toolTip** tooltip string resID, defaults to function description

**f\_menuText** menu item text string resID, defaults to buttonText or function

description

**f\_ui** UI spec if paramMap2-implemented UI (pmap blockID, mapID, control

type, button or checkbutton resID, hilight col if chkbtn)

**f\_shortcut** default keyboard shortcuts for action functions

**f\_keyArgDefault** marks a parameter as optional and supplies a default value. Optional parameters must come after the positional parameters. Example:

```
Meshop::buildMapFaces,  
  _T("buildMapFaces"), 0, TYPE_VOID, 0, 3,  
    _T("source"), 0, TYPE_FPVALUE_BR,  
      _T("keep"), 0, TYPE_BOOL,  
f_keyArgDefault, FALSE,  
    _T("channel"), 0, TYPE_INT,  
f_keyArgDefault, 0,
```

**f\_inOut** specifies whether **\_BR** parameter is just for input, just for output or both via **FPP\_OUT\_PARAM**, **FPP\_IN\_PARAM**, or **FPP\_IN\_OUT\_PARAM** argument. Default is **FP\_IN\_OUT\_PARAM**.

**f\_macroEmitter** Supply a pointer to **FPMacroEmitter** subclass instance to customize macro-recorder emission. The **Emit()** method is called on this instance with interface and function def pointers for the particular action function to be emitted.

The ActionTable system 'table ID' DWORD for Action interfaces is generated automatically from the Interface\_ID for the Action interface (by xor-ing the two DWORDS in the interface ID). If this generates an ID that clashes with built-in table IDS (in the range 0-64), an error message is generated and you should choose a more random Interface\_ID.

You define the UI context for the interface as a whole, rather than for each individual action function. The context ID should be specified immediately after the flag word in an Action interface descriptor constructor. For example:

```
static IKChainActionsImp sIKChainActionImp(  
    IKCHAIN_FP_INTERFACE_ID, _T("Action"),  
    IDS_IKCHAIN_ACT,  
    &theIKChainControlDesc, FP_ACTIONS,  
    kActionMainUIContext,  
    IKChainActionsImp::kSnap, _T("snap"),  
    IDS_IKCHAIN_SNAP, 0,  
    ...
```

The constant '**kActionMainUIContext**' is one of the built-in ActionTable system contexts that you can use (defined in **maxsdk\include\ActionTable.h**), and is most likely the one to be used. If you create an entirely new context and context ID, you will need to register and control its activation yourself (see the **IActionManager** in **maxsdk\include\ActionTable.h** for details).

The automatically-generated ActionTable for the Action interface can be accessed via a new FPInterface method: **virtual ActionTable\***

### **GetActionTable();**

By default, the action table is activated immediately and stays active throughout the 3ds max session. You can dynamically control this activation via a new FPInterface method: **virtual void EnableActions(BOOL onOff);**

This enables or disables the entire set of actions in the interface. You might do this if the actions are only to be active during certain times in the running of MAX. Usually, this control is achieved via ActionTable contexts.

### **ParamMap2 Buttons**

The **f\_ui** option for an Action Function can be used to make the **ParamMap2** system connect the action function to a button in a ParamMap2-mediated rollup in your plugin's UI. This means you have to be using the ParamBlock2 system in the interface's plugin (ie, same **ClassDesc2**) and have at least one paramblock containing a paramMap whose rollup contains the button dialog item.

In the **f\_ui** option, you first specify the BlockID of the paramblock containing this paramMap and then MapID of the map within that block (single map blocks use MapID 0). This is followed by a control type code, and its required parameters, as listed below:

#### **TYPE\_BUTTON, <dlg\_item\_ID>**

a standard push button. The dialog item must be a 3ds max **CustButton** custom control.

#### **TYPE\_CHECKBUTTON, <dlg\_item\_ID>, <highlight\_color>**

a standard check button. Again, the dialog item must be a 3ds max **CustButton** custom control, the 2<sup>nd</sup> parameters is the button highlight color as a **COLORREF** word, either one of the predefined colors in **maxsdk\include\custcont.h**, or an RGB value using the system **RGB()** macro.

This is basically all you need to do. Whenever the specified map opens its rollup, say as part of a **BeginEditParams**, it will automatically look for any Action functions associated via an **f\_ui** and will call that action function whenever the button is clicked. If an **isEnabled** predicate is supplied, the **ParamMap2** will call it at various display update times to determine whether to enable or disable (gray out) the button. For CheckButtons, an **isChecked** predicate *must* be supplied and will be called at similar times to update the pressed or not-pressed state of the button display.

## The FPInterface Class Hierarchy

The **FPInterface** class hierarchy is such that static and mixin interfaces and interface descriptors each have their own types.

**FPInterface** The base class for all interfaces, prime client type for using interfaces

**FPInterfaceDesc** Contains the interface metadata

**FPStaticInterface** Use as the base class for defining static or core virtual interface classes.

**FPMixinInterface** Use as the base class for defining object-based mixin interface

classes, use **FPInterfaceDesc** for mixin interface descriptors

The **FPInterface** class continues to provide all the original method and predicate invocation functions required by an SDK-level client of the interface. A pure virtual method, **GetDesc()**, should be used to get the **FPInterfaceDesc** instance for the interface. The metadata definition and accessing methods and the metadata data members now all live in the **FPInterfaceDesc**.

All the original interface query methods in the API (such as **Animatable::GetInterface(id)**, **ClassDesc2::GetInterface(id)**, **GetCOREInterface(id)**) still return **FPInterface** pointers, so you would use

**GetDesc()** in constructs like the following to get at an interface's metadata:

```
FPInterface* fpi = GetCOREInterface(FOO_INTERFACE);  
TCHAR* iname = fpi->GetDesc()->internal_name.data();
```

The **FPInterface::GetDesc()** method has a default implementation in **FPInterfaceDesc** (and so **FPStaticInterface**), simply returning 'this', since instances of these classes contain the metadata). **FPMixinInterface** subclasses provide implementations of **GetDesc()**, returning their associated **FPInterfaceDesc** instance.

## Parameter Validation

An interface descriptor can now contain validation information for individual parameters, so that clients such as MAXScript can validate values given as parameters to **FPInterface** calls, prior to making the call. The validation info can be in the form of a range of values for int and float types, or more generally, a validator object that is called to validate a parameter value.

MAXScript now applies the validations if supplied and generates descriptive runtime errors if the validation fails.

The validation info is specified in the **FPInterface** descriptor in optional tagged entries following the parameters to be validated. The two possible tags are **f\_range** and **f\_validator**. Here's an example from a possible mixin interface to Cylinder:

```
static FPInterfaceDesc cylfpi (  
    CYL_INTERFACE, _T("cylMixin"), 0, &cylinderDesc,  
    FP_MIXIN,  
    ...  
    cyl_setRadius, _T("setRadius"), 0, TYPE_VOID, 0, 1,  
        _T("radius"), 0, TYPE_FLOAT, f_range, 0.0, 10000.0,  
    cyl_setDirection, _T("setDirection"), 0, TYPE_VOID, 0, 1,  
        _T("vector"), 0, TYPE_POINT3, f_validator,  
        &cylValidator,  
)
```

```
...
end
);
```

In this above example, the "radius" parameter is defined to have a range 0.0 to 10000.0. An **f\_range** spec can only be used for int (**TYPE\_INT**, **TYPE\_TIMEVALUE**, **TYPE\_RADIOBTN\_INDEX**, **TYPE\_INDEX**, **TYPE\_ENUM**) and float parameters (**TYPE\_FLOAT**, **TYPE\_ANGLE**, **TYPE\_PCNT\_FRAC**, **TYPE\_WORLD**, **TYPE\_COLOR\_CHANNEL**) and is given as a pair of low and high range values. The values must be floating point or integer as needed by the **TYPE\_xxx** code, you cannot specify integer range values for float types and vice versa, hence the 0.0 and 10000.0 in the example above. MAXScript checks parameter values against these supplied ranges and will generate a descriptive error message for out-of-range values.

The "vector" parameter in the above example has a validator object specified. This must be a pointer to an instance of a class derived from the new class, **FPValidator**, defined in **iFnPub.h**. This is a virtual base class, containing a single method, **Validate()**, that is called to validate a prospective value for a parameter. You would typically subclass **FPValidator** in your code and provide an implementation of **Validate()** to do the validation. Here is the **FPValidator** virtual base class:

```
class FPValidator
{
public:
    // validate val for the given param in function in interface
    virtual bool Validate(FPInterface* fpi, FunctionID fid,
        int paramNum, FPValue& val, TSTR& msg)=0;
};
```

The **Validate()** function is called with interface, function-within-interface and parameter-within-function identifiers and an **FPValue** to validate. It can optionally install an error message string in the 'msg' TSTR& parameter for the

user of the validator to display. If there are many parameters to validate this way, you can choose to provide a separate subclass for each parameter or a single subclass and switch on the parameter identification supplied.

For the Cylinder example above, the "vector" parameter might be required to be given as a unit vector, so the validator might check for this as follows:

```
class CylValidator : public FPValidator
{
    bool Validate(FPInterface* fpi, FunctionID fid, int paramNum,
               FPValue& val, TSTR& msg)
    {
        if (fabs(Length(*val.p) - 1.0) > 1e-6)
        {
            msg = "Direction vector must be unit length."
            return false;
        }
        else
            return true;
    }
}
```

Note that the type is already checked by the caller, since it has type info for the parameter, so you don't also need to check the **FPValue** type.

Note, also, that the **FPValue& val** argument given to **Validate()** is a reference to the actual parameter value to be given to the called function, so it is also possible to massage the value rather than reporting an error. For example, the above sample **Validate()** method could normalize the vector and always return true. The type must not be changed in this process, only the value can be adjusted.

A singleton instance of this **FPValidator** subclass would be created, typically as a

static instance, to be given in the **f\_validator** specification: **static CylValidator cylValidator;**

If you need to get at the validation metadata, it is available in the new 'options' data member in an **FPParamDef** instance for a parameter. If non-NULL, this points to a **FPParamOptions** instance which contains the range or validator information for the parameter. See class **FPParamOptions** in **iFnPub.h** for details.

## Exception Handling

FnPub interface functions can now report fatal error conditions to callers by using C++ exception-handling. There is a new exception base class, **MAXException**, defined in **iFnPub.h** that can be thrown directly, or subclassed as needed for error grouping. The class is defined as follows:

```
class MAXException  
{  
public:  
    TSTR message;  
    int error_code;  
    MAXException(TCHAR* msg, int code=0) : message(msg),  
        error_code(code) { }  
};
```

It contains a message buffer and an optional error code. You would signal an error using the **MAXException()** constructor and the C++ throw statement, as in the following example:

```
...  
if (discrim < 0.0) // oh-oh, not good  
throw MAXException ("Unable to find root.", -23);  
...
```

This signals a fatal error with the message and code shown. If the error occurs

during a call to the function by MAXScript code, it will be trapped by MAXScript and the error message will be displayed and the running script will be terminated (but 3ds max will continue running). If the error occurs during a C++-level call, typically the outer 3ds max error catcher will catch and report the error and then exit MAX, or clients of the interface can install their own catch code.

## Property accessors

It is possible to define selected methods in an **FPInterface** as 'property accessor' methods so that dispatch-based clients of the interface may present these methods as properties instead of functions. MAXScript, for example, now presents property accessors defined in this way as simple dot-notation properties of the interface. These accessors remain as ordinary methods in the

C++-level interface for direct C++ clients but are marked as accessors in the descriptor and function maps. A 'property' is typically defined by a pair of accessor methods, one for getting and one for setting, but you can also define read-only methods that have a single getter method. As an example, here's a rework of the above Cylinder interface in which the radius and direction are made properties.

```
class CylInterface : public FPMixinInterface
{
    ...
    virtual void RemoveCaps()=0;
    virtual void AddBend(float offset, float angle, float radius)=0;
    ...
    virtual float GetRadius()=0;
    virtual void SetRadius(float radius)=0;
    virtual Point3 GetDirection()=0;
    virtual void SetDirection(Point3 dir)=0;
    ...
    BEGIN_FUNCTION_MAP
```

```

...
    VFN_0(cyl_removeCaps, RemoveCaps);
    VFN_3(cyl_addBend, AddBend, TYPE_FLOAT,
TYPE_ANGLE,
    TYPE_FLOAT);
...
    PROP_FNS(cyl_getRadius, GetRadius, cyl_setRadius,
SetRadius,
    TYPE_FLOAT);
    PROP_FNS(cyl_getDir, GetDirection, cy_setDir,
SetDirection,
    TYPE_POINT3_BV);
...
END_FUNCTION_MAP
FPInterfaceDesc* GetDesc();
};

```

Each property as a getter and setter virtual method. Their signatures must conform to the convention shown, namely, the getter takes no parameters and the setter one. The getter returns the same type as the setter and the setter type is void. There are also variants that take an explicit time as described below.

Properties have single entries in the function map, using one of the property-related entry macros. In this case, **PROP\_FNS()** takes a getter ID, getter function, setter ID, setter function and finally the property type code. There is also a **RO\_PROP\_FN()** macro for read-only properties that takes a getter ID, getter FN and prop type. Finally, there are variants of **PROP\_FNS** and **RO\_PROP\_FN** that indicate the accessors take an explicit **TimeValue** argument, presumably associated with animatable properties and indicating that the property access should be at the given time. These macros are **PROP\_TFNS** and **RO\_PROP\_TFN** and takes the same arguments as their corresponding base macros. If the above example properties were time-sensitive, the definitions would be as follows:

```

class CylInterface : public FPMixinInterface
{
    ...
    virtual void RemoveCaps()=0;
    virtual void AddBend(float offset, float angle, float radius)=0;
    ...
    virtual float GetRadius(TimeValue t)=0;
    virtual void SetRadius(float radius, TimeValue t)=0;
    virtual Point3 GetDirection(TimeValue t)=0;
    virtual void SetDirection(Point3 dir, TimeValue t)=0;
    ...
    BEGIN_FUNCTION_MAP
        ...
        VFN_0(cyl_removeCaps, RemoveCaps);
        VFN_3(cyl_addBend, AddBend, TYPE_FLOAT,
TYPE_ANGLE,
        TYPE_FLOAT);
        ...
        PROP_TFNS(cyl_getRadius, GetRadius, cyl_setRadius,
SetRadius,
        TYPE_FLOAT);
        PROP_TFNS(cyl_getDir, GetDirection, cy_setDir,
SetDirection,
        TYPE_POINT3_BV);
        ...
    END_FUNCTION_MAP

    FPIInterfaceDesc* GetDesc();
};

```

Recall that there are time-sensitive variants for the **FN\_0**, **FN\_1**, etc., macros,

namely **TFN\_0**, **TFN\_1**, etc. Functions specified by such macros in the function map have an implicit **TimeValue** last parameter. Note that in all the time-sensitive variants, the last **TimeValue** parameter is not defined as an explicit parameter in the **FPInterface** descriptor entry for that function. Such time-sensitive properties and functions are handled specially in MAXScript. It supplies the current MAXScript time, as defined by the current 'at time' context for this implicit parameter, making these functions and properties behave consistently with the rest of MAXScript.

Properties are defined in a special section in the **FPInterface** descriptor constructor following the function definitions, headed by the special tag 'properties'. They are also entered in the function map using new property-specific **FUNCTION\_MAP** macros. Here's an example descriptor fragment:

```
static FPInterfaceDesc cylfpi (  
    CYL_INTERFACE, _T("cylMixin"), 0, &cylinderDesc,  
    FP_MIXIN,  
    ...  
    cyl_removeCaps, _T("removeCaps"), 0, TYPE_VOID, 0, 0,  
    cyl_addBend, _T("addBend"), 0, TYPE_VOID, 0, 3,  
        _T("offset"), 0, TYPE_FLOAT,  
        _T("angle"), 0, TYPE_ANGLE,  
        _T("radius"), 0, TYPE_FLOAT,  
    properties,  
    cyl_getRadius, cyl_setRadius, _T("radius"), IDS_RADIUS,  
        TYPE_FLOAT, f_range, 0.0, 10000.0,  
    cyl_getDirection, cyl_setDirection, _T("direction"), IDS_DIR,  
        TYPE_POINT3_BV,  
    ...  
    end  
);
```

The 'properties' section follows the function definitions. Each property has a

single entry defining the function IDs for the getter and setter functions, a fixed internal property name, a descriptor string resource ID and the property type. If the property is read-only and there is no setter function, specify **FP\_NO\_FUNCTION** for the setter ID. Each property definition can optionally be followed by parameter validation options, as described in the Parameter Validation section above, and these apply to the parameter given to the setter function during property assignment. In this case, the radius is range checked.

If you need to get at it, the property metadata is accessible in the 'props' data member in an **FPInterfaceDesc**. It is a **Tab<>** of pointers to **FPPropDef** class instances, which contain individual property metadata. See the **FPPropDef** class definition in **iFnPub.h** for details.

MAXScript now exposes properties defined in this way as direct dot-notation properties on the interface. So, were before the Get/SetRadius in the example cylinder mixin would have been accessed as functions:

```
r = $cyl01.cylMixin.getRadius()  
$cyl01.cylMixin.setRadius 23
```

you now can use:

```
r = $cyl01.cylMixin.radius  
$cyl01.cylMixin.radius = 23
```

This is true for all the types of FP interfaces that turn up in MAXScript, static, mixin and core. As a further optimization, MAXScript now effectively promotes all interface methods and properties to the level of the interface, so if individual methods and properties have unique names within all the interfaces of an object or class, you can elide the interface name. The above examples could now be written:

```
r = $cyl01.getRadius()  
$cyl01. setRadius 23
```

and:

```
r = $cyl01.radius  
$cyl01. radius = 23
```

If there is a naming conflict, you can always include the interface name level to resolve this.

## **Symbolic Enums**

One or more symbolic enums, similar to C++ enums, can now be added to an FPIInterface's metadata, and individual int parameters and/or results for functions in that interface can be defined as **TYPE\_ENUM** and associated with one of the enum lists. This allows metadata clients to support symbolic encodings for these parameters and results, which MAXScript now does.

Enums are defined in the FPIInterface descriptor following the function and property definitions as sets of string/code pairs. Each enum list is identified by a unique integer, similar to function IDs, which is used to associated a **TYPE\_ENUM** parameter or result with its enum. IDs for these would normally be defined somewhere near the function IDs for an interface. For example:

```
// function IDs  
enum { bmm_getWidth, bmm_getHeight, bmm_getType,  
bmm_copyImage, ...};  
// enum IDs  
enum { bmm_type, bmm_copy_quality, ...};
```

might be some of the IDs for a possible bitmap manager interface. The two

enums provide symbolic codes for the bitmap type and copyImage quality defines in the "bitmap.h" SDK header, such as **BMM\_PALETTED**, **BMM\_TRUE\_32**, **COPY\_IMAGE\_RESIZE\_LO\_QUALITY**, etc. In the descriptor for the interface, any enum lists follow the function and property definitions. They are introduced by the special tag, 'enums', as in the following example:

```
static FPInterfaceDesc bmmfpi (  
    BMM_INTERFACE, _T("bmm"), IDS_BMMI, NULL,  
    FP_CORE,  
    ...  
    bmm_copyImage, _T("copyImage"), ...  
        _T("copyType"), IDS_COPYTYPE, TYPE_ENUM,  
    bmm_copy_quality,  
    ...  
    properties,  
        geo_getType, geo_setType, _T("type"), 0, TYPE_ENUM,  
    bmm_type,  
        enums,  
        bmm_type, 7,  
            "lineArt", BMM_LINE_ART,  
            "paletted", BMM_PALETTED,  
            "gray8", BMM_GRAY_8,  
            "gray16", BMM_GRAY_16 ,  
            "true16", BMM_TRUE_16,  
            "true32", BMM_TRUE_32,  
            "true24", BMM_TRUE_64,  
        bmm_copy_quality, 4,  
            "crop", COPY_IMAGE_CROP,  
            "resizeLo", COPY_IMAGE_RESIZE_LO_QUALITY,  
            "resizeHi", COPY_IMAGE_RESIZE_HI_QUALITY,
```

```
        "useCustom", COPY_IMAGE_USE_CUSTOM,  
    end  
);
```

In the above example, the enums are listed following the function & property definitions. They are introduced by the 'enums' tag and consist of an enum ID followed by a count of items, followed by that many string and code pairs. By attaching them to the interface like this, any number of functions and properties in the interface can use them.

The above example also has function and property definitions showing the use of `TYPE_ENUM`. The `copyImage` function takes a `copyType` parameter which uses the `bmm_copy_quality_enum` and the type property uses the `bmm_type_enum`. In all situations where `TYPE_xxx` types can be supplied in a descriptor, including the new property definitions, `TYPE_ENUM` can be used to indicate an int by-value type. `TYPE_ENUM`'s must always be followed by an enum ID. This is the only case in which the type is specified as a pair of values. `TYPE_ENUM` parameters and results show up in MAXScript as # names. For example, if a bmm interface was in the variable 'bm1' and the bitmap type was `BMM_GRAY_16`,

```
bm1.type  
-> #gray16
```

```
bm1.type = #true32 -- set it to #true24 (code is BMM_TRUE_24)  
bm2 = bm1.copyImage #resizeHi
```

the integer `TYPE_ENUM` codes are translated back-and-forth to symbolic # names by MAXScript using the definitions in the `FPInterface` descriptor's enums. If you need to access the enum metadata in an `FPInterfaceDesc`, it is available in the 'enumerations' data member. This is a `Tab<>` of pointers to `FPEnum` class instances which themselves contain a `Tab<>` of name, code pairs. See class `FPEnum` in `iFnPub.h` for details.

## Additional ParamType2 codes for Function Publishing and MAXScript

**TYPE\_FPVALUE** // FPValue\*, variant value  
**TYPE\_VALUE** // MAXScript Value\*

**TYPE\_FPVALUE** can be used to pass a variant data type, containing one of the types of data that **FPValue** can hold. This allows a function to be defined that can accept many types of values for a **TYPE\_FPVALUE** parameter, the function can determine the type from the 'type' field in the **FPValue** passed. MAXScript supports **TYPE\_PFVALUE** parameters and return values and will convert back-and-forth between the MAXScript types that correspond to the various **FPValue** types. **TYPE\_FPVALUE** also supports **TYPE\_FPVAUE\_BV** and **TYPE\_FPVALUE\_BR** variants. MAXScript arrays will attempt to convert themselves into **TYPE\_XXX\_TAB FPValues** if the array elements are all of the same type, for example all integers generate a **TYPE\_INT\_TAB**, all scene nodes generate a **TYPE\_INODE\_TAB**, etc. If the array contains mixed value types or types not in the following list, a **TYPE\_FPVALUE\_TAB** will be generated, containing an **FPValue\*** variant value for each element in the array. Supported homogeneous types are:

**TYPE\_INT\_TAB**  
**TYPE\_FLOAT\_TAB**  
**TYPE\_TIMEVALUE\_TAB**  
**TYPE\_STRING\_TAB**  
**TYPE\_NAME\_TAB**  
**TYPE\_POINT3\_TAB**  
**TYPE\_POINT2\_TAB**  
**TYPE\_INODE\_TAB**  
**TYPE\_REFTARG\_TAB** (all other ReferenceTarget\*s, modifiers, mtl, ctrls, etc.)

**TYPE\_VALUE** is basically a fallback to be used in situations where MAXScript values of types not covered by **FPValue** types need to be passed

into a published function. The called function is responsible for using the MAXScript SDK to convert to and from the **Value\*** in **TYPE\_VALUE** values.

## Parameter/Result Types

More parameter/result types have been added and the type system has been generalized to allow you to specify pass-by-reference, pass-by-pointer and pass-by-value variations of the appropriate base types. This permits a wider range of interface method signatures in FnPub interfaces, particularly those with '&' reference types typically used for passing back values via parameters. The scripter has been upgraded to support all these new types and pass-by options (see also the MAXScript section here for details).

The type codes, defined in the **ParamType2** enum, are arranged in sections with various suffixes signifying the sections. The main section gives the so-called 'base types', such as **TYPE\_INT**, **TYPE\_FLOAT**, and the other sections are variations derived from the base types. The variations are:

<**base\_type**>\_BV base type passed by value

<**base\_type**>\_BR base type passed by reference, used with & ref params & results

<**base\_type**>\_BP base type passed by pointer, used with \* pointer params& results

<**base\_type**>\_TAB a Tab<> of the base type

<**base\_type**>\_TAB\_BV a Tab<> of base type, the Tab<> is passed by value

<**base\_type**>\_TAB\_BR a Tab<> of base type, the Tab<> is passed by reference

Since some base types are naturally passed by value or pointer, and the base **Tab<>** type is passed by pointer, so not all possible combinations are actually made available. For example, there is no **TYPE\_INT\_BV**, since **TYPE\_INT** is already passed by value, and there is no **TYPE\_STRING\_BP** since **TYPE\_STRING** is already passed by pointer.

## Added base types

**TYPE\_POINT** a Win32 POINT struct

**TYPE\_TSTR** a 3ds max SDK TSTR class

**TYPE\_IOBJECT** a new FnPub system IObject

**TYPE\_INTERFACE** an FPIInterface

**TYPE\_HWND** a Win32 HWND handle

**TYPE\_NAME** a variant of TYPE\_STRING, meant to be interpreted as an interned symbol or

name in the client (eg, MAXScript represents these Name instances,  
as in #foo, etc.)

All the new base types are passed naturally as pointers, so there are **\_BV** and **\_BR** variants for all of them (except for **TYPE\_HWND**). There are also **\_TAB**, **\_TAB\_BR**, **\_TAB\_BV** variants for them all. For reference, all the currently available types are in the ParamType2 enumeration in **/include/iparmb2.h**. Some base types are naturally passed by value, others by pointer. Basically, all the int and float-derived types are passed naturally by-value and all the rest by pointer. The by-value base types are:

ints:

**TYPE\_INT**

**TYPE\_BOOL**

**TYPE\_TIMEVALUE,**

**TYPE\_RADIOBTN\_INDEX**

**TYPE\_INDEX**

floats:

**TYPE\_FLOAT**

**TYPE\_ANGLE**

**TYPE\_PCNT\_FRAC**  
**TYPE\_WORLD**  
**TYPE\_COLOR\_CHANNEL**

The **FPValue** class has a union containing fields for all the base and table types and show the natural passing mode for each. Note that the **\_BP** by-pointer variants of the base types are passed as iptr & fptr pointer fields in the **PValue** union. For the types that are passed naturally by pointer, the **\_BV** variants cause local copies to be made and owned by the **FPValue** carrying them. The **FPValue** destructor will free memory taken by these copies. Also, the **\_BR** variants of naturally-pointer types need to be supplied as pointers to the **FPValue** (or **FPParams**) constructors and are dereferenced at parameter delivery time. So, for example, the following **FPInterface** method:

```
Tab<int> Foo(INode* object, Tab<Point3*>& points);
```

would be declared in the **FUNCTION\_MAP** as

```
FN_2(my_foo, TYPE_INT_TAB_BV, Foo, TYPE_INODE,  
TYPE_POINT3_TAB_BR);
```

and in the descriptor constructor as

```
my_foo, _T("foo"), 0, TYPE_INT_TAB_BV, 0, 2,  
_T("object"), 0, TYPE_INODE,  
_T("points"), 0, TYPE_POINT3_TAB_BR,
```

## **Supported Types**

The type codes you can use to specify function return types or argument types are defined by the **ParamType2** enumeration in `\include\paramtype.h`. Several of the type codes map to the same underlying C++ type, for example there are five float types. In most cases, the alternate codes imply different UI scaling Dimensions that are honored by systems like MAXScript. For example, using

**TYPE\_ANGLE** will cause MAXScript to convert back and forth between radians internally and degrees to the user, so you should use the most specific type code.

As you can see from the list below, all the values are pointer-sized or smaller, so they fit in a single pointer-sized union in an **FPValue**. This means any object larger than a pointer is normally passed by reference. To support passing and returning by-value, a variant set of types is provided that take local copies of the object; they have an **\_BV** suffix in the type code name. This local copy is freed in the destructor of **FPValue**, so **FPValues** of these types effectively have the semantics of pass-by-value. Typically, you would use these by-value types for returning values that have been created locally in the called function, Point3s, strings, etc. All **Tab<>** types take a local copy of the table. All the reftarg types (Mtl\*, INode\*, Texmap\*) are passed only as pointers, no attempt is made to keep local references in the **FPValue** or **FPParam** instances.

#### **Built in data types (enum ParamType)**

**TYPE\_USER**

#### **Built in data types (enum ParamType2)**

**TYPE\_INDEX**

**TYPE\_MATRIX3**

**TYPE\_PBLOCK2**

The following are only for published function parameter types, not pblock2 parameter types.

**TYPE\_ENUM**

**TYPE\_VOID**

**TYPE\_INTERVAL**

**TYPE\_ANGAXIS**

**TYPE\_QUAT**  
**TYPE\_RAY**  
**TYPE\_POINT2**  
**TYPE\_BITARRAY**  
**TYPE\_CLASS**  
**TYPE\_MESH**  
**TYPE\_OBJECT**  
**TYPE\_CONTROL**  
**TYPE\_POINT**  
**TYPE\_TSTR**  
**TYPE\_IOBJECT**  
**TYPE\_INTERFACE**  
**TYPE\_HWND**  
**TYPE\_NAME**  
**TYPE\_COLOR**  
**TYPE\_FPVALUE**  
**TYPE\_VALUE**  
**TYPE\_DWORD**  
**TYPE\_bool**

The following are tables of the above data types (in the same order as base types).

**TYPE\_INDEX\_TAB**  
**TYPE\_MATRIX3\_TAB**  
**TYPE\_PBLOCK2\_TAB**

The following are only for published function parameter types, not pblock2 parameter types.

**TYPE\_ENUM\_TAB, TYPE\_VOID\_TAB,**

**TYPE\_INTERVAL\_TAB, TYPE\_ANGAXIS\_TAB,  
TYPE\_QUAT\_TAB, TYPE\_RAY\_TAB, TYPE\_POINT2\_TAB,  
TYPE\_BITARRAY\_TAB, TYPE\_CLASS\_TAB,  
TYPE\_MESH\_TAB, TYPE\_OBJECT\_TAB,  
TYPE\_CONTROL\_TAB, TYPE\_POINT\_TAB,  
TYPE\_TSTR\_TAB, TYPE\_IOBJECT\_TAB,  
TYPE\_INTERFACE\_TAB, TYPE\_HWND\_TAB,  
TYPE\_NAME\_TAB, TYPE\_COLOR\_TAB,  
TYPE\_FPVALUE\_TAB, TYPE\_VALUE\_TAB,  
TYPE\_DWORD\_TAB, TYPE\_bool\_TAB**

The following pass by-ref types, implies & parameters, int& & float& are passed via .ptr fields, only for FnPub use. These are defined as **TYPE\_xxx + TYPE\_BY\_REF.**

**TYPE\_FLOAT\_BR, TYPE\_INT\_BR, TYPE\_BOOL\_BR,  
TYPE\_ANGLE\_BR, TYPE\_PCNT\_FRAC\_BR,  
TYPE\_WORLD\_BR, TYPE\_COLOR\_CHANNEL\_BR,  
TYPE\_TIMEVALUE\_BR, TYPE\_RADIOBTN\_INDEX\_BR,  
TYPE\_INDEX\_BR, TYPE\_RGBA\_BR, TYPE\_BITMAP\_BR,  
TYPE\_POINT3\_BR, TYPE\_HSV\_BR, TYPE\_REFTARG\_BR,  
TYPE\_MATRIX3\_BR, TYPE\_ENUM\_BR,  
TYPE\_INTERVAL\_BR, TYPE\_ANGAXIS\_BR,  
TYPE\_QUAT\_BR, TYPE\_RAY\_BR, TYPE\_POINT2\_BR,  
TYPE\_BITARRAY\_BR, TYPE\_MESH\_BR, TYPE\_POINT\_BR,  
TYPE\_TSTR\_BR, TYPE\_COLOR\_BR, TYPE\_FPVALUE\_BR,  
TYPE\_DWORD\_BR, TYPE\_bool\_BR**

The following pass by-ref Tab<> types, implies & parameters, int& & float& are passed via .ptr fields, only for FnPub use. These are defined as **TYPE\_xxx + TYPE\_TAB + TYPE\_BY\_REF.**

**TYPE\_FLOAT\_TAB\_BR, TYPE\_INT\_TAB\_BR,  
TYPE\_RGBA\_TAB\_BR, TYPE\_POINT3\_TAB\_BR,**

**TYPE\_BOOL\_TAB\_BR, TYPE\_ANGLE\_TAB\_BR,

There are no specific by-pointer Tab<> types, all Tab<> types are by-pointer by default.

**TYPE\_MAX\_TYPE**

### **Published Functions and MAXScript**

MAXScript automatically provides access to all functions published by a plugin via the FnPub system. The current scheme is experimental and may change somewhat. Each plugin class appears in MAXScript as a 3ds max class object, that can be used to construct instances of the plugin, do class tests, etc. If a plugin publishes interfaces, they are visible in MAXScript as properties on this class object. The internal name for the interface is used as the property name. All the functions in the interface are accessible as named properties on the interface. So, if the above example interfaces were published by EditMesh, the following script frags would work:

**EditMesh.faceOps.extrude \$foo.mesh #{1,2,3} 10**

calls the Extrude function in the FaceOps interface on \$foo's mesh, faces 1, 2 and 3, amount 10 units.

**EditMesh.actions**

retrieves and displays the action functions. Each interface is stored as a struct definition in the class object.

**EditMesh.actions.create ()**

starts (or stops) the create mode. This would (should!) have the side-effect of highlighting/unhighlighting the Create button in the EditMesh rollups. Calls to Action functions in MAXScript return **true** if the function returns **FPS\_OK** and **false** otherwise.

**if EditMesh.actions.create.isChecked() then ...**

The predicate functions for an Action Function are available as properties on the action function object itself, as shown. You can determine if a predicate is supplied by asking:

**if EditMesh.actions.create.isChecked != undefined**

## **Extending Animatable::GetInterface()**

The following have been added to class Animatable:

**virtual FPInterface\* GetInterface(Interface\_ID id);**

Any future object-based interfaces should be allocated unique Interface\_IDs (you can use Gencid.exe for this) and made available through this call.

The default implementation of GetInterface(Interface\_ID) looks up a standalone interface of the given ID on the object's ClassDesc. This gives access to standalone FnPub interfaces via any of a plugin's objects, without having to dig around for the ClassDesc, so you should fall back to calling the default implementation if you don't recognize an ID in your implementation of GetInterface(Interface\_ID).

## **Global Functions related to Function Publishing**

### **Prototype:**

**void RegisterCOREInterface(FPInterface\* fpi);**

### **Remarks:**

This function is available in release 4.0 and later only.

This function registers an interface object. Creating Core interfaces is done in the normal FnPub manner, via public virtual interface headers and implementation interfaces through the FPInterface constructor as above, but by specifying NULL for the ClassDesc pointer. The core interfaces published this way are automatically available in the scripter, with each interface visible as a struct function package of the same name as the internal name of the interface.

### **Parameters:**

**FPInterface\* fpi**

The pointer to the function publishing interface class.

### **Prototype:**

**FPInterface\* GetCOREInterface(Interface\_ID id);**

### **Remarks:**

This function is available in release 4.0 and later only.

This function locates a Core interface object by its unique interface ID.

**Parameters:**

**Interface\_ID id**

The unique interface ID of an interface object.

**Return Value:**

A pointer to the Core interface object associated with the specified interface ID.

**Prototype:**

**int NumCOREInterfaces();**

**Remarks:**

This function is available in release 4.0 and later only.

This function returns the number of available Core interfaces.

**Prototype:**

**FPInterface\* GetCOREInterface(int i);**

**Remarks:**

This function is available in release 4.0 and later only.

This function returns a Core interface object by its index.

**Parameters:**

**int i**

The index of the Core interface object you wish to retrieve.

**Return Value:**

A pointer to the I-th Core interface object.

**Prototype:**

**FPInterface\* GetCOREInterfaceAt(int i);**

**Remarks:**

This function is available in release 4.0 and later only.

This function returns a Core interface object by its index.

**Parameters:**

**int i**

The index of the Core interface object you wish to retrieve.

**Return Value:**

A pointer to the I-th Core interface object.

**Prototype:**

```
FPInterface *GetInterface(SClass_ID super, Class_ID cls,  
Interface_ID id);
```

**Remarks:**

This function is available in release 4.0 and later only.

This function is a global helper function that finds the ID'd interface for the given plugin class and superclass ID's and saves client code from having to dig through the ClassDir to find ClassDesc's.

**Parameters:**

**SClass\_ID super**

The superclass ID of the plugin.

**Class\_ID cls**

The class ID of the plugin.

**Interface\_ID id**

The unique ID of the interface object to retrieve.

**Return Value:**

A pointer to the Core interface object associated with the specified class and superclass ID's.

## Overview

An understanding of the geometric pipeline system is important for developers creating plug-ins that deal with geometry in the scene. This section describes the pipeline system. A pipeline is the system used by 3ds max that allows a node in the scene to be altered, perhaps repeatedly, through the application of modifiers. At the beginning of a pipeline is the **Base Object**. This is a procedural object or just a simple mesh. At the end of a pipeline is the world space state of the object. This world space state is what appears in the 3D viewports and is rendered.

For the system to evaluate the state of the object at the end of the pipeline, it must apply each modification along the way, from beginning to end. As an example, say a user creates a procedural cylinder in the scene, applies a Bend modifier to it, and then applies a Taper modifier to it. As the system evaluates this pipeline, it starts with the state of the cylinder object. As this object state moves along the pipeline, it encounters the Bend modifier. The system asks the Bend modifier to apply its deformation to the object state. The result of this operation is passed as the source into the Taper modifier. The Taper then applies its deformation. The result of this operation is passed to the system which translates the result into world space, and the state of the node in the scene is complete.

To maximize the speed that the system can evaluate the state of a node, the system maintains a **World Space Cache** for each node in the scene. This world space cache is the result of the node's pipeline. It reflects the state of the object in world space after everything has been applied to it. Along with the cache, the system maintains a **Validity Interval**. The validity interval indicates the period of time over which the cache accurately reflects the state of the node.

Whenever a node needs to perform an operation, such as display itself at a certain time, the system checks the validity interval at that time to see if the cache is valid. If it is, the operation is performed using the cached representation. If it is not, the pipeline is evaluated and the cache is made valid at that time. The validity interval is also updated to reflect the new cache. The operation is then performed.

As an additional mechanism to speed up processing, a pipeline is broken up into **Channels**. Channels allow modifiers to only alter certain portions of the object. For example, there is a separate channel for geometry (i.e. the vertices of the object). If a modifier only affects the vertices and nothing else, the system has considerably less work to do than if it had to reevaluate the entire state of the

object including its face structure, UV coordinates, material assignments, etc. For example, the Bend modifier only affects the geometry channel; all the other channels do not require evaluation.

There are separate channels for geometry (vertices), topology (face or polygon structures), texture vertices (UV coordinates), sub-object selection, level of selection, and display control. These separate channels allow the cache system of 3ds max to be more sophisticated. Instead of just caching one global state for the object, it can cache separate portions of it based on the channels.

## Pipeline Details

This section discusses the details of the 3ds max pipeline architecture. The concepts of Base Objects, Derived Objects, and World Space Derived Objects are presented. The ModContext, ModApp, and ObjectState are also explained. The diagram below (Figure 1) shows the simple pipeline of a Cylinder in the scene. Each node in the scene has a reference to an object. In this case the node's object reference points directly to the **Base Object**. It is the flow of these object references that represent the pipeline. In this case it's the flow from the node's object reference to the procedural cylinder object that stores the creation parameters.

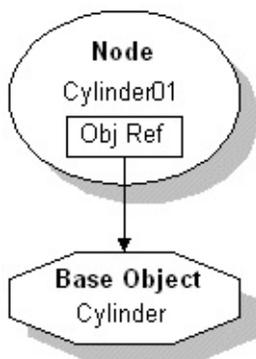

Figure 1.

In 3ds max objects can be instanced. This means that more than one node can point to the same object reference. Figure 2 below shows two pipelines. In this case there is a Cylinder and an instanced copy of it. Note how the object reference of the instanced copy points to the same Base Object as the original. If the creation parameters of the Cylinder are changed, both nodes will change in the scene since they both point at the same Base Object which stores the creation parameters.

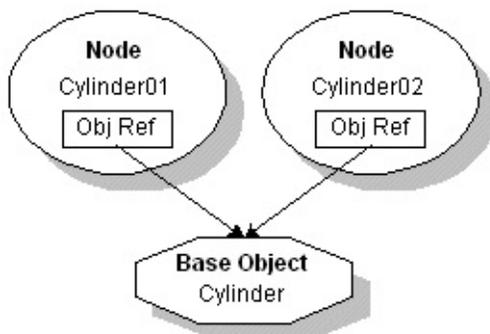

Figure 2.

3ds max supports the application of one or more modifiers to alter the pipeline in

some way. Figure 3 below shows the pipeline resulting from applying a Bend object space modifier to a Cylinder. When a modifier is first applied, a new **Derived Object** is inserted into the node's pipeline.

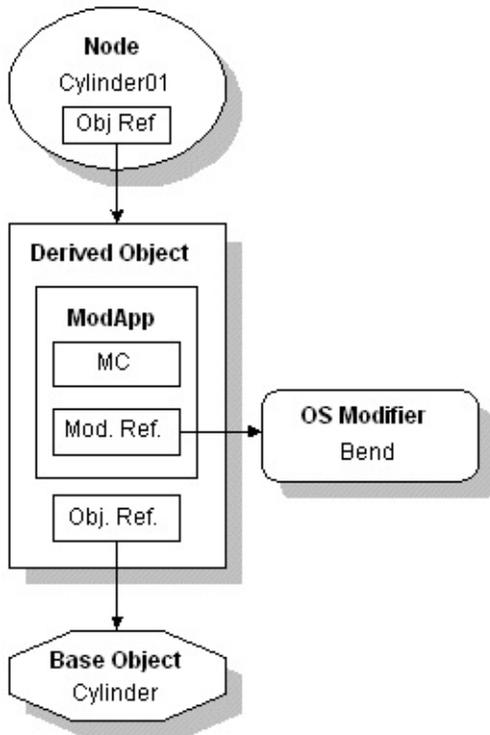

Figure 3.

This arrangement would appear in MAX's modifier stack as follows:

**Bend**

-----

**Cylinder**

This indicates that the Base Object of the pipeline is the Cylinder. The ----- indicates the start of a Derived Object. The Bend is the modifier referenced by this Derived Object.

A Derived Object consists of one or more applications of modifiers followed by a reference to another object. This other object may be a Base Object or another Derived Object. In Figure 3 above, the Derived Object has a single application of a modifier. This application of a modifier is referred to as a **ModApp**. The ModApp primarily consists of a reference to a modifier -- in this case the Bend. Note that the modifier does not sit within the pipeline, but is rather referenced by the ModApp within the pipeline.

In addition to the modifier reference, the ModApp contains an instance of the

class **ModContext**. In Figure 3 and those that follow, the ModContext is represented by a box labeled 'MC'. The ModContext stores information about the space the modifier was applied in, and allows a modifier to store data that it needs for its operation.

Specifically, the ModContext stores three items shown in Figure 4 and described below:

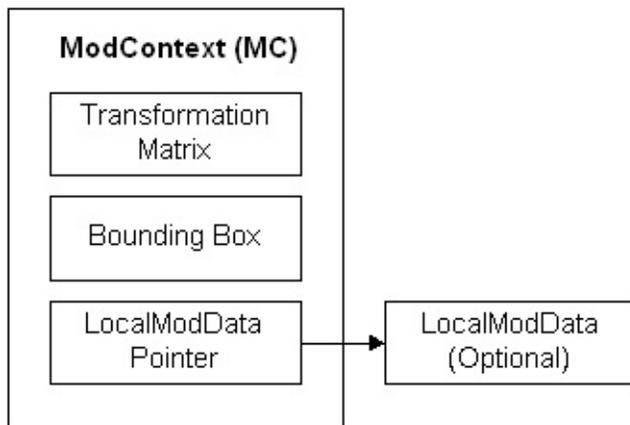

Figure 4.

- The Transformation Matrix. This matrix represents the space the modifier was applied in. The modifier plug-in uses this matrix when it deforms an object. The plug-in modifier first transforms the points with this matrix. Next it applies its own deformation. Then it transforms the points back through the inverse of this transformation matrix.
- The Bounding Box of the Deformation. This represents the scale of the modifier. For a single object it is the bounding box of the object. If the modifier is being applied to a sub-object selection it represents the bounding box of the sub-object selection. If the modifier is being applied to a selection set of objects (and the user interface 'Use Pivot Points' checkbox is off), then this is the bounding box of the entire selection set. For a selection set of objects the bounding box is constant. In the case of a single object, the bounding box is not constant. For example, if the user applies a 90 degree bend to a cylinder, then changes the height of the cylinder, one would want the cylinder to still be bent 90 degrees. If the bounding box did not adapt, the cylinder would appear to move through the bend causing the bend angle to be incorrect.
- A pointer to an instance of a class derived from LocalModData. This is the part of the ModContext that the plug-in developer controls. It is the place where a modifier may store application-specific data. The LocalModData

class has two methods the derived class must implement. One is a Clone procedure so the system can copy a ModContext. The second is a virtual destructor so the derived class can be properly deleted.

More than one modifier may be applied to an object. Figure 5 below shows the previous bent cylinder with an additional Taper modifier applied.

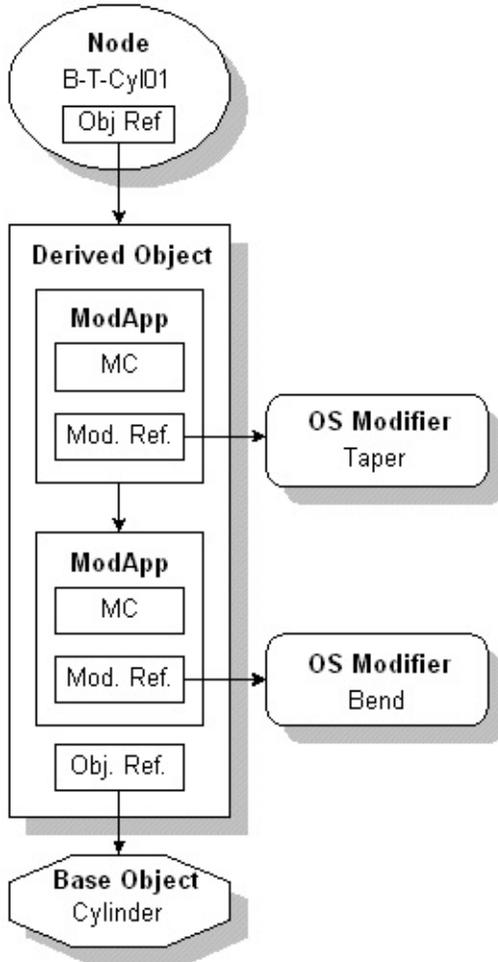

Figure 5.

In this case a new ModApp is inserted into the existing Derived Object. The modifier reference of the new ModApp points to the Taper modifier.

3ds max also allows Reference Copies of items in the scene. Note: the use of the term 'Reference' here is from the 3ds max user interface definition of reference -- not the C++ reference or the 3ds max dependency reference meanings.

When a Reference Copy is made, a new Derived Object is inserted into the item's pipeline. Modifiers applied to the Reference Copy will have their ModApps inserted into the new Derived Object. You can see this graphically illustrated in Figure 6. This diagram shows the result of a bent cylinder being

Reference Copied and having a Taper modifier applied. Note that the object reference of the new Derived Object points to the original Derived Object.

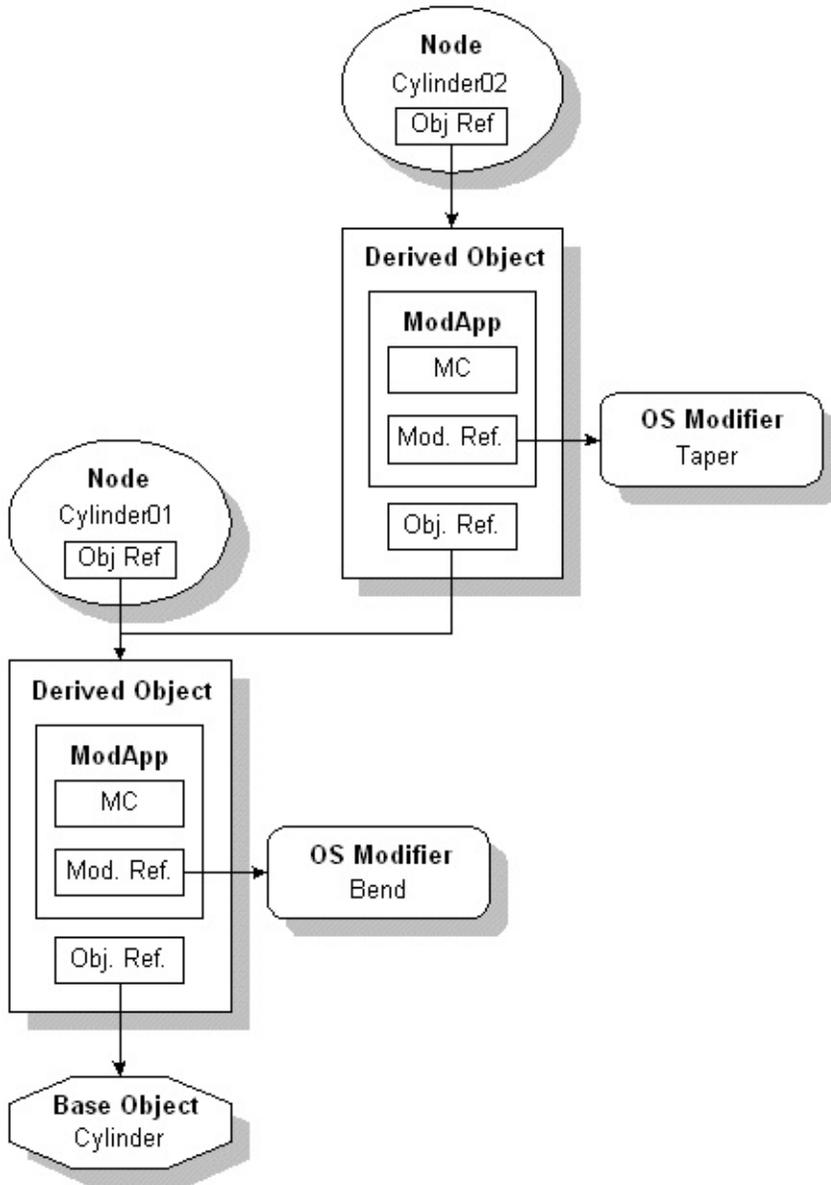

Figure 6.

The modifier stack for Cylinder02 in Figure 6 would appear as:

**Taper**

-----

**Bend**

-----

**Cylinder**

Note the two occurrences of the ----- indicating that two Derived Objects are in use. The original one points to the Bend while the new one points to the Taper.

## Instanced Modifiers

An instance of the **ModApp** class exist in addition to the modifier because the plug-in modifier itself may be instanced (used by several objects). When the user applies a modifier to more than one object, one new instance of the modifier's class is created and shared amongst the objects. Each object that the modifier is applied to gets a new ModApp inserted into its pipeline. These ModApps then reference the same modifier.

In the screen image and diagram below (Figures 7 and 8), the user has selected two independent Cylinders in the scene, checked the 'Use Pivot Points' box, and applied a Bend modifier.

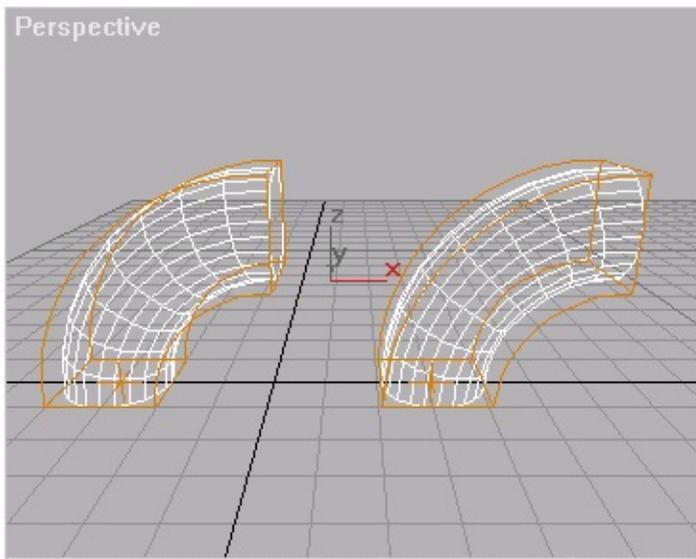

Figure 7.

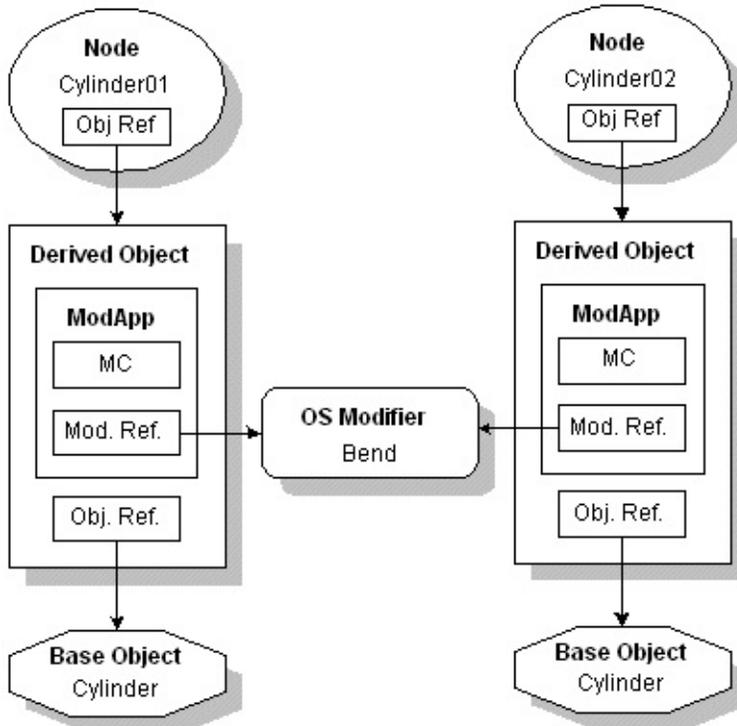

Figure 8.

Note that each cylinder has its own Derived Object. The modifier reference of each ModApp points to the same instanced modifier however. The ModApp also stores the ModContext (labeled 'MC' in the diagrams). One data member of this ModContext is the bounding box of the deformation. Because the 'Use Pivot Points' button was checked at the time the bend was applied, each bounding box stored in the ModContext is the size of each cylinder alone. Additionally, the transformation matrix of each ModContext reflects that the bend is to be applied to each cylinder in its own space. The result is the bend is applied locally and independently to each cylinder.

Contrast this with the following case. In the screen capture of Figure 9 the user applied the Bend modifier to the cylinders as follows: First the independent cylinders were selected. Then the 'Use Pivot Points' button was un-checked. Then the Bend modifier was applied. This means the bend will be applied to the entire selection set as a whole. Note that the cylinders are bent about a common center.

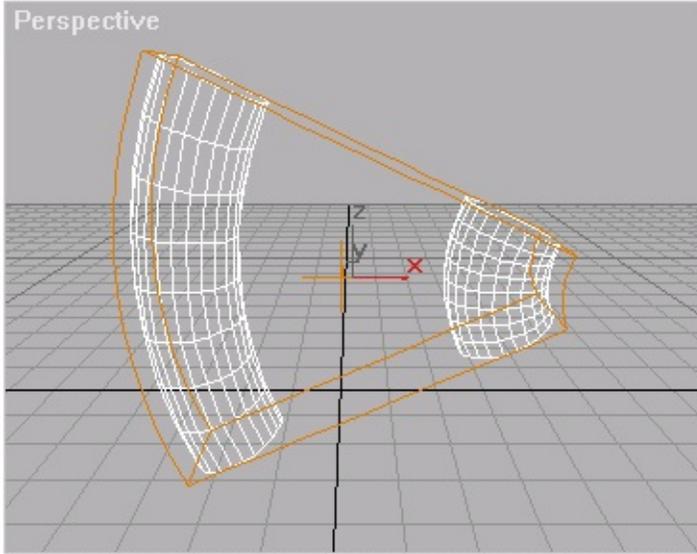

Figure 9.

In this case the bend is applied relative to the bounding box of both cylinders. Thus the bounding box of the ModContexts are the same for each cylinder. Note what happens if one cylinder is moved away from the other in the scene. The Modifier is selected so the gizmo shows the bounding box graphically. The bounding box remains the size of both even when the objects no longer share the same world space relationship.

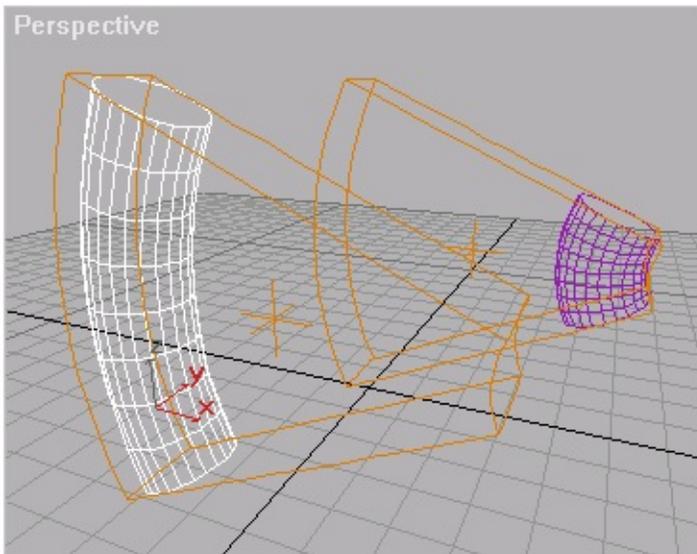

Figure 10.

The separation of the ModApps from the Modifier allow this flexibility. The bounding box stored with the ModContext of the ModApp represents the scale of the application of the modifier. The transformation matrix of the ModContext represents the space the modifier was applied in. The instanced modifier just

uses this information to properly modify each input object.

## Space Warps (World Space Modifiers) in the Pipeline

This section discusses the pipeline of items with World Space Modifiers applied. Below is a diagram of a Cylinder and a Ripple Space Warp before the Cylinder has been bound to the space warp.

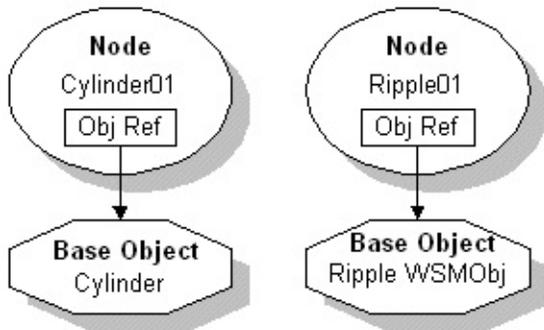

Figure 11.

The following diagram shows the pipeline of the Cylinder after it has been bound to the Ripple Space Warp.

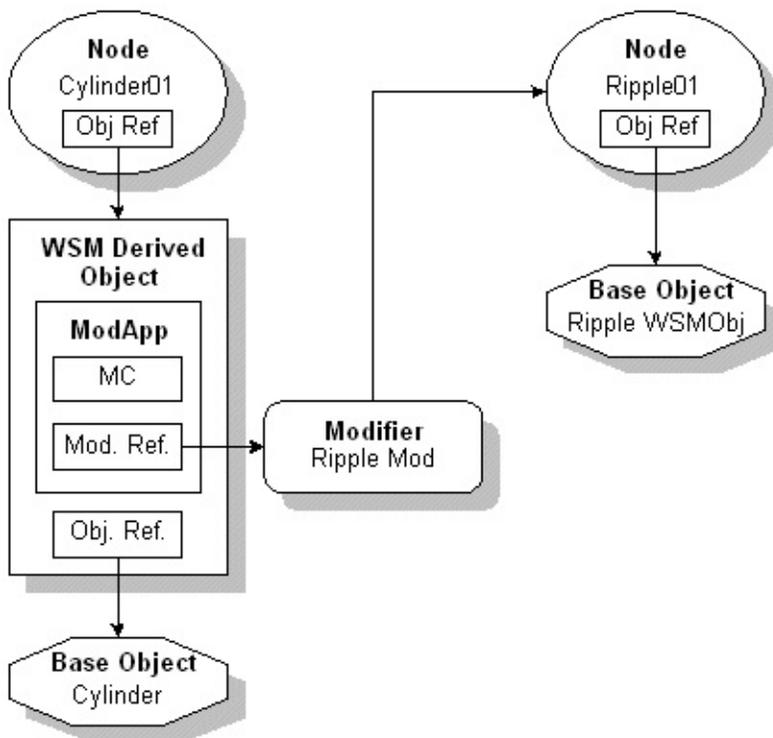

Figure 12.

The modifier stack for this condition would appear as follows:

### **Ripple Binding**

=====

## Cylinder

The Cylinder is the Base Object. The ===== represents the beginning of a WSM Derived Object. The Ripple Binding is the actual application of the world space modifier.

When the Cylinder is bound to the Ripple a new WSM Derived Object is inserted into the Cylinder's pipeline. The WSM Derived Object is similar to the Derived Objects that hold object space modifier ModApps except that these are contained in a specific node (WSM Derived Object is in fact the exact same class as Derived Object except for the **ClassID()**). Since they are associated with a specific node, they cannot be instanced.

The modifier reference of the ModApp points to a newly-created WSM Modifier. This WSM Modifier usually has a references to the node in the scene. In this case it is to the Ripple01 node. This reference is used to retrieve the position of the node (from the node's world space transformation matrix). It uses this matrix to transform the points of the object it is deforming into the space of the WSM object where it actually performs the deformation. For additional information on Space Warp plug-ins see the Advanced Topics section [Space Warp Plug-Ins](#).

## ObjectState Details

The object state is the structure that flows up the pipeline. When the **Object::Eval()** method is called on an object or a derived object, it returns an **ObjectState**. This is passed from one object reference to the next. The **ObjectState** contains these elements:

- A pointer to the object in the pipeline. A modifier will often refer to the object in the pipeline using this pointer. The object pointer is a public data member and is defined as: **Object \*obj;**
- A matrix. If an object cannot convert itself to a deformable type, 3ds max deforms a matrix instead. After the matrix is deformed, it is converted back into an [= 4\) BSPSPopupOnMouseOver\(event\);">orthonormal](#) matrix using an iterative process that 'averages' the axis. All objects are supposed to be able to convert themselves to TriObjects (which are deformable) so in general this is not used. However in the case of cameras and lights it doesn't make sense to convert them to TriObjects so this is how they are deformed. You can see an example of this by binding a camera to a space warp like ripple. The camera will bounce up and down as it is 'deformed' by the space warp.
- Flags for channels that are Boolean type. Developers do not need to be concerned with these flags.
- A material index. This is no longer used.

See [Class ObjectState](#) for details on the methods dealing with the **ObjectState**.

## Developer Access to the Pipeline

This section discusses how a developer can access and work with the results of the pipeline.

There is an API available to retrieve the result of a node's pipeline. This is **INode::EvalWorldState()**.

**Prototype:**

```
virtual const ObjectState& EvalWorldState(TimeValue  
time,BOOL evalHidden=TRUE)=0;
```

This returns the result of the node's pipeline just as it appears in the scene. This may not return an object that a developer has a reference to -- it may just be an object that has flowed down the pipeline. For example, if there is a Cylinder in the scene that has a Bend and Taper applied, **EvalWorldState()** would return an ObjectState containing a **TriObject**. This is the result of the cylinder turning into a **TriObject** and being bent and tapered. See [Class INode](#).

If a developer needs to access the object that the node in the scene references, then the method **INode::GetObjectRef()** should be used instead. See [INode - Object Reference Methods](#).

Class **IDerivedObject** also allows a developer to create derived objects and add and delete modifiers. To access the pipeline of a node in the scene first retrieve the object reference using **INode::GetObjectRef()**. Given this **Object** pointer check its SuperClassID to see if it is **GEN\_DERIVOB\_CLASS\_ID**. If it is, you can cast it to an **IDerivedObject**. See [Class IDerivedObject](#) for more details.

## Channel Details

Channels allow modifiers to only alter certain portions of the object. The pipeline is divided into the following channels:

### [List of Channel Bits](#)

Modifiers have the option of only modifying specific channels. The main purpose of this is to allow MAX's caching system to be more sophisticated. Individual caches can be constructed for different channels at different points along the pipeline. So for example, if the texture coordinate portion of the pipeline changes, and the geometric portion of the pipeline is cached, the geometry portion won't need to be reevaluated. This means that modifiers that only depend on geometry may not need to be reevaluated.

It is up to the object to define the meaning of the channels. Take the **TOPO\_CHANNEL** for example. For a **TriObject** the topology is the face structure, the materials, and the smoothing information. For a **SplineShape** the topology is undefined. This is because a **SplineShape** is essentially just an array of points and has no topology.

## Data Flow in the Pipeline - An Example

This section presents a detailed look at the flow of the pipeline from the Base Object to the resulting World Space Cache. This includes the derived objects of the object space portion of the pipeline, the application of the node's transform controller, and through the world space portion of the pipeline.

Figure 13 below is a diagram showing a procedural Cylinder with a Bend modifier applied, and bound to a Ripple space warp.

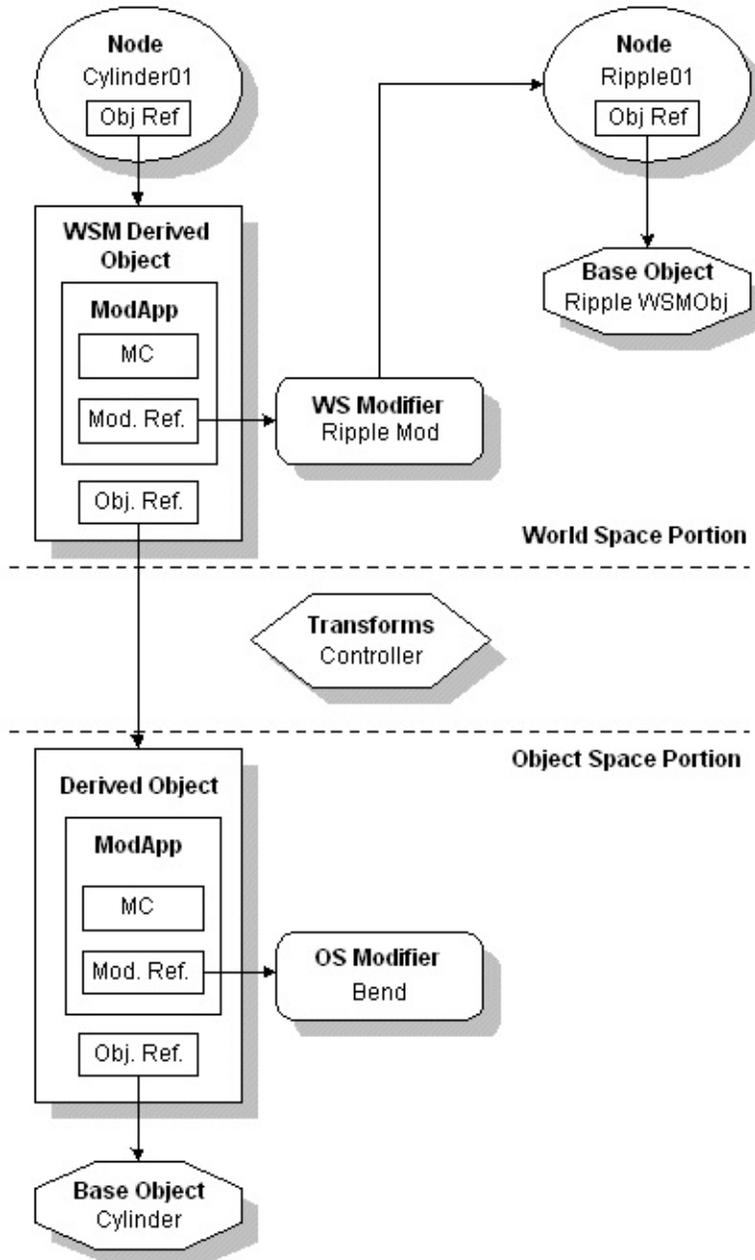

Figure 13.

The data flow in the pipeline follows the Object References. In the example above, the Cylinder01 Node has an Object Reference pointing to the WSM Derived Object. Its Object Reference points to the Derived Object. Its Object Reference points to the Cylinder Base Object. This is the path the data follows as it moves along the pipeline.

The actual object that flows between these references is an ObjectState. This ObjectState is the result of the **Object::Eval()** method being called on the Object Reference. Below is a description of the flow of this ObjectState along the pipeline starting at the procedural cylinder base object.

This pipeline starts at the Base Object -- the procedural Cylinder. The system asks the cylinder to evaluate itself. In the cylinder's implementation of **Object::Eval()**, it simply returns itself ( **return ObjectState(this);** ). It returns this ObjectState to the next Object Reference in the pipeline. This is the Object Reference of the Derived Object.

The Derived Object sends this ObjectState through each of its ModApps. In this example, the only ModApp is for the Bend Modifier. The Bend requires Deformable objects (it indicates this in its implementation of **Modifier::InputType()**). The ModApp handles converting the object to the appropriate type for the Modifier. The cylinder is asked to convert itself to a Deformable object. It does this in its implementation of **Object::ConvertToType()** by creating a new TriObject and setting the TriObject's mesh pointer to point at the cylinder's triangle mesh.

This Deformable TriObject is then sent through the Bend Modifier. The Bend is passed the ModApp's ModContext as an argument to its **Modifier::ModifyObject()** method. The Bend first modifies the points of the TriObject using the transformation matrix of the ModContext. This puts the object into the space the modifier was applied in. Next the Bend applies its deformation to the points (it bends them). Then the Bend modifies the points of the TriObject by the inverse of the ModContext transformation matrix. This restores the object, excepting it now has the bend effect applied.

At this point, the Derived Object returns the result to the next Object Reference in the pipeline. In this case the result is a TriObject that has been bent. It is returned to the Object Reference of a World Space Derived Object.

This juncture between the Derived Object and the World Space Modifier Derived Object is where the pipeline crosses from object space to world space. At this point the result of the node's transform controller, and the object offset

transformation are put into the pipeline. For more details on these various TMs see the Advanced Topics section on [Node and Object Offset Transformations](#).

To understand how the node's transform controller and the object offset transformation are put into the ObjectState we need to take a look at the ObjectState TM. There is a TM that is part of the ObjectState that flows up the pipeline. This TM starts as the identity matrix. The first thing that happens is this TM goes through the object space pipeline. At this time, any modifiers that need to be applied to it are applied. In most cases no modifiers are applied. However, if the object flowing through the pipeline is Deformable but has no points to deform (such as a camera), then modifiers acting on Deformables may be applied to it. This is because cameras are deformable, but don't have 'points' to deform (i.e. there is no 'mesh' associated with a camera). Since there are no points, this matrix is deformed instead.

At the end of the object space portion of the pipeline, out comes the ObjectState and its TM. Usually this TM is the identity, but at times (like with the camera) it is not.

Now the node's transform controller TM must be taken into account. The transform controller's TM is the result of taking the node's parent's TM, and passing it into the transform controller's **Control::GetValue()** method. The controller applies its relative effect to this matrix, and the result is the Node TM. To the Node TM, the object offset transformation is applied. This result is then multiplied by the ObjectState TM that resulted from the object space portion of the pipeline. This resulting matrix is then stored back in the ObjectState TM. Note that this TM is not applied to the object yet -- it is only carried by the ObjectState.

At this point we have the node's transform controller and the object offset transformation stored in the ObjectState TM.

Now comes the world space portion of the pipeline and the world space modifiers -- we've reached the first ModApp of the WSM Derived Object. The first World Space Modifier transforms the object's points by this ObjectState TM. It does this because it does its deformation in world space, and applying the ObjectState TM puts the object into world space. This happens automatically for deformables. If the TM does not get applied to the object (for example for a camera) the TM will continue to get deformed by the world space modifiers. As soon as this TM is applied to the object points, the TM gets set to the identity matrix. At this time, the points of the object have been transformed into world

space.

Next the ObjectState is passed to the Ripple Modifier for it to apply its effect. The Ripple modifier has a reference to the Ripple Object Node in the scene. It uses this reference to get the Object TM of the Ripple Node. It needs this because this is the space it is going to apply the ripple effect in. The Ripple Modifier also uses its reference to the Ripple Node to get the parameters of the Ripple WSM Object.

The Ripple Modifier uses this data, and applies its ripple affect. The result at this point is a TriObject with the Bend and Ripple applied. This ObjectState is returned to the next Object Reference in the pipeline. This is the Object Reference of the node in the scene.

The node maintains an ObjectState that is effectively the world space cache. This world space cache is the storage for the result of the pipeline. Associated with this cache is a validity interval. When the system needs the result of a node's pipeline, it checks to see if the validity interval of the cache is valid. If it is, the cached representation is used. If it is not, the pipeline is evaluated and the cache is made valid. The validity interval is updated, and the cached ObjectState is returned.

## The Pipeline and the INode TM Methods

This section discusses the INode methods **GetObjectTM()**, **GetObjTMBeforeWSM()** and **GetObjTMAfterWSM()** and their relationship to the pipeline.

The **INode::GetObjectTM()** method returns a matrix that is used to transform the points of the object from object space to world space. Let's look at an example of how this method is used. Consider how the cylinder node is drawn in the scene. The cylinder draws itself in its **BaseObject::Display()** method. Into this method is passed an INode pointer. What the implementation of **Display()** does is call **INode::GetObjectTM()**. This method returns the matrix that is used to transform the points of the object from object space to world space. The **Display()** method then takes the matrix returned from **GetObjectTM()** and sets it into the graphics window (using **GraphicsWindow::setTransform()**). In this way, when the object starts drawing points in object space, they will be transformed with this matrix. This puts them into world space as they are drawn.

Below is the code from the **SimpleObject** implementation of **BaseObject::Display()**. This is the code that the cylinder uses to draw itself. Note the **GetObjectTM(t)** and **setTransform(mat)** calls.

```
int SimpleObject::Display(TimeValue t, INode* inode,
    ViewExp *vpt, int flags)
{
    if (!OKtoDisplay(t)) return 0;
    GraphicsWindow *gw = vpt->getGW();
    Matrix3 mat = inode->GetObjectTM(t);
    UpdateMesh(t); // UpdateMesh just calls BuildMesh() if req'd at
    time t.
    gw->setTransform(mat);
    mesh.render(gw, inode->Mtls(),
        (flags&USE_DAMAGE_RECT) ? &vpt->GetDammageRect() :
    NULL,
        COMP_ALL, inode->NumMtls());
    return(0);
}
```

There is a case when world space modifiers are applied to an object where the points of the object may have already been transformed into world space. If a world space modifier has been applied, the points of the object may have already been transformed into world space and then deformed by the world space modifier. With the bent, rippled, cylinder example above, this is exactly what has happened. When the ripple space warp was applied, the points of the object were transformed into world space. In this case, the points should not be transformed into world space again when they are drawn (since they were already by the space warp). The problem is, the object does not know if it has been transformed into world space or not.

The way 3ds max handles this situation is by storing some state information with the node. Before the system calls **Display()**, **HitTest()**, etc. on the object it sets a flag. The flag indicates if the object has already been transformed into world space. The **GetObjectTM()** method looks at this flag to determine the proper matrix to return. In this way, when **GetObjectTM()** is called, it returns the matrix the object needs to be multiplied by in order to get into world space. If the object is already in world space it will return the identity matrix. If it's not in world space, it will return the matrix to get it there. So all any objects need to do in their **Display()** methods is call **GetObjectTM()** and use whatever matrix is returned.

There may be times when a developer needs to access the full object TM regardless of whether the points of the object have been transformed into world space already. For example, if a developer was creating a utility plug-in to align two objects. In this case, the developer would need to get the full object TM including the NodeTM and the object offset transformation. It would not matter if the points of the object had already been transformed into world space, the TM is what matters. In this case **GetObjectTM()** would not work. This is because it returns the identity matrix if the object is already in world space.

To solve this problem 3ds max provides two other **Inode** methods that may be used.

### **GetObjTMBeforeWSM()**

This method explicitly gets the full NodeTM and object-offset transformation affect before the affect of any world space modifiers.

### **GetObjTMAfterWSM()**

This method explicitly gets the full NodeTM and object-offset transformation and world space modifier affect unless the points of the object have already

been transformed into world space in which case it will return the identity matrix.

Using these methods a developer has complete access to any transformation matrix they require. Below is a code example that uses all these methods. This function computes the bounding box of the first object in the current selection set at the current time. It removes anything but scaling from the Object TM. In this way rotation of the node will not affect the bounding box.

To do this we first need to determine if the object is in world space or in object space. Since we are after the object space bounding box (and will later apply scaling) we need to convert the TM back into object space if it is in world space. To check if the object is in world space we call **GetObjTMAfterWSM()**. If this matrix is the identity we know we are in world space. This is because when the points of the object get transformed by the ObjectState TM to put them into world space the ObjectState TM is set to the identity. Therefore if the matrix is the identity we are in world space.

If the object is in world space we need to compute the object space TM. We can do this by taking the inverse of the world space TM.

If the object is not in world space we just need to get its object TM by calling **GetObjectTM()**.

Once we have the object space TM we want to extract just the scaling portion of the matrix. 3ds max provides a set of APIs that make this easy. This is done by calling **decomp\_affine()**. This function decomposes a matrix into its translation, rotation and scaling components. See [Structure AffineParts](#) for more details.

Once we have the scaling portion of the matrix we can get the bounding box and apply the scaling by calling **GetDeformBBox()**.

```
void Utility::ComputeBBox(Interface *ip) {  
    if (ip->GetSelNodeCount()) {  
        INode *node = ip->GetSelNode(0);  
        Box3 box; // The computed box  
        Matrix3 mat; // The Object TM  
        Matrix3 sclMat(1); // This will be used to apply the scaling  
        // Get the result of the pipeline at the current time  
        TimeValue t = ip->GetTime();  
        Object *obj = node->EvalWorldState(t).obj;
```

```

// Determine if the object is in world space or object space
// so we can get the correct TM. We can check this by getting
// the Object TM after the world space modifiers have been
// applied. If the matrix returned is the identity matrix the
// points of the object have been transformed into world space.
if (node->GetObjTMAfterWSM(t).IsIdentity()) {
    // It's in world space, so put it back into object
    // space. We can do this by computing the inverse
    // of the matrix returned before any world space
    // modifiers were applied.
    mat = Inverse(node->GetObjTMBeforeWSM(t));
}
else {
    // It's in object space, get the Object TM.
    mat = node->GetObjectTM(t);
}
// Extract just the scaling part from the TM
AffineParts parts;
decomp_affine(mat, &parts);
ApplyScaling(sclMat, ScaleValue(parts.k*parts.f, parts.u));
// Get the bound box, and affect it by just
// the scaling portion
obj->GetDeformBBox(t, box, &sclMat);
// Show the size and frame number
float sx = box.pmax.x-box.pmin.x;
float sy = box.pmax.y-box.pmin.y;
float sz = box.pmax.z-box.pmin.z;
TSTR title;
title.printf(_T("Result at frame %d"),
    t/GetTicksPerFrame());
TSTR buf;
buf.printf(_T("The size is: (%.1f, %.1f, %.1f)"), sx, sy, sz);
MessageBox(NULL, buf, title,
    MB_ICONINFORMATION|MB_OK);

```

}  
}

## A Note About Caching

The full details of the 3ds max pipeline cache system are beyond what a developer needs to understand to effectively work with the pipeline. There is however one detail that may be useful for a Modifier that is being adjusted interactively.

While a modifier is being edited, in its implementation of **LocalValidity()**, it can return **NEVER**. This forces a cache to be built after the previous modifier. For example, the **SimpleMod** class does this. The pipeline will try to put a cache after something that is relatively constant but before something that is changing a lot. If a modifier for its local validity starts returning **NEVER**, this will cause a cache to be created before it. This is useful if a modifier is being edited interactively. In this way, the system does not have to evaluate the whole pipeline. This can considerably improve the interactivity.

After the modifier is done being edited, if the modifier is not animated, there is no need to have a cache before it. Therefore after the modifier is done being edited, it can stop returning **NEVER** for **LocalValidity()**. Below is a code fragment from the **SimpleMod** implementation of **LocalValidity()** where this is being done:

```
Interval SimpleMod::LocalValidity(TimeValue t)  
{  
    // If we are being edited, return NEVER to forces a cache to  
    // be built after previous modifier.  
    if (TestAFlag(A_MOD_BEING_EDITED))  
        return NEVER;  
    ...  
}
```

## **Modifier Stack Branching**

Compound objects such as the boolean object and the lofter can actually cause the pipeline to branch. See the advanced topics section on [Modifier Stack Branching](#) for the details on the methods a compound object uses to implement branching in the pipeline.

## Objects Flowing through the Pipeline

Certain plug-in objects flow through the pipeline. Examples are both the **TriObject** and the **PatchObject**. Most plug-ins do not however because they convert themselves to **TriObjects** or **PatchObjects** and these objects flow through the pipeline. For developers creating objects that flow through the pipeline there are some pipeline concepts and specific methods that must be understood. These are discussed in this section.

Most of these methods relate to minimizing the amount of overhead present within the system when the object is flowing through the pipeline. To be as efficient as possible the system will try not to create any extra copies of the object flowing down the pipeline. Additionally, the object is broken into channels and the individual channel copying is kept to a minimum.

To accomplish this, the system uses a set of 'locks' that indicate when it is not okay to free memory or modify the objects. The object lock and channel lock methods are implemented and called by the system. The plug-in developer implements methods to maintain validity intervals for the channels, create new copies of channels as needed, and free the memory associated with channels that are no longer needed. Again, the main purpose of this is to minimize the overhead of the object flowing down the pipeline.

Every object has what is referred to as its "shell". The shell has channels within it. Example channels are the geometry channel named **GEOM\_CHANNEL** (typically an array of vertices) or the topology channel named **TOPO\_CHANNEL** (typically an array of faces). Some channels are always present in the shell. For example the **SUBSEL\_TYPE\_CHANNEL**, **SELECT\_CHANNEL** and **DISP\_ATTRIB\_CHANNEL** state channel are each just a single value. These are not allocated or de-allocated dynamically, and are always present. Other channels like the **GEOM\_CHANNEL**, **TOPO\_CHANNEL**, and **TEXMAP\_CHANNEL** are allocated dynamically so the system tries to not have extra copies of them when possible. The following methods from class **Object** deal with the state of the shell. These methods are implemented and called by the system.

### **void LockObject()**

This method locks the object as a whole.

### **void UnlockObject()**

This method unlocks the object as a whole.

## **int IsObjectLocked()**

Returns nonzero if the object is locked; otherwise 0.

If the shell is locked then it should not be deleted by the pipeline. For example, a sphere in the pipeline will be locked. This is because it exists in the scene and thus should not be deleted. If a bend modifier was applied to the sphere, then the sphere would convert itself to a TriObject. This TriObject is flowing down the pipeline and is just a temporary object. This object will be unlocked meaning that it may be deleted. This is true unless a ModApp decides to cache it. In this case it will become locked because the ModApp has taken ownership of it and therefore it should not be deleted. Note that these methods are implemented and called by the system and not the plug-in object. They simply manipulate a private data member inside the **Object** class.

There is a related topic to discuss -- channel locking. This is not the locking of the object as a whole (as described above) but rather the locking of only certain channels within the object. For example, a ModApp may have the geometry channel cached (say it has an array of vertices cached somewhere in the pipeline). When the system is evaluating this pipeline, if it notices a certain channel it requires is cached, instead of evaluating the rest of the pipeline, it will use the cache. It will do what is called a **shallow copy** of the cached channel into the object going down the pipeline. This is just copying the pointer to the cached channel into the object flowing down the pipeline. So essentially there are two TriObjects whose geometry channels are both pointing to the same array of vertices. This reduces the memory overhead required because instead of copying the whole array of vertices there are essentially two meshes that are sharing the same block of memory. Again this is referred to as a shallow copy. The system (MAX) takes care of all of this. It carefully keeps track of who owns what so things don't get deleted twice or get deleted when still being used.

The channel lock methods below deal with this system. These methods are implemented and called by the system and not the plug-in object. They simply manipulate a private data member inside the **Object** class.

## **void LockChannels(ChannelMask channels)**

Locks the specified channels of the object.

## **void UnlockChannels(ChannelMask channels)**

Unlocks the specified channels of the object.

## **ChannelMask GetChannelLocks()**

Returns the locked status of the channels.

### **void SetChannelLocks(ChannelMask channels)**

Sets the locked status of the object's channels.

### **ChannelMask GetChannelLocks(ChannelMask m)**

Returns the locked status of the specified channels.

If a channel is locked, this means that the object does **not** own the channel and it should not free it. If the channel is unlocked, this means the object does own it, and it may free it. A channel that is locked should also not be modified. For example, if a channel that was cached upstream in the pipeline was modified, the cached version would not be correct anymore. The locking of the cached channel prevents this modification from happening.

The **ChannelMask** that appears in the above methods is an unsigned long. Each channel is represented by a bit. Note: Developers must not get confused between channel numbers (**TOPO\_CHAN\_NUM**, **GEOM\_CHAN\_NUM**, etc.) and channel bits (**TOPO\_CHANNEL**, **GEOM\_CHANNEL**, etc.). Some methods refer to the channel by number and some by bit. Developers must not confuse these two as the compiler will not catch this as an error.

The meaning of the channels are defined by the object. The three main channels (those that get allocated dynamically) are the **GEOM\_CHANNEL**, **TOPO\_CHANNEL**, and the **TEXMAP\_CHANNEL**. The other channels are always present. The developer must determine what part of their object falls into the **GEOM\_CHANNEL**, **TOPO\_CHANNEL**, and the **TEXMAP\_CHANNEL**. The TriObject defines the **GEOM\_CHANNEL** to mean the points or vertices of the mesh. The TriObject defines the **TOPO\_CHANNEL** to mean the face or polygon structures. This includes the smoothing groups and materials as well.

It is up to the object flowing down the pipeline to store validity intervals for each channel. Consider a sphere object with an animated radius parameter. The validity interval for the geometry channel for this sphere will be instantaneous (valid for a single **TimeValue**). This is because the radius is animated and is thus always changing. However the topology channel of the sphere is never changing. Therefore the validity interval for the topology channels will be **FOREVER**. See the Advanced Topics section on [Intervals](#) for more details. The methods below are implemented by the developer of the plug-in object unless noted otherwise.

### **virtual Interval ChannelValidity(TimeValue t, int nchan);**

Retrieve the current validity interval for the nchan channel of the object.

**virtual void SetChannelValidity(int nchan, Interval v);**

Sets the validity interval of the specified channel.

**void UpdateValidity(int nchan, Interval v);**

Implemented by the system. This method is called to AND in interval **v** to the specified channel validity.

**virtual void InvalidateChannels(ChannelMask channels);**

This method invalidates the intervals for the given channel mask. This just sets the validity intervals to empty (calling **SetEmpty()** on the interval) .

At certain times the system must ask the plug-in object to prepare certain channels for modification. For example, if a channel is cached upstream in the pipeline, and was modified, the cached version would be modified as well (since they both point to the same memory). This would confuse the system and thus locked channels must not be modified. If the system needs to modify one of the channels it will call the following method implemented by the system.

**void ReadyChannelsForMod(ChannelMask channels);**

This method is used to make the channels specified by the channel mask writable.

As mentioned above, a channel that is locked should not be modified. This method will take the channels that are locked and allocate a new block of memory for them. It will then copy the locked channels into the new block of memory and set the new memory as the current channel. Then it will unlock the channel. It does this by calling **NewAndCopyChannels()** which is implemented by the plug-in and is described below. In this way the system can modify the channels and not affect the cached copy as they no longer point to the same memory.

The following methods also deal with the allocation and copying of object channels. These methods are implemented by the plug-in.

**virtual Object \*MakeShallowCopy(ChannelMask channels);**

This method creates a new shell and then shallow copies in the channels that are specified.

**virtual void ShallowCopy(Object\* fromOb, ChannelMask channels);**

This method is passed the shell, and it copies the specified channels into it.

The shallow copy just copies the pointers (for example, the vertices pointer or

the faces pointer).

**virtual void NewAndCopyChannels(ChannelMask channels);**

This method takes the channels specified and clones them, and makes them read only (by locking them).

**virtual void FreeChannels(ChannelMask channels);**

This method deletes the memory associated with the specified channels and set the intervals associated with the channels to invalid (empty).

The following method is related to caching and shallow copying. This method is only implemented by particle systems. Particle systems bypass a lot of how the pipeline works and so they implement this method to ensure that they are never cached. Particle systems handle their own caching mechanism. All objects other than particle system can use the default implementation which returns TRUE. Particles can override this and return FALSE.

**virtual BOOL CanCacheObject() {return TRUE;}**

Developers that have an object that flows down the pipeline may want to take a look at the source code for the **TriObject** which provides implementations of all the methods discussed above. This code is available in **\MAXSDK\SAMPLES\HOWTO\MISC\TRIOBJECT.CPP**.

## Getting and Setting User Preferences

See Also: [Class Interface](#), [Class ViewExp](#), [Class Point3](#).

## **Overview**

This section provides an overview of the global functions, classes and methods used to retrieve and set the user preferences of MAX. Many of these are from the various pages of the Customize / Preferences... dialog.

## User Interface Colors

A 3ds max user may set various colors in the user interface via the settings in the Customize... Preferences... Color tab dialog. A developer may access and set these settings using the following global functions:

### Prototype:

**Point3 GetUIColor(int which);**

### Remarks:

This function is available in release 2.0 and later only.

Returns the specified color value for drawing various items in the 3ds max viewports.

### Parameters:

**int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

### Prototype:

**void SetUIColor(int which, Point3 \*clr);**

### Remarks:

This function is available in release 2.0 and later only.

Sets the specified color value for drawing various items in the 3ds max viewports.

### Parameters:

**int which,**

Specifies which color to set. See [List of Viewport Drawing Color Indices](#).

**Point3 \*clr**

The color value to set.

### Prototype:

**Point3 GetDefaultUIColor(int which);**

### Remarks:

This function is available in release 2.0 and later only.

Returns the default color used for drawing various items in the 3ds max user interface. The values returned are not affected by the user's color selections or

those set by **SetUIColor()**.

**Parameters:**

**int which**

Specifies which color to retrieve. See [List of Viewport Drawing Color Indices](#).

Note the following #defines for getting the selection color, sub-object selection color and the frozen object color.

```
#define GetSelColor() GetUIColor(COLOR_SELECTION)
```

```
#define GetSubSelColor()
```

```
GetUIColor(COLOR_SUBSELECTION)
```

```
#define GetFreezeColor() GetUIColor(COLOR_FREEZE)
```

```
#define SMALL_VERTEX_DOTS 0
```

```
#define LARGE_VERTEX_DOTS 1
```

**Function:**

```
void setUseVertexDots(int b);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the Use Vertex Dots preference to on or off. This corresponds to the 'Show Vertices As Dots' in the 3ds max user interface.

**Parameters:**

**int b**

Nonzero for on; zero for off.

**Function:**

```
int getUseVertexDots();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the Use Vertex Dots preference -- nonzero for on; zero for off.

**Function:**

**void setVertexDotType(int t);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the Vertex Small Dots / Large Dots preference. This corresponds to the 'Show Vertices As Dots' Small Dots / Large Dots radio buttons in the 3ds max user interface.

**Parameters:**

**int t**

One of the following values:

**SMALL\_VERTEX\_DOTS**

**LARGE\_VERTEX\_DOTS**

**Function:**

**int getVertexDotType();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the Vertex Small Dots / Large Dots preference. One of the following values:

**SMALL\_VERTEX\_DOTS**

**LARGE\_VERTEX\_DOTS**

## **Access to the MAX Viewport settings:**

Access to the user settings includes the 3ds max toolbars, snap settings, crossing setting, animate button, 3ds max window handle, sub-object selection color, axis constraints, coordinate centers, and reference coordinate system setting.

See Class Interface - Access to User Interface Properties and Controls. The above settings and more are accessed using these methods.

Some of the viewport settings are global in nature -- that is they affect all the viewports. These methods are in class **Interface**. Examples are **getBkgImageName()**, **GetGridSpacing()**, etc.

Other viewport settings are specific to a viewport. These are available in class **ViewExp**. Examples are **getBkgImageDsp()**, **getSFDisplay()**, etc.

## **Access to the MAX gamma settings:**

The [Class GammaMgr](#) allows access to the user specified gamma settings for display gamma, file input and output gamma.

## System Settings

There is also another API that allows a plug-in to query various system settings.

### **int GetSystemSetting(int id);**

This method will return nonzero if the setting whose **id** is passed is on; otherwise zero.

You may pass the following values:

#### **SYSSET\_ENABLE\_EDITABLEMESH**

Used to verify if TriObjects created will be the standard ones or the editable variety. Nonzero is returned if editable meshes will be created; otherwise zero for standard TriObjects.

#### **SYSSET\_CLEAR\_UNDO**

For release 1.1 and later if this ID is passed to this method the undo buffer is flushed.

#### **SYSSET\_EDITABLEMESH\_ENABLE\_KEYBOARD\_ACCEL**

This option is available in release 2.0 and later only.

Determines if keyboard accelerators are enabled for the editable mesh. Nonzero if so; otherwise zero.

#### **SYSSET\_ENABLE\_EDITMESHMOD**

This option is available in release 2.0 and later only.

Determines if the edit mesh modifier is enabled. Nonzero if so; otherwise zero.

# Globalization

See Also: [Character Strings](#).

3D Studio is sold in numerous countries outside the United States. To allow your plug-in to have the largest possible audience, it is a good practice to create a globalized application. This means the language-specific strings used in the plug-in can be easily translated to another language.

To accomplish this, you should separate out all your language specific strings into a separate resource-only DLL. In this way, only the resource DLL, and not the rest of the code, needs to be changed to move the application to another language.

The basic concepts involved in creating and using a resource-only DLL are simple:

- Create a VC++ project that builds a separate DLL containing only the resources of the plug-in.

- When your plug-in begins execution, in the **DllMain()** function, attempt to load the resource DLL. This is done by calling a function of the Windows API **LoadLibraryEx()**. This maps the specified executable module into the address space of the calling process, making the strings accessible to the plug-in.

- After the resource DLL has been loaded and you need to use a string, use the Windows function **LoadString()**. This loads the string from the resource DLL and copies it into a local string buffer. The local string is then used as usual.

- Release the resource DLL when the plug-in is finished executing. This may be done using the Windows **FreeLibrary()** function. Call this from the **DLL\_PROCESS\_DETACH** case of the **DllMain()** function. This decrements the reference count of the loaded DLL module. When the reference count reaches zero, the module is unmapped from the address space of the calling process.

The sample code below demonstrates how this is done. It shows two functions from the EPS file format I/O module.

The first function is **DLLMain()**. Note the use of **LoadLibraryEx()** and **FreeLibrary()**. Also see how **GetModuleFileName()** is used to find the location of the DLL (placed in the same directory as the plug-in). For details on

these functions see the Windows API on-line help.

```
#define MAX_PATH_LENGTH 257
#define MAX_STRING_LENGTH 256
int triedToLoad = FALSE;
int resourcesLoaded = FALSE;
HINSTANCE hResource = NULL;
BOOL WINAPI DllMain(HINSTANCE hinstDLL,
    ULONG fdwReason,LPVOID lpvReserved)
{
// If we have already tried to load the resource
// file and failed just give up.
if (triedToLoad && ! resourcesLoaded)
return FALSE;
// Load our resources. We look for the file in the
// same directory where this DLL was found
if (! resourcesLoaded) {
// Where this DLL resides
char dirName[MAX_PATH_LENGTH];
// Full path name to resource DLL
char dllName[MAX_PATH_LENGTH];
char *chPtr;
GetModuleFileName (hinstDLL, dirName,
MAX_PATH_LENGTH);
// Strip off the file name
chPtr = dirName + strlen (dirName);
while (*(--chPtr) != '\\')
;
*(chPtr+1) = 0;
// Add in "epsres.dll"
strcpy (dllName, dirName);
strcat (dllName, "epsres.dll");
// Load resource DLL
// Turn off error reporting
int errorMode =
```

```

SetErrorMode(SEM_NOOPENFILEERRORBOX);
hResource = LoadLibraryEx(dllName, NULL, 0);
SetErrorMode(errorMode);
// Be sure to check to see if we succeeded
// loading resource DLL
if (hResource) {
resourcesLoaded = TRUE;
InitCustomControls (hResource);
} else {
triedToLoad = TRUE;
MessageBox (NULL,
"EPS Plugin failed to load due to missing resource file
EPSRES.DLL",
"EPS", MB_ICONINFORMATION);
return FALSE;
}
}
switch(fdwReason) {
case DLL_PROCESS_ATTACH:
break;
case DLL_THREAD_ATTACH:
break;
case DLL_THREAD_DETACH:
break;
case DLL_PROCESS_DETACH:
if (hResource)
FreeLibrary (hResource);
break;
}
return(TRUE);
}

```

To load and use one of the strings from the resource DLL, follow the approach shown below:

```

const TCHAR *EPSClassDesc::ClassName () {

```

```
static int loaded = 0;
static TCHAR stringBuffer[MAX_STRING_LENGTH];
if (! loaded) {
LoadString (hResource, IDS_CLASS_NAME, stringBuffer,
MAX_STRING_LENGTH);
loaded = 1;
}
return stringBuffer;
}
```

In summary, it is a good development practice to separate the literal strings of a plug-in into a separate resource-only DLL. This creates a globalized application with the potential to reach the largest possible audience. For additional information on the plug-in functions shown above (**DLLMain()** and **ClassName()**) see the Advanced Topics section [DLL Functions and Class Descriptors](#).

## Hit Testing

See Also: [Class BaseObject](#), [Class GraphicsWindow](#), [Class Mesh](#), [Class ViewExp](#), [Class Interface](#), [Class HitRecord](#), [Class HitRegion](#), [Class HitLog](#).

Hit testing is used throughout 3ds max as the user selects items in the scene using the mouse. Hit testing is the process of determining if a given mouse point intersects an item (node, modifier gizmo/center, or controller gizmo). A plug-in developer's responsibility regarding hit testing depends upon the type of plug-in and how much functionality is supplied by the base class the plug-in is derived from. For example, plug-ins that are sub-classed from **SimpleObject**, **SimpleMod** or **StdControl** are not required to implement methods for hit testing as it is all handled internally by the base class. Other plug-ins that don't subclass from these classes (for example the boolean object or the mapping modifier) must perform their own hit testing.

There are two types of hit testing:

Node level. This is determining if a given node in the scene has been hit.

Sub-object level. This can be for objects, modifier or controllers. This is for determining if a sub-component of an item has been hit. Object space modifiers can have a visual representation in the scene that the user can manipulate. For example, many of the 3ds max object space modifiers have a gizmo and center mark. These are the modifier's sub-object levels. In the case of an edit modifier this can be the sub-object parts of the object itself (like vertices, edges, or face for the Edit Mesh modifier). An object may hit test sub-object parts as well. For example, a compound object like the boolean object may hit test the operands of the boolean operation. The loft model compound object may hit test parts of the loft model such as the path or shapes.

There is also a distinction to be made between 'simple' hit testing and 'smart' hit testing. Simple hit testing involves finding **any** hit on an item. As soon as a single hit is found the process of searching for hits can stop. Smart hit testing involves finding the part of an item that was the **closest** to the pick point. This involves hit testing everything and then searching through all the hits to find the closest one.

If the plug-in procedural object, modifier or controller must perform its own hit testing, methods of the GraphicsWindow class make this fairly simple. There is a special rendering mode that items may be drawn or rendered in that performs the hit testing. In this mode (called **GW\_PICK**), the item is not actually drawn, but

is instead tested for intersection with the specified hit region. So if an item needs to be hit tested, a developer must simply draw the item using a rendering level **GW\_PICK** and then check the result. The following sample code demonstrates controller gizmo hit testing. This method hit tests a series of 'footstep' shaped polylines that serves as the controller's gizmo.

```
int FootStepControl::HitTest(TimeValue t, INode* inode,
int type, int crossing, int flags, IPoint2 *p, ViewExp *vpt) {
int savedLimits, res = 0;
GraphicsWindow *gw = vpt->getGW();
Matrix3 ntm = inode->GetNodeTM(t);
HitRegion hr;
MakeHitRegion(hr,type,crossing,4,p);
gw->setHitRegion(&hr);
gw->setRndLimits(((savedLimits =
gw->getRndLimits()) | GW_PICK) & ~GW_ILLUM);
gw->clearHitCode();
BOOL abortOnHit = flags&SUBHIT_ABORTONHIT?
TRUE:FALSE;
BOOL selOnly = flags&SUBHIT_SELONLY?TRUE:FALSE;
BOOL unselOnly = flags&SUBHIT_UNSELONLY?
TRUE:FALSE;
for (int i=0; i<NUM_FOOTSTEPS; i++) {
if (selOnly && !sel[i]) continue;
if (unselOnly && sel[i]) continue;
gw->setTransform(fs[i]*ntm);
gw-
>polyline(FOOT_POINTS,footPts,NULL,NULL,TRUE,NULL);
if (gw->checkHitCode()) {
res = TRUE;
vpt->CtrlLogHit(inode,gw->getHitDistance(),i,0);
if (abortOnHit) {
break;
}
}
gw->clearHitCode();
```

```

    }
    }
    gw->setRndLimits(savedLimits);
    return res;
}

```

Note that the example above hit tests polylines. If you are hit testing polygons they must be drawn as 3 sided entities for 3ds max to properly hit test them. Polygons drawn with more than 3 sides will not hit test properly. For more information on hit testing using the methods of Graphics Window see the Advanced Topics section on [The Interactive Renderer : GraphicsWindow](#).

### Setting hitCode and hitDistance in R4.0

**setHitCode()** and **setHitDistance()** are new methods that make it possible to work with GraphicsWindow hit-testing in otherwise impossible situations. Why are they necessary? An example from MAX's CORE.DLL is shown below.

#### Sample Code:

The patch object contains bezier spline-based edges which can consist of up to 102 vertices. Since the **GraphicsWindow::polyline** function can only plot lines with up to 32 vertices, it is impossible to plot these in a single call to the polyline function. Multiple calls to the polyline call do not return a proper hitcode when using a "window"-type hit region. By using the new setHitCode method, code can properly handle this situation. The code below shows the function in use from the **PatchMesh::renderEdge** method:

```

    int steps = GetMeshSteps();
    int segNum = steps+2;
    float fsegNum = (float) (segNum-1);
    // If steps are too high for GraphicsWindow's buffer,
    // we must draw it manually
    if((steps + 2) > GW_MAX_VERTS) {
        Point3 line[2];
        Point3 prev,current(.0f,.0f,.0f);
        BOOL hitAll = TRUE;
        BOOL hitAny = FALSE;
    }

```

```

        DWORD hitDist = 0xffffffff;
for(int terp = 0; terp < segNum; terp++) {
prev = current;
current = work.InterpCurve3D((float)terp / fsegNum);
if (terp != 0) {
line[0] = prev;
line[1] = current;
gw->clearHitCode();
gw->polyline(2, line, NULL, NULL, 0, NULL);
if(gw->checkHitCode()) {
hitAny = TRUE;
if(gw->getHitDistance() < hitDist)
hitDist = gw->getHitDistance();
}
else hitAll = FALSE;
}
}
if(hr && !hr->crossing && hr->type != POINT_RGN)
gw->setHitCode(hitAll);
else
gw->setHitCode(hitAny);
gw->setHitDistance(hitDist);
}
else {
for(int terp = 0; terp < segNum; terp++)
fixedBuf[terp] = work.InterpCurve3D((float)terp / fsegNum);
gw->polyline(steps+2, fixedBuf, NULL, NULL, 0, NULL);
}
}

```

Note that the **gw->polyline** call is preceded by a call to **clearHitCode**, and followed by code which checks the hit code, maintaining "hitAny" and "hitAll" flags. When all the segments are drawn, the **gw->setHitCode** call is made, setting the hit code depending on the hit region type. When the code which called this function checks the GraphicsWindow's hit code, it will contain the

proper value. This code also keeps track of the closest hit distance and places that into the GraphicsWindow when all line segments are drawn.

## Sub-Object Hit Testing

Sub-object hit testing is similar to object level hit testing except that the object is not simply determining if it was hit or not; the sub-object element that was hit needs to be determined as well.

What exactly a sub-object element is depends on the modifier. It may be a modifier's gizmo or part of its gizmo. For example, when an FFD modifier is in vertex sub-selection mode, the sub-object elements that are being hit tested are the control points of the lattice. Edit modifiers usually hit test components of the object in the pipeline such as vertices or faces.

When a modifier's **HitTest()** method is called, it traverses the sub-elements of the current sub-object selection level and checks each one to see if it has been hit. If so, it registers a hit record with the active viewport. A hit record contains the following information:

- A pointer to the node that was hit. Modifiers may be instanced across multiple nodes, so the instance that was hit must be identified.

- A pointer to the ModContext.

- The 'distance' of the hit. To classify as a hit, the sub-object component must be within some threshold distance of the mouse. This distance is recorded in the hit record so that of all the hits below the threshold, the one that is the closest can be identified. What the distance actually represents depends on the rendering level. For wireframe modes, it refers to the distance in the screen XY plane from the mouse to the sub-object component. In a shaded mode, it refers to the Z depth of the sub-object component. In both cases, smaller distances indicate that the sub-object element is 'closer' to the mouse cursor.

- A general unsigned long value. Most modifiers will just need this to identify the sub-object element. The Edit Mesh modifier uses the value to store the index of the vertex or face that was hit.

- In case the 4 bytes above isn't enough space to identify the sub-object element, a pointer to a **HitData** class is included. To use this, a developer would define a class derived from this class that would contain the necessary data. The **HitData** class has one member function, a virtual destructor, so the derived class can be properly deleted when the **HitRecord** instance is deleted.

When **HitTest()** is called on an edit modifier, the edit modifier needs to hit test elements of the object that is flowing through the pipeline. This presents a problem since a modifier usually only has a pointer to this object when its

**ModifyObject()** method is called. In order to be able to hit test the object, a modifier must keep the object cached. Caching the object the modifier is modifying is generally useful as well. For example, the Edit Mesh modifier keeps a cache of the mesh it is editing. When the Edit Mesh modifier is evaluated, if it has a cache it can simply return the cache. This way, as the user applies incremental edits to the mesh, all of the previous edits don't need to be reapplied. Instead, when an edit is made it is applied to the cache *and* stored away in some form in case the modifier needs to be reapplied.

Again, modifiers can be instanced, so storing an instance-specific cache in the modifier might not be the best idea. It is the [ModContext](#), specifically in the **localData** field, where instance-specific modifier data belongs. This is where edit modifiers can put a cache of the object that it modifies. NOTE: typically this cache is only needed while the object is being edited. A hit test will never be called on a modifier unless it is being edited. In terms of evaluation, the pipeline already places caches where appropriate so there is normally no need for the modifier to maintain a cache.

Below is a summary of the hit test related methods from [Class GraphicsWindow](#).

**virtual void setHitRegion(HitRegion \*rgn) = 0;**

Sets the hit region used for hit testing.

**virtual void clearHitCode() = 0;**

This methods clears the hit code. Call this method before performing a hit test.

**virtual BOOL checkHitCode() = 0;**

Returns TRUE if a hit was made; otherwise FALSE.

**virtual DWORD getHitDistance() = 0;**

If **checkHitCode()** returns TRUE you may call this method to return the hit distance. In wireframe mode this is the distance to the line. In shaded mode, this is the z distance. This allows you to perform 'smart' hit testing by choosing the item with the smallest hit distance.

The system maintains a list of nodes for node level hit testing, a **HitLog** for modifier sub-object hits, and a **CtrlHitLog** for controller sub-object hits. The methods of [Class ViewExp](#) are used to work with these results. After hit testing has been performed these methods are available to examine the results.

For node level hit-testing

**virtual void ClearHitList()=0;**

Clears the list of hits.

**virtual INode \*GetClosestHit()=0;**

Returns the INode pointer of the node that was the closest all those hit.

**virtual int HitCount()=0;**

Returns the number of hits recorded.

For modifier sub-object level hit-testing

**virtual void LogHit(INode \*nr, ModContext \*mc, DWORD dist, ulong info, HitData \*hitdat = NULL)=0;**

This method records a sub-object level hit record with the system using the specified parameters. This is frequently called when a plug-in needs to select a node from the scene.

**virtual HitLog& GetSubObjHitList()=0;**

Returns the sub-object hit list.

**virtual void ClearSubObjHitList()=0;**

Clears the sub-object hit list.

**virtual int NumSubObjHits()=0;**

Returns the number of sub-object hits.

For controller gizmo hit testing

**virtual void CtrlLogHit(INode \*nr,DWORD dist,ulong info, DWORD infoExtra)=0;**

This method records a sub-object level hit record with the system using the specified parameters.

**virtual CtrlHitLog& GetCtrlHitList()=0;**

Returns the sub-object hit list.

**virtual void ClearCtrlHitList()=0;**

Clears the sub-object hit list.

If a plug-in wants to perform hit testing of other nodes in the scene it may use the following methods of Class Interface.

**virtual INode \*PickNode(HWND hWnd, IPoint2 pt)=0;**

This method hit tests the screen position for nodes and returns a INode pointer if one is hit, NULL otherwise.

**virtual int SubObjHitTest(TimeValue t, int type, int crossing, int flags, IPoint2 \*p, ViewExp \*vpt)=0;**

This method performs a sub-object hit test. You may access the number of hits

using: **vpt->NumSubObjHits()**. To return a list of the hits use **vpt->GetCtrlHitList()**.

The following code demonstrates the use of this method:

```
BOOL GenControlSelectionProcessor::HitTest(  
  ViewExp *vpt, IPoint2 *p, int type, int flags )  
  {  
  vpt->ClearCtrlHitList();  
  ip->SubObHitTest(ip->GetTime(),type,ip-  
  >GetCrossing(),flags,p,vpt);  
  if (vpt->GetCtrlHitList().First()) {  
    return TRUE;  
  } else {  
    return FALSE;  
  }  
}
```

Plug-ins that are not subclassed from **SimpleObject SimpleMod** or **StdControl** need to implement one of the methods shown below. These allows the system to hit test the plug-in item.

From [Class BaseObject](#). This is the procedural object version:

```
virtual int HitTest(TimeValue t, INode* inode, int type,  
  int crossing, int flags, IPoint2 *p, ViewExp *vpt);
```

The modifier version of this method has an extra argument (**ModContext \*mc**).

```
virtual int HitTest(TimeValue t, INode* inode, int type,  
  int crossing, int flags, IPoint2 *p, ViewExp *vpt, ModContext*  
  mc)
```

From [Class Control](#).

```
virtual int HitTest(TimeValue t, INode* inode, int type,  
  int crossing, int flags, IPoint2 *p, ViewExp *vpt)
```

Finally, the following function is commonly used to initialize the **HitRegion** data structure.

```
void MakeHitRegion(HitRegion& hr, int type,  
  int crossing, int epsi, IPoint2 *p);
```

# The Interactive Renderer: GraphicsWindow

See Also: [Class GraphicsWindow](#), [Class Mesh](#), [Class Light](#), [Class HitRegion](#).

## Overview

The display of geometric structures in 3ds max is handled through a class called [GraphicsWindow](#). An instance of a GraphicsWindow sets up access to underlying drivers that allow 2D and 3D primitives to be rasterized and appear on-screen.

The methods in the GraphicsWindow class are designed to provide a fast, low-impedance pipeline to the underlying driver, and are optimized for mesh rendering.

If you wish to display a geometric object that is represented as a triangular mesh (consisting of a vertex list and a connectivity list), you should not use the GraphicsWindow methods directly. Rather, you should create a 3ds max [Mesh](#), and then call that mesh's **render()** method. This assures that your mesh is rendered using the optimal path through the display subsystem.

A GraphicsWindow provides the following services:

## **Window Access Services**

When the system creates an instance of a GraphicsWindow, the constructor opens a window for output and connects that window to an instance of a low-level rasterizer (driver). There are methods to resize and move the window, and to configure or change drivers.

Note: Since the driver has complete control over the window's palette (if one exists), each GraphicsWindow within 3ds max must be connected to the same driver.

The physical window consists of two parts: an image buffer (containing the colored pixels, as they appear on the screen) and a Z buffer. The Z buffer is used to record depth at each pixel as geometric primitives are rasterized.

Most drivers control two image buffers. One is displayed on the screen, and the other is used to rasterize geometric primitives. When rasterization of a complete frame is done, the off-screen buffer is blitted onto the display screen.

There are methods within the GraphicsWindow class that can be used to read/write the image and Z buffers.

## Rendering Modes

A GraphicsWindow instance can be in any of several different rasterizing modes. The various rendering modes may be combined in a large number of ways. For example, it is possible to request Gouraud-shaded, z-buffered lines, or textured, flat-shaded triangles. (The actual output will depend on the capabilities of the underlying device driver.)

Each GraphicsWindow has a master mode (called the rendering limit) and a current mode. The current mode is always a "subset" of the master mode, in that any limits imposed by the master mode are forced onto the current mode.

For example, if the master mode restricts primitives to wireframe rendering, then setting the current mode to filled polygons will have no effect. On the other hand, if the master mode restricts rendering to flat shading, then the current mode can be set to wireframe to force polygons to render at the wireframe level.

In MAX, the rendering limits for each viewport can be set in the Rendering Method page of the Views / Viewport Configuration dialog box. Note that even when the level is set to "Smooth + Highlights", some primitives (for example lights and cameras) appear in wireframe. This is done by setting their private mode to wireframe.

The various rendering modes may be combined in a large number of ways. For example, it is possible to get Gouraud-shaded, z-buffered lines, or textured, flat-shaded triangles.

## Coordinate Systems

There are two primary coordinate systems within a GraphicsWindow: device-independent 3D eye coordinates and device-dependent window coordinates.

Device-dependent coordinates are integer triples that have their origin at the lower-left corner of the window and increase toward the upper right. One unit corresponds to a single pixel. Z values closest to the user are 0, and they increase into the screen. The maximum Z value is driver-dependent. This coordinate system is left-handed.

Eye coordinates are floating point triples that correspond to relative distances from the camera (or "eye") associated with the window. In eye coordinates, x increases toward the right, y increases upward, and z decreases away (and in front of) the eye point. This coordinate system is right-handed.

There are two ways to set up eye coordinates. In the first, the camera is assumed to be sitting at the origin looking down the negative z axis. You specify camera parameters (perspective/orthographic, field-of-view, etc.) and then provide a transformation matrix for an object's position relative to the camera. This is most easily accomplished by concatenating the inverse affine transformation for the camera's position in world space with the (forward) affine transformation of the object in world space.

In the second method, a camera matrix is specified that includes both the world position (affine transformation) and projection information. This allows for a simple camera "look at" transformation model.

Note that the system stores two matrices: a camera matrix (which can be a pure projection), and an affine transformation matrix. When deriving device coordinates for a geometric primitive, each position is logically transformed through the affine transformation first, followed by the camera transformation. This allows each geometric primitive to be represented in its own local coordinates.

In addition to providing a method for transforming points from local, model coordinates to floating point device coordinates, a method is provided that transforms model coordinates into integer window coordinates with the origin at the upper left. These integer coordinates correspond to the coordinates used by GDI and the Windows mouse routines.

Both model-to-device coordinate methods return clipping values indicating whether the transformed point lies outside of the view volume. Flags are

provided for each of the six planes bounding the viewing frustum.

## Primitives

The geometric primitives supported by the GraphicsWindow class were designed to provide optimal support for rendering triangular meshes. As noted earlier, the preferred way to render such meshes is through the **render()** method of the Mesh class.

If you need to use the geometric primitives in the GraphicsWindow class directly, you should be aware that there is no direct support within GraphicsWindow for lit primitives, so rendering illuminated surfaces is a two-step process.

There are two levels of primitive support within the GraphicsWindow class: one set uses device-independent 3D eye coordinates and the other uses device-dependent window coordinates. At each level there are routines for polylines, polygons (triangles), markers, and annotation text.

The device-dependent routines do not provide any support for clipping or range testing! For speed, these routines assume that all coordinate values passed in are valid. If invalid values are present, the results are unpredictable, but a program crash or corruption of the 3ds max system is almost guaranteed.

The higher-level routines transform their coordinate lists through the current affine and camera transformations, clipping when necessary, and then call the corresponding low-level routines.

These routines are designed to optimize the rendering of meshes composed of vertex and connectivity lists. This process works as follows:

Each vertex is transformed using the model-to-device transformation routine, and the resulting device coordinates and clip flags are cached.

For each triangle in the connectivity list, the clip flags are examined to classify the triangle into one of the following three cases:

If all vertices lie outside the viewing frustum, the triangle is trivially rejected.

If all vertices lie inside the viewing region, it is rasterized using the cached device coordinates and the low-level primitive routines.

If the triangle is clipped by the viewing region, its model coordinates are sent to the high-level routines where the triangle is appropriately clipped and rasterized.

Note that this approach only transforms and clip-checks most vertices once. (Only in the rare case that a primitive is clipped do the associated vertices have to be transformed again.) Since most vertices in a mesh are shared, this provides

an efficient means to rasterize the entire mesh.

## Materials and Lighting

As mentioned above, the geometric primitives in a GraphicsWindow do not directly support lighting. Rather, polylines and polygons can be provided with colors for each vertex. If provided (and the rendering limit allows for it), the device driver will interpolate the vertex colors as the primitive is rasterized.

To facilitate the lighting process, there are methods to specify light properties (type, color, angles, etc.), position and direction, and to specify material properties (ambient, diffuse, and specular colors, etc.) Once a material and a set of lights are specified, a given vertex / normal vector pair may be "rendered" by calling the **lightVertex()** method. This method uses the position and normal vector direction to produce an RGB triple representing the lit color.

Logically speaking, for lit primitives the pipeline described above is modified by having each vertex lit at the time it is transformed. The resulting RGB triples can then be cached and later used during rasterization of the primitive. In the mesh class, the actual renderer uses a lazy evaluation algorithm so that only vertices that may appear on-screen get lit.

## Hit Testing

It is also possible to test each primitive for intersection or containment within a specified "hit region". The region may be a point (+/- epsilon), a rectangle, a circle, or a fence (an arbitrary polygon region).

Hit testing is done through a side-effect mechanism. When hit-testing is enabled, primitives set a flag if they pass through or are fully contained in the hit region. (When in this mode, the primitives do not cause any visual side-effects -- in particular, they do not change the image or Z buffers.)

By clearing the flag before a primitive is rendered, and checking it immediately afterwards, a hit-check for that particular primitive is made. Hit testing on vertices, edges, entire meshes, etc., can be accomplished by rendering only the desired primitives and checking the hit flag at the desired granularity.

When the hit region is a single point, each "hit" primitive also sets a distance variable (representing distance from the hit point to the line in wireframe mode, and Z distance in filled mode), so that "smart" hit testing -- i.e. choosing the closest primitive to the hit point -- may be implemented.

## Intervals

See Also: [Class Interval](#), Advanced Topics section [Time](#).

An Interval is a class that represents a length of time. It has two private data members, **start** and **end**, that are each **TimeValues**. A **TimeValue** is a single instant in time. For more information on **TimeValues** see the Advanced Topics section [Time](#).

Intervals are used throughout 3ds max in describing a range of time. The most common use is to describe a range of time over which an item is said to be 'Valid'. This type of interval is referred to as a **Validity Interval**. It is normally used in association with some item which is cached. The validity interval describes the range of time over which the cache accurately reflects the state of the item. When comparing a given time to see if the cache is up to date, if the time is inside the interval, the cache is valid at that time. If it is outside the interval, the cache is invalid.

The geometry pipeline system of 3ds max uses intervals as part of its caching scheme. Many of the methods procedural object or modifier plug-ins must call or implement (associated with intervals) are required for use with MAX's caching system. In terms of this cache, the interval represents a period of constancy for an item around a certain time. In other words, given a certain time, how far before and how far after the time is the item constant (not changing). Part of the caching algorithm needs to determine if an item is relatively constant or not.

As an example consider a procedural object which is not animated over an entire 100 frame animation. This object would have a validity interval of FOREVER. It is always up to date since nothing ever changes. Then apply a Bend modifier to this object and animate the angle parameter at frame 50. The bent object is now always changing from frame 0 to 50. After frame 50, it never changes. Any validity intervals computed in the first 50 frames would be instantaneous intervals (the **start** time equal to the **end** time). Any validity intervals computed at a time after frame 50 would be from 51 to 100.

3ds max may cache a representation of the bent object from frame 51 to 100. It will then never have to re-compute this bent object over this entire range. 3ds max would not cache a representation from frame 0 to 50 since the object is always changing.

Plug-ins must provide 3ds max with information about when they are changing

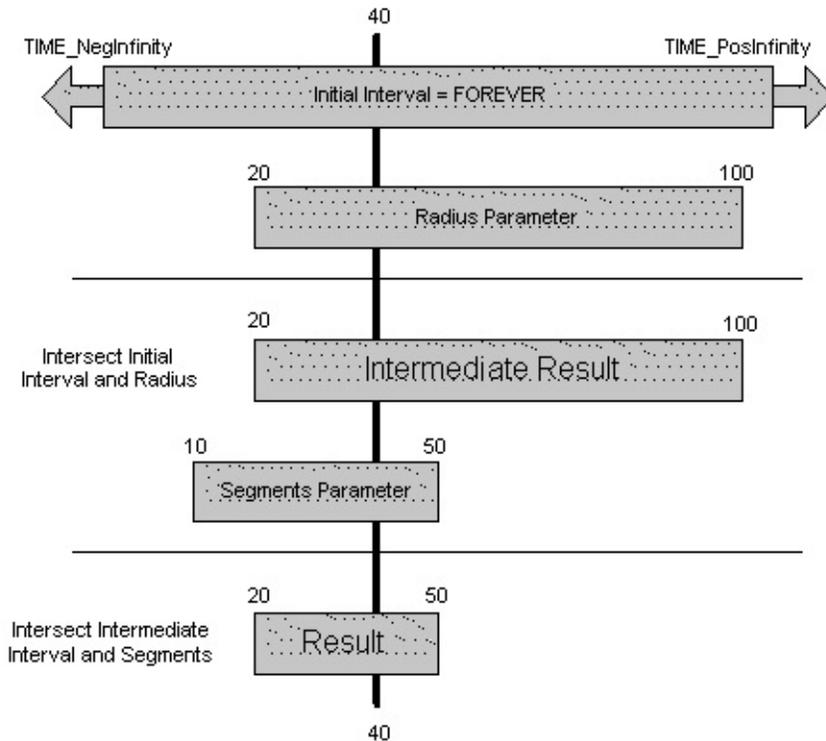

and when they are not. Below are some examples of methods which plug-in procedural objects or modifiers call or implement that return or modify intervals.

### **GetValue()**

This method of **IParamBlock** has several parameters, one of which is a C++ reference to an Interval. This method is frequently used by developers to 'whittle' down an interval. When a parameter of a parameter block is animated, for any given time there is an interval over which the parameter is constant. If the parameter is constantly changing the interval is instantaneous. If the parameter does not change for a certain period the interval will be longer. If the parameter never changes the interval will be FOREVER. By passing an interval to the **GetValue()** method of the parameter block you ask the parameter block to 'intersect' the interval passed in with the interval of the parameter. Intersecting two intervals means returning a new interval whose start value is the greater of the two, and whose end value is smaller of the two. In this way, the resulting interval represents a combined period of constancy for the two intervals.

This technique is used frequently to compute a validity interval for an object. The developer starts an interval off as FOREVER, then intersects this interval with each of its animated parameters (by calling GetValue()). GetValue() 'whittles' down the interval with each call. When all the parameters have been intersected, the result is the overall validity interval of an object at a specific time.

Consider the example shown in the diagram below. A validity interval is computed at time 40 for an object with two animated parameters, Radius, and Segments. The interval is computed by first intersecting an initial interval of FOREVER with the Radius parameter. The Radius interval is from 20 to 100. The result of this intersection is the interval from 20 to 100. This interval is intersected with the Segment parameter interval (from 10 to 50). The result of this intersection is an interval from 20 to 50. Thus the validity interval of the object at time 40 is from 20 to 50.

### **ObjectValidity(TimeValue t)**

This method, implemented by the plug-in, returns the validity interval of the procedural object around the time passed. This method is computed by the object by starting an interval at FOREVER, and intersecting this interval with the intervals of each of its animated parameters. In this way, an interval is whittled down as it is intersected with each of the parameters. The resulting interval represents a period of constancy about the TimeValue passed. The interval represents how far before the TimeValue and how far after it the object is constant.

### **LocalValidity(TimeValue t)**

This method returns the validity interval of the modifier itself around the time passed. In general, this would be the intersection of the validity intervals of all controllers that the modifier uses to control its parameters, so if a modifier was not animated, this interval would be FOREVER.

As an object flows up the pipeline, the validity interval of each modifier is intersected into the object state's validity interval. When the object gets to the end of the pipeline, its validity interval reflects the intersection of all the elements in the pipeline.

### **GetValidity(TimeValue t)**

The **SimpleMod** class calls this method to retrieve the validity interval of the modifier. The modifier provides this interval by starting an interval at FOREVER and intersecting each parameter of the modifier with the interval. **SimpleMod** then intersects the validity intervals of its own controllers with the returned interval in its implementation of **LocalValidity()**.

### **UpdateValidity(int nchan, Interval v)**

A modifier calls the **UpdateValidity()** method of an object. When a modifier is applied to an object, it needs to include its own validity interval. Frequently this is called by the modifier in its **ModifyObject()** method.

### **SetChannelValidity(int nchan, Interval v)**

This method is called to specify a validity interval for a certain channel of the pipeline.

See also: Class [Interval](#) and [Geometry Pipeline System](#) in the Reference section.

# Inverse Kinematics

See Also: [Class IKChainActions](#), [Class IKSolver](#), [Class IIKChainControl](#), [Class IIKControl](#), [Class ZeroPlaneMap](#), [Class RootLink](#), [Class Link](#), [Class LinkChain](#), [Class Animatable](#)

## Introduction to Inverse Kinematics

The Inverse Kinematics (IK for short) API's are divided over three files: **IIKSys.h**, **IKSolver.h**, and **IKHierarchy.h**. **IIKSys.h** contains the interface definition of the two types of controllers, **IIKControl** and **IIKChainControl**. They are both TM controllers. The former is used in joints (nodes on which IK will be applied), and the latter is used in the IK goals (nodes that serve as IK goals).

The **IKControl** and **IKChainControl** are knit together as the IK system. When an IK solution is called for, the IK system will invoke the IK solver, which is a mathematical algorithm that, given the goal position/orientation, and incidental parameters, produces a solution in terms of joint angles (rotation values of respective nodes). While the controllers involved in IK are not expandable via plug-in, the IK solver is actually plug-able. The IK system will recognize a plug-in solver by putting it in the solver list wherever it appears. The API of the IK solver, defined in **IKSolver.h** and **IKHierarchy.h**, contains the data structure of transformation hierarchy used in **IKSolver.h**.

An interface pointer to the **IKControl** class can be obtained by using **Animatable::GetInterface(I\_IKCONTROL)**.

An example on using the IK API can be found in the 3ds max SDK, **\MAXSDK\SAMPLES\IKSOLVERS\IKLIMB**.

## Concepts

### Degrees of Freedom

A node transform contains six degrees of freedom. Three are translational

(sliding) and three are rotational. In the API, they have enum names, **IKSys::TransX** to **IKSys::TransZ** and **IKSys::RotX** to **IKSys::RotZ**. When the context implies rotational or translational, **IKSys::DofX** to **IKSys::DofZ** are used.

A degree of freedom can be active or inactive. An inactive degree of freedom is not to be used by IK. In other words, only active degrees of freedom are degrees of freedom as far as IK is concerned. The methods **DofActive()**, **ActiveTrans()**, **ActiveRot()**, and **ActiveDofs()** are provided to determine which degrees of freedom are active and inactive. The first query answers whether a specific (translational / rotational) axis is active. The following three return a set of DOFs, which is defined in the same file. The set returned by **ActiveTrans()** and **ActiveRot()** is to be tested by **IKSys::DofX** to **IKSys::DofZ**, and the set returned by **ActiveDofs()** is to be tested by **IKSys::TransX** to **IKSys::RotZ**.

### Relationship to IK Chains

A node transformation can be conceptually viewed as consisting of two joints, sliding joint (translational degrees of freedom) and rotational joint. The enum type, **IKSys::JointType**, contains two enums: **IKSys::SlidingJoint** and **IKSys::RotationalJoint**. An IK chain starts at the rotational joint of the Start Joint and ends at the sliding joint of the End Joint. Two IK chains covering the same joint, are considered overlapping IK chains.

Let's call a node an IK chain node if its TM controller supports interface **IIKChainControl**, i.e., **node->GetTMController()->GetInterface(I\_IKChainControl) != NULL**. The following query returns a list of IK chain nodes; **InodeTab IKChains(JointType) const**  
The parameter that decides whether an individual degree of freedom is (IK) active is not animatable. There is an animatable variable of IK chain that decides whether the goal defined in the IK chain actually affects the joints it covers at a specific time, this can be queried using **IKBound()**.

### Joint Limits

A degree of freedom can be bound to a limited range. The lower bound and upper bound can be set separately. At each end, there are a boolean parameter, Limited, and a float number that sets the limit. The limit is effective only if

the boolean parameter, Limited, is true. Following queries concern the joint limits. When a **Point2** is returned, it is ordered as the lower limit followed by the upper limit. When a **Point3** is returned, the order is X, Y, and Z. For example, **TransLowerLimits()** returns lower limits of **TransX**, **TransY**, and **TransZ**, respectively.

### Preferred Angles

Some solver may start off the solution process with joint angles being set to special values, these are called preferred angles. **PrefPosition()** and **PrefRotation()** return preferred angles of the translation and rotation joints, respectively. The APIs allows them to be animatable. However, in 3ds max 4, they are constant with regard to animation time. The methods **SetPrefTrans()**, **SetPrefRot()**, and **SetPrefTR()** set their values at a specific time.

### Joint Angles

**TransValue()** and **RotValue()** will query joint angles of sliding and rotational joints, respectively, at a specific time. If the user supplies non-null pointer to a validity interval, the validity interval will be updated.

Their values can be assigned using **AssignTrans()** and **AssignRot()**. The methods **AssignActiveTrans()** and **AssignActiveRot()** will skip those degrees of freedom that are not active. These same two methods allow active DOFs to be given as the first argument of type **DofSet**, while having the new values supplied as float array whose size should be the same as the DofSet [**DofSet::Count()**]. The order in the array is: **DofZ** if the DofSet includes **DofZ**, **DofY** if the DofSet includes it, and followed by **DofX** if it is included in the **DofSet**. IK controllers are designed to be controlled by the IK goals (through the internal IK system). Therefore, their values are not to be set as independent variables are. These assignment methods just assign new values to the respective variables and that's all. They do not adjust the validity interval, this is done through the methods **SetTransValid()**, **SetRotValid()** and **SetTRValid()**. The last method sets the validity intervals for translation and rotation values to the same interval.

### FK Sub-controller

The Forward Kinematics sub-controller and the pointer to the node that holds this controller as its TM controller can be obtained using **Control\* FKSubController()** and **INode\* GetNode()**. Note that the IK controller is not designed to be instanced. It is expected to have a unique node.

## Interface Class **I IKChainControl**

### Reference Indices

The following enum constants are indices to the reference targets made by the **I IKChainControl**. For example, **GetReference(I IKChainControl::kPBlockRef)** will return a pointer to **IParamBlock2**. These reference indices are:

#### **kPBlockRef**

The IparamBlock2 parameter block.

#### **kGoalTMRef**

A Matrix3 controller representing the sub-controller that defines the transformation matrix of this node

#### **kEndJointRefINode**

The INode reference for the End Joint.

#### **kEnableRef**

Bool (float) controller. This switch indicates when the IK chain is enabled or effective.

#### **kStartJointRef**

The INode reference for the Start Joint.

#### **kLastRef**

Place holder.

### Parameter Block Indices

There is just one parameter block. Its index to **Animatable::GetParamBlock()** is given by enum constant **kParamBlock**.

Parameter Indices

The following enum constants represent the indices of the parameters in the parameter block:

**kStartJoint** INode, referenced by kStartJointRef

**kEndJoint** INode, referenced by kEndJointRef

**kSolverName** String, the solver name.

**kAutoEnable** BOOL, auto-enable.

**kSwivel** Angle, swivel angle.

**kPosThresh** Float, pos threshold.

**kRotThresh** Float, rot threshold.

**kIteration** Integer, iterations.

**kEEDisplay** BOOL, EE display.

**kEESize** Float, EE size.

**kGoalDisplay** BOOL, display goals.

**kGoalSize** Float, goal size.

**kVHDisplay** BOOL, VH display.

**kVHSize** Float, VH size.

**kVHLength** Float, VH length.

**kSolverDisplay** BOOL, display solvers.

**kAutoSnap** BOOL, auto snap.

**kVHUseTarget** BOOL, VH use target.

**kVHTarget** INode, VH target.

**kLastParam** Place holder.

Most parameters have separate querying methods. For example;

**GetParamBlock(IKChainControl::kParamBlock)>GetINode(IKC**

will return turns the same pointer as does **StartJoint()**. The **kStartJoing**

and **kEndJoint** parameters that define the IK Chain Delimiters can be

obtained by using the **INode\* StartJoint()** and **INode\* EndJoint()**

methods.

## Swivel Angles

Most of the time, joints are drawn on a plane (planar IK chains). A desirable quality of an IK solver is not to disturb this plane. Those solvers would use only the Start Joint to rotate the plane. When the End Joint is adhered to the goal, the rotation about the axis from the Start Joint to the End Joint is called Swivel. Swivel angle is the amount of this rotation.

In order for the swivel angle to make sense, however, we need a reference point. When a chain is put at the preferred pose, meaning that all the joint angles are set to preferred angles, the plane expanded by the pivots of all the joints on the chain is called *Initial Plane*, and the axis from the Start Joint to End Joint is called *Initial End Effector Axis* (EEAxis). Since Preferred Angles are animation variable, so is the *Initial Plane* and *EEAxis*. The **InitPlane()** and **InitEEAxis()** methods return the normal to the Initial Plane and the unit vector of the Initial EEAxis. These are represented in the parent space of the Start Joint. To obtain the normal in object space, use the method **ChainNormal()**. The relationship between **ChainNormal()** and **InitPlane()** is (in pseudo code):

**InitPlane() = ChainNormal() \* StartJoint()->PrefRotation().**

When the joints do not lie on a plane, the closest plane, in certain sense, can be used. Let's call this plane the *solver plane*.

The class **ZeroPlaneMap** is defined in **IKHierarchy.h**. This provides the functionality that, given a unit axis, which is to be substituted for by EE Axis, produces a unit vector, which will be interpreted as the normal to a plane. This plane will be taken as the zero plane to which the swivel angle is relative: the plane corresponds to swivel angle being zero. The amount of rotation that will bring the Zero Plane to the current solver plane is the Swivel Angle, which corresponds to the parameter of index **kSwivel** and can be obtained using the **SwivelAngle()** method. The following relationship holds (in pseudo code):

**ChainNormal() \* StartJoint()->Rotation() =  
ZeroPlaneMap(EEAxis) \* <Rotation about EEAxis by  
SwivelAngle(>**

A plugin solver may have its own ZeroPlaneMap. In case it does not have a preference, it can use the default one provided by the IK system as **IKSys::ZeroPlaneMap\* DefaultZeroPlaneMap()**.

The solver plane can be controlled by an extra node and this is often desired by the user. In this case, they want the solver plane to align with the plane defined by the Start Joint, the End Joint, and the extra node, called the *swivel angle target*. Since the target and the swivel angle are meant to control the same thing, only one of them can be used. The parameter of index **kVHUseTarget** determines which will be used. It is not animatable. If it is true, the swivel angle target will be used. The target node can be obtained from the parameter of index **kVHTarget**. When the target node is NULL, the swivel angle will be used.

### Solver Properties

The method **IKSolver\* Solver()** returns the IK solver whose responsibility it is to solve the IK problem. Its class name is stored as the parameter of index **kSolverName**. As mentioned, there is an animatable variable that determines, at a specific time, whether IK is enabled. Whether the solver is enabled or disabled can be checked using the **SolverEnabled()** method.

This is just an interface to the sub-controller with reference index **kEnableRef**. Since its value is used to determine whether joints in an IK chain depend on the IK goal when reference message is received, developers should not replace it, using the 3ds max Reference APIs, with an arbitrary controller whose dependency structure is general. This would create a time variable dependency structure and is not desirable. The built in controller is a key-frame controller.

Sometimes, we still want to invoke IK by moving the goal even if **SolverEnabled()** is false. In such cases the purpose of IK is to set keys on the FK sub-controllers of the joints. The feature is called "Use IK to FK", which is only meaningful during an interactive session. For this purpose **CanAutoEnabled()** corresponds to the parameter of index **kAutoEnable** and indicates whether the feature of "Use IK to FK" is desired. The **AutoEnableSet()** method provides the transient state of the IK chain: whether IK is currently enabled due to this feature. It is only set, if it is ever set, during the next update cycle, with regard to when the goal is moved, or its TM is set to new value.

### Valid IK Chains

A valid IK chain is one that has a good Solver, Start and End joints, where the

Start Joint is an ancestor of the End Joint in the scene hierarchy. The **Valid()** and **INode\* GetNode()** methods are available for this. The latter returns the node that holds it as its TM controller. The IK Chain Controller is not designed to be instanced. It is expected to have a unique node.

## **Class IKSolver and Solver plugins**

Being a plugin itself, the IK system allows the solver to be a separate plugin. This class defines the base class that plugin solver should derive from. The IK solver is a pure mathematical function: it does not hold state and just solves a given, self-contained, mathematical problem. In other words, the plugin solver does not have influence on when IK is invoked and what an IK problem is (what is the goal and what are the joints, etc.), but contributes to IK by answering how to solve. Structurally, it is independent of the SDK and, hence, can be built independently, except for some theoretically independent math library.

### **Class Identity**

Plugin solvers are recognized by the IK system by the Super Class ID. A unique enum, **IK\_SOLVER\_CLASS\_ID**, defined in **animtbl.h**, is given to it. The **SClass\_ID SuperClassID()** method should not to be overridden. Since it is a pure mathematical function that does not hold state, an individual plugin solver is identified by its class name which can be obtained using the **GetClassName()** method. When class name clashes, a suffix may be appended. The class name will appear in the solver list from that users can pick for or assign to IK chains.

### **Solver Traits**

Following methods are meant to be overridden by the plugin solver queried by the IK system.

**IsInteractive()**. IK can be used as a controller or as an interactive manipulation tool. In the former, the relationship between the goal and the joints are permanent: joints are completely controlled by the goal. In the latter, the relationship is transient, existing only during interactive manipulation. In the end, IK solutions are registered at each joint, mostly likely as key-frames, and it no longer matters how joints got their joint angles. Only non-interactive, or controller, IK solvers are used.

**IsHistoryDependent()**. At a specific animation time, the history dependent solver will reach solutions not only based the state of goal at the time, but also its previous states (hence they are history dependent). On the contrary, the history independent solver does its job based on the state of the goal just at the time. The procedural implication is that, when the goal is changed at time  $t$ , the IK system would have to invalidate joints, at time  $t$  for the history independent solver, and at all times that are greater or equal to  $t$  for the history dependent solver. Only history dependent solvers are used by the IK system.

The methods **UseSlidingJoint()** and **UseSwivelAngle()** are used to tell whether the plugin solver intends to use the sliding joint (translational degrees of freedom) or the swivel angle parameter of the IK chain.

When two IK chains overlap, i.e., if there's a joint belonging to both IK chains, some solvers are able to negotiate between the possibly contending goals and some are not. The method **DoesOneChainOnly()** is used to determine this. For those that can only solve one chain at a time, the IK system will pass to the solvers one chain at a time in a definitive order. Only solvers that "do one chain only" are used.

The method **DoesRootJointLimits()** and **DoesJointLimitsButRoot()** deal with the concern of joint limits. If the solver supports joint limits, the IK system will trust it. Otherwise, the IK system will, after calling the solver, clamp the results according the joint limit constraints. The root joint in **DoesRootJointLimits()** refers to the Start Joint. It is treated differently from the rest of joints.

The method **SolveEERotation()** tells whether the rotation part of the goal node will be used. If it returns false, only the position of the goal node is taken as the IK goal and rotation threshold will be irrelevant.

Solvers can reach solutions with closed formula, analytically, or going through iterations. For an analytic solver, thresholds and maximum iteration numbers are not relevant. Checking whether or not a solver is analytical can be done using the **IsAnalytic()** method.

### **Solution Parameters**

The methods **GetPosThreshold()**, **GetRotThreshold()**, **GetMaxIteration()**, **SetPosThreshold()**, **SetRotThreshold()**, **SetMaxIteration()** are used to get and set the Position Threshold, Rotation

Threshold, and the Maximum number allowed for iterations and are not relevant for all solvers. For an analytic solver, for example, these are not used at all. The IK system, however, may set values to them.

As mentioned earlier, plugin solvers may have their own Zero Plane Map. If so, they must override the **IKSys::ZeroPlaneMap\***

**GetZeroPlaneMap()** method. The IK system will need it to perform IK snapping: setting the swivel angle based on the current pose so that the pose is consistent with the swivel angle.

## Solve

**Solve()** is the method which the IK system will call when it's time to update the joints according to the IK goal and other parameters. The IK system will compile an IK problem represented in the 3ds max scene data structure, nodes, controllers, etc., into a pure mathematical representation,

**IKSys::LinkChain**. This data structure only represents one IK chain.

Overlapping IK chains are not dealt with. The **ReturnCondition**, returned by the **Solve()** method is a bit-set. Its definition is copied from

**IKHierarchy.h**:

```
typedef unsigned ReturnCondition;
enum ConditionBit {
    bLimitReached = 0x00000001,
    bLimitClamped = 0x00000002,
    bMaxIterationReached = 0x00000004,
    // The first eight bits are reserved for mild condition.
    // They are still considered successful.
    bGoalTooCloseToEE = 0x00000100,
    bInvalidArgument = 0x00000200,
    bInvalidInitialValue = 0x00000400
};
```

The data structure passed to the solver is transient, meaning that it will be discarded once the solution is copied back to the joints. If the return condition indicates failure, (**return\_condition > 0xff**) then the result will not be

copied back to the joint nodes in the 3ds max scene database.

## **Class LinkChain**

A LinkChain is a hierarchy of transformations. At the top is the **RootLink** and it is followed by a number of Link's . Each link, be it a **RootLink** or **Link**, evaluates to a matrix, called the link matrix (**LinkMatrix**). This matrix consists of two parts, one is a variable part (degrees of freedom) and the other is a relatively constant part, called rigid extend (**RigidExtend**). It can be graphically represented as:

### **RootLink**

The link variable is a rotation, **rotXYZ**. The link matrix is defined as  $\text{RigidExtend} * R_x(\text{rotXYZ}.x) * R_y(\text{rotXYZ}.y) * R_z(\text{rotXYZ}.z)$  where  $R_x(.)$  stands for rotation about the x-axis, etc.

### **Link**

The variable part of a Link is of one degree of freedom. It can be translational or rotational. A typical 3 degrees of freedom (xyz) rotational joint can be decomposed into 3 Links, with the first two being null links:

### **LinkChain**

A **LinkChain** consists of a **RootLink** and a number of Link's. The reason that the **LinkChain** can start with rotation, the variable part of the **RootLink**, is that the IK system will collapse all the node transformations from the root of the scene to the parent matrix of the Start Joint and the translation part of the Start Joint, called the parent matrix, and transform the node hierarchy of the IK chain into this space. The author of the plugin solver does not have to be concerned about **parentMatrix**. They work on the problem as it is rooted at the origin of the world. The data structure of **LinkChain** should be sufficient for those solvers that **DoesOneChainOnly()** and **UseSwivelAngle()**.

## IK System

The IK system services two interfaces, one through the CORE, and the other through the IK Chain Controller class.

### Interface Class [IKCmdOps](#)

The interface ID is defined in **IIKSys.h** as **IK\_FP\_INTERFACE\_ID** and is published through the CORE, i.e., to get a pointer to this interface, call **GetCOREInterface(IK\_FP\_INTERFACE\_ID)**.

To create a new IK chain, use the method **CreateIKChain()**. Given two pointers, **start** and **end**, that are intended for the Start and End joints respectively, and the solver's name, **solver**, this method will create a node that has an **IKChainControl** as the TM controller. This method will return false and fail if: 1) **start** joint is not a proper ancestor of **end** joint in the scene graph; or 2) there is a node along the path from the start joint to the end joint whose TM controller is not an IK Control and is not replaceable, or 3) no IK solver is found with the given name.

### Interface Class [IKChainActions](#)

The interface ID is defined in **IIKsys.h** as **IKCHAIN\_FP\_INTERFACE\_ID** and is published through the class **IKChainControl**, i.e., to get a pointer to this interface, call;

**GET\_IKCHAIN\_CD-  
>GetInterface(IKCHAIN\_FP\_INTERFACE\_ID)**

where **GET\_IKCHAIN\_CD** is a macro defined in the same file that produces a pointer to the class descriptor of class **IKChainControl**.

This interface also publishes a number of actions. An action acts on the currently selected IK chain node. The following method returns TRUE if there is exactly one valid IK chain node selected: **IsSnapEnabled()**. The following methods execute snapping on the currently selected IK chain node: **SnapAction()**, **IKSnapAction()**, and **FKSnapAction()**. The first one does IK snapping if its Enabled is false and FK snapping if its Enabled is true. The next two will do IK snapping and FK snapping, respectively.

# Keyboard Accelerators and Dialog Messages

See Also: [Class Interface](#), [Custom Controls](#).

## Keyboard Shortcuts

**Important Note:** A new system to handle keyboard accelerators was added for R4. This system supercedes those used in previous release. For information on this system see [Class ActionTable](#). The information shown below applies to previous version of the SDK APIs.

**Important Note:** In release 3.0 a new system to handle keyboard shortcuts was established. This system is used to register shortcuts in a uniform manner. In the Customize / Preference Settings / Keyboard tab dialog there is a section to assign Plug-In shortcuts to commands. For details on how this works see the topic [Keyboard Shortcut System](#).

## Keyboard Accelerators

Developers might want to implement keyboard accelerators for some of their plug-ins functions. Because 3ds max plug-ins are modeless, when using R1 there was inherently a conflict between the accelerator keys that the user expected to run standard 3ds max functions, and those supplied by the plug-in. For this reason, a developer had to limit their accelerator key usage as much as possible. However in R2 and later the 'Plug-In Keyboard Shortcut Toggle' icon was added. This controls this conflict such that the user can choose if the plug-in accelerators are in effect or if the system accelerators are. Thus in R2 and later developer are free to registers all the accelerators they need and the user can control which are available.

When a plug-in has its parameters up and registers some accelerators, these accelerators take precedence over 3ds max when the 'Plug-In Keyboard Shortcut Toggle' is on. The methods below (from Class **Interface**) enable the developer to do this.

**virtual void RegisterAccelTable( HWND hWnd, HACCEL hAccel )=0;**

This method registers a keyboard accelerator table. Window messages generated by the accelerator table are sent to the **hWnd** parameter.

**virtual int UnRegisterAccelTable( HWND hWnd, HACCEL hAccel )=0;**

This method un-registers a keyboard accelerator table.

## Receiving Input to Edit Controls

If a plug-in wants to receive keyboard input using a Windows edit control, it must disable the keyboard accelerators. 3ds max uses un-modified keys (such as 'f' to change to the front view). Unless a plug-in disabled the accelerators it would not get this input. The following global functions are used to enable, disable and check the enabled state of the keyboard accelerators.

### **void DisableAccelerators();**

When this method is called, ALL keyboard accelerators are disabled and are no longer processed.

### **void EnableAccelerators();**

When this method is called, the keyboard accelerators are processed again.

### **BOOL AcceleratorsEnabled();**

Determines if the keyboard accelerators are enabled. Returns TRUE if enabled; FALSE if disabled.

For modal dialogs, Windows itself essentially handles disabling and enabling accelerators automatically. For modeless dialogs, a plug-in may have to deal with these functions. If a plug-in uses all standard 3ds max custom edit controls for its editing, it won't need to deal with enabling and disabling accelerators as this is handled by the custom controls. On the other hand, if a plug-in uses any Windows edit controls, such as a combo box that has an edit field and drop down, they will have to call these functions.

For example, in a combo box, when an edit field gets focus, the Windows message CBN\_SETFOCUS is sent. At this time, a plug-in should call **DisableAccelerators()**. If the plug-in did not do this, and if the user typed an 'f', the current 3ds max viewport would change to the front view. By disabling all the accelerators, the plug-in will receive the characters itself. When the dialog proc receives CBN\_KILLFOCUS, the accelerators may be enabled using **EnableAccelerators()**.

## Floating Dialogs

If a plug-in creates a floating dialog box there are two important things that should be done.

1) A plug-in must use the 3ds max window handle as the parent passed to the "DialogBox" of "DialogBoxParam". One can get this handle using the method **Interface::GetMAXHwnd()**.

2) The method **Interface::RegisterDlgWnd(HWND hDlg)** must be called passing the handle of the dialog window.

Following these steps will prevent problems with the user of the dialog being able to operate the rest of 3ds max while your dialog is active.

## Keyframe and Procedural Controller Data Access

See Also: [Class IKeyControl](#), [Class INode](#), [Class Control](#), [Class Matrix3](#), [Class AngAxis](#), [Class Quat](#), [Class ScaleValue](#), [Matrix Representations of 3D Transformations](#).

## Overview

This topic presents information on accessing the data of MAX's keyframe and procedural controllers. There are sections which explain how the keyframe data for the PRS controller can be interpreted, various APIs for keyframe data access, and procedural controller data access.

Example keyframe controllers are the Tension/Continuity/Bias (TCB), Bezier, and Linear controllers. Each keyframe controller in 3ds max is used to animate a value. The keys of the controller store the values at the key frames. The controller's job is to interpolate between these keys. This topic discusses the way developers may access and interpret the keys stored by keyframe controllers (in particular the keys stored by the Position/Rotation/Scale transform controllers). 3ds max also allows the use of procedural controllers. Procedural controllers are those that compute their value algorithmically, based on user specified parameters or outside data, rather than interpolating between stored keyframes. Examples include the Noise Controller, Expression Controller, Audio Controller, Path Controller, and Waveform Controller. This topic presents information on how procedural controllers may be sampled to retrieve their data.

Source code is provided demonstrating how developers may access both keyframe and procedural controller data.

## Interpretation of Keyframe Key Data for the PRS Controller

The default keyframe transform controller in 3ds max is a PRS controller. This means that it handles orienting a node in the scene using separate controllers for Position, Rotation and Scale. To generate a complete transformation, first the position is applied, then the rotation, then the scaling.

Position and scale keys are stored in the local coordinate system of the controller, with each key independent of the others. Rotation keys are stored in local coordinates as well, but each is stored relative to the previous key in the track. Thus the first key stored represents the actual value for the rotation key in terms of the relative space of the controller. The second key is just an offset from the first key. Thus to get the actual rotation for the second key you need to multiply it on the left by the first key. To get the third key, you need to multiply it by the second computed key (which was computed from the first). These computed rotation key values will then be the absolute quaternions for each key for that controller.

It is important to understand however that the entire animation track for position, rotation and scale are all relative to the matrix passed into the controller when its **GetValue()** method is called. For additional details on how a controller updates **GetValue()** see the Advanced Topics section [Node and Object Offset Transformations](#).

Note the following:

- When developers access key data from MAX, the data is returned in the local coordinate system of the controller.
- The key values that appear in the Key Info dialog for a controller are in the local coordinate system of the controller (with the appropriate units for display -- for example, angles are shown in degrees in Key Info but are stored in radians).

## Keyframe Access Classes and Methods

This section discusses access to keyframe controller data. The 3ds max API provides a class **IKeyControl**. This class provides an interface into the TCB, Bezier, and Linear keyframe controllers allowing a developer to add, delete, retrieve and update the keys of the controller.

Use of the **IKeyControl** methods requires you to include `\MAXSDK\INCLUDE\ISTDPLUG.H`, i.e.:

```
#include "ISTDPLUG.H"
```

The standard 3ds max PRS keyframe controllers provide access to their keys using this class. To get an interface you can use to call methods of **IKeyControl** use the following macro (defined in `\MAXSDK\INCLUDE\ANIMTBL.H`):

```
#define GetKeyControlInterface(anim)  
((IKeyControl*)anim->GetInterface(I_KEYCONTROL))
```

A plug-in developer may use this macro as follows:

```
IKeyControl *ikc = GetKeyControlInterface(anim);
```

The return value will either be NULL or a pointer to a valid controller interface. A NULL pointer indicates the controller does not support this interface to allow access to its data.

The following is an example of getting a position controller interface from a node in the scene. The first thing that happens is the position controller is retrieved from the node (using methods of class **Inode** and **Control**) and then the controller interface is returned via the **GetKeyControlInterface()** macro:

```
Control *c;  
c = node->GetTMController()->GetPositionController();  
IKeyControl *ikeys = GetKeyControlInterface(c);  
if (!ikeys) return; // No interface available to access the keys...
```

The methods of **IKeyControl** may be called using the **ikeys** pointer. For example the method **GetKey(int i,IKey \*key)** retrieves the 'i-th' key and stores the result in **key**. You'll need to check the ClassID of the controller so you can pass the appropriate class to the method to retrieve the keys. There are three type of controllers and five data types that are supported by the **IKeyControl** interface. The controller types are Tension/Continuity/Bias (TCB), Bezier, and Linear. The data types are floating point (**float**), Position (**Point3**), Rotation

(**Quat** or **AngAxis**), and Scale (**ScaleValue**). The type of key you pass to the **GetKey()** or **SetKey()** methods depends on both the controller and data type. The following classes are used for key storage for each valid possibility:

**Tension/Continuity/Bias:**

[Class ITCBFloatKey](#)

[Class ITCBPoint3Key,](#)

[Class ITCBRotKey](#)

[Class ITCBScaleKey](#)

**Bezier:**

[Class IBezFloatKey](#)

[Class IBezPoint3Key](#)

[Class IBezQuatKey](#)

[Class IBezScaleKey](#)

**Linear:**

[Class ILinFloatKey](#)  
[Class ILinPoint3Key](#)  
[Class ILinRotKey](#)  
[Class ILinScaleKey](#)

See the following code for an example:

```
ITCBPoint3Key tcbPosKey;  
int numKeys = ikeys->GetNumKeys();  
if (c->ClassID() ==  
Class_ID(TCBINTERP_POSITION_CLASS_ID, 0)) {  
  for (i = 0; i < numKeys; i++) {  
    ikeys->GetKey(i, &tcbPosKey);  
    DebugPrint(_T("\nPosition Key: %d=(%.1f, %.1f, %.1f)",  
      i, tcbPosKey.val.x, tcbPosKey.val.y, tcbPosKey.val.z);  
  }  
}
```

Note how an instance of the **ITCBPoint3Key** class was passed to **GetKey()** since the ClassID indicates the controller is a TCB controller and we want position keys (which operate on **Point3s**).

## Keyframe Interpolation in MAX

The function used for interpolation between keys depends on the type of controller. In general, 3ds max uses cubic (polynomial of degree three) splines for interpolation. Rotations are done using spherical linear interpolation (slerps). Registered developers who are interested in the exact details of keyframe interpolation have the source code 3ds max uses internally as part of the Debug SDK. The bezier interpolation code is available in

`\MAXSDKDB\SDKSRC\INTERP.CPP` and the TCB interpolation is in `\MAXSDKDB\SDKSRC\TCBINTRP.CPP`. This code is not available for non-registered developers. See the Advanced Topics section on [Debugging](#) for more details on the Debug SDK.

Several developers have tried to use the **IKeyControl** interface and then operate on the keys to get and interpolate them in 'world space'. This is really a problematic thing to try do because the keys are interdependent. For instance, consider scale keys. In world space scale keys are dependent on the position and rotation of the controller as well as the parent transformation. This is because first an object is scaled, then it is rotated, then its position is applied, then the parent transformation is applied. So the scale is rotated. If you scale an object along its X axis and then rotate it the scale becomes rotated. The scale is no longer rotated about the world X axis, it's rotated about some other axis. This is normally what you want, i.e. you don't want the object to rotate through the scaled space (this would cause it to skew). So to talk about the scale in world space is a strange concept.

Further, the interpolation of keys that are in world space is equally problematic. If keys are put into world space, then interpolated in world space, the resulting animation will be very different that what would be seen inside MAX. For example, consider an object that is rotating 360 degrees about its local Z axis and is tilted at some arbitrary angle. If you interpolate the way 3ds max does, all the interpolation is done in the local coordinate system. Thus the object would rotate about its local Z axis (which is tilted). However if you were to try to interpolate about in world space the rotation would occur about the world Z axis. The object will still end up in the same place, but it will be a very different animation than what 3ds max would have.

The bottom line is that developer need to understand the way 3ds max computes its node transformation based on the keyframes and use the information to interpolate between keys accordingly.

## Procedural Controller Data Access

3ds max allows users to use procedural controllers in addition to keyframe controllers. Procedural controllers are those that compute their value algorithmically rather than interpolate between stored keyframes. Developers may need to retrieve values from these controllers but won't be able to use the **IKeyControl** interface since no keys are available. In these cases, one must sample the controller to retrieve its value at each frame required. This is done by calling the **Control::GetValue()** method directly. The following sample code samples the controller for each frame in the current animation interval and **DebugPrint()**s the values to the VC++ IDE debug window. Note how the parent matrix of the node is passed into the **GetValue()** call. This allows **GetValue()** to update the appropriate matrix. In the code below, the position coordinates printed by **DebugPrint()** will be in world space.

```
void Utility::SampleController(INode *n, Control *c) {
    TimeValue t;
    Point3 trans;
    Matrix3 pmat;
    Interval ivalid;
    int tpf = GetTicksPerFrame();
    int s = ip->GetAnimRange().Start()/tpf,
        e = ip->GetAnimRange().End()/tpf;

    // Sample the controller at every frame in the anim range
    for (int f = s; f <= e; f++) {
        t = f*tpf;
        ivalid = FOREVER;
        pmat = n->GetParentTM(t);
        c->GetValue(t, &pmat, ivalid, CTRL_RELATIVE);
        trans = pmat.GetTrans();
        DebugPrint(_T("\nPosition at frame: %d of %d=(%.1f, %.1f, %.1f)"),
            f, e, trans.x, trans.y, trans.z);
    }
}
```

A developer could also get the relative values from the PRS controller by passing in the identity matrix and not the parent matrix to **GetValue()**. This is appropriate for the PRS transform controller but not the Look At transform

controller. With a Look At controller, its relative values are actually a function of the input matrix. If you pass in the identity to its **GetValue()** method, it will think that the object is positioned at the center of the world and the results won't be meaningful.

## Sample Code

The following sample code demonstrates access to the controller data for the first node in the current selection set. The code checks to see if the controller provides its data via the **IKeyControl** interface. If it does, this interface is used to get the keys. If it does not, the controller is sampled at each frame to get its data. For the keyframe controllers, note how the ClassIDs are checked to ensure the proper classes are used when getting key values. Also note how the rotation keys are derived by multiplying on the left by the previous key. For the procedural controllers, note how the parent matrix of the node is passed to the **GetValue()** method.

```
// Display the data of the controller. For TCB, Bezier and Linear  
// keyframe PRS controllers the position, rotation and scale values  
// are displayed in the local space of the controller. For  
// procedural controllers (or those that don't support the  
// IKeyControl interface), position data is displayed in world space.  
void Utility::KeyTest() {  
    int i, numKeys;  
    INode *n;  
    Control *c;  
    Quat newQuat, prevQuat;  
    IKeyControl *ikeys;  
    ITCBPoint3Key tcbPosKey;  
    ITCBRotKey tcbRotKey;

    }
}
}

```

## Summary

This section provided an overview of accessing 3ds max controller data. Since 3ds max supports both keyframe and procedural controllers different techniques are required to retrieve the data. Keyframe controller can usually use the **IKeyControl** interface. Procedural controller must be sampled using **GetValue()**, usually at each frame. The values that a controller stores are in the local coordinate system of the controller. The matrix passed to **GetValue()** for a transform controller defines the coordinate system of the transformation.

## Loading and Saving Plug-In Data

See Also: [Class ReferenceMaker](#), [Class ILoad](#), [Class ISave](#), [Class AppSave](#), [Class AppLoad](#).

## Overview

Plug-in developers need to be aware of the way 3ds max saves and loads a plug-in's data from disk. In certain cases, the plug-in's data will be saved automatically without the plug-in developer having to provide any special code. In other cases, the plug-in must save and load the data it maintains for its operation.

The following two cases are examples of 3ds max automatically saving plug-in data.

- 1 3ds max takes care of loading and saving any references the plug-in has when it is saved to disk. The plug-in does not need to explicitly save its references, nor does it need to load its references. After a scene is loaded, the references will automatically be restored. See the Advanced Topics section on [References](#) for more details on the loading and saving of references.
- 2 If a plug-in's parameters are all handled by parameter blocks, the plug-in does not need to save its parameters because the parameter block is responsible for loading and saving to disk.

If the plug-in maintains any other type of data it needs for its operation, it **must** specifically save this data to disk.

There are two methods of the **ReferenceMaker** class which are called by the system when the plug-in's data needs to be loaded or saved. These methods are named **Load()** and **Save()**. The plug-in implements these methods to load or save any special data it has.

The process works as follows: When a 3ds max file is saved, each plug-in object is asked to save its data. It is provided with an interface which has methods to write data. This data can be partitioned into chunks. A chunk is simply a container used to organize the data in the file. When an object needs to be saved, 3ds max creates a chunk for the object. Inside that chunk, another chunk is created to contain reference information which the system writes. The plug-in's **Save()** method is then called. When the plug-in begins execution in its **Save()** procedure, the file pointer is positioned inside the plug-in's chunk but after the first chunk containing the reference data. The plug in can then create its own chunks. Each chunk may contain sub-chunks or data, but not both. In other words, any single chunk may contain either data only, or other sub-chunks only. If you want to put both data and chunks inside another chunk, the data needs to be bracketed inside a chunk itself. To save data, a **Write()** method is used that

simply writes a block of bytes to the output stream. See the sample program below for an example using chunks and data to save information.

Loading a 3ds max file is similar. The plug-in is asked to load its data and is given an interface pointer which allows it to read chunks. When a plug-in DLL is asked to create a new instance of its class (using the **Create()** method of the plug-ins class descriptor), a parameter is passed to indicate whether the new instance is being created with the intention of loading an object from a disk file.

In this way, if the parameter is TRUE, the object doesn't have to perform any initialization because it is guaranteed that it will be asked to read data from a file. The parameter referred to here is the loading flag passed into

**ClassDesc::Create(BOOL loading).**

## Sample Code

The following code demonstrates how both **Save()** and **Load()** may be implemented for a plug-in with two pieces of data it needs to save and restore. This sample writes an array of 10 floating point values and a single DWORD containing flags. The process of saving is very simple. The output file is already open and ready to be written to. A pointer to the [ISave](#) class has been passed in with which the plug-in can call methods to save data. The plug-in begins by creating a chunk using the **BeginChunk()** method and passing an ID it has defined. This ID can be any **USHORT**, as only the plug-in's loading and saving procedures will ever use it. It then writes the data using the **Write()** method. It then closes the chunk using **EndChunk()**. It begins a new chunk and writes the flag data. After ending this chunk it returns **IO\_OK** to indicate a successful save.

The data is saved in chunks like this so that it may be loaded in a manner which is not order dependent. One could write the flags first and the array second and it would still be read correctly.

```
#define SAMPLE_DATA_CHUNK 1000
#define SAMPLE_FLAGS_CHUNK 1010
IOResult Sample::Save(ISave* isave) {
    ULONG nb;
    isave->BeginChunk(SAMPLE_DATA_CHUNK);
    isave->Write(myArray, sizeof(float) * 10, &nb);
    isave->EndChunk();
    isave->BeginChunk(SAMPLE_FLAGS_CHUNK);
    isave->Write(&flags, sizeof(DWORD), &nb);
    isave->EndChunk();
    return IO_OK;
}
```

The following code demonstrates the loading process. Again, in preparation for this call the system has opened the file and positioned the file pointer at the plug-in's objects chunk. The code loops, opening chunks and reading the data until **OpenChunk()** no longer returns **IO\_OK**. This indicates there are no more chunk at this level and the process is done.

Inside the loop, the code switches on the chunk ID. For each ID it recognizes it

reads the data using **Read()**. The chunk is then closed using **CloseChunk()**. If **Read()** did not return **IO\_OK** an error occurred and this error code is returned. Otherwise, the loop begins again.

If the loading was successful, **IO\_OK** is returned to indicate so.

```
IOResult Sample::Load(ILoad* iload) {  
    ULONG nb;  
    IOResult res;  
    while (IO_OK==(res=iload->OpenChunk())) {  
        switch(iload->CurChunkID()) {  
            case SAMPLE_DATA_CHUNK:  
                res=iload->Read(myArray, sizeof(float)*10, &nb);  
                break;  
            case SAMPLE_FLAGS_CHUNK:  
                res=iload->Read(&flags, sizeof(DWORD), &nb);  
                break;  
        }  
        iload->CloseChunk();  
        if (res!=IO_OK)  
            return res;  
        }  
    return IO_OK;  
}
```

The possible return values for **IOResult** are:

**IO\_OK** - The result was acceptable - no errors.

**IO\_END** - This is returned from **OpenChunk()** when the end of the chunks at a certain level have been reached. It is used as a signal to terminate the processing of chunks at that level.

**IO\_ERROR** - This is returned if an error occurred. Note that the plug-in should **not** put up a message box if a read error occurred. It should simply return the error status. This prevents a overabundance of messages from appearing.

For Reference information see: [ILoad](#), [ISave](#).

## **Loading and Saving Hierarchical Data**

There are two classes available for writing and reading hierarchical data structures to a linear stream, such as an AppData block. These are [Class AppSave](#) and [Class AppLoad](#). Please see those classes for more details.

# Matrix Representations of 3D Transformations

See Also: [Class Matrix3](#), [Class Inode](#), [Class Quat](#), [Class AngAxis](#), [Structure AffineParts](#), [Class BigMatrix](#).

## Overview

This section discusses the way transformation matrices are constructed and used in MAX, and various APIs that are available for working with these matrices.

Transformation matrices can be used, for example, to transfer the coordinates of an object from local space to world space, or to position nodes in the scene. The transformations these matrices provide are translation, scaling and rotation.

Methods of the **Matrix3** class (and several global functions) are provided to easily create transformation matrices and perform matrix arithmetic.

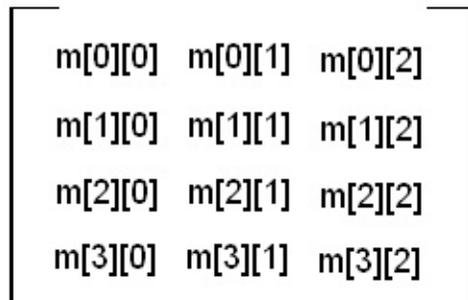

## Matrix Fundamentals

A matrix is a two-dimensional array of numbers. In MAX, 4x3 matrices are used. For 3ds max matrices, the first number is the number of rows (4) and the second number is the number of columns (3). Thus there are a total of 12 elements.

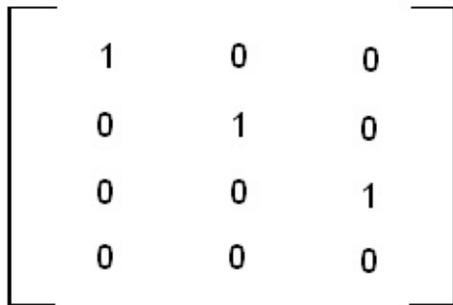

An instance of **Matrix3** has a private data member that contains the values:

```
float m[4][3];
```

The layout of these elements is shown in the following diagram:

The following matrix is called the 'Identity Matrix'. This special matrix, when multiplied by a vector or another matrix, yields the original matrix.

The 3ds max API provides several ways to create identity matrices. If a value of 1 is passed to the constructor of a **Matrix3** it is initialized to the identity. For example

```
Matrix3 tmat(1); // Identity matrix
```

You may also use a method of **Matrix3** to reset a matrix to the identity, for example:

```
tmat.IdentityMatrix(); // Reset to the identity matrix
```

You can verify if a matrix is equal to the identity by using:

```
BOOL isIdent = tmat.IsIdentity();
```

The following sections discuss the ways matrices can be used in transformations.

## **Multiplying a Vector by a Matrix**

One thing that can be done is to multiply a vector (**Point3**) by a matrix (**Matrix3**). This results in a new vector as a result. This is often used to transform vectors from one coordinate space to another. There is a global function in the SDK that does this.

**Point3 VectorTransform(const Matrix3& M, const Point3& V);**

Transform the vector (**Point3**) with the specified matrix.

Note: In MAX, all vectors are assumed to be row vectors. Under this assumption, multiplication of a vector with a matrix using the \* operator can be written either way (Matrix\*Vector or Vector\*Matrix), for ease of use, and the result is the same -- the (row) vector transformed by the matrix.

## **Multiplying Two Matrices**

It is often also very useful to compute the multiplication of a matrix by another matrix. This produces a matrix as the result. Matrix multiplication is associate but not commutative. That is,  $AB$  is not the same as  $BA$ , but  $(AB)C$  is the same as  $A(BC)$ . This property is very useful since separate matrix transformations can be concatenated together and then all applied at once. 3ds max provides several methods to perform matrix multiplication; each are operators of the **Matrix3** class.

**Matrix3& operator\*=(const Matrix3& M);**

Multiplies this Matrix3 by the specified Matrix3.

**Matrix3 operator\*(const Matrix3&) const;**

Performs matrix multiplication.

## Scaling

Now that we have seen some basic matrix math, let's see how we can create matrices capable of performing typical transformations. Scale transformations can be used, for example, to multiply each component of a vector by a scale factor. Scale transformations use the following matrix positions:

$$\begin{bmatrix} S_x & 0 & 0 \\ 0 & S_y & 0 \\ 0 & 0 & S_z \\ 0 & 0 & 0 \end{bmatrix}$$

The following global function is provided in the API to create a scale matrix given a **Point3** with the individual scale factors (the scale factors are in the **x**, **y**, **z** data members of the **Point3**):

**Matrix3 ScaleMatrix(const Point3& s);**

Builds a new matrix for use as a scale transformation.

The following method of the **Matrix3** class nulls out the scale values in a matrix:

**void NoScale();**

This method nulls the scale portion of the matrix.

## Translation

Translation matrices use the following matrix positions:

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \\ T_x & T_y & T_z \end{bmatrix}$$

There are global functions in the 3ds max API to create these translation matrices and to apply translation to existing matrices. Several of these are given below:

### **Matrix3 TransMatrix(const Point3& p);**

Builds a new matrix for use as a translation transformation.

A method of **Matrix3** allows the translation portion of the matrix to be set.

### **void SetTrans(const Point3 p)**

Sets the translation portion of this matrix to the specified values.

### **void NoTrans();**

This method zeros the translation portion of this matrix.

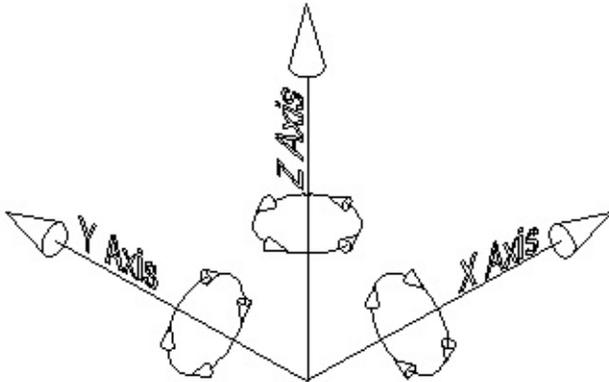

One can also retrieve the translation portion of a matrix using the **Matrix3** method:

### **Point3 GetTrans();**

Returns the translation component of this matrix.

## Rotation

The cells in a rotation matrix are the sines and cosines of the angle of rotation. In the **Matrix3** right-handed coordinate system, positive angles move in a counterclockwise direction, when looking down an axis from positive to negative. In the diagram below, the cones along the XYZ axes point in the positive direction, and the cones in the circles around each axis point in the positive direction of rotation.

The matrices for rotation about the three axes are shown below. In each case **a** represents the angle of rotation in radians:

### X rotation

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & \cos(a) & \sin(a) \\ 0 & -\sin(a) & \cos(a) \\ 0 & 0 & 0 \end{bmatrix}$$

### Y rotation

$$\begin{bmatrix} \cos(a) & 0 & -\sin(a) \\ 0 & 1 & 0 \\ \sin(a) & 0 & \cos(a) \\ 0 & 0 & 0 \end{bmatrix}$$

### Z rotation

$$\begin{bmatrix} \cos(a) & \sin(a) & 0 \\ -\sin(a) & \cos(a) & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix}$$

There are global functions in the 3ds max API to create these rotation matrices and to apply rotation to existing matrices. Several of these are given below:

**Matrix3 RotateXMatrix(float angle);**

Builds a new matrix for use as a X rotation transformation. The angle is specified in radians.

**Matrix3 RotateYMatrix(float angle);**

Builds a new matrix for use as a Y rotation transformation.

**Matrix3 RotateZMatrix(float angle);**

Builds a new matrix for use as a Z rotation transformation.

Developer can also remove the rotation from a given matrix using the **Matrix3** method:

**void NoRot();**

This method nulls the rotation portion of the matrix.

## Creating Quaternions from Rotation Matrices

A quaternion can be created from a rotation matrix. By passing the **Matrix3** to the constructor of the **Quat**, its rotation values are used to initialize the quaternion. The following code shows an example of this. It takes a **Point3 v** and creates a quaternion based on the angles stored after snapping them using the current 3ds max angle snap settings.

```
Matrix3 mat;  
mat.IdentityMatrix();  
mat.RotateX(ip->SnapAngle(v.x));  
mat.RotateY(ip->SnapAngle(v.y));  
mat.RotateZ(ip->SnapAngle(v.z));  
Quat q(mat);
```

## A **Matrix3** as an Axis System

A **Matrix3** can also be used to specify an axis system. For example, the **INode** method **Rotate()** is used to rotate a node about a specified axis system. One of the arguments to this method is a **Matrix3** that specifies this axis system.

Essentially, a matrix **is** just an axis system.

For example, if you think of an axis tripod in a viewport, this is basically all the information a matrix has. The axis tripod has three vectors (the directions of the axes: X, Y, Z) and a position in space (the point where the axes converge). A transformation matrix holds this same information. The 0th row of a matrix is the X vector, the 1st row of the matrix is the Y vector, the 2nd row of the matrix is the Z vector, and the 3rd row of the matrix is the position.

You can picture this if you consider the identity matrix. Its 0th row (X) is [ **1 0 0** ] and this is just a vector along the X axis. Its 1st row (Y) is [ **0 1 0** ] and this is simply a vector along the Y axis. Its 2nd row (Z) is [ **0 0 1** ] and this is just a vector along the Z axis. And the 3rd row (position) is [ **0 0 0** ] and this is the origin. Therefore the identity matrix is just an axis system without any rotation, positioned at the origin. This same thing holds true for any transformation matrix, it's just not as easy to visualize as it is with the identity matrix.

Therefore, any transformation matrix is really just an axis system.

To construct an axis system then, you can simply create an identity matrix, and apply transformations to the matrix to put the matrix into the coordinate system you need. For example, if you had an axis system that was rotated 45 degrees about the Z axis and centered at (10, 20, 30) you could use the following code to build it:

```
Matrix3 mat(1); // Identity  
mat.RotateZ(DegToRad(45.0f));  
mat.SetTrans(Point3(10.0f, 20.0f, 30.0f));
```

## **Transformation Matrix Demonstration Program**

There is a program available in `\MAXSDK\SAMPLES\HOWTO\TMATTEST\TMATTEST.CPP` that shows visually how matrices are constructed for move/rotate/scale transformations. This program also shows the results of some of the **INode** methods that return transformation matrices (for example, **GetNodeTM()**, **GetObjectTM()**, etc.). Developers can load this project into VC++ and build it. Then copy the DLU from `\MAXSDK\PLUGIN\TMATTEST.DLU` into the **STDPLUGS** directory where 3ds max can load it. To run it select **TMatTest** from the **HowTo** section of the Utilities menu. The program operates on the first object in the selection set. Create a node in the scene (for instance a Box) and experiment with animating the node, binding it to space warps, etc., and viewing the resulting matrices returned from the INode methods. You can also build transformations from scratch and apply them to the first selected object.

# Memory Allocation

See Also: [Class Animatable](#), [Dll Functions and Class Descriptors](#), [Class ClassDesc](#).

## Overview

The 3ds max API provides a method used to allocate memory when a new instance of a plug-in class is required. It also provides several different ways to deallocate this memory depending on the plug-in type. In the most common case, these methods are **ClassDesc::Create()** and **Animatable::DeleteThis()**.

## Methods

When 3ds max needs to create a new instance of a plug-in class, it calls the **Create()** method of the class descriptor. This method returns a new instance of the plug-in class. The memory for the class may be allocated by using the **new** operator as shown below:

```
void *Create(BOOL loading = FALSE) { return new MyObject; }
```

For example, when 3ds max loads a file from disk it needs to create instances of the plug-ins that are used (the geometric objects, lights, cameras, materials, controllers, etc.). It does this by calling **ClassDesc::Create()**.

The memory must be freed when 3ds max is done with the item. Usually a method named **DeleteThis()** is called. This method is called to free the memory associated with the plug-in class. Since the memory was allocated with the **new** operator, it must be de-allocated using the **delete** operator as shown below:

```
void DeleteThis() { delete this; }
```

For plug-ins that are part of the **Animatable** class hierarchy, **DeleteThis()** is a method of **Animatable**. For plug-ins that are **not** derived from **Animatable** there may be a non-inherited **DeleteThis()** method. For example, the **UtilityObj** class used to create Utility plug-ins is **not** derived from **Animatable** and has its own **DeleteThis()**.

The **DeleteThis()** method also gives the developer control over deleting. For example, a Utility Plug-In object may be statically declared and not actually declared in the heap. A utility plug-in such as this would implement **DeleteThis()** to do nothing since there is no heap memory to free.

```
void DeleteThis() {}
```

This is just what the

**\MAXSDK\SAMPLES\UTILITIES\ASCIIOUT.CPP** code does.

A few plug-in types have no **DeleteThis()** method at all -- 3ds max deletes the memory directly. The Image Filter and Compositor plug-in types (subclassed from **ImageFilter**) are allocated using **ClassDesc::Create()** but are deleted by the system. In this case the plug-in has no **DeleteThis()** method to implement. The system just calls delete on the plug-in internally (using the **delete** operator).

## Modifier Stack Branching

See Also: [Geometry Pipeline](#), [Class Object](#), [Class INodeTransformed](#).

## Overview

This section discusses the concept of modifier stack branching. This section uses the boolean object plug-in as an example. The SDK sample code for the boolean object is available in

**\MAXSDK\SAMPLES\OBJECTS\BOOLOBJ.CPP**. Note: A developer may wish to read through the Advanced Topics section on the [Geometry Pipeline System](#) before reading the material below.

Normally the geometry pipeline is a single string of object references. For example, the node may have a reference to a derived object. This derived object may reference another derived object. That derived object may then reference the base object. Normally this is where the pipeline would end.

In some cases however, the base object itself has references to other objects. For example, the boolean object (referred to as a compound object) has references to its two operands. The boolean object acts like a multiplexer that decides which parts of the history is available to the user.

In the 3ds max user interface the modifier history is just a linear list. It does not show any kind of tree (branch) structure. Thus at any one time the user can only go down a single branch of the tree. It is up to the object to decide which branch the user is to go down. The standard way of doing this is to provide a user interface control to allow the user to select which branch they want to go down.

With the boolean object the user can go into sub-object selection and select one of the operands. Then that operand's history will become available in the modifier stack. Alternatively the boolean object provides a list of the operands and the user can select them there. When this is done this history becomes available and the user can operate on the selected history.

## Methods used in Modifier Stack Branching

This section presents the class methods a developer works with to manage an object that uses modifier stack branching. The following methods from class **Object** are involved:

### **virtual int NumPipeBranches()**

This method returns the number of pipeline branches combined by the object. This is not the total number of branches, but rather the number that are active. For example, in the boolean object, if the user does not have any operands selected, this methods would return zero. If they have one selected it would return one. Here is the boolean object implementation of this method:

```
int BoolObject::NumPipeBranches()  
{  
    int num=0;  
    if (TestFlag(BOOL_OB1SEL) && ob1) num++;  
    if (TestFlag(BOOL_OB2SEL) && ob2) num++;  
    return num;  
}
```

The boolean object is set up so that a user can only branch down one pipeline at a time. This is not always the case for all compound objects. In the 3ds max loft object, the user may select many shapes on the loft path. For example, the user could select five shapes on the path. **NumPipeBranches()** would return five to indicate that five pipelines are currently active. If all five shapes were the same instance, the user could go down their history all at the same time. This is analogous to when you select five objects in the scene, and if all these objects are all instances (they have commonality) then their history is available. If you select five objects and they don't have commonality their history is not available. If they share commonality to a certain point, their history is available up to and including this point and then the history stops. The pipeline branches are similar. If there is commonality, the common history will be displayed.

### **virtual Object \*GetPipeBranch(int i)**

This method is called to return the 'i-th' branch of the compound object. As the system is calculating the history, when it reaches the base object where it would normally stop, it checks to see if there is any branching. The system calls **NumPipeBranches()** on the object. If this returns anything greater than zero it will then get each of the branches and continue its evaluation. Here is the

boolean object implementation of this method:

```
Object *BoolObject::GetPipeBranch(int i)  
{  
if (i) return ob2;  
if (TestFlag(BOOL_OB1SEL)) return ob1;  
return ob2;  
}
```

```
virtual INode *GetBranchINode(TimeValue t,INode *node,int i)
```

Compound objects like the boolean object or the lofted contain multiple objects and the history of each of these objects can be edited. A problem arises because these compound objects usually apply a transformation to their input objects. For example, the boolean object has a transformation for each of its two operand objects. The boolean object has two operands and each has a transform controller. These transform controllers represent the transformation relative to the boolean object's transformation (its local space). This allows the user to move the two boolean operands around relative to each other without modifying the boolean object's node's transform controller. This arrangement simply provides an additional transformation for the operands.

If the user goes back into the history to edit one of the boolean object's operands and applies an Edit Mesh modifier, the Edit Mesh modifier does not know about the transformation that is happening in the pipeline downstream. Thus it thinks the object is positioned somewhere where it is not since it has no way of knowing about this other transformation. This is a problem (for example if you try to hit test) because the plug-in thinks the object is in the wrong place.

In general every item in the pipeline applies a transformation of some sort. An Edit Mesh modifier deals with this by forcing 'Show End Result' to be off. Currently show end result only effects downstream **modifiers** and not downstream objects so the transformation by the compound object still applies.

The transformation applied by the compound object typically is a linear transformation which, of course, can be inverted. So one **can** edit in the context of the transformation if it is known what it is. Methods are available to make it possible for compound objects to provide access to this transformation:

```
INode *GetBranchINode(TimeValue t, INode *node, int i)
```

This **Object** method will allow a compound object to alter a node's transformation. The way it does this is by creating an item called an

**INodeTransformed.** An **INodeTransformed** is simply a wrapper around an **INode** that adds in an extra transformation to the node's transformation. An object can implement this method by returning a pointer to a new **INodeTransformed** that is based on the node passed into this method. Here is the boolean object implementation of this method:

```
INode *BoolObject::GetBranchINode(TimeValue t, INode *node,  
int i)  
{  
    assert(i<2);  
    int index = 0;  
    if (i) index = 1;  
    else if (TestFlag(BOOL_OB1SEL)) index = 0;  
    else index = 1;  
    return CreateINodeTransformed(node,GetOpTM(t,index));  
}
```

When a modifier, like an Edit Mesh, calls **GetModContexts()** some of the **INodes** in the **INodeTab** may actually be pointing to **INodeTransforms**. When the modifier is done with the table, these wrappers need to be discarded. The method **INodeTransformed::DisposeTemporary()** is provided for this purpose.

## Notifying Dependents of the History Change

One other task needs to be done by a compound object that deals with modifier stack branching. The system needs to be notified when the branching changes. For example, in the boolean object if the user has selected operand A, and then selects operand B (which de-selects operand A) the history must be updated to show the history for operand B. 3ds max does not know that the user just changed operands as that is handled by the boolean object. To let the system know, the boolean object sends the message **REFMSG\_BRANCHED\_HISTORY\_CHANGED** via **NotifyDependents()**. This lets the system know it needs to re-build the history from this point on. For more details on sending messages see the Advanced Topics section on [References](#).

# Network Rendering

See Also: [Class MaxNetManager](#), [Class MaxNet](#)

## Overview

One of the new components of 3ds max R4 is a redesigned Network Rendering pipeline and API that allows developers to take full advantage to this easily accessible architecture. The core of the Network Rendering API is exposed through the **MaxNetManager** class which allows clients to connect to the Network Rendering Manager to perform any and all functions offered. The Network Rendering API encapsulates all the network rendering details and thus leaves the client code to concentrate on whatever it needs to do. The API handles all the networking code and communication protocols.

Within MAX, the Network Job Assignment dialog uses the Network Rendering API to submit new jobs to the network queue while the Queue Manager uses the API to provide all of its functionality. Neither of these components have any other type of network access or private access to network rendering facilities. The **MaxNet** API provides all of these itself.

The entire API is derived from the **MaxNet** class, which is used solely for exception handling. In order to handle exceptions you can catch a MaxNet type as follows:

```
try {  
    // the code being tried  
} catch (MaxNet* maxerr) {  
    // handle the error  
    // do NOT delete maxerr  
    // use maxerr->GetErrorText() to get the error description  
    // use maxerr->GetError() to get the error code  
}
```

The MaxNet class provides the error code in both numeric form, through **GetError()** in the form of **maxnet\_error\_t** type, and in text form, through **GetErrorText()**. Most methods in the Network Rendering API will return errors only through this mechanism, particularly methods that handle network transactions.

The Network Rendering API provides two functions that deal with the creation and destruction of the **MaxNetManager** class instance, these are, **MaxNetManager\* CreateManager()** and **DestroyManager(MaxNetManager\* mgr)**. The **CreateManager()** function will return a newly created instance of the **MaxNetManager** class which can be deleted, when done, by **DestroyManager()**.

## Queue Control

At any given moment, only one connected client can be in control of the network queue. This means, only one connected client can perform changes. All other clients operate in a "read only" mode.

## MaxNetCallback

The Network Rendering API provides a callback mechanism through the **MaxNetManager** class. If you wish to use the callback mechanism you can create your own class derived from **MaxNetCallback** and pass it as the argument for **MaxNetManager::SetCallback()**. All methods are optional, thus you only need to implement those you require.

## Network Rendering API by Example

Two full examples on how to use the MaxNet API are included in the SDK under **\MAXSDK\SAMPLES\NETRENDER\LISTJOBS** and **\MAXSDK\SAMPLES\NETRENDER\JOBASSIGN**.

Note with these samples that the use of the Network Rendering API is not limited to 3ds max plugins only.

# Nodes

See Also: [Class INode](#), [The Node and Object Offset Transformations](#).

## **Overview**

This section presents information on nodes. This includes what they are, their function within MAX, the main class for working with nodes, an overview of their reference structure, and a section on instancing nodes.

## **What are Nodes?**

Nodes are the items in the 3ds max that have a one to one correspondence with objects in the scene. Every procedural object, light, camera, helper object, etc. that appears in the viewports has an associated node. The node stores many properties that allow the item associated with the node to relate to the scene. These are properties such as a transform controller, a material used for rendering, a visibility controller, hidden/unhidden state, frozen/thawed state, wireframe color, and many more.

## **Class INode**

The methods available to work with nodes are from [Class INode](#). These methods provide the functions such as evaluating the geometry pipeline for the node, getting and setting the node name, working with parent/child hierarchies, accessing display attributes of the node, providing access to controllers, etc.

## Node Grouping

A 3ds max user can take a node in the scene and make it part of a group. Groups allow the user to select all the nodes in the group as one element without having to select each piece. Groups can be included in other groups so nesting can occur. There is a method in **INode** that indicates if a node is included in a group. This is **IsGroupMember()**. It returns TRUE if the node is in a group and FALSE if not.

The group is constructed by creating an invisible dummy object and linking the group members to this dummy. The dummy node is called the group head. The **INode** method **IsGroupHead()** tells if the node is one of the dummy nodes that heads a group. It returns TRUE if the node is a group head dummy and FALSE if not. Note that if the group was nested, that is it's a member of another group, it may have its **IsGroupMember()** boolean set as well.

If you have a member of a group and want to get a pointer to the group head use **GetParentNode()**. If you go through the children of the head (and all their children), and all the member booleans are set, the nodes are still part of the same group.

Groups may be opened allowing the user to edit the individual components (without otherwise breaking up the group). The method **IsOpenGroupMember()** returns TRUE if the node is a member of an open group and FALSE if not. Heads can check if they are open by calling **IsOpenGroupHead()**.

## Nodes and References

A node maintains six references (see the Advanced Topics section [References](#) for more details) that allow it to get notified when items that affect it change. These references are listed and defined below:

### **Reference 0: The Transform Controller.**

This is a reference to the node's transform controller. This controller governs the position, rotation and scaling of the node in the scene. Developers can get and set the transform controller used by the node using **INode::**

**GetTMController()** and **SetTMController()**. Most nodes use the Position/Rotation/Scale transform controller (for example mesh objects). Other items (such as target spotlights and cameras) use the Look At transform controller.

### **Reference 1: The Object Reference.**

Each node maintains a pointer to an object. This is a pointer to the base procedural object (mesh, light, camera) or a derived object (see the section [Geometry Pipeline System](#) for details on derived objects). The path that follows between object references are what make up a geometry pipeline in MAX. The node's object reference is where the pipeline starts.

### **Reference 2: The Pin Node for IK.**

This reference is a pointer to the pin node for Inverse Kinematics. This reference is not assigned by default and is thus NULL initially.

### **Reference 3: The Material Reference.**

Materials in 3ds max are assigned at the node level. There is a single material assigned per node. This reference is a pointer to the material for the node. A developer can get and set the material using the methods **INode::GetMtl()** and **SetMtl()**. If a material is assigned, this reference tracks it. This reference is not assigned by default and is thus NULL initially.

### **Reference 4: The Visibility Controller.**

In Track View the user can assign this visibility controller using the 'Add Visibility Track' icon. When this controller is assigned this reference points to the controller managing the node visibility. This reference is not assigned by default and is thus NULL initially.

### **Reference 5: The Image Blur Controller.**

This reference is not assigned by default and is thus NULL initially.

## **Node Hierarchies -- Parent / Child and Groups**

Nodes in 3ds max can be linked to one another to form parent / child hierarchies.

When a node is linked it receive the reference message

**REFMSG\_NODE\_LINK**. When it is unlinked it receives this same message.

Developers can manipulate the hierarchy using methods

**Inode::AttachChild()**, **Detach()**, and **GetParentNode()**. One can check if

a node is linked using **GetParentNode()**. If the pointer returned from that

method is the same as that returned from **IsRootNode()** then the node is not

linked.

## **Nodes and Transformations**

There are two transformation that affect all nodes. These are the node transformation and the object-offset transformation. For details on these see the Advanced Topic Section [Node and Object Offset Transformations](#).

## **Nodes and Instancing**

Nodes cannot be instanced. However, a developer can achieve functionally the same thing by instancing everything that the node points to. So, given two different nodes, if you instance the controllers, objects, and materials of all the child nodes then the hierarchies will behave as instances.

## The Node and Object Offset Transformations

See Also: [Class INode](#), [Class Interval](#), [Class Quat](#), [Class ScaleValue](#), [Matrix Representations of 3D Transformations](#), [Keyframe and Procedural Controller Data Access](#).

## Overview

This topic provides information on two transformations related to nodes -- the node transformation matrix and the object-offset transformation. This section also presents information on how these transformation are constructed, how they are used by MAX, and how they may be used by developers. This section also discusses the methods of the **Inode** class that access these transformations.

## **The Pivot Point -- The Node Transformation Matrix**

The transform center, or pivot point, is the location about which a rotation takes place, or to and from which a scale occurs. All nodes in 3ds max have a pivot point. You can think of the pivot point as representing a node's local center and local coordinate system.

The pivot point of a node is used for a number of purposes:

- As the center for rotation and scaling.
- Defines the transform origin for linked children.
- Defines the joint location for Inverse Kinematics.

The thing that most users think of as the pivot point -- graphically represented in 3ds max by the axis tripod that is displayed when a node is selected and the coordinate system is set to local -- is actually just a visual representation of the node's transformation matrix (NodeTM).

The node's transformation matrix is what is controlled by the transform controller that places the node in the scene. The transform controller controls the transformation relative to the node's parent.

## How a Transform Controller Computes the NodeTM

This section provides an overview of how 3ds max gets data from a transform controller to create the node transformation matrix (NodeTM).

A controller can be thought of as operating internally within its own local coordinate system. For both keyframe and procedural controllers, the data generated is provided in the local space of the controller. It is not until the controller supplies its transformation to 3ds max does the coordinate system become relative to anything other than the controller itself. The way this works is as follows:

All controllers are derived from class **Control** (or **StdControl**, which is itself derived from **Control**). Every controller, regardless of type, provides data to 3ds max at a specified time via a method of the **Control** class called **GetValue()**.

**Prototype:**

```
virtual void GetValue(TimeValue t, void *val, Interval &valid,  
    GetSetMethod method=CTRL_ABSOLUTE)=0;
```

One of the parameters passed to this method is **void \*val**. Depending on the controller type, different data types are passed using this pointer (see [Class Control::GetValue\(\)](#) for a complete discussion of all the data types). For example, a transform controller will be passed a **Matrix3** data type. It is the job of this transform controller to update the matrix with its transformation. It does this by **pre-multiplying** its transformation with the matrix passed. The controller operates within its own space internally, but when it pre-multiplies its data with the matrix passed, it essentially means the controller is then working in the coordinate system of the matrix. Another way to think of this is that the **Matrix3** passed is actually transforming the controllers data. Thus, what the final coordinate system ends up being depends upon the client of the controller and not on the controller itself -- it depends on the matrix passed to **GetValue()**.

To better understand this consider the following examples. For a transform controller, the matrix passed to **GetValue()** is the transformation matrix of the node's parent. Consider a simplified keyframe transform controller that only provided position (no rotation or scale). This controller would just update the bottom row of the matrix (translation data) passed by pre-multiplying its value. If the node the controller was assigned to was not hierarchically linked, that is it had no parent other than the world, then the matrix passed to **GetValue()** would

be the identity. In this case, when the controller pre-multiplied its value, it would simply be setting the translation row.

Consider a different case when the node the controller is assigned to is hierarchically linked. As before, the keys of the controller are stored in the local space of the controller. But in this case, when **GetValue()** is called, the matrix passed is not necessarily the identity. Rather it will be the transformation matrix of the parent of the node the controller is assigned to. If the parent is not located at the origin, or is scaled or rotated in some way, the parent matrix passed will provide an additional transformation to the one the controller itself provides.

For transform controllers, the matrix that is updated in **GetValue()** becomes the NodeTM and is used to position and orient the node in the scene. The next section discusses the way the transformations are applied to the matrix by the PRS controller to create the NodeTM.

## Construction of the NodeTM for the PRS Transform Controller

This section describes how 3ds max constructs the NodeTM for the PRS controller. The PRS controller uses sub-controllers to create the final transformation. There are three sub-controllers -- one for Position, one for Rotation and one for Scale. The PRS controller is passed a matrix to its **Control::GetValue()** method. This matrix is the parent of the node. If the node has no parent, the matrix starts out as the identity matrix. **GetValue()** is first called on the position controller, then the rotation controller, then the scale controller. In the case of a node with no parent, when its position controller's **GetValue()** method is called, the identity is passed. First the position controller pre-multiplies its position. If the matrix passed is the identity, this is equivalent to setting the bottom row (the translation row) of the matrix. Next, **GetValue()** is called on the rotation controller and the matrix passed includes the position controller information. The rotation is pre-multiplied in. Next, **GetValue()** is called on the scale controller and the matrix passed includes the position and rotation controller information. The scale is pre-multiplied in.

The position is not affected by rotation or scale. The rotation is affected by the position. The scale is affected by the position and rotation. Said another way, the position is in the space of the parent. The rotation is in the space of the parent PLUS the position (the position has already applied itself to the matrix). Scale works in the coordinate system of the parent PLUS position PLUS rotation. The scaling is pre-multiplied however, so the scaling takes place about the local coordinate system, but then if the node is rotated, this scaling is rotated around. If the transformations were not applied in this way, the scaling would be skewed by the rotation.

Note that some position controllers can actually apply more than just position to the matrix. For example, the Path Controller when the Follow switch is active. In this case, the position controller actually applies some rotation to have the node remain tangent to the path it is following. Thus when the rotation controllers receives the matrix in **GetValue()**, the matrix already has some rotation applied. The matrix passed to **GetValue()**, after the position, rotation and scale transformation have updated it, becomes the NodeTM 3ds max uses to position, rotate and scale nodes in the scene.

## Methods

There is a method of the **INode** class that a developer may use to get the node transformation matrix:

```
virtual Matrix3 GetNodeTM(TimeValue t, Interval*  
valid=NULL)=0;
```

This method returns the world space transformation matrix of the node at the specified time. This matrix contains its parents transformation. The Node TM is inherited. The Node TM may be considered the world space transformation as far as kinematics is concerned.

There are two methods that a developer may use to set the node transformation matrix. From **INode** is:

```
virtual void SetNodeTM(TimeValue t, Matrix3& tm)=0;
```

This sets the node's world space transformation matrix. This will call **SetValue()** on the transform controller.

The following method is from Class **Interface**:

```
virtual void SetNodeTMRelConstPlane(INode *node, Matrix3&  
mat)=0;
```

This sets the node's transform relative to the current construction plane. This may be used during creating so you can set the position of the node in terms of the construction plane and not in world units.

## **The Object-Offset Transformation**

The object offset transformation provides an offset of the geometry of an object from its node. This section describes the object offset transformation and its function in MAX.

One can see a node's pivot point graphically represented in 3ds max by selecting a node, going to the Hierarchy branch of the command panel, selecting the 'Pivot' button, and choosing either the 'Affect Pivot Only' or 'Affect Object Only' button. This displays a large axis tripod that shows the location and orientation of the node's pivot point (NodeTM). By choosing one of these buttons, and using the Move/Rotate/Scale toolbar controls, a user can manipulate the position of the geometry of the object independent of the pivot point. Or they may manipulate the pivot point independent of the geometry of the object position. One can think of the geometry of the object as the 'mesh' of the object.

The way the user is able to independently manipulate the pivot and the object is managed internally using the object-offset transformation. The object-offset transformation affects how the geometry of the object is related to the node. The object-offset transformation transforms the geometry of the object itself some amount from the node.

To understand how the object-offset is used, consider the following example from the 3ds max user interface. In the Hierarchy branch under 'Pivot', when the user has chosen the 'Affect Object Only' button they are free to move the geometry of the object around independent of the node. The pivot point does not move -- only how the geometry of the object is oriented relative to the pivot. What is happening internally is the object-offset transformation is being manipulated. This transformation is simply an additional offset that may be applied to the geometry of the object that is independent of the node. The object-offset transformation is not inherited by any child nodes.

As another example consider the use of the 'Affect Pivot Only' button. This mode lets the user move the pivot without affecting the position of the geometry of the object. When the system allows the user to move the pivot point, what is actually happening is the node's transformation is being altered (to re-orient the pivot point), then the object-offset transformation is adjusted to counter the node transformation. This lets the geometry of the object stay in the same place while the pivot point moves around. So again, when the user is moving the pivot point, 3ds max is actually adjusting the node transformation matrix and counter-adjusting the object-offset transformation.

## **Construction of the Object Offset Transformation**

The object offset transformation consists of separate position, rotation and scale transformations. Like the NodeTM, these are applied by pre-multiplying position, then rotation, then scale. Thus the object offset transformation is:

Object Offset Transformation = Offset Scale \* Offset Rotation \* Offset Position

Unlike the NodeTM, the Object Offset Transformation is not inherited by children of the node.

## Methods

The **INode** class has methods to get and set individual transformations of the object offset. These are:

**virtual void SetObjOffsetPos(Point3 p)=0;**

Sets the position portion of the object offset from the node.

**virtual Point3 GetObjOffsetPos()=0;**

Returns the position portion of the object-offset from the node as a Point3.

**virtual void SetObjOffsetRot(Quat q)=0;**

Sets the rotation portion of the object offset from the node.

**virtual Quat GetObjOffsetRot()=0;**

Returns the rotation portion of the object-offset from the node.

**virtual void SetObjOffsetScale(ScaleValue sv)=0;**

Sets the scale portion of the object offset from the node.

**virtual ScaleValue GetObjOffsetScale()=0;**

Returns the scale portion of the object-offset from the node.

Constructing an offset TM for a node is done with the following code:

```
Matrix3 tm(1);
```

```
Point3 pos = node->GetObjOffsetPos();
```

```
tm.PreTranslate(pos);
```

```
Quat quat = node->GetObjOffsetRot();
```

```
PreRotateMatrix(tm, quat);
```

```
ScaleValue scaleValue = node->GetObjOffsetScale();
```

```
ApplyScaling(tm, scaleValue);
```

The **INode** class has a set of methods that allow a developer to transform the node or geometry in the same way as the hierarchy Affect Pivot Only and Affect Object Only modes do. The entire node and object may be transformed, just the pivot, or just the geometry of the object. These methods are:

```
virtual void Move(TimeValue t, const Matrix3& tmAxis,  
const Point3& val, BOOL localOrigin=FALSE,  
BOOL affectKids=TRUE, int pivMode=PIV_NONE,  
BOOL ignoreLocks=FALSE)=0;
```

This method may be called to move the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the

object may be transformed. Optionally, any children of the node can be counter transformed so they don't move.

```
virtual void Rotate(TimeValue t, const Matrix3& tmAxis,  
    const AngAxis& val, BOOL localOrigin=FALSE,  
    BOOL affectKids=TRUE, int pivMode=PIV_NONE,  
    BOOL ignoreLocks=FALSE)=0;
```

This method may be called to rotate the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't rotate. There is also a Quat version of this method.

```
virtual void Scale(TimeValue t, const Matrix3& tmAxis,  
    const Point3& val, BOOL localOrigin=FALSE,  
    BOOL affectKids=TRUE, int pivMode=PIV_NONE,  
    BOOL ignoreLocks=FALSE)=0;
```

This method may be called to scale the node about the specified axis system. Either the pivot point, or the geometry of the object, or both the pivot and the object may be transformed. Optionally, any children of the node can be counter transformed so they don't scale.

## The ObjectTM

The `INode` method **GetObjectTM()** returns the transformation matrix an object needs to be multiplied by to transform it into world space. This includes the parent transformation, the node transformation (NodeTM) and the Object Offset Transformation. Thus, the entire transformation used to transform the points of any object is:

$$\text{ObjectTM} = \text{Offset Scale} * \text{Offset Rotation} * \text{Offset Position} * \text{Controller Scale} * \text{Controller Rotation} * \text{Controllers Position} * \text{Parent Transformation}.$$

A developer can retrieve the entire transformation of the object-offset, node and parent using the **INode** method:

```
virtual Matrix3 GetObjectTM(TimeValue time, Interval* valid=NULL)=0;
```

This is the entire transformation of a node. When an object is actually translated into world space, this is the matrix used. This is the Object Offset Transformation, plus the NodeTM, plus the world space modifier effect.

This matrix could be used, for example, if you have a **TriObject** and wanted to get the world space coordinate of one of its vertices. You could do this by taking the vertex coordinate in object space and multiplying it by the matrix returned from this method.

The ObjectTM is not inherited. See the remarks on this method in the reference section documentation for more details.

## **A Sample Plug-In Using the Node and Object Offset Transformations**

The following code is from the Reset Transform utility (**MAXSDK\SAMPLES\MODIFIERS\RESETTM.CPP**). This utility is used to push object rotation and scale values onto the Modifier Stack and align object pivot points and bounding boxes with the world coordinate system. Reset Transform removes all rotation and scale values from selected objects and places those transforms in an XForm modifier. The code below demonstrates the use of the TMs discussed above.

As previously noted, there are two transforms that affect an object: the node transform which is the result of the transform controller plus inheritance, and the object offset transform which positions the geometry relative to the pivot point. The Reset Transform utility takes the node transform (minus inheritance), and the offset transform, and combines them into a matrix which is given to an XForm modifier which is then placed at the top of the modifier stack.

The node and offset transforms can then be set back to the identity (actually, the position component of the node TM is left unchanged). Here is the code -- it operates on all the selected nodes.

```
for (int i=0; i<ip->GetSelNodeCount(); i++) {  
    INode *node = pi->GetSelNode(i);  
    Matrix3 ntm, ptm, rtm(1), piv(1), tm;  
  
    // Get Parent and Node TMs  
    ntm = node->GetNodeTM(ip->GetTime());  
    ptm = node->GetParentTM(ip->GetTime());  
  
    // Compute the relative TM  
    ntm = ntm * Inverse(ptm);  
  
    // The reset TM only inherits position  
    rtm.SetTrans(ntm.GetTrans());  
  
    // Set the node TM to the reset TM  
    tm = rtm*ptm;  
    node->SetNodeTM(ip->GetTime(), tm);
```

```
// Compute the pivot TM
piv.SetTrans(node->GetObjOffsetPos());
PreRotateMatrix(piv,node->GetObjOffsetRot());
ApplyScaling(piv,node->GetObjOffsetScale());

// Reset the offset to 0
node->SetObjOffsetPos(Point3(0,0,0));
node->SetObjOffsetRot(IdentQuat());
node->SetObjOffsetScale(ScaleValue(Point3(1,1,1)));

// Take the position out of the matrix since
// we don't reset position
ntm.NoTrans();

// Apply the offset to the TM
ntm = piv * ntm;

// Apply a derived object to the node's object
Object *obj = node->GetObjectRef();
IDerivedObject *dobj = CreateDerivedObject(obj);

// Create an XForm mod
SimpleMod *mod = (SimpleMod*)ip->CreateInstance(
OSM_CLASS_ID,
Class_ID(CLUSTOSM_CLASS_ID,0));

// Apply the transformation to the mod.
SetXFormPacket pkt(ntm);
mod->tmControl->SetValue(ip->GetTime(),&pkt);

// Add the modifier to the derived object.
ModContext* mc = new ModContext(new Matrix3(1), NULL,
NULL);
dobj->AddModifier(mod, mc);
```

```
// Replace the node's object  
node->SetObjectRef(dobj);  
}
```

## The 'Local' Transformation Matrix

To retrieve what is considered the local transformation (the transformation of a node relative to its parent) you must perform some matrix arithmetic on the nodes world space transformation (NodeTM). This is because there is not a local transformation matrix of a node stored by MAX.

What is often considered the local transformation is the transformation matrix of the node relative to its parent. However, the transformation of a node relative to its parent may be some function of the node's parent's transform. For example, a transform controller takes the parent's TM and modifies it. When a node evaluates itself it takes the parent's TM and passes it as an argument when it calls **GetValue()** on its transform controller. The task of a transform controller in its implementation of **GetValue()** is to modify this matrix. It applies its transformation to the parent transformation passed in.

In some cases this modification may be just a simple pre-multiplication by what is considered the local transformation matrix. But it may be some other more-complicated process. For example, if rotation or scale inheritance is turned off, the transform controller takes the parent's matrix and perhaps removes rotation from it, or removes scaling from it, and then applies itself. As another example, it may use the parent's position as a function to derive rotation -- as in a Look At controller. Thus, what is considered the local transformation is a function of the transform controller and is not stored by MAX.

What 3ds max does store is the node's world space transformation matrix (NodeTM). This matrix includes the parent's transformation. To understand how the local transformation can be extracted from the world space transformation consider the following:

Any transformation is made up by starting with the node, and then multiply it by its parent, and then by its parent, and so on, all the way through the ancestors.

This is shown below:

$$\text{NodeWorldTM} = \text{NodeLocalTM} * \text{ParentLocalTM} * \text{ParentLocalTM} * \text{ParentLocalTM}, \text{ etc.}$$

The parents world transformation is equal to the product of all its ancestors, so:

$$\text{ParentWorldTM} = \text{ParentLocalTM} * \text{ParentsLocalTM} * \text{ParentsLocalTM}, \text{ etc.}$$

The nodes world transform can then be expressed as:

$$\text{NodeWorldTM} = \text{NodesLocalTM} * \text{ParentWorldTM}.$$

If we multiply both sides of this equation by the Inverse of the ParentsWorldTM

and simplify we get:

$$\text{NodeLocalTM} = \text{NodeWorldTM} * \text{Inverse}(\text{ParentWorldTM})$$

So, to retrieve what is considered the local transformation you must get the parent's transform and multiply the node's transform by the inverse of the parent. The way this is computed using the methods of 3ds max is shown in the following code fragment. This example assumes **node** is the **INode\*** that we want the local TM from, and the result will get stored in **localTM**:

```
...
INode *parent;
Matrix3 parentTM, nodeTM, localTM;
nodeTM = node->GetNodeTM(0);
parent = node->GetParentNode();
parentTM = parent->GetNodeTM(0);
localTM = nodeTM*Inverse(parentTM);
...
```

## Node Linking and Grouping

This section discusses the linking and grouping of nodes, and the effect this has on the transformations of the nodes.

In MAX, nodes in the scene may be linked together to form a hierarchy. A node that is linked to another node is referred to as a child node. A node that has children is referred to as a parent node. A node may have several children, but only a single parent. See [Parent Child Hierarchy](#) for more details.

Nodes may also be grouped. When nodes are grouped together, 3ds max effectively creates a new dummy node, and links the group nodes to the parent dummy node. 3ds max maintains other information such as if the group is open or closed, etc., but this just effects the user interface. Essentially grouping is just like linking all the nodes to a dummy.

The following discussion applies to both linking and grouping (since grouping is just a special case of linking).

When a parent-child link is created, the user will not want the nodes in the scene to move. To ensure that the nodes won't move, the transform controllers of the nodes need to be modified. This is because the reference coordinate system has changed. The TM controller is working in a coordinate system which is its parent's coordinates system. When a node is unlinked, its reference coordinate system is the world coordinate system. When a node is linked, its reference coordinates system becomes its parents. So, when nodes are linked the parents change, and 3ds max must adjust the transformation matrices to counteract the change in reference coordinates system. All the keys created by a keyframe transform controller must be updated to reflect the change. When a developer creates the link, the nodes and keys must be adjusted in a similar fashion. An option to the INode method **AttachChild()** that links a node as a child allows this to be done automatically.

**virtual void AttachChild(INode\* node, int keepPos=1)=0;**

Makes the specified node a child of this node. If **keepPos** is nonzero, the child is adjusted as needed to keep it from moving. **keepPos** counters the change in the reference coordinate system.

## Access to Node Controller Data

In addition to accessing the node and object offset transformations, developers may want to access the keyframes or data of a node's transform controller. See the Advanced Topics section [Keyframe and Procedural Controller Data Access](#) for information and sample code.

## Summary

The node maintains two transformations. The node's transformation matrix is what is controlled by the transform controller that places the node in the scene. The object-offset transformation represents a separate position, rotation and scale orientation of the geometry of the object independent of the node. The primary methods available to work with the node and these matrices are part of the **INode** class.

## Object Creation Methods

See Also: [Class BaseObject](#), [Class Interface](#), [Class CommandMode](#), [Class MouseCallBack](#), [Class ClassDesc](#), [Class Matrix3](#), [Class IDerivedObject](#).

## Overview

This section discusses several different approaches a developer may use to manage the object creation process for their plug-in.

In many cases the creation process of an object is handled by the system. For example, in the procedural sphere, the developer simply provides a callback object to handle the user / mouse interaction. This is done using the method **BaseObject::GetCreateMouseCallback()**. This method returns a callback object that handles the user input during the creation process. The system takes care of calling this callback as the user works with the mouse. It also takes care of creating the instance of the plug-in class, creates the node in the scene, and sets the node's object reference to point to the plug-in object. Thus the system handles most of the work.

In certain cases a developer may need to manage the creation process at a lower level in order to provide special functionality. Two methods of the plug-in's Class Descriptor, **BeginCreate()** and **EndCreate()**, allow the plug-in to manage the process. When the system is about to create a plug-in object **BeginCreate()** is called. If the plug-in does not wish to have a custom creation process it can return 0 from this method and the system will invoke the default process. The default implementation of this method returns 0, so if the plug-in does not override it the system handles the creation. If the plug-in does require a custom creation phase, it does so in its implementation of this method. When it is finished it returns nonzero to indicate it does not want the default process invoked.

The target camera is an example of a plug-in that must handle its own creation process. This is because it creates two nodes in the scene: the camera and the target. It also must link the camera to the target using a lookat controller that ensures the camera is always 'looking at' the target. The system-managed creation procedure using **GetCreateMouseCallback()** is not adequate to meet the needs of this plug-in. Therefore the target camera implements **ClassDesc::BeginCreate()** and **ClassDesc::EndCreate()**. You may review the source code for this plug-in in **\MAXSDK\SAMPLES\OBJECTS\CAMERA.CPP**.

Note that **GetCreateMouseCallback()** is pure virtual. Therefore plug-ins derived from **BaseObject** that use **ClassDesc::BeginCreate()** must still provide a NULL implementation of this method. This may be done by

implementing it as:

```
CreateMouseCallBack* GetCreateMouseCallBack() {return NULL;}
```

Another plug-in that manages its own creation process by implementing

**BeginCreate()** and **EndCreate()** is the Ring Array system.

As a final note about these methods, a plug-in developer can force the system to call **ClassDesc::EndCreate()** by calling the method

**Interface::StopCreating()**. This terminates the creation process.

## Objects, Nodes and Derived Objects

A developer may wish to create instances of the standard 3ds max primitives. For example, an import / export plug-in might want to create standard 3ds max spheres, cones, tori, etc. APIs are provided so a plug-in can create objects and nodes in the scene. Additionally plug-ins can create derived objects to add modifiers to objects. This section introduces the methods required and provides some sample code demonstrating their use.

The standard 3ds max primitives, or in fact any plug-in procedural object that 3ds max has registered, may be created given the ClassID and SuperClassID of the object. This is done using the following method:

```
virtual void *CreateInstance(SClass_ID superID, Class_ID classID)=0;
```

This creates an instance of a registered class. This will call **Create()** on the class descriptor. This method returns a pointer to the specified object. For reference see [List of Class IDs](#) and [List of Super Class IDs](#). Note: This method is from class Interface, but there is also a global version of this API that may be used at any time (defined in `\MAXSDK\INCLUDE\PLUGAPI.H`).

To set the parameters for these objects methods of **BaseObject** are available:

```
virtual IParamArray *GetParamBlock();
```

If an object or modifier wishes, it can make its parameter block available for other plug-ins to access. This method returns a pointer to the item's parameter block.

```
virtual int GetParamBlockIndex(int id);
```

If a plug-in makes its parameter block available (using **GetParamBlock()**) then it will need to provide #defines for indices into the parameter block. These #defines should not be directly used with the parameter block but instead converted by this function that the plug-in implements. In this way if a parameter moves around in a future version of the plug-in the #define can be remapped.

For reference see [List of Parameter Block IDs](#). This lists all the parameter block indices for the standard plug-ins that ship with MAX.

Note: To use these parameter block IDs, make sure you have the following statement in your source code:

```
#include "istdplug.h"
```

To create a node in the scene given an object pointer use this method from class Interface:

```
virtual INode *CreateObjectNode( Object *obj )=0;
```

This creates a new node in the scene with the given object. Methods of INode allow the node to be named, and assigned a transform controller.

Developers may also create derived objects and add modifiers to objects.

Methods of class **IDerivedObject** are available for this purpose. For example:

```
virtual void AddModifier(Modifier *mod, ModContext  
*mc=NULL,  
int before=0)=0;
```

Adds a modifier to this derived object.

The following code, from

**\MAXSDK\SAMPLES\UTILITIES\UTILTEST.CPP**, demonstrates the use of these methods.

```
#include "istdplug.h"  
void UtilTest::MakeObject()  
{  
    // Create a new object through the CreateInstance() API  
    Object *obj = (Object*)ip->CreateInstance(  
        GEOMOBJECT_CLASS_ID,  
        Class_ID(CYLINDER_CLASS_ID,0));  
    assert(obj);  
    // Get a hold of the parameter block  
    IParamArray *iCylParams = obj->GetParamBlock();  
    assert(iCylParams);  
    // Set the value of radius, height and segs.  
    int rad = obj->GetParamBlockIndex(CYLINDER_RADIUS);  
    assert(rad>=0);  
    iCylParams->SetValue(rad,TimeValue(0),30.0f);  
    int height = obj->GetParamBlockIndex(CYLINDER_HEIGHT);  
    assert(height>=0);  
    iCylParams->SetValue(height,TimeValue(0),100.0f);  
    int segs = obj->  
>GetParamBlockIndex(CYLINDER_SEGMENTS);
```

```

assert(segs>=0);
iCylParams->SetValue(segs,TimeValue(0),10);
// Create a derived object that references the cylinder
IDerivedObject *dobj = CreateDerivedObject(obj);
// Create a bend modifier
Modifier *bend = (Modifier*)ip->CreateInstance(
    OSM_CLASS_ID,
    Class_ID(BENDOSM_CLASS_ID,0));
// Set the bend angle
IParamArray *iBendParams = bend->GetParamBlock();
assert(iBendParams);
int angle = bend->GetParamBlockIndex(BEND_ANGLE);
iBendParams->SetValue(angle,TimeValue(0),90.0f);
// Add the bend modifier to the derived object.
ModContext* mc = new ModContext(new Matrix3(1), NULL,
NULL);
dobj->AddModifier(bend, mc);
// Create a node in the scene that references the derived object
INode *node = ip->CreateObjectNode(dobj);
// Name the node and make the name unique.
TSTR name(_T("MyNode"));
ip->MakeNameUnique(name);
node->SetName(name);
// Redraw the viewports
ip->RedrawViews(ip->GetTime());
}

```

Here is another piece of sample code that creates a shape object using the CreateInstance API. This example creates a circle, but one could modify it to create lines or other shapes.

```

// Vector length for unit circle
#define CIRCLE_VECTOR_LENGTH 0.5517861843f

void Utility::Test() {
    Interface *ip = theUtility.ip;
    Object *obj =

```

```

(Object*)ip->CreateInstance(SHAPE_CLASS_ID, splineShapeClassID);

SplineShape *ss =(SplineShape *)obj;
BezierShape &ashape = ss->GetShape();
ashape.NewShape();
Spline3D *spline = ashape.NewSpline();

float radius = 300.0f;
float vector = CIRCLE_VECTOR_LENGTH * radius;

for(int ix=0; ix<4; ++ix) {
    float angle = 6.2831853f * (float)ix / 4.0f;
    float sinfac = (float)sin(angle), cosfac = (float)cos(angle);
    Point3 p(cosfac * radius, sinfac * radius, 0.0f);
    Point3 rotvec = Point3(sinfac * vector, -cosfac * vector, 0.0f);
    spline->AddKnot(SplineKnot(KTYPE_BEZIER,LTYPE_CURVE,
        p,p + rotvec,p - rotvec));
}
spline->SetClosed();
spline->ComputeBezPoints();
ashape.UpdateSels();
ashape.InvalidateGeomCache();

INode *node = ip->CreateObjectNode(obj);
TSTR name(_T("MySplineNode"));
ip->MakeNameUnique(name);
node->SetName(name);

// Redraw the views
ip->RedrawViews(ip->GetTime());
}

```

## Other Methods of Object Creation - NonMouseCreate()

A method of class Interface named **NonMouseCreate()** may be used to create a new object / node without going through the usual create mouse proc sequence. This call must be made when the system is ready to create -- that is during execution of the system-provided default object creation process. To understand how this works consider the example of the procedural sphere.

When the user selects Sphere from the 3ds max UI, an instance of the sphere is created and its parameters appear. There is not a node in the scene, but an instance of the object is created. The user can then edit the sphere parameters before it is put in the scene. After a sphere is created, the creation process is in a different phase -- the user is editing the parameters of the sphere that was just created -- not the one about to be created. Therefore the first sphere is a special case -- the user can edit the parameters both before and after it is created. Subsequent spheres can only have their parameters edited after they are created. The procedural sphere's user interface allows the user to type in a center position and radius value and then press a 'Create' button. This creates a new sphere in the scene with these parameters. When the button is pressed it calls the method **NonMouseCreate()**.

When the **NonMouseCreate()** method is used, the default creation manager looks to see if a sphere has just been created in the scene. If there is one, it ends the creation phase on that sphere and creates a new one and puts it in the scene. If there is not a newly-created sphere yet, **NonMouseCreate()** will simply put the object into the scene.

Thus calling **NonMouseCreate()** treats the object creation just as if the user clicked the mouse in the viewport to create the object -- but they cannot interactively adjust the parameters. The method takes a single **Matrix3** argument which is the transformation relative to the construction plane. In the code below, the translation part of this matrix is set to the values the user typed in for the X, Y, and Z location of the sphere. The user is thus typing in values that are relative to the current construction plane.

The following code is from the procedural sphere. This is the code that is executed if the user presses the 'Create' button in the 'Keyboard Entry' rollup page. This allows the user to type in the values for the sphere's position and radius using the keyboard and then create the object.

**BOOL SphereTypeInDlgProc::DlgProc(**

```

TimeValue t,IParamMap *map,HWND hWnd,UINT msg,
WPARAM wParam,LPARAM lParam) {
switch (msg) {
case WM_COMMAND:
switch (LOWORD(wParam)) {
case IDC_TI_CREATE: {
// The user has pressed the create button...
// If the radius is zero there is nothing to create
// so just return.
if (so->crtRadius==0.0) return TRUE;
// We only want to set the value if the object is
// not in the scene.
if (so->TestAFlag(A_OBJ_CREATING)) {
so->pblock->SetValue(PB_RADIUS,0,so->crtRadius);
}
// Create an identity matrix
Matrix3 tm(1);
// Update the translation portion of the matrix to the
// creation position type-in parameter
tm.SetTrans(so->crtPos);
// Call the interface method to create the node...
// This will use the values in the objects pblock.
so->ip->NonMouseCreate(tm);
so->suspendSnap = FALSE;
// NOTE that calling NonMouseCreate() will cause this
// object to be deleted. DO NOT DO ANYTHING BUT RETURN.
return TRUE;
}
}
break;
}
return FALSE;
}

```

## **Summary**

There are several ways a developer may create objects in the scene. Some rely on the developer providing a custom creation process command mode and mouse proc. Others use the default object creation manager. In either case, developers may create any plug-in object that the system has loaded from its DLL at 3ds max start up. Plug-ins have access to the parameter block of all the standard 3ds max primitives. Developers may also add object modifiers to any of the objects created.

## Object Modification

See Also: [Class Modifier](#), [Class SimpleMod](#), [Class Object](#), [Class Deformer](#), [Class ModContext](#), [Class Mesh](#), [List of Channel Bits](#), [List of Class IDs](#), [Class BitArray](#).

## **Overview**

This topic presents information on modifying objects in MAX. It discusses how objects and modifiers interact to enable object modification, explains the various types of object modification, and shows key portions of sample code from modifiers of each type.

## Objects, Modifiers, and the Geometry Pipeline

Modifiers operate on objects flowing down a geometry pipeline. A geometry pipeline is the system 3ds max uses to process the modification of objects. There are several methods implemented by the objects and the modifiers that allow this to happen. First we'll look at what modifiers need to do to inform 3ds max about the nature of their modification. Then we'll examine what procedural objects need to do to make themselves 'modifyable'.

### Modifiers Request A Certain Type of Input

Modifiers may only operate on certain type of object. For example, the Edit Spline modifier only works on spline shapes. The Volume Select Modifier only works on TriObjects (triangle mesh objects). In order for the modifier to inform 3ds max what type of object it needs it implements the method

**Modifier::InputType()**. This method returns the **Class\_ID** of the type of object it needs for input. For example, the Edit Spline modifier implements this method as shown below:

```
Class_ID InputType() { return  
Class_ID(SPLINESHAPE_CLASS_ID,0); }
```

This tells 3ds max which objects the modifier can be applied to. Only those objects that are spline shapes, or are able to convert themselves to spline shapes, may be modified by Edit Spline. The same is true for Volume Select Modifier. It requires objects that are triangle meshes for it to do its work. Therefore it implements **InputType()** as shown below:

```
Class_ID InputType() { return Class_ID(TRIOBJ_CLASS_ID,0);  
}
```

When an object is selected in MAX, only those modifiers that are appropriate for modifying it are enabled in the user interface. This is done by querying the modifiers to see if their **InputType()** matches the **Class\_ID** of the selected object, or the objects that it can convert itself to. If it is, the modifier is enabled, otherwise its disabled.

### Modifiers Need To Indicate Which Geometry Pipeline Channels They Require and Alter

Objects flowing down the geometry pipeline are broken into separate channels. That is, the pipeline can operate on only portions of objects and not the entire thing as a whole. Some examples of channels that objects are broken into are the geometry portion (points), the topology portion (polygons or faces), the selection

level of the object (object, face, vertex, etc.), and its texture coordinates. The purpose of this is basically to allow the pipeline to operate more efficiently. Modifiers must inform 3ds max which channels they require to perform their modification. Copies of the needed channels are made and passed up the pipeline. 3ds max will only pass copies of a minimum set of needed channels up the pipeline. If a certain channel is not required by any modifiers anywhere in a pipeline it is not copied and passed along.

Modifiers inform 3ds max which channels they require by implementing the method **Modifier::ChannelsUsed()**. This list of channels must include the channels the modifier actually alters but may include more. Here is the implementation of **ChannelsUsed()** by the Volume Select modifier:

```
ChannelMask ChannelsUsed()  
{  
    return OBJ_CHANNELS;  
}
```

Note that **OBJ\_CHANNELS** is defined as:

```
#define OBJ_CHANNELS  
(TOPO_CHANNEL | GEOM_CHANNEL |  
SELECT_CHANNEL | TEXMAP_CHANNEL |  
MTL_CHANNEL | SUBSEL_TYPE_CHANNEL |  
DISP_ATTRIB_CHANNEL | VERTCOLOR_CHANNEL |  
GFX_DATA_CHANNEL)
```

This means that the pipeline must have all these channels up to date in the object that gets passed to the modifier before it can properly do its work. Technically, this is actually overkill for the Normals modifier. It wouldn't need the **TEXMAP\_CHANNEL** and **VERTCOLOR\_CHANNEL** since they aren't in fact used. It really only needs the **GEOM\_CHANNEL**, **TOPO\_CHANNEL**, and the **SELECT\_CHANNEL**.

A modifier must also inform 3ds max which channels it will actually alter its function as a modifier. It does this by implementing the method **Modifier::ChannelsChanged()**. Here is the implementation of **ChannelsChanged()** by the Volume Select modifier:

```
ChannelMask ChannelsChanged()  
{
```

```

return
    SELECT_CHANNEL|SUBSEL_TYPE_CHANNEL|GEOM_CH
}

```

This indicates that this modifier alters the selection channel, the sub-object selection channel, and the geometry channel. Note that the geometry channel is modified because the vertices themselves get selected via the **vertSel BitArray** in the **Mesh** class and are thus modified.

### **Objects May Need to Convert Themselves**

Procedural Objects don't always start out in a form suitable for a particular type of modifier. Consider the case of a 3ds max user putting a volume select modifier on a procedural sphere in order to select some vertices within it. A procedural sphere is not defined by vertices and faces. Rather it is defined by its procedural definition, i.e. its radius, segment count, hemisphere setting, etc. But a user can put a volume select modifier on a procedural sphere. The way this is handled is that 3ds max asks the object if it can be converted to a triangle mesh object (which has vertices and faces). If the sphere responds yes, then 3ds max asks the sphere to convert itself to one. Then, once the object is in the form of the triangle mesh, the modifier may alter it. There are two methods that procedural objects implement to allow this to happen. These are **Object::CanConvertToType()** and **Object::ConvertToType()**.

The code executed by the procedural sphere implementation of **CanConvertToType()** is as follows:

```

int SphereObject::CanConvertToType(Class_ID obtype)
{
    if (obtype==patchObjectClassID || obtype==defObjectClassID ||
        obtype==triObjectClassID ||
        obtype==EDITABLE_SURF_CLASS_ID) {
        return 1;
    } else {
        return SimpleObject::CanConvertToType(obtype);
    }
}

```

```

int SimpleObject::CanConvertToType(Class_ID obtype)
{

```

```

if (obtype==defObjectClassID || obtype==mapObjectClassID ||
    obtype==triObjectClassID || obtype==patchObjectClassID) {
    return 1;
}
return Object::CanConvertToType(obtype);
}

```

```

int Object::CanConvertToType(Class_ID obtype)
{
    return obtype==ClassID();
}

```

Note that the sphere answers true when asked if it can convert itself to a patch object, a deformable object (a generic object with points that can be modified), a triangle mesh object, and an editable surf object (NURBS object). In other cases it calls the base class method from **SimpleObject**. If **SimpleObject** doesn't recognize the type it calls its base class method from **Object**. The **Object** implementation returns nonzero if the object is asked to convert to itself, otherwise zero.

When 3ds max needs to actually have the object convert itself to the type required by the modifier it calls **ConvertToType()** on the object as passes the needed **Class\_ID**. Below is the code from the procedural sphere's implementation.

```

Object* SphereObject::ConvertToType(TimeValue t, Class_ID
obtype)
{
    if (obtype == patchObjectClassID) {
        Interval valid = FOREVER;
        float radius;
        int smooth, genUVs;
        pblock->GetValue(PB_RADIUS,t,radius,valid);
        pblock->GetValue(PB_SMOOTH,t,smooth,valid);
        pblock->GetValue(PB_GENUVS,t,genUVs,valid);
        PatchObject *ob = new PatchObject();
        BuildSpherePatch(ob->patch,radius,smooth,genUVs);
    }
}

```

```

ob->SetChannelValidity(TOPO_CHAN_NUM,valid);
ob->SetChannelValidity(GEOM_CHAN_NUM,valid);
ob->UnlockObject();
return ob;
} else if (obtype == EDITABLE_SURF_CLASS_ID) {
Interval valid = FOREVER;
float radius, hemi;
int recenter, genUVs;
pblock->GetValue(PB_RADIUS,t,radius,valid);
pblock->GetValue(PB_HEMI,t,hemi,valid);
pblock->GetValue(PB_RECENTER,t,recenter,valid);
pblock->GetValue(PB_GENUVS,t,genUVs,valid);
Object *ob = BuildNURBSSphere(radius, hemi,
recenter,genUVs);
ob->SetChannelValidity(TOPO_CHAN_NUM,valid);
ob->SetChannelValidity(GEOM_CHAN_NUM,valid);
ob->UnlockObject();
return ob;

} else{
return SimpleObject::ConvertToType(t,obtype);
}
}

```

The cases handled above cover converting to a patch or NURBS representation. The other cases are handled by the base classes.

In summary, an object must implement two methods to allow a modifier to operate upon it. These are **CanConvertToType()** and **ConvertToType()**.

## Types of Object Modification

This section presents information on the general types of modifiers possible in 3ds max and an overview of how they accomplish their modification. Code is presented for each showing the needed input type, channels changed and used, and the method that does the object modification.

There are many types of modifiers possible in MAX. The way they are classified is by which channel(s) of the geometry pipeline they operate on. Modifiers may operate on one or more channels. These channels are things such as geometry, topology, texture coordinates, sub-object selection level, vertex colors, as well as several others. See [List of Channel Bits](#) to review the full list of channels the pipeline is broken down into. The sections below show examples of modifiers that operate on many of these different channels. For each of these an analysis of the critical code fragment that actually handles the alteration of the object is shown -- this is the method **Modifier::ModifyObject()**. This method is defined like this:

### Prototype:

```
virtual void ModifyObject(TimeValue t, ModContext &mc,  
ObjectState* os, INode *node)=0;
```

### Remarks:

This is the method that actually modifies the input object. This method is responsible for altering the object and then updating the validity interval of the object to reflect the validity of the modifier.

### Parameters:

#### **TimeValue t**

The time at which the modification is being done.

#### **ModContext &mc**

A reference to the ModContext. The ModContext stores information about the space the modifier was applied in including.

#### **ObjectState\* os**

The object state flowing through the pipeline. This contains a pointer to the object to modify.

#### **INode \*node**

The node the world space modifier is applied to. This parameter is always

NULL for Object Space Modifiers and non-NULL for World Space Modifiers (Space Warps). This is because a given WSM is only applied to a single node at a time whereas an Object Space Modifier may be applied to several nodes. This may be used for example by particle system space warps to get the transformation matrix of the node at various times.

Below are examples of many of the modifier types.

### **Modifiers Which Change Topology**

These modifiers alter the face or polygon structures of the objects they are applied to. Smoothing groups and materials are also part of the topology channel. Edge visibility is also part of this channels since it is an attribute of the face structure. The face normals are also part of the topology channel. The example below is from the Normals modifier which allows the user to unify and flip the face normals of a mesh. The full source code is available in `\MAXSDK\SAMPLES\MODIFIERS\SURFMOD.CPP`.

Below are the implementations of **InputType()**, **ChannelsUsed()**, and **ChannelsChanged()**.

```
Class_ID InputType() {return triObjectClassID;}  
ChannelMask ChannelsUsed() {return OBJ_CHANNELS;}  
ChannelMask ChannelsChanged() {return  
GEOM_CHANNEL|TOPO_CHANNEL;}
```

Note that this modifier only operates on triangle mesh objects, or those objects able to convert themselves to triangle meshes. Also note that this modifier specifies the object channels for those that it needs up to date to perform its modification. Since this modifier changes the vertex and face structure of the mesh to alter the normals it specifies it modifies the geometry channel and the topology channel in **ChannelsChanged()**.

Here is the implementation of **ModifyObject()**. Note that when the modifier is done it updates the validity of the object flowing down the pipeline by calling **UpdateValidity()** and passing the topology channel number.

```
void NormalMod::ModifyObject(TimeValue t, ModContext &mc,  
    ObjectState *os, INode *node)  
{  
    Interval valid = FOREVER;  
    int flip, unify;
```

```

pblock->GetValue(PB_FLIP,t,flip,valid);
pblock->GetValue(PB_UNIFY,t,unify,valid);

assert(os->obj->IsSubClassOf(triObjectClassID));
TriObject *triOb = (TriObject *)os->obj;
BOOL useSel = triOb->mesh.selLevel==MESH_FACE;

if (unify) {
    triOb->mesh.UnifyNormals(useSel);
}

if (flip) {
    for (int i=0; i<triOb->mesh.getNumFaces(); i++) {
        if (!useSel || triOb->mesh.faceSel[i]) {
            FlipMeshNormal(&triOb->mesh,(DWORD)i);
        }
    }
}

triOb->UpdateValidity(TOPO_CHAN_NUM,valid);
}

```

### **Modifiers Which Change Mapping (Texture Coordinates)**

These modifiers alter the texture coordinates of the objects they modify. These can add new mapping coordinates to unmapped objects or modify the existing mapping coordinates of objects. A modifier that adds new mapping coordinates is the UVW Mapping Modifier. The full source code is available in **\MAXSDK\SAMPLES\MODIFIERS\MAPMOD.CPP**. Below are the implementations of **InputType()**, **ChannelsUsed()**, and **ChannelsChanged()**.

```

Class_ID InputType() { return mapObjectClassID; }
ChannelMask ChannelsUsed()
{
    return PART_GEOM | PART_TOPO | PART_SELECT |
        PART_SUBSEL_TYPE | PART_VERTCOLOR;
}

```

```

    }
ChannelMask ChannelsChanged()
    {
        return TEXMAP_CHANNEL|PART_VERTCOLOR;
    }

```

The mapping modifier requests a modifier that is mappable by specifying the Class\_ID **mapObjectClassID**. Objects that know how to make themselves mappable respond to this Class\_ID in **CanConvertToType()** and return TRUE. This indicates that they may have texture coordinates assigned to them and they implement the method **Object::ApplyUVWMap()**. Note how the Vertex Color channel is needed and changed as well as the texmap channel. This is because 3ds max uses the second mapping channel as the vertex color channel and the user is able to specify that the second mapping channel may be used for the mapping coordinates.

Here is the implementation of **ModifyObject()**. Note that when the modifier is done it updates the validity of the texture map channel by calling **UpdateValidity()**.

```

void MapMod::ModifyObject(TimeValue t, ModContext &mc,
    ObjectState *os, INode *node)
    {
        // If it's not a mappable object then we can't help
        Object *obj = os->obj;
        if (!obj->IsMappable()) return;

        // Get pblock values
        int type, uflip, vflip, wflip, cap, channel;
        float utile, vtile, wtile;
        pblock->GetValue(PB_MAPTYPE,t,type,FOREVER);
        pblock->GetValue(PB_UTILE,t,utile,FOREVER);
        pblock->GetValue(PB_VTILE,t,vtile,FOREVER);
        pblock->GetValue(PB_WTILE,t,wtile,FOREVER);
        pblock->GetValue(PB_UFLIP,t,uflip,FOREVER);
        pblock->GetValue(PB_VFLIP,t,vflip,FOREVER);
        pblock->GetValue(PB_WFLIP,t,wflip,FOREVER);

```

```
pblock->GetValue(PB_CAP,t,cap,FOREVER);  
pblock->GetValue(PB_CHANNEL,t,channel,FOREVER);
```

```
// Prepare the controller and set up mats  
if (!tmControl || (flags&CONTROL_OP) ||  
(flags&CONTROL_INITPARAMS))  
    InitControl(mc,obj,type,t);  
    Matrix3 tm;  
    tm = Inverse(CompMatrix(t,&mc,NULL));
```

```
obj-  
>ApplyUVWMap(type,utile,vtile,wtile,uflip,vflip,wflip,cap,tm,char
```

```
// The tex mapping depends on the geom and topo so make sure  
the validity interval reflects this.
```

```
Interval iv = LocalValidity(t);  
iv = iv & os->obj->ChannelValidity(t,GEOM_CHAN_NUM);  
iv = iv & os->obj->ChannelValidity(t,TOPO_CHAN_NUM);  
os->obj->UpdateValidity(TEXMAP_CHAN_NUM,iv);  
}
```

To see an example of a modifier that alter existing texture coordinates take a look at the source code for the UVW XForm modifier in **\MAXSDK\SAMPLES\MODIFIERS\UVWXFORM.CPP**. or the UVW Unwrap modifier in **\MAXSDK\SAMPLES\MODIFIERS\UNWRAP.CPP**.

### **Modifiers Which Change Materials**

These modifiers alter the material ID stored by the object. An example of this type of modifier is the Material Modifier (**\MAXSDK\SAMPLES\MODIFIERS\SURFMOD.CPP**). Below are the implementations of **InputType()**, **ChannelsUsed()**, and **ChannelsChanged()**. Note that materials are rolled into the face structure of the object so this modifier alters the topology channel.

```
Class_ID InputType() {return triObjectClassID;}  
ChannelMask ChannelsUsed() {return OBJ_CHANNELS;}
```

```
ChannelMask ChannelsChanged() {return  
GEOM_CHANNEL|TOPO_CHANNEL;}
```

This modifier specifies it changes the geometry channel. Technically it doesn't need to since it only changes the material index at the face level and nothing at the vertex level. Again, this is a bit of overkill.

Here is the implementation of **ModifyObject()**. Note that when the modifier is done it updates the validity of the object flowing down the pipeline by calling **UpdateValidity()** and passing the topology channel number.

```
void MatMod::ModifyObject(TimeValue t, ModContext &mc,  
    ObjectState *os, INode *node)  
{  
    Interval valid = FOREVER;  
    int id;  
    pblock->GetValue(PB_MATID,t,id,valid);  
    id--;  
    if (id<0) id = 0;  
    if (id>0xffff) id = 0xffff;  
  
    assert(os->obj->IsSubClassOf(triObjectClassID));  
    TriObject *triOb = (TriObject *)os->obj;  
    BOOL useSel = triOb->mesh.selLevel==MESH_FACE;  
  
    for (int i=0; i<triOb->mesh.getNumFaces(); i++) {  
        if (!useSel || triOb->mesh.faceSel[i]) {  
            triOb->mesh.setFaceMtlIndex(i,(MtlID)id);  
        }  
    }  
  
    triOb->UpdateValidity(TOPO_CHAN_NUM,valid);  
}
```

### **Modifiers Which Change Selection**

These modifiers alter the selection level of objects. An example is the Volume Select modifier. The full source code is available in **\MAXSDK\SAMPLES\MODIFIERS\SELMOD.CPP**.

Below is the implementations of **InputType()**, **ChannelsUsed()**, and **ChannelsChanged()**.

```
Class_ID InputType() {return triObjectClassID;}
ChannelMask ChannelsUsed() {return OBJ_CHANNELS;}
ChannelMask ChannelsChanged()
{
    return
    SELECT_CHANNEL|SUBSEL_TYPE_CHANNEL|GEOM_CHAI
}
```

Note that **ChannelsChanged()** for the Volume Select Modifier doesn't specify **DISP\_ATTRIB\_CHANNEL** in **ChannelsChanged()**. Technically it really should since it changes the Mesh display flags. The reason this isn't a problem however is that this is only a single int in the Mesh and isn't dynamically allocated. So it is actually **always** present even without specifically specifying it.

Here is the implementation of **ModifyObject()**. Note that when the modifier is done it updates the validity of the object flowing down the pipeline by calling **UpdateValidity()** on all the appropriate channels.

```
void SelMod::ModifyObject(TimeValue t, ModContext &mc,
    ObjectState *os, INode *node)
{
    Interval valid = LocalValidity(t);
    int level, method, type, vol, invert;

    pblock->GetValue(PB_LEVEL,t,level,FOREVER);
    pblock->GetValue(PB_METHOD,t,method,FOREVER);
    pblock->GetValue(PB_TYPE,t,type,FOREVER);
    pblock->GetValue(PB_VOLUME,t,vol,FOREVER);
    pblock->GetValue(PB_INVERT,t,invert,FOREVER);

    assert(os->obj->IsSubClassOf(triObjectClassID));
    TriObject *obj = (TriObject*)os->obj;
    Mesh &mesh = obj->mesh;

    // Prepare the controller and set up mats
```

```

if (!tmControl || (flags&CONTROL_OP))
InitControl(mc,obj,type,t);
Matrix3 tm;
tm = Inverse(CompMatrix(t,&mc,NULL,TRUE,FALSE));

Box3 mcbox = *mc.box;
FixupBox(mcbox);

switch (level) {
case SEL_OBJECT:
    obj->mesh.selLevel = MESH_OBJECT;
    obj-
>mesh.ClearDispFlag(DISP_VERTTICKS|DISP_SELVERTS|DISP_S
break;

case SEL_VERTEX:
    obj->mesh.selLevel = MESH_VERTEX;
    obj->mesh.SetDispFlag(DISP_VERTTICKS|DISP_SELVERTS);
    SelectVertices(obj->mesh,method,type,vol,invert,tm,mcbox);
break;

case SEL_FACE:
    obj->mesh.selLevel = MESH_FACE;
    obj->mesh.SetDispFlag(DISP_SELFACES);
    SelectFaces(obj->mesh,method,type,vol,invert,tm,mcbox);
break;
}

obj->UpdateValidity(SELECT_CHAN_NUM,valid);
obj->UpdateValidity(GEOM_CHAN_NUM,valid);
obj->UpdateValidity(TOPO_CHAN_NUM,valid);
obj->UpdateValidity(SUBSEL_TYPE_CHAN_NUM,FOREVER);
}

```

Note how **UpdateValidity()** is called on four channels.

## Modifiers Which Change Geometry

These modifiers just alter the 'points' of the object. Many modifiers in 3ds max do this. For example, Bend, Taper, Twist, Spherify, and Wave all operate on the just the points of objects. Note that the 'points' may mean different things to different objects. For example, a Bend modifier may be applied to both a Cylinder object and a NURBS curve object. That's because they both have 'points' that can be modified, although the nature of the 'points' is quite different between them. Modifiers that operate on these generic points are said to operate on 'deformable' objects.

Modifiers that only alter the geometry channel can be sub-classed from **SimpleMod** rather than **Modifier** and have fewer methods to implement. In this case, the base class **SimpleMod** provides the default implementation of **InputType()**, **ChannelsUsed()** and **ChannelsChanged()**. Here they are:

```
Class_ID InputType() {return defObjectClassID;}  
ChannelMask ChannelsUsed()  
  {  
    return  
PART_GEOM|PART_TOPO|SELECT_CHANNEL|SUBSEL_TYPE_  
  }  
ChannelMask ChannelsChanged() { return PART_GEOM; }
```

Note that **InputType()** return the Class\_ID of deformable objects. As noted above, these are a type of objects that have 'points' to deform. Also notice that **SimpleModifiers** require the geometry, topology, and selection channels. They need the topology channel up to date because these modifiers can work on the selection set. It needs to find the vertices that are selected because they are part of selected faces. To make sure the face selection is up to date the topology channel is specified. The selection channels are required for the same reason -- the modifier may operate on only the selection set if that's what the object flowing down the pipeline is at.

**SimpleModifiers** don't directly implement **ModifyObject()**. Rather they implement a method called **GetDeformer()**. This method returns a callback object which is an instance of the class **Deformer**. This callback object is really like a pointer to a function that is called to perform the alteration of a single point of an object. The **Deformer** callback object returned from **GetDeformer()** has a single virtual method that the plug-in modifier

implements called **Map()**. This method is passed a single point of the object and its job is to modify the point and return it in altered form. To see an example of an implementation of this method see **BendDeformer::Map()** in **\MAXSDK\SAMPLES\MODIFIERS\BEND.CPP**.

The base class **SimpleMod** provides the implementation of **ModifyObject()** and calls a method of the input object called **Deform()** which in turn calls the deformer provided by **GetDeformer()**. Here is the implementation of **SimpleMod::ModifyObject()**:

```
void SimpleMod::ModifyObject(TimeValue t, ModContext &mc,
ObjectState *os, INode *node)
{
    Interval valid = GetValidity(t);
    Matrix3 modmat,minv;

    // These are inverted because that's what is usually needed
    // for displaying/hit testing
    minv = CompMatrix(t,mc,idTM,valid,TRUE);
    modmat = Inverse(minv);

    os->obj->Deform(&GetDeformer(t,mc,modmat, minv), TRUE);
    os->obj->UpdateValidity(GEOM_CHAN_NUM,valid);
}
```

Notice that the **Deform()** method of the input object is called passing the deformer provided by the modifier plug-in. The object that is being modified provides the implementation of **Deform()** (for example a triangle mesh object that is being modified). Here is the default implementation.

```
void Object::Deform(Deformer *defProc,int useSel) {
    int nv = NumPoints();
    for (int i=0; i<nv; i++)
        SetPoint(i,defProc->Map(i,GetPoint(i)));
    PointsWereChanged();
}
```

Notice how this method loops through the points of the object and calls the **Map()** method on each point. The **GetPoint()** method of the object returns the

'i-th' point of the object. This is passed to **Map()** which deforms and returns it. The result returned from **Map()** is set back into the object by calling **SetPoint()**. Then a method called **PointsWereChanged()** is called to let that object know that its points have been altered.

Some objects override the base class definition of this method to provide other ways of modifying the object. For example the **PatchObject** and **SplineShape** objects provide alternate implementations. If an object wanted to modify the selected points only for example, it would need to override **Object::Deform()** and respect the **useSel** flag that indicates it should use the current selection. The base class method shown above ignores that flag. In each case however, they still call the **Map()** method of the deformer passing it each point to modify.

### **Modifiers Which Change The Entire Object**

There are some modifiers that don't alter one or more parts of the object, they completely replace it with a new object. These modifiers effectively convert the object from one form to another. Examples of this are the Extrude and Lathe modifiers. Both Extrude and Lathe convert a spline object into a mesh, patch or NURBS object, thus completely replacing the entire object. The full source code for Extrude is available in

**\MAXSDK\SAMPLES\MODIFIERS\EXTRUDE.CPP.**

Below are the implementations of **InputType()**, **ChannelsUsed()**, and **ChannelsChanged()**.

```
Class_ID InputType() { return genericShapeClassID; }  
ChannelMask ChannelsUsed() { return  
PART_GEOM|PART_TOPO; }  
ChannelMask ChannelsChanged() { return PART_ALL; }
```

Note that the modifier indicates it changes **all** the channels by returning **PART\_ALL** from **ChannelsChanged()**.

Below is a subset of the implementation of **ModifyObject()** (the code for the NURBS and PATCH cases are removed for brevity and simplicity). In the mesh case, the key thing to notice is that a new **TriObject** is created, the TriObject's mesh is created from the spline, and the new object is placed into the pipeline by assigning it's pointer to the **ObjectState**'s object pointer.

```
void ExtrudeMod::ModifyObject(TimeValue t, ModContext
```

```

&mc,
    ObjectState *os, INode *node) {

// Get our personal validity interval...
Interval valid = GetValidity(t);
valid &= os->obj->ChannelValidity(t,TOPO_CHAN_NUM);
valid &= os->obj->ChannelValidity(t,GEOM_CHAN_NUM);

int output;
pblock->GetValue(PB_OUTPUT, TimeValue(0), output,
FOREVER);

switch (output) {
case NURBS_OUTPUT: {
// ...
break;
}
case PATCH_OUTPUT: {
// ...
break;
}
case MESH_OUTPUT: {
// BuildMeshFromShape fills in the TriObject's mesh,
// then we stuff the TriObj into the pipeline.
TriObject *tri = CreateNewTriObject();
BuildMeshFromShape(t, mc, os, tri->mesh);

tri->SetChannelValidity(TOPO_CHAN_NUM, valid);
tri->SetChannelValidity(GEOM_CHAN_NUM, valid);
tri->SetChannelValidity(TEXMAP_CHAN_NUM, valid);
tri->SetChannelValidity(MTL_CHAN_NUM, valid);
tri->SetChannelValidity(SELECT_CHAN_NUM, valid);
tri->SetChannelValidity(SUBSEL_TYPE_CHAN_NUM, valid);
tri->SetChannelValidity(DISP_ATTRIB_CHAN_NUM, valid);

```

```
os->obj = tri;  
break;  
}  
}  
os->obj->UnlockObject();  
}
```

## How Long is the Modification Valid For?

This section presents information on validity intervals. These describe a range of time over which the modification performed by the modifier is accurate. This is needed because so many things in 3ds max can be animated and thus change over time. For example, consider the case above of the procedural sphere and the volume select modifier applied to select a set of vertices. A 3ds max user might animate the number of segments in the sphere as an animated camera gets closer to it -- this keeps the silhouette of the sphere from appearing faceted. The volume select modifier applied to the sphere needs to select all the vertices in the region defined by its gizmo which represents its volume. Since the segment count in the sphere is changing, the number of vertices in the region defined by the modifier's gizmo is changing. Therefore the selection done at one frame may not be valid at the next frame. In order to tell 3ds max how long the modification is valid, what's called a validity interval is computed and returned. This describes the range of time over which the modification is accurate and up to date.

There are two methods that a modifier needs to call or implement. These are **Object::UpdateValidity()** and **Modifier::LocalValidity()**.

When a modifier is finished altering an object it needs to include its interval in the validity interval of the object. This way if an object was static, but had an animated modifier applied to it, 3ds max would know that the modifier would need to be re-evaluated if the user moves to a new time. To do this, the modifier calls the **UpdateValidity()** method on the object, specifying the channel and the modifier's interval. Modifiers that only affect the geometry channel would specify **GEOM\_CHAN\_NUM**. Modifiers that affect other channels would have to call this method once for each channel modified. The interval that is passed in to this method is then intersected with the interval that the object keeps for each channel. So as the object travels through the pipeline, its validity intervals are potentially getting smaller as (possibly) animated modifiers are applied to it.

Here are the calls to **UpdateValidity()** that the Volume Select Modifier makes to the object it modifies. These calls are made inside the modifiers

**ModifyObject()** method.

```
obj->UpdateValidity(SUBSEL_TYPE_CHAN_NUM,FOREVER);  
obj->UpdateValidity(SELECT_CHAN_NUM,valid);  
obj->UpdateValidity(GEOM_CHAN_NUM,valid);
```

**obj->UpdateValidity(TOPO\_CHAN\_NUM,valid);**

The modifier must also implement a method to return to 3ds max it's own validity, independent of the object it is modifying. This method is **Modifier::LocalValidity()**. This value is computed by starting an interval off at **FOREVER**, and intersecting the validity intervals of all the animated parameters of the modifier. In the case of the Volume Select Modifier, it has a single animated parameter -- it's gizmo which represents the actual extents of the volume it selects. Below is the implementation of this method by Volume Select.

**Interval SelMod::LocalValidity(TimeValue t)**

```
{  
Interval valid = FOREVER;  
if (tmControl) {  
Matrix3 tm(1);  
tmControl->GetValue(t,&tm,valid,CTRL_RELATIVE);  
}  
return valid;  
}
```

Note the interval is started as **FOREVER**. Then the gizmo's transform controller's **GetValue()** method is called passing it this initial interval of **FOREVER**. The controller's **GetValue()** method will update this interval to reflect the validity of the gizmo. This interval is then returned. Note that if the volume has not been animated yet, and thus there is not a controller assigned to the gizmo yet, **FOREVER** is returned. This means the modifier is valid at all times. To learn more about validity intervals see the Advanced Topics section [Intervals](#).

Some modifiers are sub-classed from SimpleMod and not Modifier. To return the validity interval of the modifier to **SimpleMod**, the developer must implement a method named **GetValidity()**. **SimpleMod** then provides the implementation of **LocalValidity()** itself but calls **GetValidity()** on the **SimpleModifier**.

## Summary

This section presented information about how objects and modifiers work together to accomplish object modification. Objects may need to convert themselves to another form to be modified. They do this in their **ConvertToType()** method. Modifiers need to specify which object types they operate on (**InputType()**) and which pipeline channels they need and use (**ChannelsUsed()** and **ChannelsChanged()**). Modifiers also perform their modification in the method **ModifyObject()**. Finally, Modifiers must update the validity intervals of the objects they modify to reflect their own validity. This is done inside the method **UpdateValidity()**.

# Palettes

See Also: [Class GPort](#), [Class Quantizer](#), [Class ColorPacker](#).

## Overview

When operating in 8-bit mode, 3ds max uses a 256 color palette. Plug-ins should avoid changing the system palette because this can cause the quality of the 3ds max display to degrade. The palette used by 3ds max reserves the bottom 10 slots and top 10 slots of the palette for Windows colors. It also contains a 6x6x6 RGB color cube, and a 16 gray level ramp. This palette should be adequate for most purposes. When a plug-in wants to output bitmaps and colored areas with dither, so as to get good approximations of 24 bit colors in 8-bit modes, it should make use of the **GPort** class. The **GPort** also provides access to 8 "animated palette slots" to allow dynamically altering system palette entries.

## Support Classes

This section discusses several class that are helpful in working with 3ds max palettes and paletted images.

[Class GPort](#) - This class has several purposes. It maintain the default 3ds max palette for doing 256 color graphics. It also provides a mechanism for allocating "animated color slots" in the default palette for use in the user interface. Additionally it provide various functions for doing dithered graphics using the default 3ds max palette.

There is one instance of **GPort** that is shared globally. It is accessed by the function:

```
GPort* GetGPort();
```

Here is an example of a typical use of this class. In this case the developer wants to put up a dialog box with two color swatches in it, and have these be painted using an "animated color slot" in the default 3ds max palette. To set things up, the following is done in the **WM\_INITDIALOG** code:

```
// Plug the standard MAX palette into the hdc  
HDC hdc = GetDC(hwndDlg);  
hOldPal = GetGPort()->PlugPalette(hdc);  
// Get one anim palette slot  
animSlot[0] = GetGPort()->GetAnimPalSlot();  
// Get another anim palette slot  
animSlot[1] = GetGPort()->GetAnimPalSlot();
```

The routine **GetAnimPalSlot()** is used to get an animatable palette slot. There are a total of 8 slots available. This method may return -1. This indicates that **GPort** has no more remaining animatable palette slots. In this case, using the routine **GPort::PaintColorSwatch()** will do the proper thing, that is dithering the swatch instead of trying to paint it with a single palette index.

Next, in the **WM\_PAINT** code before drawing the following is done:

```
// Just to be safe: if the palette is there, unchanged, this is cheap.  
GetGPort()->PlugPalette(hdc);  
GetGPort()->SetAnimPalEntry(animSlot[0], rgb1); // set an rgb  
into slot  
GetGPort()->SetAnimPalEntry(animSlot[1], rgb2); // set an rgb
```

into slot

```
GetGPort()->AnimPalette(hdc); // update the palette with these colors
```

```
PaintColorSwatch(hdc, rgb1, 0, 10,10,40,20); // see below
```

```
PaintColorSwatch(hdc, rgb2, 0, 10,30,40,40);
```

To finish up, in **WM\_DESTROY** you should do the following:

```
GetGPort()->ReleaseAnimPalSlot(animSlot[0]); // Release palette slot
```

```
GetGPort()->ReleaseAnimPalSlot(animSlot[1]); // Release palette slot
```

```
GetGPort()->RestorePalette(hdc,hOldPal); // Restore palette
```

The code for **PaintColorSwatch()** is also included below to illustrate in more detail how **GPort** works. This is a routine to draw a color swatch using an animated palette entry, if available.

```
void PaintColorSwatch(HDC hdc, DWORD col, int slot,  
int left, int top, int right, int bottom) {  
    HPEN oldPen = (HPEN) SelectObject(hdc,  
GetStockObject(NULL_PEN));  
    HBRUSH oldBrush;  
    if (slot>=0) {  
        HBRUSH brush = GetGPort()->MakeAnimBrush(slot,col);  
        oldBrush = (HBRUSH)SelectObject (hdc, brush);  
        Rectangle (hdc, left,top,right,bottom);  
        DeleteObject(brush);  
    }  
    else {  
        oldBrush = (HBRUSH)SelectObject (hdc,  
        GetStockObject( NULL_BRUSH ));  
        Rectangle (hdc, left, top, right,bottom); // Paint the border  
        Rect rect;  
        rect.left = left++;  
        rect.top = top++;  
        rect.right = right--;  
        rect.bottom = bottom--;
```

```

GetGPort()->DitherColorSwatch(hdc, rect , col);
}
SelectObject (hdc, oldPen);
SelectObject (hdc, oldBrush);
}

```

[Class Quantizer](#) - This class is used for dithering output to files. This class computes a palette when going from 24-bit to 8-bit color.

[Class ColorPacker](#) - This class is used to pack the pixels down using the **Quantizer** computed palette.

The following code shows how the methods of **Quantizer** and **ColorPacker** may be used to compute a palette for an image.

```

/* Make a palette for the given image */
int BitmapIO::CalcOutputPalette(int palsize, BMM_Color_48
*pal) {
    Quantizer *q = BMMNewQuantizer();
    if (!q->AllocHistogram()) {
        bail_out:
        q->DeleteThis();
        return(0);
    }
    PixelBuf line(map->Width());
    if (!line.Ptr())
        goto bail_out;
    int y;
    for(y=0; y<map->Height(); ++y) {
        // call GetOutputPixels to get fileOutputGamma corrected
        values.
        if (!GetOutputPixels(0,y,map->Width(),line.Ptr()))
            goto bail_out;
        q->AddToHistogram(line.Ptr(),map->Width());
    }
    // Reserve the background color (assuming the upper left pixel is
    a
    // representative) and make a palette.

```

```
BMM_Color_64 bgpix;  
GetOutputPixels(0,0,1,&bgpix);  
int n = q->Partition(pal, palsize, &bgpix);  
q->DeleteThis();  
return n;  
}
```

## Parameter Blocks

See Also: [Parameter Blocks and Maps in Release 3 and Later](#), [Parameter Maps](#), [Class IParamBlock](#), [Class ParamDimension](#), [Class GetParamName](#), [Class GetParamDim](#).

## Overview

The parameter block class provides a mechanism for storing values for a plug-ins parameters. When a parameter block is created, the developer specifies the number of parameters and the types of each parameter. Parameter types consist of a range of built in types like integer, float, 3D Point, and Color.

Parameters may be animated or constant. In order for a parameter to be animatable, it must have a controller to control the animation. Different parameter types require different controller types. For example, a floating point value, like the angle parameter for the bend modifier, requires a floating point controller. A node transformation matrix requires a transform controller. The most common controllers are interpolating or 'key frame' controllers.

One of the main purposes of parameter blocks is to manage the complexity of maintaining different controllers for different parameters. To access the values in the parameter block, the plug-in developer uses **GetValue()** and **SetValue()** methods, each take a TimeValue as a parameter. The parameter block stores values in an efficient a manner as possible. If the value hasn't yet been animated, that is, **SetValue()** hasn't been called with time not equal to 0, then a constant value is stored. When **SetValue()** is called with time not equal to 0, and MAXs 'Animate' button is on, a new instance of the default controller for the parameter type is plugged in to the parameter block and initialized with the parameter's values. Plug-ins are required to display their animated parameters in the track view. If all the plug-in's parameters are handled by a parameter block, then the parameter block will take care of this task as well.

## **Parameter Blocks in Use**

In this section we'll explore the definition and creation of parameter blocks. Then we'll look at the method of setting and retrieving values from the parameter block. Finally we'll look at how parameter blocks and references may be used together for processing animated user interface parameters. Note: This section provides only a minimal description of the reference mechanism. For an in depth discussion of references, see the Advanced Topics section [References](#).

## Creating a Parameter Block

Throughout this section an example of a plug-in with three parameters is used. An angle, a length, and an integer count parameter. A parameter block descriptor is used to describe each parameter. It is initialized by passing three arguments per parameter. (Note that another version uses four arguments. The version with four arguments is used to help maintain backward compatibility. The two descriptors are otherwise the same).

### Prototype:

```
class ParamBlockDesc {  
  public:  
    ParamType type;  
    UserType *user;  
    BOOL animatable;  
};  
// This version of the descriptor has an ID for each parameter.  
class ParamBlockDescID {  
  public:  
    ParamType type;  
    UserType *user;  
    BOOL animatable;  
    DWORD id;  
};
```

The arguments to ParamBlockDesc are:

### **ParamType type**

The Parameter Type - The following types may be used:

- **TYPE\_INT** - Integer values.
- **TYPE\_FLOAT** - Floating point value.
- **TYPE\_POINT3** - Point values.
- **TYPE\_RGBA** - Color values - Red, Green, Blue and Alpha.
- **TYPE\_BOOL** - Boolean values.

### **UserType \*user**

The next value is NOT USED - it must always be passed as NULL.

### **BOOL animatable**

This is a flag indicating if the parameter may be animated or not. Pass TRUE

if the value may be animated and FALSE if it is constant.

**DWORD id** (Second version only)

This is an ID used to identify this parameter. This provides a solution to the problem of backwards compatibility. If you alter the parameter structure of your plug-in in the future (by adding or deleting parameter for example) previously saved 3ds max files will be incompatible. You can however use a mechanism which uses these IDs to convert older versions to the current version. See the Advanced Topics section on [Parameter Maps](#) for more detail. Items in the parameter block are referred to by index. The index is derived from the order in which the descriptors appear in the ParamBlockDesc array.

```
// Parameter block indices  
#define PB_INDEX_ANGLE 0  
#define PB_INDEX_LENGTH 1  
#define PB_INDEX_COUNT 2  
ParamBlockDesc pdesc[] = {  
    { TYPE_FLOAT, NULL, TRUE }, // Angle  
    { TYPE_FLOAT, NULL, TRUE }, // Length  
    { TYPE_INT, NULL, FALSE } // Count  
};
```

A parameter block is created from this array by calling **CreateParameterBlock()**. This function requires two values, a pointer to the ParamBlockDesc array and a count of the number of parameters. (Note there is an alternate version for use with the backwards compatibility mechanism discussed above that uses three arguments. The third argument is used to indicate a version of the parameter block. See the Advanced Topics section on [Parameter Maps](#) for more information).

**Prototype:**

```
IParamBlock *CreateParameterBlock(ParamBlockDesc *pdesc,  
int count);
```

or

```
IParamBlock *CreateParameterBlock(ParamBlockDescID *pdesc,  
int count,DWORD version);
```

```
IParamBlock *pblk = CreateParameterBlock(pdesc, 3);
```

The function returns a pointer to the parameter block it creates.

## Retrieving Parameter Block Values

Whenever the developer needs to retrieve a value from the parameter block, the **GetValue()** method is used. There are overloaded functions for each type of value to retrieve (int, float, Point3, and RGBA). Each method has four parameters. Below is the float version.

```
BOOL GetValue( int i, TimeValue t, float &v,  
Interval &ivalid );
```

The **i** parameter is the integer index of the parameter to retrieve. This is the index into the ParamBlockDesc array.

If the parameter is animated it will be varying over time. The **t** parameter specifies at what time to retrieve the value.

The **v** parameter is a C++ reference to a float. The value is returned through **v**.

The **ivalid** parameter is a C++ reference to an Interval. The **GetValue()** method updates the interval passed in. This method is frequently used by developers to 'whittle' down an interval. When a parameter of a parameter block is animated, for any given time there is a interval over which the parameter is constant. If the parameter is constantly changing the interval is instantaneous. If the parameter does not change for a certain period the interval will be longer. If the parameter never changes the interval will be FOREVER. By passing an interval to the **GetValue()** method you ask the parameter block to 'intersect' the interval passed in with the interval of the parameter. Intersecting two intervals means returning a new interval whose start value is the greater of the two, and whose end value is smaller of the two. In this way, the resulting interval represents a combined period of constancy for the two intervals.

This technique is used frequently to compute a validity interval for an object. The developer starts an interval off as FOREVER, then intersects this interval with each of its animated parameters (by calling **GetValue()**). **GetValue()** 'whittles' down the interval with each call. When all the parameters have been intersected the result is the overall validity interval of an object at a specific time. For more information see the Advanced Topics section on [Intervals](#).

The return value is TRUE if a value was retrieved. Otherwise it is FALSE.

## Setting Parameter Block Values

Whenever the developer needs to store a value into the parameter block, the **SetValue()** method is used. There are overloaded functions for each type of value to set (int, float, Point3, and RGBA). Each method has three parameters. Below is the float version.

**BOOL SetValue( int i, TimeValue t, float v );**

The **i** parameter is the integer index of the parameter to set. This is the index into the ParamBlockDesc array of the parameter.

The **t** parameter specifies at what time to set the value.

The value to store is passed in **v**.

The return value is TRUE if the value was set. It is FALSE otherwise.

## Setting Values and Handling References

The **IParamBlock** class is derived from class **ReferenceTarget**. Since parameter blocks are reference targets, plug-ins may create references to them. By creating a reference to the parameter block, the plug-in may be notified whenever any of the parameters are set to new values.

The sample code below creates a parameter block from the array of descriptors and then makes a reference to the parameter block.

```
//This is the index of the Param Blk reference.  
#define PARAM_BLK_REF 0  
MakeRefByID(  
    FOREVER, // Interval - always use FOREVER.  
    PARAM_BLK_REF, // Index of the PB reference.  
    CreateParameterBlock(pdsc, 3) // Create the PB  
);
```

When values of the parameter block are changed, the plug-in needs to be informed. This notification is done by calling the ReferenceMaker method **NotifyDependents()**. The code fragment below shows how this is done. Whenever our sample plug-in needs to adjust its angle parameter it calls the function below. This function calls the **SetValue()** method of the parameter block and then calls **NotifyDependents()**.

```
void Sample::SetAngle(TimeValue t, float r)  
{  
    // pblock is a pointer to our param blk  
    pblock->SetValue(PB_INDEX_ANGLE, t, r);  
    NotifyDependents(FOREVER, PART_OBJ,  
    REFMSG_CHANGE);  
}
```

When the **NotifyDependents()** method is called after a parameter has been changed, the plug-in is notified via a **REFMSG\_CHANGE** message sent to its **NotifyRefChanged()** method. Here the developer may respond to the change in the parameter's value.

There are two other messages which may be sent to this method to handle parameter block processing. These are **REFMSG\_GET\_PARAM\_NAME** and **REFMSG\_GET\_PARAM\_DIM**.

The message **REFMSG\_GET\_PARAM\_DIM** is sent by the system when it needs a parameter dimension for the parameter. Any parameter that can be controlled by a controller has a dimension. This dimension can be considered a unit of measure. It describes its type and its order of magnitude. When a controller needs to display the parameter values (for example in the function curve editor) it converts the value using its parameter dimension **Convert()** function. It can also convert back using the **Unconvert()** function.

There are several default parameter dims implemented. See [ParamDimension](#) for details.

The **REFMSG\_GET\_PARAM\_NAME** messages is sent by the system when it needs a name for the parameter. For example, in the track view a name for the parameter needs to be displayed. When this message is received from the system the name is provided. The parameter which it needs the name for is passed in the **partID**.

The plug-in implements this method to receive messages. See below for how the messages associated with the parameter block are handled.

```
RefResult Sample::NotifyRefChanged(  
Interval changeInt,  
RefTargetHandle hTarget,  
PartID& partID,  
RefMessage message)  
{  
  switch (message) {  
    case REFMSG_CHANGE:  
      // Code to handle the changed parameter...  
      break;  
    case REFMSG_GET_PARAM_DIM:  
      // When a client of a parameter block receives the  
      // REFMSG_GET_PARAM_DIM message, the partID  
      // field is set to point at one of these structs.  
      // The client should set dim to point at its dim descriptor.  
      GetParamDim *gpd = (GetParamDim*)partID;  
      // Based on which index it wants...  
      switch (gpd->index) {
```

```

// ...provide the appropriate dim
case PB_INDEX_ANGLE:
    gpd->dim = stdAngleDim;
    break;
case PB_INDEX_LENGTH:
    gpd->dim = stdWorldDim;
    break;
case PB_INDEX_COUNT:
    gpd->dim = stdSegmentsDim;
    break;
}
return REF_STOP;
case REFMSG_GET_PARAM_NAME:
    // When a client of a parameter block receives the
    // REFMSG_GET_PARAM_NAME message, the
    // partID field is set to point at one of these
    // structures. The client should fill in the parameter name.
    GetParamName *gpn = (GetParamName*)partID;
    switch (gpn->index) {
    case PB_INDEX_ANGLE:
        gpn->name = _T("Angle");
        break;
    case PB_INDEX_LENGTH:
        gpn->name = _T("Length");
        break;
    case PB_INDEX_COUNT:
        gpn->name = _T("Count");
        break;
    }
    return REF_STOP;
}
return(REF_SUCCEED);
}

```

# Parameter Editing in the Command Panel

See Also: [Class Animatable](#), [Custom Controls](#), [Parameter Maps](#).

## **Overview**

This section discusses the editing of an item's parameters in the command panel. Plug-In types such as procedural objects, modifiers, space warps, and controllers may all present their user interface in the command panel.

## Methods Called During Parameter Editing

There are two methods that are called when a user begins and ends editing an item's parameters. In the case of procedural objects, modifier, and controllers, these methods are from class **Animatable**. They are named **BeginEditParams()** and **EndEditParams()**. Other plug-in types, such as utilities, may have their own version of these methods (for instance **UtilityObj::BeginEditParams()**). The text below discusses the more common **Animatable** version.

### Beginning Parameter Editing

When the user begins to edit an item the **BeginEditParams()** method is called on it. At this point it is expected to do two things: Put up its user interface via rollup pages, and register any sub-object selection types it may have. Each of these is discussed below.

Adding rollup pages can be done using the method **Interface::AddRollupPage()** or by creating a parameter map (**CreateCPPParamMap()**) which puts up the rollup pages itself.

The **BeginEditParams()** prototype looks like this:

```
virtual void BeginEditParams(IObjParam *ip,ULONG flags,  
Animatable *prev=NULL);
```

The **flags** parameter passed is used to indicate which branch of the command panel the item is being edited in. For instance it may be the Create branch, the Modifier branch, the Hierarchy branch, or the Motion branch.

Some items may have specific parameters that are particular to the creation process. The **flags** parameter indicates whether the user is in the create branch or not. For example, procedural spheres have an option to create them by dragging out the radius or the diameter. These parameters shouldn't be displayed in the Modify branch since they are only for creating. The sphere checks the flag to see if rollup should be added. Here's the code fragment from the sphere code where that is done:

```
void SphereObject::BeginEditParams(IObjParam *ip,ULONG  
flags,Animatable *prev) {  
    // ...  
  
    if (flags&BEGIN_EDIT_CREATE) {
```

```
pmapCreate = CreateCPPParamMap(
    descCreate,CREATEDESC_LENGTH,
    this,
    ip,
    hInstance,
    MAKEINTRESOURCE(IDD_SPHEREPARAM1),
    GetString(IDS_RB_CREATIONMETHOD),
    0);
```

```
pmapTypeIn = CreateCPPParamMap(
    descTypeIn,TYPEINDESC_LENGTH,
    this,
    ip,
    hInstance,
    MAKEINTRESOURCE(IDD_SPHEREPARAM3),
    GetString(IDS_RB_KEYBOARDENTRY),
    APPENDROLL_CLOSED);
}
```

```
pmapParam = CreateCPPParamMap(
    descParam,PARAMDESC_LENGTH,
    pblock,
    ip,
    hInstance,
    MAKEINTRESOURCE(IDD_SPHEREPARAM2),
    GetString(IDS_RB_PARAMETERS),
    0);
}
```

Note above how the 'Creation Method' or 'Keyboard Entry' rollups are only added if the **BEGIN\_EDIT\_CREATE** flag is set. In either case the 'Parameters' rollup is added.

The following bit flags may be compared with the **flag** parameter to test the branch (or sub-task of the branch).

**BEGIN\_EDIT\_CREATE**

Indicates the item is being edited in the create branch.

### **BEGIN\_EDIT\_MOTION**

Indicates a controller is being edited in the motion branch.

### **BEGIN\_EDIT\_HIERARCHY**

Indicates a controller is being edited in the Pivot subtask of the hierarchy branch.

### **BEGIN\_EDIT\_IK**

Indicates a controller is being edited in the IK subtask of the hierarchy branch.

### **BEGIN\_EDIT\_LINKINFO**

Indicates a controller is being edited in the Link Info subtask of the hierarchy branch.

Inside **BeginEditParams()** the item is also expected to register any sub-object selection levels with the system. . For example, a modifier plug-in may have sub-object selection levels like 'Gizmo' and 'Center'. These need to appear in the sub-object drop down allowing the user to select them. In the case of a bend modifier for example, this is accomplished by calling **BeginEditParams()** on the base class **SimpleMod**, i.e.:

```
void BendMod::BeginEditParams(IObjParam *ip, ULONG flags, Animatable *prev) {  
    SimpleMod::BeginEditParams(ip,flags,prev);  
    // ...
```

What the base class **SimpleMod** does is the following:

```
void SimpleMod::BeginEditParams(IObjParam *ip, ULONG flags, Animatable *prev){  
    // ...  
    // Add our sub object type  
    TSTR type1(GetResString(IDS_RB_APPARATUS) );  
    TSTR type2(GetResString(IDS_RB_CENTER) );  
    const TCHAR *ptype[] = { type1, type2 };  
    ip->RegisterSubObjectTypes( ptype, 2 );  
    // ...
```

Note how it retrieves two string resources using **GetResString()** ("Gizmo" and "Center") and registers them using **Interface::RegisterSubObjectTypes()**.

## Ending Parameter Editing

When the user is finished editing the item's parameters its **EndEditParams()** method is called. For example, if the user switches branches of the command panel, or selects a different object type to be created, it's called on the item currently being edited.

The prototype looks like this:

```
virtual void EndEditParams(IObjParam *ip, ULONG flags,  
Animatable *next=NULL);
```

This method is also passed a **flag** value. If the **END\_EDIT\_REMOVEUI** flag is set to the item should remove its rollup pages from the command panel. For example, when in the create branch, procedural objects can be created one after the other so there is no need to remove the UI when one instance of a class is finished with its create stage if another instance of that same class is about to be created. In such a case, **END\_EDIT\_REMOVEUI** won't be set since the user interface should stay in place.

## User Interface Related Variables

The best way to handle user interface-related variables is to make them [= 4\) BSPSPopupOnMouseOver\(event\);">class variables](#) (by declaring them static). Class variables are **shared** by every instance of the class (rather than stored with each instantiated object of the class). This way, an object doesn't suffer the overhead of these variables that are only used when it is editing. Only one item may have its parameters being edited at any one time so the class variables work well.

For example, consider a procedural sphere. It may have class variables that contain the handles to its parameter maps in the command panel. When a sphere is first created, it is immediately edited so its **BeginEditParams()** method is called. It creates the parameter maps and stores the handles to them in its class variables. If the user chooses to make another sphere, the first sphere's **EndEditParams()** method is called, but **END\_EDIT\_REMOVEUI** flag is set to FALSE, indicating that the sphere should leave the rollup pages in the command panel. A new instance of the Sphere class is then created and its **BeginEditParams()** method is called. It notices that the parameter map handles are not NULL so it doesn't need to create them. For instance, consider how the procedural sphere checks this in the code below. If its pointer to the 'Creation Method' and 'Parameters' parameter maps are still valid (non-NULL) it

doesn't recreate the rollup pages. Rather it simply updates the parameter block pointer stored by the parameter map to point to the new sphere object.

```
if (pmapCreate && pmapParam) {  
  // Left over from last sphere ceated  
  pmapCreate->SetParamBlock(this);  
  pmapTypeIn->SetParamBlock(this);  
  pmapParam->SetParamBlock(pblock);  
} else {  
  // . . .
```

### **Interface Pointer Validity**

The interface pointer passed to **BeginEditParams()** is usually stored by the plug-in since it is likely that the plug-in will need it to call its methods. This pointer is only valid while the item is being edited. Therefore, another important thing to do when **EndEditParams()** is called is to set the object's interface pointer to NULL. This pointer is only valid between the **BeginEditParams()** and **EndEditParams()** methods. A plug-in should not call methods on this pointer outside of this interval.

## Parameter Maps

See Also: [Parameter Blocks and Maps in Release 3 and Later](#), [Class IParamMap](#), [Class IParamArray](#), [Class IParamBlock](#), [Class ParamBlockDescID](#), [Class ParamUIDesc](#).

## Overview

Parameter Maps are used to minimize the programming effort required to manage the user interface parameters of a plug-in. A simple plug-in, such as the procedural sphere, has a user interface consisting of controls like spinners, radio buttons and check boxes. Each of these controls has a one-to-one correspondence with a variable or parameter in a parameter block. Parameter maps can be used to map the UI controls to a parameter handler of the appropriate data type. The use of parameter maps has several advantages:

For standard processing, the developer will not need to write message-processing code to handle events generated by the user. For example, if a developer does not use parameter maps they must provide a dialog proc which processes the messages sent by the controls as the user works with them. For instance the spinner control sends a message when the user operates the up and down arrows or enters new values. Parameter maps handle this message processing internally.

The developer is freed from dealing with the complexity of having to manage controllers to control the animation of user interface values. The appropriate type of controller is assigned and managed by the parameter block which the parameter map controls. The developer simply uses **GetValue()** and **SetValue()** methods to retrieve and store values.

Undo and Redo are handled automatically for changes to a parameter's value. The Loading and Saving of the parameters to and from disk is handled automatically.

The following user interface controls are available for use with parameter maps:

## Spinner Custom Control

The spinner control is used to provide input of values limited to a fixed type. For example, the control may be limited to the input of only positive integers. The input options are integer, float, universe (world space units), positive integer, positive float, positive universe, and time. This control allows the user to increment or decrement a value by clicking on the up or down arrows. The user may also click and drag on the arrows to interactively adjust the value. The Ctrl key may be held to accelerate the value changing speed, while the Alt key may be held to decrease the value changing speed.

## Radio Button

Radio buttons are used to provide the user with a single boolean choice, or when used in groups, to select among several options.

## Single Check Box

Check boxes are used to provide the user with a single boolean choice.

## **Multiple Check Box**

Multiple Check boxes are also supported. This interface allows each bit of a single integer to control a different check box.

## Color Swatch Custom Control

The Color Swatch control presents the user with the standard 3ds max modeless color selector when the user clicks on the control. The color swatch control displays the currently selected color.

Note that you may use a combination of parameter maps and other techniques to manage your plug-in's user interface. If you don't specifically inform the parameter map about a UI control, it will be ignored. If your plug-in has UI controls that require special processing, a mechanism is provided to allow you to do so. If you wish to use other types of controls such as custom buttons, toolbars or image controls see the Advanced Topics section [Custom Controls](#)

## Basic Concepts of Parameter Maps

A parameter map may be considered a table of parameter handlers. The parameter map provides the processing required to map the UI controls to the variables these controls affect. The parameter map operates on a [= 4\) BSPSPopupOnMouseOver\(event\);">virtual array](#) of parameters. Each control is one element of the virtual array. Each rollup page in the command panel is treated as its own virtual array.

For processing parameter blocks, the parameter map manages everything. As a user operates the UI controls of the plug-in, the parameter map processes the messages sent by the controls and stores any values in the parameter block which need to be set.

For processing other variables, the developer needs to provide a way for the parameter map to get and set the i-th element of the virtual array. To do this, the developer assigns an integer index to each parameter. The developer also implements a set of **GetValue()** and **SetValue()** methods. One parameter to these methods is an index to which parameter to get or set. If the parameter map needs the i-th variable to be stored, the developer stores it. If the parameter map needs to retrieve the i-th value the developer supplies it. A section below discusses how this is done.

These are the primary classes involving parameter maps the developer should be aware of:

[Class ParamUIDesc](#) - These are descriptors that define the properties of the UI control such as its type (spinner, radio button, check box, etc.), which resource ID it refers to (which control in the dialog template), and which index into the virtual array to use.

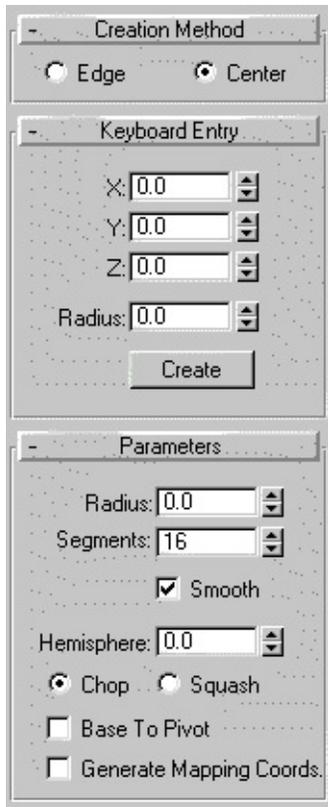

[Class ParamBlockDescID](#) - This class describes each parameter of a parameter block by its type (int, float, point, color), whether it may be animated or is constant, and a ID used to help manage backwards compatibility of parameter blocks.

[Class IParamArray](#) - This is the base class from which parameter maps and parameter blocks are derived. This class represents a virtual array of parameters.

[Class IParamMap](#) - This class provides a set of methods to work with the parameter map, for example, retrieving a pointer to the parameter block used.

## Using Parameter Maps

This section discusses how to use parameter maps to manage the user interface parameter of a plug-in. The example of the procedural sphere object is examined to see how it uses parameter maps. Parameter maps handle most of the command panel user interface processing of the procedural sphere. Shown below are the three rollup pages of the command panel added by the procedural sphere. Except for the "Create" button, all the controls are managed by the parameter map.

The sphere object has two types of parameters managed by parameter maps.

One type of parameter is a simple non-animated value which is driven by a control in the user interface. An example of this is the value associated with the creation method radio buttons in the UI of the sphere. These buttons control if the sphere is created by dragging its radius or its diameter. This is simply a variable which contains the number of the radio button selected by the user (0 or 1). The parameter map allows the variable to be updated as the user chooses radio buttons.

Another type of value is a parameter of a parameter block. Parameter blocks are the mechanism used by 3ds max to manage the animation of parameters. If a parameter is animated, it must have a controller to control the animation.

For example, a floating point value, like the radius of the sphere, uses a floating point controller. The primary purpose of parameter blocks is to manage the complexity of handling different controllers for different parameters. The parameter map updates parameter in the parameter block resulting from any user input, like adjusting the radius spinner.

The following is a description of how the procedural sphere uses parameter maps. It describes how the parameter map was set up and initialized.

The SphereObject class is sub-classed from **IParamArray**.

```
class SphereObject : public GenSphere, public IParamArray {  
    ...  
};
```

This is done so the sphere may use the virtual array mechanism to allow the parameter map to work with its variables. The details of the way the parameter map access these variables is described later in this section.

## Declare the UI Variables

The developer must declare several [= 4\)](#) [BSPSPopupOnMouseOver\(event\);">class variables](#) which are pointers to IParamMaps. Each parameter map manages a **single** rollup page in the command panel.

```
static IParamMap *pmapCreate;  
static IParamMap *pmapParam;
```

The developer must also declare class variables needed for the parameters in the user interface.

```
static int dlgSegments;  
static int dlgCreateMeth;  
static int dlgSmooth;  
static Point3 crtPos;  
static float crtRadius;
```

## Describe the Controls

The developer must define the **ParamUIDesc** arrays to establish the properties of the UI controls such as their type (spinner, radio button, check box, etc.), which resource ID they refer to, and which index into the virtual array they use. Below is the **ParamUIDesc** array for the Parameters rollup page. It calls several overloaded constructors passing the values needed to describe the controls. See the [ParamUIDesc](#) Reference section for detailed information on the constructors.

```
static int squashIDs[] = {IDC_HEMI_CHOP, IDC_HEMI_SQUASH};
static ParamUIDesc descParam[] = {
    // Radius
    ParamUIDesc(
        PB_RADIUS, // Virtual array index
        EDITTYPE_UNIVERSE, // Type of value to edit
        IDC_RADIUS, IDC_RADSPINNER, // Resource IDs
        MIN_RADIUS, MAX_RADIUS, // Upper and lower limits on the
value
        SPIN_AUTOSCALE), // Scale factor for up/down arrow clicks
    // Segments
    ParamUIDesc(
        PB_SEGS,
        EDITTYPE_INT,
        IDC_SEGMENTS, IDC_SEGSPINNER,
        (float)MIN_SEGMENTS, (float)MAX_SEGMENTS,
        0.1f),
    // Smooth
    ParamUIDesc(PB_SMOOTH, TYPE_SINGLECHECKBOX, IDC_OBSM
    // Hemisphere
    ParamUIDesc(
        PB_HEMI,
        EDITTYPE_FLOAT,
        IDC_HEMISPHERE, IDC_HEMISPHERESPINNER,
        0.0f, 1.0f,
        0.005f),
    // Chop/squash
    ParamUIDesc(PB_SQUASH, TYPE_RADIO, squashIDs, 2),
```

```
// Recenter  
ParamUIDesc(PB_RECENTER,TYPE_SINGLECHECKBOX,IDC_HE  
};  
#define PARAMDESC_LENGTH 6
```

## Set Up the Parameter Block

Several of the controls used allow animated values. For example, the radius, and segments parameters may be animated. The developer uses a parameter block to store these values. The developer must define the parameter block descriptor which describes the properties of each parameter.

### Prototype:

```
class ParamBlockDescID {  
    public:  
    ParamType type;  
    UserType *user;  
    BOOL animatable;  
    DWORD id;  
};
```

This class is initialized by passing four values per parameter. These values are:

### **ParamType type**

The Parameter Type - The following are the types which may be used:

- **TYPE\_INT** - Integers values.
- **TYPE\_FLOAT** - Floating point values.
- **TYPE\_POINT3** - Point values.
- **TYPE\_RGBA** - Colors values - Red, Green, Blue and Alpha.
- **TYPE\_BOOL** - Boolean values.

### **UserType \*user**

This value is NOT USED - it must always be passed as NULL.

### **BOOL animatable**

This is a flag indicating if the parameter may be animated or not. Pass TRUE if the value may be animated and FALSE if just a constant value should be stored.

### **DWORD id**

This is an ID assigned to each parameter. This is used for backwards compatibility if you change the parameter block structure in the future. There is a mechanism that allows older format parameter blocks to be converted to a newer format using these IDs to match corresponding parameters between the new and old format. This is described below under Backwards Compatibility.

## Create an Array of Descriptors

The developer must create an array of the descriptors. Items in the parameter block are referred to by index. The index is derived from the order in which the descriptors appear in the ParamBlockDescID array.

```
#define PB_RADIUS 0  
#define PB_SEGS 1  
#define PB_SMOOTH 2  
#define PB_HEMI 3  
#define PB_SQUASH 4  
#define PB_RECENTER 5  
static ParamBlockDescID descVer1[] = {  
  { TYPE_FLOAT, NULL, TRUE, 0 }, // Radius  
  { TYPE_INT, NULL, TRUE, 1 }, // Segs  
  { TYPE_INT, NULL, TRUE, 2 }, // Smooth  
  { TYPE_FLOAT, NULL, TRUE, 3 }, // Hemi  
  { TYPE_INT, NULL, FALSE, 4 }, // Squash  
  { TYPE_INT, NULL, FALSE, 5 } }; // Recenter  
#define PBLOCK_LENGTH 6
```

For more detailed information see the Advanced Topics section [Parameter Blocks](#).

## Create the Parameter Block and Make a Reference to it

A parameter block must be created from the parameter block descriptors. This is done in the constructor of the sphere object. A reference is made to the parameter block as well. For more information on references see the Advanced Topic section [References](#). After the parameter block is created, default values are initialized. This is done using the **SetValue()** method of the parameter block. The developer must pass the index of the parameter, the time to set the value at, and the value to set.

```
SphereObject::SphereObject()  
{  
  MakeRefByID(FOREVER, 0,  
    CreateParameterBlock(descVer1, PBLOCK_LENGTH,  
      CURRENT_VERSION));  
  assert(pblock);  
  pblock->SetValue(PB_RADIUS,0,crtRadius);  
  pblock->SetValue(PB_SMOOTH,0,dlgSmooth);  
  pblock->SetValue(PB_SEGS,0,dlgSegments);  
  pblock->SetValue(PB_SQUASH,0,0);  
}
```

## Add the Rollup Page to the Command Panel

When the user may edit the sphere's parameters the developer must add the rollup pages to the command panel. This is done using the **CreateCPPParamMap()** method. This method creates a parameter map to handle the display of parameters in the command panel. Shown below are two samples from the sphere's **BeginEditParams()** method.

This first call to **CreateCPPParamMap()** manages the variables of the SphereObject (not the parameter block).

The **CreateCPPParamMap()** method takes several arguments. The first is the array of **ParamUIDescs**, one element for each control to be managed. The second is the number of items in this array. The third parameter is a pointer to the virtual array of parameters. The example below uses the **this** pointer of the sphere object to indicate which parameter array. The **this** pointer means the **SphereObject** itself is the **IParamArray** pointer (the **SphereObject** was derived from **IParamArray**). In this way, the parameter map may access the variables of the sphere object. The fourth parameter is the interface pointer passed into the **BeginEditParams()** method. The fifth parameter is the DLL instance handle of the plug-in. The sixth parameter is the dialog template for the rollup page (created using the resource editor). The next parameter is the title displayed in the rollup page title bar. The final parameter is a set of flags to control settings of the rollup page. After this call finishes, the "Creation Method" rollup has been added to the command panel.

```
pmapCreate = CreateCPPParamMap(
    descCreate,CREATEDESC_LENGTH,
    this,
    ip,
    hInstance,
    MAKEINTRESOURCE(IDD_SPHEREPARAM1),
    _T("Creation Method"),
    0);
```

The example below is similar, however it uses the parameter block pointer **pblock** to indicate which virtual array to manage. The parameters in this case are all stored as part of the parameter block (the **IParamBlock** class is derived from **IParamArray**). After this call finishes, the "Parameters" rollup has been

added to the command panel.

```
pmapParam = CreateCPPParamMap(  
descParam,PARAMDESC_LENGTH,  
pblock,  
ip,  
hInstance,  
MAKEINTRESOURCE(IDD_SPHEREPARAM2),  
_T("Parameters"),  
0);
```

## Allowing the Parameter Map to Access plug-in Variables

The developer must implement the **GetValue()** and **SetValue()** methods of the **IParamArray** class to allow the parameter map to manage the **SphereObject** variables. The virtual array mechanism works by using an index to specify which parameters are to be retrieved and set. Shown below are samples for the integer creation method variable. Each method uses a switch statement that checks the index into the virtual array and gets or sets the appropriate variable. Note that the way the developer assigns the index to the variables is important since this is an index into the virtual array. Start at 0 and assign each one 0, 1, 2, 3...

```
BOOL SphereObject::SetValue(int i, TimeValue t, int v)
{
  switch (i) {
    case PB_CREATEMETHOD: dlgCreateMeth = v; break;
  }
  return TRUE;
}
BOOL SphereObject::GetValue(int i, TimeValue t, int &v, Interval
&ivalid)
{
  switch (i) {
    case PB_CREATEMETHOD: v = dlgCreateMeth; break;
  }
  return TRUE;
}
```

## Removing the Rollup Page from the Command Panel

When the user is done editing the sphere's parameters, the **DestroyCPParamMap()** method is used to remove the rollup page from the command panel and release the controls associated with the parameter map. It is called from the **EndEditParams()** method.

**Prototype:**

```
void DestroyCPParamMap(IParamMap *m);  
if (pmapCreate) DestroyCPParamMap(pmapCreate);  
DestroyCPParamMap(pmapParam);  
pmapCreate = NULL;  
pmapParam = NULL;
```

## Processing Controls not managed by the Parameter Map

Some controls may need to be processed by the developer directly. The sphere has a 'Create' button in the 'Keyboard Entry' rollout. Button controls are not processed by parameter maps. In order to process the messages sent when the user operates the button, the developer needs to derive a class from [ParamMapUserDlgProc](#) and set it as the parameter map's user [= 4](#)) [BSPSPopupOnMouseOver\(event\);">callback](#) using **SetUserDialogProc()**.

```
class SphereTypeInDlgProc : public ParamMapUserDlgProc {
public:
    SphereObject *so;
    SphereTypeInDlgProc(SphereObject *s) {so=s;}
    BOOL DlgProc(TimeValue t,IParamMap *map,
        HWND hWnd,UINT msg,WPARAM wParam,LPARAM lParam);
    void DeleteThis() {delete this;}
};
```

The **SetUserDlgProc()** method of [IParamMap](#) is used to set the callback to handle the messages. Note that the callback is called after the default processing is complete.

```
pmapTypeIn->SetUserDlgProc(new SphereTypeInDlgProc(this));
```

For more information on Dialog Procs see the Advanced Topics section on [Custom Controls](#).

## Providing a Name and Dimension for the Parameter Block Parameters

The developer must provide a name for each parameter used in a parameter block. This name is needed because the animated parameters show up in the track view and must be labeled. The parameter block takes care of displaying them in the track view, but has no idea of the name for each one, it only knows them by index. The developer provides the name to display by implementing the method **GetParameterName()** and returning the name of the parameter whose index into the parameter block is passed.

```
TSTR SphereObject::GetParameterName(int pbIndex)
{
  switch (pbIndex) {
    case PB_RADIUS:
      return TSTR(_T("Radius"));
    case PB_HEMI:
      return TSTR(_T("Hemisphere"));
    case PB_SEGS:
      return TSTR(_T("Segments"));
    case PB_SMOOTH:
      return TSTR(_T("Smooth"));
    default:
      return TSTR(_T(""));
  }
}
```

The developer must provide a dimension for each parameter used in a parameter block. This dimension is basically the type and magnitude of the value stored in the parameter block. Pre-defined constants are used as the return values. For more information, see the Reference section [ParamDimension](#).

```
ParamDimension *SphereObject::GetParameterDim(int pbIndex)
{
  switch (pbIndex) {
    case PB_RADIUS:
      return stdWorldDim;
    case PB_HEMI:
      return stdNormalizedDim;
    case PB_SEGS:
      return stdSegmentsDim;
  }
}
```

```
case PB_SMOOTH:  
    return stdNormalizedDim;  
default:  
    return defaultDim;  
}  
}
```

## Backwards Compatibility

As development evolves on a plug-in, the use of its parameter blocks may change. For example, more parameters may be added or some may be deleted. 3ds max files that were saved using the old version of the plug-in would not normally load properly under the new format. In order to provide backward compatibility with the older format a mechanism exists to allow the old format to be converted to the new format.

To accomplish the conversion you must define both the old and the new format of the parameter block.

```
static ParamBlockDescID descVer0[] = {
    { TYPE_FLOAT, NULL, TRUE, 0 },
    { TYPE_INT, NULL, TRUE, 1 },
    { TYPE_INT, NULL, TRUE, 2 } };
static ParamBlockDescID descVer1[] = {
    { TYPE_FLOAT, NULL, TRUE, 0 },
    { TYPE_INT, NULL, TRUE, 1 },
    { TYPE_INT, NULL, TRUE, 2 },
    { TYPE_FLOAT, NULL, TRUE, 3 },
    { TYPE_INT, NULL, FALSE, 4 },
    { TYPE_INT, NULL, FALSE, 5 } };
#define PBLOCK_LENGTH 6
```

The fourth argument of the **ParamBlockDescID** is the ID of the parameter. These are used to match the old version of the parameter to the new version. The code which does the conversion matches the IDs between the two versions, for example, it will match the ID=1 of the old version to the ID=1 of the new version.

You create an array of the class **ParamVersionDesc**, one element for each old version of the parameter block. This structure describes a version of the parameter block. You also create an instance of **ParamVersionDesc** for the new version.

```
// Array of old versions
static ParamVersionDesc versions[] = {
    ParamVersionDesc(descVer0,3,0)
};
#define NUM_OLDVERSIONS 1
```

```
// Current version
static ParamVersionDesc curVersion(descVer1,PBLOCK_LENGTH,1);
#define CURRENT_VERSION 1
```

When the plug-in is loaded, its **Load()** method is called. From within this method you call a method of the **ILoad** class which registers the parameter block post load callback object. The callback object is an instance of the class **ParamBlockPLCB**. This callback creates a new parameter block. The new parameter block inherits any parameters from the old parameter block whose parameter IDs match. In this way the older format is automatically converted to the new format by matching the corresponding IDs.

```
IOResult SphereObject::Load(ILoad *iload)
{
  iload->RegisterPostLoadCallback(
    new
    ParamBlockPLCB(versions,NUM_OLDVERSIONS,&curVersion,1)
  )
  return IO_OK;
}
```

See also: [Loading and Saving](#), [ParamBlockPLCB](#).

# Parent-Child Hierarchy

See Also: [Class INode](#).

## Overview

In 3ds max nodes in the scene may be linked together to form a hierarchy. 3ds max provides a developer with methods to work with this hierarchy via the **Inode** class.

A node that is linked to another node is referred to as a child node. A node that has children is referred to as a parent node. A node may have several children, but only a single parent. 3ds max provides access to the children of a node using an array mechanism.

## Methods

The **INode** method **NumberOfChildren()** may be used to retrieve the number of children a node has. To retrieve any of the children, use the method **GetChildNode(int i)**. This returns an **INode** pointer to the 'i-th' child. To retrieve the parent of a node use the method **GetParentNode()**. This returns an **INode** pointer to the parent node.

To attach a node to another node, use the method **AttachChild(INode\* node, int keepPos=1)**. This method attaches the specified node to the calling node.

To detach a child node use **Detach(TimeValue t, int keepPos=1)**. Both these methods allow the original position of the node prior to the hierarchy change to be maintained.

The method **IsRootNode()** determines if this node is a root node (does not have a parent node other than the world).

Note the following regarding cycles in hierarchical links:

Cycles with both hierarchical links and references can be legal or illegal, depending on the nature of the references. If a node's transform controller depends on one of the node's child nodes (or on any of its descendent nodes) this is illegal. However there is some special case code so that if a node's \*object depends on any of the node's descendent nodes, it is not considered a cycle, and is legal.

To review the full details on these methods see the reference section [Class INode](#).

# Profiling Plug-In Performance

See Also: [Debugging](#).

## **Overview**

There is a utility plug-in called the 3ds max Profiler that is available to allow developers to analyze the execution and performance of their plug-ins. The profiler supports analyzing Release build plug-ins. This allows profiling to take place with full optimization, inlining, etc. (Hybrid and Debug builds can also be profiled however this doesn't provide accurate information since the code is not optimized).

## **Two Types of Profiling**

There are two types of profiling that may be done. One is called **Polling** and the other is called **Instrumented**.

**Polling Profiling** requires no special compiler settings other than generating debug information (a PDB file). This works by setting up a separate thread and periodically looking at the context of the main thread. It looks at the instruction pointer to determine what instruction the CPU is at and stores this information. When finished, the stored addresses are used to report the module, source file and line number of the function (see below for the details on enabling these options).

**Instrumented Profiling** requires a special compiler setting but provides much more accurate profiling information.

Typically both of these are used. The polling profiler is used first to get a rough idea of where the greatest amount of execution time is being spent. Then instrumented profiling is done for those time consuming areas. This allows one to get a quick overview using polling and then collect very accurate, detailed information using instrumented profiling.

## Preparing For Profiling -- Compiler and Link Settings

There are several things that need to be done to get a plug-in ready for profiling. These are:

1. Generating debugging information.
2. For Instrumented Profiling Only -- Linking to the profiling LIB file.
3. For Instrumented Profiling Only -- Compiling using a special compiler flag.

These steps are outlined below:

1. You need to make sure debugging information is available. This can be turned on in the IDE using **Project / Settings / C++ Tab** and choosing **General** from the **Category** dropdown and choosing **Program Database** from the **Debug info** combo box. You'll also need to check the **Generate Debug Info** check box in the **General Category** of the **Link Tab** of the dialog. This will cause a PDB file to be written. The profiler needs the PDB file in order associate the addresses it collects as the program executes with actual entry points in the code.
2. For Instrumented Profiling Only -- You must add **ACAP.LIB** to the plug-ins link libraries. This is done using the **Project / Add To Project / Files** command from the pulldown menus. From the dialog presented choose **\MAXSDK\LIB\ACAP.LIB**.
3. For Instrumented Profiling Only -- to work the plug-in must be compiled with a special compiler flag: **/Gh**. This option isn't available through the IDE in a check box -- it must be manually typed into the Project Options list. You access this list from the IDE using **Project / Settings / C++ Tab / General Category**. At the beginning of the list of options add **/Gh**. What the **/Gh** option does is instruct the compiler to call a special function named **penter()** prior to doing anything for every procedure entry point. The **penter()** function is provided by the profiler and is used to collect all the profiling information.

## Using the MAX Profiler Plug-In

The profiler is a utility plug-in (**MAXSDK\PLUGIN\MAXPROF.DLU**) with an interface in both the command panel and a small floating dialog. The command panel interface is used to indicate which type of profiling is done, which information is written to the output file, and what file name it's written to. The floating dialog is used for starting, stopping, saving and clearing the profile recording.

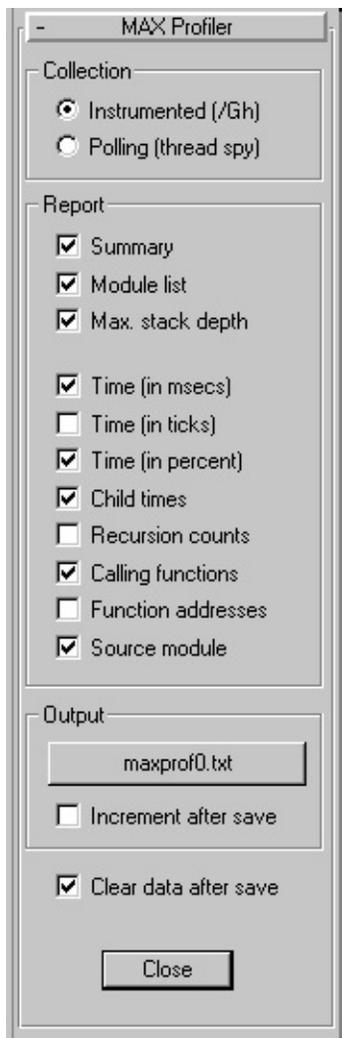

To run the profiler select **3ds max Profiler** from the list of utility plug-ins. A smaller floating dialog appears as well as the command panel interface. Via radio buttons in the Collection area choose if you want to perform Instrumented or Polling profiling.

To collect profiling information you select the options you want to record using the check boxes in the **Report** area of the command panel rollup. Next choose the desired output file name, from the **Output** rollup. By default the output file is written to **maxprof0.txt** in the same directory as the currently loaded 3ds max file.

Once these choice have been made, click on the **Record** button in the floating dialog. This puts the profiler in record mode -- ready for the collection of profiling information.

Next, simply use the plug-in you wish to profile. For instance, if your plug-in is a modifier, apply it to an object and adjust its settings. As you work with the plug-in, or 3ds max calls its methods, the profiling information is collected. The floating dialog stays active even if you leave the utility branch of the command panel so you're free to use all of 3ds max to fully test your plug-in. Note that the profiler is persistent even through a 3ds max File / Reset operation. This allows developers to track what calls are made during a Reset as well. If you want to reset the profiling information, press the Clear button on the floating dialog.

This section list each of the controls in the command panel user interface:

### Report section:

The check boxes in this section determine which portions of the output file are written. Below is a description of each of the options in this dialog. The sample output file shown later in this topic shows an example what is written for each of these.

**Summary:** This generates some basic information about the speed of the machine 3ds max is running on, the amount of time spent profiling, and the number of functions that were profiled.

**Module list:** This generates a list of all the modules that are loaded into process memory.

**Max stack depth:** This reports the maximum depth of function calls the profiler reached.

The following options are reported for every function that is called. These

items appear as columns of data in a table where each row represents one function call.

**Time (in msec):** This is the amount of time spent in the function in milliseconds. This is labeled **SelfTime** in the output table.

**Time (in ticks):** This is amount of time spent in the function in ticks. This is labeled **SelfTicks** in the output table.

**Time (in percent):** This is the time in a function as a percent of the overall time spent in all the functions that were profiled. This is labeled **SelfPercent** in the output table.

**Child times:** If this is checked, three new columns are added to the output table. These are labeled **HierTicks**, **HierTime** and **HierPercent**. These are similar to those above, but include not only the function itself, but also any functions it calls. This one is useful because you can sort the table by child times (in a spreadsheet such as Excel) and it will display the most time intensive functions first.

**Recursion counts:** This option is useful if you have recursive functions. It shows how many time the function calls back on itself. This is labeled **Recursions** in the output table.

**Calling functions:** This generates a multiline entry. For each function profiled, a list of all the functions, or places within a function, that called it are shown. This also lists how many times each of the functions called it.

**Function addresses:** This generates the address in memory for the function. This is labelled **Address** in the output.

**Source module:** This generates the name of the module (the name of the DLL that the profiled function lives in). If you are running under NT5 and have **IMAGEHLP.DLL** you'll get the source file name and line number. This is labelled **Module** in the output.

The number of calls (labeled **Count** in the output table) is always reported. This is the number of times the function was entered.

### **Output section:**

**Output file selector button:** By default, the output is written to the path where the 3ds max file was loaded. Clicking on this button brings up the file selector dialog for choosing a new output file.

**Increment after save:** This check box is enabled only when the filename has a number or numbers at the end. If checked, the file name shown on the

button is incremented each time the profiling information is saved. If unchecked, the file is overwritten on a save.

**Clear data after save:** This check box resets the profiler after each time the profiling information is saved. If this is off, profiling information continues to accumulate after a save.

**Close:** This closes the 3ds max Profiler plug-in in the user interface.

This section list the controls in the floating dialog.

The floating dialog has three buttons used for starting/stopping, saving and clearing the profile recording.

**Record / Stop:** This button is used to start and stop the collection of profiling information.

**Save:** This button is used to save the collected profiling information to disk.

**Clear:** This button is used to reset the profiling information so new recording will start from a clear state. If you want to clear out any existing profiling information generated press this button.

## Interpreting the Profiler Output File

This section presents an example of output from the profiler and describes the meaning of each section.

### The summary section:

This section is written if the 'Summary' check box is checked.

**Tue Jul 29 15:46:10 1997**

**WinNT 4.0**

**microSecsPerTick 0.12126**

This simply gives data about the timing of the CPU. This is the number of micro seconds per tick. Tick counts are used in several places in the profiler output.

**Ticks (elapsed/collected) 1860866843/305119085**

This tells how many CPU ticks went by during the run of the profiler (between when the Record and Stop buttons were pressed) over how many were actually collected (counted) by the profiler.

**Secs (elapsed/collected) 225.649/36.9988**

This tells the same information as above, only in seconds.

**Total functions 76**

This is the total number of functions that were profiled.

**Total calls 7493**

This is the total number of calls that were found while profiling.

### The module list section:

This section is written if the 'Module list' check box is checked.

**module base**

**3dsmax 0x400000**

**ntdll 0x77f60000**

**...etc...**

**GDI5 0x33600000**

**SZB5 0x33200000**

**msafd 0x77660000**

**wshtcpip 0x77690000**

This simply lists all the modules that are loaded into process memory and the

address of where they actually wound up.

### Max stack depth section.

This section is written if the 'Max stack depth' check box was checked.

### Max Stack Depth 8

This indicates how far into the procedure chain the profiler was used. That is, how many calls deep was the profiler involved in. This number is exclusive of recursion.

### The profiling data section.

The data shown below is copied from an Excel spreadsheet to make it appear in a table format. In pure text form as output by the profiler the data is tab delimited. One can simply copy this data to the clipboard, paste it into Excel, and it fills out the spreadsheet cleanly into rows and columns. The data here is just as described above under the user interface controls. Of particular note is the list of calling functions. When that option is checked the table may contain multiple lines per function. For each function profiled, a list of all the functions, or places within a function, that called it are shown. This also lists how many times each of the functions called it. For example, in the table below,

**GetString()** was called 13 times, 1 time by **EnterMode()**, 4 times by **DoPoint()**, 1 time by **DefineStroke()**, 2 times by **DefineStroke()** at a different address, 3 times by **UpdateStrokeInfo()**, and 2 times by **ReviewStrokes()**.

## **Profiling and Processors**

This section discusses how the profiler deals with multiple processors.

The profiler forces 3ds max to run on a single processor. This is beneficial because it provides more accurate timing results than trying to collect the data from multiple processors.

## Profiling in MAX 3.0

With some combinations of system software and Visual C development environments, the profiler will fail to output symbols, even though the .pdb information is present. This is caused not by the profiler itself, but by the imagehlp.dll upon which it relies. This imagehlp.dll is supplied by Microsoft, and while it has undergone some changes, it has not stayed completely current with the rest of the OS DLL naming conventions. This is to say that they're loading some old DLLs explicitly - clearly a bug in the imagehlp.dll.

Consequently, you have two options for how you can resolve the problem. You must choose one of these two work arounds:

1. See that you have the NT4.0 version of %SYSTEMROOT%\system32\imagehlp.dll installed. It should have the file version of 4.0.1381.125 as seen in the explorer's file properties. Now, curiously, this file loads MSPDB50.DLL via hard-coded string. Of course if you're using VC6, you'll have MSPDB60.DLL rather than MSPDB50.DLL. Fortunately, the two are compatible at the interface level, so you can "copy MSPDB60.DLL MSPDB50.DLL" to provide one for imagehlp.dll to load. The drawback of using this fix is that the imagehlp.dll from NT4 does not support filename/line number information, and the most discrete info you can retrieve from the profiler's output is the names of the functions.

2. If you have access to NT5b2, you can use some of the DLLs supplied there. On that CD, in \i386 you'll find "imagehlp.dll" and "msdbi.dll". Taken together these files will work in NT4 just fine. Moreover, they'll supply the cool-ofilename and line number info that makes the profiler more valuable. Be sure that the file versions you get are 5.0.1878.1 for imagehlp.dll and 6.0.8337.0 for msdbi.dll. Again, this version info is available from the explorer's file properties dialog.

With whichever method you elect, you can put the required files either in your system32 directory so that they're available to the system as a whole, or in max's executable directory, in which case they'll affect only 3ds max .

## Read Only Plug-Ins

See Also: [Anti-Piracy Protection](#).

Plug-ins can read the 3ds max hardware lock ID number. Using the hardware lock ID, developers can provide versions of their plug-in that are slightly disabled. When the plug-in was loaded, if the current hardware lock wasn't the one it was authorized to run on, it would put itself in a disabled mode.

For example, this might mean the user interface for the plug-in was only partially enabled. Or perhaps the plug-in's parameters might not be fully editable in MAX. Possibly they are assigned fixed values, or values of a limited range, so the user can get the general idea of the plug-in but not really work with it in production.

These disabled versions could be freely distributable and contain information on how the complete versions can be purchased. This kind of information can be shown to the user via the 3ds max File/Summary Info.../Plug-In Info...

command. This is accomplished using the DLL function **LibDescription()**.

See [DLL Functions and Class Descriptors](#) for more information on this function.

A developer could implement a system where the user could phone the plug-in distributor and get a key number to unlock the disabled version. This key would allow the plug-in to be bound to the hardware lock of the new machine.

Sample code using an anti-piracy / authorization scheme can be found in **\MAXSDK\SAMPLES\MODIFIERS\TWIST.CPP**.

## References

See Also: [Class ReferenceMaker](#), [Class ReferenceTarget](#), [List of Reference Messages](#).

## Overview

In the 3ds max architecture, elements of the scene often form dependencies on one another. The typical manner these dependencies are handled in 3ds max are through References\*. A reference is a record of dependency between a reference maker and a reference target. The reference maker is said to be dependent upon the reference target. If the target changes in some way that affects the maker, the maker must be notified so it may take appropriate action.

\* Note: This use of the term reference in this section should not be confused with the term reference used in the 3ds max interface and user manuals. Nor is it to be confused with the C++ definition of reference. In this section, the term reference will always apply to the notion of a dependent relationship unless specifically stated otherwise.

Below are a few examples of dependent relationships between elements of a 3ds max scene that are managed using references:

A loft model is dependent upon its path shapes. When one of the path shapes changes, the model must be notified so it may update itself.

The path controller is dependent upon the spline path the controller is assigned to follow. When the spline path changes shape, the controller must be notified so it may realign its node to the revised path.

The procedural sphere is dependent upon its animated parameters. When the parameters are changed, the object must be notified so that it can update its cached representation to reflect the new settings.

The above examples show how references have been used in 3ds max plug-in development. Any time a developer wants to set up a dependent relationship between two elements of the scene and be notified of any changes, a reference may be used.

There are two key classes involved in the 3ds max reference system. These are the **ReferenceMaker** class, and the **ReferenceTarget** class. The **ReferenceTarget** class is derived from the **ReferenceMaker** class. Most plug-in classes are derived from **ReferenceTarget**. Thus most plug-ins may make references themselves.

There are three key methods involved when working with references. These are **MakeRefByID()**, **NotifyDependents()**, and **NotifyRefChanged()**.

## Change Notification Methods

The reference scheme allows a reference target to notify all its dependent reference makers when it changes. This section presents an overview of how this is done.

Having a reference is similar to having a pointer to an object, however when a maker references a target, that target maintains a pointer back to the maker. The reference target keeps a list of back pointers to all the reference makers which reference it. This gives the target the ability to notify each of its dependent reference makers when it has changed in some fashion. There are several methods that must be called or implemented by the plug-in when it uses references:

The reference maker must inform the reference target that it is dependent upon it. It does this by creating a reference to the target using a method called **MakeRefByID()**. The target then maintains this record of dependency via its pointer back to the reference maker.

When a reference target changes it must notify its dependent reference makers of this change. It does this by calling a method **NotifyDependents()**.

A reference maker must implement a method to receive the change notification messages sent by the target. It does this by implementing a method called **NotifyRefChanged()**.

Let's look at each of these methods and how they are handled by a specific 3ds max plug-in. We'll use the example of the path controller. The path controller governs the position of a node in the scene allowing it to track along a selected spline path. A spline path node in the scene is chosen to follow, and a parameter controls the amount of banking applied to the node as it follows along the path. (The path controller has other parameters, but concerning references the others are similar to the two covered here). The processing of these parameters involves several references.

The path controller tracks another node in the scene. This node is a spline and it is of course free to change shape and orientation at any time. By creating a reference to the spline node using **MakeRefByID()**, the controller will be notified whenever the spline changes. The path controller also must monitor its own banking parameter which may be animated and change over time. By creating a reference to this parameter the controller will be informed whenever the parameter changes.

A reference target is responsible for notifying all its dependent reference makers when it has changed. The spline path is a reference target. It is therefore responsible for informing its dependent reference makers when it changes. It does this by calling a method of ReferenceMaker **NotifyDependents()**. Any reference target maintains a list of pointers to the items that reference it. Internally, the **NotifyDependents()** function loops through all these pointers and calls a method **NotifyRefChanged()** on each one. **NotifyRefChanged()** is the method implemented by the reference maker responsible for receiving and responding to the change notification messages.

The path controller also maintains a banking parameter and has created a reference to it, so the parameter has become a reference target. Whenever the user alters the value of the banking parameter, a message must be sent to notify the path controller it has changed. This is done by calling **NotifyDependents()**. As part of this function call it passes the message **REFMSG\_CHANGE**. The **NotifyDependents()** call broadcasts this message to all the items which reference it. The bank parameter has one reference to it -- the path controller.

As a reference maker, the path controller must have a way to receive and respond to messages sent to it. The path controller must respond to the notification of the banking parameter changing and the spline path changing. It does this by implementing a method of the ReferenceMaker class called **NotifyRefChanged()**. The usual implementation of this method has a switch statement where each case is one of the messages the plug-in must respond to. The messages the plug-in must respond to depend upon the types of references it makes. There are additional messages which the system itself may need the plug-in to respond to. For example, say the spline which the path controller is following is deleted from the scene. The system needs to inform the plug-in that this has occurred. The plug-in developer must handle this possible condition by providing a case in **NotifyRefChanged()** to respond to the message **REFMSG\_TARGET\_DELETED**. See [List of Reference Messages](#).

## **Details of the Change Notification Methods**

This section looks in detail at the methods used by reference makers and targets for change notification.

## Making References

To create a dependency upon an item, the developer creates a reference to the item. This is done by calling a method of ReferenceMaker called **MakeRefByID()**.

```
RefResult MakeRefByID(  
    Interval refInterval,  
    int which,  
    RefTargetHandle htarget  
);
```

This method creates a reference between the object which calls the method, and the ReferenceTarget specified by the **htarget** parameter.

The **refInterval** parameter indicates the interval of time over which this reference is active. Outside this interval, the reference is not considered to be a dependency. This allows the plug-in to have dependent relationship over only portions of an entire animation time range. If a plug-in has a dependency over the entire animation it may use the pre-defined interval **FOREVER** for this parameter. In the current implementation all plug-ins must use **FOREVER** for this interval.

The **which** parameter indicates which reference index this newly created reference is assigned to. The system uses a virtual array mechanism to access the references an item has. The developer simply assigns an integer index to each reference. For example, the path controller might use an index of 0 for the bank amount parameter reference, and an index of 1 for the node to follow reference. The path controller would then pass either 0 or 1 as the **which** parameter depending upon which reference it was making. This is discussed in greater detail below under Reference Access Methods.

The **hTarget** parameter is the handle of the item to which a reference is being made.

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the reference was created and is registered by the reference target.

## Sending Change Notification Messages

When a reference target changes it must notify its dependent reference makers of this change. It does this by calling **NotifyDependents()**.

```
RefResult NotifyDependents(  
    Interval changeInt,  
    PartID partID,  
    RefMessage message,  
    SClass_ID sclass=NOTIFY_ALL,  
    BOOL propagate=TRUE,  
    RefTargetHandle hTarg=NULL  
);
```

This method broadcasts the message specified by the **message** parameter to all the items which reference the caller.

The **partID** parameter is used to pass message specific information to the items which will receive the message. See the Reference section [Class ReferenceMaker NotifyRefChanged\(\)](#) method for more details.

The **changeInt** parameter indicates the interval of time over which the change reported by the message is in effect. Currently all plug-ins must pass **FOREVER** for this interval.

The **sclass** parameter defaults to **NOTIFY\_ALL**. If this value is passed to **NotifyDependents()** all dependents will be notified. Other super class values may be passed to only send the message to certain items whose SuperClassID matches the one passed.

The **propagate** parameter defaults to **TRUE**. This indicates that the message should be sent to all 'nested' dependencies. If passed as **FALSE**, this parameter indicates the message should only be sent to first level dependents. Normally this should be left to default to **TRUE**.

The **hTarg** parameter defaults to **NULL**. A plug-in developer should never pass anything for this parameter. It must always default to **NULL**.

## Responding to Change Notification Message

A plug-in which makes references must implement a method to receive and respond to messages broadcast by its dependents. This is done by implementing the **NotifyRefChanged()** method of **ReferenceMaker**.

```
virtual RefResult NotifyRefChanged(  
    Interval changeInt,  
    RefTargetHandle hTarget,  
    PartID& partID,  
    RefMessage message  
);
```

The plug-in developer usually implements this method as a switch statement where each case is one of the messages the plug-in needs to respond to. The **message** parameters passed into this method is the specific message which needs to be handled.

The **changeInt** interval is the interval of time over which the message is active. Currently, all plug-ins will receive **FOREVER** for this interval.

The **hTarget** parameter is the handle of the reference target the message was sent by. The reference maker uses this handle to know specifically which reference target sent the message.

The **partID** parameter contains information specific to the message passed in. Some messages don't use the **partID** at all. See the section below on Reference Messages and PartIDs for more information about the meaning of the **partID** for some common messages.

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the message was processed. Sometimes, the return value may be **REF\_STOP**. This return value is used to stop the message from being propagated to the dependents of the item.

Below is an example of the code structure usually used to implement **NotifyRefChanged()**. It is a simplified version taken from the path controller:

```
RefResult PathPosition::NotifyRefChanged(  
    Interval changeInt,  
    RefTargetHandle hTarget,  
    PartID& partID,
```

```
RefMessage message)
{
switch (message) {
case REFMSG_CHANGE:
// Code to handle the target changing...
break;
case REFMSG_TARGET_DELETED:
if (hTarget == pathNode) {
// Code to handle to path node being deleted...
}
break;
};
return REF_SUCCEED;
}
```

Note: A plug-in should NOT normally call **NotifyDependents()** from its **NotifyRefChanged()** method. All the appropriate dependents are notified automatically and thus doing so is unnecessary.

## Reference Access Methods

The system manages the access to an item's references by using a virtual array. If the plug-in makes references, it must implement three methods of

**ReferenceMaker** to handle access to its references. These methods are:

### **int NumRefs();**

The plug-in implements this method to return the total number of references it makes.

### **RefTargetHandle GetReference(int i);**

The plug-in implements this method to return a reference handle to its 'i th' reference. The plug-in keeps track of its references using an integer array index for each one. When the system calls this method, the plug-in returns its 'i th' reference.

### **void SetReference(int i, RefTargetHandle rtarg);**

The plug-in implements this method to store the reference handle passed into its 'i-th' reference. The plug-in simply keeps track of its references using an integer array index for each one. When the system calls this method, the plug-in stores its 'i-th' reference.

Below is an example of how these methods might be implemented

```
#define PATHPOS_BANK_REF 0
#define PATHPOS_PATH_REF 1
int NumRefs() { return 2; }
RefTargetHandle PathPosition::GetReference(int i)
{
    if (i==PATHPOS_BANK_REF) {
        return bankAmount;
    } else {
        return pathNode;
    }
}
void PathPosition::SetReference(
    int i,
    RefTargetHandle rtarg)
{
    if (i==PATHPOS_BANK_REF) {
```

```
bankAmount = (Control*)rtarg;  
} else {  
  pathNode = (INode*)rtarg;  
}  
}
```

## Maintenance Methods

The following are methods that may be used to delete references when they are no longer needed:

### **DeleteAllRefFromMe();**

This deletes all references from the calling reference maker.

### **DeleteAllRefs();**

Deletes all references to and from the calling reference maker.

### **DeleteMe();**

This method deletes all references to and from the calling reference maker, sends the **REFMSG\_TARGET\_DELETED** message, handles Undo, and deletes the object.

## Deleting and Replacing References as the Reference Structure Changes

The number of references maintained by a plug-in may change over time. This section presents information on the different approaches developers may use to allow the reference structure to change.

Basically, a developer can have two kinds of reference structures. One approach is to have the number fixed, where some references may go to NULL occasionally, but the number stays the same. Alternatively, a developer can have a variable number of references, and move them around as they are added and deleted.

The first option, where the number stays fixed, is accomplished by keeping the number of references returned by **NumRefs()** constant. An example of this from 3ds max is the 3D Texmap Marble (**\MAXSDK\SAMPLES\MATERIALS\MARBLE.CPP**). It has 4 references: the pblock, the xyzGen instance, and two sub-texmaps. When the texmap starts up fresh it doesn't have sub-maps. Yet it still returns 4 from **NumRefs()**. When the user clicks on a user interface button to add a sub-map, the texmap calls **ReplaceReference()** on the sub-texmap index and a reference to the new sub-texmap gets plugged-in. Thus the pointer to it is no longer NULL. Again, **NumRefs()** doesn't change, it is just that reference is no longer NULL. A user can also set the sub-texmap back to 'None' to stop using it. In this case **DeleteReference()** will be called (**DeleteReference()** breaks the connection between the pointer stored and the system -- this is done so 3ds max will not send change notification messages any longer). Again, even though the reference was deleted **NumRefs()** still returns 4.

**DeleteReference()** will set the pointer to NULL.

The other approach to structuring references involves altering the number of references returned from **NumRefs()**. A developer can, after deleting a reference, change **NumRefs()** to one less and move around the pointers so **GetReference()** and **SetReference()** still return the proper values. An example of when this might be used is if the data structure for the plug-in had a variable number of references that the user could directly alter. The Multi-SubObject material is structured like this (**\MAXSDK\SAMPLES\MATERIALS\MULTI.CPP**). It maintains a table of the sub-materials and the user can alter the number of these on the fly via the user interface. In its implementation of **NumRefs()** it returns the

number of items in the table at that moment. When the user asks for fewer sub-materials (and thus fewer references) **ReplaceReference()** is called passing NULL and **NumRefs()** returns a smaller value. When the user adds additional sub-materials, new materials are created and **ReplaceReference()** is called passing pointers to these new materials.

## Pointers and References

When a plug-in has a pointer to an item it should usually make a reference to the item as well. This will ensure the item is not deleted by the system (which would make the pointer invalid).

In 3ds max when the last reference to an item is deleted, the item itself is deleted.

For example, say your plug-in has a pointer to a sub-anim, but you have not created a reference to it. If this sub-anim appears in track view, the system will create a reference to it because track view needs a reference to the items it displays. When track view is finished displaying this sub-anim, it will delete the reference. If this is the last reference to the sub-anim, the sub-anim itself will be deleted. This would invalidate the pointer you are maintaining to the sub-anim. The way to prevent this from happening is to create a reference to the sub-anim. The system does not delete items that still have references to them. Therefore by making a reference to the item you ensure that the system will not delete it.

The one exception to this is nodes in the scene. Nodes may be deleted by the user by simply selecting the node and pressing the delete key. If an item has a reference to the node the user may still delete it. However the item that referenced the node will receive the message

**REFMSG\_TARGET\_DELETED** via **NotifyRefChanged()**. It can then respond appropriately to the deletion.

At certain times a plug-in may need to have a two-way reference. For example, if there is an item that references another item, the referenced item cannot have a reference back to the thing that referenced it, because this would create a loop (a cyclic reference). Cyclic references are illegal. In other words if A has a reference to B, then B **cannot** have a reference to A.

The Ring Array plug-in has a situation where A has a reference to B, but B has a **pointer** to A (but doesn't have a reference to A since that would cause a loop). Again, whenever you have a pointer to something you should have a reference to the item as well. But B cannot reference A.

What is done in this case, where you want a two-way reference, is as follows. A has a reference to B, and A can give B a pointer to itself. A is then responsible for informing B if it gets deleted so B can set its pointer to A to NULL. So A is responsible for making sure B's pointer to A doesn't end up invalid. This is the way you can set up a two-way dependency yet not create a cyclic reference. The

item that is being pointed at must manage the pointer for the item that maintains the pointer.

When this setup is saved to disk another problem arises. How does one save a pointer, since the value will of course be different when loaded. The solution to this is to use methods of the **ISave** and **ILoad** classes that let a developer save and restore pointers. This must be a pointer to one of the objects that the scene saves with the reference hierarchy, but it is not a pointer that itself is a reference. When the pointer is saved the method **ISave::GetRefID()** is used. This returns an integer ID that can be saved to disk. When loading, a method **ILoad::RecordBackpatch()** is used. This takes the ID and a pointer to a pointer and sets the pointer to point back at the item that was pointed at when things were saved. See [Class ISave](#), [Class ILoad](#) for more details.

## The Loading and Saving of References

The system takes care of loading and saving references when an object is saved to disk. An object does not need to explicitly save its references, nor does an object need to load its references. After a scene is loaded, an object's references will automatically be restored. The system does this by using the **NumRefs()**, **GetReference()** and **SetReference()** methods of the plug-in.

For example, the path controller plug-in has a reference to the spline shape node in the scene it follows. It does not save this node explicitly in its implementation of **ReferenceMaker::Save()**. Yet this reference will be restored whenever the file is loaded from disk. This happens because the reference is saved and restored automatically by the system.

For anything that you have a reference to that you want saved and reloaded, you need to have a class descriptor registered with the system. This is because the system needs to call **ClassDesc::Create()** on the item to create it upon reloading. See [Class ClassDesc](#).

Note that since references are restored automatically at loading time 3ds max needs to call **ReplaceReference()**. This **ReplaceReference()** will cause a call to **DeleteReference()**, which checks if the return value of **GetReference()** is NULL. Therefore developers have to initialize their references to NULL, if the **ClassDesc::Create()** method is called with **loading==TRUE**. If they don't and **GetReference()** is called with a non initialized return value at loading time, 3ds max will crash.

While loading, that is in a plug-in's implementation of its **Load()** method, the references are NOT in place yet. The references are not in place until everything in the 3ds max file is loaded. If a developer needs to do something with the references when loading, a post load callback may be used. This is done using the method **ILoad::RegisterPostLoadCallback()**. The callback is called after all loading is complete. Inside the callback the plug-in's references will be in place and they may be processed by the plug-in.

Another way a post load callback is used is to restructure references during a **Load()**. For example, say a plug-in references a static number of objects followed by any number of additional objects. Later, as development progresses on the plug-in, another static object is added to the reference structure. It would be nice if old files that still used the older reference structure could be loaded. The way to solve this is as follows: After the plug-ins **Load()** method is called

its references are put in place using **SetReference()**. What needs to happen is that the plug-in should check for older versions of files (by checking a saved version number) and set a flag to indicate the old version is being loaded. Then a post load callback is registered to turn off this flag once all the references have been established. With this mechanism in place, the **SetReference()** method can check this flag and integrate the old reference structure or the new reference structure accordingly.

For users of the r2 or later version of the SDK a new method is available to handle the above. See the method

**ReferenceMaker::RemapRefsOnLoad()**.

## Referencing a Global Instance of a Non-Plugin Class

If a plug-in needs to have some sort of global instance that its other objects reference, but is itself not a specific plug-in type, then the super class ID of **REF\_TARGET\_CLASS\_ID** should be used. The class of the global instance should be derived from **ReferenceTarget**.

## Viewing Reference Messages

This section discusses a utility plug-in called the Reference Watcher. This plug-in may be used to help understand the reference structure of a chosen item and to monitor the reference messages it sends. This provides a quick, visual way to examine the use of references in MAX.

To run this plug-in you'll first need to build it. The project is in **\MAXSDK\SAMPLES\HOWTO\REFCHECK**. Load this project into VC++ and press F7 to build it. Place **REFCHECK.DLU** into your 3ds max DLL search path (for example in the **STDPLUGS** directory). You can then run the program by choosing How To/Reference Watcher in the utility panel.

This plug-in allows you to create a reference to a chosen Reference Target and then watch the messages sent as you work with the target. For instance, follow the steps below to analyze the reference messages sent by a node in the scene.

Reset 3ds max and create a single Box in the scene called **Box01**. Leave it selected after creation.

Launch the **Reference Watcher** from the **Utility** branch of the command panel. Click on the **Pick Reference Target to Watch** button and choose the **Box01** node from the dialog. This is done by opening the **Objects** branch and selecting the **Box01 label** then pressing **OK**.

Result: The Reference Watcher utility creates a reference to the box node in the scene and displays information about it. The upper most list box shows this list of reference messages. Since we haven't done anything to the node yet the message list is blank.

The second list box in the dialog shows the items that are referencing the node we've selected. This provides a way to get a general idea of who is referencing an item. In the case of the Box01 node these are:

- 0: Node
- 1: (This Reference Watcher)
- 2: Node Selection
- 3: Material Editor
- 4: Scene
- 5: Material Editor
- 6: Scene
- 7: Animatable.

The bottom most list box shows the references that the node itself has. For the **Box01** node it has six reference targets. These are:

- 0: The Transform Controller
- 1: The Object Reference
- 2: The Pin Node for IK (not currently assigned -- NULL)
- 3: The Material Reference (not currently assigned -- NULL)
- 4: The Visibility Controller (not currently assigned -- NULL)
- 5: The Image Blur Controller (not currently assigned -- NULL)

As you work with the node (select it/deselect it, assign modifiers, bind to space warps, assign materials, change controllers, drag the item in the viewports, etc.), you can monitor the reference messages sent. They'll show up using the **#define** name from **REF.H** (for example **REFMSG\_CHANGE**) in the upper most window. If you want to clear the message list so you can see what messages are sent for a particular action press the **Clear Message List** button first.

Developers can use this utility to help study the use of references inside MAX.

## Additional Global Functions Related to the Reference Hierarchy

The following global functions are available for working with references:

### Function:

```
void EnumRefHierarchy(ReferenceMaker *rm, RefEnumProc  
&proc);
```

### Remarks:

This function provides a general purpose reference enumerator. It simply calls the **RefEnumProc::proc()** on each element in the reference hierarchy. See [Class RefEnumProc](#).

### Parameters:

**ReferenceMaker \*rm**

The reference maker whose dependents will be enumerated.

**RefEnumProc &proc**

The callback object whose **proc()** method is called for each element.

### Function:

```
ReferenceTarget *CloneRefHierarchy(ReferenceTarget *rm);
```

### Remarks:

A new global function has been added for release 2.0 to clone a reference target and the hierarchy emanating from it. This function encapsulates the code necessary to clone a **ReferenceTarget** and the reference hierarchy emanating from it. It handles multiple instances correctly, using a **RemapDir**.

### Parameters:

**ReferenceTarget \*rm**

The reference target to clone.

### Return Value:

A duplicate of the entire reference hierarchy of the item passed.

### Sample Code:

In this example, a material is being copied from one **MtlBase** to another (**source** to **dest**). To copy all the sub-materials this function is used:

```
dest[i] = (MtlBase *)CloneRefHierarchy(source[i]);
```

**Function:**

**BOOL DependsOn(RefMakerHandle mkr, RefMakerHandle targ);**

**Remarks:**

This global function is available in release 2.0 and later only.

Returns TRUE if there is a path of references from **mk**r to **ta**rg; otherwise FALSE. Note that this returns TRUE if **mk**r == **ta**rg.

**Parameters:**

**RefMakerHandle mkr**

The reference maker to check.

**RefMakerHandle targ**

The reference target to check.

**Function:**

**void ClearAFlagInHierarchy(ReferenceMaker \*rm, int flag);**

**Remarks:**

This function is available in release 2.0 and later only.

Clears the specified Animatable flag(s) from each item in the reference hierarchy.

**Parameters:**

**ReferenceMaker \*rm**

The reference maker whose dependents will be enumerated and have their flags cleared.

**int flag**

See [List of Animatable Flags](#).

## Summary

References are used to handle dependencies between items in the scene. A plug-in making references is responsible for implementing several methods. The method **NotifyRefChanged()** is used to receive messages that something it references has changed. The plug-in must also implement a method **NumRef()** to return the number of references it makes. Methods **GetReference()** and **SetReference()** must be implemented by the plug-in to allow the system to access its references. If an item is a reference target, it must call **NotifyDependents()** to broadcast a message whenever it has changed in a way which affects other elements in the scene.

# Render Elements

See Also: [Class IRenderElementMgr](#) , [Class IRenderElement](#), [Class IRenderElementCompatible](#), [Class MaxRenderElement](#)

## Overview

Render Elements allow renderers to output to separate bitmaps portions of the final shaded image so that they can be manipulated/composited at a later time, without re-rendering.

Render Elements are specific to a given renderer. 3ds max defines both a general interface that all render elements must support & an interface specific to elements supporting the max default renderer. Mental Ray specific elements will support the general interface, but probably define their own specific interface. Part of the general interface allows the system to figure out which installed render elements belong to which renderer, & to only list those compatible elements.

3ds max render elements are supported by code in each material. After shading each active render element's PostIllum method is called in turn. It is provided with;

- · the full shade context used to do the shading
- · pointers to the material & (if there is one) shader used to do the computation
- · textured inputs to the shader (e.g. diffuse color blended w/ diffuse texture color by the amount spinner)
- · component-wise output from the shading process (diffuse term, reflection term...)
- · there is provision for extending the component-wise outputs to include arbitrary name-matched channels (this allows materials w/ special components, e.g. fluorescence in ray material, to be communicated to an element. The element must of course be looking for the special component. The component-wise outputs maybe computed either with or without shadows, depending on a query on the element interface.

Essentially, this is all of the information that is passed to 3ds max Shaders, plus

the shadowed or unshadowed component-wise output from the materials shading process. This means that each render element may in fact be a complete, alternate, special-purpose shader. This is intentional, of course, so that any wacky thing might be created. Most current render elements don't take advantage of this, tho, they merely process the component-wise output from the materials shading process, but the potential is very powerful.

3ds max Render elements then store their computed shade in an extended ShadeOutput class (imtl.h) that is part of the ShadeContext. The ShadeOutput has an array of element output values, one per element & each max render element is given an index into the array to use. The ShadeOutput will follow the fragments being shaded all through the compositing process, so that transparency & partial coverage is properly resolved.

Atmosphere cannot be properly computed at shading time since the object may be covered by a transparent object, dividing the needed calculation into two: atmosphere from the eye to the transparent object, composited over atmosphere between the two objects & the final objects color. Hence there is a second, optional call to each render element after the atmosphere is computed. The general interface tells the system whether to apply atmosphere to the render elements color, does so if desired & calls the PostAtmosphere call on the max render element.

Finally, a last query on the general interface determines whether to apply the AA filter when outputting the element to its bitmap, or merely blending with other elements in the pixel.

A sample plugin of a Render Element can be found in the SDK samples;  
**\\MAXSDK\\SAMPLES\\RENDER\\RENDERELEMENTS.**

# Rotation Concepts

See Also: [Class Quat](#), [Class AngAxis](#), [Class Matrix3](#).

## Overview

This section describes the different ways rotation is represented in the 3ds max SDK and the various classes used in storing and interpolating rotation.

There are several class used in 3ds max that describe rotations in 3D space.

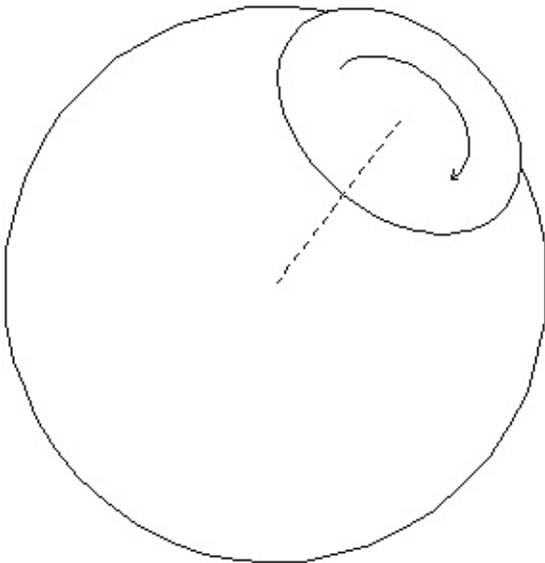

These classes are **Quat**, **AngAxis**, and **Matrix3**. There are also methods that convert between these classes.

## The Visualization of Rotation Space

The set of **all** rotations in space may be visualized as:

- 1) The set of all unit length axis vectors with one endpoint centered at the sphere center  $(0,0,0)$  and the other endpoint on the surface of the unit sphere.
- 2) The set of rotations about each vector axis (rotations about the radius vectors that point to each endpoint on the sphere).

One way to visualize this is to imagine that you could nail a dinner plate to the surface of a ball that is fixed in space (with the top surface of the plate facing the center of the ball, and the nail going from the center of the plate to the center of the sphere -- see the figure below). For each nailed position on the ball, imagine you can rotate the plate about the nail (axis). The point of placement of the nail on the ball, and the plate's rotation about it describes each of the possible rotations of the plate in a unique way.

Unit sphere with axis and plate shown.

## Quaternion Representation of Rotation

A quaternion may be visualized in a similar way:

- 1) An arbitrary unit length axis vector (one of the endpoints on the unit sphere...or the nail position).
- 2) A rotation about the axis (one on the rotations about the radius vectors that point to each endpoint on the sphere).

In the simplest terms, the rotational space described by each quaternion is a 3D unit vector plus a rotation. The **Quat** class has four public data members that store this information:

**float x, y, z, w;**

A normalized quaternion can represent  $-\pi$  to  $+\pi$  rotation -- that is -180 to 180 degrees of rotation. Quaternions use the left-hand rule for determining positive rotation.

## **AngAxis Representation of Rotation**

This class is similar to a quaternion, except that a normalized quaternion only represents  $-\pi$  to  $+\pi$  rotation (that is  $-180$  to  $180$  degrees of rotation). The **AngAxis** class can instead have any number of revolutions stored. It has two public data members:

**Point3 axis;**

**float angle;**

The **axis** is similar to the values in the **Quat** class. The **angle** value can represent any rotation amount in radians.

## **Matrix Representation of Rotation**

A matrix may be used to describe rotation. See the Advanced Topics section on [Matrix Representations of 3D Transformations](#) for more information. That section describes not only rotation, but translation and scaling as represented by matrices.

## Euler Angles

Multiple rotations are not independent. When you rotate something twice, the second rotation rotates the first rotation. For this reason, the order of rotation is important. The 3ds max Euler angle controller, by default, has an XYZ ordering. That is, the first rotation is done along the X axis, then along the Y axis, and finally along the Z axis. In other words, the default Euler angle controller has a type of EULERTYPE\_XYZ (described below). The 3ds max local Euler angle controller is similar, but specifies rotations around an object's local coordinates instead of the world coordinates. It has a type of (EULERTYPE\_XYZ | EULERTYPE\_RF).

The SDK provides functions for converting from a Matrix3 to Euler angles using various rotation orderings. You need the different types because you get different interpolation of the float values with the each type.

### Prototype:

```
void MatrixToEuler(const Matrix3 &mat, float *ang, int type);
```

### Remarks:

This function is available in release 2.0 and later only.

Converts the specified matrix to Euler angles using the **type** parameter to determine the order.

### Parameters:

**const Matrix3 &mat**

The rotation matrix to convert to Euler angles.

**float \*ang**

The result is stored here. The array ordering is based on the **type** parameter below.

**int type**

This parameter specifies the order of application of the angles. One of the following values:

```
EULERTYPE_XYZ  
EULERTYPE_XZZ  
EULERTYPE_YZX  
EULERTYPE_YXZ  
EULERTYPE_ZXY
```

**EULERTYPE\_ZYX**  
**EULERTYPE\_XYX**  
**EULERTYPE\_YZY**  
**EULERTYPE\_ZXZ**

Note: Internally, 3ds max uses static coordinate frames. OR in the **EULERTYPE\_RF** bit if you have a special need to use a rotating coordinate frame. This is described in Ken Shoemake's paper in Graphic Gems IV, pp. 222-229.

**Prototype:**

**void EulerToMatrix(float \*ang, Matrix3 &mat, int type);**

**Remarks:**

This function is available in release 2.0 and later only.

Converts from the specified Euler angle format (specifying rotation with a triple of angles) to a Matrix3 format.

**Parameters:**

**float \*ang**

The Euler angles to convert. The expected format is based on the **type** parameter below.

**Matrix3 &mat**

The matrix result is stored here.

**int type**

This parameter specifies the order of application of the angles. One of the following values:

**EULERTYPE\_XYZ**  
**EULERTYPE\_XZZ**  
**EULERTYPE\_YZX**  
**EULERTYPE\_YXZ**  
**EULERTYPE\_ZXY**  
**EULERTYPE\_ZYX**  
**EULERTYPE\_XYX**  
**EULERTYPE\_YZY**  
**EULERTYPE\_ZXZ**

Note: Internally, 3ds max uses static coordinate frames. OR in the

**EULERTYPE\_RF** bit if you have a special need to use a rotating coordinate frame. This is described in Ken Shoemake's paper in Graphic Gems IV, pp. 222-229.

**Function:**

**void QuatToEuler(Quat &q, float \*ang, int type, BOOL b=FALSE);**

**Remarks:**

Converts the quaternion to Euler angles. When converting a quaternion to Euler angles using this method, the correct order of application of the resulting three rotations is specified by the **type** parameter.

**Parameters:**

**Quat &q**

The quaternion to convert.

**float \*ang**

The angles are returned here in the same order as specified by **type** (for example **EULERTYPE\_XYZ** would be **ang[0]=x, ang[1]=y, ang[2]=z.**)

**int type**

This parameter specifies the order of application of the angles. One of the following values:

**EULERTYPE\_XYZ**

**EULERTYPE\_XZZ**

**EULERTYPE\_YZX**

**EULERTYPE\_YXZ**

**EULERTYPE\_ZXY**

**EULERTYPE\_ZYX**

**EULERTYPE\_XYX**

**EULERTYPE\_YZY**

**EULERTYPE\_ZXZ**

Note: Internally, 3ds max uses static coordinate frames. OR in the **EULERTYPE\_RF** bit if you have a special need to use a rotating coordinate frame. This is described in Ken Shoemake's paper in Graphic Gems IV, pp. 222-229.

**BOOL b=FALSE**

This parameter is available in release 4.0 and later only.

When this argument is set to false (or omitted), each function performs as it did before version 4.0. When the boolean is TRUE, the matrix is made with its terms transposed. When this transposition is specified, **EulerToQuat()** and **QuatToEuler()** are consistent with one another. (In Shiva, they have opposite handedness).

**Function:**

**void EulerToQuat(float \*ang, Quat &q, int type);**

**Remarks:**

Converts Euler angles to a quaternion.

**Parameters:**

**Quat &q**

The quaternion result is returned here.

**float \*ang**

The angles are specified in the same order as specified in the application (for example **EULERTYPE\_XYZ** would be **ang[0]=x, ang[1]=y, ang[2]=z.**)

**int type**

This parameter specifies the order of application of the angles. One of the following values:

**EULERTYPE\_XYZ**  
**EULERTYPE\_XZZ**  
**EULERTYPE\_YZX**  
**EULERTYPE\_YXZ**  
**EULERTYPE\_ZXY**  
**EULERTYPE\_ZYX**  
**EULERTYPE\_XYX**  
**EULERTYPE\_YZY**  
**EULERTYPE\_ZXZ**

Note: Internally, 3ds max uses static coordinate frames. OR in the **EULERTYPE\_RF** bit if you have a special need to use a rotating coordinate frame. This is described in Ken Shoemake's paper in Graphic Gems IV, pp. 222-229.

**Handling Sign Flips when Converting a Rotation Controller to an**

## Euler Controller

When converting any rotation controller to an Euler controller it is possible for sign flips to occur in the resulting animation. This is due to the fact that one single rotation matrix can be expressed through many different triplets of Euler angles. Sometimes the produced Euler angles are not interpolatable. There is code in the SDK which solves this problem. It samples the whole animation range and produces Euler angles that result in the same animation as the original, if interpolated. This code is generally valuable for developers who want to convert keys of any type of 3ds max controller that uses quaternions internally into a Euler angle keys (for example an export plug-in).

The code can be found in

**\MAXSDK\SAMPLES\CONTROLLERS\EULRCTRL.CPP** in the method **void EulerRotation::Copy(Control \*from)**. The algorithm works as follows:

The code samples the entire animation range and incrementally adds up the angles for each time step. During resampling it detects possible sign flips by comparing the Euler/Quat ratio of two successive time steps. The Euler/Quat ratio is the relation of the angle difference in Euler space to the angle difference in Quat space. If this ratio is bigger than PI the rotation between the two time steps contains a flip. The Euler/Quat ratio can be determined using the SDK functions **GetEulerQuatAngleRatio()** or **GetEulerMatAngleRatio()** (see below). If a flip is detected the algorithm calculates the actual angle not containing a flip and adds it to the incremental angle.

The actual detection of the flip is dependent on the amount of rotation in between the time steps. It is obvious, that the smaller the time step, the more accurate the detection is. In the code described above a time step of 1 tick is used, which is most accurate, but also most time intensive. The THRESHHOLD value describes the maximum intended rotation allowed between two time increments. In the code described above the THRESHHOLD is 1.0 which is equal to 57 degrees of rotation (a lot of rotation for one tick).

### Function:

```
float GetEulerQuatAngleRatio(Quat &quat1,Quat &quat2, float *euler1, float *euler2, int type = EULERTYPE_XYZ);
```

### Remarks:

This global function is available in release 3.0 and later only.

The Euler/Quat ratio is the relation of the angle difference in Euler space to the angle difference in Quat space. If this ratio is bigger than PI the rotation between the two time steps contains a flip. See the description above for details.

**Parameters:**

**Quat &quat1**

The 'previous' rotation.

**Quat &quat2**

The 'current' rotation.

**float \*euler1**

The 'previous' rotation as an euler angle.

**float \*euler2**

The 'current' rotation as an euler angle.

**int type = EULERTYPE\_XYZ**

This parameter specifies the order of application of the angles. One of the following values:

**EULERTYPE\_XYZ**  
**EULERTYPE\_XZZ**  
**EULERTYPE\_YZX**  
**EULERTYPE\_YXZ**  
**EULERTYPE\_ZXY**  
**EULERTYPE\_ZYX**  
**EULERTYPE\_XYX**  
**EULERTYPE\_YZY**  
**EULERTYPE\_ZXZ**

**Return Value:**

The Euler/Quat ratio between the time steps.

**Function:**

**float GetEulerMatAngleRatio(Matrix3 &mat1,Matrix3 &mat2,  
float \*euler1, float \*euler2, int type = EULERTYPE\_XYZ);**

**Remarks:**

This global function is available in release 3.0 and later only.

The Euler/Matrix Angle ratio is the relation of the angle difference in Euler space to the angle difference in Matrix space. If this ratio is bigger than PI the

rotation between the two time steps contains a flip. See the description above for details.

**Parameters:**

**Matrix3 &mat1**

The 'previous' rotation.

**Matrix3 &mat2**

The 'current' rotation.

**float \*euler1**

The 'previous' rotation as an euler angle.

**float \*euler2**

The 'current' rotation as an euler angle.

**int type = EULERTYPE\_XYZ**

This parameter specifies the order of application of the angles. One of the following values:

**EULERTYPE\_XYZ**

**EULERTYPE\_XZZ**

**EULERTYPE\_YZX**

**EULERTYPE\_YXZ**

**EULERTYPE\_ZXY**

**EULERTYPE\_ZYX**

**EULERTYPE\_XYX**

**EULERTYPE\_YZY**

**EULERTYPE\_ZXZ**

**Return Value:**

The Euler/Matrix Angle ratio between the time steps.

## Schematic View

See Also: [Class IGraphObjectManager](#), [Class IGraphNode](#), [Class Animatable](#).  
[Class SubClassList](#).

## Overview

The Schematic View window allows 3ds max users to browse, and perform certain operations on, many of the objects that compose a 3ds max scene. Like Track Views, multiple Schematic Views can be opened within MAX, both in modeless windows and docked in viewports.

Within a Schematic View window, a subset of the set of all Animatable objects within the 3ds max scene is represented by a collection of rectangular "nodes." These nodes are organized in tree form (or directed acyclic graph). The set of objects displayed depends on the current filter settings, the hide/show state of the nodes, and which objects were added to the Schematic View during the traversal phase. Schematic View is a **GlobalReferenceMaker** and any time it detects a change in the structure of the 3ds max scene it performs a traversal of the scene's object network and updates the Schematic View graph. During the traversal, the actual Animatable objects (object's derived from Animatable) are responsible for adding themselves to the Schematic View and continuing the traversal by recursively calling **SvTraverseAnimGraph(...)**. In practice, many objects in the scene are not added to the schematic view. In general, these omitted objects are either internal data structures that might confuse the user if displayed or they are objects whose sheer quantity might overwhelm the user (vertices, for example). Furthermore, although the Schematic View requires that the represented objects be derived from Animatable, there are very few restrictions on the reference pointers between objects (called "node pointers" in this section to distinguish them from 3ds max references). In particular, node pointers need not necessarily correspond to actual 3ds max references (though in practice they usually do). This flexibility allows the schematic view to represent object relationships in a manner different from the actual internal reference relationships. This can be useful in places where the internal structure does not agree with the user's notion of how the objects are structured (e.g., a linked list displayed as siblings under a parent node, or vice-versa).

## **Topology**

The topology of the objects added to the schematic view must be a directed acyclic graph (DAG). Cyclic references are currently not allowed.

Currently, nodes in the schematic view are arranged in tree form even if the underlying topology is a DAG. This is accomplished by duplicating shared nodes in the DAG. The DAG is essentially "flattened" into a tree. This is also how the track view works but, as will be explained in detail later, the schematic view stores additional information about the context of "shared" nodes which allows greater insight into instance relationships in the tree (multiple objects referencing a common node).

## The Schematic View API

There currently are three interfaces into the schematic view objects.

**IGraphObjectManager**, **IGraphNode**, and **IGraphRef**.

**IGraphObjectManager** essentially represents an instance of a schematic view window and provides methods for adding nodes and node pointers, refreshing the schematic view, accessing filter bits and updating and controlling the various editors within 3ds max in ways that are not surfaced in the general interface. **IGraphNode** represents a node in the schematic view graph and provides a few methods for querying information about the node. Finally, **IGraphRef** represents a node pointer and, currently, has no methods. Each of these three interfaces is described in greater detail below.

In addition to the three schematic view interfaces, there is a set of methods in **Animatable** that can be overridden, all or in part, to specialize the behavior of the schematic view node(s) which represents the Animatable object. Most of these methods are appropriately implemented for the various abstract base classes from which plug-in developers derive their classes. In most cases, there is no need for the plug-in developer to override any of these methods. All of the schematic view **Animatable** methods are prefixed by "Sv". In addition to the "Sv" methods, there are a half dozen or so "Sv" prefixed functions in **Animatable** which are called to perform various schematic view related tasks. They are implemented in **Animatable** instead of **IGraphNode** because they are more closely associated with the **Animatable** than with the graph node or because they are called in places where the **IGraphNode** and **IGraphObjectManager** interfaces are not available.

Taken as a whole, the three interfaces (**IGraphObjectManager**, **IGraphNode**, and **IGraphRef**) along with the "Sv" **Animatable** methods and functions represent about 95% of the complete schematic view API and 100% of the public (plug-in developer) API. The other 5% or so represents a small collection of functions scoped to the application and an interface, **ISchematicView**, which is used by the application code to control the schematic view window.

In general, the **IGraphObjectManager**, **IGraphNode**, and **IGraphRef** interfaces are not accessible to plug-ins outside of the scope of the Animatable "Sv" methods and should not be cached by the plugin.

## **Overview of the Chain of Events in Schematic View**

The events that occur in the schematic view are either generated by the user (clicking on a node, etc.) or transmitted to the schematic view via a **GlobalReferenceMaker::NotifyRefChanged(...)** message.

In response to these events, the schematic view performs one or more of the "Sv" methods on the effected nodes. The **IGraphObjectManager**, **IGraphNode**, and **IGraphRef** interfaces are passed to the "Sv" methods where appropriate.

The "Sv" methods perform some action and/or return some value and/or call one or more methods in the passed schematic view interface(s).

For example, the user selects a modifier in the schematic view and hits the "Delete" key. In response to the delete request, the schematic view calls the "**bool SvRemoveThis(IGraphObjectManager \*gom, IGraphNode \*gNode)**" method in Modifier which, in turn, calls the "**DeleteModifier(IGraphNode \*gNode)**" method in the **IGraphObjectManager** interface.

# Snapping

See Also: [Class Osnap](#), [Class IOSnapManager](#), [Class HitMesh](#), [Class OsnapHit](#), [Class OsnapMarker](#), [Structure SnapInfo](#), [Class Interface](#), [Class ViewExp](#).

## Overview

This topic presents information on object snapping in MAX. Object snaps are a plug-in type that allow objects to provide the 3ds max snapping system with additional points that may be snapped to. For example, the built in snap system provides the ability to snap to points such as vertices, endpoints, midpoints, etc. A developer of a procedural sphere object might want to provide additional snaps for center point and quadrant points. By deriving a class from **Osnap** and implement its methods a developer can seamlessly provide this functionality in MAX.

The 3ds max scene has a single object called the **Osnap Manager**. At 3ds max startup it will load any object snap plug-ins (those with a **DLS** extension). Object snap plug-ins are derived from class **Osnap**. This class has various methods that allow the system to query it about potential objects to be snapped to. That is, when 3ds max is traversing the scene doing a hit test the Osnap Manger will call each of the plug-ins to snap against a particular node. The **Osnap** class has a method that allows it to tell the Osnap Manager if it wants to snap to the specified object type based on its Super Class ID and Class ID. For example, NURBS snaps only respond to NURBS objects. Tangent and Perpendicular snaps only respond to Spline objects. If the object snap plug-ins do want to snap to the object type, they can register a set of points to snap to. For instance, the sphere above would register the center and quadrant points. This system allows developers to implement very specific snapping behaviors. For example, a door object might have a special snap mode that always snaps to the hinge point.

## Principal Classes

The following are the main classes associated with creating object snap plug-ins.

### [Class Osnap](#)

This is the base class for creating osnap plug-ins. Conceptually, the osnap class represents a "rule" for locating points in an object's local space. Typically, an instance of this class will only make sense for certain object types. It's the job of the **ValidInput()** method to filter out uninteresting nodes in the scene. When the scene is traversed, each object which passes the input test will be passed into the **Snap()** method. This method is the workhorse of object snap plug-ins and is responsible for computing, allocating and recording its hits.

### [Class IOsnapManager](#)

This class provides an interface to the Osnap Manager. Developers who implement osnaps need to record hits with the osnap manager.

### [Class OsnapHit](#)

This class encapsulates the data required to record a snapped point. Typically a plug-in creates instances of this class and records them with the Osnap Manager. If a snap plug-in needs to record additional data for its hits, it should derive from this class and provide a clone method which copies this additional data and calls the base classes clone method.

### [Class OsnapMarker](#)

This class is used for drawing osnap markers in the viewports. The marker is drawn as a polyline. The Osnap class must implement the **GetMarkers()** method which typically returns pointers to these static instances.

### [Class HitMesh](#)

This is a class to hold a list of object space points for highlighting the geometry associated with a hit. In practice, developers need only implement two methods of this class.

### [Class Interface](#)

There are several methods in this class related to object snap. The most important one returns a pointer to the Osnap Manager. See Interface Osnap Methods.

## Handling Snap Preview and Point Snap in Creation Procedures

The **ViewExp::SnapPoint()** method has been enhanced in 3ds max 2.0 to work with the new object snap system. A change that developers will need to make is that any mouse procs which will be calling **ViewExp::SnapPoint()** will need to add a call to **ViewExp::SnapPreview()** as in the following code fragment from `\MAXSDK\SAMPLES\OBJECTS\CYL.CPP`.

```
int CylinderObjCreateCallBack::proc(ViewExp *vpt,int msg, int
point,
    int flags, IPoint2 m, Matrix3& mat ) {
float r;
if (msg == MOUSE_FREEMOVE) {
vpt->SnapPreview(m,m,NULL, SNAP_IN_3D);
}
if (msg==MOUSE_POINT||msg==MOUSE_MOVE) {
switch(point) {
case 0:
ob->suspendSnap = TRUE;
sp0 = m;
p[0] = vpt->SnapPoint(m,m,NULL,SNAP_IN_3D);
...

```

## **Sample Code**

Some simple sample code provided in the SDK for demonstrating object snap is the sphere object snap plug-in. It provides two additional snaps to MAX. These are the center of the sphere and the quadrant points on the sphere. This code is available in **\MAXSDK\SAMPLES\SNAPS\SPHERE\SPHERE.CPP**.

The main code where snapping is handled for Geometric Objects, Shape Objects, Cameras, Lights and Helpers is available in **\MAXSDK\SAMLES\SNAPS\XMESH\XMESH.CPP**.

## Space Warp Plug-Ins

See Also: [Class Modifier](#), [Class ModContext](#), [Class WSMObject](#), [Class WSMModifier](#).

In addition to Object Space Modifiers (such as Bend, Taper, Skew, etc.), 3ds max supports another type of modifier referred to as a Space Warp. Another name for this type of modifier is a World Space Modifier. Example space warps are Ripple, Wave and Bomb.

A World Space Modifier (WSM) has two components: A WSM Object and a WSM Modifier. A WSM object is just another type of procedural object (derived from **WSMObject**). It exists in the scene and can have modifiers (including other WSMs) applied to it. When an item is bound to a WSM object, a WSM modifier (derived from **Modifier** or **WSMModifier**) is created and inserted in the object's history.

World space modifiers are very similar to regular object space modifiers -- in fact, they are derived from the same base class: **Modifier**. They have a mod app that is actually in the pipeline that refers to the modifier, although WSM modifiers aren't instanced. When a user binds more than one object to a WSM object at once, a unique WSM modifier is created for each object so there is a one to one correspondence between WSM modifiers and their mod apps. This is done because a WSM modifier may contain parameters specific to that application of the modifier. For example, the Ripple world space modifier has a 'Flexibility' parameter which allows the affect of the Ripple to be scaled on a per application basis.

The main difference between a regular object space modifier and a WSM modifier is that WSM modifiers usually have a reference to the WSM object's node. Also, WSM modifiers are applied after the object has been transformed into world space.

A WSM modifier references its corresponding WSM object's node so it can get the node's world space transformation matrix. It uses this matrix to transform the points of the object it is deforming into the space of the WSM object where it actually performs the deformation. After the deformation is applied, the points are transformed back to world space. This is similar to the way object space modifiers transform their points into the space defined by the ModContext transformation matrix -- however this space is defined by the WSM object's node. So in general, if an object's node is moved, the object appears to move

through the deformation field defined by the WSM object it is bound to. If the WSM object moves, a similar effect is apparent. Of course, if an object and the WSM object it is bound to move together (if one is a child of the other, for example) then the affect appears to be more like an object space modifier.

Also of note is that WSM modifiers (actually their mod apps) live in special world space derived objects. These are similar to the derived objects that hold object space modifier mod apps, except that these are contained in a specific node. Since they are associated with a specific node, they cannot be instanced.

There are two places where WSM user interface parameters can appear:

In the parameters of the WSM object. Any centralized parameters should be contained in the WSM object. Since WSM modifiers are never instanced, any parameters that the user would want to change and affect all objects bound to the WSM would belong here. For example, the Ripple WSM has its

Amplitude, Phase, WaveLength and Decay parameters in the WSM Object.

In the parameters of the WSM modifier. These parameters are specific to the object bound to the WSM. For example, Ripple has its flexibility parameter here. Often time these modifiers won't need to have any parameters at all. An example might be a dynamics WSM that has modifier parameters for the objects mass and surface characteristics.

# Style Guidelines for Creating Pipeline-Friendly Meshes

See Also: [Working with Meshes](#), [Class MNMesh](#).

3ds max meshes allow the developer a great deal of flexibility. There are very few rules. Meshes can have holes in them, such as you get when deleting any face from a box or a sphere. They may be composed of separate, disconnected units, which may even self-intersect. A 'fan' of 10 faces can use the same edge, simply by using the same two vertices. A grid may be created which is simply a 2-D collection of points with one set of faces pointing up and another pointing down.

However, not all of the possible meshes are appropriate for operations that may be done to them later in the 3ds max pipeline. For instance, the 3ds max Boolean, like any other Boolean, regards meshes as the outside boundary of solid objects. A Boolean intersection, for instance, is defined by the intersection of the volumes contained by the two operands. A mesh with a hole in it, such as the teapot, contains no volume, and therefore produces surprising results in Boolean.

Furthermore, Boolean, like several other compound objects and modifiers, converts meshes internally into MNMeshes. The **MNMesh** winged-edge structure can only handle 2 faces on a single edge, so the 'fan' described above gives it some difficulty. A mesh that doesn't gracefully convert to an **MNMesh** won't always behave as expected in MeshSmooth, Tesselate, ShapeMerge, Connect, Boolean, Slice, and possibly many more to come.

Also, if a mesh is not constructed in a straightforward manner, the user may experience some difficulty working with it in modifiers such as Edit Mesh. Of course, the user can construct very strange meshes themselves in Edit or Editable Mesh, but it's best if parametric objects and modifiers avoid introducing this sort of complexity when it isn't needed.

To that end, the following style guidelines for creating pipeline-friendly meshes in 3ds max are presented. None of these are hard-and-fast rules, but the more you are able to follow, the more flexible your mesh will be within the 3ds max environment.

## 1. Reference each edge at most once in each direction.

3ds max meshes don't really have edges, so what this means is that if you use

the vertices (a,b) in a face, you should only have one other face that uses both of these vertices, and it should reference them in the other direction (b,a). This other face is the 'other side' of the edge (a,b). If the same edge is used more than twice, or more than once in the same direction, MeshSmooth and other MNMesh-based effects have to compensate by duplicating the vertices used in the edge, once for each extra face using this edge.

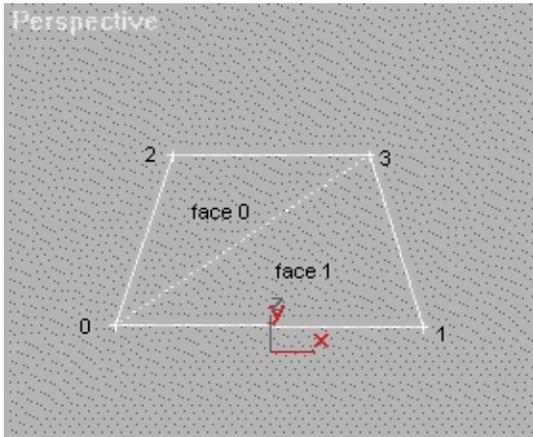

Figure 1A: Typical use of an edge

Face 0, which has vertices (0,3,2), uses the hidden edge in the (0,3) direction. Face 1, with vertices (0,1,3), uses the same edge in the (3,0) direction. The other edges are '1-sided', since there's no face on their other side.

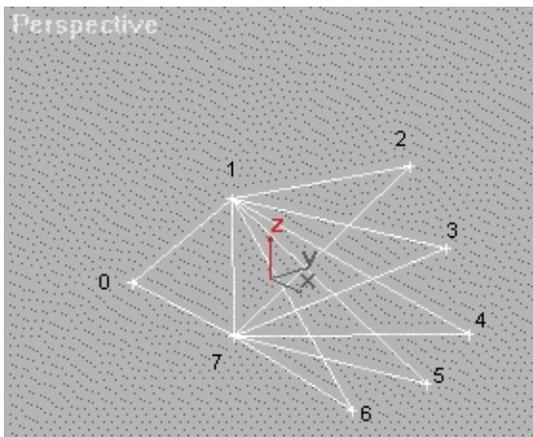

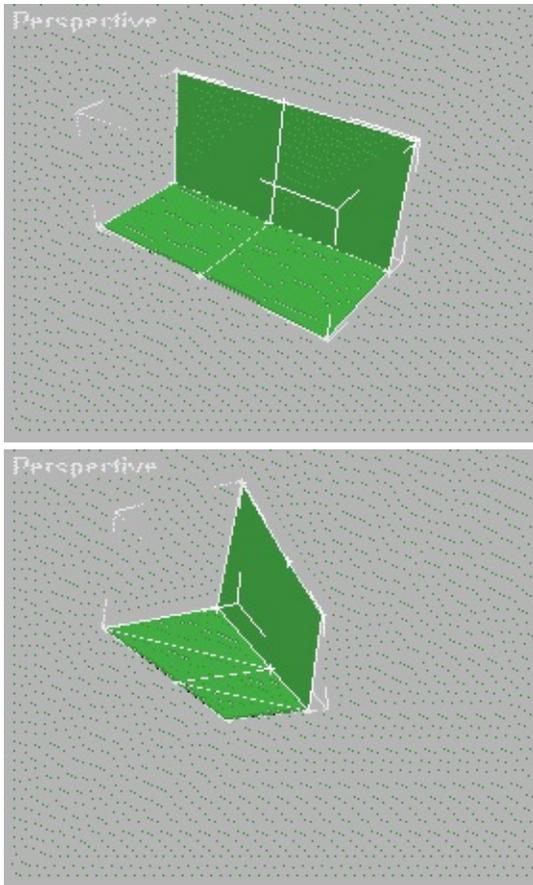

Figure 1B: Overuse of an edge

The face on the left uses the central edge in the (7,1) direction; the other 5 use it in the (1,7) direction. This can be inconvenient for the user and for many pipeline modifiers. Also, it generally doesn't respond well to smoothing groups.

Another situation in which edges are referenced too many times is when a zero-thickness mesh is constructed, with faces on both sides.

The above two views show the same zero-thickness mesh, with 9 points, that has faces representing both the front and back. The edges connecting the outside to the central point are used twice by front-facing faces and twice by back-facing edges. This also can cause problems in the pipeline.

Additionally, some systems may not display edges properly, as shown above at right: the edge connecting the top middle and base middle vertices should be visible, but doesn't show up because both the front-facing and back-facing faces have the same Z-depth.

## 2. Avoid self-intersection

For an example of self-intersecting meshes, we need look no further than the standard 3ds max primitive Teapot. Each of the four Teapot components is a separate mesh element, but the handle and spout elements both intersect the main body. Even if this mesh is closed with the CapHoles modifier, it causes trouble for Booleans because once again, what is 'inside' and what is 'outside' the teapot isn't very well defined.

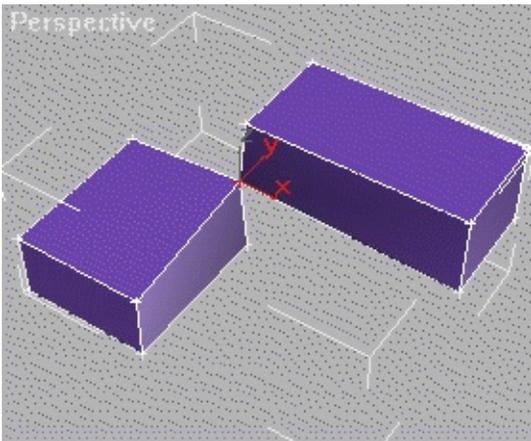

For an alternative to self-intersection, when (as in the teapot) computing the proper, connected result would be taxing, you may want to use the Boolean

itself within the SDK. If separate mesh elements are closed and otherwise acceptable to Boolean, you can just Union them together. Boolean is a bit slow, however, and there are still some known cases where it actually produces an open result. See the **MakeBoolean** method in class **MNMesh** ([MNMesh Boolean Operations](#)).

**3. Avoid creating faces with vertices located at the same place.**

A face referencing the same vertex twice, or two different vertices located in the same place, makes no contribution to your mesh and can interfere with display and rendering. Also, it confuses algorithms that traverse faces, such as ShapeMerge or Editable Mesh's new Cut function. Finally, Edit Mesh users can find it very frustrating to have to sort through multiple vertices at the same location in order to move the one they want.

**4. Try not to 'bridge' separate mesh components with a single vertex.**

The above two boxes share a single vertex, which is selected. Such vertices are split by **MNMesh** conversions. **MNMesh** effects deal with such vertices adequately, but the duplication is occasionally a surprise.

**5. If a mesh looks like a single element, it probably should be.**

A user shouldn't be able to take what looks like a single object apart by moving 'element' selections in Edit Mesh. If a model looks like a box, it shouldn't behave like a collection of 6 separate faces. This will give the user more reasonable results not only in modifiers like MeshSmooth, but also when they edit the object in Edit Mesh.

**6. Whenever convenient, close your meshes.**

A 'closed' mesh is one in which every edge has exactly two faces: one on each side. Closed meshes represent 3-dimensional objects. Open meshes are mere shells. Closed objects respond well to Boolean operations; open ones

can't, since there's no way for the Boolean to know which parts of operand A are supposed to be 'inside' operand B, and vice versa. Closed meshes have measurable volume; open ones do not.

This style point is less important than the others, because users are used to dealing with it. Any user who has models in Editable Mesh, for instance, deletes faces and constructs new ones all the time. However, avoid catching users off-guard: try not to leave tiny holes that can't be seen, say by putting open edges very close to each other. Users may not see them, but any hole will cause problems in pipeline effects that depend on solid, closed meshes, and may affect rendering adversely.

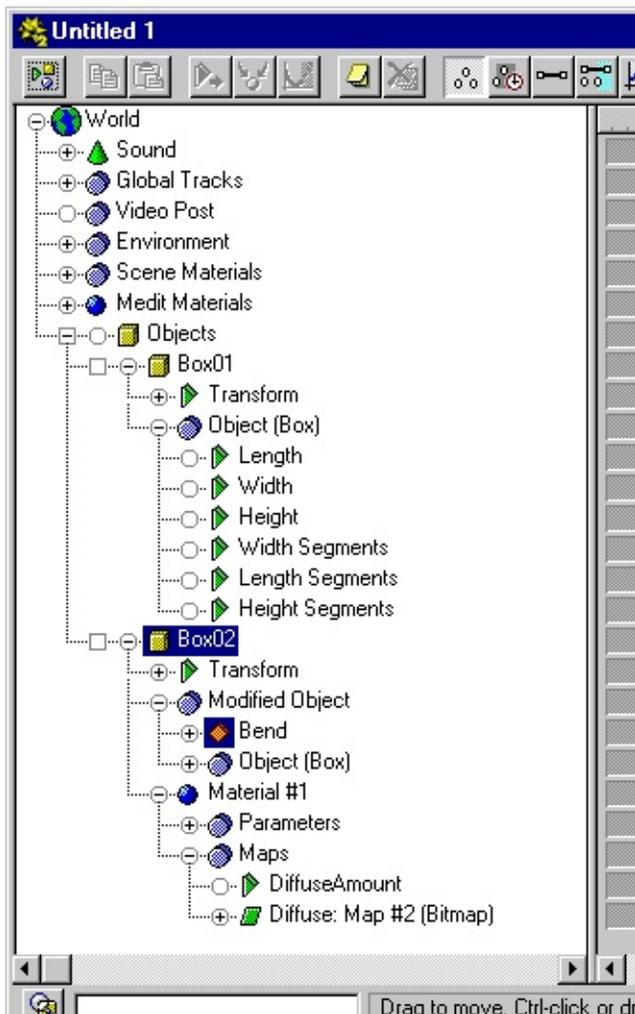

## Sub-Anims

See Also: [Track View](#), [Class Animatable](#), [Parameter Blocks](#).

## Overview

In the SDK the term **anim** refers to something derived from class **Animatable**. This anim can be anything such as a node, object, controller, material, texmap, parameter block, etc. Further, any item that has sub-items has what are referred to as **sub-anims**. This hierarchy of items, the parent item and it's sub-items, is referred to as the sub-anim hierarchy. The sub-anim hierarchy can be thought of as the Track View hierarchy.

Below is a partial screen capture of Track View showing a few anims and their sub-anims.

For example, a node has six sub-anims. These are: Space Warp Bindings, the Transform Controller, the Object Reference of the node, the Material, the Visibility Controller, the Image Motion Blur Controller. If a node does not have some of these assigned (for example the material and visibility controller) these sub-anims are NULL. Any sub-anims that are NULL don't appear in Track View.

In the example above, the node **Box01** has two sub-anim s that are non-NULL: the transform controller (labeled **Transform**) and the object reference (labeled **Object(Box)**). The other node, **Box02**, has three non-NULL sub-anim s. These are the transform controller (**Transform**), the derived object (**Modified Object**), and the Material (**Material01**).

Note that sub-anim s may have sub-anim s themselves. This can be seen in the parameters of **Box01** sub-anim **Object(Box)**. Procedural objects derived from **SimpleObject** (like **Object(Box)**) have a single sub-anim and that is the parameter block. The box's parameter block has six sub-anim s (Length, Width, etc.). Note also that the node **Box02** sub-anim **Material #1** has sub-anim s of its own. These are its parameters and its texture maps.

Sub-Anim s are often the animatable parameters of a plug-in. In 3ds max any animated parameter has a controller to control the animation. The controller for a parameter appears in the track view. This allows the user to view the animation associated with a parameter in several formats such as in key frames, as a range of time over which the animation takes place, and graphically as a function curve.

3ds max accesses the sub-anim s of a plug-in using a virtual array mechanism. That is, each sub-anim is given an index and is accessed by a method that returns a pointer to the 'i-th' sub-anim. These methods are **Animatable::NumSubs()**, **Animatable::SubAnim(i)** and **Animatable::SubAnimName(i)**.

## Methods

The plug-in can store its parameters in any way it chooses. When the system needs to access a parameter, it passes the plug-in an index and the plug-in returns the parameter it has assigned to that index. Below is a description of the three methods associated with sub-anims.

### **virtual int NumSubs();**

This method returns the total number of sub-anims maintained by the plug-in. If a plug-in is using a parameter block to manage its parameters it should just return 1 for all those parameters. Below is the **SimpleMod** implementation of this method. It returns 3 as it has a controller for the Center, the Gizmo, and a parameter block.

```
int NumSubs() {return 3;}
```

### **virtual Animatable\* SubAnim(int i);**

This method returns a pointer to the 'i-th' sub-anim. If a plug-in is using a parameter block to manage all of its parameters it should just return a pointer to the parameter block itself from this method. Below is the **SimpleMod** implementation of this method.

### **Animatable\* SimpleMod::SubAnim(int i)**

```
{  
  switch (i) {  
    case 0: return posControl; // Center  
    case 1: return tmControl; // Gizmo  
    case 2: return pblock; // Parameter block  
    default: return NULL;  
  }  
}
```

### **virtual TSTR SubAnimName(int i);**

This method returns the name of the 'i-th' sub-anim to appear in track view. The system has no idea what name to assign to the parameter (it only knows it by the array index), so this method is called to retrieve one to display. Below is the **SimpleMod** implementation of this method. Note that it returns a descriptive name for each controller, i.e. "Center" for the center mark position controller, and "Gizmo" for the gizmo controller. However it just returns "Parameters" for the parameter block. The parameter block name itself does

not show up in track view, only its sub-controllers. This is because the parameter block implements a method that tells the system to not show it in track view. This prevents the user from having to navigate another nested level to simply get to the parameters.

```
TSTR SimpleMod::SubAnimName(int i)  
{  
  switch (i) {  
    case 0: return TSTR(_T("Center"));  
    case 1: return TSTR(_T("Gizmo"));  
    case 2: return TSTR(_T("Parameters"));  
    default: return TSTR(_T(""));  
  }  
}
```

## Summary

The sub-anim hierarchy of a plug-in corresponds to the Track View hierarchy. Any non-NULL sub-anim that a plug-in has appear in Track View as branches under the parent item. A developer implements three methods of the **Animatable** class, **NumSubs()**, **SubAnim(i)** and **SubAnimName(i)** to provide 3ds max with access to its sub-anim.

## Sub-Object Selection

See Also: [Class CommandMode](#), [Class Interface](#), [Class XFormModes](#), [Class BaseObject](#), [Class Modifier](#).

Certain modifiers may wish to provide the system with different levels of sub-object selection. There are two general types of sub-object selection:

Selection of the modifier's gizmo. A modifier's gizmo is a visual representation in the scene the user can manipulate. This can be something as simple as the 3D box used by the bend modifier or something more complex like a FFD lattice. The Bend modifier provides sub-object levels of Center and Gizmo.

Selection of components of the object flowing through the geometry pipeline. If the object in the pipeline is a TriObject, for example, the sub-object selection levels may be things such as vertices, faces, and edges. The Edit Spline modifier supplies sub-object levels for Spline, Segments and Vertex.

A modifier registers its sub-object selection levels when its

**BeginEditParams()** method is called. A method of the Interface class named **RegisterSubObjectTypes()** handles this. It provides the system with a list of strings. These strings are the names of the sub-object selection levels that will appear in the Sub-Object drop down list. For example, the following code would register two sub-object levels, "Gizmo" and "Center".

```
const TCHAR *ptype[] = { "Gizmo", "Center" };  
ip->RegisterSubObjectTypes( ptype, 2 );
```

When the user presses the Sub-Object button or changes the selection in the sub-object drop down list the modifier is notified. The system calls the Modifier's

**ActivateSubobjSel()** method. In its implementation of this method the modifier is expected to provide an instance of a class derived from

**CommandMode** to support Move, Rotate, Uniform scale, Non-uniform scale, and Squash. These modes replace their object level counterparts although the user still uses the move/rotate/scale toolbar buttons to activate these modes.

Certain sub-object levels may not support all of these modes. For example, the Bend modifier (derived from **SimpleMod**) has two sub-object levels: "Gizmo" and "Center". The Gizmo level supports Move, Rotate, Non-uniform scale, Uniform scale and Squash while the Center level only supports Move. Any modes that the modifier does not support will have the corresponding button grayed out in the toolbar.

In addition to move/rotate/scale, a plug-in may provide other modes. For instance the Edit Mesh modifier has an extrude mode where the user can click and drag to interactively extrude faces of a mesh.

Users will expect sub-object move, rotate and scale transformations to behave like their object level counterparts. To make this very easy to implement, there are a set of standard modes defined by the system that a developer may use. These modes handle all this logic internally -- the developer simply uses them. Most modifiers will be able to use these modes. The sample code below demonstrates how the modes are used. This example is from the implementation of class **SimpleMod**.

In the class declaration the mode pointers are defined:

```
class SimpleMod : public Modifier {  
    ...  
    protected:  
    static MoveModBoxCMode *moveMode;  
    static RotateModBoxCMode *rotMode;  
    static UScaleModBoxCMode *uscaleMode;  
    static NUScaleModBoxCMode *nuscaleMode;  
    static SquashModBoxCMode *squashMode;  
    ...
```

In the **BeginEditParams()** method the modes are allocated:

```
void SimpleMod::BeginEditParams( IObjParam *ip, ULONG  
flags,  
    Animatable *prev )  
    {  
        ...  
        // Create sub object editing modes.  
        moveMode = new MoveModBoxCMode(this,ip);  
        rotMode = new RotateModBoxCMode(this,ip);  
        uscaleMode = new UScaleModBoxCMode(this,ip);  
        nuscaleMode = new NUScaleModBoxCMode(this,ip);  
        squashMode = new SquashModBoxCMode(this,ip);  
        ...  
    }
```

In the method **ActivateSubobjSel()** the modes are activated. This method is defined in [BaseObject](#).

```
void SimpleMod::ActivateSubobjSel(int level, XFormModes&
modes )
{
switch ( level ) {
  case 1: // Modifier box
    modes = XFormModes(moveMode,rotMode,nuscaleMode,
      uscaleMode,squashMode,NULL);
    break;
  case 2: // Modifier Center
    modes =
XFormModes(moveMode,NULL,NULL,NULL,NULL,NULL);
    break;
  }
  ...
}
```

When the item is finished being edited the modes can be deleted:

```
void SimpleMod::EndEditParams( IObjParam *ip, ULONG flags,
Animatable *next)
{
  ...
ip->DeleteMode(moveMode);
ip->DeleteMode(rotMode);
ip->DeleteMode(uscaleMode);
ip->DeleteMode(nuscaleMode);
ip->DeleteMode(squashMode);
if ( moveMode ) delete moveMode;
moveMode = NULL;
if ( rotMode ) delete rotMode;
rotMode = NULL;
if ( uscaleMode ) delete uscaleMode;
uscaleMode = NULL;
if ( nuscaleMode ) delete nuscaleMode;
```

```
nuscaleMode = NULL;  
if ( squashMode ) delete squashMode;  
squashMode = NULL;  
}
```

For a complete list of the classes that may be used see [List of Standard Sub-Object Modes](#).

Both the standard transformation modes and custom modes are expected to treat sub-object selection in the same way 3ds max handles object selection. This means all the keypress options, such as Ctrl to add to a selection and Alt to subtract from a selection, should work in the same manner. To avoid forcing plug-in developers to implement all this logic, a **SelectionProcessor** class is provided. This class represents a mouse proc derived from the **MouseCallback** class. When you create an instance of the **SelectionProcessor** class you give its constructor a pointer to another **MouseCallback** -- the mouse proc to handle the mode being implemented. The **SelectionProcessor** receives the mouse input first. It processes the mouse input using a standard selection logic and then calls the **MouseCallback** it was given.

The sample code below is from `\MAXSDK\SAMPLES\MESH`. It shows how the extrude command mode of the Edit Mesh modifier uses the **SelectionProcessor** class to handle selection yet performs its own work after the selection process has been handled. The extrude command mode allows the user to select items with the mouse using all the standard logic such as box selection, and using the Ctrl and Alt keys. If the user drags the mouse however, the extrude operation is performed. By using the selection processor all the logic for selection is handled automatically.

The overall manner this is set up is as follows:

A command mode has a method **MouseProc()** that returns an instance of **MouseCallback** to handle the user / mouse interaction. In the extrude command mode's implementation of **MouseProc()** it returns an instance of a selection processor (which is derived from **MouseCallback**). The constructor for the selection processor takes a pointer to another **MouseCallback**. This is the extrude mouse callback. When the command mode is processing mouse input, the selection processor mouse callback is called first. It processes all the logic for the selection. If the user drags the mouse however the selection processor calls the extrude mouse callback to handle the extrude operation.

Below are the class definitions showing how this is set up.

The mouse callback below implements the user / mouse interaction for the extrude operation.

```
class ExtrudeMouseProc : public MouseCallBack {  
  private:  
    MoveTransformer moveTrans;  
    EditMeshMod *em;  
    IObjParam *ip;  
    IPoint2 om;  
  public:  
    ExtrudeMouseProc(EditMeshMod* mod, IObjParam *i)  
      : moveTrans(i) {em=mod;ip=i;}  
    int proc(  
      HWND hwnd,  
      int msg,  
      int point,  
      int flags,  
      IPoint2 m );  
  };
```

The code below defines a class from **GenModSelectionProcessor**. The constructor passes on the mouse proc for the extrusion interaction to the base class **GenModSelectionProcessor**. This allows the selection processor to call the extrusion mouse proc.

```
class ExtrudeSelectionProcessor : public  
GenModSelectionProcessor {  
  protected:  
    HCURSOR GetTransformCursor();  
  public:  
    ExtrudeSelectionProcessor(ExtrudeMouseProc *mc,  
      Modifier *m, IObjParam *i)  
      : GenModSelectionProcessor(mc,m,i) {}  
  };
```

The command mode declares an instance of the selection processor and extrude mouse proc. The extrude mouse proc is passed into the selection processor.

```

class ExtrudeCMode : public CommandMode {
private:
    ChangeFGObject fgProc;
    ExtrudeSelectionProcessor mouseProc;
    ExtrudeMouseProc eproc;
    EditMeshMod* em;
public:
    ExtrudeCMode(EditMeshMod* mod, IObjParam *i) :
        fgProc(mod), mouseProc(&eproc,mod,i), eproc(mod,i)
    {em=mod;}
    int Class() { return MODIFY_COMMAND; }
    int ID() { return CID_EXTRUDE; }
    MouseCallback *MouseProc(int *numPoints)
        { *numPoints=2; return &mouseProc; }
    ChangeForegroundCallback *ChangeFGProc()
        { return &fgProc; }
    BOOL ChangeFG( CommandMode *oldMode )
        { return oldMode->ChangeFGProc() != &fgProc; }
    void EnterMode();
    void ExitMode();
};

```

See the source code in **EDITMOPS.CPP** for the full implementation of the methods of these classes.

## Modifier Methods

The overall process of sub-object selection relies upon the implementation of several methods in the modifier. These methods are from class **BaseObject**. These involve selecting, identifying, moving, rotating and scaling sub-object components. These methods are:

**virtual void ClearSelection(int selLevel);**

This method is called to clear the selection for the given sub-object level. All sub-object elements of this type should be deselected.

**virtual void SelectSubComponent(HitRecord \*hitRec, BOOL selected, BOOL all, BOOL invert=FALSE)**

This method is called to change the selection state of the component identified by **hitRec**.

**virtual int SubObjectIndex(HitRecord \*hitRec);**

Returns the index of the sub-object element identified by the HitRecord **hitRec**. The sub-object index identifies a sub-object component. The relationship between the index and the component is established by the modifier. For example, an edit modifier may allow the user to select a group of faces and these groups of faces may be identified as group 0, group 1, group 2, etc. Given a hit record that identifies a face, the edit modifier's implementation of this method would return the group index that the face belonged to.

**virtual void CloneSelSubComponents(TimeValue t);**

This method is called to make a copy of the selected sub-object components.

**virtual void Move(TimeValue t, Matrix3& partm, Matrix3& tmAxis,**

**Point3& val, BOOL localOrigin=FALSE )**

When this method is called the plug-in should respond by moving its selected sub-object components.

**virtual void Rotate(TimeValue t, Matrix3& partm, Matrix3& tmAxis,**

**Quat& val, BOOL localOrigin=FALSE )**

When this method is called the plug-in should respond by rotating its selected sub-object components.

**virtual void Scale(TimeValue t, Matrix3& partm, Matrix3& tmAxis,**

**Point3& val, BOOL localOrigin=FALSE )**

When this method is called the plug-in should respond by scaling its selected sub-object components.

## Sub-Object Selection in Edit Modifiers

A certain class of modifiers, referred to as edit modifiers, allow specific object types to be edited. For example, the Edit Mesh modifier allows TriObjects to be edited while the Edit Patch modifier allows patch objects to be edited. A generic Edit Point modifier would edit any object that supports the deformable interface. The sub-object selection levels for these edit modifiers reflect the sub-object types for the object type that the edit modifier is designed to edit. For example, the Edit Mesh modifier supports three sub-object selection levels: vertex, face and edge. These correspond to actual elements of a TriObject. In contrast, the sub-object levels of the Bend modifier, are gizmo and center. These have no correspondence with the object that the bend modifier is modifying.

Edit modifiers typically allow the user to select sub-object elements of the object and perform at least the standard move/rotate/scale transformations. They may also support other operations such as the Edit Mesh modifier's extrude operation.

When the user creates sub-object selections with an edit modifier, they are typically stored in the object because they correspond to actual parts of the object. The sub-object selection is actually part of the object's state that flows up the pipeline. For example, the Edit Mesh modifier allows the user to select vertices, faces or edges. If a Bend modifier is then applied after the Edit Mesh modifier, it will operate on the selected vertices or faces. If the user goes back in the history to the Edit Mesh modifier and changes the selection, the set of vertices that the bend affects will change. Essentially just editing the selection is a form of editing an object because the selection is part of the object.

Edit modifiers have to store the selection themselves. If the input to an edit modifier changes, the modifier will need to reapply its modifications. Since changing the selection set is a modification to the object, the edit modifier will need to recreate the selection set.

Selection sets are not the only thing edit modifiers need to store. If an edit modifier moves points on a modifier, then it needs to store, in some form, the changes it made to the points. For example, the Edit Mesh modifier stores changes made to the vertices of a mesh by maintaining an array of 3D vectors that represent a delta for each vertex. This delta is applied to an object by simply adding each delta to its corresponding vertex. This brings up a couple of issues: What happens if the number of vertices of the input object change? Since the vertex index is used to find its corresponding delta, if the topology of an object changes, a vertex's index might change. If this is the case the user is given a

warning message that a modifier exists in the stack that depends on topology (see the method **Modifier::DependOnTopology()** for the details on how an edit modifier informs the system it is dependent on topology). If the user selects OK from the warning message dialog the topology may be changed. The least that an edit modifier should do is not reference a vertex out of the range of an object's vertex array. The Edit Mesh modifier continually scales the length of its delta array to match the length of the vertex array of the incoming object. This ensures that the deltas are all applied to legitimate vertices, but if the topology changes, the effect is rarely useable.

The user may use the volumetric selector modifier to help eliminate this problem. This modifier uses spheres, 3D boxes, and cylinders to define a 3D region. Points inside the region become selected while points outside are not. This method of selection is independent of topology and therefore does not exhibit the previously-described problems.

Modifiers can be instanced and therefore a modifier, in general, isn't just applied to a single object. This raises the question of what happens when an edit modifier is instanced. It must store its changes to a particular object somewhere. One of the fields of the [ModContext](#) is a pointer to a LocalModData derived class. The most convenient place to store this data is here in the ModContext. When an object is copied, the ModContext (and therefore the LocalModData) is also copied making it possible to copy objects with edit modifiers applied to them.

## Named Sub-Object Selection Sets

A modifier that supports sub-object selection can choose to support named sub-object selection sets. This allows the user to save and restore certain sub-object selection sets and not have to pick them over and over. The modifier indicates it wishes to do so by returning TRUE from the following method of BaseObject.

### **virtual BOOL SupportsNamedSubSels();**

Returns TRUE if the plug-in supports named sub-object selection sets; otherwise FALSE.

A modifier that wishes to support this capability maintains its list of named sub-object selections. When the user enters sub-object selection mode the modifier should add its named selection sets into the drop down using the following method of Class Interface:

### **virtual void AppendSubObjectNamedSelSet(const TCHAR \*set)=0;**

A modifier may call this method to add sub-object named selection sets to the named selection set drop down list in the 3ds max toolbar. This should be done whenever the selection level changes (in the Modifiers

**BaseObject::ActivateSubobjSel()** method).

The following methods of BaseObject are called when the user picks items from the drop down list:

### **virtual void ActivateSubSelSet(TSTR &setName);**

When the user chooses a name from the drop down list this method is called. The plug-in should respond by selecting the set identified by the name passed.

### **virtual void NewSetFromCurSel(TSTR &setName);**

If the user types a new name into the named selection set drop down then this method is called. The plug-in should respond by creating a new set and give it the specified name.

### **virtual void RemoveSubSelSet(TSTR &setName);**

If the user selects a set from the drop down and then chooses Remove Named Selections from the Edit menu this method is called. The plug-in should respond by removing the specified selection set.

The following methods from Class Interface also deal with named sub-object selection sets:

### **virtual void ClearSubObjectNamedSelSets()=0;**

This method clears the named selections from the drop down.

**virtual void ClearCurNamedSelSet()=0;**

This method clears the current edit field of the named selection set drop down.

For sample code that deals with named sub-object selection sets see

**\\MAXSDK\\SAMPLES\\MODIFIERS\\EDITMESH.CPP.**

## Sub-Object Coordinate Systems:

See Also: [Class BaseObject](#), [Class Control](#), [Class SubObjAxisCallback](#).

When a modifier or controller is in a sub-object selection level, it has the ability to define the meaning of some of MAX's reference coordinate systems. MAX's reference coordinate system has two parts: The reference coordinate system drop down list and the center button. These are described below:

**1** The reference coordinate system drop down list. This lets the user select the orientation of the reference coordinate system. While the user is in a sub-object selection state, 'local' refers to the local coordinate system of the currently selected sub-object element and 'parent' refers to the node's local coordinate system.

What a sub-object's local coordinate system means is up to the modifier or controller. For example, Bend (and in fact, any modifier using **SimpleMod** as a base class) define local to mean the coordinate system of the gizmo. The Edit Mesh modifier defines local to mean different things for face and vertex selection levels. For face, the modifier constructs a coordinate system where the Z axis is parallel to the face's normal and X lies somewhere in the world XY plane perpendicular to Z. The Y axis is then given by X and Z. For vertices, a similar thing is done -- the vertex normal used for smoothing is used to define the Z axis. X and Y are constructed the same way as above.

**2** The center button. This button allows the user to choose the position of the center of the reference coordinate system. It has 3 options: Center of the selection set, Center of the reference coordinate system, and Pivot point. If the reference drop down list is set to local and the center button is set to center of the reference coordinate system, then the modifier or controller defines the position of the center when it constructs the local coordinate system. For center of selection and pivot point, it is up to the modifier or controller to decide what these mean. The Edit Mesh modifier defines center of the selection set to be the average of all vertices referenced by selected faces and the pivot point to be the center of a face cluster.

When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current modifier or controller being edited so that it can display the axes. Two methods (from **BaseObject** or **Control**) allow the system to do this:

**GetSubObjectCenters(SubObjAxisCallback \*cb, TimeValue**

**t,INode \*node)**

This method specifies the position of the center. The plug-in enumerates its centers and calls the callback **cb** once for each.

**GetSubObjectTMs(SubObjAxisCallback \*cb,TimeValue t,INode \*node)**

This method returns the axis system of the reference coordinate system. The plug-in enumerates its TMs and calls the callback **cb** once for each.

## Thread Safe Plug-Ins

See Also: [Main Plug-In Classes](#).

## Overview

Plug-ins that relate to the renderer have specific methods that need to be thread safe. This is because the renderer launches several threads of execution when rendering an image. Therefore the same method could get called from several threads at the same time. If one of the methods is writing a value that the other is reading or writing this can interfere with valid values being accessed.

Plug-in materials, texture maps and atmospheric effects are the plug-in types that have methods that need to be `= 4)`

`BSPSPopupOnMouseOver(event);">reentrant`. Any method of these plug-ins that is called while rendering, like **Texmap::EvalColor()**, **Mtl::Shade()**, **Atmospheric::Shade()**, etc. must be written in a way that is thread safe.

The methods listed above can be re-entered from another thread while the renderer is processing. For example, while **Texmap::EvalColor()** was executing it could get called again, totally asynchronously. At a certain time this method could be changing a variable, and another thread could be changing that same variable at the same time. Or it could be setting the value while another thread is attempting to read it. This can interfere with valid values being set or read.

The main rule for class variables is if a method changes a variable it won't be thread safe unless it takes specific steps to ensure it is. Any variables in the class must not be written to without taking steps. This is because both threads can see the same variable and could write to it at the same time.

There are conditions where a plug-in does NOT have to do anything to be thread safe. If the method just reads variables, it will be thread safe. Any local variables (those on the stack) can be read and written without concern. Any global variables can also be read without concern. If a method does all of its work on the stack then it will be thread safe.

## How To Ensure a Function is Thread Save

The code fragments below are from the 3ds max fog atmospheric effect. The code for this plug-in can be found in the SDK in `\MAXSDK\SAMPLES\HOWTO\MISC\FOG.CPP`. The synchronization object used to make the method thread safe here is called **CRITICAL\_SECTION**. Developers can look in the Win32 API for documentation for this and other synchronization objects.

First a developer declares a **CRITICAL\_SECTION**. This is a data type that is declared, initialized, and deleted when one is finished with it. When the class is created, like in the class constructor this object is initialized. Below are a pair of code fragment from the Fog plug-in where the **CRITICAL\_SECTION** is declared and initialized:

This creates the **CRITICAL\_SECTION** object.

```
class FogAtmos : public StdFog {
    public:
        CRITICAL_SECTION csect;
        ...
}
```

Here it is initialized in the constructor.

```
FogAtmos::FogAtmos() {
    ...
    InitializeCriticalSection(&csect);
    ...
}
```

In code where data that is accessible to several threads is to be modified, you call a Win32 API named **EnterCriticalSection()** and pass the **CRITICAL\_SECTION** object.

For example, thread A enters the code and **EnterCriticalSection()** is called. This sets a state in the **CRITICAL\_SECTION** data structure. Now thread B enters the same section of code. It also calls **EnterCriticalSection()** and passes in the **CRITICAL\_SECTION** object. The **CRITICAL\_SECTION** object knows that another thread is already in that code. Therefore it will sit and wait until thread A finishes and calls **LeaveCriticalSection()**. When thread A calls **LeaveCriticalSection()** this will trigger thread B that it may return from

**EnterCriticalSection()**. At this point it can then enter the code. Thus bracketing code with **EnterCriticalSection()** and **LeaveCriticalSection()** will make the code thread safe.

Below is a fragment from a method of the fog plug-in that is made thread safe using this technique.

```
void FogAtmos::UpdateCaches(TimeValue t)  
{  
  EnterCriticalSection(&csect);  
  if (!valid.InInterval(t)) {  
    valid = FOREVER;  
    pblock->GetValue(PB_COLOR,t,fogColor,valid);  
    ...  
  }  
  LeaveCriticalSection(&csect);  
}
```

Note that at the beginning of the method **EnterCriticalSection()** is called. Just before it exits **LeaveCriticalSection()** is called.

When a plug-in is done with the **CRITICAL\_SECTION** object, it can call **DeleteCriticalSection()**. Here this is done in the destructor for the Fog plug-in:

```
~FogAtmos() {  
  DeleteCriticalSection(&csect);  
}
```

Developers should also be aware of the following two points:

**1** Critical sections, or any other synchronization objects, should only surround the part of the code that requires synchronization. Otherwise, if the critical section surrounds a large block of computationally-expensive code unnecessarily, performance will suffer on multiprocessor machines.

As an example, if an algorithm needs to write to a class variable, do a long computation, then write to another class variable, it would be bad to structure the code like this:

```
Enter Critical Section  
write to var1  
do long computation...
```

write to var2

Leave Critical Section

This structure stops any other processor from accessing this routine until the long computation is done. It would be better to structure the code like this:

Enter Critical Section

write to var1

Leave Critical Section

do long computation...

Enter Critical Section

write to var2

Leave Critical Section

- 2 Synchronization problems often don't show up until you are running on a multi-processor system. All plug-in developers should test their code on multi-processor systems as much as possible. Intermittent crashes or erratic behavior is often a symptom of non-reentrancy.

## **Summary**

3ds max is a multi-threaded application and plug-ins that run inside 3ds max where multiple threads are used need to be thread safe. This section has presented the data structures and calls from the Windows Win32 API used to create thread safe code.

# Time

See Also: [Time Function Reference](#).

This section discusses the concept of time as used by 3ds max.

Time is stored internally in 3ds max as an integer number of **ticks**. Each second of an animation is divided into 4800 ticks. This value is chosen in part because it is evenly divisible by the standard frame per second settings in common use (24 -- Film, 25 -- PAL, and 30 -- NTSC).

The data type used to store a specific instance of time is the **TimeValue**. A **TimeValue** stores the number of ticks the time represents. When a developer specifies time to almost all the functions in the SDK they use **TimeValues**.

In MAX, time may be displayed in one of four formats. These are just display formats (the internal representation never changes). The formats are:

**Frames** - Integer number of frames.

**SMPTE** - SMPTE time code. This format uses

**hours:minutes:seconds:frames**. 3ds max abbreviates this by not including the hours designation to **minutes:seconds.frames**.

**FRAME:TICKS** - Integer number of frames:number of ticks.

**MM:SS:TICKS** - Minutes:Seconds:Ticks.

A developer may get and set the current time displayed format. The functions to accomplish this are **GetTimeDisplayMode()** and **SetTimeDisplayMode()**. When these settings are changed a message is sent throughout 3ds max to handle updating any UI controls that reflect time settings (including plug-in custom controls).

A developer can retrieve the number of ticks per frame using the function **GetTicksPerFrame()**, and can set this number using **SetTicksPerFrame()**.

A developer can also get and set the current frame rate. This is the number of frames per second. The functions for this are **GetFrameRate()** and **SetFrameRate()**. This is just an alternate way to specify the number of ticks per frame.

There are also functions to convert between the numeric and ASCII representations of time. The functions for this are **TimeToString()** and **StringToTime()**.

To review the methods discussed above see [Time Function Reference](#).

Note that some methods related to time are part of various interface classes. For example [Class Interface](#) provides methods to retrieve the current frame slider setting and the current animation range. These methods are **GetTime()** and **GetAnimRange()**. You can also set these using **SetTime()** and **SetAnimRange()**. There is also a method **RegisterTimeChangeCallback()** that allows a plug-in to be notified every time the user changes the frame slider.

## Track View

See Also: [Class Animatable](#).

## Overview

The track view of 3ds max provides a view into time. Track view is organized as a nested hierarchy showing both parent/child relationships, and sub-anim (parameter) relationships.

Many different plug-in types may participate in track view. For example, system plug-ins, sound object plug-ins, and many controller types all may have interfaces in track view. The methods of the **Animatable** class allow a developer to participate. This section is an overview of the concepts of track view, and an outline of the specific methods involved in providing an interface.

The track view provides a hierarchical view of the scene. All controllers appear in the track view as children of the objects they control. For example, every node has a transform controller and this controller appears under the node in the track view. Also, procedural objects and modifiers appear in the track view. If these have animatable parameters, the controllers plugged in to those parameters appear underneath the object or modifier. If a controller itself has animatable parameters, then any controllers plugged into those parameters would be found underneath it in the track view.

On the right side of each item in the track view there is a long horizontal track window. In this window, a controller can represent the track it controls. For example, a keyframe controller draws marks in the track representing points in time that have keyframes. Other procedural controllers may only present a time line displaying the duration of the animation.

Each controller is also able to display a function curve. This may or may not be editable by the user depending on the type of controller. For example, the standard keyframe controllers allow the user to edit the function curve while the expression controller simply displays a graph of the function that the user specified. The user has the ability to overlay function curves for different controllers on top of each other, regardless of the types of the controllers. For example, the user could place a function curve that represents the red component of a spotlight on top of the function curve that represents the position along a path of one of the nodes in the scene and edit the two.

In addition to function curves and tracks, a modal dialog may be brought up by the controller that contains additional parameters which the user can edit.

## Appearing in Track View

By default an anim (controller, parameter, etc.) will appear in track view. If the anim should not, the following method may be used:

### **virtual BOOL BypassTreeView()**

This method indicates to the system that this item should not appear in the track view. Note: Track View was formally referred to as Tree View. The default implementation returns FALSE, so items will appear unless this method is implemented to return TRUE.

## Copy and Paste Operations

There are two types of copy and paste in track view. These are available using two buttons in track view dialog. There is the Copy Controller button, and in Edit Time Mode, there is the Copy Tracks button.

Copy Controller lets the user copy the entire controller plug-in. A method of **Animatable** is available to prevent an item from being copied.

### **virtual BOOL CanCopyAnim()**

If an animatable doesn't want to be copied in track view it can return FALSE from this method, otherwise it can return TRUE.

Copy Tracks lets the user select a block of time and copy keys. An item (usually a controller) can participate in the copy and pasting of tracks. To indicate that it will participate in copying, a controller implements the following method and returns TRUE:

### **virtual BOOL CanCopyTrack(Interval iv, DWORD flags)**

Returns TRUE if this item can copy its data over the specified range; otherwise returns FALSE.

If a plug-in can copy its track data, the following method will be called to allow the item to do so:

### **virtual TrackClipObject \*CopyTrack(Interval iv, DWORD flags)**

This method is called to copy the item's track data over the specified interval. A plug-in should derive a class from the **TrackClipObject** base class to store the data associated with the objects tracks, and implement the methods that identify the creator of the clip object.

When the user has asked to paste the track, the system will call the following method to see if the track data can be pasted to the item.

### **virtual BOOL CanPasteTrack(TrackClipObject \*cobj, Interval iv, DWORD flags)**

Returns TRUE if this item can paste its data over the specified range; otherwise returns FALSE. The item can check the **TrackClipObject** creator and see if the data is appropriate for it to accept.

If the data is okay, the following method will be called to paste the data from the **TrackClipObject** to the item.

### **virtual void PasteTrack(TrackClipObject \*cobj, Interval iv, DWORD flags)**

This method is called to paste the specified clip object to this track. This method will not be called unless **CanPasteTrack()** returned TRUE.

## Operations to Time

This section shows several of the methods of Animatable that relate to the manipulation of time in track view:

### **virtual BOOL SupportTimeOperations()**

If an item supports time operations in the track view (cut, copy, paste, etc.), it should implement this method to return TRUE. When it is FALSE the user cannot select blocks of time in the item's track.

### **virtual void DeleteTime(Interval iv, DWORD flags);**

This method is called to delete the specified interval of time (or the keys within the interval).

### **virtual void ReverseTime(Interval iv, DWORD flags);**

This method is called to reverse the data within the specified interval.

### **virtual void ScaleTime(Interval iv, float s);**

This method is called to scale an interval of time by the specified scale factor.

### **virtual void InsertTime(TimeValue ins, TimeValue amount)**

This method is called to insert the specified amount of time at the specified insertion point.

## Drawing and Hit Testing Tracks and Function Curves

This section discusses how an item may display and hit test itself in the track and function curve modes of track view.

To indicate the amount of space it needs to draw itself, the item implements the following method:

### **virtual int GetTrackVSpace(int lineHeight)**

Returns the vertical space occupied by the track in units of one line.

An item may have a custom appearance for itself in the track view. It does this custom drawing in its implementation of the following method:

### **virtual int PaintTrack(HDC hdc, Rect& rcTrack, Rect& rcPaint, float zoom, int scroll, DWORD flags)**

This method is called to display the item in the track view. If an item needs to draw itself in a special fashion, it implements this method to do so. For example, a sound plug-in may draw its waveform using this method. If an item does not need to draw itself, the default implementation may be used. This draws the range bar for the item in the track instead.

Note: When drawing something to appear in Track View, a developer should not do any clipping of their own. 3ds max will take care of all clipping itself.

The next method is used to hit test a track. Hit testing is checking to see which keys have been selected by the user. This selection may be a single pick point or a dragged rectangular region. This method is passed a table of **TrackHitRecords** to update. Each key that lies within the hit rectangle (is hit) should be added to this table.

### **virtual int HitTestTrack(TrackHitTab& hits, Rect& rcHit, Rect& rcTrack, float zoom, int scroll, DWORD flags)**

This method is called to determine which keys lie within the **rcHit** rectangle. Keys that are hit are added to the **hits** table.

When the user has selected Function Curve mode, 3ds max displays the item in a graph with time along the horizontal axis and the value of the item along the vertical axis. An item can draw itself in track view in any way it wishes. It does so by implementing the following method:

### **virtual int PaintFCurves(ParamDimensionBase \*dim, HDC hdc, Rect& rcGraph,**

**Rect& rcPaint, float tzoom,int tscroll,  
float vzoom, int vscroll, DWORD flags)**

This method is called to draw the function curve of the item.

There are a set of macros that are handy for scaling time and values into and out of screen space. These are often used in the implementations of **PaintFCurve()** and **HitTestFCurves()**. See [List of Screen-Time-Value Macros](#).

When the user executes zoom extents on the item, this method is called:

**virtual int GetFCurveExtents(ParamDimensionBase \*dim,  
float &min, float &max, DWORD flags)**

This method is called to calculate the largest and smallest values of the item.

The next method is used to hit test the keys of a function curve. This selection may be a single pick point or a dragged rectangular region. This method is passed a table of **TrackHitRecords** to update. Each key that lies within the hit rectangle (is hit) should be added to this table.

**virtual int HitTestFCurves(ParamDimensionBase \*dim,  
TrackHitTab& hits, Rect& rcHit, Rect& rcGraph,  
float tzoom, int tscroll,  
float vzoom,int vscroll, DWORD flags)**

This method is called to hit test the item's function curves. It is called to determine which keys on the curve lie within the **rcHit** rectangle. Keys that are hit are added to the **hits** table.

## Operations to Keys

This section discusses some of the various Animatable method for dealing with keys in track view. These methods perform operations such as adding, deleting and scaling keys.

### **virtual void AddNewKey(TimeValue t,DWORD flags);**

This method is called to add a new key at the specified time. The value of the key is set to the value of the previous key, or interpolated between keys, based on the flags passed.

### **virtual void DeleteKeys(DWORD flags)**

This method is called to delete keys, as specified by the flags passed.

### **virtual void SelectKeys(TrackHitTab& sel, DWORD flags);**

This method is called to select or deselect a set of keys identified by the **TrackHitTab** and the specified flags.

### **virtual void MoveKeys(ParamDimensionBase \*dim,float delta,DWORD flags);**

This method is called to move selected keys vertically in the function curve editor. This moves the key values but does not alter the key times.

### **virtual void ScaleKeyValues(ParamDimensionBase \*dim, float origin, float scale, DWORD flags)**

This method is called to scale selected keys values. This scales the key values but does not alter the key times.

### **virtual void MapKeys(TimeMap \*map, DWORD flags);**

This method is called to update the keys specified by the flags, using the TimeMap passed. The plug-in should go through the specified keys and change their time to **TimeMap::map(time)**.

## **Track View and References**

3ds max maintains a reference to every sub-anim in the track view. This is how track view monitors if the sub-anim is changing. This reference is created when the sub-anim appears in track view, and is deleted when the sub-anim is no longer shown.

## Summary

This section has provided an overview of many of the methods related to participating in track view. The main methods developers must use to work with keys, time ranges, function curves, and copying/pasting operations were discussed. The primary methods associated with track view are from class **Animatable**. See this class for more detailed information on the methods presented above as well as the others associated with track view.

## UI Customization

See Also: [Class ActionTable](#), [Class ActionCallback](#), [Class ActionContext](#), [Class IActionManager](#), [Class DynamicMenu](#), [Structure ActionDescription](#), [Class DynamicMenuCallback](#), [Class ClassDesc](#), [Class Interface](#).

## **Overview**

This section describes the various classes and functions used to customize the user interface in 3ds max R4. This includes the ability to customize the 3ds max main pulldown menus, the toolbars, quad menus and keyboard shortcuts.

Discussed below is the Action System. This is a new system used for customizing the user interface. Plug-ins may use this to customize the 3ds max main menu, toolbars, quad menus and keyboard shortcuts. This system supercedes the system used by previous version of 3ds max for keyboard accelerators.

The system relies on plug-ins creating Action Tables. These are tables of UI related operations. These operations are called Action Items. When a UI operation is performed the code that carries out that operation is done by code in an Action Callback object.

## Overview of the Principal Classes of the Action System

### [Class ActionTable](#)

The class ActionTable is a generalization of the ShortcutTable class from R3. An ActionTable holds a set of ActionItems, which are operations that can be tied to various UI elements, such as keyboard shortcuts, Custom User Interface buttons, the 3ds max main menu and the Quad menu. MAX's core code exports several ActionTables for built-in operations in MAX. Plug-ins can also export their own action tables via methods available in Class ClassDesc.

### [Class ActionItem](#)

The class ActionItem is used to represent a single operation that lives in an ActionTable. ActionItem is an abstract class with operations to support various UI operations. The system provides a default implementation of this class that works when the table is build with the **ActionTable::BuildActionTable()** method. However, developers may want to specialize this class for more specific-purpose applications. For example, MAXScript does this to export macroScripts to an ActionTable.

### [Structure ActionDescription](#)

This structure is used when creating Action Tables. An array of these structures is created with one element for each action in the table to be built. This array of structures is then passed as a parameter to the ActionTable constructor.

### [Class ActionCallback](#)

This is the callback class that actually execute the action when a user requests it. The **ExecuteAction()** method of this class is called and performs the work. Developers create a sub-class of this class and implement **ExecuteAction()**. This usually consists of a case statement which switches on the ID of the command being executed.

### [Class ActionContext](#)

This class functions like an identifier for a group of actions. Several Action Tables can share a single ActionContext. The class maintains an ID, a name, and an active state for the context and has methods to retrieve these. When a Action Context is active all the Action Tables that use that context are active as well.

### [Class IActionManager](#)

This class provides methods to work with the available Action Tables. There are methods to get the number of and a pointer to specific action tables, activate and

deactivate action tables, work with action contexts and determine if they are active. A pointer which may be used to call the methods of this class is returned from **Interface::GetActionManager()**.

### [Class DynamicMenu](#)

This is a helper class used in putting up additional quad or toolbar menus 'on the fly'. This class has a few methods related to adding new menu items, beginning and ending sub-menus, checking menu flags, and getting a pointer to the menu after it has been created. The dynamic menu created by this class is provided to the method **ActionItem::GetDynamicMenu()**.

### [Class DynamicMenuCallback](#)

This is the callback used when creating dynamic menus. An instance of this class is passed to the constructor of the helper class DynamicMenu. This class has a single method called **MenuItemSelected()** which is called when the user has chosen an item from the menu.

### [Class MAXIcon](#)

### [Class ClassDesc](#)

There are two new method of this class related to ActionTables. When a plug-in wants to make its keyboard accelerators available it uses the following new methods:

**virtual int NumActionTables();**

**virtual ActionTable\* GetActionTable(int i);**

### [Class Interface](#)

There is a new method to access the Action Manager interface. This is:

**virtual IActionManager\* GetActionManager() = 0;**

See [Class IActionManager](#) for details.

## **Building Action Tables**

This section discusses the approach developers may use to build action tables and make them available to the system. In most cases building an ActionTable is fairly easy. It is a bit more work if you choose to implement your own custom sub-class of ActionItem, but in most cases that isn't needed (see next section). The system provides a helper class called ActionDescription that helps in building tables.

```
struct ActionDescription {  
// A unique identifier for the command (must be unique per table)  
int mCmdID;  
// A string resource id that describes the command  
int mDescriptionResourceID;  
// A string resource ID for a short name for the action  
int mShortNameResourceID;  
// A string resource for the category of an operation  
int mCategoryResourceID;  
};
```

An ActionTable is built by making a static table of action descriptions and passing it to the constructor for ActionTable. For example, here is the code that builds the action table for the FFD modifier:

```
#define NumElements(array) (sizeof(array) / sizeof(array[0]))  
static ActionDescription spActions[] = {  
ID_SUBOBJ_TOP,  
IDS_SWITCH_TOP,  
IDS_SWITCH_TOP,  
IDS_RB_FFDGEN,  
ID_SUBOBJ_CP,  
IDS_SWITCH_CP,  
IDS_SWITCH_CP,  
IDS_RB_FFDGEN,  
ID_SUBOBJ_LATTICE,  
IDS_SWITCH_LATTICE,  
IDS_SWITCH_LATTICE,  
IDS_RB_FFDGEN,
```

```

ID_SUBOBJ_SETVOLUME,
IDS_SWITCH_SETVOLUME,
IDS_SWITCH_SETVOLUME,
IDS_RB_FFDGEN,
};
ActionTable* BuildActionTable()
{
TSTR name = GetString(IDS_RB_FFDGEN);
HACCEL hAccel = LoadAccelerators(hInstance,
MAKEINTRESOURCE(IDR_FFD_SHORTCUTS));
int numOps = NumElements(spActions);
ActionTable* pTab;
pTab = new ActionTable(kFFDActions, kFFDContext, name, hAccel,
numOps, spActions, hInstance);
GetCOREInterface()->GetActionManager()-
>RegisterActionContext (kFFDContext, name.data());
return pTab;
}

```

The constructor for ActionTable takes the ID of the table, the context id, a name for the table, a windows accelerator table that gives default keyboard assignments for the operations, the number of items, the table of operation descriptions, and the instance of the module where the string resources in the table are stored.

At the same time the table is built, you also need to register the action context ID with the system. This is done with the

**IActionManager::RegisterActionContext()** method.

The other part of implementing an ActionTable is implementing an ActionCallback class. This is an abstract class with a virtual method called **ExecuteAction(int id)**. You need to sub-class this and pass an instance of it to the system when you activate the ActionTable. Then when the system wants to execute an action, you will get a callback to **ActionCallback::ExecuteAction()**.

For the FFD modifier, this looks like:

```

template <class T>

```

```

class FFDActionCB : public ActionCallback
{
public:
T* ffd;
FFDActionCB(T *ffd) { this->ffd = ffd; }
BOOL ExecuteAction(int id);
};
template <class T>
BOOL FFDActionCB<T>::ExecuteAction(int id) {
switch (id) {
case ID_SUBOBJ_TOP:
ffd->ip->SetSubObjectLevel(SEL_OBJECT);
ffd->ip->RedrawViews(ffd->ip->GetTime());
return TRUE;
case ID_SUBOBJ_CP:
ffd->ip->SetSubObjectLevel(SEL_POINTS);
return TRUE;
case ID_SUBOBJ_LATTICE:
ffd->ip->SetSubObjectLevel(SEL_LATTICE);
return TRUE;
case ID_SUBOBJ_SETVOLUME:
ffd->ip->SetSubObjectLevel(SEL_SETVOLUME);
return TRUE;
}
return FALSE;
}

```

FFD uses a template class to implement several versions of this callback, but this is not required.

Finally, the system needs to activate and deactivate the table at the appropriate time. When to do this depends on the scope of applicability of the table. If your ActionTable is exported from an editable object of modifier plug-in, then you typically want it only to be active when editing the object or modifier. This is done by activating it in the BeginEditParams() method, and deactivating it in EndEditParams().

For FFD, this looks like this:

```
ffdActionCB = new FFDActionCB<FFDMod >(this);  
ip->GetActionManager()->ActivateActionTable(ffdActionCB,  
kFFDActions);
```

The first parameter is the ID of the table to activate, and the second is an instance of the ActionCallback class that is responsible for executing actions. In EndEditParams(), we deactivate the table:

```
ip->GetActionManager()->DeactivateActionTable(ffdActionCB,  
kFFDActions);  
delete ffdActionCB;
```

For other types of plug-ins the table can be activated at different times. For example, you could write a GUP plug-in that activates the table when the plug-in is loaded to provide actions that are always available.

### **To Sub-Class or not to Sub-Class?**

Developers have the option of sub-classing both the ActionTable class and the ActionItem class, but are not required to do either. Only the ActionCallback is required to be sub-classed in all cases.

For the ActionItem class, developers only need to sub-class in rare cases. The default implementation of this class stores internal strings for its name, description, category, icon, etc. In some cases this might lead to duplicate storage if that information is stored elsewhere. In that case, you might want to provided a specialization of this class for memory efficiency.

The ActionTable class also has several virtual methods that the developer might want to implement. All these methods have default implementations, so sub-classing is not required unless special behavior is needed.

The default handlers for some of the handlers may not be appropriate. For example IsEnabled(int cmdId) returns TRUE in every case in the default implementation. If you want command to be disabled under some conditions, then you will need to build a specialization of ActionTable and implement this method. Other methods that you might want to implement are:

```
virtual BOOL GetButtonText(int cmdId, TSTR& buttonText);  
virtual BOOL GetMenuText(int cmdId, TSTR& menuText)  
virtual BOOL GetDescriptionText(int cmdId, TSTR& descText);  
virtual BOOL IsChecked(int cmdId);
```

```
virtual BOOL IsItemVisible(int cmdId);  
virtual BOOL IsEnabled(int cmdId);  
virtual void WritePersistentActionId(int cmdId, TSTR& idString);  
virtual int ReadPersistentActionId(TSTR& idString);
```

You only need to implement the last two methods if your table uses command identifiers that are not persistent from session to session. An example of this is the ActionTable that exports macroScripts from MAXScript. This system reads all the macroScripts in your system and assigns command IDs that are based on the order the macroScripts are read from the file. This might change from session to session, so when we want a persistent ID to write out to our keyboard or CUI files, we need one that doesn't change. For macroScripts, it writes the name of the script concatenated with the category of the script. The ReadPersistentID method takes that string and returns its integer command ID for the current session.

For tables that use constant integer identifiers that don't change from session to session, like the FDD example above, there is no need to implement this method.

### **Registering Action Tables**

In order for the system to use an action table, it need to be registered. For most plug-ins, this is done by returning it's action table in the following methods in ClassDesc:

```
virtual int NumActionTables();  
virtual ActionTable* GetActionTable(int i);
```

The system will call these methods on start-up, so if your plug-in exports action tables, it cannot be demand loaded. This is required because the ActionItems need to be displayed in the customization dialogs even if your plug-in is not in use.

### **Action Context IDs used by MAX**

The following action context IDs are used internally in MAX.

```
const ActionContextId kActionMainUIContext = 0;  
const ActionContextId kActionTrackViewContext = 1;  
const ActionContextId kActionMaterialEditorContext = 2;  
const ActionContextId kActionVideoPostContext = 3;  
const ActionContextId kActionSchematicViewContext = 5;  
const ActionContextId kActionIReshadeContext = 6;
```

## **Menu Manager**

The menu manager API lets plug-ins register menus and menu contexts that are saved in MAX's menus customization file, and can be configured by the user.

Menus are populated with ActionItems published from ActionTables. Menu contexts are places where menus can appear in MAX's UI. Menu contexts can be either for the main menu bar, or for places where a Quad menu can be displayed. 3ds max ships with a few pre-defined menu contexts, including the main menu bar, the viewport Quad menu and the ActiveShade Quad menu. Only a single menu-bar context is allowed, but plug-ins may register new Quad menu context as appropriate. For example, the UVW Unwrap plug-in in the 3ds max SDK defines a Quad menu context that is used when the user right-clicks in the UVW Unwrap window.

Menu creation is handled with the IMenu API defined in the iMenus.h header in the 3ds max SDK.

### **Adding to MAX's default menus**

A plug-in can use a MenuContext to register new menu items on to MAX's default menu bar or Quad menus. Since 3ds max gets its menu configuration from a file (in UIMaxMenus.mnu by default), plug-ins should only register their extensions a single time. To determine if the menu extensions have been registered yet, the plug-in should register a menu context with the ImenuManager::RegisterMenuContext() method. This method will return false if the context has not been registered, and true if it has. After the context is registered, it is saved in the menu file, and the next time 3ds max starts, the call to RegisterMenuContext() will return false.

To add items to MAX's main menu, the plug-in should check the return value of RegisterMenuContext(), and if it is true, that means that this is the first time it has been registered, and the plug-in can then create new menus, add items to MAX's main menu and Quad menus. In this case the MenuContext is used only as a place holder for determining when to add items to menus, not as a place where menus can appear.

Plug-ins can also register Quad menu contexts to be used as places Quad menus can appear in their UI. Typically this only applies if the plug-in creates its own floating window, such as UVW Unwrap. Normally, plug-in just need to register ActionItems, and possibly add items to MAX's main menu or default menus. Once items have been added to menus, and new menus have been registered,

they will appear in MAX's menu customization dialogs. Users can then move the items around, or remove them from menus.

If a plug-in wants to add menus and items to MAX's existing menus, or create its own Quad menu context, it should be done when 3ds max starts. This is best done with a GUP-style plug-in. These plug-ins have a Start() method that is called when MAX's first starts up. It is in that method that plug-ins should register new contexts and add menus and items.

### **Menu Context Ids**

Every menu context needs a unique 32-bit integer identifier. The ids for MAX's built-in contexts are defined in the iMenuMan.h header file. New plug-ins should use a random, fixed, integer value for the context. This can be generated using the "gencid.exe" program in MAX's SDK. Just use one of the 2 32-bit values generated.

### **Class IMenuBarContext**

3ds max comes with one pre-defined MenuBarContext, which is used to obtain the menu used on MAX's main menu bar. Its context id is

**kMenuContextMenuBar**. When a plug-in wants to add items or sub-menus to the main menu bar, it should get the menu from the main menu bar context as follows:

```
IMenuBarContext* pMenuBarContext = (IMenuBarContext*)  
GetCOREInterface()->GetMenuManager-  
>GetContext(kMenuContextMenuBar);  
IMenu* pMenu = pMenuBarContext->GetMenu();
```

The program can then use the IMenu class methods to add items or sub-menus to the main menu. It is recommended that plug-ins add their own top-level menu rather than adding items to existing menus.

The other use of the IMenuBar context is mentioned above. Plug-ins can register a menu bar context with its own ID to determine whether it should extend the main menu or not.

## **Sample Code**

Examples of Action Table APIs in use are found in many places in the SDK. A simple example is `\MAXSDK\MODIFIERS\FFD`.

## Units of Measurement

See Also: [Units of Measurement Reference](#).

This section discusses how developers work with the units of measurement used by 3ds max.

3ds max allows users to work with units that they are most comfortable with. Users may specify that they wish to work in US Standard units (Inches, Feet, Miles) or Metric units (Millimeters, Centimeters, Meters or Kilometers). Or they may specify a custom setting (for example perhaps they want to work in fathoms). Users may also work with generic units (these are the same as the default 3ds max master units).

Internally 3ds max keeps track of all measurements in its own internal unit called the master unit. The program converts measurements from user-defined units into the master defined unit for storage and computation. The master unit is defined as 1.0 inch. The user is able to change this master unit using Customize/Preferences, selecting the General page, and adjusting the System Unit Scale controls.

To retrieve the current unit display information one can use

**GetUnitDisplayInfo()**. This returns the information describing MAX's current system of measurement. This includes the type of units used, how they are displayed and custom unit name and scale. A developer may also use

**SetUnitDisplayInfo()**. This allows the developer to control the unit settings.

Two functions are available for converting units in and out of ASCII form. These are **FormatUniverseValue()** and **DecodeUniverseValue()**.

**FormatUniverseValue()** converts the specified value to its ASCII representation using the current unit display settings. **DecodeUniverseValue()** parses the specified measurement string and converts it to a floating point value.

Developers can use the method **GetMasterScale(int type)** to retrieve the master scale in terms of the specified unit type. For example:

**GetMasterScale(UNITS\_INCHES)** returns the number of inches per unit (unless altered by the user this would be 1.0).

To review the methods discussed above in detail see the section [Units of Measurement Reference](#).

## Undo/Redo

See Also: [Class RestoreObj](#), [Class Hold](#).

## Overview

3ds max has a built-in system for handling undo and redo. This allows users to undo their previous modifications to the database. The user may undo several operations, and also redo several undo operations.

The undo/redo system uses a global object call **theHold**. This is an instance of the class **Hold**. The developer calls methods of **theHold** to participate in undo/redo. Another class involved is **RestoreObj**. The developer creates instances of a class derived from **RestoreObj** to save the data needed to undo and redo the operation of the plug-in and to implement several methods required by MAX. The process works as follows:

Any operation that will modify the database checks to see if **theHold** is 'holding'. This means the 3ds max undo system has had the **Begin()** method called. If **theHold** is not 'holding' the developer should call **theHold.Begin()**. This signals the start of a potential undo operation. If **theHold** is holding, any operation that modifies the database must register a restore object with the system before it modifies the database. A restore object is an instance of the class **RestoreObj**. The restore object saves just enough data to restore the database to the state it was in when **theHold.Begin()** was called. It also saves data to allow a Redo operation to occur.

As a simple example consider a utility plug-in that allows the user to change the wireframe color of a node in the scene. The restore object would need to save the previous color and a pointer to the node being changed. It would also need to have storage to save the current color prior to an undo. This would allow it to undo the undo, or redo the operation.

In order to register the restore object with the system the developer calls **theHold.Put()**. This methods passes a pointer to the restore object. For example:

```
if ( theHold.Holding() ) {  
    theHold.Put(new ColorRestoreObj(currentColor,this));  
}
```

In the example above the **ColorRestoreObj** is a developer defined class derived from **RestoreObj**.

Once the restore object has been registered with **theHold** there are two potential cases to terminate the **Begin()**. The user can complete the operation or they may

cancel it.

If the user completes the operation, the developer calls **theHold.Accept()**. This registers an undo object with the undo system and leaves the database in its modified state.

If the user cancels the operation, the developer calls **theHold.Cancel()**. This restores the database to its previous state and throws out the restore object.

In addition to saving the data it needs to restore the database, the restore object has three main methods it must implement:

### **Restore(int isUndo)**

This is called to restore the database to the state it was in when **theHold.Begin()** was called. In the earlier example, the **Restore()** method would reset the wireframe color to the previous color. A flag, **isUndo**, is passed into this method to indicate if it was called in response to the Undo command. In the above example, if the flag is TRUE the developer must save the current color before restoring the previous color so if the user selects the Redo command the color could be reset to the state before the undo.

### **Redo()**

This is called by the system if the user has selected the Redo command. This means the user wants to undo the undo. The developer restores the database to the state it was in before the last undo was called on the restore object.

### **Size()**

This is called by the system to retrieve the size in bytes of the restore object. This is used to make sure all the accumulated restore objects do not grow beyond a manageable size.

Sometimes the **Restore()** method of the restore object may be called but not in response to the user selecting the Undo command. The undo system also allows values to be held in a buffer and then restored programmatically. For example, consider the operation of moving a node in the scene using the mouse. When the user first clicks the mouse button down to begin the operation, the state of the node's [= 4\) BSPSPopupOnMouseOver\(event\);">transform controller](#) is saved as part of a restore object. As the user moves the mouse, the plug-in tracks its position and updates the position of the node in the scene. Over and over the plug-in receives a message that the mouse has moved and the node in the scene must be re-positioned. Rather than storing incremental moves from the previously calculated position (which may accumulate error) it is more accurate

to restore the mouse position to where it started and recalculate the transformation based on the distance from the original mouse point to the new mouse point. In order to reset the original position, the system calls **Restore()**. This puts the node back into its original position. Then when the new position is calculated this is applied to the node. This happens over and over until the user releases the mouse. When the mouse is released **theHold.Accept()** is called to register an undo object with the system.

In iterative operations such as this it is often useful to set one of the flags of Animatable to indicate that a restore object is being held. In the example above, when the user first clicks down on the mouse the developer checks if **theHold** is holding and if it is calls **theHold.Put()** to register a restore object. Then the developer calls a method of Animatable **SetAFlag(A\_HELD)**. This sets the **A\_HELD** bit of the Animatable **aflag** data member to indicate the restore object is held. Then on each iteration the bit is tested to see if it is set and if so another restore object is not registered. A single restore object can be restored over and over again.

When **theHold.Accept()** or **theHold.Cancel()** is called, the system calls a method of the restore object called **EndHold()**. The developer may then clear the **A\_HELD** bit to indicate the restore object is no longer being held.

## Database Changes that are not Undoable

When 3ds max is exited, reset, etc., the save requester is only brought up if there is something on the undo stack. If a plug-in makes a change that is not undoable, the 'save dirty bit' must be set. This will indicate to the system that the save requester needs to be brought up. There are three APIs related to this:

### Function:

**BOOL GetSaveRequiredFlag();**

### Remarks:

Implemented by the System.

Returns TRUE if the 'save required' flag is set; otherwise FALSE. Note: this method does not tell you if saving is required, it just returns the value of the 'save required' flag. To really know if saving is required, you have to check the undo buffer as well as this flag. This is the purpose **IsSaveRequired()** below.

### Function:

**void SetSaveRequiredFlag(BOOL b=TRUE);**

### Remarks:

Implemented by the System.

Sets the 'save required flag'. Note that calling

**SetSaveRequiredFlag(TRUE)** will cause the 'Save Changes' prompt to appear, but **SetSaveRequiredFlag(FALSE)** will not prevent it from coming up unless you also reset the undo buffer.

### Parameters:

**BOOL b=TRUE**

TRUE to set the save dirty bit; FALSE to clear it.

### Function:

**BOOL IsSaveRequired();**

### Remarks:

Implemented by the System.

Returns TRUE if a change was made to the 3ds max database that would require the file to be saved. In other words, it returns TRUE if the save requester will be brought up when the user exits, resets, etc.; otherwise

FALSE.

## Flushing the Undo Buffer

If a plug-in developer needs to clear the undo buffer, two APIs are available to do so. A method of class **Interface** will flush the undo buffer:

**void FlushUndoBuffer();**

Developers may also use:

**int GetSystemSetting(int id);**

If the ID **SYSSET\_CLEAR\_UNDO** is passed to this method, the undo buffer is flushed. This function will return 0. Note that this will only work with version 1.1 of 3ds max or later.

An example of when to do this is when a creation object is deleted after some undo items have been put on the stack that refer to that object, for instance when a plug-in is doing a custom creation process. See the sample code in **\MAXSDK\SAMPLES\OBJECTS\LIGHT.CPP**.

If the creation object is deleted without being attached to a node, or if the creation is canceled, and if some undo objects have been logged since the creation object was created, then one should flush the entire undo stack. This brute force way of doing it is, unfortunately, the only safe way to ensure that the 3ds max undo stack is not corrupt with restore objects that point to deleted objects.

## Summary

In summary, plug-In developers are encouraged to have their plug-ins fully participate in the undo redo system of MAX. The developer works with two classes. **RestoreObj** is used to store data for undoing and redoing modifications to the database. **Hold** is used to call methods of the system and the restore object to manage undo and redo.

For reference information see [Class Hold](#) and [Class RestoreObj](#).

## Working with Action Tables

See Also: [Class ActionTable](#), [Class ActionItem](#), [Structure ActionDescription](#), [Class ActionCallback](#), [Class ActionContext](#), [Class IActionManager](#).

## Working with Bitmaps

See Also: [BitmapManager](#), [BitmapInfo](#), [Bitmap](#), [BitmapIO](#), [BitmapStorage](#).

## Overview

This section presents information about working with bitmap images. It discusses the main classes used, and presents information about concepts such as creating, loading and saving bitmaps, memory management when working with bitmaps, palettes, alpha, gamma, the geometry/graphics buffer (G-buffer), working with multi-frame images, handling errors that occur, and pixel storage formats. This section also documents a few utility functions in the API that are not part of any class.

## Overview of the Principal Classes

The following three classes are the main ones used when working with bitmaps:

### [BitmapManager](#)

There is a global object defined by 3ds max called **TheManager**. This is an instance of the class **BitmapManager**. This object manages and enables developers to work with bitmaps in MAX. For example, this class provides methods for creating and loading bitmaps. It also has methods for displaying some common dialogs that let users interactively specify files and devices to work with, and set options for bitmaps.

### [BitmapInfo](#)

**BitmapInfo** is the class used to describe the properties of a bitmap. The developer can declare an instance of this class and use its methods such as **SetWidth()**, **SetHeight()**, **SetGamma()**, and **SetName()** to describe the bitmap properties. The other classes related to bitmaps then use this information. Thus **BitmapInfo** is the heart of all image input/output. For example, all but a few methods in the **BitmapManager** use a **BitmapInfo** object as the main argument. For instance, if you wish to create a bitmap, you declare an instance of **BitmapInfo** and use its methods to establish the bitmap properties. Then when you call the **BitmapManager** method **Create()**, you pass the **BitmapInfo** object. The **BitmapManager** uses this information to determine how much memory to allocate based on the width, height and color depth.

This class also has methods to get and set the number of frames used in multi-frame bitmaps, and to define 'custom' properties of the bitmap. Custom properties let you specify only a portion of the main bitmap, such as a smaller, sub-region of the original, or fewer frames than the original (different begin and end settings or a different frame increment step size for multi-frame bitmaps). These custom properties are read and used by bitmap copying operations for example.

### [Bitmap](#)

The **Bitmap** class is the bitmap itself. All image access is done through this class. This class provides standard methods to retrieve and store pixels from the image. The **Bitmap** class has methods to retrieve parameters of the bitmap such as its width, height, whether it is dithered, or has an alpha

channel. Additional methods allow developers to open bitmaps for output, write multi-frame images, and to copy pixel data between bitmaps.

There are other bitmap related classes used only by developers who create 3ds max plug-ins used to load and save new bitmap file formats. The methods of these classes are called by the **BitmapManager** and **Bitmap** classes and not by developers themselves. The primary classes used for creating image loading and saving plug-ins are:

### [BitmapIO](#)

This is the main plug-in class used by developers creating image loader / saver plug-ins. For example, a developer creating a plug-in to support the PCX file format would derive their plug-in class from **BitmapIO**. This class is used for both files and devices (devices are items such as digital disk recorders). Developers implement pure virtual methods of this class to provide information about the image loader / saver they are creating. This is information such as the plug-in author name, copyright data, image format description, filename extension(s) used, and other capabilities of the image loader / saver. The developer also implements methods to load the image from disk, prepare it for output, write image data to it, and close it. Image loader / saver plug-ins use the **BitmapStorage** class described below to load and save their actual pixel data.

### [BitmapStorage](#)

When an image is loaded or created, the buffer that will hold the image data is an instance of the **BitmapStorage** class. This class allows developers to access the image in a uniform manner even though the underlying storage might be 1, 8, 16, 32 or 48 bit. For example, a paletted 8-bit format is perfect for loading GIF files but not for loading 32-bit Targa files. The inverse is also true. There is no point in creating a true color 64-bit storage to load a GIF file that only has 8-bit color information.

Thus the **BitmapStorage** mechanism was created so images could be kept in memory in a more efficient way. Instead of loading everything in MAX's internal 64-bit format, bitmaps are loaded and/or created using the most efficient storage for their type. The **BitmapStorage** class provides an uniform set of pixel access methods to hide these different formats from the developer using bitmaps. For example, standard methods are available for getting and putting pixels at various color depths. In this way, even though an image may be a 1-bit monochrome line art bitmap, pixels may be retrieved or

stored at other color depths. For example the **BitmapStorage** methods **Get16Gray()/Put16Gray()**, **GetTruePixels()/PutTruePixels()**, and **GetIndexPixels()/PutIndexPixels()** provide access to pixel data at various color depths.

Again, note that the **BitmapStorage** class is a low level access mechanism used by image loader / saver (**BitmapIO**) plug-ins. Developers wanting to access an image use the methods in the **Bitmap** class instead.

## Needed #include and LIB files

When working with bitmaps, make sure you add the bitmap include file to your source file, i.e. use the statement:

```
#include "bmmlib.h"
```

Also be sure to set your MS VC++ project settings to link to  
**\MAXSDK\LIB\BMM.LIB**

Using **bmmlib.h** and **bmm.lib** will ensure you have access to all the bitmap classes, methods, and functions.

## Creating, Opening, Writing, and Closing Bitmaps

This section shows how the **BitmapInfo** and **BitmapManager** classes may be used to create, open, and write to bitmaps. Following this is code that demonstrates how to open an existing bitmap using the standard 3ds max Open File dialog box. Both these examples show how to properly delete the bitmaps after they are used.

To create a bitmap from scratch, we need to declare a pointer to point to it:

```
Bitmap *bmap;
```

Remember that the **Bitmap** class represents the bitmap itself. Next, we need to declare an instance of the **BitmapInfo** class to describe the properties of the bitmap to create:

```
BitmapInfo bi;
```

Then we initialize the **BitmapInfo** with the properties of the bitmap we wish to create. This is done using the methods of **BitmapInfo** such as **SetType()**, **SetWidth()**, etc.:

```
// Initialize the BitmapInfo instance  
bi.SetType(BMM_TRUE_64);  
bi.SetWidth(320);  
bi.SetHeight(200);  
bi.SetFlags(MAP_HAS_ALPHA);  
bi.SetCustomFlag(0);
```

Note in the above code how the type is set. The type describes the number of bits per pixel used to describe the image, whether the image is paletted (has a color map), and if it has an alpha channel. To see a list of the types of bitmaps that may be created see [List of Bitmap Types](#). In this example, we use **BMM\_TRUE\_64**. This format has 16-bits for each color (RGB) and alpha component. This is the format that 3ds max uses internally in the renderer.

Once the **BitmapInfo** is initialized, we can call a method of the bitmap manager to create the bitmap. A global instance of the **BitmapManager** class exists called **TheManager**. This is what we use to call methods of **BitmapManager** as shown below:

```
// Create a new bitmap  
bmap = TheManager->Create(&bi);
```

Note that we pass it our **BitmapInfo** instance. This is where the bitmap manager gets the information on the bitmap to create. If the pointer returned is NULL, an error has occurred in creating the bitmap. If the pointer is non-NULL, it's valid and we can use it to call methods of the **Bitmap** class to work with the bitmap. The code below shows how the **PutPixels()** method is used to write data to the bitmap. This code sets every pixel of the image to the color and opacity specified by **r**, **g**, **b** and **alpha**.

```
...
BMM_Color_64 *line, *lp, color = {r, g, b, alpha};
int bmapWidth = bmap->Width(), bmapHeight = bmap->Height();

if ((line = (BMM_Color_64 *)calloc(bmapWidth,
sizeof(BMM_Color_64)))) {
    int ix, iy;
    for(ix = 0, lp = line; ix < bmapWidth; ix++, lp++)
        *lp = color;
    for(iy = 0; iy < bmapHeight; iy++)
        int res = bmap->PutPixels(0, iy, bmapWidth, line);
    free(line);
}
```

When we are done using the bitmap, we need to delete it. This is done by simply using the delete operator:

```
if (bmap) bmap->DeleteThis();
```

That's all that's required to create a bitmap from scratch.

The following code demonstrates two other methods of the bitmap manager -- **SelectFileInput()** to allow the user to choose a file to load (and initialize the **BitmapInfo** instance passed to it) and **Load()** to create a bitmap to hold the image. Again, we declare a **Bitmap** pointer and a **BitmapInfo** instance.

```
Bitmap *bmap;
BitmapInfo bi;
```

Next, we use a method of the bitmap manager to allow the user to choose an image file. This method returns FALSE if the user cancels and TRUE if they select an image. If you want to directly indicate which file to load, just set the fields of **BitmapInfo** yourself (for example

```

bi.SetName(_T("TEST.JPG"));
// Let the user choose the file to open
BOOL res = TheManager->SelectFileInput(&bi, ip-
>GetMAXHwnd(),
  _T("Open File"));
if (!res) return; // User cancelled...

```

After **SelectFileInput()** returns, the **BitmapInfo** instance passed to it contains the necessary information about the bitmap to load. To load the bitmap, the **Load()** method of the bitmap manager is used.

```

// Load the selected image
BMMRES status;
bmap = TheManager->Load(&bi, &status);
if (status != BMMRES_SUCCESS) {
  MessageBox(ip->GetMAXHwnd(), _T("Error loading bitmap."),
  _T("Error"), MB_ICONSTOP);
}

```

Once the image is loaded, you can work with it like any other bitmap. For example to display the bitmap in a window, use the **Bitmap::Display()** method.

```

// Display the opened bitmap
bmap->Display(title, BMM_CN, FALSE, TRUE);

```

A few more notes on the bitmap manager **Load()** method -- Additional options may be set by calling **BitmapManager::ImageInputOptions()** before calling **Load()**. This method will ask the user for special details such as custom positioning of smaller/larger images, etc. This method sets the proper fields in **BitmapInfo**.

The examples above show how to create and load a bitmap. Once you have the bitmap what if you want to save it to disk? Also, how do you deal with multi-frame files (like a FLC or AVI)? The example below demonstrates both these things for a multi-frame file. Again, we declare a **Bitmap** pointer and a **BitmapInfo** instance.

```

Bitmap *bmap;
BitmapInfo bi;

```

To allow the user to choose an output file type, use the **BitmapManager** method **SelectFileOutput()**. This brings up the 'Browse Images for Output' dialog box. This method returns TRUE if the user selected a file; it returns FALSE if they cancel the dialog box. This method also handles checking if the filename chosen already exists, and if so provides an overwrite question dialog. This method will fill in the proper fields of the **BitmapInfo** passed.

```
BOOL gotIt = TheManager->SelectFileOutput(&bi, ip-  
>GetMAXHwnd());  
if (!gotIt) return; // User cancelled...
```

Next we need to set the image size and the properties of **BitmapInfo** related to multi-frame images. Below we do this for a 30 frame sequence.

```
bi.SetWidth(640)  
bi.SetHeight(480)  
bi.SetFirstFrame(0)  
bi.SetLastFrame(29)
```

With the **BitmapInfo** setup, we can call the **BitmapManager** to create the sequence:

```
bmap = TheManager->Create(&bi);
```

The next code is used to open the bitmap for output. This indicates to the system that the bitmap is open for output and we can write to.

```
bmap->OpenOutput(&bi);
```

Next we simply write the images for each frame:

```
for (frame = 0; frame < 30; frame++) {  
    // Do something to the image  
    // ...  
    // Write the image  
    bmap->Write(&bi, frame);  
}
```

When we are done we need to close the image:

```
bmap->Close(&bi)
```

Note: You can add any number of outputs to a bitmap. Just keep calling **bmap->OpenOutput()** with different outputs (for instance a TGA file and Frame Buffer). To write or close a specific output, use **Write()** and **Close()**. To write

and close them all at once, use the **Bitmap** methods **WriteAll()** and **CloseAll()**. It is okay to use **WriteAll()** and **CloseAll()** if you have just one output defined.

## Multi-frame Files

Certain file types (and most devices) are multi-frame. **AVI**, **IFL**, **FLI**, and **FLC** are all formats that support multiple frames. The **Bitmap** class has methods for dealing with these multi-frame bitmaps. For example, you can set the current frame to load or save. Also, the **BitmapInfo** class has methods that will let you work with only a subset of frames of a multi-frame image, for example, **SetStartFrame()**, **SetEndFrame()**, and **SetCustomStep()** let you specify a different start, end and frame increment to be used.

When loading files, **BitmapInfo** defaults to frame 0. For multi-frame files you should specify the frame number you want to load. This is done by using **bi.SetCurrentFrame(f)** before calling **Load()**.

## High Dynamic Range Bitmaps

Newly added to the bitmap system in R4 are High Dynamic Range bitmaps. This was accomplished by adding methods to get and put floating point color values into the Bitmap and BitmapStorage classes. Conversions between floating point and fixed point representations are handled by the BitmapStorage, include clamping and scaling of floating point values.

There are four high dynamic range BitmapStorage formats:

- LogLUV32: This format uses a logarithmic encoding of luminance and U' and V' in the CIE perceptively uniform space. It spans 38 orders of magnitude from  $5.43571 \cdot 10^{-20}$  to  $1.84467 \cdot 10^{19}$  in steps of about 0.3% luminance steps. It includes both positive and negative colors. A separate 16 bit channel is kept for alpha values.
- LogLUV24: This format is similar to LogLUV32 except it uses smaller values to give a span of 5 order of magnitude from 1/4096 to 16 in 1.1% luminance steps. A separate 8 bit channel is kept for alpha values.
- LogLUV24A: This format is identical to LogLUV24, except the 8 bit alpha value is kept with the 24 bit color value in a single 32 bit word.
- RealPixel: This format encodes the exponent, e, of the largest rgb component of the pixel, and the ratio of each component with  $2^e$ .

[Structure BMM\\_Color\\_fl](#)

Added BMM\_Color\_fl for floating point access to bitmaps.

[Structure LogLUV32Pixel](#)

[Structure LogLUV24Pixel](#)

[Class BitmapStorage](#)

There are new methods in Bitmap and BitmapStorage that allow data to be retrieved in floating point values rather than integer values so 3ds max can get the high dynamic range data without clamping.

**BMM\_Color\_fl** uses floats to hold the RGBA color components, rather than 16 bit integers which are used in **BMM\_Color\_64**. To convert from **BMM\_Color\_64** to **BMM\_Color\_fl** you divide each component by 65535.0 and to go back you multiply each component by 65535.0. High Dynamic Range bitmaps are not restricted to the range 0.0 to 1.0. Some formats allow negative values and all of the formats can go well above 1.0.

There is a problem is when converting from **BMM\_Color\_fl** to

**BMM\_Color\_64**, since the value may exceed 65535. The bitmap will either clamp the values to 0 to 65535, or scale the values by the largest component value so all of the components are in the range 0 to 65535.

[Class BitmapStorageLDR](#)

[Class BitmapStorageHDR](#)

The class hierarchy of BitmapStorage was changed a little. Two new classes BitmapStorageLDR and BitmapStorageHDR are derived from BitmapStorage and should be used as the base class for BitmapStorage implementations. BitmapStorageLDR provides default implementations of the new floating point BitmapStorage methods and BitmapStorageHDR provides default implementations of the 64 bit pixel BitmapStorage methods.

[Class AColor](#)

Implemented converters between AColor and BMM\_Color\_fl.

[Class Color](#)

Implemented converter between Color and high dynamic range pixel formats.

[Class Texmap](#)

Added method IsHighDynamicRange to Texmap so we can determine when a texmap is returning high dynamic range data.

PreShade and PostShade store high dynamic range data when a Texmap indicates that it returns high dynamic range data.

[Class StdCubic](#)

[Class StdMirror](#)

Added interface method UseHighDynamicRange to allow StdMirror and StdCubic to use high dynamic range bitmaps.

[Structure BMM\\_Color\\_24](#)

[Structure BMM\\_Color\\_32](#)

[Structure BMM\\_Color\\_48](#)

[Structure BMM\\_Color\\_64](#)

[Structure BMM\\_Color\\_fl](#)

[Structure RealPixel](#).

## Custom Bitmap Properties

You may occasionally want to work with only a portion of a bitmap or series of images. For example, when copying one file to another, if you had a 640x480, 30 frame FLC file, you might want to work with the lower right corner 160x100 portion, using every other frame, perhaps starting at frame 5 and ending at frame 15. The 'Custom' methods of the **BitmapInfo** class let you specify these options. Methods such as **SetCustomWidth()**, **SetCustomX()**, and **SetCustomStep()** let you specify the part of the source image that should be manipulated. The method that copied the image would see that these custom properties were set and would act accordingly. See the [BitmapInfo](#) class for details on these methods.

You may use the **BitmapManager::ImageInputOptions()** method to allow the user to specify these options via the standard 3ds max Input Image Options dialog. This dialog simply sets the appropriate data members in **BitmapInfo** based on the user's choices.

## Memory Management for Plug-Ins that work with Bitmaps

Memory is allocated and de-allocated by the bitmap classes in various ways. It is important to understand when memory needs to be freed by the developer, and when the system will take care of freeing it. This section discusses this issue.

The bitmap manager methods **Create()** and **Load()** both return pointers to bitmaps that need to be freed when the developer is done working with them. This is accomplished by simply using the delete operator on the pointer returned from the methods. The pseudo code below shows both of these cases.

This is the **BitmapManager::Create()** case:

```
Bitmap *bmap;  
BitmapInfo bi;  
bmap = TheManager->Create(&bi);  
// Work with the bitmap...  
// ...  
// Free the bitmap when done  
if (bmap) bmap->DeleteThis();
```

This is the **BitmapManager::Load()** case:

```
BMMRES status;  
Bitmap *bmap;  
BitmapInfo bi;  
BOOL res = TheManager->SelectFileInput(&bi, ip-  
>GetMAXHWnd(),  
_T("Open File"));  
bmap = TheManager->Load(&bi, &status);  
// Work with the bitmap...  
// ...  
// Free the bitmap when done  
if (bmap) bmap->DeleteThis();
```

As the code above shows, the developer is responsible for freeing memory from both these methods.

Another example of getting a pointer to a bitmap and needing to free it is the pointer returned from the **Bitmap** method **ToDIB()**. This method creates a new Windows Device Independent Bitmap (DIB) and returns a pointer to it. The DIB bitmap is created from the bitmap whose method is called. The DIB is allocated

internally using **LocalAlloc()** and must be freed by the developer using **LocalFree()**. The pseudo-code below show how this is done.

```
PBITMAPINFO pDib;  
pDib = bmap->ToDib();  
// Work with the bitmap...  
// ...  
// Free the bitmap when done  
LocalFree(pDib);
```

There is a different case where the developer receives a pointer to a bitmap, but is NOT responsible for deleting it when done. If you have a video post Image Filter plug-in, it receives a pointer to the video post bitmap queue. This bitmap should not be deleted as video post is using it internally. For example, in the **ImageFilter::Render()** method, the filter plug-in has access to a source bitmap named **srcmap**. The methods of this pointer may be called, but the bitmap itself should not be deleted by the plug-in. Video post will take care of it.

## Memory Management for Image Loader/Saver Plug-Ins

This section discusses how memory is managed internally by image loader / saver plug-ins. These are the plug-ins derived from class **BitmapIO**. Examples of this type of plug-in are the GIF, FLC and JPG IO modules. Developers who are not creating these types of plug-ins do not need to be concerned with these details.

The memory allocated to a bitmap is managed internally by an instance of **BitmapStorage**. This class provides access to the pixels through a uniform interface.

When a developer creates an image, the memory is allocated by the system. As long as the bitmap is being used within the system, the bitmap remains allocated. This is handled internally by a usage counter that tracks if a bitmap is still being used. If another use of the bitmap takes place, the usage count is incremented. If the use of a bitmap ends, the usage count is decremented. When the usage count for the bitmap goes to zero, the system frees the memory. This happens automatically without intervention from the plug-in.

For example, once a bitmap is loaded (this is never the case when a bitmap is created), a storage for the image is created to hold the actual bitmap. If a second attempt to open this same bitmap is made (the same file and the same frame), instead of creating a new storage, the bitmap is created pointing to the existing storage. In the storage a counter is incremented to tell how many bitmaps are using it. When a developer deletes the bitmap (i.e. **delete MyMap;**) the destructor calls the storage and asks to be unlinked from the storage. The storage decrements the usage count and if it reaches 0, the storage itself is also deleted.

Note that this is only the case when a bitmap is loaded because when you create a bitmap, it doesn't yet exist in the file system. There is no way for someone else to "open" it. This is why when you create a bitmap, it is said this is a "WRITE ONLY" bitmap, and when you load a bitmap it is said this is a "READ ONLY" bitmap. In order to read and write a bitmap you must load the original bitmap, create a second, copy the data (doing whatever processing in between), and then write the newly created bitmap.

## **Bitmap Adjustment - Changes to Resolution and Color Depth**

There are several ways to change the resolution of a bitmap. In each case this involves creating a new bitmap and copying the existing bitmap to the new. To change the image size without any scaling of the pixel data, use

**Bitmap::CopyImage()** and specify the **COPY\_IMAGE\_CROP** operation.

To resize the bitmap you use **Bitmap::CopyImage()** as well. This method lets you specify either a low quality (faster) or a higher quality (slower) copy. See [List of Copy Image Operations](#) for examples of each.

To change the color depth (number of bits per pixel), you must create a new bitmap of the desired color depth, and copy the original to the new using **Bitmap::CopyImage()**.

## Palettes

Some color bitmaps use only 8-bits per pixel. These images, unlike true color images where every pixel can be a unique color, are limited by the colors stored in a palette. For example, an 8-bit GIF file has a 256 color palette. The color values stored by the palette can be any color, but the actual bitmap image can only be comprised of colors from the palette. And since the palette is limited to 256 colors, the image has a maximum of 256 unique colors. For paletted bitmaps, each pixel in the image is actually an index into the palette (sometimes called a color lookup table). So the pixel value tells the system which palette slot to look in, and the value in that palette slot determines the exact color.

In contrast, true color images, for example a 24-bit TGA file, store the color of the pixel directly in the pixel value. There is no palette used.

In MAX, every bitmap has storage for a palette even if it is not used. There are methods of the `Bitmap` class used to work with palettes. A developer may use **`Bitmap::IsPaletted()`** to determine if an image is indeed paletted. To access the palette of a bitmap, **`Bitmap::GetPalette()`** and **`Bitmap::SetPalette()`** may be used.

Palettes are primarily a concern for image loader plug-in derived from **`BitmapIO`**. When loading an 8 bit image, the loader would create an 8-bit storage and set the palette through **`BitmapStorage::SetPalette()`**. Sample code is available showing how this is done in `\MAXSDK\SAMPLES\IO\BMP\BMP.CPP` in the **`Load()`** method.

## Pixel Storage

There are several in-memory storage formats for pixel data. For a list of the available formats see the section [Pixel Storage Types](#). Also see [Class PixelBuf](#), and [Template Class PixelBufT](#) for some useful utility classes that manage single scanline buffers.

## Pre-Multiplied Alpha

The following is a discussion of the concept of pre-multiplied alpha as used by MAX. A 32-bit bitmap file contains four channels of data: red, green, blue, and alpha. The first three provide color information to the pixels, while the alpha channel provides transparency information. There are two methods of storing alpha in a bitmap -- pre-multiplied and non-pre-multiplied.

To composite an image that is in non-pre-multiplied format, the alpha must be multiplied by each of the R,G, and B channels before adding it in to the color of the background image. This provides the correct transparency effect, but must be done each time you composite. With pre-multiplied alpha, you store the R,G, and B components with the alpha already multiplied in, so compositing is more efficient.

However, this is not the only reason that 3ds max stores images in the pre-multiplied format. When you render an image, you typically want the edges of the objects to be anti-aliased. This effect is achieved by determining the fractional coverage of pixels on the edge of the object, and then adjusting the alpha of the pixel to reflect this. For example, a pixel which is 30% covered by the object will have an alpha of 0.30. To anti-alias the edges, the alpha **must** be pre-multiplied to darken these edge pixels. (This is basically equivalent to compositing the image over a black image). So it is natural, in a sense, for rendered images to have pre-multiplied alpha. If you didn't pre-multiply in the alpha of a rendered image, then just looking at the RGB you would see jaggies on the edges of objects: you'd have to composite it against black using the alpha channel whenever you wanted to display it.

Pre-multiplied alpha works as follows: If you have an image A which is partially transparent, and you want to composite it over an image B, the alpha channel of A tells you at each pixel how much of A and B to mix in. If A's alpha is pre-multiplied (as it always is in MAX) then the formula is:

$$\text{color} = A + (1-A.\text{alpha})*B$$

alpha can also be thought of as the "opacity" of A at a given pixel.

If image A was stored with Non-Pre-Multiplied Alpha (NPMA) then the formula for compositing would be:

$$\text{color} = A.\text{alpha}*A + (1-A.\text{alpha})*B$$

To understand why pre-multiplied alpha is used consider an anti-aliased edge of an object, rendered against a black background. The pixels along the edge will

have an alpha less than 1.0, and when the alpha is multiplied in, it will make the edge look smooth (i.e. anti-aliased). If you **don't** pre-multiply the alpha, the RGB image displayed as-is (with out taking into account alpha) looks jagged: multiplying by the alpha is what anti-aliases the image.

This begs the question "Why would you ever use non-pre-multiplied alpha?". Say you have an image without an alpha channel. You want to create an alpha channel to mask out all but a certain object, but want to leave the original image unchanged: you may be using the same image at other places in your rendering. In this case, you would want to paint an alpha channel using an image editor (such as Photoshop) which would mask out the image, and combine it using the non-pre-multiplied alpha formula.

MAX's Mask texture map allows you to do this, in fact. Basically Mask lets you combine a texture with an mask channel, where the mask channel acts as a NON pre-multiplied alpha channel. What the mask texture actually does is multiply all four channels of the map with the mask channel, so what is passed up the pipeline is RGBA with pre-multiplied alpha.

## Dithering and Filtering

When converting images with a palette of a greater number of colors to an image with a palette of fewer colors, dithering is a means of simulating colors not in the more limited palette by mixing different colored pixels together.

Dithering is also a method of smoothing the edges between two color regions by mixing their pixels so the edges appear to blend together.

In MAX, you have the option of setting dithering if you are rendering for the limited colors of an 8-bit display (256 colors). It can help prevent a banding effect in color gradients. Dithering does increase the size of 8-bit files and slows down the playback speed of animations.

3ds max is designed to render 64-bit color output. Consequently, you also have the option of setting dithering for true color (24 or 32-bit color). The Dither True Color option ensures that you get the best quality on true-color displays.

Users turn dithering on and off in the Rendering page of the Preferences dialog. Users can also set dithering for scene motion blur in Video Post. Here, dithering provides a smoothing effect between the separate images making up the "blur". Video Post dither is set as a percentage of total dither.

A developer can determine if a bitmap is dithered by calling **Bitmap::IsDithered()**. A developer can ask the system to dither an image at render time using the method **Bitmap::SetDither()**.

Normally, a developer is not directly concerned with the dithering or filtering of bitmaps. These two operations are performed by the renderer, and the 3ds max user sets these characteristics of the bitmaps using the 3ds max user interface. A developer can however determine if a bitmap will be filtered by calling **Bitmap::HasFilter()**. A developer can also ask the system to filter an image when it's rendered. This is done using the method **Bitmap::SetFilter()**. See [List of Bitmap Filter Types](#) for more details on the types of filtering available. There is also a method of the **Bitmap** class called **GetFiltered()** to compute averaged colors over a specified area of the bitmap using the bitmap's current filtering algorithm.

## Gamma Correction

This section contains an overview of the concept of gamma followed by a discussion of the methods available to developers in dealing with bitmaps and gamma correction.

Gamma correction compensates for the differences in color display on different output devices so that images look the same when viewed on different monitors. A gamma value of 1.0 corresponds to an "ideal" monitor; that is, one that has a perfectly linear progression from white through gray to black. However, the ideal display device doesn't exist. Computer monitors are "nonlinear" devices. The higher the gamma value, the greater the degree of nonlinearity. The standard gamma value for NTSC video is 2.2. For computer monitors, gamma values in the range of 1.5 to 2.0 are common.

When you create an image on your computer, you base your color values and intensities on what you see on your monitor. Thus, when you save an image that looks perfect on your own monitor, you're compensating for the variance caused by the monitor gamma. The same image displayed on another monitor (or recorded to another media affected by gamma) will look different, depending on that media's gamma values.

Two basic procedures are required to compensate for changes in gamma:

1. Calibrate your output display devices so that the midtones generated by 3ds max are accurately duplicated on your display device. You do this in the Gamma panel of the Preferences dialog (Display Gamma).
2. Determine the gamma value to be applied to files output by the 3ds max renderer and files input into 3ds max, such as texture maps. This control is also in the Gamma panel of the Preferences dialog (Files Gamma).

The most important rule about gamma correction is to do it only once. If you do it twice, the image quality is over bright and loses color resolution.

With regard to output file gamma, video devices such as video tape recorders have their own hardware gamma-correction circuitry. Therefore, you need to decide whether to let 3ds max do the output gamma correction or to let the output device handle it.

Gamma correction is not required for hardcopy print media.

Files coming into 3ds max from programs such as Adobe Photoshop will have been gamma-corrected already. If you've been viewing the files on the same monitor and they look good, you won't need to set input file gamma in 3ds max.

A developer can indicate that a bitmap should have a custom gamma setting using the method **BitmapInfo::SetGamma()**. To retrieve the gamma setting stored with the bitmap use **Bitmap::Gamma()**.

There are several ways to access pixel values in a bitmap. Some of these methods return gamma corrected pixels while other do not. Normally, a plug-in that access the pixels directly (for example an image filter plug-in that modifies the pixels) should use the method **GetLinearPixels()**. This method returns pixels that are NOT gamma corrected. The method **GetPixels()** is employed to access pixels that are gamma corrected.

Developers may also use the methods of [Class GammaMgr](#) to gamma correct colors.

## Aspect Ratio

Aspect ratio is usually expressed either as a ratio of bitmap width over bitmap height (for example, 4:3) or as a real value relative to 1 (for example, 1.333).

Methods are available in the **BitmapInfo** class to get and set the aspect ratio property of the **BitmapInfo** (**BitmapInfo::Aspect()** and **SetAspect()**).

Methods are available from the **Bitmap** and **BitmapStorage** classes to return the value of the **BitmapInfo** instance associated with the **Bitmap** or **BitmapStorage**.

3ds max also allows users to set the pixel aspect ratio, so that there is a different value for the distance covered by one pixel measured horizontally and one pixel measured vertically. A developer can check the pixel aspect ratio setting that is being used by the renderer using the method **Interface::GetRendAspect()**.

## **Hot Check Utilities**

There are functions that may be used to correct a pixel with RGB values that will give "unsafe" values of chrominance signal or composite signal amplitude when encoded into an NTSC or PAL color signal. This happens for certain high-intensity, high-saturation colors that are rare in real scenes, but can easily be present in computer generated images. See: [List of Video Color Check Utilities](#).

## G-Buffer Image Channels

Image Filter and Image Layer events in Video Post can use masks that are based on geometry/graphics buffer (G-Buffer) channels instead of the more widely used RGB and alpha channels. Also, some kinds of Filter and Layer events can post-process objects or materials designated by these channels. The 3ds max G-Buffer system allows developers to access additional data about rendered objects.

A G-buffer is used to store, at every pixel, information about the geometry at that pixel. All plug-ins in video post can request various components of the G-buffer. When video post calls the renderer it takes the sum of all the requests and asks the renderer to produce the G-buffer.

This allows a developer writing an image processing plug-in to locate parts of the image using a specific material, locate a specific node in the scene, and access UV coordinates, surface normals, and unclamped color values. This also allows the developer to access the Z (depth) buffer. In release 3.0 and later developers can access, color, transparency and weight for sub-pixel fragments as well as velocity (for motion blur).

A filter plug-in (derived from class **ImageFilter**) implements a method **ChannelsRequired()** to indicate what channels it needs. Then, at the time the filter's **Render()** method is called it will have access to these channels. See [List of Image Channels](#) for details on the available channels.

## Error Reporting

When an image loader/saver plug-in (derived from class **BitmapIO**) encounters an error during a bitmap operation (for example "No Disk Space" when attempting to write a bitmap) there is a system flag that controls how the error should be reported to the user.

The image loader/saver base class **BitmapIO** provides a method for reporting errors named **ProcessImageIOError()**. This presents a standard dialog that provides the user with options to cancel or retry the operation. So, when a developer runs into an error condition while processing a bitmap, they would use the **BitmapIO::ProcessImageIOError()** method to report it. Some "common" error messages are already defined, and for those you would simply use one of the error codes defined in **BITMAP.H**. These are:

**BMMRES\_MEMORYERROR** Generic memory error.

**BMMRES\_CANTSTORAGE** Generic can't create storage error.

**BMMRES\_BADFRAME** Generic Invalid Frame Number Requested.

More of these exist but are for internal use only. To send your own message, simply pass a **TCHAR** string instead. The file name and/or device name are taken from the given **BitmapInfo** object.

The **ProcessImageIOError()** returns either **BMMRES\_ERRORRETRY** or **BMMRES\_ERRORTAKENCARE** depending on the users selection from the dialog box. Normally a developer doesn't care about the return value and simply returns it and exits.

The idea of a standard error processing dialog is to control the display of dialogs. For example, when 3ds max is running in network rendering mode, no dialogs should be displayed. That would cause the machine to just sit there since there would be no user to respond to the dialog.

If you must handle the error yourself (that is, if you want to display your own error dialog), you should first check to see if dialogs are allowed by checking the **BitmapManager::SilentMode()** method. This method returns a value indicating if dialogs should indeed be displayed or not.

## Utility Functions for Use with Bitmaps.

The following functions are general utility routines for dealing with bitmap files (but are not methods of a specific class):

### Prototype:

```
BOOL BMMCreateNumberedFilename( const TCHAR  
*namein,DWORD frame, TCHAR *nameout );
```

### Remarks:

Implemented by the System.

This appends a 4 digit frame number string to the end of the name passed. For example, this will convert **BIGFILE.TGA** to **BIGFILE0000.TGA** (or **BIGF0000.TGA**). This function checks the file system to see if it supports long file names and manages the length appropriately.

### Parameters:

**const TCHAR \*namein**

The input name to append the numbers to.

**DWORD frame**

The frame number to append.

**TCHAR \*nameout**

The output string.

### Return Value:

TRUE if the function succeeded; otherwise FALSE.

### Prototype:

```
BOOL BMMGetFullFilename(BitmapInfo *bi);
```

### Remarks:

This function will search the system for a bitmap. The BitmapInfo pointer contains the name of the bitmap that is searched for (**bi->Name()**). If the filename found in the BitmapInfo is incorrect, and the bitmap is found somewhere else, this function will replace **bi->Name()** with the correct path.

The order of the search is as follows:

- The full UNC path/filename saved in the BitmapInfo object.
- The path where the current 3ds max file was loaded from.

- The directory tree under the directory where the current Max files was loaded.
- The Map path.

**Parameters:**

**BitmapInfo \*bi**

Describes the bitmap to find (using **bi->Name()**). This name is updated if the bitmap is found in a different location.

**Return Value:**

TRUE if the file was found; otherwise FALSE.

**Prototype:**

**BOOL BMMIsFile(const TCHAR \*filename);**

**Remarks:**

Returns TRUE if the specified filename is indeed an existing file; otherwise FALSE.

**Parameters:**

**const TCHAR \*filename**

The filename to check.

**Prototype:**

**void BMMSplitFilename(const TCHAR \*name, TCHAR \*p,  
TCHAR \*f, TCHAR \*e);**

**Remarks:**

This function will break the specified filename into path, file and extension components. **\*p**, **\*f**, and/or **\*e** can be NULL. It is possible, for example, to call with just **\*e** to collect just the file extension.

**Parameters:**

**const TCHAR \*name**

The filename to split apart.

**TCHAR \*p**

The path name is stored here.

**TCHAR \*f**

The file name is stored here.

**TCHAR \*e**

The file name extension is stored here. The name includes the period character (.).

**Prototype:**

**void BMMAppendSlash(TCHAR \*path);**

**Remarks:**

This function appends a slash character to the end of the path passed unless one already exists.

**Parameters:**

**TCHAR \*path**

The path name to append.

**Prototype:**

**BOOL BMMGetUniversalName(TCHAR \*out\_uncname, const TCHAR\* in\_path, BOOL nolocal = FALSE);**

**Remarks:**

This function is available in release 4.0 and later only.

Given a path (**E:\path\filename.ext**), the function will check and see if this drive is mapped to a network share. If successful, the full UNC version will be returned in **out\_uncname** ("**\\computer\share\path\file.ext**"). If the function returns **FALSE**, **out\_uncname** will be undefined.

This function has been enhanced to also return an UNC for a local drive that happens to be shared. For instance, if you pass in something like **d:\data\images\maps\background\rottenredmond.tga** and it happens that d:\data is shared as "Image Data", the function will return:

**\\computername\Image Data\images\rottenredmond.tga.**

**Parameters:**

**TCHAR \*out\_uncname**

This is a buffer you pass to it to receive the UNC path (if any). It must be at least **MAX\_PATH** long.

**const TCHAR \*in\_path**

The path for which to obtain the UNC name.

**BOOL nlocal = FALSE**

Pass this as TRUE if you just want to see if this is a network share (don't check if this local drive is shared).

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**BOOL BMMFindNetworkShare(const TCHAR\* in\_localpath,  
TCHAR\* out\_sharename, TCHAR\* out\_sharepath);**

**Remarks:**

This method is available in release 4.0 and later only.

Given a path (**E:\path\filename.ext**) this function will check and see if this [local] path is shared. If successful, it will return both the share name and the path of the share.

**Parameters:**

**TCHAR \*in\_localpath**

The local path provided.

**TCHAR \*out\_sharename**

The share name which is returned if the provided path is shared.

**TCHAR \*out\_sharepath**

The path of the share which is returned if the provided path is shared..

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**BOOL BMMGetLocalShare(const TCHAR \*local\_path, TCHAR  
\*share);**

**Remarks:**

This method is available in release 4.0 and later only.

This method represents the "second half" of **BMMGetUniversalName()**

above. This method will check local paths only and return a UNC version if a share exists somewhere up in the path hierarchy.

**Parameters:**

**const TCHAR \*local\_path**

The local path provided.

**TCHAR \*share**

The share name which is returned.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**LPTSTR BMMGetLastErrorText(LPTSTR lpszBuf, DWORD dwSize);**

**Remarks:**

This function is available in release 2.0 and later only.

Whenever you call a Win32 function and there is an error, this method may be used to return the descriptive string associated with the error.

**Parameters:**

**LPTSTR lpszBuf**

This is the string that is updated.

**DWORD dwSize**

The maximum length of the string that may be returned in **lpszBuf**.

## Working with Controllers

See Also: [Class Control](#), [Class StdControl](#), [Class SetXFormPacket](#), [Class IKeyControl](#), [Class IKDeriv](#), [Class IKEnumCallback](#), [Class JointParams](#), [Class AngAxis](#), [Class Quat](#), [Class Matrix3](#), [Class Point3](#), [Class ScaleValue](#), [Class Interval](#).

## Overview

Controllers are the plug-in type responsible for directing all animation in MAX. This topic provides information on working with controllers. There is an overview of the principal classes involved when creating and working with controllers, a list of the various controller types in MAX, information on accessing the keyframe for the systems controllers, and a note about the importance of undo / redo as related to controllers.

## Principal Classes

The following classes are the main ones used when dealing with controllers in the SDK.

### [Class Control](#)

This is the base class for the creation of controller plug-ins.

### [Class StdControl](#)

This class provides a simplified way to create controller plug-ins. Developers who sub-class their plug-in from this class will have fewer methods to implement.

### [Class IKeyControl](#)

This class is used to access the properties of controllers. The standard 3ds max plug-ins support this interface. Plug-In developers are encouraged to do so as well. This allows other third-party developers to access your controller's data.

### [Class SetXFormPacket](#)

This class is used to allow a transform controller to know that it is being specifically moved, rotated, or scaled.

### [Class EaseCurveList](#)

Ease curves vary the timing of a superior function curve. A normal function curve charts an animated parameter value over time. An Ease curve charts changes to the time of a function curve over time. A 3ds max user may apply multiple ease curves to a parameter. This class holds a list of ease curves and allows developers to access their data.

### [Class MultCurveList](#)

The value of a multiplier curve is a scale factor applied to the value of its superior function curve. This class holds a list of multiplier curves and allows developers to access their data.

There are several interface classes that provide access to the parameters for the standard 3ds max controllers. These are listed below:

Path Controller: [Class IPathPosition](#).

Noise Controller: [Class INoiseControl](#).

Surface Position: [Class ISurfPosition](#).

Link Inheritance Controller: [Class ILinkCtrl](#).

Look At Controller: [Class ILookatControl](#).

## Controller Types in MAX

The basic data types that can be animated by controllers are:

Integer values (**int**).

Floating point values (**float**).

Three floats (**Point3**). Note: The **Point3** class is also used for Color Controllers.

Position (**Matrix3**).

Scale (**ScaleValue**).

Transform (**Matrix3**).

## Accessing Keyframe Data of Controllers

Developers have access to the data of MAX's keyframe and procedural controllers. There is a separate Advanced Topics section on this topic. See [Keyframe and Procedural Controller Data Access](#).

## The Undo Mechanism and Transform Controllers

The following is a discussion of how a transform controller responds to movement of the mouse when the user is dragging and how the undo mechanism is involved.

When the user first clicks the mouse button down to begin a drag operation, the initial position of a node is stored. As each move takes place a new vector is calculated from the initial position to the new position of the mouse. This new calculation is used to update the position of the node. This is different than accumulating the new position from the previous position. The accumulation approach can introduce error. It may also be a problem for the user to get back to the initial position of the node if they move the mouse back to the initial position.

3ds max uses the undo mechanism to avoid the problems associated with the accumulation approach. Every time the user moves the mouse 3ds max re-computes the entire modification. So 3ds max uses the original point and the current location of the mouse to compute the position. What this means internally is that every time the user moves the mouse the state at initial mouse down must be restored. To do this, when the mouse is initially pressed, **theHold.Begin()** is called to create a **RestoreObj** that stores the initial state. When the mouse is moved, **theHold.Restore()** is called. This restores the state to when **theHold.Begin()** was called.

As noted above, when the user initially mouses down, **theHold.Begin()** is called. Then at each mouse move **theHold.Restore()** is called. In iterative operations such as this it is often useful to set one of the flags of **Animatable** to indicate that a restore object is being held. In the example above, when the user first clicks down on the mouse the developer checks if theHold is holding and if it is calls **theHold.Put()** to register a restore object. Then the developer calls a method of **Animatable SetAFlag(A\_HELD)**. This sets the **A\_HELD** bit of the **Animatable aflag** data member to indicate the restore object is held. Then on each iteration the bit is tested to see if it is set and if so another restore object is not registered. A single restore object can be restored over and over again. When **theHold.Accept()** or **theHold.Cancel()** is called, the system calls a method of the restore object called **EndHold()**. The developer may then clear the **A\_HELD** bit to indicate the restore object is no longer being held.

For sample code that does this see any of the transform controllers, for

example,

**\MAXSDK\SAMPLES\CONTROLLERS\BOOLCTRL.CPP**. Also, see the Advanced Topics section on [Undo / Redo](#).

## Global Functions

There are some global functions developer may use that relate to controllers. These provide things such as setting the default controllers used for various controller types, creating new instances of different controller types, turning animation mode on and off, temporarily suspending animate mode, and getting/setting the animation start and end times. There are also some global functions which provide access to the default tangent types for both the Bezier and TCB controllers. See [List of Additional Controller Related Functions](#) to review them.

## Working with Lights

See Also: [Class LightObject](#), [Class GenLight](#), [Class Light](#), [Class DefaultLight](#), [Structure LightState](#), [Class LightDesc](#), [Class LightRayTraversal](#), [Class ObjLightDesc](#), [Class ShadeContext](#).

## Overview

This topic provides information on working with lights. Covered are the main classes used when dealing with lights and a description of how these relate to one another. Also discussed are the types of lights, and how the parameters that define their characteristics may be retrieve and assigned.

There are several tasks lights are responsible for accomplishing. One is to provide an interface so the user can adjust their properties. Another is to provide access to these same parameters so other plug-ins (utilities, exporters, renderers, etc.) can get and set them. Another one is the actual illumination objects in the scene. Also, certain lights need to work with the 3ds max atmosphere system (such as fog and volume lighting).

## Overview of the Principal Classes

The following classes are the main ones used when dealing with lights in the SDK.

### [Class LightObject](#)

This is a base class for plug-in lights. It has a method used to retrieve the light's properties at a certain time, a method to create an **ObjLightDesc** object (described below). It also has methods that allow the many properties of the light to be read and altered.

### [Class GenLight](#)

This is also a possible candidate for plug-in lights to sub-class from. This class, sub-classed from **LightObject**, provides a set of additional methods (for example access to the controllers handling the animation of the light's properties).

### [Class Light](#)

This class describes the properties of the lights used in the interactive renderer. See [Light methods in Class GraphicsWindow](#) for methods which use this class.

### [Class DefaultLight](#)

An array of these objects is passed in the **Open()** method of a renderer plug-in. This class contains the transformation matrix of the light and a **LightState** object (described below) that describes the characteristics of the light.

### [Structure LightState](#)

This structure describes the properties of a light. When the **LightObject** method **EvalLightState()** is called, **LightState** is the structure that is updated. This is used, for example, by many of the file format export plug-ins to grab data about the lights they are exporting.

### [Class LightDesc](#)

This class has a single method **Illuminate()** used to determine the color and direction of the light striking a point. It has two public data members that indicate if the diffuse and/or specular color of objects should be affected by the light.

### [Class ObjLightDesc](#)

This class is sub-classed from **LightDesc** (described above). There is an

instance of this class for every instance of a light in the scene. The renderer asks each light in the scene to create one of these objects by calling **LightObject::CreateLightDesc()** and passing it the light node. This class has data members that provide information such as a pointer to the node for the light, a **LightState** object, various transformation matrices that provide conversions between the light's space and world and camera space. It has a method to retrieve the lights exclusion list, and a method to update the light's data members in this class once per render. It also has a method used in computing volume lighting effects, **TraverseVolume()**.

## Accessing Light Parameters

There are several approaches developers may use to access the parameters that define the properties of a light. One way is to call the **EvalLightState()** method of the light. This method updates the **LightState** structure passed to it. This structure contains basic information about the light such as its type, color, attenuation ranges, etc.). The structure is valid for a single point in time for animated lights.

Another approach is to call the individual Get/Set methods of the light directly. Since lights are sub-classed from **LightObject** or **GenLight**, the methods of these classes may be called to get and set additional properties. This provides not only read access but also the ability to change the lights properties. If animate mode is set to on, a developer may animate the lights in this way.

Finally, developers may access the controllers that handle the animation of lights. This can be used to determine exactly what type of interpolation is being done by the lights when they are animated (by looking at the Controller's Class\_ID). Also, the **GetValue()** and **SetValue()** method of the controller may be used to access the lights properties.

## **Global Light Scaling and Tinting**

In 3ds max 2.0 a new area, called 'Global Lighting' has been added to the Environment dialog. It contains two new controls that globally affect all lights in the scene, except the Ambient light. The two new controls are as follows:

**A Level spinner control:** The value in this spinner acts as a multiplier to all lights in the scene, except ambient light. Thus, a level of 1 (default) preserves the normal light settings, while higher numbers raise the lighting, and lower numbers reduce the lighting.

**A Tint color swatch:** The user may use this for to tint all lights in the scene by that color.

Both of these new controls can be animated. Developers that retrieve light color values from the Get/Set methods of the lights themselves do not have this global lighting factor applied. There are several methods of the Interface class that provide access to these properties. See [Interface -- Environment Access](#).

## Working with Materials and Textures

See Also: [Class MtlBase](#), [Class Mtl](#), [Class Texmap](#), [Class ShadeContext](#), [Class StdMat](#), [Class Mesh](#), [Class INode](#).

## Overview

This section provides information on working with materials and textures. This includes an overview of the principal classes, how plug-ins can access components of materials (such as their maps, colors, etc.), and how materials may be created and applied to nodes in the scene. Information is also provided about how the user interface is managed for plug-in materials and textures.

A texture and a material are similar in many ways. In MAX, every texture or material may have sub-texture or sub-materials. Materials that have sub-materials are referred to as meta-materials.

## Overview of the Principal Classes

The following are the main classes associated with **creating** plug-in materials and textures.

### [MtlBase](#)

This is the base class that the materials and texture classes are derived from.

### [Mtl](#)

This is the class plug-in materials are sub-classed from.

### [Texmap](#)

This is the class plug-in procedural textures are sub-classed from.

### [ShadeContext](#)

An instance of this class is passed into various methods associated with materials and texture maps. It provides data members and methods used in communication between the renderer and the plug-in material or texture.

### [RenderGlobalContext](#)

A pointer to an instance of this class is a data member of the ShadeContext (**RenderGlobalContext \*globContext**). This can be used by materials, texmaps, etc. to retrieve information about the global rendering environment. This is information such as the renderer in use, the project type for rendering, the output device width and height, several matrices for transforming between camera and world coordinates, the environment map, the atmospheric effects, the current time, field rendering information, and motion blur information.

### [IMtlParams](#)

This is an interface class passed to a material or texture map when it is being edited in the materials editor. The class has methods to do things such as add rollup pages to the dialog, remove rollup pages, and retrieve the current time (frame slider position).

### [ParamDlg](#)

Every **MtlBase** sub-class (i.e. texture map and material) defines a **ParamDlg** to manage its part of the material editor user interface. See the section below on Editing Material or Texture Parameters for details on how this class is used.

### [UVGen](#)

Most texture maps that use UVs will use a **UVGen**. This class encapsulates a

lot of the user interface for setting mirroring, tiling and so on. The **UVGen** is given a **MapSampler** callback, and the plug-in lets the **UVGen** call it. This lets the **UVGen** figure out the components for anti-aliasing, and it includes any transform including scaling, rotation, moving, and noise on the UVs.

### [MapSampler](#)

A texture map implements this class and passes it into the UVGen methods **EvalUVMaP()**, **EvalUVMaPMono()**, and **EvalDeriv()** to evaluate itself with tiling & mirroring. Each of the methods of this class are used to sample the map at a single UV coordinate.

### [XYZGen](#)

This class generates **Point3** coordinates based on the **ShadeContext**. A reference to one of these is referenced by all 3D texture maps. **XYZGen** does for 3D Texmaps what **UVGen** does for 2D Texmaps. It puts up the 3D "Coordinates" rollup, and supplies the 3D Texmap with transformed 3D coordinates.

### [TextureOutput](#)

This class may be used by textures to provide control over their output. The standard rollup page 'Output' is managed by this class. The Output Amount, RGB Level, and RGB Offset are settable. In the future this may be enhanced to include other things that are often desirable on the output stage such as tinting, color shifting, etc.

The following are the main classes associated with **accessing** properties of materials and textures:

### [StdMat](#)

This class provides access to the parameters of the 3ds max Standard material.

### [MultiMtl](#)

This class provides access to the developer alterable properties of the 3ds max Multi/Sub-Object material.

### [BitmapTex](#)

This class provides access to the parameters of the 3ds max Bitmap texture.

### [StdUVGen](#)

This class provides access to the parameters of the 3ds max UVGen class. These are the settings in the 'Coordinates' and 'Noise' rollups such as UV offsets, angle, blur, noise level, etc.

### [StdXYZGen](#)

This class provides access to the parameter of the 3ds max XYZGen class.

### [MtlBaseLib](#)

This class provides access to the materials stored in a materials library. See the sample code below for an example of use.

## Accessing Material Properties

This section covers how the various properties of a material may be retrieved from a node in the scene. These are properties such as color, mapping parameters, bitmaps used, etc.

In 3ds max there is only one material per node. In the **INode** class there are methods **GetMtl()** and **SetMtl()** that provide access to the node's material. **GetMtl()** returns a pointer to an instance of class **Mtl**.

**virtual Mtl \*GetMtl()=0;**

Returns the renderer material for the node. If the value returned is NULL this means the user has not assigned a material to the node. In such a case the renderer simply uses the wireframe color of the node (as well as many defaults) for the rendering properties.

The material returned can be any material that may be assigned by the user. These include those from 3ds max itself as well as those created by third party developers. One may look at the **Class\_ID** of the material to determine its type. For example, the 3ds max Standard material has a **Class\_ID** of **DMTL\_CLASS\_ID** while the Multi/Sub-Object material uses **MULTI\_CLASS\_ID**. See [List of Class IDs](#) to review the complete list provided by MAX.

Let's consider the case of accessing properties of the 3ds max Standard material first. If the **Class\_ID** returned is **DMTL\_CLASS\_ID** then it's a Standard material. This material does not have any sub-materials, but has many parameters that a developer may need to access.

The primary class for accessing the Standard material is [Class StdMat](#). It provides methods to get and set the material's properties. These are things like the shading limit, the diffuse, ambient and specular colors, and the shininess and opacity of the material. Developers may also need to access the mapping parameters, for example, to find the texture used in the diffuse slot. A developer may access these using **MtlBase::GetSubTexmap(int i)** and **MtlBase::SetSubTexmap(int i, Texmap \*m)**. The index passed to these method are a series of #defines. See [List of Texture Map Indices](#).

Next, let's consider access to the properties a Multi/Sub-Object material. If the **Class\_ID** returned is **MULTI\_CLASS\_ID** then it's a Multi/Sub-Object material. The multi-material is a plug-in that uses the **MtlID** assigned to each face of a mesh as an index into the list of sub-materials. There are methods of

the [Face](#) class **getMatID()** and **setMatID()** to access the MtlID for each face. Additionally, the [Mesh](#) class has methods **getFaceMtlIndex(int i)** and **setFaceMtlIndex(int i, MtlID id)**.

Note that the meaning of this material index assigned to the face is specific to the type of material. A third party developer could write a material that used the ID in an entirely different manner than 3ds max does.

For a multi-material, a developer can use the methods of **MtlBase**: **NumSubMtls()**, **GetSubMtl(i)** and **SetSubMtl(i, Mtl\* m)** to access the sub materials. Note that some 3ds max primitive have pre-assigned material ids (such as the Box and the Hedra). Since the object is not really aware of the material, it can happen that the material ID on a face is higher than the total number of sub materials in a material. Developers should look at the number of sub materials on the material, and use a modulo function to bring the material ID of the face down to a legal value before trying to access it.

The following code demonstrates access to material and texture properties. It shows how the ClassIDs are checked for the material and the texture map. It also demonstrates how to access materials properties using the **StdMat** class and the bitmap properties using the **BitmapTex** class.

```
// Test of access to material and texture map properties of a selected node.  
// This code determines if the two sided flag is set for the material  
// and retrieves the U and V tiling options for the diffuse texture.  
// It checks if the material is a 3ds max Standard material, and if the diffuse  
// texture map is a 3ds max Bitmap texture.  
#include "stdmat.h"  
void Utility::Test (Interface *ip) {  
    BOOL two;  
    float utile, vtile;  
    TSTR buf;  
  
// Get the material and texture properties from the node.  
if (ip->GetSelNodeCount() < 1) return;  
INode *node = ip->GetSelNode(0);
```

```

// Get the material from the node
Mtl *m = node->GetMtl();
if (!m) return; // No material assigned
// See if it's a Standard material
if (m->ClassID() == Class_ID(DMTL_CLASS_ID, 0)) {
// It is -- Access the two sided property of the material
StdMat* std = (StdMat *)m;
two = std->GetTwoSided();
// Access the Diffuse map and see if it's a Bitmap texture
Texmap *tmap = m->GetSubTexmap(ID_DI);
if (tmap->ClassID() == Class_ID(BMTEX_CLASS_ID, 0)) {
// It is -- Access the UV tiling settings at time 0.
BitmapTex *bmt = (BitmapTex*) tmap;
StdUVGen *uv = bmt->GetUVGen();
utile = uv->GetUScl(0);
vtile = uv->GetVScl(0);
buf.printf(_T("Two sided=%d, U Tile = %.1f, V Tile = %.1f"),
two, utile, vtile);
MessageBox(ip->GetMAXHwnd(), buf, _T("Info..."),
MB_ICONINFORMATION);
}
}
}

```

## Accessing Material Libraries

3ds max stores groups of materials in a library. The API provides methods to access the materials stored in these libraries. You can use the methods of class **Interface** to load and save material libraries. These methods are **LoadMaterialLib()** and **SaveMaterialLib()**. This class also has a method **GetMaterialLibrary()** which returns a reference to the currently loaded library. You may then use class **MtlBaseLib** to access the materials themselves. The sample code below shows how this is done. It loads a materials library, removes a single material, and saves it again.

```
void Utility::TestMaterialLib() {
    TCHAR *n1 = _T("D:\\3DSMAX\\MAPS\\3DSMAX.MAT");

    int okay = ip->LoadMaterialLib(n1);
    if (! okay) return;

    // Declare this as references since we want to manipulate the
    // original material library and not a copy.
    MtlBaseLib &mlib1 = ip->GetMaterialLibrary();
    int index = mlib1.FindMtlByName(TSTR(_T("Aqua Glaze")));
    if (index != -1)
        mlib1.Remove(mlib1[index]);
    ip->SaveMaterialLib(n1);
}
```

## Texture Coordinates

This section discusses how UVW texture coordinates are interpreted by the renderer for texture maps in 3ds max. The **Mesh** class provides access to the texture coordinates of a Mesh. The **PatchMesh** class provides access to the texture coordinates of a Patch. Both use a very similar approach. In this section we'll look at how this is done for the Mesh class.

The texture coordinates are available in the Mesh class public data member **UVVert \*tVerts;**

Note that a **UVVert** is simply a **Point3**, i.e.: **typedef Point3 UVVert;** **tVerts** is a pointer to the list of texture vertices. Each **UVVert** stores a single UVW coordinate (as the X, Y and Z public data members of the **Point3**). The UVW coordinates parallel the relative direction of the XYZ coordinates. If you look at a 2D map image, U is equivalent to X, and represents the horizontal direction of the map; V is the equivalent of Y, and represents the vertical direction of the map; W is the equivalent of Z and represents a direction perpendicular to the UV plane of the map. For a 2D mapping, only two of the coordinates are used, i.e. UV, VW, or WU. This provides greater flexibility for the user as it allows them to flip the orientation of the map relative to the geometry. Radio buttons in the Materials Editor user interface allow the user to choose which two are used. The texture coordinates don't provide exclusive control over the mapping -- the material containing the map may apply other transformations that affect how the texture coordinates are interpreted by the renderer. First we'll look at the default case where the material imparts no additional transformations. Later we'll see what happens when the material applies a transformation, and how we can access and interpret additional material transformations.

The texture coordinates stored in the **tVerts** array can be any floating point values. If we assume that the settings in the material do not apply any additional transformations (the default settings), then an image is fit in its entirety between texture coordinates 0.0 to 1.0. For example, if the two triangles pictured below in Figure 0 had the mapping coordinates shown at each vertex, the bitmap image in figure 1 would be mapped across the entire two triangles. This mapping is shown in Rendering 1. As you can see, the mapping coordinates from 0.0 to 1.0 provide an exact match, fitting the bitmap across the entire quad.

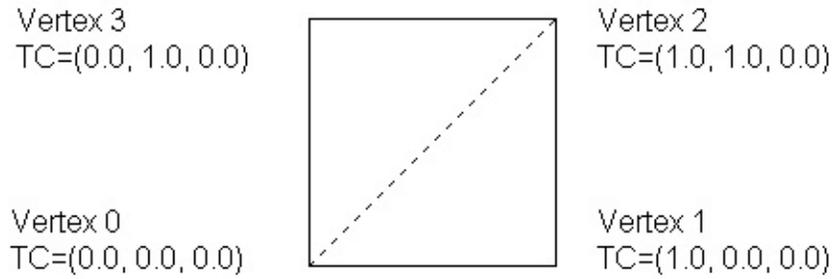

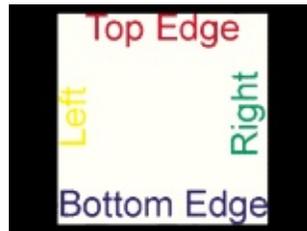

Figure 0:

Note: In figure 0 and those below 'TC' stands for Texture Coordinate (i.e. the value in the **tVerts** array)

Figure 1: The original bitmap (on a black background).

Rendering 1:

The next example shows how an image can be tiled across the geometry by using mapping coordinates greater than 1.0. The X mapping coordinate for vertex 1 and vertex 2 are 2.0 (and the material tiling check box are enabled in the Materials Editor). This results in the image being repeated in the U direction twice as shown below. Note that it is only tiled once in V since the Y coordinates are still 1.0.

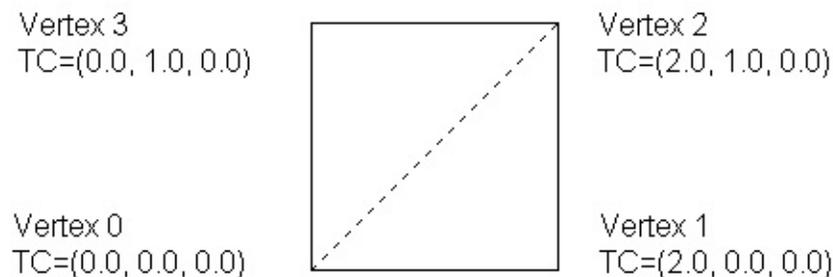

Figure 2:

Rendering 2:

The next example shows how negative texture coordinates are used to reverse the way the image is mapped to the geometry. In the figure below, the X texture coordinates are -2.0 for vertex 1 and vertex 2. This results in the image being mirrored about the vertical axis of the map. It is also repeated twice since the coordinates are -2.0 and not -1.0.

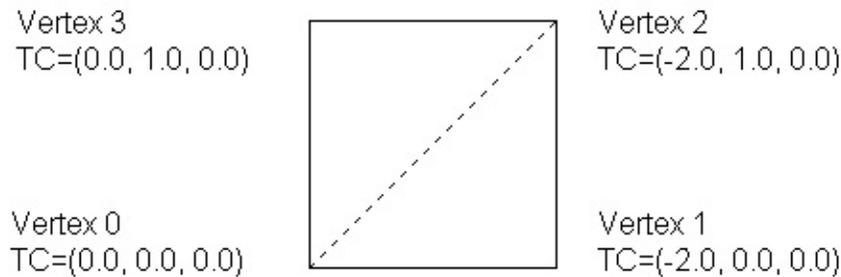

Figure 3:

Rendering 3:

The next diagram shows how mapping coordinate greater than 0.0 start the image off at an offset within the image. Here the coordinates are the same as in example 1, except all the values have been shifted by 0.5 in X and 0.5 in Y. This results in the image being shifted on the geometry. Here again, tiling is on, so the pattern begins in the center of geometry, but is tiled and thus reappears from the left and bottom edges.

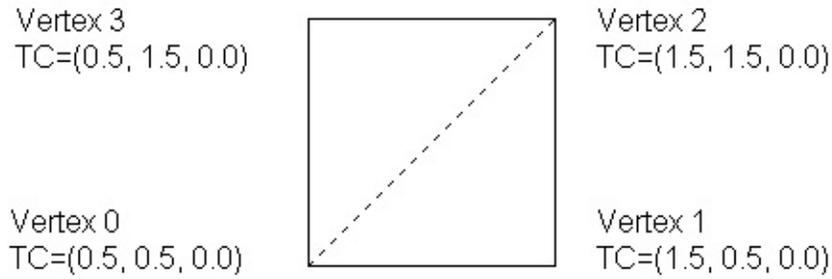

Figure 4:

Rendering 4:

There is something special about UVW coordinates in the range of 0.0 to 1.0. If image tiling is turned off in the Materials Editor (the 'Tile' check box is unchecked for a certain direction), then the image will only appear where the texture coordinates are in this range. UV values outside the range 0.0 to 1.0 will not be mapped when tiling is off in that direction. This is shown in the diagram below. The material editor settings have tiling off in both the U and V directions, and the mapping coordinates are from [0.0 to 2.0]. Note that the image only appears where the mapping coordinates are in the range [0.0 to 1.0], i.e. the lower left corner.

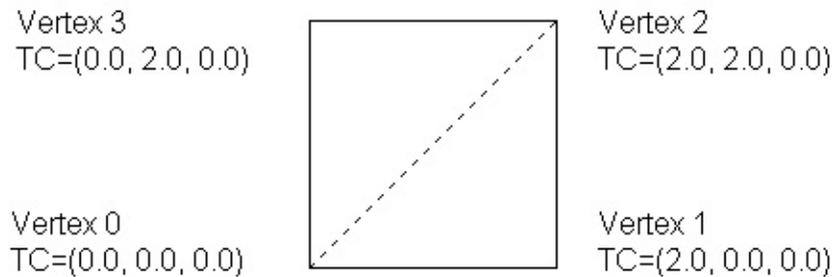

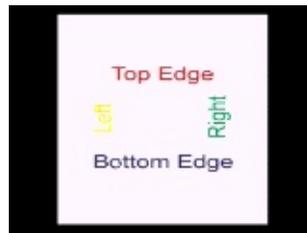

Figure 5:

Rendering 5:

As mentioned above, users may alter the tiling, mirroring, angle, and offset settings from within the material. These controls adjust the position of the map relative to the mapping coordinates. In the figure shown below, the material controls have been used to add an additional transformation to the mapping shown above in figure 5. The texture coordinates stored with the geometry are just the same, but a U Offset of 0.5 and a V Offset of 0.5 were used to shift the map onto the center of the geometry. Additionally, a U tiling setting of 0.75 was used to 'stretch' the mapping in the U direction. Thus the image is no longer square, but is rather elongated in U. Rendering 6 below shows the resulting image.

Rendering 6:

Developers may access all the users material transformation settings using the methods of class **StdUVGen**. The code shown above in the section **Accessing Materials Properties** sections shows how this is done.

## Texture Mapping

This section provides a quick look at how the texture coordinates described above are applied to objects in 3ds max using the standard mapping methods (planar, cylindrical, spherical, etc.).

In general this is quite simple. Basically, the geometric vertices of the object being mapped are transformed into some space (another coordinate system) and then these transformed geometric coordinates become the texture coordinates. For example in a simple planar mapping, the geometric vertices are transformed into the coordinate system of the mapping icon. Once transformed, the X, Y geometric coordinates become the UV mapping coordinates. For a cylindrical mapping the same thing is done except instead of taking just the X, Y coordinates, they are further transformed into a cylindrical coordinate system. Then these values become the UV mapping coordinates.

In camera mapping, where the texture coordinates of an object are used to match a background image, the geometric coordinates are transformed into camera screen space, and then screen X, Y becomes the UV coordinates.

## Face-Map Materials

There is another method of applying mapped materials that requires no application of mapping coordinates by the user whatsoever. In the Materials Editor, you can create a face-map material. When a face-map material is applied to an object, the map is automatically applied to each facet of the object. Below is the code used internally by 3ds max that computes the texture coordinates for face mapping:

```
static Point3 basic_tva[3] = {
    Point3(0.0,0.0,0.0),Point3(1.0,0.0,0.0),Point3(1.0,1.0,0.0)};
static Point3 basic_tvb[3] = {
    Point3(1.0,1.0,0.0),Point3(0.0,1.0,0.0),Point3(0.0,0.0,0.0)};
static int nextpt[3] = {1,2,0};
static int prevpt[3] = {2,0,1};

static void make_face_uv(Face *f, Point3 *tv) {
    int na,nhid,i;
    Point3 *basetv;
    /* make the invisible edge be 2->0 */
    nhid = 2;
    if (!(f->flags&EDGE_A)) nhid=0;
    else if (!(f->flags&EDGE_B)) nhid = 1;
    else if (!(f->flags&EDGE_C)) nhid = 2;
    na = 2-nhid;
    basetv = (f->v[prevpt[nhid]]<f->v[nhid]) ? basic_tva : basic_tvb;
    for (i=0; i<3; i++) {
        tv[i] = basetv[na];
        na = nextpt[na];
    }
}
```

## Bump Mapping in Procedural Textures

Bump mapping is a technique that enables a surface to appear wrinkled or dimpled without the need to model these depressions geometrically. Rather, the surface normal is perturbed according to information given in the 'bump map'. This results in variations to the smooth surface.

A 2D bump map is applied to the surface of an object. The space along the surface is called the UV space. The 2D bump map can be thought of as its own surface, where bright areas are hills and dark areas are valleys. On the surface then you can define a gradient, which can be thought of as the 'downhill' or 'uphill' directions. This gradient of values gives you a direction in UV space where you are going to perturb the surface normal. If you have a bump in a texture (a steep hill up for example) then you want to perturb the normal to make it look like there is a steep hill up there. Given the gradient in UV space, you need to figure out what direction in 3D (XYZ) space to perturb the normal that corresponds to that gradient in UV space. The **bump basis vectors** are used for this purpose. These are the vectors that represent the UVW axes of that texture in 3D. These are unit vectors that can be used to perturb the normal.

To understand how this is done, let's look at some sample code. The method responsible for returning the perturbed normal is

**Texmap::EvalNormalPerturb()**. The code below happens to be from `\MAXSDK\SAMPLES\MATERIALS\CHECKER.CPP` but all the other 2D textures use a similar approach.

```
Point3 Checker::EvalNormalPerturb(ShadeContext& sc) {  
    Point3 dPdu, dPdv;  
    if (!sc.doMaps) return Point3(0,0,0);  
    if (gbufID) sc.SetGBufferID(gbufID);  
    uvGen->GetBumpDP(sc,dPdu,dPdv);  
    Point2 dM = uvGen->EvalDeriv(sc,&mysamp);  
    return dM.x*dPdu+dM.y*dPdv;  
}
```

The first significant line related to bump mapping is:

```
uvGen->GetBumpDP(sc,dPdu,dPdv);
```

This method of **UVGen** gets the bump vectors. Developers can also get the bump vectors directly from the method **ShadeContext::DPdUVW()** although

these would not be affected by the **UVGen** transformations. In our case, since all the coordinates are coming through **UVGen**, we must use **GetBumpDP()** since the **UVGen** has rotated things around -- it has transformed the bump vectors to a new position. Basically, the UVGen has rotated the UV space into another position locally. So again, this method gets the bump basis vectors, which are really the U and V axes in 3D space (unit vectors in the U direction and the V direction, but in 3D space).

The next line computes **dM**. This is the derivative of the function across the pixel. This is the rate of change of the function in the U direction (**dM.x**) and the V direction (**dM.y**). So for example, if this is a flat function, these will both be zero. If the function is increasing in U but is constant in V then the value in the U direction will correspond to how fast it is changing while V will still be zero. Thus, **dM** can be thought of as the gradient -- how fast things are changing up and down.

**Point2 dM = uvGen->EvalDeriv(sc,&mysamp);**

Next, we need to compute the perturbation to the normal. This can be thought of as a small vector that will be added to the end of the existing normal that will move it over a little bit. There are several ways to do this. The common textbook algorithm (Blinn's algorithm for bump mapping) is not used by the 3ds max textures. Rather, the calculation shown below was found to be simpler and faster with no visual difference. To compute the perturbation to apply to the normal the following code is used:

**return dM.x\*dPdu+dM.y\*dPdv;**

This takes the sum of the U component (**dM.x**) multiplied by the U basis vector (**dPdu**) and the V component (**dM.y**) multiplied by the basis vector in the V direction. This gives the change (perturbation) to the normal as a unit vector.

The result of **EvalNormalPerturb()**, the perturbation to apply to the surface normal, is used by 3ds max as follows: Outside the procedural texture, for example in the Standard material, the value returned is added on to the surface normal. Then the normal is re-normalized (made a unit vector again). This altered normal results in the surface appearing 'bumped' when rendered.

## Assigning Materials to Nodes in the Scene

A developer may also wish to create materials and assign them to nodes in the scene. There are functions available for creating the standard 3ds max materials and textures such as Standard, Multi/Sub-Object, Bitmap texture, Composite texture, Mix, etc. These functions are not part of a class but are globally accessible (they are defined in `\MAXSDK\INCLUDE\STDMAT.H`).

### **StdMat \*NewDefaultStdMat();**

This function creates a new 3ds max Standard material. See [Class StdMat](#).

### **MultiMtl \*NewDefaultMultiMtl();**

This function creates a new 3ds max Multi/Sub-Object material. See [Class MultiMtl](#).

### **BitmapTex \*NewDefaultBitmapTex();**

This function creates a new 3ds max Bitmap texture. See [Class BitmapTex](#).

### **MultiTex \*NewDefaultCompositeTex();**

This function creates a new 3ds max Composite texture. See [Class MultiTex](#).

### **MultiTex \*NewDefaultMixTex();**

This function creates a new 3ds max Mix texture. See [Class MultiTex](#).

### **MultiTex \*NewDefaultTintTex();**

This function creates a new 3ds max Tint texture. See [Class MultiTex](#).

### **GradTex \*NewDefaultGradTex();**

This function creates a new 3ds max Gradient texture. See [Class GradTex](#).

### **StdCubic \*NewDefaultStdCubic();**

This function creates a new 3ds max Reflect/Refract texture. See [Class StdCubic](#).

### **StdMirror \*NewDefaultStdMirror();**

This function creates a new 3ds max Flat Mirror texture. See [Class StdMirror](#).

### **StdFog \*NewDefaultStdFog();**

This function creates a new 3ds max Fog atmospheric effect. See [Class StdFog](#).

Sample code using many of these functions is available in the 3D Studio DOS file import plug-in. This code may be found in `\MAXSDK\SAMPLES\IMPEXP\3DSIMP.CPP`.

The code below demonstrates how a 3ds max Standard material may be assigned to a mesh object. It assigns a material with Red Ambient and Diffuse settings to

the first node in the current selection set.

```
void Sample::AssignMtl(Interface *ip)  
{  
if (! ip->GetSelNodeCount()) return; // Nothing to assign.  
INode *node = ip->GetSelNode(0);  
// Create a new Standard material.  
StdMat *m = NewDefaultStdMat();  
// Set its properties...  
m->SetName(_T("Sample"));  
m->SetAmbient(Color(1.0f,0.0f,0.0f),0); // Pure Red  
m->SetDiffuse(Color(1.0f,0.0f,0.0f),0);  
m->SetSpecular(Color(1.0f,1.0f,1.0f),0);  
m->SetShininess(0.5f,0);  
m->SetShinStr(.7f,0);  
// Assign it to the node.  
node->SetMtl(m);  
ip->RedrawViews(ip->GetTime());  
}
```

## Editing Material or Texture Parameters in the Materials Editor

This section discusses the manner in which plug-in texture and materials manage their user interface in MAX. This is only a concern of developers creating plug-in materials or textures.

The way materials and texture maps handle their user interface is different than the way other plug-ins handle their UI in the command panel of MAX. For materials and textures, a developer derives a class from **ParamDlg** and implements its methods.

A method of **MtlBase** named **CreateParamDlg()** is called by the system when the material or texture is to be displayed in the material editor parameters area. This method is expected to create a new instance of a class derived from **ParamDlg**. The system then maintains the **ParamDlg** pointer. When the system needs to delete the memory associated with this instance it calls the method **ParamDlg::DeleteThis()**.

Within the instance of the class derived from **ParamDlg** a developer can store any data needed to handle the user interface (for example, spinner control handles, window handles, etc.). The class will also need to have a pointer to the 'thing' that is being edited. This 'thing' is either a texture or the material.

As the user works with different materials in the materials editor, these materials have to put up their user interfaces. For example, if the user is editing a Standard material in one sample window, then selects another Standard material in another sample window, the user interface changes to reflect the new material settings. The user interface does not 'flash' however -- in other words the entire rollup page is not deleted and replaced. Rather the fields are simply updated to reflect the new values. What the system is doing is effectively 'passing off' the user interface from one material to another. Two methods of **ParamDlg** allow this to happen. These are **SetThing()** and **GetThing()**.

When a system calls **SetThing()** it passes a pointer to a **ReferenceTarget**. This is the item that is being edited. So normally a developer would implement this method to store the item being edited (the 'thing') and update the user interface controls to reflect the state of the new 'thing'.

When the system calls **GetThing()**, the plug-in returns the 'thing' that is currently being edited.

As an example, consider the following code from the Checker texture map. Checker derives a class from **ParamDlg** and uses data members to store the

data needed for its operation. A portion of this code is shown below:

```
class CheckerDlg: public ParamDlg {
public:
    HWND hwmedit; // window handle of the materials editor dialog
    IMtlParams *ip;
    Checker *theTex; // current Checker being edited.
    HWND hPanel; // Rollup pane
    ISpinnerControl *blurSpin;
    IColorSwatch *cs[2];
    TimeValue curTime;
    ParamDlg *uvGenDlg;
    int isActive;
    ...
}
```

Note that **CheckerDlg** has a data member that is a pointer to an instance of **Checker** (**theTex**). This is where it stores the 'thing', i.e. the current **Checker** being edited. Shown below are **Checker**'s implementations of **GetThing()** and **SetThing()**.

```
ReferenceTarget* GetThing() { return (ReferenceTarget *)theTex;
}
```

When the system calls **GetThing()**, **Checker** just returns the pointer to the item that is currently being edited.

```
void CheckerDlg::SetThing(ReferenceTarget *m) {
    assert (m->ClassID()==checkerClassID);
    assert (m->SuperClassID()==TEXMAP_CLASS_ID);
    if (theTex) theTex->paramDlg = NULL;
    theTex = (Checker *)m;
    uvGenDlg->SetThing(theTex->uvGen);
    if (theTex)
        theTex->paramDlg = this;
    LoadDialog(TRUE);
}
```

When the system calls **SetThing()**, **Checker** store the pointer to the item that is currently being edited into **theTex**. The **Checker** class itself maintains a pointer to the instance of **ParamDlg** that is handling the user interface. Note that **Checker** stores the **this** pointer (**theTex->paramDlg = this;**).

Also note that **CheckerDlg** maintains a pointer to a **UVGen** (**UVGenDlg**). **UVGen** is a class developers use to encapsulate the user interface for UV coordinates. This pointer is initialized in the **CheckerDlg** constructor as follows:

```
uvGenDlg = theTex->uvGen->CreateParamDlg(hwmedit, imp);
```

In the **CheckerDlg** implementation of **SetThing()** it also calls the **SetThing()** method on the **uvGenDlg**. This allows the **UVGen** to update its user interface in the dialog. These are the controls in the 'Coordinate' and 'Noise' rollups.

## Pre-defined Categories of Texture Maps

Developers creating texture maps should use the text strings shown below to distinguish between the various types of maps so they can be separated in the Material/Map Browser.

**TCHAR TEXMAP\_CAT\_2D[];** - 2D maps.

**TCHAR TEXMAP\_CAT\_3D[];** - 3D maps.

**TCHAR TEXMAP\_CAT\_COMP[];** - Composite.

**TCHAR TEXMAP\_CAT\_COLMOD[];** - Color modifier.

**TCHAR TEXMAP\_CAT\_ENV[];** - Environment.

The appropriate string should be returned by the **ClassDesc::Category()** method of the Texmap. For example:

```
const TCHAR* Category() { return TEXMAP_CAT_3D; }
```

See [Class ClassDesc](#) for more details on this method.

## Miscellaneous Function and Macros for use with Materials

The following functions are not part of any class but are available for use by plug-ins.

Developers that have created a 3D Studio/DOS SXP and a corresponding 3ds max texture plug-in may want to have a look at [Class Tex3D](#). It provides a way to have an instance of your 3ds max texture plug-in created automatically when the corresponding SXP is found in a 3DS file being imported (using the standard 3ds max 3DS importer).

Another handy materials related function is **CombineMaterials()**. This function combines the two specified materials into a multi-material.

### Prototype:

```
Mtl *CombineMaterials(Mtl *mat1, Mtl *mat2, int &mat2Offset);
```

### Remarks:

Implemented by the System.

This function is available in release 3.0 and later only.

This function combines the two specified materials into a multi-material.

Either of the two input materials can themselves be multi materials.

### Parameters:

**Mtl \*mat1**

Points to the one of the source materials.

**Mtl \*mat2**

Points to the other source material.

**int &mat2Offset**

The index of the first **mat2** material in the combined material is returned here.

### Return Value:

A pointer to the new multi-material.

The following function may be used to determine if the MtlBase pointer passed is a material (Mtl):

```
inline int IsMtl(MtlBase *m)  
{ return m->SuperClassID()==MATERIAL_CLASS_ID; }
```

The following function may be used to determine if the MtlBase pointer passed is a texture (Texmap):

```
inline int IsTex(MtlBase *m)
{ return m->SuperClassID()==TEXMAP_CLASS_ID; }
```

The following functions return the intensity of the color passed:

```
static inline float Intens(const AColor& c)
{ return (c.r+c.g+c.b)/3.0f; }
static inline float Intens(const Color& c)
{ return (c.r+c.g+c.b)/3.0f; }
```

The following functions return default instances of several classes implemented by the system:

```
UVGen* GetNewDefaultUVGen();
XYZGen* GetNewDefaultXYZGen();
TextureOutput* GetNewDefaultTextureOutput();
```

Note the following typedef's used with materials and textures:

```
typedef MtlBase* MtlBaseHandle;
typedef Mtl* MtlHandle;
typedef Texmap* TexmapHandle;
```

## Working with Meshes

See Also: [Class Mesh](#), [Class TriObject](#), [Class Face](#), [Class TVFace](#), [Class MNMesh](#).

## **Overview**

This topic presents information on working with meshes. The main classes dealing with meshes are discussed as well as several support classes. The way texture mapping works with meshes is presented. How materials are assigned to meshes is also reviewed.

## Overview of the Principal Classes

This section presents an overview of the principal classes used when working with meshes.

### [Class Mesh](#)

This is the main class for working with mesh objects. It has data members that point to the vertices, faces, texture vertices and texture faces. Methods are provided to access all properties of the mesh and to render, snap to, and hit test the mesh. There are also methods to optimize, apply mapping coordinates, and perform boolean operations on the mesh.

### [Class TriObject](#)

All procedural objects must be able to convert themselves to TriObjects. This is the class that actually flows down the geometry pipeline. This class contains an instance of the Mesh class.

### [Class Face](#)

This is the class used to hold a single triangular face of the mesh object. It maintains three indices into the vertex array of the mesh. Methods are provided for setting materials, smoothing groups, edge visibility and hidden status.

### [Class TVFace](#)

This is the class used to hold a texture face. It contains an array of three indices into the texture vertex array of the mesh.

## Support Classes

This section lists several classes that are handy when dealing with mesh objects. There are a set of classes for working with parts of the mesh such as its face structure, element structure, and cluster structure. For details see: [Class AdjEdgeList](#), [Class AdjFaceList](#), [Class FaceElementList](#), [Class FaceClusterList](#). New for release 2.0 and later, the **MNMesh** class is provided for temporary use by plug-ins, to help with complex topology-based modifications to Meshes. It has capabilities, such as the ability to recognize faces with more than 3 sides, that are useful in certain applications. See [Class MNMesh](#) for details.

## Extracting the Mesh from a Node

Developers who want to get the **TriObject** representation of a geometric object from its node can use the source code shown along with the method **Inode::EvalWorldState()**. See [Inode::EvalWorldState\(\)](#).

## **Building Meshes Suitable for MAX Modifiers**

Developers should follow a few simple but important rules when building meshes to function ideally with modifiers in the Geometry Pipeline. The six basic rules are:

- 1) Referencing each edge at most once in each direction.
- 2) Avoiding self-intersection of faces.
- 3) Avoiding creating faces with vertices located at the same place.
- 4) Not 'bridging' separate mesh components with a single vertex.
- 5) Breaking the mesh into sensible elements.
- 6) Whenever convenient, closing the mesh.

See the Advanced Topics section [Style Guidelines for Creating Pipeline-Friendly Meshes](#) for details on these rules.

## **Material Assignment**

Materials are assigned in 3ds max at the node level. There is one material assigned per node. The material itself defines the meaning of how it acts upon a mesh. For example, the 3ds max Multi/Sub-Object material uses the material ID assigned to each mesh face as indices into its list of sub-materials. In this way, the user may assign several materials to a single mesh object. The Mesh class provides methods to get and set the material ID assigned to a face. For more details see [Working with Materials and Textures](#).

## **Texture Vertices and Texture Faces**

The mesh class keeps a pointer to a list of texture vertices. If mapping coordinates are assigned to the mesh these extra vertices are allocated. These vertices are completely independent of the regular vertices in the mesh. In addition to the texture vertices there are also texture faces. There needs to be one texture face for every regular face in the mesh. Each texture face has three indices into the texture vertex array. This allows every face of the mesh to have its own mapping.

## Mapping Channels in Release 3.0 and Later

In the Materials Editor a user can choose which of the channels a texture map is applied to. In the Coordinates rollout of the user interface, in the Texture Mapping dropdown the user may choose "Explicit Map Channel". In this case the Map Channel spinner is enabled and the user may choose a number between 1 and 99. This number is effectively an index into the Mesh class mapping methods. The number 1 corresponds to the pre-R3 Mesh class **TVerts** array. The numbers 2 through 99 correspond to the R3 and later channels. If the user chooses "Vertex Color Channel" from the dropdown then the Map Channel spinner is disabled and the vertex color channel is used. This corresponds to an index of 0 in the Mesh class mapping methods.

In release 2.0 there were just two possible mapping channels. The original release 1.x mapping channel and the color per vertex channel. These two still exist. However the map channel index numbers have changed. Henceforth at the object level, map channel 0 refers to what was map channel 1, the vertex color channel, while map channel 1 refers to the original map channel. The reason for this change is that vertex colors are treated differently than map channel vertices for some topological operations, and it's better to separate this map channel from all the other map channels.

Note the following details on adding map channels:

- 1) To support a map channel in a mesh, call **Mesh::setMapSupport(channel, TRUE)**. This works for the vertex colors (channel 0) or the original TVFaces (channel 1) as well as the new channels.
- 2) The method **Mesh::setMapSupport** allocates the map faces, since there are always **Mesh::numFaces** of these, but it does not allocate the map verts, since the number of these can change from map to map.
- 3) Use **Mesh::setNumMapVerts(int mp)** to set the number of map verts.
- 4) Calls to **Mesh::setNumFaces(int nf, BOOL keep)** also set the number of map faces in all supported maps.
- 5) Keep in mind that the **Mesh::mapVerts(int mp)** and **Mesh::mapFaces(int mp)** methods return pointers that may be invalid later if the number of verts or faces is reallocated. For example, the following **won't** work:

```
UVVert *mv = mesh.mapVerts(43); // map channel 43  
mesh.setNumMapVerts(43, 98);  
for (i=0; i<98; i++) mv[i] = UVVert(0,0,0);
```

For reference information on the new mapping related methods in 3.0 see [Mesh Mapping Related Methods](#).

## Color Per Vertex Information

In 3ds max 2.0 and later color per vertex information is stored with a Mesh. This allows the user to assign colors to vertices. This ability is primarily for game developers and developers of radiosity renderers. This information can be used in conjunction with the Vertex Color map

(**MAXSDK\SAMPLES\MATERIALS\VERTCOL.CPP**) or the Color Per Vertex utility and modifier

(**MAXSDK\SAMPLES\UTILITIES\APPLYVC\APPLYVC.CPP** and **AVCMOD.CPP**).

Three public data members and several methods in the Mesh class provide access to this data.

**int numCVerts;**

The number of color vertices.

**VertColor \*vertCol;**

Array of color vertices. Note: **typedef Point3 VertColor;**

**TVFace \*vcFace;**

Array of vertex color faces.

## Color Per Vertex Enhancements in Release 4.0 and Later

In 3ds max 4.0 and later it is possible to have the source data for vertex colors come from other than the internal vertex color array (**vertCol**). The data can come from an external array or one of the map channels. When 3ds max is rendering the color values come from the **vertColArray** variable.

**VertColor \*vertColArray;**

This array defaults to the internal array (**vertCol**) but can be set to an external array or a mapping channel.

If an external array is used the following data member is a pointer to it (this defaults to NULL):

**VertColor \*curVCArray;**

If a mapping channel is used the following data member indicates which one (this defaults to 0).

**int curVCChan;**

When 3ds max is rendering the vertex lookup comes from the **vcFaceData** variable. This defaults to the **vcFace** data but if a mapping channel is used for color lookup 3ds max uses its TVFace structure.

**TVFace \*vcFaceData;**

The methods associates with this are as follows:

To set the number of vertex colors:

**BOOL setNumVertCol(int ct, BOOL keep=FALSE);**

To retrieve the number of vertex colors:

**int getNumVertCol() const**

To set the number of vertex color faces:

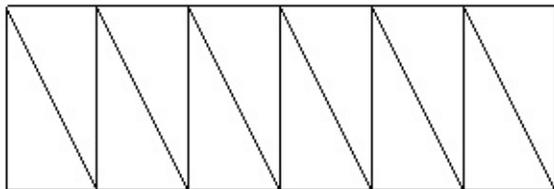

**BOOL setNumVCFaces(int ct, BOOL keep=FALSE, int oldCt=0);**

To use a different source array for vertex color data (this can be either an external array or one of the mapping channels):

**void setVCDisplayData(int mapChan = 0, VertColor \*VCArray=NULL, TVFace \*VCf=NULL);**

## Stripping

Stripping is the process of taking a mesh and turning it into all set of strips as shown below. Without stripping, when a triangle mesh is sent down the graphics display pipeline, three vertices plus three normals or colors must be sent for each triangle. However, if the triangles are turned into a 'strip', where one triangle points up, the next points down, then the next up, etc., forming parallel lines along the top and bottom (see diagram below), then for each new triangle in the strip, all that is sent down the graphics pipeline is the one new vertex. Since the communication between the CPU and the graphics card is one of the bottlenecks in the graphics pipeline this results in a significant speed increase.

This can only happen if 3ds max knows that each new triangle is adjoining the previous one. Stripping then, is the process of taking whatever configuration the mesh is in originally, and turning it into a sequence of sequence of vertices that all correspond to strips as shown above. This speeds up the display process dramatically.

Developers who create their own mesh objects for display need to be aware of two new methods for dealing with stripping if maximum speed is to be achieved. These method are **Mesh::BuildStrips()** and **Mesh::BuildStripsAndEdges()**. These builds the strip (and edge) databases inside the mesh. The standard 3ds max primitives call **BuildStripsAndEdges()** after creating their meshes for instance.

Changes have been made to the 3ds max geometry pipeline that make this important. In 3ds max 1.x, an algorithm was used to build the edge database when the mesh was about to be displayed. So for example, if a mesh was built, and some modifiers acted upon it, for instance a Bend, the geometry pipeline would be evaluated and then the when the object was about to be displayed its edge list would be built. If the modifiers were animated (say the Bend angle changed), the geometry pipeline would be evaluated and the edge list would be built again. This was very inefficient because the edge list would only get used for one display, and then would be thrown out, and then calculated again. Since a Bend modifier doesn't alter the mesh topology the edge list was actually still

valid.

In 3ds max 2.0 this changed. The edge and new strip topology flows down the pipeline. In this way, if a primitive builds its own edges and strips by calling **BuildStripsAndEdges()**, when animated modifiers are applied the display is dramatically faster. This is because the strip and edge database is never rebuilt unless the topology changes. Therefore when a developer creates a mesh to be displayed they should call **BuildStripsAndEdges()**. If this is not done, they won't be available to flow down the pipeline, and must be build automatically at the end of the pipeline.

If a developer knows that their strips are invalid, for example they've deleted a vertex or face, or otherwise changed the topology of the mesh, then the method **InvalidateStrips()** and **InvalidateEdgeList()** should be called. A developer could also call **InvalidateTopologyCache()** which simply calls both of the above.

However, if a modifier is written that changes topology (**ChannelsChanged()** includes **TOPO\_CHANNEL**), for example Bomb, then the invalidation happens automatically. Other objects or modifiers may have to make an explicit call to **InvalidateTopologyCache()**. For example, the Editable Mesh Object or the Edit Mesh Modifier can operate on a mesh at the push and pull vertex level rather than at the pipeline level. In these cases the mesh is being directly modified and thus the invalidate call is required.

## Working with NURBS

See Also: [Class NURBSObject](#), [Class NURBSSurface](#), [Class NURBSSet](#), [Class NURBSControlVertex](#), [Class NURBSPoint](#), [Class NURBSCurve](#), [Class NURBSFuseSurfaceCV](#), [Class NURBSFuseCurveCV](#), [Class TessApprox](#), [Class Object](#), [Class ShapeObject](#), [Class Matrix3](#), [Class Point3](#).

## Overview

This section presents an overview of working with NURBS using the SDK. It defines some terms and concepts related to NURBS, describes the main classes used, provides an overview of some key concepts when using NURBS, and discusses the sample code available in the SDK. There is also a section of reference information for some global functions available.

## The NURBS API

The NURBS API provides an interface into the NURBS objects used by MAX. Unlike much of the 3ds max API, the NURBS objects 3ds max provides don't use this API. Rather, the NURBS API has been added to allow developers to access the NURBS objects 3ds max uses internally. Using the API developer can create new NURBS objects or modify existing ones.

## ClassIDs of the NURBS Objects

Developers can check if an object is a NURBS object by checking it **ClassID()**. If it matches any of the following

```
#define EDITABLE_SURF_CLASS_ID Class_ID(0x76a11646,  
0x12a822fb)  
#define FITPOINT_PLANE_CLASS_ID Class_ID(0x76a11646,  
0xbadbeef)  
#define EDITABLE_CVCURVE_CLASS_ID  
Class_ID(0x76a11646, 0x12a82144)  
#define EDITABLE_FPCURVE_CLASS_ID  
Class_ID(0x76a11646, 0x12a82142)
```

then it's a NURBS object and the NURBS API may be used to manipulate it.

## Necessary Include File

The main NURBS include file is **\MAXSDK\INCLUDE\SURF\_API.H**. This is not included by default by **MAX.H** so you need to specifically include it via the following statement:

```
#include "surf_api.h"
```

## Reference Information on NURBS Mathematics

Developers who wish to understand the mathematics of NURBS should see: The NURBS Book: Les Piegl, Wayne Tiller, The NURBS Book (Berlin Heidelberg New York: Springer-Verlag, 1995). ISBN: 3-540-55069-0.

## **Providing Valid Data to the NURBS Methods**

The NURBS API is not intended to be bomb proof, i.e. it is possible to pass values to the methods than can cause a crash. It is up to the developer to insure that valid data is provided. As with the rest of the SDK it is easy to write a piece of code that will crash 3ds max if improper values are supplied.

## **Definition of Terms**

This section provides definitions of various terms used later in this topic and in the NURBS classes.

### **NURBS**

The term NURBS stands for Non-Uniform Rational B-Splines. Specifically: Non-Uniform means that the extent of a control vertex's influence can vary. This is useful when modeling irregular surfaces.

Rational means that the equation used to represent the curve or surface is expressed as a ratio of two polynomials, rather than a single summed polynomial. The rational equation provides a better model of some important curves and surfaces, especially conic sections, cones, spheres, and so on.

A B-spline (for basis spline) is a way to construct a curve that is interpolated between three or more points. Shape curves you create in 3ds max using the Line tool and other Shape tools are Bézier curves, which are a special case of B-splines.

### **Point**

A point in three-space. A Point Curve or Point Surface is constrained to pass through its points. Points behave somewhat like vertices for 3ds max spline objects, but their behavior is not identical and they are a distinct object type.

### **Curve**

This is a NURBS Curve. There are two kinds of NURBS curves in MAX. A Point Curve is controlled by points, which always lie on the curve. A CV Curve is controlled by control vertices (CVs), which don't necessarily lie on the curve.

### **CV**

This is a Control Vertex of a NURBS Curve or NURBS Surface. It's a vertex that controls a CV Curve or CV Surface. The 3D location of each CV affects the shape of the curve or surface. CVs aren't constrained to lie on the curve or surface. Each CV has a rational weight that can be used to adjust the influence of the CV on the curve's or surface's shape.

### **Point Curve**

A NURBS curve defined by points. The points are constrained to lie on the curve.

### **CV Curve**

A NURBS curve defined by CVs. The CVs don't necessarily lie on the curve. Instead, they form a control lattice that affects the curvature of the curve.

### **Surface**

This is an individual quadrilateral NURBS Surface. NURBS surfaces have essentially the same properties as NURBS curves, extended from a one-dimensional parameter space to two dimensions.

There are two kinds of NURBS surfaces: A Point Surface is controlled by points, which always lie on the surface. A CV Surface is controlled by control vertices (CVs). Instead of lying on the surface, CVs form a control lattice that surrounds the surface.

### **Point Surface**

A NURBS surface defined by points. The points are constrained to lie on the surface. More than one NURBS solution is possible for a Point Surface.

### **CV Surface**

A surface defined by CVs. Instead of lying on the surface, CVs form a control lattice that surrounds the surface.

### **Independent <object>**

This is an object (point, curve, surface) that is not dependent on any other object.

### **Dependent <object>**

This is an object (point, curve, surface) that depends on another object to define what it is. For example, a Blend Curve depends on the two curves that it blends between (as well as its own two tension parameters).

### **Constrained point**

Another term for a dependent point. A NURBS Point that is dependent on either another Point, Curve, or Surface, and that exists either on the object or relative to it. The relative cases are XYZ-relative, along a normal, or along a tangent (or set of tangents for a surface-dependent constrained point).

### **Continuity**

A curve is continuous if it is unbroken. There are different levels of continuity. A curve with an angle or cusp in it is C0 continuous<sup>3/4</sup>that is, the curve is continuous but has no derivative at the cusp. A curve with no such cusps but whose curvature changes is C1 continuous. Its derivative is also continuous, but its second derivative is not. A curve with uninterrupted, unchanging curvature is C2 continuous. Both its first and second derivatives

are also continuous.

A curve can have still higher levels of continuity, but for computer modeling these three are adequate. Usually the eye can't distinguish between a C2 continuous curve and one with higher continuity.

Continuity and degree are related. A degree 3 equation can generate a C2 continuous curve. This is why higher-degree curves aren't generally needed in NURBS modeling. Higher-degree curves are also less stable numerically, so using them isn't recommended.

Different segments of a NURBS curve can have different levels of continuity. In particular, by placing CVs at the same location or very close together, you reduce the continuity level. Two coincident CVs sharpen the curvature. Three coincident CVs create an angular cusp in the curve. This property of NURBS curves is known as multiplicity. In effect, the additional one or two CVs combine their influence in that vicinity of the curve.

By moving one of the CVs away from the other, you increase the curve's continuity level again. In MAX, multiplicity also applies when you fuse CVs. Fused CVs create a sharper curvature or a cusp in the curve. Again, the effect goes away if you unfuse the CVs and move one away from the other.

### **Multiplicity**

The property that coincident or nearly coincident CVs reduce the continuity level of the curve or surface. Two coincident CVs locally increase curvature. Three coincident CVs (or more) create an angular cusp. Fusing CVs shows the effect of multiplicity.

### **Degree**

The degree of a curve is highest exponent in the equation used to represent it. A linear equation is degree 1, a quadratic equation degree 2. NURBS curves typically are represented by cubic equations and have a degree of 3.

### **Order**

The order of a curve refers to its mathematical order. For instance a cubic curve is order 4, a quadratic curve is order 3, a linear curve is order 2. This is one more than the degree of polynomial of any segment of the curve.

### **Iso Line**

This is short for isoparametric line. It's a line of constant parameter value, similar to a contour line. Iso lines can be used to display a NURBS surface.

### **Segment**

The portion of a curve between two of its controlling points or CVs.

### **Knot**

This is a mathematical construct that helps define the span of control of CVs and blending functions that define NURBS Curves and Surfaces. The knots are an array of **double** precision values that determines the parameterization of a curve. . Values in the knot vector are nondecreasing. The knots specify the region of influence of the CVs on the curve. It is a way of partitioning the parameter space up into different segments. A B spline curve or a NURBS curve is a curve that is defined by a series of segments. On each one of the segments the curve is like a polynomial, or in the case of a rational one, it's like the ratio of polynomials. The knot vector describes how to partition the parameter space of the curve up for each of the different pieces of the polynomial.

### **Parameter space**

In addition to their existence in 3D space, NURBS objects have a parameter space that includes the array of knot values. NURBS curves have a single U dimension in parameter space. NURBS surfaces have two dimensions, UV, in parameter space.

### **Refine**

To increase the number of CVs on a curve or surface.

### **B-spline**

Short for basis spline. A kind of spline generated by so-called basis functions. The advantage of B-splines over Bézier curves (which are a special case of B-splines) is that the control vertices (CVs) of a B-spline affect only their local region of the curve or surface.

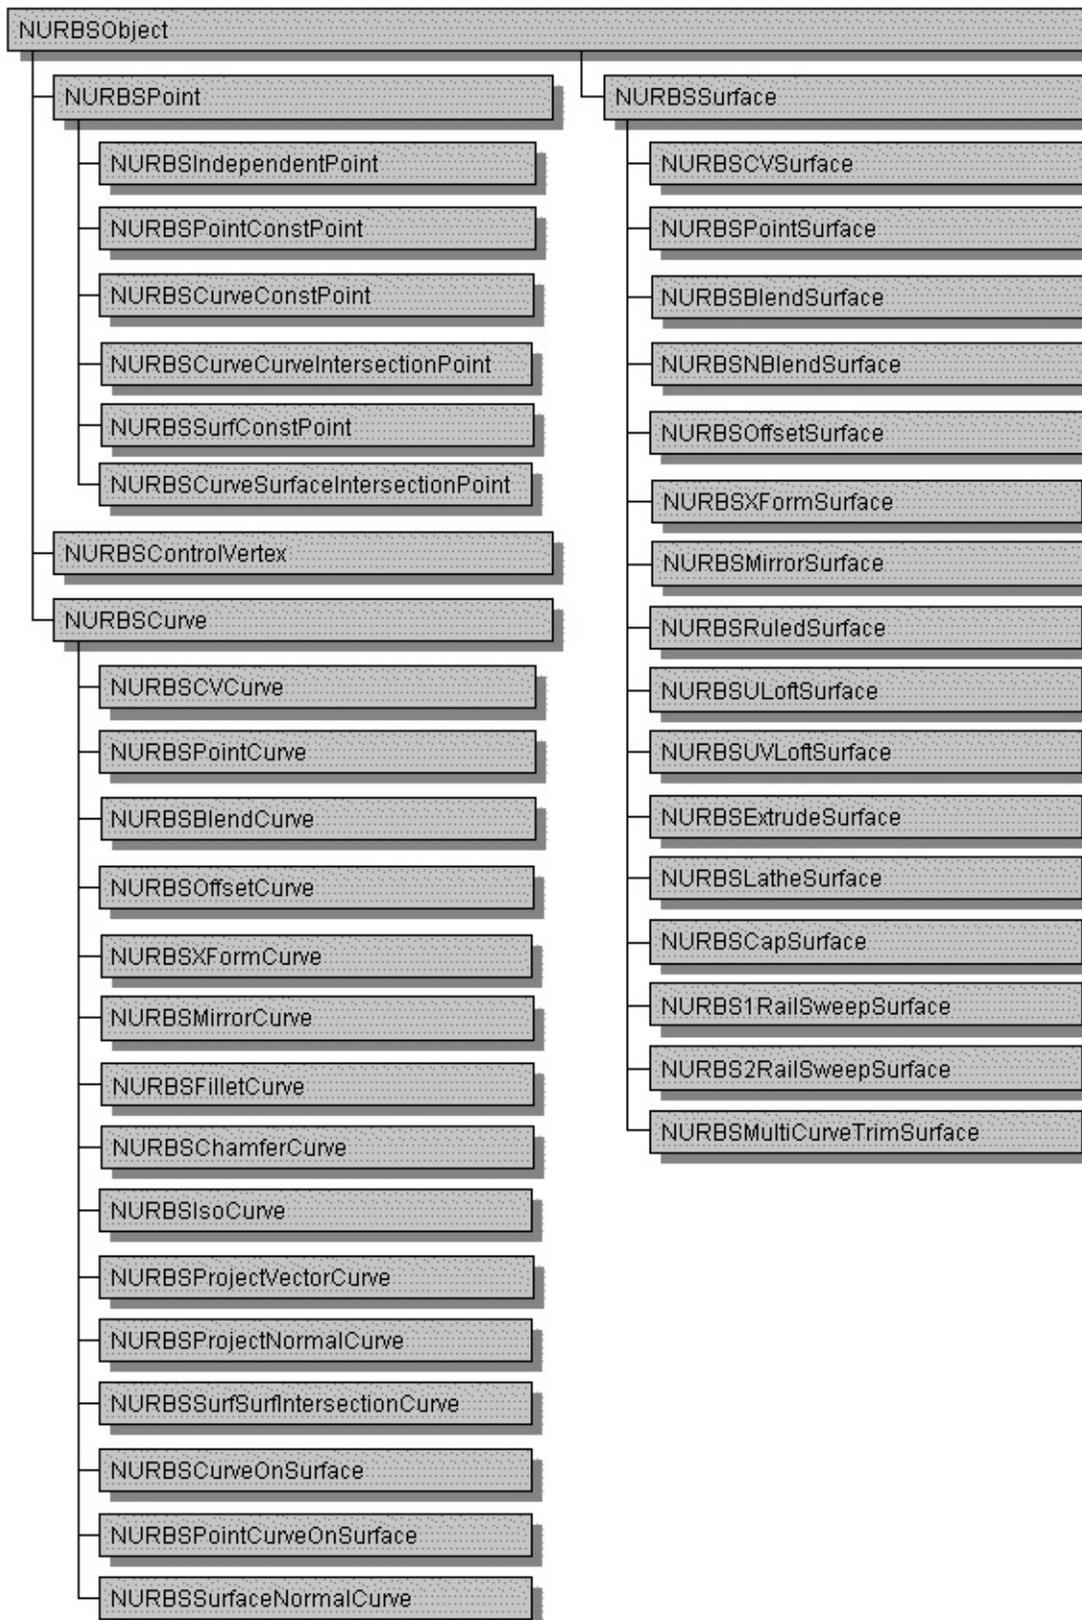

### **Bézier curve**

A curve modeled using a parametric polynomial technique. Bézier curves were developed by P. Bézier for computer modeling in automobile design. They are a special case of B-splines.

## Overview of the Principal Classes

The following diagram shows the inheritance tree of the principal classes in the NURBS API. The base classes are shown at the top, and the inheritance hierarchy proceeds toward the bottom and to the right. **NURBSObject** is the main base class, with **NURBSPoint**, **NURBSCurve** and **NURBSSurface** also functioning as base classes.

### Class Hierarchy

**The Base Class for NURBS Points, Curves and Surfaces:**

### [Class NURBSObject](#)

This is the base class for many of the other NURBS classes. It provides a set of methods that are common to the other classes such as getting and setting the name of the item, returning error messages, and determining the specific type of NURBS object. It also has a method to return a **NURBSId** which is an ID used to specify a particular object in communication between the NURBS classes.

### **Sets of NURBS Objects:**

#### [Class NURBSSet](#)

This is the class used when developers want to create 3ds max NURBS objects, or retrieve data from existing 3ds max NURBS objects. The **NURBSSet** acts as a container for the other objects.

This class contains a table of the various **NURBSObject** derived entities (points, curves, surfaces) used to make up the set. Additionally it has two 'fuse' tables: one for fuse curves and one for fuse surfaces. These are used to allow the CVs in the curves or surfaces to be 'stitched' or 'fused' together so that if one curve or surface moves the other moves with it. This class also has information required to tessellate the objects to triangle meshes for use in the viewports and the production renderer.

### **Independent Points:**

Independent Points are those that don't rely on other objects to define their location. This is different than the dependent (or constrained) points described later.

#### [Class NURBSPoint](#)

This class describes a point in 3 space. It is used as a base class for many of the dependent points in the API. It has methods to set and get the point position in various formats and floating point precisions. This is an abstract base class so only objects that are subclasses of this class can be created.

#### [Class NURBSIndependentPoint](#)

This class is derived from **NURBSPoint**. It is used to create an independent, free-standing point. There are methods to set the position of the point in various floating point formats and operators to compare points.

#### [Class NURBSControlVertex](#)

This is a Control Vertex of a NURBS Curve or NURBS Surface. This class

shares many of the same properties as a **NURBSPoint** and has the added property of a rational weight. The weight value of a CV is rational. That is, it is relative to other CVs in the curve or surface. Changing the weight of all CVs at once has no effect, because this doesn't change the ratio between weights.

#### [Class NURBSTrimPoint](#)

This class defines a point on a curve used to trim a portion of the curve from the point towards one of the ends of the curve.

### **Dependent (Constrained) Points:**

The following classes provide the ability to create dependent points. Dependent points are related to the objects they depend on such that the relationship established initially remains if the point, curve or surface moves. For example, a point can be created such that it always remains a certain distance from another point. The options are XYZ-relative, along a normal, or along a tangent (or set of tangents for a surface-dependent constrained point).

All the following classes are derived from **NURBSPoint**.

#### [Class NURBSPointConstPoint](#)

This class is used to create a dependent point that lies at a point or relative to it. It is a point constrained relative to another point. This can be a point used to define a point surface or point curve, it can be a trim point, or just a point in space.

#### [Class NURBSCurveConstPoint](#)

This class is used to create a dependent point that lies on a curve or relative to it.

#### [Class NURBSCurveCurveIntersectionPoint](#)

This class is used to create a dependent point at the intersection of two curves.

#### [Class NURBSSurfConstPoint](#)

This class is used to create a dependent point on a surface or related to it.

### **Independent Curves:**

The following classes provide the ability to create independent curves.

#### [Class NURBSCurve](#)

This base class describes the properties of a NURBS curve. This includes its open/closed state, and number of trim points. The **Evaluate()** method is

used to compute points and tangents on the curve.

#### [Class NURBSPointCurve](#)

This class is derived from **NURBSCurve**. It defines a curve that uses points to describe its shape. All the points lie on the curve itself. There are methods to get/set the number of points in the curve, get/set the points themselves, refine the curve (add points without changing its shape), and to get/set the transformation matrix used by the curve to position it within a NURBSSet.

#### [Class NURBSCVCurve](#)

This class is derived from **NURBSCurve**. It defines a curve that uses control vertices (CVs) to describe its shape. The CVs define a control lattice which surrounds the curve. This class has methods to close the curve, set its order, number of knots and number of CVs, and get/set the knots and CVs. There is also a method to add additional CVs to the curve.

### **Dependent Curves:**

The following classes are used to create dependent curves. A dependent curve is an object that depends on one or more other objects to define what it is. For example, a Blend Curve depends on the two parent curves that it blends between when it was created (as well as on its two tension parameters).

All the following classes are derived from **NURBSCurve**.

#### [Class NURBSBlendCurve](#)

This class defines a dependent blend curve. A blend curve connects the specified end of one curve to the specified end of another, blending the curvature of the parents to create a smooth curve between them.

#### [Class NURBSOffsetCurve](#)

This class defines a dependent offset curve. An offset curve is offset from the original, parent curve. It lies in the same plane as its parent, and is normal to the original.

#### [Class NURBSXFormCurve](#)

This class defines a dependent transform (xform) curve. A transform curve is a copy of the original curve with a different position, rotation, or scale

#### [Class NURBSMirrorCurve](#)

This class defines a dependent mirror curve. A mirror curve is similar to a mirror object that you create using the Mirror tool (on the 3ds max toolbar) or the Mirror modifier. It is the original curve reflected about one or two

axes.

#### [Class NURBSFilletCurve](#)

This class defines a dependent fillet curve. A fillet is a curve that creates a circular arc corner between two parent curves.

#### [Class NURBSChamferCurve](#)

This class defines a dependent chamfer curve. A chamfer is a curve that creates a straight line corner between two parent curves.

#### [Class NURBSIsoCurve](#)

This class defines a dependent iso curve. U and V iso curves are dependent curves created along lines of constant parameter value of a NURBS surface. Note the difference between "Iso Lines", which are a display artifact, and "Iso Curves" which are the dependent objects.

### **Independent Surface:**

#### [Class NURBSSurface](#)

This base class describes the properties of a NURBS surface. This includes its material ID, texture/tiling options, renderable state, and open/closed state, and normal inverted state. The **Evaluate()** method is used to compute points and tangents on the surface.

#### [Class NURBSPointSurface](#)

This class is derived from **NURBSSurface**. It defines a surface that uses points to describe its shape. This class has methods to close the surface in U and V, set the number of points in U and V, and get/set the points in U and V. There is also a method to add additional points to the surface. The point surface has a transformation matrix used to set the position of the surface within a **NURBSSet**.

#### [Class NURBSCVSurface](#)

This class is derived from **NURBSSurface**. It defines a surface that uses control vertices (CVs) to describe its shape. The CVs define a control lattice which surrounds the surface. This class has methods to close the surface in U and V, set its order in U and V, set the number of knots and CVs in U and V, and get/set the knots and CVs in U and V. There is also a method to add additional CVs to the surface. The CV surface has a transformation matrix used to position the surface within a **NURBSSet**.

### **Dependent Surfaces:**

Dependent surfaces are surface sub-objects whose geometry depends on other surfaces or curves in the NURBS model. When you change the geometry of the original parent surface or curve, the dependent surface changes as well.

#### [Class NURBSBlendSurface](#)

This class defines a dependent blend surface. A blend surface connects the edge of one surface to the edge of another, blending the curvature of the parents to create a smooth surface between them.

#### [Class NURBSOffsetSurface](#)

This class defines a dependent offset surface. An Offset surface is offset a specified distance from the original along the parent surface's normals.

#### [Class NURBSXFormSurface](#)

This class defines a dependent transform (xform) surface. A transform surface is a copy of the original surface with a different position, rotation, or scale

#### [Class NURBSMirrorSurface](#)

This class defines a dependent mirror surface. A mirror surface is similar to a mirror object that you create using the Mirror tool (on the 3ds max toolbar) or the Mirror modifier. It is the original surface reflected about one or two axes.

#### [Class NURBSRuledSurface](#)

This class defines a dependent ruled surface. A ruled surface is generated from two curve sub-objects. It lets you use curves to design the two opposite borders of a surface.

#### [Class NURBSULoftSurface](#)

This class defines a dependent U Loft surface. A U Loft surface interpolates a surface across multiple curve sub-objects. The curves become U-axis contours of the surface.

#### [Class NURBSExtrudeSurface](#)

This class defines a dependent extrude surface. An extrude surface is extruded from a curve sub-object. It is similar to a surface created with the Extrude modifier. The advantage is that an extrude sub-object is part of the NURBS model, so you can use it to construct other curve and surface sub-objects

#### [Class NURBSLatheSurface](#)

This class defines a dependent lathe surface. A lathe surface is generated from a curve sub-object. It is similar to a surface created with the Lathe modifier. The advantage is that a lathe sub-object is part of the NURBS model, so you can use it to construct other curve and surface sub-objects.

#### [Class NURBSCurveSurfaceIntersectionPoint](#)

This class is used to create a dependent point at the intersection of a curve and a surface.

#### [Class NURBSProjectNormalCurve](#)

This class provides access to the Normal Projected Curve. A Normal Projected curve lies on a surface. It is based on an existing curve, which is projected onto the surface in the direction of the surface's normals

#### [Class NURBSProjectVectorCurve](#)

This class provides access to the Vector Projected Curve. A Vector Projected curve lies on a surface. This is almost the same as a Normal Projected curve, except that the projection from the existing curve to the surface is in the direction of a vector that you can control. Vector projected curves may be used for trimming.

#### [Class NURBSSurfaceNormalCurve](#)

This provides access to the Surface Normal Curve. This is a curve created at a specified distance from a surface and normal to it.

#### [Class NURBSSurfSurfIntersectionCurve](#)

This class provides access to the Surface-Surface Intersection Curve. This is a curve that is defined by the intersection of two surfaces. You can use surface-surface intersection curves for trimming.

#### [Class NURBSCurveOnSurface](#)

This class provides access to the CV curve on surface parameters. These curves can be used for trimming the surface they lie on.

#### [Class NURBSPointCurveOnSurface](#)

This class provides access to the point curve on surface parameters. These curves can be used for trimming the surface they lie on.

#### [Class NURBSUVLoftSurface](#)

This class provides access to the UV Loft Surface. This surface is similar to the U Loft surface, but has a set of curves in the V dimension as well as the U dimension.

### [Class NURBSNBlendSurface](#)

This class provides access to the Multisided Blend surface. A Multisided Blend surface is a surface that "fills in" the edges defined by three or four other curve or surfaces. Unlike a regular, two-sided Blend surface, the curves or surfaces edges must form a closed loop<sup>¾</sup>that is, they must completely surround the opening the Multisided Blend will cover.

### [Class NURBS1RailSweepSurface](#)

This class provides access to the 1-Rail Sweep Surface. A 1-Rail Sweep Surface uses at least two curves. One curve, the "rail," defines one edge of the surface. The other curves define the surface's cross sections. The cross-section curves should intersect the rail curve. If the cross sections don't intersect the rail, the resulting surface is unpredictable.

### [Class NURBS2RailSweepSurface](#)

This class provides access to the 2-Rail Sweep Surface. A 2-Rail Sweep surface uses at least three curves. Two curves, the "rails," define the two edges of the surface. The other curves define the surface's cross sections. A 2-Rail Sweep surface is similar to a 1-Rail sweep. The additional rail gives you more control over the shape of the surface.

### [Class NURBSCapSurface](#)

This class provides access to the Cap Surface. A Cap Surface is a surface that caps a closed curve or the edge of a closed surface. Caps are especially useful with extruded surfaces.

### [Class NURBSMultiCurveTrimSurface](#)

This class provides access to the Multicurve Trim Surface which is a surface that is trimmed by multiple curves forming a loop.

## **Texture Mapping:**

The following classes are those involved in texture mapping NURBS surfaces. In 3ds max 3.0 and later there may be 99 texture channels assigned to each surface.

### [Class NURBSSurface](#)

This class (also described above) has a **NURBSTextureChannelSet** which is a table of pointers to all the mapping channels used by this surface. This class also has methods to return a reference to the **NURBSTextureSurface** associated with a specific channel.

### [Class NURBSTextureChannelSet](#)

This class holds a table of pointers to all the **NURBSTextureChannel** data for a surface. There are methods to return the table data by channel or by index and a method to add a new texture channel

#### [Class NURBSTextureChannel](#)

This class holds and provides access to a single texture channel. It holds the **NURBSTextureSurface** instance associated with the channel. It also holds the channel number (a number in the range 0 to 98), the tiling, offset, and angle parameters as well as the Generate UV flag.

#### [Class NURBSTextureSurface](#)

A texture surface is a surface associated with the surface sub-object. 3ds max uses the texture surface to control how materials are mapped. In effect, changing the texture surface stretches or otherwise changes the UV coordinates for the surface, altering the mapping. This class maintains a mapper type which controls how the texture surface generates the mapping. This class also provides access to the individual UV mapping coordinates. These coordinates are **NURBSTexturePoint** objects.

#### [Class NURBSTexturePoint](#)

This class holds and provides access to a single UV mapping coordinate.

## **NURBSIds and Indexes**

An important concept to understand when working with **NURBS**Sets and the other **NURBS** classes is the way you identify component items that are in the set. Before a **NURBS**Set is instantiated in the scene as a **NURBS** object, the individual points, curves, and surfaces are identified by an index number. As you append objects to the set they are assigned successive indexes, starting at 0. When you want to refer to a particular item, say to specify the parent surfaces in a blend surface, you use this index. Once an object has been added to a **NURBS**Set, its index can be retrieved using.

However, once a **NURBS**Set is associated with a scene object, either by being instantiated or because it was directly created from an existing scene object, this index is no longer valid. Instead, a different number, called a **NURBS**Id, is assigned to each item and you must use that Id when referring to items from then on. The **NURBS**Id of any item in an instantiated **NURBS**Set can be obtained through the **NURBS**Object::GetId() method of that object.

Seed Value Parameters

## **Seed Value Parameters**

Some kinds of dependent objects depend on geometry that might have more than one solution. For example, if you want to create a surface-curve intersection point but the curve intersects the surface more than once, 3ds max must decide which intersection is to be the location of the point.

For these kinds of objects, seed value parameters control the decision. The seed location is a location on a parent object, and the location nearest to the seed value that satisfies the creation condition is the one that 3ds max chooses.

For example, the seed location for a surface-curve intersection point is a U position along the length of the parent curve. The surface-curve intersection closest to the seed is chosen as the location of the dependent point.

For a surface, the seed location is a pair of UV coordinates in the surface's parameter space.

## Using the API to Create and Modify MAX NURBS Models

As mentioned above, 3ds max itself uses a different internal representation of NURBS objects than the API does. The API is simply a means to access these internal 3ds max NURBS objects and allow them to be manipulated.

The object used in communication between the internal 3ds max NURBS objects and the classes in the SDK available to work with these objects is the **NURBSSet**. There are also two global functions used in this communication. These are **CreateNURBSObject()** and **GetNURBSSet()**. How these are used is described below:

### Creating New NURBS Objects

The API can be used to create new NURBS objects. This is done by adding the objects (points, curves and surfaces) to an item called a NURBS 'set' and calling the global function **CreateNURBSObject()**. The **NURBSSet** is a container for the objects. Then the global function **CreateNURBSObject()** makes an internal 3ds max NURBS object out of the set.

As an example, consider the following code fragment that creates a **NURBSCVCurve** object (with **NURBSControlVertex** sub-objects) and puts it in the scene:

```
// Create an empty NURBSSet object  
NURBSSet nset;  
  
// Allocate a new NURBSCVCurve and set the knots and CVs  
NURBSCVCurve *c = new NURBSCVCurve();  
c->SetName(_T("CV Curve"));  
c->SetNumCVs(4);  
c->SetOrder(4);  
c->SetNumKnots(8);  
for (int k = 0; k < 4; k++) {  
  c->SetKnot(k, 0.0);  
  c->SetKnot(k+4, 1.0);  
}  
NURBSControlVertex cv;  
cv.SetPosition(0, Point3(0, 0, 50));  
c->SetCV(0, cv);
```

```

cv.SetPosition(0, Point3(-100, 0, 50));
c->SetCV(1, cv);
cv.SetPosition(0, Point3(-100, 100, 50));
c->SetCV(2, cv);
cv.SetPosition(0, Point3(0, 100, 50));
c->SetCV(3, cv);

// Add the NURBSCVCurve object to the set
nset.AppendObject(c);

// Create the NURBS object from the NURBSSet
Matrix3 mat(1);
Object *obj = CreateNURBSObject(ip, &nset, mat);

// Create the node in the scene and point it at the NURBS object
INode *node = ip->CreateObjectNode(obj);
node->SetName(_T("NURBS Set 1"));

```

The NURBS object created (**obj**) will have the Class\_ID:  
**EDITABLE\_SURF\_CLASS\_ID.**

### **Modifying Existing NURBS Objects**

The API can also be used to modify the properties of existing NURBS objects in the scene. To gain access to an internal 3ds max NURBS object you must have the data copied into a **NURBSSet**. This is done using the global function **GetNURBSSet()**. You can then use the methods of the **NURBSSet** to access the objects. After checking the type of the object you can cast it to the appropriate class and use that class's methods to alter the item.

For example, the following sample code attempts to grab the first NURBS sub-object from the first node in the current selection set. It then checks if it's a blend surface and if so adjust one of the tension parameters.

```

// Get the first selected node
INode* node = ip->GetSelNode(0);
if (!node) return;
// Get the object reference of the node
Object* obj = node->GetObjectRef();

```

```

// Make sure it's a NURBS object
if (obj->ClassID() == EDITABLE_SURF_CLASS_ID) {
    NURBSSet getSet;
    BOOL okay = GetNURBSSet(obj, ip->GetTime(), getSet,
    TRUE);
    if (okay) {
        NURBSObject *nObj;
        nObj = getSet.GetNURBSObject(0), ip->GetTime());
        if (nObj->GetType() == kNBlendSurface) {
            // It's a blend, adjust the tension
            NURBSBlendSurface *bSurf = (NURBSBlendSurface
            *)nObj;
            bSurf->SetTension(ip->GetTime(), 0, 2.0);
        }
    }
}

```

There are other global functions that may be used to modify NURBS objects. These functions are documented at the end of this topic. For instance, developers can use the function **BreakSurface()** to take an existing NURBS surface and break it into two separate surfaces.

## Accessing Details of NURBS Objects

Developers that need to access that internal of 3ds max NURBS objects can see the following methods to get at details such as knot counts, CV counts, order, weight and position data. The main call is:

```
BOOL GetNURBSSet(Object *object, TimeValue t, NURBSSet  
&nset, BOOL Relational);
```

with **Relational** set to **FALSE**. This will fill in the **NURBSSet** with the surfaces, curves and independent points of the object passed. The surfaces will all be **NURBSCVSurface**'s and the curves will all be **NURBSCVCurve**'s. These can be gotten from the **NURBSSet** with:

```
int GetNumObjects();  
NURBSObject* GetNURBSObject(int index);
```

The following can be called to get the knots (for surfaces, there is an equivalent for curves, of course):

```
int GetNumUKnots(void);  
int GetNumVKnots(void);  
double GetUKnot(int index);  
double GetVKnot(int index);
```

and the CVs can be retrieved with:

```
int GetNumUCVs(void);  
int GetNumVCVs(void);  
NURBSControlVertex* GetCV(int u, int v);
```

The order of the surface can be determined with:

```
int GetUOrder(void);  
int GetVOrder(void);
```

Finally, given a **NURBSControlVertex** the position and weights can be retrieved via member functions:

```
Point3 GetPosition(TimeValue t);  
void GetWeight(TimeValue t, double& wt);
```

## Parameter Ranges for Curves and Surfaces

Methods that deal with points in the parameter space of a curve work with arguments in U. Methods that deal with points in the parameter space of surfaces deal with arguments in U and V. For example, the function

**NURBSSurfConstPoint::SetUpParam()** sets the position of a dependent point in the parent surface's U parameter space. The valid U and V values that may be passed to this method must be obtained by calling

**NURBSSurface::GetParameterRange()** on the parent surface. This method retrieves the minimum and maximum values for U and V that may be used. For curves there is a similar function for getting the valid range for U. This is **NURBSCurve::GetParameterRange()**.

Developers should be aware that a curve or surface needs to be instantiated in the 3ds max data base before it is okay to call these methods (for example by calling **CreateNURBSObject()**). Prior to the object existing in the data base these calls will fail.

Generally, when CV curves and surfaces are created, the valid parameter range is known because they were specified in the beginning and ending knot values. In cases where they are not known, one can instantiate a **NURBSSet** that has just the base curves or surfaces. Once instantiated **GetParameterRange()** can be used. Then one can build the rest of the parametric model by making additions and/or modifications to the already instantiated object. The global function **AddNURBSObjects()** makes this easy to do.

## Materials Assignment and Texture Coordinates

### Materials and NURBS

Each NURBS surface has its own material ID. If you assign a Multi-SubObject material you can apply a different material to each surface in a NURBS object. The method to do this is **NURBSSurface::MatID()**. In release 3.0 and later each **NURBSCurve** can have an associated material. This is used by the Lathe and Extrude modifiers for example.

### Texture Coordinates and NURBS

Texture coordinates are assigned to each of the four corners of a NURBS surface. On the standard 3ds max primitives for example most are assigned to use (0,0) to (1,1) across the surface. Some primitive, such as the Prism, don't use (0,0) to (1,1) because of the way they wrap. Developers may of course assign any values using the API. The method to do this is **NURBSSurface::SetTextureUVs()**.

## Sample Code

There is a demonstration utility plug-in that exercises the NURBS API. This is available in

**\MAXSDK\SAMPLES\UTILITIES\NURBS\SDK\_TEST.CPP**. This is an excellent place to look for simple, clear sample code.

The standard 3ds max primitives also use the NURBS API. See this code in the various primitive objects in directory **\MAXSDK\SAMPLES\OBJECTS**.

Additionally, the Lathe and Extrude use the API. Developers can review this code in **\MAXSDK\SAMPLES\MODIFIERS\EXTRUDE.CPP** and **SURFREVS.CPP**.

## Additional Functions for Working with NURBS

The following global functions are available for working with NURBS. The hyperlinks below take you to the start of groups of related functions:

[Creating and Retrieving MAX NURBS Objects](#)

[Creating Primitive NURBS Objects \(Spheres, Cylinders, etc.\)](#)

[Modifying Existing NURBS Objects](#)

### Creating and Retrieving MAX NURBS Objects

#### Prototype:

```
Object *CreateNURBSObject(IObjParam* ip, NURBSSet *nset,  
Matrix3& mat);
```

#### Remarks:

This function is available in release 2.0 and later only.

This function takes a **NURBSSet** as input and outputs a pointer to an editable NURBS object. For example, this is what all the standard 3ds max primitives do when they implement **Object::ConvertToType()**. If you want to make a node in the scene reference a NURBS object, put the objects into a **NURBSSet** and use this function to create the NURBS object. Then pass this object to **Interface::CreateObjectNode()**.

#### Parameters:

##### **IObjParam\* ip**

The 3ds max interface pointer. If non-NULL, this is used to get at the 3ds max function to do unique naming. If a NULL is specified the names are not made unique.

##### **NURBSSet \*nset**

Points to the set of input objects to create. These are defined in object space. The matrix below is used to transform these. For instance, the **NURBSSet** could be defined in a unit cube and the **mat** parameter could be used to scale it up.

Note: The NURBSIds and parent NURBSIds in this NURBS set are filled in the process of doing the creation. Thus, you pass this set in, and the function modifies it so you can work with the set immediately (you don't have to later call **GetNURBSSet()** to get an appropriate one to work with). For example,

say you create a **NURBSCVSurface** using this API and then want to animate some of the CVs on the surface. You'd pass in this set, then when the object is created the CVs on the surface will have the parent ids filled in so you can actually manipulate the surface in the scene.

### **Matrix3& mat**

This is a transformation applied to all of the objects.

### **Return Value:**

A pointer to an editable NURBS object whose Class\_ID is **EDITABLE\_SURF\_CLASS\_ID**.

### **Prototype:**

**BOOL GetNURBSSet(Object \*object, TimeValue t, NURBSSet &nset, BOOL Relational);**

### **Remarks:**

This function is available in release 2.0 and later only.

This function is used to retrieve a **NURBSSet** that corresponds to the specified NURBS object. This allows a developer to access the internal objects inside a 3ds max editable NURBS object.

If the **Relational** parameter is FALSE the **NURBSSet** will contain CV curves and CV surfaces. So for example, if you pass an object that has a relational model (perhaps two CV surfaces and a dependent blend surface) it will decompose them into three CV surfaces. This will be the CV surfaces that represent the two surfaces and the blend, but you won't have the blend relational data. If **Relational** is TRUE, you'd get back two CV surfaces and a NURBS blend surface. If you get back a relational model, check the type of object using the base class method **NURBSObject::GetType()** and then cast the object to the appropriate type. Then you may call that classes methods on the object to work with it.

If you were using this API as part of an export plug-in, you'd probably want to set **Relational** to FALSE because getting back a relational blend surface would not be useful, but having CV surface data you could export would. On the other hand, if you simply wanted to animate the tension parameters on the blend surface you'd set **Relational** to TRUE and then call the methods of the blend surface object to change the tension parameters

**(NURBSBlendSurface::SetTension()).**

Important Note: Developers must use the method **NURBSSet::DeleteObjects()** when done with the **NURBSSet** to free the memory used.

**Parameters:**

**Object \*object**

The input object. This need to be a NURBS object (Class\_ID **EDITABLE\_SURF\_CLASS\_ID**).

**TimeValue t**

The time at which the object is evaluated and converted.

**NURBSSet &nset**

A NURBSSet that corresponds to the specified object is returned here.

**BOOL Relational**

If TRUE the **NURBSSet** will contain relational data; if FALSE the **NURBSSet** will contain a CV curve or CV surface equivalent of the object.

## **Creating primitive NURBS Objects (spheres, cylinders, etc.)**

**Prototype:**

```
NURBSResult GenNURBSLatheSurface(NURBSCurve& curve,  
Point3& origin, Point3& north, float start, float end,  
NURBSSurface& surf);
```

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS surface of revolution given an input curve, origin, up axis, and start and end angles. The output of this function is a NURBS Surface. Note that this is a CV surface that matches the definition, not a relational surface.

**Parameters:**

**NURBSCurve& curve**

This is the NURBS curve that is revolved.

**Point3& origin**

Specifies the origin of the revolution.

**Point3& north**

This is the axis that specified the up direction.

**float start**

This is the start angle of the revolution in radians.

**float end**

This is the end angle of the revolution in radians.

**NURBSSurface& surf**

The surface definition is returned here.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

```
NURBSResult GenNURBSSphereSurface(float radius, Point3&  
center, Point3& northAxis, Point3& refAxis, float startAngleU,  
float endAngleU, float startAngleV, float endAngleV,  
NURBSSurface& surf);
```

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS sphere. The output of this function is a NURBS Surface. Note that this is a CV surface that matches the definition, not a relational surface.

Note: This surface is not closed surface.

**Parameters:****float radius**

The radius of the sphere.

**Point3& center**

The center point of origin of the sphere.

**Point3& northAxis**

This specifies the up axis. Use **Point3(0,0,1)** for the Z axis for example.

**Point3& refAxis**

This is the direction of the seam. The sphere primitive uses **Point3(0,-1,0)** as this value.

**float startAngleU**

The start angle for the sphere in the U direction, specified in radians.

**float endAngleU**

The end angle for the sphere in the U direction, specified in radians.

**float startAngleV**

The start angle for the sphere in the V direction, specified in radians.

**float endAngleV**

The end angle for the sphere in the V direction, specified in radians.

**NURBSSurface& surf**

The surface definition is returned here. This is a CV surface that matches the definition, not a relational surface.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSResult GenNURBSCylinderSurface(float radius, float height, Point3& origin, Point3& symAxis, Point3& refAxis, float startAngle, float endAngle, NURBSSurface& surf);**

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURS cylinder. The output of this function is a NURBS Surface. Note that this is a CV surface that matches the definition, not a relational surface.

Note: This surface is not closed surface.

**Parameters:**

**float radius**

The radius of the cylinder.

**float height**

The height of the cylinder.

**Point3& origin**

The origin of the cylinder.

**Point3& symAxis**

The axis of symmetry. The standard cylinder primitive specifies **Point3(0,0,1)**.

**Point3& refAxis**

This is the direction of the seam. The standard cylinder primitive specifies **Point3(0,1,0)**.

**float startAngle**

The start angle in radians.

**float endAngle**

The end angle in radians.

**NURBSSurface& surf**

The surface definition is returned here.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSResult GenNURBSConeSurface(float radius1, float radius2, float height, Point3& origin, Point3& symAxis, Point3& refAxis, float startAngle, float endAngle, NURBSSurface& surf);**

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS cone surface. The output of this function is a NURBS Surface. Note that this is a CV surface that matches the definition, not a relational surface.

Note: This surface is not closed surface.

**Parameters:**

**float radius1**

One of the radii of the cone.

**float radius2**

The other radius of the cone.

**float height**

The height of the cone.

**Point3& origin**

The origin of the cone.

**Point3& symAxis**

The axis of symmetry.

**Point3& refAxis**

This is the direction of the seam.

**float startAngle**

The start angle in radians.

**float endAngle**

The end angle in radians.

**NURBSSurface& surf**

The surface definition is returned here.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSResult GenNURBSTorusSurface(float majorRadius, float minorRadius, Point3& origin, Point3& symAxis, Point3& refAxis, float startAngleU, float endAngleU, float startAngleV, float endAngleV, NURBSSurface& surf);**

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS torus surface. The output of this function is a NURBS Surface. Note that this is a CV surface that matches the definition, not a relational surface.

Note: This surface is not closed surface.

**Parameters:**

**float majorRadius**

This is the radius of the entire 'donut' shape.

**float minorRadius**

The is the radius of the 'tube'.

**Point3& origin**

The origin of the cone.

**Point3& symAxis**

The axis of symmetry.

**Point3& refAxis**

This is the direction of the seam.

**float startAngleU**

The start angle of the torus in the U direction.

**float endAngleU**

The end angle of the torus in the U direction.

**float startAngleV**

The start angle of the torus in the V direction.

**float endAngleV**

The end angle of the torus in the V direction.

**NURBSurface& surf**

The surface definition is returned here.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**Object \*CreateNURBSLatheShape(IObjParam\* ip, TSTR name, TimeValue t, ShapeObject \*shape, Matrix3& axis, float degrees, int capStart, int capEnd, int capType, BOOL weldCore, BOOL flipNormals, BOOL texturing, int segs, BOOL matIds, BOOL shapeIDs);**

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS object based on the specified lathe (surface of revolution) definition and returns a pointer to it. This is used by the lathe modifier.

**Parameters:**

**IObjParam\* ip**

The 3ds max interface pointer. If non-NULL, this is used to get at the 3ds max function to do unique naming. If a NULL is specified the names are not made unique.

**TSTR name**

The name for the object. If the pointer above is non-NULL this name is made unique.

**TimeValue t**

The time at which to revolve the shape.

**ShapeObject \*shape**

Points to the shape object to revolve. Note that if the **ShapeObject** pointed to is a bezier spline then capping won't work properly.

**Matrix3& axis**

This specifies the axis of revolution.

**float degrees**

The angle for the surface of revolution in degrees.

**int capStart**

Specifies if the surface should be capped at the beginning: TRUE to cap; FALSE to leave open. Note that this is only used if the ShapeObject is a NURBS curve.

**int capEnd**

Specifies if the surface should be capped at the ending: TRUE to cap; FALSE to leave open. Note that this is only used if the ShapeObject is a NURBS curve.

**int capType**

This parameter is not currently used and the value passed is ignored.

**BOOL weldCore**

TRUE to collapse any coincident vertices at the center of the surface; otherwise FALSE.

**BOOL flipNormals**

TRUE to invert the orientation of surface normals; otherwise FALSE.

**BOOL texturing**

TRUE to generate mapping coordinates; otherwise FALSE.

**int segs**

This parameter is not currently used and the value passed is ignored.

**BOOL matIds**

If TRUE special material Ids are assigned to the surfaces and caps.

**BOOL shapeIDs**

This parameter is available in release 3.0 and later only.

If TRUE shape IDs are used. When on, this function uses the material ID values assigned to segments in the spline to be lathed, or curve sub-objects in the NURBS curve to be lathed. This is available only when **matIds** is TRUE.

**Prototype:**

**Object \*CreateNURBSExtrudeShape(IObjParam\* ip, TSTR name, TimeValue t, ShapeObject \*shape, float amount, int capStart, int capEnd, int capType, BOOL texturing, BOOL matIDs, BOOL shapeIDs);**

**Remarks:**

This function is available in release 2.0 and later only.

This function generates a NURBS object based on the specified extrusion definition and returns a pointer to it. This is used by the extrude modifier.

**Parameters:****IObjParam\* ip**

The 3ds max interface pointer. If non-NULL, this is used to get at the 3ds max function to do unique naming. If a NULL is specified the names are not made unique.

**TSTR name**

The name for the surface. If the pointer above is non-NULL this name is made unique.

**TimeValue t**

The time at which to extrude the shape.

**ShapeObject \*shape**

Points to the shape object to extrude. Note that if the **ShapeObject** pointed to is a bezier spline then capping won't work properly.

**float amount**

Specifies the height of the extrusion.

**int capStart**

Specifies if the surface should be capped at the bottom: TRUE to cap; FALSE to leave open. Note that this is only used if the ShapeObject is a NURBS curve.

**int capEnd**

Specifies if the surface should be capped at the top: TRUE to cap; FALSE to leave open. Note that this is only used if the ShapeObject is a NURBS curve.

**int capType**

This parameter is not currently used and the value passed is ignored.

### **BOOL texturing**

If TRUE texture coordinates are assigned; otherwise they are not.

### **BOOL matIds**

If TRUE special material Ids are assigned to the surfaces and caps.

### **BOOL shapeIDs**

This parameter is available in release 3.0 and later only.

If TRUE shape IDs are used. When on, this function uses the material ID values assigned to segments in the spline to be extruded, or curve sub-objects in the NURBS curve to be extruded. This is available only when **matIds** is TRUE.

## **Modifying Existing NURBS Objects**

### **Prototype:**

```
int AddNURBSObjects(Object* obj, IObjParam* ip, NURBSSet *nset);
```

### **Remarks:**

This function is available in release 2.0 and later only.

This function adds the specified **NURBSSet** to the specified object.

### **Parameters:**

#### **Object\* obj**

Points to the object to have the specified **NURBSSet** added to. This object must be a NURBS object (otherwise it will simply return 0).

#### **IObjParam\* ip**

The 3ds max interface pointer. If non-NULL, this is used to get at the 3ds max function to do unique naming. If a NULL is specified the names are not made unique.

#### **NURBSSet \*nset**

Points to the NURBS set that is added to the object.

### **Return Value:**

Nonzero if the object was added; otherwise zero.

### **Prototype:**

**NURBSResult SetSurfaceApprox(Object\* obj, BOOL viewport, TessApprox \*tess, BOOL clearSurfs=FALSE);**

**Remarks:**

This function is available in release 3.0 and later only.

This function sets the surface approximation characteristics of an existing NURBS object.

**Parameters:**

**Object\* obj**

The NURBS object to modify.

**BOOL viewport**

TRUE to set the viewport approximation settings; FALSE to set the rendering settings.

**TessApprox \*tess**

Specifies the properties of the tessellation approximation to the mathematical surface.

**BOOL clearSurfs=FALSE**

This tells the NURBS object to clear any over-ridden values on individual surfaces. The NURBS UI lets users set surface approximation value on individual surfaces that over-ride the values for the whole object. When this is TRUE, then these are cleared out.

**Return Value:**

See [List of NURBS Results](#).

**Function:**

**NURBSResult SetCurveApprox(Object\* obj, BOOL viewport, TessApprox \*tess, BOOL clearSurfs);**

**Remarks:**

This function is available in release 3.0 and later only.

This function sets the curve approximation characteristics of an existing NURBS object.

**Parameters:**

**Object\* obj**

The NURBS object to modify.

**BOOL viewport**

TRUE to set the viewport approximation settings; FALSE to set the rendering settings.

**TessApprox \*tess**

Specifies the properties of the tessellation approximation to the mathematical curve.

**BOOL clearSurfs**

This tells the NURBS object to clear any over-ridden values on individual curves. The NURBS UI lets users set surface approximation value on individual surfaces that over-ride the values for the whole object. When this is TRUE, then these are cleared out.

**Return Value:**

See [List of NURBS Results](#).

**Function:**

**NURBSResult SetDispApprox(Object\* obj, TessApprox \*tess, BOOL clearSurfs);**

**Remarks:**

This function is available in release 3.0 and later only.

This function sets the displacement mapping approximation characteristics of an existing NURBS object.

**Parameters:****Object\* obj**

The NURBS object to modify.

**TessApprox \*tess**

Specifies the properties of the tessellation approximation to the mathematical curve.

**BOOL clearSurfs**

This tells the NURBS object to clear any over-ridden values on individual surfaces. The NURBS UI lets users set surface approximation value on individual surfaces that over-ride the values for the whole object. When this is TRUE, then these are cleared out.

**Return Value:**

See [List of NURBS Results](#).

**Function:**

**NURBSResult SetSurfaceDisplaySettings(Object\* obj,  
NURBSDisplay& disp);**

**Remarks:**

This function is available in release 3.0 and later only.

This function sets the display properties of an existing NURBS object.

**Parameters:**

**Object\* obj**

The NURBS object to modify.

**NURBSDisplay& disp**

The display properties to use. See [Class NURBSDisplay](#).

**Return Value:**

See [List of NURBS Results](#).

**Function:**

**NURBSResult GetSurfaceDisplaySettings(Object\* obj,  
NURBSDisplay& disp);**

**Remarks:**

This function is available in release 3.0 and later only.

This function retrieves the display properties of an existing NURBS object.

**Parameters:**

**Object\* obj**

The NURBS object to check.

**NURBSDisplay& disp**

The display properties are returned here. See [Class NURBSDisplay](#).

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSResult Transform(Object\* obj, NURBSIdTab& ids,  
SetXFormPacket& xPack, Matrix3& mat, TimeValue t);**

**Remarks:**

This function is available in release 2.0 and later only.

This function transforms the specified sub-objects within the NURBS object passed. Note that the parameter **xPack** is used for the transformation when Animate mode is on, and **mat** is used when Animate is off. This stems from the fact that 3ds max delays creation of controllers on NURBS sub-objects until they are animated.

**Parameters:****Object\* obj**

The NURBS object whose sub-objects are modified.

**NURBSIdTab& ids**

The table of NURBS Ids of the sub-objects to transform. These are the sub-objects within the 3ds max NURBS object **obj** that are transformed.

**SetXFormPacket& xPack**

When Animate mode is on, this matrix is used for the transformation. See [Class SetXFormPacket](#).

**Matrix3 mat**

When not in Animate mode, this matrix is used for the transformation.

**TimeValue t**

The time at which to do the transformation.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

```
NURBSResult BreakCurve(Object* obj, NURBSId id, double u,  
TimeValue t);
```

**Remarks:**

This function is available in release 2.0 and later only.

This function takes the specified NURBS curve sub-object and generates two curves from it.

**Parameters:****Object\* obj**

The NURBS object whose curve sub-object is broken.

**NURBSId id**

The id of the curve sub-object to break.

**double u**

The point along the curve at which the break is made.

**TimeValue t**

The time at which the curve is broken. The **u** parameter is relative to the state of the curve at this time (for instance if it's animated).

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

```
NURBSResult BreakSurface(Object* obj, NURBSId id, BOOL  
breakU, double param, TimeValue t);
```

**Remarks:**

This function is available in release 2.0 and later only.

This function takes the specified NURBS surface sub-object and generates two surfaces from it.

**Parameters:****Object\* obj**

The NURBS object whose surface sub-object is broken.

**NURBSId id**

The id of the surface sub-object to break.

**BOOL breakU**

If TRUE the break occurs along a constant U parameter; otherwise along a constant V parameter.

**double param**

The distance in U or V space that the break should happen in.

**TimeValue t**

The time at which the surface is broken. The **u** parameter is relative to the state of the surface at this time (for instance if it's animated).

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSId JoinCurves(Object\* obj, NURBSId id1, NURBSId id2, BOOL begin1, BOOL begin2, double tolerance, double ten1, double ten2, TimeValue t);**

**Remarks:**

This function is available in release 3.0 and later only.

This function takes two curves and joins them together and makes a single curve out of them. That is, the endpoints of the two curve objects are connected by new segments, and the two original curves are replaced by a single curve.

**Parameters:****Object\* obj**

The NURBS object whose curve sub-objects are joined.

**NURBSId id1**

The id of the first curve sub-object.

**NURBSId id2**

The id of the second curve sub-object.

**BOOL begin1**

Specifies if the beginning or the end of curve 1 is joined. If TRUE the beginning is used; otherwise the end is used. The beginning of the curve is the point of minimum parameter value.

**BOOL begin2**

Specifies if the beginning or the end of curve 2 is joined. If TRUE the beginning is used; otherwise the end is used. The beginning of the curve is the point of minimum parameter value.

**double tolerance**

A distance in 3ds max units. If the gap between the curves you are joining is greater than this value, this function creates the join by first creating a blend curve and then joining the three parts. If the gap is less than this value, or if the curves are overlapping or coincident, no blend is created.

Creating a blend and then joining the three curves into a single curve is the better technique. The result matches the parent curves well. Without the blend step, the resulting curve can deviate from the parent curves, in order to maintain smoothness. (The amount of deviation depends on how far from

tangent the two input curves were at the join.)

A problem arises when there is a gap but it is too small. In this case, this function generates the blend but because there isn't enough room for it, the resulting curve has a loop in it. To avoid this loop, set this parameter higher than the gap distance.

If you use a value of 0.0, the function chooses a value to use for the tolerance.

**double ten1**

Specifies the tension of the new curve at the end of the first curve sub-object.

**double ten2**

Specifies the tension of the new curve at the end of the second curve sub-object.

**TimeValue t**

The time at which the curves are joined.

**Return Value:**

The NURBSId of the newly joined curve.

**Prototype:**

**NURBSId JoinSurfaces(Object\* obj, NURBSId id1, NURBSId id2, int edge1, int edge2, double tolerance, double ten1, double ten2, TimeValue t);**

**Remarks:**

This function is available in release 2.0 and later only.

This function takes two surfaces and joins them together and makes a single surface out of them. That is, the specified edges of the two surface objects are connected by a new surface, and the two original surfaces are replaced by a single surface.

**Parameters:**

**Object\* obj**

The NURBS object whose surface sub-objects are joined.

**NURBSId id1**

The id of the first surface sub-object.

**NURBSId id2**

The id of the second surface sub-object.

**int edge1**

The index of the edge of surface 1 to join.

**int edge2**

The index of the edge of surface 2 to join.

**double tolerance**

A distance in 3ds max units. If the gap between the surfaces you are joining is greater than this value, this function creates the join by first creating a blend surface. If the gap is less than this value, or if the surfaces are overlapping or coincident, 3ds max doesn't create the blend.

Creating a blend and then joining the three surfaces into a single surface is the better technique. The result matches the parent surfaces well. Without the blend step, the resulting surface can deviate from the parent surfaces, in order to maintain smoothness. (The amount of deviation depends on how far from tangent the two input surfaces were at the join.)

A problem arises when there is a gap but it is too small. In this case, this function generates the blend but because there isn't enough room for it, the resulting surface has a loop in it. To avoid this loop, set the tolerance parameter higher than the gap distance.

If you set the tolerance to 0.0, the function chooses a value to use for the tolerance.

**double ten1**

Specifies the tension of the new surface at the edge of the first surface sub-object.

**double ten2**

Specifies the tension of the new surface at the edge of the second surface sub-object.

**TimeValue t**

The time at which the surfaces are joined.

**Return Value:**

The NURBSId of the newly joined surface.

**Function:**

```
NURBSResult ZipCurves(Object* obj, NURBSId id1, NURBSId id2, BOOL begin1, BOOL begin2, double tolerance, TimeValue t);
```

**Remarks:**

This function is available in release 3.0 and later only.

This method 'zips' two curves. Zipping concatenates the CV lattices of the two original curves. Zipping can change the shape of the original curves, but usually it produces a better result than joining. If both curves are untrimmed point curves, the result is a point curve. In all other cases, the result of zipping is a CV curve.

**Parameters:**

The NURBS object whose curve sub-objects are zipped.

**NURBSId id1**

The id of the first curve sub-object.

**NURBSId id2**

The id of the second curve sub-object.

**BOOL begin1**

Specifies if the beginning or the end of curve 1 is joined. If TRUE the beginning is used; otherwise the end is used. The beginning of the curve is the point of minimum parameter value.

**BOOL begin2**

Specifies if the beginning or the end of curve 2 is joined. If TRUE the beginning is used; otherwise the end is used. The beginning of the curve is the point of minimum parameter value.

**double tolerance**

A distance in 3ds max units. If the gap between the curves you are zipping is greater than this value, this function creates the join by first creating a blend curve and then joining the three parts. If the gap is less than this value, or if the curves are overlapping or coincident, no blend is created.

If you use a value of 0.0, the function chooses a value to use for the tolerance.

**TimeValue t**

The time at which the surfaces are joined.

**Return Value:**

See [List of NURBS Results](#).

**Function:**

**NURBSResult ZipSurfaces(Object\* obj, NURBSId id1, NURBSId**

**id2, int edge1, int edge2, double tolerance, TimeValue t);**

**Remarks:**

This function is available in release 3.0 and later only.

This method 'zips' two surface. Zipping concatenates the CV lattices of the two original surfaces. Zipping can change the shape of the original surfaces, but compared to joining it usually produces a simpler surface that is easier to edit.

**Parameters:**

**Object\* obj**

The NURBS object whose surface sub-objects are zipped.

**NURBSId id1**

The id of the first surface sub-object.

**NURBSId id2**

The id of the second surface sub-object.

**int edge1**

The index of the edge of surface 1 to join.

**int edge2**

The index of the edge of surface 2 to join.

**double tolerance**

A distance in 3ds max units. If the gap between the surfaces you are zipping is greater than this value, this function creates the join by first creating a blend surface. If the gap is less than this value, or if the surfaces are overlapping or coincident, 3ds max doesn't create the blend.

If you set the tolerance to 0.0, the function chooses a value to use for the tolerance.

**double ten1**

Specifies the tension of the new surface at the edge of the first surface sub-object.

**double ten2**

Specifies the tension of the new surface at the edge of the second surface sub-object.

**TimeValue t**

The time at which the surfaces are joined.

**Return Value:**

See [List of NURBS Results](#).

**Prototype:**

**NURBSId MakeIndependent(Object\* obj, NURBSId id, TimeValue t);**

**Remarks:**

This function is available in release 2.0 and later only.

This function takes a dependent sub-object (fillet, offset, blend, etc.) and turns it into a CV variant of itself such that it is independent (no longer dependent on a parent).

**Parameters:****Object\* obj**

The NURBS object whose sub-object is made independent.

**NURBSId id**

The id of the dependent sub-object.

**TimeValue t**

The time at which the sub-object is made independent.

**Return Value:**

The NURBSId of the resulting object or zero if it could not be done.

**Function:**

**NURBSId MakeRigid(Object\* obj, NURBSId id, TimeValue t);**

**Remarks:**

This function is available in release 3.0 and later only.

To improve performance, you can make any kind of surface sub-object into a rigid surface. Once you have made a surface rigid, the only editing allowed is to transform it at the Surface sub-object level. You can't move a rigid surface's points or CVs, or change the number of points or CVs.

Rigid surfaces reduce the amount of memory used by the NURBS model.

Making surfaces rigid improves performance, especially for large and complex models.

**Parameters:**

**Object\* obj**

The NURBS object whose surface sub-objects is made rigid.

**NURBSId id**

The id of the sub-object who is made rigid.

**TimeValue t**

The time at which to make it rigid.

**Return Value:**

The NURBSId of the rigid surface.

**Function:**

```
void SetApproxPreset(Object* pObj, int i);
```

**Remarks:**

This function is available in release 3.0 and later only.

This allows choosing one of the Tessellation Presets which appear in the 3ds max UI in the Surface Approximation rollup. These are the Low, Medium and High buttons. See **GetTessPreset()** and **SetTessPreset()** below.

**Parameters:****Object\* pObj**

The objects whose specified Tessellation Preset is set.

**int i**

Specifies which preset to make active. One of the following values:

**0**: Low

**1**: Medium

**2**: High

**Function:**

```
void ToggleShadedLattice(Object* pObj);
```

**Remarks:**

This function is available in release 3.0 and later only.

Inverts the state of the Shaded Lattice setting for the object. This goes between 'Tesselated Mesh' and 'Shaded Lattice' surface display mode.

**Parameters:**

## **Object\* pObj**

The object whose Shaded Lattice setting is toggled.

### **Function:**

**TessApprox\* GetTessPreset(int which, int preset);**

### **Remarks:**

This function is available in release 3.0 and later only.

Returns a pointer to the tessellation object corresponding to the specified type of tessellation preset.

### **Parameters:**

#### **int which**

Determines which type of tessellation is set. One of the following values:

- 0:** Curve tessellation in the viewports.
- 1:** Curve tessellation by the production renderer.
- 2:** Surface tessellation in the viewports.
- 3:** Surface tessellation by the production renderer.
- 4:** Displacement mapping (by the production renderer).

#### **int preset**

Specifies which preset to get. One of the following values:

- 0:** Low
- 1:** Medium
- 2:** High

### **Return Value:**

See [Class TessApprox](#).

### **Function:**

**void SetTessPreset(int which, int preset, TessApprox& tess);**

### **Remarks:**

This function is available in release 3.0 and later only.

Sets the tessellation object corresponding to the specified type of tessellation preset.

**Parameters:****int which**

Determines which type of tessellation is set. One of the following values:

- 0:** Curve tessellation in the viewports.
- 1:** Curve tessellation by the production renderer.
- 2:** Surface tessellation in the viewports.
- 3:** Surface tessellation by the production renderer.
- 4:** Displacement mapping (by the production renderer).

**int preset**

Specifies which preset to get. One of the following values:

- 0:** Low
- 1:** Medium
- 2:** High

**TessApprox & tess**

The tessellation object to set. See [Class TessApprox](#).

**Function:**

**Object \*BuildEMObjectFromLofterObject(Object \*loftObject, double tolerance);**

**Remarks:**

This function is available in release 3.0 and later only.

Generates a new NURBS object from the specified loft object at the current time. This is a special call used internally in the lofter to convert a loft object to a NURBS surface.

**Parameters:****Object \*loftObject**

Points to the source loft object.

**double tolerance**

This parameter is the maximum deviation of the NURBS approximation to the true loft surface.

**Return Value:**

A pointer to the new NURBS object.

**Function:**

**Object \*BuildEMObjectFromPatchObject(Object \*patchObject);**

**Remarks:**

This function is available in release 3.0 and later only.

Generates a new NURBS object from the specified patch object at the current time.

**Parameters:**

**Object \*patchObject**

Points to the source patch object.

**Return Value:**

A pointer to the new NURBS object.

**Function:**

**Object \*DetachObjects(TimeValue t, INode \*pNode, Object\* pObj, NURBSIdList list, char \*newObjName, BOOL copy, BOOL relational);**

**Remarks:**

This global function is available in release 3.0 and later only.

Creates a NURBS object in the scene named **newObjName** respecting the copy and relational flags like the 3ds max Detach operation.

**Parameters:**

**TimeValue t**

The time at which to detach the object.

**INode \*pNode**

The node of the existing object.

**Object\* pObj**

Points to the NURBS object whose sub-objects are detached.

**NURBSIdList list**

The list of objects to detach. Note: **typedef Tab<NURBSId> NURBSIdList**. See [Template Class Tab](#).

**char \*newObjName**

The name for the new node created.

**BOOL copy**

TRUE to create a copy for the detached objects leaving the original; FALSE to remove the originals.

**BOOL relational**

If TRUE the object will contain relational data; if FALSE the object will contain a CV curve or CV surface equivalent of the object.

**Return Value:**

A pointer to the new object created by the detach. If an error occurs, NULL is returned.

**Function:**

**NURBSSubObjectLevel GetSelectionLevel(Object\* pObj);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the current sub-object selection level for the specified NURBS object.

**Parameters:**

**Object\* pObj**

The object to check.

**Return Value:**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Function:**

**NURBSResult SetSelectionLevel(Object\* pObj,  
NURBSSubObjectLevel level);**

**Remarks:**

This global function is available in release 3.0 and later only.

Sets the current sub-object selection level for the specified NURBS object.

**Parameters:**

**Object\* pObj**

Points to the object whose sub-object selection state is set.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult GetSelection(Object\* pObj,  
NURBSSubObjectLevel level, BitArray& selset);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns a BitArray containing the sub-object selection state of the NURBS object passed.

**Parameters:**

**Object\* pObj**

Points to the object whose sub-object selection data is retrieved.

**NURBSSubObjectLevel level**

The sub-object level data to get. See [List of NURBSSubObjectLevel Options](#).

**BitArray& selset**

The BitArray for the result. Bits set are selected components. See [Class BitArray](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult SetSelection(Object\* pObj, NURBSSubObjectLevel  
level, BitArray& selset);**

**Remarks:**

This global function is available in release 3.0 and later only.

Sets the specified sub-object selection state of the NURBS object passed.

**Parameters:**

**Object\* pObj**

Points to the object whose sub-object selection state is set.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

## **BitArray& serset**

The BitArray with the selection data. Bits which are set indicate items to select.

### **Return Value:**

See [List of NURBS Results](#) .

### **Function:**

**NURBSResult MoveCurrentSelection(Object\* pObj,  
NURBSSubObjectLevel level, TimeValue t, Matrix3& partm,  
Matrix3& tmAxis, Point3& val, BOOL localOrigin);**

### **Remarks:**

This global function is available in release 3.0 and later only.  
Moves the current sub-object selection at the specified level.

### **Parameters:**

#### **Object\* pObj**

The object whose components are transformed.

#### **NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

#### **TimeValue t**

The time to transform the sub-objects.

#### **Matrix3& partm**

The 'parent' transformation matrix.

#### **Matrix3& tmAxis**

The axis system about which the selection is transformed.

#### **Point3& val**

The amount of the transformation relative to the axis system.

#### **BOOL localOrigin**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

### **Return Value:**

See [List of NURBS Results](#) .

### **Function:**

**NURBSResult RotateCurrentSelection(Object\* pObj,  
NURBSSubObjectLevel level, TimeValue t, Matrix3& partm,  
Matrix3& tmAxis, Quat& val, BOOL localOrigin);**

**Remarks:**

This global function is available in release 3.0 and later only.  
Rotates the current sub-object selection at the specified level.

**Parameters:**

**Object\* pObj**

The object whose components are transformed.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**TimeValue t**

The time to transform the sub-objects.

**Matrix3& partm**

The 'parent' transformation matrix.

**Matrix3& tmAxis**

The axis system about which the selection is transformed.

**Quat& val**

The amount of the transformation relative to the axis system.

**BOOL localOrigin**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult ScaleCurrentSelection(Object\* pObj,  
NURBSSubObjectLevel level, TimeValue t, Matrix3& partm,  
Matrix3& tmAxis, Point3& val, BOOL localOrigin);**

**Remarks:**

This global function is available in release 3.0 and later only.  
Scales the current sub-object selection at the specified level.

**Parameters:****Object\* pObj**

The object whose components are transformed.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**TimeValue t**

The time to transform the sub-objects.

**Matrix3& partm**

The 'parent' transformation matrix.

**Matrix3& tmAxis**

The axis system about which the selection is transformed.

**Point3& val**

The amount of the transformation relative to the axis system.

**BOOL localOrigin**

If TRUE the transformation takes place about the nodes local origin; otherwise about the world origin.

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

```
int SubObjectCount(Object* pObj, NURBSSubObjectLevel level);
```

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the number of sub-objects at the specified level.

**Parameters:****Object\* pObj**

Points to the object to check.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Function:**

```
int NamedSelSetCount(Object* pObj, NURBSSubObjectLevel
```

**level);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the number of named selection sets at the specified level

**Parameters:**

**Object\* pObj**

Points to the object to check.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Function:**

**TCHAR\* GetNamedSelSetName(Object\* pObj,  
NURBSSubObjectLevel level, int i);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the name of the 'i-th' named selection set of the specified sub-object level.

**Parameters:**

**Object\* pObj**

Points to the object to check.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**int i**

The zero based index of the selection set (between **0** and **NamedSelSetCount()-1**).

**Function:**

**NURBSResult GetNamedSelSet(Object\* pObj,  
NURBSSubObjectLevel level, TCHAR\* name, BitArray& selSet);**

**Remarks:**

This global function is available in release 3.0 and later only.

Retrieves the name of, and BitArray holding, the named selection set for the

specified sub-object level.

**Parameters:**

**Object\* pObj**

Points to the object whose named selection set is retrieved.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**TCHAR\* name**

The retrieved name of the set.

**BitArray& selSet**

The retrieved selection set data. See [Class BitArray](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult SetNamedSelSet(Object\* pObj,  
NURBSSubObjectLevel level, TCHAR\* name, BitArray& sel);**

**Remarks:**

This global function is available in release 3.0 and later only.

Set the specified named selection set. The set must exist. To add a new set see **AppendNamedSelSet()**.

**Parameters:**

**Object\* pObj**

Points to the object whose named selection set is stored.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**TCHAR\* name**

The name of the set.

**BitArray& sel**

The selection data. See [Class BitArray](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult AppendNamedSelSet(Object\* pObj,  
NURBSSubObjectLevel level, TCHAR\* name, BitArray& sel);**

**Remarks:**

This global function is available in release 3.0 and later only.  
Adds a new named selection set to the specified object.

**Parameters:****Object\* pObj**

Points to the object whose named selection set list is appended.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**TCHAR\* name**

The name for the set.

**BitArray& sel**

The selection data. See [Class BitArray](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult DeleteCurrentSelection(Object\* pObj,  
NURBSSubObjectLevel level);**

**Remarks:**

This global function is available in release 3.0 and later only.  
Deletes the current sub-object selection.

**Parameters:****Object\* pObj**

Points to the object whose current selection is deleted.

**NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult MapNURBSIdToSelSetIndex(Object\* pObj,  
NURBSId id, int& index, NURBSSubObjectLevel& level);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the index into a sub-object selection set of the sub-object component whose NURBSId is passed.

**Parameters:****Object\* pObj**

Points to the object whose sub-object component selection set index is returned.

**NURBSId id**

The ID of the sub-object to find.

**int& index**

The zero based selection set index is returned here.

**NURBSSubObjectLevel& level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

**Return Value:**

See [List of NURBS Results](#) .

**Function:**

**NURBSResult MapSelSetIndexToNURBSId(Object\* pObj, int  
index, NURBSSubObjectLevel level, NURBSId& id);**

**Remarks:**

This global function is available in release 3.0 and later only.

Returns the NURBSId of the sub-object component whose selection set index is passed.

**Parameters:****Object\* pObj**

Points to the object whose sub-object component NURBSId is returned.

**int index**

The zero based index into the selection set.

## **NURBSSubObjectLevel level**

The sub-object level. See [List of NURBSSubObjectLevel Options](#).

## **NURBSId& id**

The ID is returned here.

### **Return Value:**

See [List of NURBS Results](#) .

### **Function:**

```
void ApplyUVWMapAsTextureSurface(Object* pObj, int type,  
float utile, float vtile, float wtile, int uflip, int vflip, int wflip, int  
cap, const Matrix3 &tm,int channel);
```

### **Remarks:**

This global function is not currently supported as of 3ds max release 3.1.

### **Function:**

```
void UpdateSurfaceMapper(Modifier* pMod);
```

### **Remarks:**

This global function is available in release 3.0 and later only.

When called, passing in an instance of a NURBS Surface Mapper WSM, this has the effect of pressing the "Update" button. If any other modifier is passed in, the function does nothing.

### **Parameters:**

**Modifier\* pMod**

Points to the NURBS Surface Mapper WSM.

## Working with Patches

See Also: [Class Patch](#), [Class PatchMesh](#), [Class PatchObject](#), [Class PatchVec](#), [Class PatchVert](#), [Class PatchEdge](#), [Class TVPatch](#).

## Overview

This section provides an overview of how to work with Patches. It covers the main classes used when working with patches, and an example of creating a patch mesh.

The SDK provides a set of classes for creating and working with patches. A Patch is a three or four sided surface. Each edge of a patch is a bezier curve. Each edge has a vertex at the end and a vector attached to each of those ends. Inside a four sided patch are four interior vertices used to generate the surface inside. Inside a three sided patch are three interior vertices. Normally these vertices are set to be automatically calculated by the program to maintain continuity at the corners. They can however be set to be user-definable interior points.

## Overview of the Principal Classes

The SDK provides a set of classes for creating patch objects. These classes are listed below.

### [Class PatchObject](#)

This is the base class for the creation of Patch Objects in MAX. The **PatchObject** is the object that flows down the 3ds max geometry pipeline. This object stores a **PatchMesh** as well as a **Mesh** cache. This is similar to the way a **TriObject** has a **Mesh**. The **TriObject** provides methods to manage the operations associated with flowing down the pipeline, while the **Mesh** stores the vertex, edge and face information. In the **PatchObject** case, the **PatchObject** provides methods for working with the pipeline while the **Mesh** cache is used for display in the viewports.

### [Class PatchMesh](#)

A **PatchMesh** can be made up of any number of Patches. Each of these patches can be three or four sided. The topology of these patches are not quite as freeform as a regular **TriObject** mesh. For example, in a normal triangle mesh you can have an edge that is used by any number of faces. However with patches, in order for the system to figure out how the topology is connected together, each edge can only be used by either one patch (which makes it an open edge), or two patches (which makes it a transitional edge between the two).

### [Class Patch](#)

A **PatchMesh** is made up of a series of Patch objects derived from this class. This is similar to the way faces relate to a mesh, i.e. a **Patch** is like the face, and the **PatchMesh** is like the **Mesh**. Each Patch can be three or four sided. The **Patch** contains the vertices (three or four), and a set of vectors (six or eight) that go between the vertices (two per edge). There are also a set of vertices in the interior of the patch (three or four of these).

### [Class PatchVec](#)

This class represents a patch vector. This can be either an interior vector or an edge vector.

### [Class PatchVert](#)

This class stores the information associated with a patch vertex and provides methods to access this data. This information includes the vertex location, a table of vectors attached to the patch, and a table of patches using the vertex.

### [Class PatchEdge](#)

This class describes a patch edge using the vertices at the edge ends, and the indices of the patches sharing the edge.

### [Class TVPatch](#)

This class is a texture vertex patch structure. This is similar to the **TVFace** class used with a **Mesh**.

## Main Methods in Creating a Patch

A good sample to look at to see how patches are created is the patch grid plug-in. The source code is in

**\MAXSDK\SAMPLES\OBJECTS\PATCHGRD.CPP.**

The code below is a portion of the source of this plug-in. This section discusses some of the key methods used in the creation of the patch.

```
// Quad patch layout  
//  
// A---> ad ----- da <---D  
// | |  
// | |  
// v v  
// ab i1 i4 dc  
//  
// | |  
// | |  
//  
// ba i2 i3 cd  
// ^ ^  
// | |  
// | |  
// B---> bc ----- cb <---C  
//  
// Vertices ( a b c d ) are in counter clockwise order when viewed  
from  
// outside the surface  
void QuadPatchObject::BuildPatch(TimeValue t,PatchMesh&  
amesh)  
{  
int ix,iy,np,kv;  
int wsegs,lsegs,nv;  
Point3 v,p;  
float l, w;
```

**// Start the validity interval at forever and widdle it down.**

```
ivalid = FOREVER;  
pblock->GetValue( PB_LENGTH, t, l, ivalid );  
pblock->GetValue( PB_WIDTH, t, w, ivalid );  
pblock->GetValue( PB_LSEGS, t, lsegs, ivalid );  
pblock->GetValue( PB_WSEGS, t, wsegs, ivalid );  
int lv = lsegs + 1;  
int wv = wsegs + 1;  
int nverts = lv * wv;  
int npatches = lsegs * wsegs;  
int nexteriors = npatches * 4 + lsegs * 2 + wsegs * 2;  
int ninteriors = npatches * 4;  
int nvecs = ninteriors + nexteriors;
```

Here the number of vertices, texture vertices, vectors, patches and texture patches are established in the **PatchMesh**.

```
amesh.setNumVerts(nverts);  
amesh.setNumTVerts(textured ? nverts : 0);  
amesh.setNumVecs(nvecs);  
amesh.setNumPatches(npatches);  
amesh.setNumTVPatches(textured ? npatches : 0);  
v = Point3(-w, -l, 0.0f) / 2.0f;  
float dx = w/wsegs;  
float dy = l/lsegs;  
float fws = (float)wsegs;  
float fls = (float)lsegs;
```

Next the vertices are created. The **setVert()** method of the **PatchMesh** is used to do this.

```
// Create the vertices.  
nv = 0;  
p.z = v.z;  
p.y = v.y;  
for(iy=0; iy<=lsegs; iy++) {  
    p.x = v.x;  
    for (ix=0; ix<=wsegs; ix++) {
```

```

if(textured)
    amesh.tVerts[nv] = UVVert((float)ix /
        fws, (float)iy / fls, 0.0f);
amesh.verts[nv].flags = PVERT_COPLANAR;
amesh.setVert(nv++, p);
p.x += dx;
}
p.y += dy;
}

```

Next the patches are created. The **PatchMesh** method **MakeQuadPatch()** is used once the vertices, vectors, and interiors are set up.

```

// Create patches.
np = 0;
int interior = nexteriors;
int vecRowInc = lsegs * 2;
int vecColInc = wsegs * 2;
for(iy=0; iy<lsegs; iy++) {
    kv = iy*(wsegs+1);
    int rv = iy * vecColInc; // Row vector start
    int cv = vecColInc * lv + iy * 2; // column vector start
    for (ix=0; ix<wsegs; ix++,++np) {
        Patch &p = amesh.patches[np];
        int a = kv, b = kv+1, c = kv+wsegs+2, d = kv + wsegs + 1;
        int ab = rv, ba = rv+1;
        int bc = cv+vecRowInc, cb = cv + vecRowInc + 1;
        int cd = rv+vecColInc+1, dc = rv+vecColInc;
        int da = cv + 1, ad = cv;
        amesh.MakeQuadPatch(np, a, ab, ba, b, bc, cb, c, cd, dc,
            d, da, ad, interior+1, interior+2,
            interior+3, 1);
    }
}

```

If textures are being used, then **setTVerts()** is called.

```

if(textured) {
    TVPatch &tp = amesh.tvPatches[np];
    tp.setTVerts(a,b,c,d);
}

```

```
}
```

Next the vectors are set using **setVec()**. One third of the distance from vertex **a** to vertex **b** is vector **ab**, and one third of the distance from vertex **b** to vertex **a** is **ba**.

```
// Create the default vectors
Point3 pa = amesh.getVert(a).p;
Point3 pb = amesh.getVert(b).p;
Point3 pc = amesh.getVert(c).p;
Point3 pd = amesh.getVert(d).p;
amesh.setVec(ab, pa + (pb - pa) / 3.0f);
amesh.setVec(ba, pb - (pb - pa) / 3.0f);
amesh.setVec(bc, pb + (pc - pb) / 3.0f);
amesh.setVec(cb, pc - (pc - pb) / 3.0f);
amesh.setVec(cd, pc + (pd - pc) / 3.0f);
amesh.setVec(dc, pd - (pd - pc) / 3.0f);
amesh.setVec(da, pd + (pa - pd) / 3.0f);
amesh.setVec(ad, pa - (pa - pd) / 3.0f);
kv++;
cv += vecRowInc;
rv += 2;
interior += 4;
}
}
```

```
// Verify that we have the right number of parts!
```

```
assert(np==npatches);
```

```
assert(nv==nverts);
```

Next the **PatchMesh** method **buildLinkages()** is called. This makes sure that everything is connected correctly and there are not any edges that are used by more than two patches. It will return **FALSE** if these conditions are not met.

```
// Finish up patch internal linkages (and bail out if it fails!)
```

```
assert(amesh.buildLinkages());
```

Next the method **computeInteriors()** is called. For any automatic patches, the interior vertices will be computed.

```
// Calculate the interior bezier points on the PatchMesh's patches  
amesh.computeInteriors();
```

Then the geometry cache is cleared to make sure that any cache that might have been in the **PatchMesh** is emptied.

```
amesh.InvalidateGeomCache();
```

Finally the validity of the **Mesh** cache is set to FALSE to indicate the **PatchMesh** has been changed.

```
// Tell the PatchObject its mesh just got changed  
meshValid = FALSE;  
}
```

## Patch Interpolation

The patch system supports any combination of quadrilateral and triangular patches, as long as they are set up so that a single edge is only shared by at most two patches.

Adjacent patches share control points and vectors on their common edges. This minimizes the amount of data and makes book keeping easier. It also guarantees matching patch edges.

The only problem with this system is that the 3ds max quad patches are bicubic (degree 3), and if they are connected to degree 3 triangular patches, discontinuities will result at the boundaries. The solution used in 3ds max is to store the patch information and allow users to manipulate it in a degree-3 manner (4 points on the side of a patch). When we go to interpolate it, however, we convert all the triangular patches' control points to degree 4, where they can be completely compatible with their quad neighbors.

Below is the source code for the interpolators for both the quad and tri patches.

Note: Interested developers should see the "Patch Tessellation" upload in the private [Sparks Developer](#) section on the webboard. Here developers can get a working example on how to tessellate a PatchMesh for use in a game engine. This modifier sample is available in the [Sparks Developer](#) section of the webboard at <http://sparks.discreet.com>

Also Note: The UpdateHooks() method shown below is modified from the original version in PATCH.CPP.

**// Triangular patch interpolator**

**Point3 Patch::interp(PatchMesh \*pMesh,float pu, float pv, float pw) {**

**// It had better be a triangular patch!**

**assert(type == PATCH\_TRI);**

**Point3 p;**

**PatchVert \*vp = pMesh->verts;**

**PatchVec \*vecp = pMesh->vecs;**

**float pu2 = pu \* pu;**

**float pu3 = pu2 \* pu;**

**float pu4 = pu3 \* pu;**

**float pv2 = pv \* pv;**

**float pv3 = pv2 \* pv;**

```

float pv4 = pv3 * pv;
float pw2 = pw * pw;
float pw3 = pw2 * pw;
float pw4 = pw3 * pw;
// Hold on to your hats -- Here it comes!
p = vp[v[0]].p * pw4 +
aux[0] * 4.0f * pu * pw3 +
aux[1] * 6.0f * pu2 * pw2 +
aux[2] * 4.0f * pu3 * pw +
vp[v[1]].p * pu4 +
aux[3] * 4.0f * pv * pu3 +
aux[4] * 6.0f * pu2 * pv2 +
aux[5] * 4.0f * pv3 * pu +
vp[v[2]].p * pv4 +
aux[6] * 4.0f * pw * pv3 +
aux[7] * 6.0f * pv2 * pw2 +
aux[8] * 4.0f * pw3 * pv +
vecp[interior[0]].p * 12.0f * pu * pv * pw2 +
vecp[interior[1]].p * 12.0f * pu2 * pv * pw +
vecp[interior[2]].p * 12.0f * pu * pv2 * pw;
return p;
}
// Quadrilateral patch interpolator
Point3 Patch::interp(PatchMesh *pMesh,float pu, float pv) {
// It had better be a quad patch!
assert(type == PATCH_QUAD);
Point3 p;
PatchVert *vp = pMesh->verts;
PatchVec *vecp = pMesh->vecs;
float pu2 = pu * pu;
float pu1 = 1.0f - pu;
float pu12 = pu1 * pu1;

```

```

float u0 = pu12 * pu1;
float u1 = 3.0f * pu * pu12;
float u2 = 3.0f * pu2 * pu1;
float u3 = pu2 * pu;
float pv2 = pv * pv;
float pv1 = 1.0f - pv;
float pv12 = pv1 * pv1;
float v0 = pv12 * pv1;
float v1 = 3.0f * pv * pv12;
float v2 = 3.0f * pv2 * pv1;
float v3 = pv2 * pv;
// Hold on to your hats -- Here it comes!
p = vp[v[0]].p * u0 * v0 +
vecp[vec[7]].p * u1 * v0 +
vecp[vec[6]].p * u2 * v0 +
vp[v[3]].p * u3 * v0 +
  vecp[vec[0]].p * u0 * v1 +

vecp[vec[2]].p * u1 * v3 +
vecp[vec[3]].p * u2 * v3 +
vp[v[2]].p * u3 * v3;
return p;
}

```

Building the vertices are just a matter of looping through your patches and then running through each patches UV space to get the corresponding point on the

surface. Below is sample showing the basics.

```
float fpd = (float)patchDivs;
for(px = 0; px < numPatches; ++px) {
    Patch &p = patches[px];
    switch(p.type) {
        case PATCH_TRI: {
            for(int ax = patchDivs - 1; ax > 0; --ax) {
                for(int bx = 1; bx < ax; ++bx) {
                    float u = (float)bx / fpd;
                    float v = (float)(patchDivs - ax) / fpd;
                    float w = 1.0f - u - v; // Barycentric validity guaranteed!
                    mesh.setVert(vert++, p.interp(this, u, v, w));
                }
            }
        }
        break;
        case PATCH_QUAD: {
            for(int u = 1; u < patchDivs; ++u) {
                float fu = (float)u / fpd;
                for(int v = 1; v < patchDivs; ++v) {
                    float fv = (float)v / fpd;
                    mesh.setVert(vert++, p.interp(this, fu, fv));
                }
            }
        }
        break;
    }
}
```

Below is the sample code that puts it all together. It shows the interpolation of the surface points, the book keeping code for shared edges, the construction of the mesh faces, the handling of texture vertices and faces, and how bind patches are handled.

```

// vertices ( a b c d ) are in counter clockwise order when viewed from
// outside the surface

## Working with Shapes and Splines

See Also: [Class SplineShape](#), [Class BezierShape](#).

## Overview

This section presents information about working with shapes and splines. It covers the main classes used, provides an overview of creating splines, and discusses the capping of shapes with meshes and patches.

A good example shape for study is the Donut plug-in. This shape has two circles, an inner and an outer that make up the shape. The code for this plug-in is in **`\MAXSDK\SAMPLES\OBJECTS\DONUTS.CPP`**.

## Overview of the Principal Classes

The following are the main classes used when working with shapes and splines:

### [Class ShapeObject](#)

These are open or closed hierarchical shape objects. This is the base class that **SimpleSpline**, **SimpleShape**, **SplineShape**, and **LinearShape** are derived from. This class is defined in `\MAXSDK\INCLUDE\OBJECT.H`.

### [Class SplineShape](#)

The **SplineShape** is the shape object flows down the geometry pipeline of MAX. The **SplineShape** contains a **BezierShape**. A **SplineShape** and its contained **BezierShape** are analogous to a **TriObject** which flows down the pipeline and its **Mesh**. This class is defined in `\MAXSDK\INCLUDE\SPLSHAPE.H`.

### [Class BezierShape](#)

The **BezierShape** is effectively a collection of Bezier Splines. For example, the 3ds max Donut object has two splines in a hierarchy to make a shape. The **BezierShape** contains these splines. The **BezierShape** is analogous to the **Mesh** of the **TriObject**. This class is defined in `\MAXSDK\INCLUDE\SHAPE.H`.

### [Class Spline3D](#)

This is a general 3D spline class. The **BezierShape** class has a list of these splines that make up the bezier shape. This class is defined in `\MAXSDK\INCLUDE\SPLINE3D.H`.

### [Class PolyShape](#)

This class is used in the caching of bezier shapes. This is used for doing a one time interpolation of a bezier shape into a form that is the same shape but doesn't require any further interpolation. In this way the system can do the complex calculations once, store the shape into this **PolyShape** representation, and not have to go through the cubic spline calculations to figure out where the points are in the future. This class maintains an array of **PolyLines**. This class is defined in `\MAXSDK\INCLUDE\POLYSH.P.H`.

### [Class PolyLine](#)

This class describes a single polygon in a **PolyShape** using linear segments. This class is defined in **\MAXSDK\INCLUDE\POLYSHP.H**.

#### [Class SimpleSpline](#)

This is a class used in the creation of shape plug-ins. Most of the 3ds max shapes and splines are derived from this class. For example, Line, Arc, Circle, Ellipse and Star are all **SimpleSplines**. This class is defined in **\MAXSDK\INCLUDE\SIMPSPL.H**.

#### [Class SimpleShape](#)

This class is used to make procedural shape primitives easier to create. The 3ds max Helix procedural shape is derived from this class. It's defined in **\MAXSDK\INCLUDE\SIMPSHP.H**.

#### [Class LinearShape](#)

This class is similar to a **SplineShape** except this class uses a **PolyShape** as its data while a **SplineShape** uses a **BezierShape** as its data. Therefore this is a shape made up of entirely linear segments. This class is defined in **\MAXSDK\INCLUDE\LINSHAPE.H**.

## Main Methods in Creating a Spline

Below is a section of code from the Circle plug-in. This plug-in is derived from class **SimpleSpline**. This code demonstrates the key methods used in building a shape. The method **SimpleSpline::BuildShape()** is called to build the shape at the specified time and store the results in **ashape**.

```
void CircleObject::BuildShape(TimeValue t, BezierShape& ashape) {  
    // Start the validity interval at forever and whittle it down.  
    ivalid = FOREVER;  
    float radius;  
    pblock->GetValue(PB_RADIUS, t, radius, ivalid);  
    LimitValue( radius, MIN_RADIUS, MAX_RADIUS );
```

The first thing to notice is the call to **NewShape()**. This ensures the shape is flushed out and emptied.

Next this method calls **MakeCircle()**. See the code for this method below.

```
    ashape.NewShape();  
    // Get parameters from SimpleSpline and place them in the BezierShape  
    int steps;  
    BOOL optimize,adaptive;  
    ipblock->GetValue(IPB_STEPS, t, steps, ivalid);  
    ipblock->GetValue(IPB_OPTIMIZE, t, optimize, ivalid);  
    ipblock->GetValue(IPB_ADAPTIVE, t, adaptive, ivalid);  
    ashape.steps = adaptive ? -1 : steps;  
    ashape.optimize = optimize;
```

Next this method calls **MakeCircle()**. See the code for this method below.

```
    MakeCircle(ashape,radius);
```

After **MakeCircle()** has returned, another important call is made. This is **UpdateSels()**. This should be called when you are done adding all the polygons to the shape. This method updates the selection set information maintained by the shape. It is vital to call this before you are done.

```
    ashape.UpdateSels(); // Make sure it readies the selection set info
```

Finally we clear any caches from the shape.

```

ashape.InvalidateGeomCache();
}
static void MakeCircle(BezierShape& ashape, float radius) {
float vector = CIRCLE_VECTOR_LENGTH * radius;

```

First create a new spline. This is done by calling the **NewSpline()** method on the shape. The shape adds a polygon to itself and returns a pointer to it.

```

Spline3D *spline = ashape.NewSpline();
// Now add all the necessary points
for(int ix=0; ix<4; ++ix) {
float angle = 6.2831853f * (float)ix / 4.0f;
float sinfac = (float)sin(angle), cosfac = (float)cos(angle);
Point3 p(cosfac * radius, sinfac * radius, 0.0f);
Point3 rotvec = Point3(sinfac * vector, -cosfac * vector, 0.0f);

```

Next points or knots are added to the spline by calling **AddKnot()**. This allows you to add different types of knots and line segments.

```

spline-
>AddKnot(SplineKnot(KTYPE_BEZIER,LTYPE_CURVE,
    p,p + rotvec,p - rotvec));
}

```

After adding four knots, the **SetClosed()** method is called to make sure it's a closed circle.

```

spline->SetClosed();

```

Next, an important call is made. The spline has a cached set of bezier points inside it. This needs to be called if you change the points of the spline. This methods updates the information internal to the spline.

```

spline->ComputeBezPoints();
}

```

## Capping a Shape with a Mesh

This section discusses the capping of shapes using a mesh. The SDK provides tools for easily creating these mesh caps for shapes.

Typically for an extruded object, the capping on the front of the object is exactly the same as the capping on the back of the object. For example, if you extrude the letter 'M'. It's redundant to have to cap this separately for the front and back (as they are the same). When dealing with complex shapes, having to go back and do the second cap is very time consuming. So the capping system tries to cache information to speed up the process.

Sample code for capping can be found in the extrude and lathe modifiers. These plug-ins are in `\MAXSDK\SAMPLES\MODIFIERS\SURFREV.CPP` and `\MAXSDK\SAMPLES\MODIFIERS\EXTRUDE.CPP`.

The following code fragments are taken from `EXTRUDE.CPP`. This demonstrates the basic process for capping a shape. This code is part of the method `ExtrudeMod::BuildMeshFromShape()`.

For this example, we are starting of with a `ShapeObject` **shape** that we want capped with a mesh. The first thing to do is convert the shape to a **PolyShape**. This greatly simplifies the mesh conversion. The code below shows how this is done.

```
// Make the shape convert itself to a PolyShape.  
// This makes our mesh conversion MUCH easier!  
PolyShape pShape;  
shape->MakePolyShape(t, pShape);
```

Next, we organize the curves into a hierarchy. This automatically figures out the shape nesting and directions for proper capping.

```
ShapeHierarchy hier = pShape.OrganizeCurves(t);
```

Next we need to reverse the shapes whose directions are incorrect for the hierarchy. The hierarchy calculated above contains a **BitArray** that describes which shapes need to be reversed. This is passed into the `Reverse()` method of the **PolyShape** to tell it which shapes to reverse.

```
// Need to flip the reversed curves in the shape!  
pShape.Reverse(hier.reverse);
```

At this point the **PolyShape** is all set up with the proper clockwise/counter-

clockwise ordering on all the polygons so all that needs to be done is to generate the faces. You may refer to the full source of **EXTRUDE.CPP** to see how this is done.

The next thing is just to create the caps. This begins by instantiating a **MeshCapInfo** class and asking the **PolyShape** to make a cap. This fills up the **MeshCapInfo** class with all the information it needs to create a cap. The type can be morph or grid capping. Morph capping only uses the existing vertices in the **PolyShape** to generate the cap. The capping code does the best job it can given this constraint, however it is possible to wind up with long sliver-like faces on the cap. This is referred to as a morph cap because if you cap a shape using this method it does not generate any new vertices and you can then morph between shapes with the same number of vertices. A Grid cap generates new vertices in the interior of the shape in a grid pattern. This helps to break up the shape and helps reduce slivering. Grid capping will generate different number of vertices based on the shape and thus the shapes are not morphable.

```
MeshCapInfo capInfo;  
pShape.MakeCap(t, capInfo, capType);
```

After this is done, the **MeshCapInfo** is cached within the shape. Therefore if this is needed again, no work needs to be done.

Next, a **MeshCapper** object is created. This is done by passing the **PolyShape** as an argument to the constructor. This gets the **MeshCapper** ready for the topology of the shape. Developers don't need to understand the inner workings of the **MeshCapper**, it's just a tool used to aide in capping.

```
// Build information for capping  
MeshCapper capper(pShape);
```

Below is the code where the start of the extrusion is capped. Inside the capper is a **MeshCapPoly**. There is one for each polygon in the shape. The **MeshCapPoly** needs to know the corresponding mesh vertex for each vertex in the **PolyLine**. This is done by calling **SetVert()** on the **MeshCapPoly**. For example, this might associate vertex 0 in the **PolyLine** with vertex 200 in the mesh, vertex 1 with mesh vertex 220, etc.

```
if(capStart) {  
vert = 0;  
for(poly = 0; poly < polys; ++poly) {
```

```

PolyLine &line = pShape.lines[poly];
MeshCapPoly &capline = capper[poly];
int lverts = line.numPts;
for(int v = 0; v < lverts; ++v)
    // Gives this vert's location in the mesh!
    capline.SetVert(v, vert++);
vert += lverts * levels;
}

```

The next thing that is done is used only for grid capping. A grid cap generates new vertices inside the shape that make up the grid. In the case of a SurfRev for example, the end cap might be rotated, or scaled in some manner. A matrix is required so the capper knows how to orient the vertices into the correct location. This matrix is ignored for non-grid capping.

```

// Create a work matrix for grid capping
Matrix3 gridMat = TransMatrix(offset1);

```

The final step is to cap the mesh. This is done using a method of the capper named **CapMesh()**. This method is passed the output mesh, the **MeshCapInfo**, a flag that indicates if the cap should be flipped, the smoothing group number for all the faces in the cap, and a pointer to the orientation matrix.

```

capper.CapMesh(mesh, capInfo, TRUE, 16, &gridMat);

```

Once this is done the shape has been capped with a mesh.

## Capping a Shape with a Patch

This section discusses the capping of shapes with patches. This is very similar to the mesh capping discussed above.

Again, the following code fragments are taken from **EXTRUDE.CPP**. This demonstrates the basic process for capping a shape with a patch.

Here we try to use a **BezierShape** to create the cap. First a **BezierShape** object is created. Then the shape to be capped is asked if it can make a transformation from itself to a **BezierShape**. If it can, we just ask it to make a **BezierShape**. If it cannot, we are forced to use a **PolyShape**. For patch capping this is much less desirable, but if we can't make a **BezierShape**, then this is used. The shape is asked to convert to a **PolyShape**, and then the **PolyShape** is converted to a **BezierShape**. This is a very poor conversion, as all it does is make a linear spline out of the **PolyShape**.

```
// If the shape can convert itself to a BezierShape, have it do so!  
BezierShape bShape;  
if (shape->CanMakeBezier())  
    shape->MakeBezier(t, bShape);  
else {  
    PolyShape pShape;  
    shape->MakePolyShape(t, pShape);  
    bShape = pShape; // UGH -- Convert it from a PolyShape -- not  
    good!  
}
```

Next, the curves are organized into a hierarchy. This automatically figures out the shape nesting and directions for proper capping.

```
ShapeHierarchy hier;  
bShape.OrganizeCurves(t, &hier);
```

Next we need to reverse the shapes whose direction is incorrect for the hierarchy. The hierarchy calculated above contains a **BitArray** that describes which shapes need to be reversed. This is passed into the reverse method of the **BezierShape** to tell it which shapes to reverse.

```
// Need to flip the reversed polys...  
bShape.Reverse(hier.reverse);
```

At this point the **BezierShape** is all set up with the proper clockwise/counter-clockwise ordering on all the polygons. Next the extrude modifier generates the patches. You may refer to the full source of **EXTRUDE.CPP** to see how this is done.

The next step is to create the caps. This begins by instantiating a **PatchCapInfo** class and asking the **BezierShape** to make a cap. This fills up the **PatchCapInfo** class with all the information it needs to create a cap.

```
PatchCapInfo capInfo;  
bShape.MakeCap(t, capInfo);
```

After this is done, the **PatchCapInfo** is cached within the shape. Therefore if this is needed again, no work needs to be done.

Next, a **PatchCapper** object is created. This is done by passing the **BezierShape** as an argument to the constructor. This gets the **PatchCapper** ready for the topology of the shape. Developers don't need to understand the inner workings of the **PatchCapper**, it's just a tool used to aide in capping.

```
// Build information for capping  
PatchCapper capper(bShape);
```

Below is the code where the start of the extrusion is capped. Inside the capper is a **PatchCapPoly**. There is one for each polygon in the shape. The **PatchCapPoly** needs to know the vertex number in the patch mesh that corresponds to the given knot in the bezier spline. This is done by calling **SetVert()** on the **PatchCapPoly**. After this is done, the same thing happens for each of the vectors when **SetVec()** is called.

```
if(capStart) {  
  vert = 0;  
  int baseVec = 0;  
  for(poly = 0; poly < polys; ++poly) {  
    Spline3D *spline = bShape.splines[poly];  
    PatchCapPoly &capline = capper[poly];  
    int lverts = spline->KnotCount();  
    for(int v = 0; v < lverts; ++v)  
      // Gives this vert's location in the mesh!  
      capline.SetVert(v, vert++);  
    vert += lverts * levels;  
  }  
}
```

```

vec = baseVec;
int lvecs = spline->Segments() * 2;
for(v = 0; v < lvecs; ++v)
  // Gives this vec's location in the mesh!
  capline.SetVec(v, vec++);
  baseVec += lvecs * (levels + 1) + spline->KnotCount() * levels * 2;
}

```

There are vectors generated inside the patch cap. In the case of a SurfRev for example, the end cap might be rotated, or scaled in some manner. A matrix is required so the capper knows how to orient the vectors into the correct location.

```

// Create a work matrix for capping
Matrix3 mat = TransMatrix(offset1);

```

The final step is to cap the patch mesh. This is done using a method of the capper named **CapPatchMesh()**. This method is passed the output patch mesh, the **PatchCapInfo**, a flag that indicates if the cap should be flipped, the smoothing group number for all the patches in the cap, and a pointer to the orientation matrix.

```

capper.CapPatchMesh(pmesh, capInfo, TRUE, 16, &mat);

```

Once this is done the shape has been capped with a patch.

## Modifier Pipeline Note

The ShapeObject class has a special method, **CopyBaseData()**, which is used by derived classes to make sure that, when they copy themselves, they are also copying the data in the **ShapeObject**. This is usually used in the assignment operator of derived classes. It is also used in the **ShallowCopy** method of objects that are passed up the modifier pipeline. In this case, it is VITAL that you wrap the **CopyBaseData** call in Suspend and Resume calls to the undo mechanism:

```

theHold.Suspend();
CopyBaseData(*fob);
theHold.Resume();

```

If this is not done, when certain undo functions are performed, a crash will occur

due to the temporary pipeline object being destroyed. Just remember to wrap the call as shown in any code that is used as part of the modifier pipeline evaluation.

## **Common Problems and Solutions**

This section provides a series of commonly-encountered problems and their solutions.

**Problem:**

Your DLL compiles and links fine, but when you run 3ds max it complains that **LibVersion()** is not implemented. You know that you implemented this, so what is going on?

**Solution:**

Did you remember to create a **.DEF** file with this listed, and if so did you remember to include the file in your project?

**Problem:**

When you link **InitCommonControls** comes up unresolved.

**Solution:**

Did you remember to link in **COMCTL32.LIB** (which is not included by default by Visual C++ in the list of libraries to link)?

**Problem:**

You have a dialog proc to process a button in your user interface. The code is in place to process the button but it never gets called.

**Solution:**

You may have a macro redefinition for one of the buttons in another header file in your project. The compiler takes the first definition and uses it instead of your definition. Therefore yours never gets processed. The compiler will flag this condition as a warning but not as an error.

**Problem:**

When you de-allocate memory the system crashes. You have checked that the item being de-allocated exists and is OK to delete. What is happening?

**Solution:**

In Visual C++ the debug and release C runtime libraries use different heap management. This means that allocating an object in debug mode and de-allocating it in release mode (and vice versa) can cause a crash. You need to change your settings for your DEBUG configuration. Choose **Build/Settings...** from the pulldown menus. From the **Settings For:** section choose your Debug configuration. From the **C/C++** tab, under the **Categories:** drop down list choose **Code Generation**. From the **Use runtime library:** drop down list choose **Multithreaded DLL** instead of **Debug Multithreaded DLL**.

**Problem:**

You have a plug-in which when compiled under the hybrid settings works fine. When you go to make it in release mode, it works fine except for any time it is used and 3ds max is exited you get a "Runtime error. R6017 unexpected multithread lock error".

**Solution:**

The project settings for the Release configuration in the code generation section for run-time library are set to DLL instead of Multithreaded DLL. Changing to Multithreaded DLL corrects the problem.

**Problem:**

You have created a plug-in that runs fine on certain machines but on other machines it simply won't load.

**Solution:**

You probably have a missing system DLL. The easiest way to see what DLLs your plug-in requires is to use the **DUMPBIN.EXE** program (which comes with Visual C++ and is usually found in **\MSDEV\BIN**) and use the **/IMPORTS** switch. This will tell you all of the DLLs that your DLL depends upon. Make sure the machines that need to run the plug-in have the proper DLLs.

For example: **dumpbin /imports utility.dlu**

**Problem:**

You have a plug-in whose interface won't show up in the command panel yet everything seems fine code wise. What's wrong?

**Solution:**

You may have forgotten to enter the class names for the custom controls in the VC++ dialog editor. See the Advanced Topic [Custom User Interface Controls](#) -- especially the section How to a Create a Rollup Page using the Custom Controls for a description of the values to be used in the Class field of the Custom Control Properties dialog.

# Class Interface

See Also: [Class FPStaticInterface](#), [Class ViewExp](#), [Class INode](#), [Class INodeTab](#), [Class CommandMode](#), [Class Interval](#), [Class Renderer](#), [Class Modifier](#), [Class Control](#), [Class Atmospheric](#), [Class Point3](#), [Class Matrix3](#), [Class ModContext](#), [Class ReferenceTarget](#), [Template Class Tab](#)

```
class Interface : public FPStaticInterface
```

## Description:

This class provides an interface for calling functions that are exported from the 3DStudio MAX executable. All the methods in this class are implemented by MAX itself.

Methods are provided for putting up many standard MAX dialogs, working with command modes, working with viewports, controlling the prompt, toolbar and status areas, and working with selection sets. There are also methods for creating objects and nodes in the scene, setting and getting the current time and animation ranges, working with the standard directories of MAX, and many more. See the Method Groups listed below for a breakdown of the various kinds of methods available.

## Important Note for Finding Specific Methods:

To find documentation for a specific method choose the **Help Topics** button and the **Index** tab, then type:

**methods**, followed by the name of the method. Note the space after the comma -- this is required.

For example, enter

**methods, ForceCompleteRedraw**

This will jump directly to the **Interface::ForceCompleteRedraw()** method.

Note: When editing in the command panel, a developer gets passed an interface pointer during **BeginEditParams()**. This pointer is only valid before **EndEditParams()** is finished. A developer should not hang on to this pointer and call methods on it after **EndEditParams()** has returned.

## Method Groups

These hyperlinks take you to the start of groups of related methods within the class.

## **Methods:**

## **Animation / Time / Playback Related Methods**

**Prototype:****virtual TimeValue GetTime()=0;****Remarks:**

Returns the current time, i.e. the frame slider position. See the Advanced Topics section on [Time](#) for an overview of time in MAX.

**Prototype:****virtual void SetTime(TimeValue t, BOOL redraw=TRUE)=0;****Remarks:**

Set the current time, updates the frame slider, and optionally redraws the viewports.

**Parameters:****TimeValue t**

The time to set as current.

**BOOL redraw=TRUE**

If set to FALSE, the current time will be set to the specified time but the viewports will not be redrawn.

**Prototype:****virtual Interval GetAnimRange()=0;****Remarks:**

Returns the current setting of the animation interval. This can be used to get the total number of frames in the animation. Note: The values stored in the interval returned represent ticks not frames.

**Prototype:****virtual void SetAnimRange(Interval range)=0;****Remarks:**

Sets the animation interval. Note: The values passed in the interval are ticks not frames.

**Parameters:****Interval range**

Specifies the new animation range to set.

**Prototype:**

**virtual void StartAnimPlayback(int selOnly=FALSE)=0;**

**Remarks:**

Begins animation playback. The animation may be played for all objects, or just the selected ones.

**Parameters:**

**int selOnly=FALSE**

If TRUE only the selected objects are updated as the animation is played; otherwise all objects are.

**Prototype:**

**virtual void EndAnimPlayback()=0;**

**Remarks:**

Terminates the animation playback.

**Prototype:**

**virtual BOOL IsAnimPlaying()=0;**

**Remarks:**

Returns TRUE if the animation is currently playing; otherwise FALSE.

**Prototype:**

**virtual void EnableAnimateButton(BOOL enable)=0;**

**Remarks:**

Sets the state of the Animate button to enabled or disabled. When disabled the user cannot turn on Animate mode.

Note: Developers have additional functions available for controlling the state of the animate button. These functions are defined in **\MAXSDK\INCLUDE\CONTROL.H**. These functions can be used to determine if animating is on or off, or toggle it on and off without affecting the appearance of the Animate button in the user interface. In this way, a user will not be aware anything is happening. See [List of Additional Controller Related](#)

[Functions](#) for documentation.

**Parameters:**

**BOOL enable**

Pass TRUE to enable the button; FALSE to disable it.

**Prototype:**

**virtual BOOL IsAnimateEnabled()=0;**

**Remarks:**

Returns TRUE if the Animate button is enabled; otherwise FALSE. See the note in the method above as well.

**Prototype:**

**virtual void SetAnimateButtonState(BOOL onOff)=0;**

**Remarks:**

Turns the animate button (and animate mode) on or off.

**Parameters:**

**BOOL onOff**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**virtual BOOL GetRealTimePlayback()=0;**

**Remarks:**

Returns the state of the real-time animation playback toggle.

**Prototype:**

**virtual void SetRealTimePlayback(BOOL realTime)=0;**

**Remarks:**

Sets the state of the real-time animation playback toggle.

**Parameters:**

**BOOL realTime**

TRUE if frames should be dropped if necessary for the animation to play back in real time. FALSE specifies that every frame should be played.

**Prototype:****virtual BOOL GetPlayActiveOnly()=0;****Remarks:**

This method returns the flag controlling which viewports are updated when the animation is played.

**Return Value:**

TRUE if all the viewports are updated during play; FALSE if only the active viewport is updated.

**Prototype:****virtual void SetPlayActiveOnly(BOOL playActive)=0;****Remarks:**

This method sets the flag controlling which viewports are updated when the animation is played. This may be all the viewports, or just the active one.

**Parameters:****BOOL playActive**

If TRUE, only the active viewport is updated as the animation is played; otherwise all the viewports are updated.

**Auto Backup Time Related Methods****Prototype:****virtual float GetAutoBackupTime()=0;****Remarks:**

This method is available in release 2.0 and later only.  
Returns the auto backup interval in minutes.

**Prototype:****virtual void SetAutoBackupTime(float minutes)=0;****Remarks:**

This method is available in release 2.0 and later only.  
Sets the auto backup time interval.

**Parameters:**

**float minutes**

The time to set in minutes.

**Prototype:**

**virtual BOOL AutoBackupEnabled()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if auto backup mode is enabled; FALSE if it's disabled.

**Prototype:**

**virtual void EnableAutoBackup(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Enables or Disables the auto backup system.

**Parameters:**

**BOOL onOff**

TRUE to turn it on; FALSE to turn it off.

## **Action Table and Menu Manager Methods**

**Prototype:**

**virtual IActionManager\* GetActionManager()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the Action Manager interface class. The action manager is used to manage ActionTables which plug-ins can use to export operations that can be tied to UI elements like keyboard shortcuts, menus and toolbars. See [Class IActionManager](#).

**Prototype:**

**virtual IMenuManager\* GetMenuManager()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the manager for customizable menus. See [Class IMenuManager](#).

## Axis System Related Methods

### Prototype:

```
virtual Matrix3 GetTransformAxis(INode *node,int  
subIndex,BOOL* local = NULL)=0;
```

### Remarks:

An item that is doing sub-object hit testing gets to specify what their sub-object axes systems are. For example a mesh may have separate coordinate systems for every face or group of selected faces, while, for instance, a bend modifier has its own axes system for the gizmo. This method gets the axes system for a particular node. Each node may have several axes systems identified by an index.

See **EDITMESH.CPP** for an example of use.

### Parameters:

**INode \*node**

The node to get the axis coordinates system of.

**int subIndex**

The index of the axis system of the node.

**BOOL\* local = NULL**

If 'local' is not NULL, it will be set to TRUE if the center of the axis is the pivot point of the node, FALSE otherwise.

### Return Value:

The axis system of the node.

### Prototype:

```
virtual int GetNumAxis()=0;
```

### Remarks:

This returns the number of axis tripods in the scene. When transforming multiple sub-objects, in some cases each sub-object is transformed in a different space.

**Return Value:**

One of the following values:

**NUMAXIS\_ZERO**

Nothing to transform.

**NUMAXIS\_ALL**

Use only one axis.

**NUMAXIS\_INDIVIDUAL**

Do all, one at a time.

**Prototype:**

```
virtual Matrix3 GetTransformAxis(INode *node, int subIndex,  
BOOL* local = NULL)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the axis which defines the space in which transforms should take place.

**Parameters:**

**INode \*node**

The object the axis system should be based on.

**int subIndex**

The sub object which the axis system should be based on (the thing the user clicked on).

**BOOL\* local = NULL**

If 'local' is not NULL, it will be set to TRUE if the center of the axis is the pivot point of the node, FALSE otherwise.

**Return Value:**

A matrix representing the axis system that transforms take place in.

**Prototype:**

```
virtual void LockAxisTripods(BOOL onOff)=0;
```

**Remarks:**

This method locks axis tripods so that they will not be updated.

**Parameters:**

**BOOL onOff**

TRUE to lock; FALSE to unlock.

**Prototype:**

**virtual BOOL AxisTripodLocked()=0;**

**Remarks:**

This method returns TRUE if axis tripods are locked.

## **Bitmap / Texmap Related Methods**

**Prototype:**

**virtual void FreeSceneBitmaps()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method traverses the scene reference hierarchy, calling

**Animatable::FreeAllBitmaps()** on every Animatable. This will free up all the memory used by bitmaps.

**Prototype:**

**virtual void EnumAuxFiles(NameEnumCallback& nameEnum,  
DWORD flags)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method may be used to enumerate all the bitmap files in the scene. The **flags** allow control over which files are enumerated.

**Parameters:**

**NameEnumCallback& nameEnum**

The callback, called once for each bitmap. See [Class NameEnumCallback](#).

**DWORD flags**

See [List of EnumAuxFiles\(\) Flags](#).

**Prototype:**

**virtual void RenderTexmap(Texmap \*tex, Bitmap \*bm, float scale3d=1.0f, BOOL filter=FALSE, BOOL display=FALSE)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method may be called to render a texmap (or an entire texmap tree) to the specified bitmap.

**Parameters:**

**Texmap \*tex**

The Texmap to render to a bitmap.

**Bitmap \*bm**

A pointer to a bitmap to render to. This bitmap must be created at the resolution you wish to render to.

**float scale3d=1.0f**

This is a scale factor applied to 3D Texmaps. This is the scale of the surface in 3d space that is mapped to UV. This controls how much of the texture appears in the bitmap representation.

**BOOL filter=FALSE**

If TRUE the bitmap is filtered. It is quite a bit slower to rescale bitmaps with filtering on.

**BOOL display=FALSE**

If TRUE the resulting bitmap is displayed using the virtual frame buffer; otherwise it is not.

**Prototype:**

**virtual bool CanImportBitmap(const TCHAR\* filename)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will check if the system can import the specified bitmap file.

**Parameters:**

**const TCHAR\* filename**

The file name to check.

**Return Value:**

TRUE if the specified file is a bitmap file of a format that is supported by one of the bitmap reader plug-ins; otherwise FALSE.

**Prototype:**

**virtual bool CaptureSubObjectRegistration(bool OnOff, Class\_ID cid)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to lock and unlock subobject mode registrations and is primarily used by the FileLink wrapper classes acting as proxies to other classes in 3D Studio VIZ. When a class calls this method with OnOff set to TRUE, then other classes are prevented from registering new subobject modes. This continues until the original class "releases" by calling CaptureSubObjectModes(FALSE, myClassID). The second argument insures that only the class which does the capture can do the release. Note that this is used only by certain VIZ plugins.

**Parameters:**

**bool OnOff**

TRUE to prevent other classes from registering new subobject modes.

**Class\_ID cid**

The class ID.

**Return Value:**

TRUE is successful, otherwise FALSE.

**Prototype:**

**virtual bool DownloadUrl(HWND hwnd, const TCHAR\* url, const TCHAR\* filename, DWORD flags = 0)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method simplifies downloading files from any given URL and displays a floating progress dialog.

**Parameters:**

**HWND hwnd**

The window handle for owner window (required for the progress floating dialog).

**const TCHAR\* url**

The string for the resource/file to download.

**const TCHAR\* filename**

The target location and filename for the downloaded file.

**DWORD flags = 0**

Additional controls to the download behavior. Currently only one flag is supported, **DOWNLOADDLG\_NOPLACE**, which hides an option in the progress dialog that allows the user to place (move) a dropped object immediately after being dropped.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

```
virtual INode* GetImportCtxNode(void)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

On drag-and-drop, if the drop type is a file, the drop handler searches for an importer plugin that can handle the file (based on its extension). Some drop operations, such as bitmaps and material XML files, can or must be dropped on to an object in the scene.

**Return Value:**

The node that the operation is performed on, if one is "hit" at the drop location. It returns NULL if no nodes were found at the drop location.

**Callback / Notification Registration**

Related to callbacks is [Structure NotifyInfo](#) and its associated functions.

Please see this topic for additional ways a developer can register a callback for events like the user performing a File/Reset or File/New, the system unit settings changing, etc.

**Prototype:**

**virtual void RegisterTimeChangeCallback(TimeChangeCallback \*tc)=0;**

**Remarks:**

Registers a callback object that will get called every time the user changes the MAX frame slider.

**Parameters:**

**TimeChangeCallback \*tc**

Points to the callback object to register. See: [Class TimeChangeCallback](#).

**Prototype:**

**virtual void**

**UnRegisterTimeChangeCallback(TimeChangeCallback \*tc)=0;**

**Remarks:**

This method un-registers the time change callback.

**Parameters:**

**TimeChangeCallback \*tc**

Points to the callback object to un-register. See: [Class TimeChangeCallback](#).

**Prototype:**

**virtual void**

**RegisterCommandModeChangedCallback(CommandModeChange \*cb)=0;**

**Remarks:**

Register a callback object that will get called when the user changes the command mode.

**Parameters:**

**CommandModeChangedCallback \*cb**

Points to the callback object to register. See [Class CommandModeChangedCallback](#).

**Prototype:**

**virtual void**

**UnRegisterCommandModeChangedCallback(CommandModeChar \*cb)=0;**

**Remarks:**

Un-registers the command mode change callback object.

**Parameters:**

**CommandModeChangedCallback \*cb**

Points to the callback object to un-register. See [Class CommandModeChangedCallback](#).

**Prototype:**

**virtual void RegisterViewportDisplayCallback(BOOL preScene, ViewportDisplayCallback \*cb)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Registers a **ViewportDisplayCallback** whose **Display()** method will be called to allow a plug-in to draw in the MAX viewports.

**Parameters:**

**BOOL preScene**

If TRUE the callback will be called before objects are rendered (typically, but not always); if FALSE the callback is called after the objects are rendered.

In some cases redrawing the viewports may take two passes; once to re-render the background plane and once to rerender the foreground plane. In this case the order of events would be:

Call pre callbacks

Render scene

Call post callbacks

Call pre callbacks

Render scene

Call post callbacks

The two calls to callbacks in the middle are neither pre nor post callbacks. However you could also look at this as two separate redraws.

**ViewportDisplayCallback \*cb**

Points to the callback object. See [Class ViewportDisplayCallback](#).

**Prototype:**

```
virtual void UnRegisterViewportDisplayCallback(BOOL  
preScene, ViewportDisplayCallback *cb)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Call this method to un-register the viewport display callback object.

**Parameters:**

**BOOL preScene**

If TRUE the callback will be called before object are rendered (typically, but not always); if FALSE the callback is called after the objects are rendered.

**ViewportDisplayCallback \*cb**

Points to the callback object. See [Class ViewportDisplayCallback](#).

**Prototype:**

```
virtual void NotifyViewportDisplayCallbackChanged(BOOL  
preScene, ViewportDisplayCallback *cb)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to inform MAX that the viewport callback has changed. This is similar to when an object that is part of the reference hierarchy changes and it needs to call **NotifyDependents()** with the message **REFMSG\_CHANGE** to inform the items that depend on it. In a sense a **ViewportDisplayCallback** is like an object in the scene in that it has a **Display()** method that is called. However, the callback is not actually an object that is part of the reference hierarchy so it cannot send a **REFMSG\_CHANGE** message when it changes. So this method provides the equivalent functionality. If the callback changes this method needs to be called.

To understand why this is needed consider that if a plug-in called **RedrawViews()** five times in a row, the viewports may be redrawn the first time (if something has changed), but the next four calls won't do anything.

This is because MAX maintains some flags that indicate if things have changed or not and these flags are reset on the first redraw to indicate that everything is up to date. Therefore, when a **ViewportDisplayCallback** changes, it needs to call this method to let MAX know that changes have been made and the viewports indeed need to be redrawn the next time **RedrawViews()** is called.

**Parameters:**

**BOOL preScene**

If TRUE the callback will be called before objects are rendered (typically, but not always); if FALSE the callback is called after the objects are rendered.

**ViewportDisplayCallback \*cb**

Points to the callback object. See [Class ViewportDisplayCallback](#).

**Prototype:**

```
virtual void RegisterExitMAXCallback(ExitMAXCallback  
*cb)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Registers a **ExitMAXCallback** whose **Exit()** method will be called when MAX is about to exit. The return value from the callback allows the plug-in to decide if MAX exits or not.

**Parameters:**

**ExitMAXCallback \*cb**

Points to the callback object. See [Class ExitMAXCallback](#).

**Prototype:**

```
virtual void UnRegisterExitMAXCallback(ExitMAXCallback  
*cb)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Un-registers the exit callback so it's no longer called.

**Parameters:**

## **ExitMAXCallback \*cb**

Points to the callback object. See [Class ExitMAXCallback](#).

### **Prototype:**

```
virtual void RegisterAxisChangeCallback(AxisChangeCallback  
*cb)=0;
```

### **Remarks:**

Registers a callback object that will get called any time the user changes the reference coordinate system by:

Changing the transform coordinate system drop-down menu.

Changing the state of the transform center fly-off.

Changing X, Y, Z, XY, YZ, ZX constraint buttons/fly-off.

Using an accelerator or anything else that changes the above.

### **Parameters:**

**AxisChangeCallback \*cb**

Points to the callback to register. See [AxisChangeCallback](#).

### **Prototype:**

```
virtual void UnRegisterAxisChangeCallback(AxisChangeCallback  
*cb)=0;
```

### **Remarks:**

Un-registers the axis change callback.

### **Parameters:**

**AxisChangeCallback \*cb**

Points to the callback to un-register. See [AxisChangeCallback](#).

### **Prototype:**

```
virtual void  
RegisterRedrawViewsCallback(RedrawViewsCallback *cb)=0;
```

### **Remarks:**

Registers a call back object that gets called every time the viewports are redrawn. The **proc()** method is called after the views are finished redrawing.

**Parameters:**

**RedrawViewsCallback \*cb**

Points to the callback object whose **proc()** method is called when the viewports are redrawn. See [Class RedrawViewsCallback](#).

**Prototype:**

**virtual void**

**UnRegisterRedrawViewsCallback(RedrawViewsCallback \*cb)=0;**

**Remarks:**

Un-registers the viewport redraw callback.

**Parameters:**

**RedrawViewsCallback \*cb**

Points to the callback object to un-register. See [Class RedrawViewsCallback](#).

**Prototype:**

**virtual void RegisterSelectFilterCallback(SelectFilterCallback \*cb)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Registers a call back object that gets called to filter the selection of nodes.

**Parameters:**

**SelectFilterCallback \*cb**

Points to the callback object to register. See [Class SelectFilterCallback](#).

**Prototype:**

**virtual void UnRegisterSelectFilterCallback(SelectFilterCallback \*cb)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Un-registers the select filter callback.

**Parameters:**

### **SelectFilterCallback \*cb**

Points to the callback object to un-register. See [Class SelectFilterCallback](#).

#### **Prototype:**

```
virtual void RegisterDisplayFilterCallback(DisplayFilterCallback *cb)=0;
```

#### **Remarks:**

This method is available in release 4.0 and later only.

Registers a call back object that gets called to filter the display of nodes.

#### **Parameters:**

### **DisplayFilterCallback \*cb**

Points to the callback object to register. See [Class DisplayFilterCallback](#).

#### **Prototype:**

```
virtual void UnRegisterDisplayFilterCallback(DisplayFilterCallback *cb)=0;
```

#### **Remarks:**

This method is available in release 4.0 and later only.

Un-registers the display filter callback.

#### **Parameters:**

### **DisplayFilterCallback \*cb**

Points to the callback object to un-register. See [Class DisplayFilterCallback](#).

#### **Prototype:**

```
virtual PickModeCallback* GetCurPickMode()=0;
```

#### **Remarks:**

This method is available in release 4.0 and later only.

If a Pick Mode is on top of the command stack, then this function will return the **PickModeCallback**. If the Pick Mode is not on top of the command stack the it returns NULL.

## Creation Related Methods

### Prototype:

```
virtual INode *CreateObjectNode( Object *obj )=0;
```

### Remarks:

Creates a new node in the scene with the given object. Normally a developer will use the standard creation methods for procedural objects and this method is not used. However if the developer wants to handle the creation process on their own they may need to use this method. See Also: [Object Creation Methods](#).

### Parameters:

**Object \*obj**

Pointer to the Object to create.

### Return Value:

Pointer to the node created.

### Prototype:

```
virtual void *CreateInstance(SClass_ID superID, Class_ID classID)=0;
```

### Remarks:

Creates an instance of a registered class. This will call **Create()** on the class descriptor.

### Parameters:

**SClass\_ID superID**

The super class ID of the item to create an instance of.

**Class\_ID classID**

The class ID of the item to create an instance of. See [Class Class\\_ID](#).

### Return Value:

Pointer to the created instance.

### Also Note:

There is a global method that duplicates the functionality of this class method to let you create an instance of any registered class wherever you are (without the interface pointer):

**void \*CreateInstance(SClass\_ID superID, Class\_ID classID);**

**Prototype:**

**virtual void NonMouseCreate(Matrix3 tm)=0;**

**Remarks:**

This creates a new object/node without going through the usual create mouse proc sequence. The matrix is relative to the construction plane. This must be called during the creation phase of an object. For example, the procedural sphere uses it when the user clicks on the 'Create' button after they type in the parameters for the sphere. See [Object Creation Methods](#).

**Parameters:**

**Matrix3 tm**

The transformation matrix relative to the construction plane.

**Prototype:**

**virtual void NonMouseCreateFinish(Matrix3 tm)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is presently only used in the Line object. It's used for repositioning the pivot point of the object at the end of the creation process. You simply pass it the new matrix, and the creation manager sets the TM for the node being created to the given TM \* the construction plane TM.

**Parameters:**

**Matrix3 tm**

The transformation matrix relative to the construction plane for the node.

**Prototype:**

**virtual void StopCreating()=0;**

**Remarks:**

When a plug-in object implements its own **ClassDesc::BeginCreate()** / **ClassDesc::EndCreate()** it can cause **EndCreate()** to be called by calling this method. See [Object Creation Methods](#).

**Prototype:**

```
virtual int BindToTarget(INode *laNode, INode *targNode)=0;
```

**Remarks:**

This method binds a node to a target using a lookat controller.

**Parameters:**

**INode \*laNode**

Pointer to the node to assign the lookat controller to.

**INode \*targNode**

Pointer to the target node.

**Return Value:**

Returns TRUE if the node was bound; otherwise FALSE.

**Sample Code:**

This method is used in

**\MAXSDK\SAMPLES\OBJECTS\CAMERA.CPP.**

## Command Modes

For more information on CommandModes, see the Advanced Topics section [Command Modes and Mouse Procs.](#)

**Prototype:**

```
virtual void PushCommandMode(CommandMode *m)=0;
```

**Remarks:**

This method pushes the specified command mode on the stack. Typically this is used by developers handling their own creation using

**ClassDesc::BeginCreate()**. See [Class ClassDesc](#) for more details.

Note: This method works as documented but a developer may not want to use it. The problem is that other modes can be pushed on the stack (such as viewport transformation modes) and it becomes complicated to track when it is OK to pop your mode. See the methods below for alternatives (such as **SetCommandMode**).

**Parameters:**

**CommandMode \*m**

A pointer to the command mode to push.

**Prototype:**

**virtual void SetCommandMode(CommandMode \*m)=0;**

**Remarks:**

This method sets the top of the stack to the specified command mode. A developer should call **DeleteMode()** to delete their command mode when done using it.

**Parameters:**

**CommandMode \*m**

The command mode to set.

**Prototype:**

**virtual void PopCommandMode()=0;**

**Remarks:**

Pops the command mode off the top of the stack.

**Prototype:**

**virtual CommandMode\* GetCommandMode()=0;**

**Remarks:**

Returns the current mode on the top of the stack.

**Prototype:**

**virtual int GetCommandStackSize();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of command modes in the command mode stack.

**Prototype:**

**virtual CommandMode\* GetCommandStackEntry(int entry);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the command mode at the specified position in the command mode stack. A developer may use this to determine if their

command mode is in the stack.

**Parameters:**

**int entry**

The index into the command mode stack of the entry to get. Pass 0 to get the current command mode.

**Prototype:**

**virtual void SetStdCommandMode(int cid)=0;**

**Remarks:**

This is the typical method called by the developer to handle mouse interaction. It allows the developer to set the command mode to one of the standard command modes. For example: **CID\_OBJMOVE, CID\_OBJROTATE, CID\_OBJSCALE, CID\_OBJUSCALE, CID\_OBJsquash, CID\_OBJSELECT**, etc.

**Parameters:**

**int cid**

The index of the command mode to set. See [List of Standard Command Modes](#) to review the full list.

**Prototype:**

**virtual void PushStdCommandMode(int cid)=0;**

**Remarks:**

Allows the developer to push one of the standard command modes on the command stack. For example: **CID\_OBJMOVE, CID\_OBJROTATE, CID\_OBJSCALE, CID\_OBJUSCALE, CID\_OBJsquash, CID\_OBJSELECT**, etc.

**Parameters:**

**int cid**

The index of the command mode to set. See [List of Standard Command Modes](#) to review the full list.

**Prototype:**

**virtual void RemoveMode(CommandMode \*m)=0;**

**Remarks:**

Removes the specified command mode from the stack. This method pops items off the command mode stack up to and including the specified mode. The top item in the stack is then set as the active command mode. As usual, **ExitMode()** is called on the specified mode before it is popped and **EnterMode()** is called on the newly active mode.

**Parameters:**

**CommandMode \*m**

Points to the command mode to remove.

**Prototype:**

**virtual void DeleteMode(CommandMode \*m)=0;**

**Remarks:**

If the developer sets or pushes a command mode, this method should be called when the developer is done with the mode to ensure that it is no longer anywhere in the stack. If the mode is already deleted this method does nothing.

Note: It is normal for a developer to set the 'Select and Move' command mode to be the active one if their mode was at the top of the stack and is being deleted. For instance:

```
ip->SetStdCommandMode(CID_OBJMOVE);
```

```
ip->DeleteMode(&myCMode);
```

**Parameters:**

**CommandMode \*m**

The command mode to delete.

## **Command Panel and Rollup Page methods**

**Prototype:**

```
virtual HWND AddRollupPage(HINSTANCE hInst, TCHAR  
*dlgTemplate, DLGPROC dlgProc, TCHAR *title, LPARAM  
param=0, DWORD flags=0, int category =
```

**ROLLUP\_CAT\_STANDARD)=0;**

**Remarks:**

This method is used to add a rollup page to the command panel. It returns the window handle of the rollup page.

**Parameters:**

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the messages sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar of the rollup page.

**LPARAM param=0**

Any specific data to pass along may be stored here. This may be later retrieved using the **GetWindowLong()** call from the Windows API if it was set in the window using **SetWindowLong()**.

For example, at the beginning of the dialog proc do something like:

```
BOOL CALLBACK MyDlgProc(  
    HWND hWnd, UINT message, WPARAM wParam, LPARAM  
    lParam) {
```

```
    MyUtil *u = (MyUtil *)GetWindowLong(hWnd,  
    GWL_USERDATA);  
    if (!u && message != WM_INITDIALOG ) return FALSE;  
    ...
```

Then inside the code block handling the **WM\_INITDIALOG** message do something like:

```
switch (message) {  
case WM_INITDIALOG:  
    u = (MyUtil *)lParam;  
    SetWindowLong(hWnd, GWL_USERDATA, (LONG)u);  
    ...
```

Then later in the dialog you can access the object passed in -- in the case above an instance of **MyUtil** (using **u->**).

### **DWORD flags=0**

The following flag value may be used:

#### **APPENDROLL\_CLOSED**

Starts the page in the rolled up (closed) state.

### **int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

### **Sample Code:**

```
hBendParams = ip->AddRollupPage(  
    hInstance,  
    MAKEINTRESOURCE(IDD_BEND_ROLLUP),  
    BendParamDialogProc,  
    _T("Parameters"),  
    (LPARAM)this );
```

### **Return Value:**

The window handle of the rollup page.

### **Prototype:**

```
virtual HWND AddRollupPage(HINSTANCE hInst,  
    DLGTEMPLATE *dlgTemplate, DLGPROC dlgProc, TCHAR
```

**\*title, LPARAM param=0, DWORD flags=0, int category =  
ROLLUP\_CAT\_STANDARD)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to add a rollup page to the command panel. It returns the window handle of the rollup page. This method is currently not being used.

**Parameters:**

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the messages sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar of the rollup page.

**LPARAM param=0**

Any specific data to pass along may be stored here. This may be later retrieved using the **GetWindowLong()** call from the Windows API if it was set in the window using **SetWindowLong()**.

**DWORD flags=0**

The following flag value may be used:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up (closed) state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**. When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The window handle of the rollup page.

**Prototype:**

**virtual void DeleteRollupPage(HWND hRollup)=0;**

**Remarks:**

Removes a rollup page and destroys it.

**Parameters:**

**HWND hRollup**

The window handle of the rollup window. This is the handle returned from **AddRollupPage()**.

**Prototype:**

**virtual HWND ReplaceRollupPage(HWND hOldRollup, HINSTANCE hInst, TCHAR \*dlgTemplate, DLGPROC dlgProc, TCHAR \*title, LPARAM param=0, DWORD flags=0, int category = ROLLUP\_CAT\_STANDARD)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This replaces an existing rollup with another one and (deletes the original).

**Parameters:**

**HWND hOldRollup**

The window handle of the old rollup.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**TCHAR \*dlgTemplate**

The dialog template for the rollup page.

## **DLGPROC dlgProc**

The dialog proc to handle the messages sent to the rollup page.

## **TCHAR \*title**

The title displayed in the title bar of the rollup page.

## **LPARAM param=0**

Any specific data to pass along may be stored here.

## **DWORD flags=0**

The following flag value may be used:

### **APPENDROLL\_CLOSED**

Starts the page in the rolled up (closed) state.

## **int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the **RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

## **Return Value:**

The window handle of the rollup.

## **Prototype:**

```
virtual HWND ReplaceRollupPage(HWND hOldRollup,  
HINSTANCE hInst, TCHAR *dlgTemplate, DLGPROC dlgProc,  
TCHAR *title, LPARAM param=0,DWORD flags=0, int category  
= ROLLUP_CAT_STANDARD)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This replaces an existing rollup with another one and (deletes the original).

This method is currently not being used.

**Parameters:****HWND hOldRollup**

The window handle of the old rollup.

**HINSTANCE hInst**

The DLL instance handle of the plug-in.

**DLGTEMPLATE \*dlgTemplate**

The dialog template for the rollup page.

**DLGPROC dlgProc**

The dialog proc to handle the messages sent to the rollup page.

**TCHAR \*title**

The title displayed in the title bar of the rollup page.

**LPARAM param=0**

Any specific data to pass along may be stored here.

**DWORD flags=0**

The following flag value may be used:

**APPENDROLL\_CLOSED**

Starts the page in the rolled up (closed) state.

**int category = ROLLUP\_CAT\_STANDARD**

The category parameter provides flexibility with regard to where a particular rollup should be displayed in the UI. RollupPanels with lower category fields will be displayed before RollupPanels with higher category fields. For RollupPanels with equal category value the one that was added first will be displayed first. Although it is possible to pass any int value as category there exist currently 5 different category defines: **ROLLUP\_CAT\_SYSTEM**, **ROLLUP\_CAT\_STANDARD**, and **ROLLUP\_CAT\_CUSTATTRIB**.

When using **ROLLUP\_SAVECAT**, the rollup page will make the provided category sticky, meaning it will not read the category from the

**RollupOrder.cfg** file, but rather save the category field that was passed as argument in the **CatRegistry** and in the **RollupOrder.cfg** file.

The method will take the category of the replaced rollup in case the flags

argument contains **ROLLUP\_USEREPLACEDCAT**. This is mainly done, so that this system works with param maps as well.

**Return Value:**

The window handle of the rollup.

**Prototype:**

**virtual IRollupWindow \*GetCommandPanelRollup()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns a rollup window interface to the command panel rollup. This interface provides methods for showing and hiding rollups, adding and removing rollup pages, etc. Note: This interface does not need to be released with **ReleaseIRollup()** as MAX takes care of this when it shuts down.

See [Class IRollupWindow](#).

**Prototype:**

**virtual void RollupMouseMessage(HWND hDlg, UINT message, WPARAM wParam, LPARAM lParam )=0;**

**Remarks:**

This method allows hand cursor scrolling in the command panel when the user clicks and drags the mouse in an unused area of the dialog. When the user mouse-es down in dead area of the command panel, the plug-in should pass mouse messages to this function which will pass them on to the rollup.

Note: This method is obsolete in MAX 2.0 and later. These messages no longer need to be passed along as this is handled internally.

**Parameters:**

**HWND hDlg**

The window handle of the dialog.

**UINT message**

The message sent to the dialog proc.

**WPARAM wParam**

Passed in to the dialog proc. Pass along to this method.

**LPARAM lParam**

Passed in to the dialog proc. Pass along to this method.

**Sample Code:**

```
case WM_LBUTTONDOWN: case WM_LBUTTONUP: case  
WM_MOUSEMOVE:  
ip->RollupMouseMessage(hDlg,message,wParam,lParam);
```

**Prototype:**

```
virtual int GetCommandPanelTaskMode()=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a value to indicate which branch of the command panel is currently active.

**Return Value:**

One of the following values:

```
TASK_MODE_CREATE  
TASK_MODE_MODIFY  
TASK_MODE_HIERARCHY  
TASK_MODE_MOTION  
TASK_MODE_DISPLAY  
TASK_MODE_UTILITY
```

**Prototype:**

```
virtual void SetCommandPanelTaskMode(int mode)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the branch of the command panel that is currently active.

**Parameters:**

**int mode**

One of the following values:

```
TASK_MODE_CREATE  
TASK_MODE_MODIFY
```

**TASK\_MODE\_HIERARCHY**  
**TASK\_MODE\_MOTION**  
**TASK\_MODE\_DISPLAY**  
**TASK\_MODE\_UTILITY**

## **Delete Key Notification**

### **Prototype:**

**virtual void RegisterDeleteUser(EventUser \*user)=0;**

### **Remarks:**

Registers a callback invoked when the user presses the Delete Key. This allows the developer to override the default processing of the Delete Key.

### **Parameters:**

**EventUser \*user**

Pointer to an instance of the [EventUser](#) class.

### **Sample Code:**

See **\\MAXSDK\\SAMPLES\\MODIFIERS\\EDITSPL.CPP**.

### **Prototype:**

**virtual void UnRegisterDeleteUser(EventUser \*user)=0;**

### **Remarks:**

Un-registers a Delete Key callback.

### **Parameters:**

**EventUser \*user**

Pointer to an instance of the [EventUser](#) class.

## **Dialogs -- Methods to Display MAX dialogs**

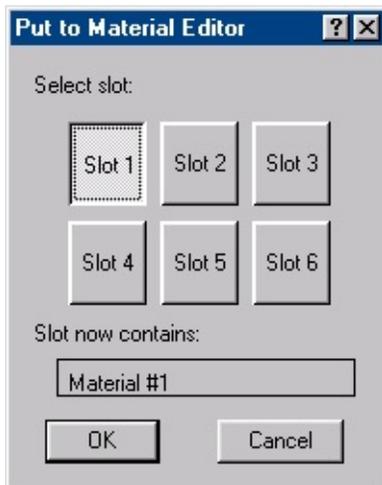

This section describes methods to put up many of the standard dialog boxes used by MAX. Some dialogs are accessed outside of this class. For the Arc Rotate dialog box see [Class ArcballDialog](#). For the modal or modeless color selector dialog see [Class ColorPicker](#). For a Win32 MessageBox() like function that supports 'Hold' and 'Don't show this dialog again' items see [List of Miscellaneous Utility Functions](#).

**Prototype:**

```
virtual void PutMtlToMtlEditor(MtlBase *mb , int slot=-1)=0;
```

**Remarks:**

Puts the specified material into the material editor. The material is put to the specified slot, or if -1 is passed, the following dialog is presented which allows the user to choose a sample slot for the material.

**Parameters:**

**MtlBase \*mb**

The material to put to the material editor.

**int slot=-1**

This parameter is available in release 3.0 and later only.

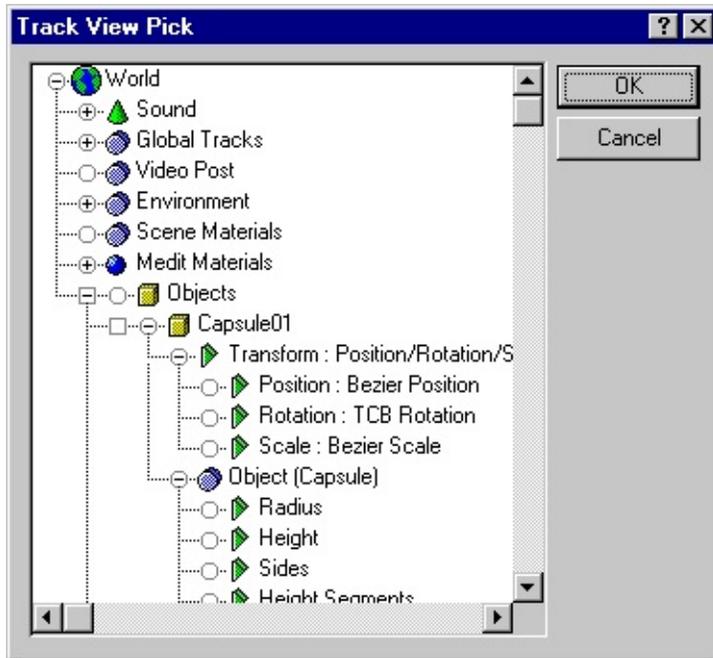

The Materials Editor slot number (a value in the range 0 to 23). If a slot number is specified, then this method will replace that material in the Materials Editor without user interaction. If -1 is passed (the default) then the function brings up the put dialog.

**Prototype:**

```
virtual BOOL TrackViewPickDlg(HWND hParent,  
TrackViewPick *res, TrackViewFilter *filter=NULL, DWORD  
flags=0)=0;
```

**Remarks:**

This method brings up the track view pick dialog. This dialog appears below:

### Parameters:

#### **HWND hParent**

The handle of the parent window.

#### **TrackViewPick \*res**

The item chosen by the user. See [Class TrackViewPick](#)

#### **TrackViewFilter \*filter=NULL**

The call back object to filter selection in the track view. See [Class TrackViewFilter](#).

#### **DWORD flags=0**

Currently not used.

### Return Value:

TRUE if the user selected OK to exit the dialog; otherwise FALSE.

### Sample Code:

This code brings up the Track View Pick Dialog and filters the input to MAX's controllers. After the controller is selected GetValue() is called on it.

```

class MyTVFilter : public TrackViewFilter {
    BOOL proc(Animatable *anim, Animatable *client,int subNum) {
        Control *c = (Control*)anim->GetInterface(I_CONTROL);
        return (c) ? TRUE : FALSE;
    }
};

```

```

void DoTest() {
    TrackViewPick res;
    MyTVFilter tvf;
    BOOL okay = IP->TrackViewPickDlg(IP->GetMAXHwnd(), &res,
    &tvf);
    if (!okay) return;
    Control *c = (Control *)res.anim;
    SClass_ID sid = c->SuperClassID();
    GetSetMethod method = CTRL_ABSOLUTE;
    switch(sid) {
    case CTRL_FLOAT_CLASS_ID:
        float r;
        Interval ivalid;
        c->GetValue(IP->GetTime(), &r, ivalid, method);
        ...
    }
}

```

**Prototype:**

```

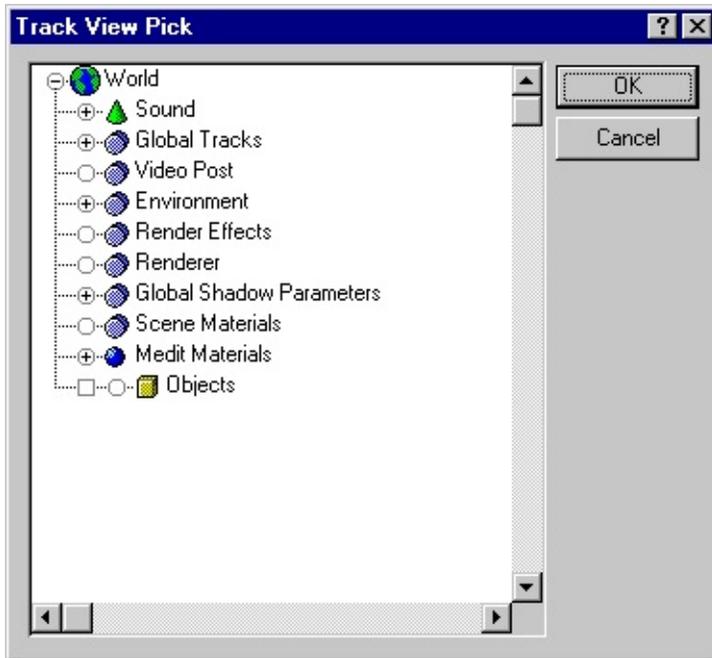

virtual BOOL TrackViewPickMultiDlg(HWND hParent,
    Tab<TrackViewPick> *res, TrackViewFilter
    *filter=NULL,DWORD flags=0)=0;

```

**Remarks:**

This method is available in release 3.0 and later only.

This methods brings up a dialog that allows one to select multiple tracks. This method works much like the **TrackViewPickDlg** method above except it is passed a pointer to a table of a **TrackViewPick** items instead.

### Parameters:

#### **HWND hParent**

The handle of the parent window.

#### **Tab<TrackViewPick> \*res**

This is a table (See [Template Class Tab](#)) of items chosen by the user. See [Class TrackViewPick](#)

#### **TrackViewFilter \*filter=NULL**

The call back object to filter selection in the track view. See [Class TrackViewFilter](#).

#### **DWORD flags=0**

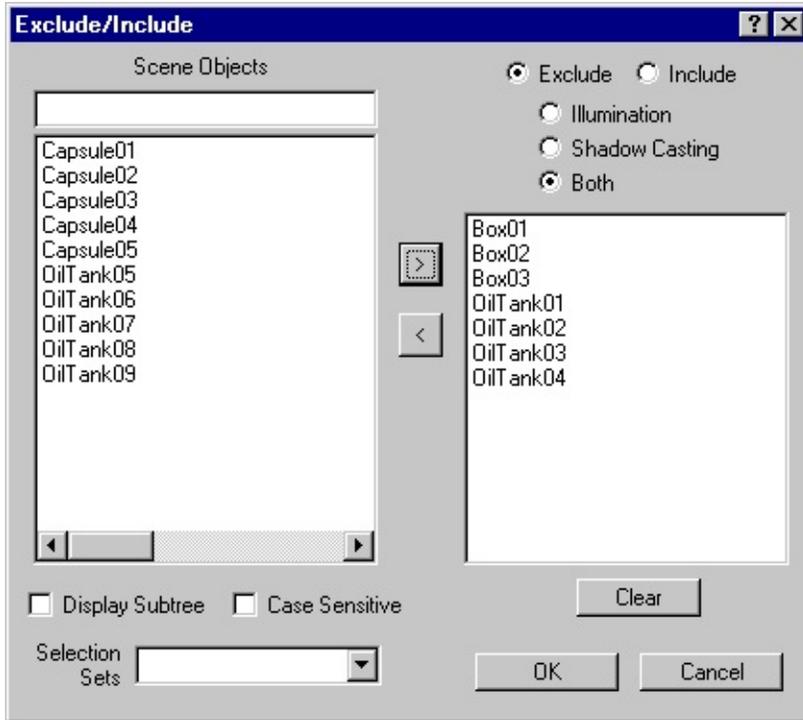

Currently not used.

### Prototype:

```
virtual int DoExclusionListDialog(ExclList *nl, BOOL  
doShadows=TRUE)=0;
```

### Remarks:

This brings up the standard Exclude / Include dialog box used for light exclusion / inclusion lists. This dialog appears below:

### Parameters:

#### **ExclList \*nl**

If the user selects OK, this is the list of names chosen by the user. See [Class ExclList](#).

#### **BOOL doShadows=TRUE**

The shadows switch.

### Return Value:

Nonzero if the user selected OK to exit the dialog; otherwise 0.

### Prototype:

```
virtual void ConvertNameTabToExclList(const NameTab *nt,  
ExclList *excList)=0;
```

### Remarks:

This method is available in release 4.0 and later only.

This method will convert a NameTab to an ExclList (the new format for Exclusion lists).

### Parameters:

**const NameTab \*nt**

A pointer to the name table.

**ExclList \*excList**

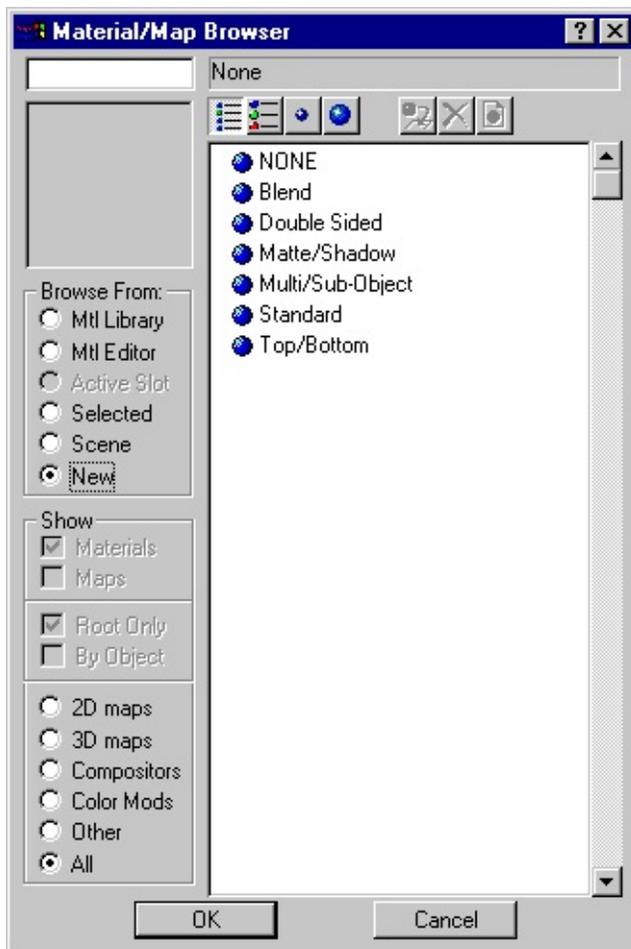

A pointer to the resulting exclusion list.

**Prototype:**

**virtual MtlBase \*DoMaterialBrowseDlg(HWND hParent,DWORD flags,BOOL &newMat,BOOL &cancel)=0;**

**Remarks:**

This method brings up the Material / Map Browser dialog box. This dialog appears below:

**Parameters:**

**HWND hParent**

The parent window handle.

**DWORD flags**

See [List of Material Browser Flags](#).

**BOOL &newMat**

TRUE if the user has selected a new item; otherwise FALSE. If TRUE it is safe to modify this item. If FALSE the item may be an instance and a developer should not modify this as other materials may be using this same item.

**BOOL &cancel**

TRUE if the user canceled the dialog; otherwise FALSE.

**Return Value:**

If **cancel** is FALSE, the item chosen by the user is returned. See [Class MtlBase](#).

**Prototype:**

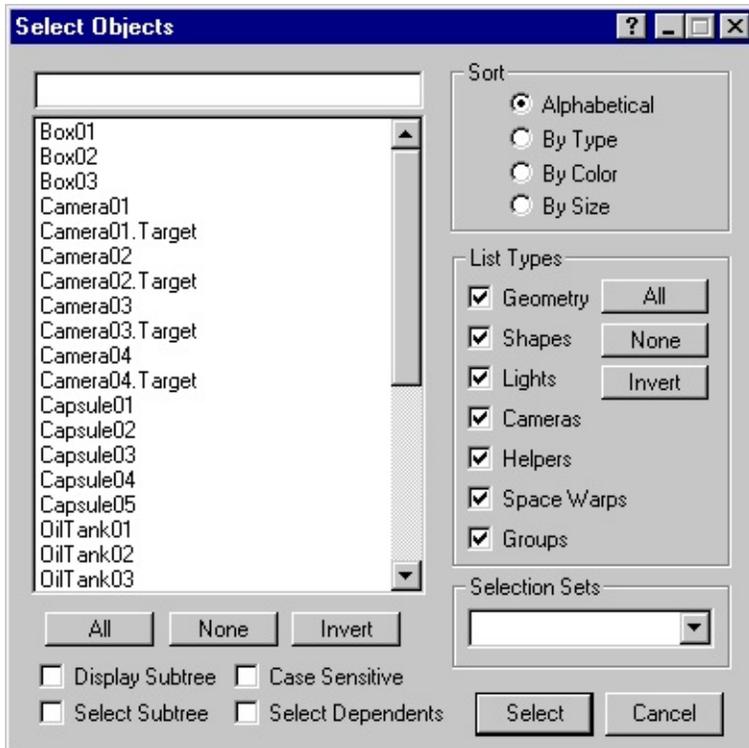

**virtual BOOL DoHitByNameDialog(HitByNameDlgCallback \*hbncb=NULL)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to put up the standard MAX Hit By Name dialog. This dialog appears below:

If the callback is NULL this method does a standard select by name. The nodes chosen by the user are selected if the user selects 'Select' from the dialog to exit. Use **Interface::GetSelNodeCount()** and **GetSelNode(i)** to retrieve the results.

**Parameters:**

**HitByNameDlgCallback \*hbnCb=NULL**

Points to the callback object. See [Class HitByNameDlgCallback](#). Developers should delete this callback when done.

**Return Value:**

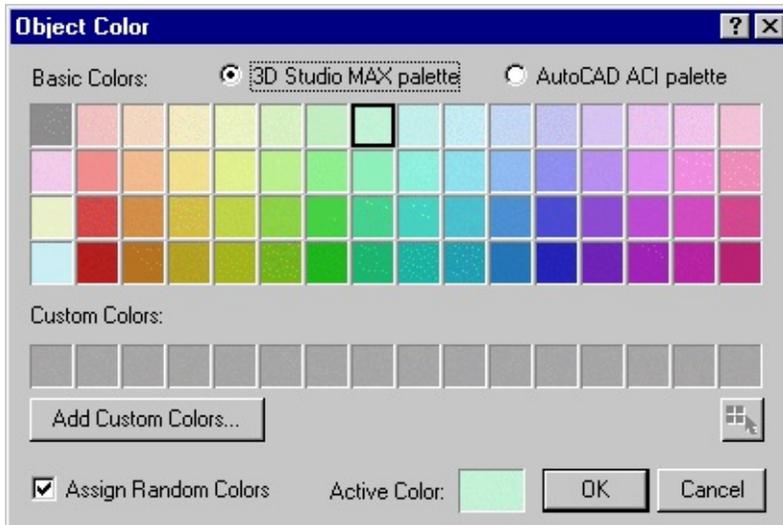

TRUE if the user selects 'Select' from the dialog; otherwise FALSE.

**Prototype:**

**virtual BOOL NodeColorPicker(HWND hWnd,DWORD &col)=0;**

**Remarks:**

This method brings up the standard MAX object color picker dialog. This dialog appears below:

### Parameters:

#### **HWND hWnd**

The parent window handle.

#### **DWORD &col**

If the user picks a color then this will be set to the chosen color. This is stored in a 32 bit format, with the high order 8 bits as 0's, the next 8 bits as the Blue amount, the next 8 bits as the Green amount, and the low order 8 bits as the Red amount (**0x00BBGGRR**). See [COLORREF - DWORD Color Format](#).

### Return Value:

TRUE if the user picks a color and FALSE if the user cancels the dialog.

### Prototype:

```
virtual void ChooseDirectory(HWND hWnd, TCHAR *title,  
TCHAR *dir, TCHAR *desc=NULL)=0;
```

### Remarks:

This method is available in release 2.0 and later only.

This methods puts up the Choose Directory dialog box to allow the user to select a directory. The choosen directory including the drive and path is stored in **dir**. This dialog appears below:

**Parameters:**

**HWND hWnd**

The parent window handle.

**TCHAR \*title**

The title in the dialog box.

**TCHAR \*dir**

The chosen directory is stored here. This points to an empty string on cancel.

**TCHAR \*desc=NULL**

The string to go into the Label field of the dialog. This string may be changed by the user and is returned here.

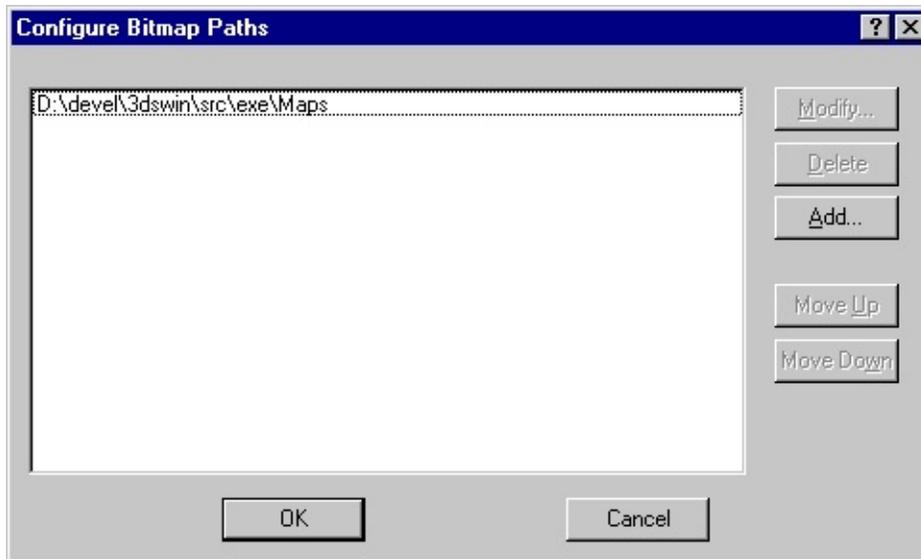

**Prototype:**

**virtual int ConfigureBitmapPaths()**=0;****

**Remarks:**

This method is available in release 3.0 and later only.

This method puts up the dialog to let the user configure the bitmap loading paths. This dialog appears below:

**Return Value:**

Nonzero on user selecting OK, zero on Cancel.

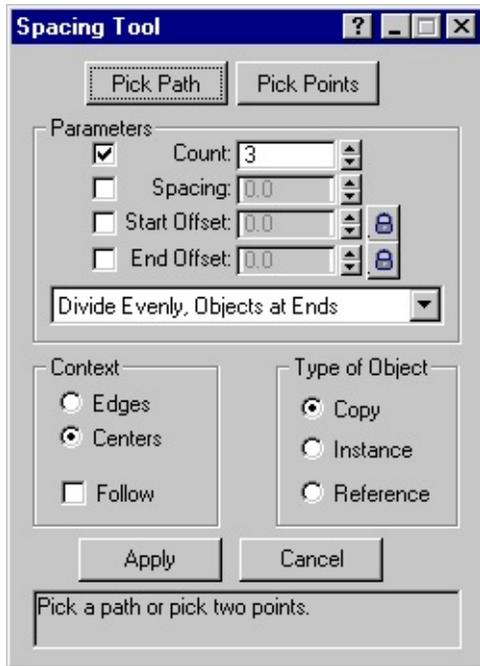

**Prototype:**

```
virtual BOOL DoSpaceArrayDialog(SpaceArrayCallback  
*sacb=NULL)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Puts up the space array dialog. If the callback is NULL it just does the standard space array tool.

### Parameters:

**SpaceArrayCallback \*sacb=NULL**

The callback. See [Class SpaceArrayCallback](#).

### Return Value:

Returns TRUE if the user OKs the dialog, otherwise FALSE.

## RAM Player

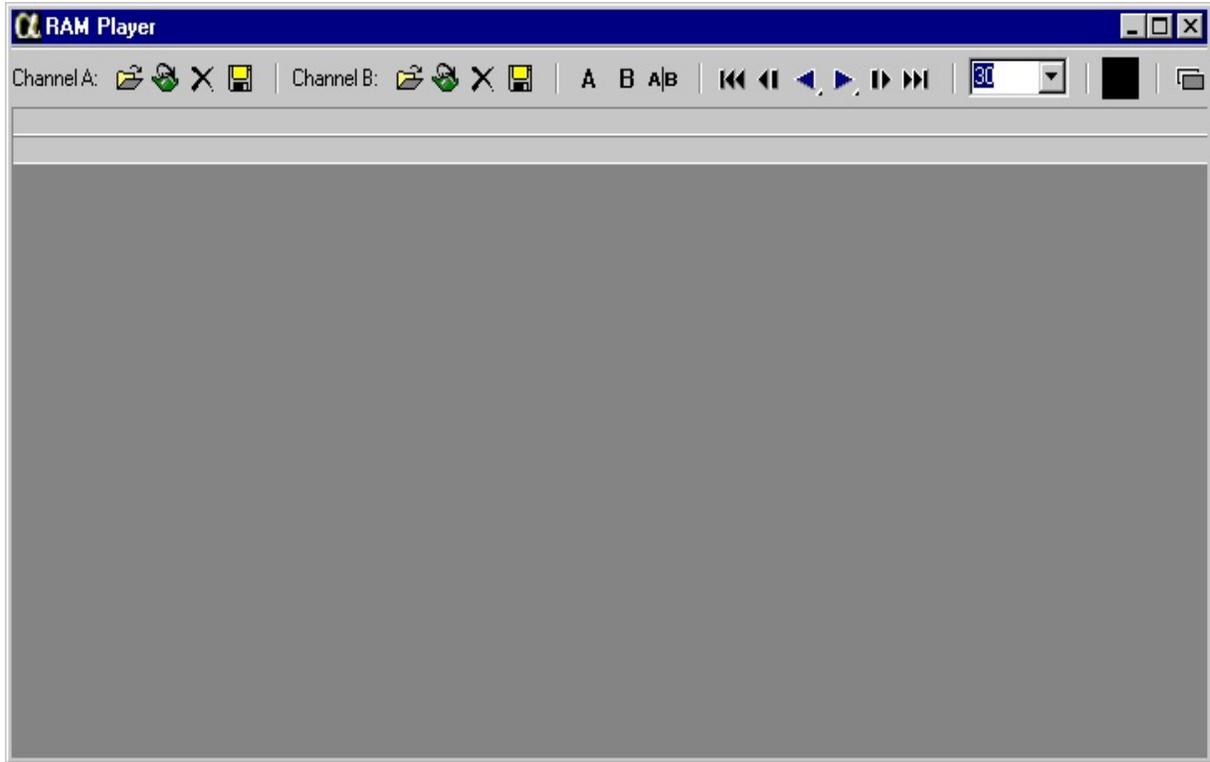

### Prototype:

```
virtual void RAMPlayer(HWND hWndParent, TCHAR*  
szChanA=NULL, TCHAR* szChanB=NULL)=0;
```

### Remarks:

This method is available in release 3.0 and later only.

Brings up the RAMPlayer dialog and optionally loads one, or both channels with the supplied files.

### Parameters:

#### **HWND hWndParent**

The parent window handle.

#### **TCHAR\* szChanA=NULL**

The file to load for channel A (for example, `_T("movie.avi")`). If NULL is passed no file is loaded into the channel.

#### **TCHAR\* szChanB=NULL**

The file to load for channel B. If NULL is passed no file is loaded into the channel.

## Dialogs -- Register Windows

### Prototype:

```
virtual void RegisterDlgWnd(HWND hDlg)=0;
```

### Remarks:

Registers a dialog window so **IsDialogMessage()** gets called for it. This is not required if you add rollup pages to the command panel as this is done automatically, however if you create a floating, modeless dialog you **must** call this method.

**Important Note:** ALL modeless dialogs in MAX must be registered to the application window with this method so that it, and any sub dialogs, will behave as they should.

**Parameters:**

**HWND hDlg**

The window handle of the dialog.

**Prototype:**

**virtual int UnRegisterDlgWnd(HWND hDlg)=0;**

**Remarks:**

Un-registers a dialog window so **IsDialogMessage()** is no longer called for it.

**Parameters:**

**HWND hDlg**

The window handle of the dialog.

**Return Value:**

Nonzero if successful; otherwise 0.

## **Directory Access -- Plug-In and Bitmap Paths**

**Prototype:**

**virtual TCHAR \*GetDir(int which)=0;**

**Remarks:**

Returns the pathname of a directory used by 3ds max.

**Parameters:**

**int which**

One of the following directories. See [List of Directory Names](#).

**Return Value:**

The pathname of the directory.

**Prototype:**

**virtual int GetPlugInEntryCount()=0;**

**Remarks:**

This is the number of entries in **PLUGIN.INI**. **PLUGIN.INI** contains a list of descriptions and directories used by plug-in DLLs. See Also: [Plug-In Directory Search Mechanism](#).

**Return Value:**

The number of entries in **PLUGIN.INI**.

**Prototype:**

```
virtual TCHAR *GetPlugInDesc(int i)=0;
```

**Remarks:**

Returns the 'i-th' description string from **PLUGIN.INI**. See Also: [Plug-In Directory Search Mechanism](#).

**Parameters:**

**int i**

Specifies which description to return.

**Return Value:**

The 'i-th' description string from **PLUGIN.INI**.

**Prototype:**

```
virtual TCHAR *GetPlugInDir(int i)=0;
```

**Remarks:**

Returns the pathname string for the 'i-th' plug-in directory from **PLUGIN.INI**. See Also: [Plug-In Directory Search Mechanism](#).

**Parameters:**

**int i**

Specifies which directory to return.

**Return Value:**

The 'i-th' pathname string from **PLUGIN.INI**.

## DLL Directory Access

**Prototype:**

**virtual DllDir& GetDllDir()=0;**

**Remarks:**

Returns a reference to the central DLL directory. See [Class DllDir](#).

**Prototype:**

**virtual DllDir \*GetDllDirectory()=0;**

**Remarks:**

Returns a pointer to the central DLL directory. See [Class DllDir](#).

## **Error Logging**

The following methods allow a developer to write to the error log file created in each network server's directory. These three methods allow more detailed information to be recorded than the single line error message that is returned to the network "master" when a render fails. If there is any place in your code where an Alert is put up that might be encountered during rendering, you can print the information out to the error log instead.

**Prototype:**

**virtual LogSys \*Log()=0;**

**Remarks:**

Returns a pointer which may be used for calling methods to write information to the system log. See [Class LogSys](#) for details.

## **Environment Access**

**Prototype:**

**virtual Texmap \*GetEnvironmentMap()=0;**

**Remarks:**

Returns the current environment map.

**Prototype:**

**virtual void SetEnvironmentMap(Texmap \*map)=0;**

**Remarks:**

Sets the current environment map to the specified map. See **\MAXSDK\SAMPLES\UTILITIES\UTILTEST.CPP** for sample code.

**Parameters:**

**Texmap \*map**

The map to set.

**Prototype:**

**virtual BOOL GetUseEnvironmentMap()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the 'Use Map' checkbox is checked in the Environment / Background dialog; otherwise FALSE.

**Prototype:**

**virtual void SetUseEnvironmentMap(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the state of the 'Use Map' checkbox in the Environment / Background dialog.

**Parameters:**

**BOOL onOff**

TRUE for checked; FALSE for unchecked.

**Prototype:**

**virtual Point3 GetAmbient(TimeValue t,Interval &valid)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves the color of the ambient light at the time passed and updates the validity interval passed to reflect the validity of the ambient light.

**Parameters:**

**TimeValue t**

The time to retrieve the ambient light color.

## **Interval &valid**

The validity interval to update.

### **Return Value:**

The color as a **Point3**.

### **Prototype:**

```
virtual void SetAmbient(TimeValue t, Point3 col)=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

Sets the color of the ambient light in the scene to the color passed at the specified time.

### **Parameters:**

#### **TimeValue t**

The time to set the color.

#### **Point3 col**

The new color for the ambient light.

### **Prototype:**

```
virtual Control *GetAmbientController()=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

Retrieves a pointer to the controller use to animate the ambient light.

### **Prototype:**

```
virtual void SetAmbientController(Control *c)=0;
```

### **Remarks:**

This method is available in release 2.0 and later only.

Sets the controller used for handling the animation of the ambient light.

### **Parameters:**

#### **Control \*c**

The controller to set.

**Prototype:**

**virtual Point3 GetLightTint(TimeValue t,Interval &valid)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the rendering environment global lighting tint color at the specified time and updates the validity interval passed to reflect the validity of the tint color controller.

**Parameters:****TimeValue t**

The time at which to return the color.

**Interval &valid**

The validity interval that is updated.

**Prototype:**

**virtual void SetLightTint(TimeValue t, Point3 col)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the rendering environment global lighting tint color at the specified time to the color passed.

**Parameters:****TimeValue t**

The time at which to set the color.

**Point3 col**

The color to set.

**Prototype:**

**virtual Control \*GetLightTintController()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the controller use to animate the tint color.

**Prototype:**

**virtual void SetLightTintController(Control \*c)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the controller use to animate the tint color.

**Parameters:**

**Control \*c**

Points to the controller to set.

**Prototype:**

**virtual float GetLightLevel(TimeValue t,Interval &valid)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the rendering environment global lighting level at the specified time and updates the validity interval passed to reflect the validity of the lighting level controller.

**Parameters:**

**TimeValue t**

The time at which to return the level.

**Interval &valid**

The validity interval that is updated.

**Prototype:**

**virtual void SetLightLevel(TimeValue t, float lev)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the rendering environment global lighting level at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the lighting level.

**float lev**

The level to set.

**Prototype:**

**virtual Control \*GetLightLevelController()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the controller use to animate the lighting level.

**Prototype:**

**virtual void SetLightLevelController(Control \*c)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the controller use to animate the lighting level.

**Parameters:**

**Control \*c**

Points to the controller to set.

**Prototype:**

**virtual int NumAtmospheric()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of atmospheric effects currently assigned.

**Prototype:**

**virtual Atmospheric \*GetAtmospheric(int i)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the 'i-th' atmospheric effect.

**Parameters:**

**int i**

Specifies which atmospheric effect to retrieve.

**Prototype:**

**virtual void SetAtmospheric(int i,Atmospheric \*a)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Sets the 'i-th' atmospheric effect.

**Parameters:**

**int i**

Specifies which effect to set.

**Atmospheric \*a**

A pointer to the atmospheric effect.

**Prototype:**

**virtual void AddAtmosphere(Atmospheric \*atmos)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Adds the specified atmospheric effect to the list of effects.

**Parameters:**

**Atmospheric \*a**

A pointer to the atmospheric effect to add.

**Prototype:**

**virtual void DeleteAtmosphere(int i)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Deletes the specified atmospheric effect.

**Parameters:**

**int i**

The index of the atmospheric effect to delete.

**Prototype:**

**virtual void EditAtmosphere(Atmospheric \*a, INode \*gizmo=NULL)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method selects the specified atmosphere's gizmo and displays the parameters for it (if any).

**Parameters:**

**Atmospheric \*a**

Points to the Atmospheric plug-in. See [Class Atmospheric](#).

**INode \*gizmo=NULL**

Points to the gizmo node associated with the plug-in.

**Render Effects Methods****Prototype:**

**virtual int NumEffects()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of Render Effects currently assigned.

**Prototype:**

**virtual Effect \*GetEffect(int i)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the 'i-th' Render Effect. See [Class Effect](#).

**Parameters:**

**int i**

The zero based index of the effect to return.

**Prototype:**

**virtual void SetEffect(int i, Effect \*e)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the specified Render Effect to the one passed.

**Parameters:**

**int i**

The zero based index of the effect to set.

**Effect \*e**

Points to the Renderer Effect to set.

**Prototype:**

**virtual void AddEffect(Effect \*eff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Adds the specified Renderer Effect to the existing list of effects.

**Parameters:**

**Effect \*eff**

Points to the render effect to add. See [Class Effect](#).

**Prototype:**

**virtual void DeleteEffect(int i)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the specified Renderer Effect.

**Parameters:**

**int i**

The zero based index of the effect to delete.

**Prototype:**

**virtual void EditEffect(Effect \*e, INode \*gizmo=NULL)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method selects the specified gizmo and displays the parameters for it (if any).

**Parameters:**

**Effect \*e**

Points to the Effect plug-in. See [Class Effect](#).

**INode \*gizmo=NULL**

Points to the gizmo node associated with the effect.

**Prototype:**

**virtual Point3 GetBackGround(TimeValue t,Interval &valid)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves the background color at the specified time and updates the validity interval passed to reflect the validity of the background color.

**Parameters:**

**TimeValue t**

The time to retrieve the color.

**Interval &valid**

The validity interval to update.

**Prototype:**

**virtual void SetBackGround(TimeValue t,Point3 col)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the background color to the specified color at the specified time.

**Parameters:**

**TimeValue t**

The time to set the color.

**Point3 col**

The color to set.

**Prototype:**

**virtual Control \*GetBackGroundController()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the controller animating the background color.

**Prototype:**

**virtual void SetBackGroundController(Control \*c)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the controller used for animating the background color.

**Parameters:**

**Control \*c**

Specifies which controller to set.

## Execute MAX Commands

**Prototype:**

**virtual void ExecuteMAXCommand(int id)=0;**

**Remarks:**

This method may be used to execute a MAX command. These are the same commands that may be assigned using the MAX

**Customize/Preferences.../Keyboard Tab** key assignment system.

For MAX version 1.1 or later, this method may also be used to set various aspects of the preview display. The **id** to pass for these options is shown below:

**ExecuteMAXCommand(MAXCOM\_API\_PVW\_GRID\_OFF)**

This turns off the preview grid display.

**ExecuteMAXCommand(MAXCOM\_API\_PVW\_GRID\_ON)**

This turns on the preview grid display.

**ExecuteMAXCommand(MAXCOM\_API\_PVW\_SMOOTH\_MODE)**

This sets the preview rendering mode to "smooth".

**ExecuteMAXCommand(MAXCOM\_API\_PVW\_FACET\_MODE)**

This sets the preview rendering mode to "facet".

**ExecuteMAXCommand(MAXCOM\_API\_PVW\_WIRE\_MODE)**

This sets the preview rendering mode to "wireframe".

Note: In MAX 2.0 and later there is an alternate (better) way to do this. See the method:

**virtual void CreatePreview(PreviewParams \*pvp=NULL)=0;**

**Parameters:**

**int id**

The command to execute. See [List of MAX Command IDs](#).

## **Execute -- General API Expansion Function**

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG\_PTR arg1=0, ULONG\_PTR arg2=0, ULONG\_PTR arg3=0, ULONG\_PTR arg4=0, ULONG\_PTR arg5=0, ULONG\_PTR arg6=0)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is a general purpose function that allows the API to be extended in the future. The MAX development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API.

Note: In R4 the return value changed from int to INT\_PTR

**New in R5.1** An additional Command was added to allow the setting of certain directories such as Plugins. It looks like this:

**Execute(I\_EXEC\_SET\_DIR, (ULONG\_PTR)(int) which, ULONG\_PTR (TCHAR \*)dir)**

where 'which' designates the particular Max directory to be changed (like the corresponding argument of Interface::GetDir()), and 'dir' is the path as a string.

**Parameters:**

**int cmd**

The index of the command to execute. See [List of Interface::Execute Command Options](#).

**ULONG arg1=0**

Optional argument 1. See the documentation where the **cmd** option is discussed for more details on these parameters.

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**ULONG arg4=0**

This parameter is available in release 4.0 and later only.

Optional argument 4.

**ULONG arg5=0**

This parameter is available in release 4.0 and later only.

Optional argument 5.

**ULONG arg6=0**

This parameter is available in release 4.0 and later only.

Optional argument 6.

**Return Value:**

An INT\_PTR return value. See the documentation where the **cmd** option is discussed for more details on the meaning of this value.

## Extended Display Modes

**Prototype:**

**virtual void SetExtendedDisplayMode(int flags)=0;**

**Remarks:**

This method is used internally to set the extended display mode.

**Parameters:**

**int flags**

See [List of Extended Display Modes](#).

**Prototype:**

**virtual int GetExtendedDisplayMode()=0;**

**Remarks:**

Returns the extended display mode flags. This method provides a mechanism to retrieve some additional information about an object that is more dependent on MAX than on the particular object. For example, when a spotlight is selected, it can use this method to detect that it is the only item selected, and display its cone. It checks this using and extended display mode

**EXT\_DISP\_ONLY\_SELECTED.** See [List of Extended Display Modes](#).

## **Filenames and Pathnames**

### **Prototype:**

**virtual TSTR &GetCurFileName()=0;**

### **Remarks:**

Returns the name of the current MAX file (but not the path). For example, if the currently loaded file is "D:\3DSMAX\SCENES\Expgears.max" this method returns " **Expgears.max**".

### **Prototype:**

**virtual TSTR &GetCurFilePath()=0;**

### **Remarks:**

Returns the file and path of the current MAX file. For example, if the currently loaded file is "D:\3DSMAX\SCENES\Expgears.max" this method returns "D:\3DSMAX\SCENES\Expgears.max ".

### **Prototype:**

**virtual TCHAR \*GetMatLibFileName()=0;**

### **Remarks:**

Returns the current material library file name.

## **File Open/Merge/Save/Reset/Hold/Fetch Methods**

For file IO using the MAX import / export mechanism see the section: [Import / Export Related Methods](#).

### **Prototype:**

**virtual bool IsMaxFile(const TCHAR\* filename)=0;**

### **Remarks:**

This method is available in release 4.0 and later only.

Returns true if the specified file is a valid MAX file; otherwise false.

### **Parameters:**

**const TCHAR\* filename**

The name of the file to check.

**Prototype:**

**virtual bool IsInternetCachedFile(const TCHAR\* filename)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns true if the specified file is an internet cached file; otherwise false.

**Parameters:**

**const TCHAR\* filename**

The name of the file to check.

**Prototype:**

**virtual void SetMAXFileOpenDlg(MAXFileOpenDialog\* dlg)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows a custom file open dialog to be registered.

**Parameters:**

**MAXFileOpenDialog\* dlg**

Points to the file open dialog object to use. See [Class MAXFileOpenDialog](#).

**Prototype:**

**virtual void SetMAXFileSaveDlg(MAXFileSaveDialog\* dlg)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows a custom file save dialog to be registered.

**Parameters:**

**MAXFileSaveDialog\* dlg**

Points to the file save dialog object to use. See [Class MAXFileSaveDialog](#).

**Prototype:**

**virtual void FileOpenMatLib(HWND hWnd)=0;**

**Remarks:**

This method brings up the File Open dialog box and allows the user to select a material library to load.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual void FileSaveMatLib(HWND hWnd)=0;**

**Remarks:**

If the current material library has been saved previously (has been named) this method saves the material library to the same file. Otherwise it brings up the standard Save File As dialog box to allow the user to save the current material library.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual void FileSaveAsMatLib(HWND hWnd)=0;**

**Remarks:**

Brings up the standard Save File As dialog box to allow the user to save the current material library.

**Parameters:**

**HWND hWnd**

The parent window handle.

**Prototype:**

**virtual void LoadDefaultMatLib()=0;**

**Remarks:**

This method loads the default material library **3DSMAX.MAT** (if this file

exists).

**Prototype:**

**virtual int LoadFromFile(const TCHAR \*name, BOOL refresh=TRUE)=0;**

**Remarks:**

Loads the specified MAX file. A developer should normally specify a complete path name. This method does not bring up a file dialog.

**Parameters:**

**const TCHAR \*name**

The MAX file to load.

**BOOL refresh=TRUE**

This parameter is available in release 2.0 and later only.

Set this to FALSE to prevent the viewports from automatically being refreshed.

**Return Value:**

Nonzero if the file was loaded; otherwise 0.

**Prototype:**

**virtual int SaveToFile(const TCHAR \*fname)=0;**

**Remarks:**

Saves the current scene to the specified MAX file. This method does not bring up a file dialog.

**Parameters:**

**const TCHAR \*name**

The MAX file to save.

**Return Value:**

Nonzero if the library was saved; otherwise 0.

**Prototype:**

**virtual void FileSaveSelected(TCHAR \*fname)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Saves the selected nodes to the specified file.

**Parameters:**

**TCHAR \*fname**

The MAX file to save.

**Prototype:**

**virtual void FileSaveNodes(INodeTab\* nodes, TCHAR \*fname)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Saves the specified nodes to the specified file.

**Parameters:**

**INodeTab\* nodes**

Points to the table of nodes to save. See [Class INodeTab](#).

**TCHAR \*fname**

The MAX file to save.

**Prototype:**

**virtual int LoadMaterialLib(const TCHAR \*name, MtlBaseLib \*lib=NULL)=0;**

**Remarks:**

Loads the specified material library. This method does not bring up a file dialog.

**Parameters:**

**const TCHAR \*name**

The material library to load.

**MtlBaseLib \*lib=NULL**

This parameter is available in release 2.0 and later only.

Points to the material library to load into. If NULL the library is loaded into the current material library. See [Class MtlBaseLib](#).

Note: You need to call **MtlBaseLib::DeleteAll()** on the library during a MAX reset operation. This will remove all its references to the materials and

set its count to zero.

**Return Value:**

Nonzero if the library was loaded; otherwise 0.

**Prototype:**

**virtual int SaveMaterialLib(const TCHAR \*name, MtlBaseLib \*lib=NULL)=0;**

**Remarks:**

Saves the specified material library to the specified file. This method does not bring up a file dialog.

**Parameters:**

**const TCHAR \*name**

The material library to save.

This parameter is available in release 2.0 and later only.

Points to the material library to save from. If NULL the library is saved from the current material library. See [Class MtlBaseLib](#).

**Return Value:**

Nonzero if the library was saved; otherwise 0.

**Prototype:**

**virtual int MergeFromFile(const TCHAR \*name, BOOL mergeAll=FALSE, BOOL selMerged=FALSE, BOOL refresh=TRUE, int dupAction = MERGE\_DUPS\_PROMPT, NameTab\* mrgList=NULL)=0;**

**Remarks:**

Merges the specified MAX file into the current scene. In MAX 2.0 and later additional parameters allow automatic viewport updates to be optionally be turned off, cases of duplicate objects being merged may be handled, a table of names of the merged objects may be generated, and only specific named objects from the file may be merged.

**Parameters:**

**const TCHAR \*name**

The MAX file to merge.

**BOOL mergeAll=FALSE**

If TRUE all the items in the file are merged; otherwise the selector dialog appears allowing the user to choose.

**selMerged=FALSE**

If TRUE the nodes are selected when they are merged.

**BOOL refresh=TRUE**

This parameter is available in release 2.0 and later only.

Set this to FALSE to prevent the viewports from automatically being refreshed.

**int dupAction = MERGE\_DUPS\_PROMPT**

This parameter is available in release 2.0 and later only.

Determines what to do when duplicate named objects are encountered during the merge. One of the following values specifies what to do:

**MERGE\_DUPS\_PROMPT**

Prompt the user for what to do when duplicates are encountered.

**MERGE\_DUPS\_MERGE**

Merge new objects, but keep original objects when duplicates are encountered.

**MERGE\_DUPS\_SKIP**

Skip any duplicates encountered (don't merge them).

**MERGE\_DUPS\_DELOLD**

Delete the old objects and merge the new ones when duplicates are encountered.

**MERGE\_LIST\_NAMES**

Specifies that the name table **mrgList** below should be filled in with the names of the merged objects.

**NameTab\* mrgList=NULL**

This parameter is available in release 2.0 and later only.

When you specify a pointer to a **NameTab** for this parameter, and don't set **dupAction** to **MERGE\_LIST\_NAMES**, then this method will merge the nodes whose names are listed in the **mrgList**.

If **dupAction==MERGE\_LIST\_NAMES**, (and **mergeAll==TRUE**,

and **mrgList** != NULL) then this method puts a list of the nodes in the file into **mrgList**, and simply returns (no merging is done).

See [Class NameTab](#).

**Return Value:**

Nonzero if the file was merged; otherwise 0.

**Prototype:**

**virtual void FileOpen()=0;**

**Remarks:**

This brings up the standard MAX file open dialog and allows the user to load a new scene.

**Prototype:**

**virtual BOOL FileSave()=0;**

**Remarks:**

This saves the current file. If the file has not been saved yet (and is thus unnamed) this brings up the standard MAX file Save As dialog box and allows the user to choose a name.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL CheckForSave()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method can be used to write out a .MAX file if needed. First it ends animation if it's in progress. Next it determines whether a save operation is required (change marked in scene, or undo operations present).

**Return Value:**

If the save is not required, it returns TRUE; otherwise, it puts up a dialog box asking if the user wants to save. If the user picks No, it returns TRUE. If the user picks Cancel it returns FALSE. If the user picks Yes then the method proceeds as for **FileSave()** above.

**Prototype:****virtual BOOL FileSaveAs()=0;****Remarks:**

This brings up the standard MAX file saveas dialog box and allows the user to save the current scene to a new file.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:****virtual void FileSaveSelected()=0;****Remarks:**

This brings up the standard MAX file save selected dialog box and allows the user to save the selected items from the current scene.

**Prototype:****virtual void FileReset(BOOL noPrompt=FALSE)=0;****Remarks:**

This resets MAX to its startup condition after a confirmation prompt. This performs the same operation as choosing File / Reset from the MAX menus.

**Parameters:****BOOL noPrompt=FALSE**

If TRUE the confirmation prompt is not presented.

**Prototype:****virtual void FileMerge()=0;****Remarks:**

This allows the user to merge another MAX file with the current scene. This performs the same operation as choosing File / Merge from the MAX menus.

**Prototype:****virtual void FileHold()=0;****Remarks:**

This saves the current state of the scene to a temporary hold buffer (same as Edit / Hold). This state may later be restored using **FileFetch()** or (Edit / Fetch from MAX).

**Prototype:**

**virtual void FileFetch()=0;**

**Remarks:**

This restores the current state of the scene from the temporary hold buffer created using **FileHold()** (or from the MAX menu command Edit / Hold).

## **File Import / Export Related Methods**

**Prototype:**

**virtual BOOL FileImport()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method simply brings up the 'Select File to Import' dialog just as if the user picked this option from the File / Import... pulldown menu.

**Return Value:**

TRUE if the file was imported successfully; otherwise FALSE.

**Prototype:**

**virtual BOOL FileExport()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method simply brings up the 'Select File to Export' dialog just as if the user picked this option from the File / Export... pulldown menu.

**Return Value:**

TRUE if the export file was written successfully; otherwise FALSE.

**Prototype:**

**virtual BOOL ImportFromFile(const TCHAR \*name, BOOL suppressPrompts=FALSE, Class\_ID \*importerID=NULL)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method allows the import of the specified file by any of the supported import formats. This is done by specifying a full filename thus bypassing the file browser. If **suppressPrompts** is set to TRUE, the import mechanism will not display any prompts requiring user action.

Note: Developers of Import plug-ins need to support the **suppressPrompts** mechanism for this to work properly. Developers of such plug-ins should see the [Class SceneImport](#) for details.

**Parameters:**

**const TCHAR \*name**

The full file name (including extension -- which identifies the importer used) of the input file.

**BOOL suppressPrompts=FALSE**

If TRUE the default choices in the import plug-in are used and no options dialogs are presented. If FALSE any options dialogs provided by the importer are presented to the user.

**Class\_ID \*importerID=NULL**

This parameter is available in release 3.0 and later only.

The parameter specifies the Class\_ID of the import module to use. This is for those cases where more than one import module uses the same file extension. Omitting this class ID operates in the pre-R3 mode, i.e. the first importer found is used.

**Return Value:**

TRUE if the export file was written successfully; otherwise FALSE.

**Prototype:**

```
virtual BOOL ExportToFile(const TCHAR *name, BOOL  
suppressPrompts=FALSE, DWORD options, Class_ID  
*exporterID=NULL)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method allows the export of the current MAX file to any of the supported export formats. This is done by specifying a full filename thus bypassing the

file browser. If **suppressPrompts** is set to TRUE, the export mechanism will not display any prompts requiring user action.

Note: Developers of Export plug-ins need to support the **suppressPrompts** mechanism for this to work properly. Developers of such plug-ins should see the [Class SceneExport](#) for details.

#### **Parameters:**

##### **const TCHAR \*name**

The full file name (including extension -- which identifies the exporter used) of the output file.

##### **BOOL suppressPrompts=FALSE**

If TRUE the default choices in the export plug-in are used and no options dialogs are presented. If FALSE any options dialogs provided by the exporter are presented to the user.

##### **DWORD options**

This option is available in release 4.0 and later only.

There is currently one option; **SCENE\_EXPORT\_SELECTED** which allows you to export only selected nodes.

##### **Class\_ID \*exporterID=NULL**

This parameter is available in release 3.0 and later only.

The parameter specifies the Class\_ID of the export module to use. This is for those cases where more than one export module uses the same file extension. Omitting this class ID operates in the pre-R3 mode, i.e. the first exporter found is used.

#### **Return Value:**

TRUE if the export file was written successfully; otherwise FALSE.

#### **Prototype:**

```
virtual bool CanImportFile(const TCHAR* filename)=0;
```

#### **Remarks:**

This method is available in release 4.0 and later only.

This method will check is the specified file can be imported.

#### **Parameters:**

```
const TCHAR* filename
```

The file name to check.

**Return Value:**

TRUE if the specified file can be imported by one of the import plug-ins; otherwise FALSE.

**Prototype:**

**virtual BOOL GetImportZoomExtents()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This returns the state of the system zoom extents flag. Note that individual SceneImport plug-ins can override this in their **ZoomExtents()** method. See [Class SceneImport](#).

**Return Value:**

TRUE indicates that zoom extents will occur after imports, FALSE indicates that no zoom extents.

**Prototype:**

**virtual void SetImportZoomExtents(BOOL onOff)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the state of the system zoom extents flag.

**Parameters:**

**BOOL onOff**

TRUE indicates that zoom extents will occur after imports, FALSE indicates that no zoom extents.

## **Fonts / Cursor Related Methods**

**Prototype:**

**virtual HFONT GetAppHFont()=0;**

**Remarks:**

Returns the handle of the font used by MAX. The default font is the same one returned from **GetAppHFont()**. So if a developer makes a dialog in the

rollup page the correct font will be used automatically.

**Prototype:**

**virtual HCURSOR GetSysCursor( int id )=0;**

**Remarks:**

This method returns the cursor handle for the standard MAX cursors. Use **SetCursor()** from the Windows API to set the cursor.

**Parameters:**

**int id**

One of the following values:

**SYSCUR\_MOVE, SYSCUR\_ROTATE, SYSCUR\_USCALE,  
SYSCUR\_NUSCALE,  
SYSCUR\_SQUASH, SYSCUR\_SELECT,  
SYSCUR\_DEFARROW.**

**Return Value:**

The handle of the cursor.

**Prototype:**

**virtual void SetCrossHairCur(BOOL onOff)=0;**

**Remarks:**

This method is reserved for future use.

**Prototype:**

**virtual BOOL GetCrossHairCur()=0;**

**Remarks:**

This method is reserved for future use.

## **Grid Related Methods**

**Prototype:**

**virtual float GetGridSpacing()=0;**

**Remarks:**

This method returns the grid spacing value that the user specifies in the Views / Grid and Snap Settings dialog in the Home Grid tab under Grid Spacing.

**Prototype:**

**virtual int GetGridMajorLines()=0;**

**Remarks:**

This method returns the value that the user specifies in the Views / Grid and Snap Settings dialog in the Home Grid tab under Major Lines every Nth.

**Prototype:**

**virtual void SetActiveGrid(INode \*node)=0;**

**Remarks:**

Sets the given node as the active grid object. This is used with grid helper objects to allow them to take effect. This method may also be used to activate the home grid.

Note: This API is not working in the SDK prior to version 2.5.

**Parameters:**

**INode \*node**

The node to set as the active grid object. To activate the home grid pass NULL.

**Prototype:**

**virtual INode \*GetActiveGrid()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the active grid node or NULL if the home grid is in use.

**Prototype:**

**virtual void AddGridToScene(INode \*node)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is not operative in MAX (only in 3D Studio VIZ).

## Hide By Category Flags

### Prototype:

**virtual DWORD GetHideByCategoryFlags()=0;**

### Remarks:

Returns the state of the hide by category flags.

### Return Value:

One or more of the following values:

**HIDE\_OBJECTS**  
**HIDE\_SHAPES**  
**HIDE\_LIGHTS**  
**HIDE\_CAMERAS**  
**HIDE\_HELPERS**  
**HIDE\_WSMS**  
**HIDE\_SYSTEMS**  
**HIDE\_ALL**  
**HIDE\_NONE**

### Prototype:

**virtual void SetHideByCategoryFlags(DWORD f)=0;**

### Remarks:

Sets the state of the hide by category flags.

### Parameters:

**DWORD f**

One or more of the following values:

**HIDE\_OBJECTS**  
**HIDE\_SHAPES**  
**HIDE\_LIGHTS**  
**HIDE\_CAMERAS**  
**HIDE\_HELPERS**  
**HIDE\_WSMS**  
**HIDE\_SYSTEMS**  
**HIDE\_ALL**

## HIDE\_NONE

### Keyboard Accelerators

See the Advanced Topics section [Keyboard Accelerators and Dialog Messages](#) for more details. Also see the [Keyboard Shortcut System](#) topic for details of the system used in release 3.0 and later.

#### Prototype:

```
virtual void RegisterAccelTable(HWND hWnd, HACCEL  
hAccel)=0;
```

#### Remarks:

Registers a keyboard accelerator table.

#### Parameters:

**HWND hWnd**

The window handle.

**HACCEL hAccel**

The handle of the accelerator table (from the Windows API). See the Windows API for more details on accelerator tables.

#### Prototype:

```
virtual int UnRegisterAccelTable(HWND hWnd, HACCEL  
hAccel)=0;
```

#### Remarks:

Un-registers a keyboard accelerator table.

#### Parameters:

**HWND hWnd**

The window handle.

**HACCEL hAccel**

The handle of the accelerator table (from the Windows API). See the Windows API for more details on accelerator tables.

#### Return Value:

Nonzero if successful; otherwise 0.

**Prototype:**

**virtual BOOL GetPluginKeysEnabled()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Note that this method has been removed in release 4.0 and later.

In the MAX UI there is a icon button for toggling between the MAX system keyboard accelerators and those registered by the plug-in. This icon has a tooltip 'Plug-in Keyboard Shortcut Toggle'.

**Return Value:**

TRUE if the state is set such that the plug-in accelerators are enabled and FALSE if the system accelerators are enabled.

**Prototype:**

**virtual void SetPluginKeysEnabled(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Note that this method has been removed in release 4.0 and later.

In the MAX UI there is a icon button for toggling between the MAX system keyboard accelerators and those registered by plug-ins. This method may be used to set the state such that the plug-in accelerators are enabled or disabled.

**Note: Normally the user should decide which accelerators are enabled. The user will probably find it disconcerting to have a plug-in change the state of this button. Therefore developers should simply register their accelerators and let the user toggle them on and off.**

**Parameters:**

**BOOL onOff**

TRUE to enable plug-in accelerators; FALSE to enable system accelerators.

**Keyboard Shortcut Table Related Methods**

The keyboard shortcut system used prior to release 4 of MAX has been replaced by a more comprehensive system. See the Advanced Topics section [UI Customization](#) for details.

## Light Related Methods

### Prototype:

**virtual float GetLightConeConstraint()=0;**

### Remarks:

Returns the light cone constraint angle (in radians). This is the hotspot / falloff separation angle.

### Prototype:

**virtual void AddLightToScene(INode \*node)=0;**

### Remarks:

Adds a light to the scene and registers the light with the viewports.

### Parameters:

**INode \*node**

The light to add.

### Prototype:

**virtual void AddSFXRollupPage(ULONG flags=0)=0;**

### Remarks:

This method is available in release 3.0 and later only.

This method should be called in an light's **BeginEditParams()** method, after adding rollups to the modify panel: it puts up a rollup containing a list of all Atmospherics and Effects that use the current selected node as a "gizmo".

### Parameters:

**ULONG flags=0**

These are reserved for future use.

### Prototype:

**virtual void DeleteSFXRollupPage()=0;**

### Remarks:

This method is available in release 3.0 and later only.

This is called in a light's **EndEditParams()** when removing rollups.

**Prototype:**

**virtual void RefreshSFXRollupPage()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

An Atmospheric or Rendering Effect calls this when it adds or removes a "gizmo" reference. This is called to refresh the Special Effects rollup. The Atmospherics and Rendering Effects may also use the **REFMSG\_SFX\_CHANGE** message, though calling this method would have the same effect.

**Material Related Methods****Prototype:**

**virtual MtlBaseLib& GetMaterialLibrary()=0;**

**Remarks:**

This method provides access to the currently loaded material library.

**Return Value:**

See [Class MtlBaseLib](#).

**Prototype:**

**MtlBaseLib\* GetSceneMtls();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a list of all the materials used in the scene.

**Return Value:**

See [Class MtlBaseLib](#).

**Prototype:**

**MtlBase\* GetMtlSlot(int slot);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the material in the specified slot in the Materials Editor.

**Parameters:**

**int slot**

The number of the slot in the Materials Editor (a value in the range 0 to 23).

**Prototype:**

```
virtual BOOL OkMtlForScene(MtlBase *m)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Before assigning material to scene, call this to avoid duplicate names.

**Return Value:**

TRUE if it is okay to assign the material; FALSE if not.

**Prototype:**

```
virtual void AssignNewName(Mtl *m)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Modifies the name of the material to make it unique. The name is of the form "**Material #1**" where the number is incremented as required to make ensure it's unique.

**Parameters:**

**Mtl \*m**

The material whose name is modified.

**Prototype:**

```
virtual void AssignNewName(Texmap *m)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Modifies the name of the texture to make it unique. . The name is of the form "**Map #1**" where the number is incremented as required to make ensure it's unique.

**Parameters:**

**Texmap \*m**

The texmap whose name is modified.

**Prototype:**

```
void ActivateTexture(Texture *tx, Mtl *mtl, int subNum=-1);
```

**Remarks:**

This method is available in release 2.0 and later only.

The method activates the texture map in the viewports.

Note: In the MAX 2.0 SDK a bug prevents this function from being used -- it results in a link error. This is fixed in the 2.5 SDK.

**Parameters:**

**Texture \*tx**

Points to the texture map to activate.

**Mtl \*mtl**

The **top level** material containing the texture map.

**int subNum=-1**

If **mtl** above is a Multi-material, this specifies which sub-branch of the material contains **tx**.

**Prototype:**

```
void DeActivateTexture(Texture *tx, Mtl *mtl, int subNum=-1);
```

**Remarks:**

This method is available in release 2.0 and later only.

The method deactivates the texture map in the viewports.

Note: In the MAX 2.0 SDK a bug prevents this function from being used -- it results in a link error. This is fixed in the 2.5 SDK.

**Parameters:**

**Texture \*tx**

Points to the texture map to deactivate.

**Mtl \*mtl**

The **top level** material containing the texture map.

**int subNum=-1**

If **mtl** above it a Multi-material, this specifies which sub-branch of the material contains **tx**.

**Prototype:**

```
virtual void UpdateMtlEditorBrackets()=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method makes sure the Materials Editor slots correctly reflect which materials are used in the scene, which are used by selected objects, etc. This is used internally for the drag-and-drop of materials to nodes -- there is no reason why a plug-in developer should need to call it.

**Prototype:**

```
virtual void ConvertMtl(TimeValue t, Material &gm, Mtl *mtl,  
BOOL doTex, int subNum, float vis, BOOL &needDecal, INode  
*node, BitArray *needTex, GraphicsWindow *gw)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This function converts a material (class Mtl) to a viewport material (class Material).

**Parameters:****TimeValue t**

The time to convert the material.

**Material &gm**

The viewport material (output). See [Class Material](#).

**Mtl \*mtl**

The material to convert (input). See [Class Mtl](#).

**BOOL doTex**

Determines whether or not to include textures. TRUE for yes; FALSE for no.

**int subNum**

If the input material **mtl** is a sub-material then pass its subnum; otherwise pass 0.

**float vis**

The visibility value in the range of 0.0 (completely transparent) to 1.0 (fully opaque) for the viewport representation.

**BOOL &needDecal**

Pass TRUE if the texture needs decal mapping; otherwise FALSE.

### **INode \*node**

Points to the node that the material is assigned to. See [Class INode](#).

### **BitArray \*needTex**

A BitArray that returns which map channels are needed. The BitArray is enlarged if needed. See [Class BitArray](#).

### **GraphicsWindow \*gw**

The GraphicsWindow to do the conversion for. See [Class GraphicsWindow](#).

## **Modifier Related Methods**

### **Prototype:**

```
virtual void GetModContexts(ModContextList& list, INodeTab& nodes)=0;
```

### **Remarks:**

A modifier may be applied to several objects in the scene. This method retrieves a list of all the ModContexts for the modifier at the current place in the modifier stack. It also gets a list of the nodes the modifier is applied to. For example a modifier may store data into the local data portion of the ModContext for each object affected by the modifier. In order to get at this data it needs to get each ModContext.

Note: this method returns only the ModContext of the currently selected objects, even if the modifier is applied to several objects.

### **Parameters:**

#### **ModContextList& list**

A reference to the list of ModContexts. See [ModContextList](#).

#### **INodeTab& nodes**

A reference to the table of each of the nodes. See [INodeTab](#).

### **Prototype:**

```
virtual BaseObject* GetCurEditObject()=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the object (or modifier) that is currently being edited in

the modifier panel. See [Class BaseObject](#).

## Node Grouping

### Prototype:

```
virtual INode *GroupNodes(INodeTab *nodes=NULL,TSTR  
*name=NULL,BOOL selGroup=TRUE)=0;
```

### Remarks:

Combines the specified nodes into a MAX group.

### Parameters:

**INodeTab \*nodes=NULL**

The table of nodes to combine into a MAX group. If NULL is passed, the current selection set is used.

**TSTR \*name=NULL**

The name of the group to create. If the name is NULL, a dialog box will prompt the user to select a name.

**BOOL selGroup=TRUE**

If TRUE, the group of nodes will be selected after the operation is completed.

### Return Value:

A pointer to the group of nodes created.

### Prototype:

```
virtual void UngroupNodes(INodeTab *nodes=NULL)=0;
```

### Remarks:

Un-groups the specified nodes.

### Parameters:

**INodeTab \*nodes=NULL**

The table of nodes to un-group. If NULL is passed, the current selection set is used.

### Prototype:

```
virtual void ExplodeNodes(INodeTab *nodes=NULL)=0;
```

**Remarks:**

Explodes the grouped nodes. This completely un-groups nested groups.

**Parameters:**

**INodeTab \*nodes=NULL**

The table of nodes to explode. If NULL is passed, the current selection set is used.

**Prototype:**

**virtual void OpenGroup(INodeTab \*nodes=NULL,BOOL clearSel=TRUE)=0;**

**Remarks:**

Opens the grouped nodes. Items in an opened group may be edited individually.

**Parameters:**

**INodeTab \*nodes=NULL**

The table of nodes comprising a group that will be opened. If NULL is passed, the current selection set is used.

**BOOL selGroup=TRUE**

If TRUE, the group of nodes will be selected after the operation is completed.

**Prototype:**

**virtual void CloseGroup(INodeTab \*nodes=NULL,BOOL selGroup=TRUE)=0;**

**Remarks:**

Closes the specified group of nodes. Items in a closed group cannot be edited individually.

**Parameters:**

**INodeTab \*nodes=NULL**

The table of nodes to close. If NULL is passed, the current selection set is used.

**BOOL selGroup=TRUE**

If TRUE, the group of nodes will be selected after the operation is completed.

## Node Names -- Creating Unique

### Prototype:

```
virtual void MakeNameUnique(TSTR &name)=0;
```

### Remarks:

Given a name, this method will modify it to ensure it is unique. It does this by appending a two digit number to the end of the name, or incrementing the existing number, until the name created is unique. Important Note: See **NewNameMaker()** below for a much faster version of this method when creating **many** nodes whose names must be unique.

### Parameters:

**TSTR &name**

The name to make unique.

### Prototype:

```
virtual NameMaker* NewNameMaker(BOOL initFromScene =  
TRUE)=0;
```

### Remarks:

Returns a class used for efficiently creating unique names. To use, do the following:

```
NameMaker *nm = interface->NewNameMaker();  
for(;;) {  
    ...  
    nm->MakeUniqueName(nodename);  
    ...  
}  
delete nm;
```

### Parameters:

**BOOL initFromScene = TRUE**

This parameter is available in release 2.0 and later only.

If FALSE then the name maker is not seeded with the names of the objects in the current scene.

### Return Value:

See [Class NameMaker](#) for details.

## Node Related Methods

### Prototype:

```
virtual INode *GetINodeByName(const TCHAR *name)=0;
```

### Remarks:

This method may be called to retrieve the **INode** pointer for the node with the given name.

### Parameters:

**const TCHAR \*name**

The name of the node to find.

### Prototype:

```
virtual INode *GetINodeByHandle(ULONG handle)=0;
```

### Remarks:

This method is available in release 4.0 and later only.

Returns a pointer to the node whose handle is specified. In 3dsmax version 4.0 and later each node is assigned a unique handle.

### Parameters:

**ULONG handle**

The handle of the node to find.

### Prototype:

```
virtual void DeleteNode(INode *node, BOOL redraw=TRUE,  
BOOL overrideSlaves=FALSE)=0;
```

### Remarks:

This deletes the specified node from the scene and handles setting up for an undo.

In order to be able to undo this deletion properly the undo system must be in a holding state. A developer can do this by calling **theHold.Begin()** before calling **DeleteNode()** and calling **theHold.Accept()** after. For example, to delete the first node in the current selection set, you could use the following

code:

```
theHold.Begin();  
ip->DeleteNode(ip->GetSelNode(0));  
theHold.Accept(_T("Delete"));
```

The string used in the **Accept()** method is what appears to the user in the Undo menu choice.

Note that the object reference of the node is deleted as well if the only item referencing that object is the node. This is because when the node is deleted, it first deletes all its references. Whenever a reference is deleted, if the item is the last reference, then the system deletes the item as well.

### **Parameters:**

**INode \*node**

The node to delete.

**BOOL redraw=TRUE**

This parameter is available in release 2.0 and later only.

If FALSE the viewports will not be redrawn after the node is deleted. This allows several nodes to be deleted at once without the viewports having to be redrawn after each one.

**BOOL overrideSlaves=FALSE**

This parameter is available in release 2.0 and later only.

If TRUE then this method **will** delete nodes whose TM controllers implement the **Control::PreventNodeDeletion()** method to return TRUE. If a TM controller implements that method then normally **DeleteNode()** won't work on the nodes associated with that controller. However if this parameter is TRUE then these nodes still can be deleted. This allows a master controller to easily delete slaves nodes if it needs to.

### **Prototype:**

```
virtual INode *GetRootNode()=0;
```

### **Remarks:**

Returns a pointer to the root node. From the root node one can retrieve the children (using **INode::NumberOfChildren()**, and **INode::GetChildNode(i)**). This allows a developer enumerated the scene

by enumerating the node tree.

**Prototype:**

**virtual void NodeInvalidateRect( INode \*node )=0;**

**Remarks:**

This invalidates the rectangle in the viewports that the node occupies. Rectangles flagged as invalid will be updated on the next screen redraw.

**Parameters:**

**INode \*node**

Specifies the node whose rectangle is invalidated.

**Prototype:**

**virtual void SetNodeTMRelConstPlane(INode \*node, Matrix3& mat)=0;**

**Remarks:**

Sets the nodes transform relative to the current construction plane. This may be used during creating so you can set the position of the node in terms of the construction plane and not in world units.

**Parameters:**

**INode \*node**

The node whose transform will be set.

**Matrix3& mat**

The transformation matrix.

## **Node Selection Sets**

**Prototype:**

**virtual int GetSelNodeCount()=0;**

**Remarks:**

Returns the number of nodes in the selection set.

**Prototype:**

**virtual INode \*GetSelNode(int i)=0;**

**Remarks:**

Selection sets are handled as a virtual array and accessed using an index starting at 0. This method returns a pointer to the 'i-th' node in the current selection set. See also: **GetSelNodeCount()**.

**Parameters:****int i**

Index of the node in the selection set.

**Return Value:**

Pointer to the 'i-th' node in the selection set.

**Prototype:****virtual void GetSelectionWorldBox(TimeValue t,Box3 &box)=0;****Remarks:**

This method retrieves the world space bounding box of the current selection set.

**Parameters:****TimeValue t**

The time to retrieve the bounding box.

**Box3 &box**

The bounding box is returned here.

**Prototype:****virtual void SelectNode(INode \*node, int clearSel = 1)=0;****Remarks:**

This selects the specified node, either adding it to the current selection set, or creating a new selection set with the node.

Note: A developer should call **theHold.Begin()** before this method and **theHold.Accept()** after this call. Otherwise, MAX may crash if the user selects undo after this call has been issued. See the sample code below. Also see [Undo / Redo](#) for more details on this system.

**Parameters:****INode \*node**

The node to select.

**int clearSel = 1**

If zero, the node is added to the current selection set. If nonzero, the node replaces the selection set.

**Sample Code:**

```
theHold.Begin();  
ip->SelectNode(node);  
TSTR undostr; undostr.printf("Select");  
theHold.Accept(undostr);
```

**Prototype:**

```
virtual void DeSelectNode(INode *node)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method unselects the specified node.

**Parameters:**

**INode \*node**

The node to deselect.

**Prototype:**

```
virtual void SelectNodeTab(INodeTab &nodes,BOOL sel,BOOL  
redraw=TRUE)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method may be used to select or deselect a group of nodes all at once and optionally redraw the viewports when done.

**Parameters:**

**INodeTab &nodes**

The Table of nodes to select or deselect.

**BOOL sel**

If TRUE the nodes are selected; otherwise they are deselected.

**BOOL redraw=TRUE**

If TRUE the viewports are redrawn when done; otherwise they are not.

**Prototype:**

**virtual void ClearNodeSelection(BOOL redraw=TRUE)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method may be used to clear the current selection set and optionally redraw the viewports.

**Parameters:**

**BOOL redraw=TRUE**

If TRUE the viewports are redrawn when done; otherwise they are not.

**Prototype:**

**virtual BOOL SelectionFrozen()=0;**

**Remarks:**

In MAX the space bar freezes the selection set. This keeps the selection set from being inadvertently changed. This method access the status of the selection set frozen state.

**Return Value:**

TRUE if the selection set is frozen; otherwise FALSE.

**Prototype:**

**virtual void FreezeSelection()=0;**

**Remarks:**

Toggles the selection set to the frozen state.

**Prototype:**

**virtual void ThawSelection()=0;**

**Remarks:**

Toggles the selection set to the thawed state.

**Prototype:**

```
virtual bool CloneNodes(INodeTab& nodes, Point3& offset, bool  
expandHierarchies = true, CloneType cloneType = NODE_COPY,  
INodeTab* resultSource = NULL, INodeTab* resultTarget =  
NULL) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to clone nodes and node hierarchies.

**Parameters:**

**INodeTab& nodes**

The node table containing the nodes you wish to clone.

**Point3& offset**

The position offset you wish to apply to the cloned nodes.

**bool expandHierarchies = true**

This determines if children will be cloned in hierarchies.

**CloneType cloneType = NODE\_COPY**

The type of cloning you wish to do, which is one of the following;

**NODE\_COPY**, **NODE\_INSTANCE** or **NODE\_REFERENCE**.

**INodeTab\* resultSource = NULL**

This node table will be filled in with the original nodes to be cloned. The reason for this is that there can be dependencies between nodes that cause other nodes to be added to the list. For example light/camera targets, nodes part of systems, belonging to groups or expanded hierarchies etc.

**INodeTab\* resultTarget = NULL**

This node table will be filled in with the new cloned nodes. There is a one to one relationship between the nodes in the resultSource and the resultTarget.

**Return Value:**

TRUE if the nodes were cloned successfully, otherwise FALSE. Note that with R4.0 the return value will always be TRUE since no actual error checking is undertaken.

## **Node Picking (interactive selection in the scene)**

**Prototype:**

```
virtual INode *PickNode(HWND hWnd, IPoint2
```

**pt, PickNodeCallback \*filt=NULL)=0;**

**Remarks:**

This method hit tests the screen position for nodes and returns an INode pointer if one is hit, NULL otherwise.

**Parameters:**

**HWND hWnd**

Handle of the window to check.

**IPoint2 pt**

Point to check in screen coordinates.

**PickNodeCallback \*filt=NULL**

This callback may be used to filter nodes from being picked. See [Class PickNodeCallback](#).

**Return Value:**

INode pointer of node that was hit; NULL if no node was found.

**Prototype:**

**virtual void BoxPickNode(ViewExp \*vpt, IPoint2 \*pt, BOOL crossing, PickNodeCallback \*filt=NULL)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method performs a node level hit test on the specified rectangular region. Use either the **ViewExp::GetClosestHit()** or **ViewExp::GetHit()** method to access the result.

**Parameters:**

**ViewExp \*vpt**

The viewport to perform the hit testing.

**IPoint2 \*pt**

These points specify the box region to hit test. The first point in the array is the lower left. The second point is the upper right.

**BOOL crossing**

If TRUE Crossing selection is used; otherwise Window selection is used.

**PickNodeCallback \*filt=NULL**

This callback may be used to filter nodes from being picked. See [Class PickNodeCallback](#).

**Prototype:**

```
virtual void CirclePickNode(ViewExp *vpt,IPoint2 *pt,BOOL crossing,PickNodeCallback *filt=NULL)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method performs a node level hit test on the specified circular region. Use either the **ViewExp::GetClosestHit()** or **ViewExp::GetHit(int i)** method to access the result.

**Parameters:**

**ViewExp \*vpt**

The viewport to perform the hit testing.

**IPoint2 \*pt**

These points specify the circular region to hit test. The first point in the array is the center. The second point is a point on the radius.

**BOOL crossing**

If TRUE Crossing selection is used; otherwise Window selection is used.

**PickNodeCallback \*filt=NULL**

This callback may be used to filter nodes from being picked. See [Class PickNodeCallback](#).

**Prototype:**

```
virtual void FencePickNode(ViewExp *vpt,IPoint2 *pt,BOOL crossing,PickNodeCallback *filt=NULL)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method performs a node level hit test on the specified arbitrary polygonal region. Use either the **ViewExp::GetClosestHit()** or **ViewExp::GetHit()** method to access the result.

**Parameters:**

## **ViewExp \*vpt**

The viewport to perform the hit testing.

## **IPoint2 \*pt**

These points specify the fence region to hit test. It is assumed the last point is connected to the first point to close the region. The fence knows when it's out of points when it hits a point that has negative **x** and **y** values. So, the initializer **IPoint2(-1, -1)** added to the bottom of this **IPoint2** list signals the end.

## **BOOL crossing**

If TRUE Crossing selection is used; otherwise Window selection is used.

## **PickNodeCallback \*filt=NULL**

This callback may be used to filter nodes from being picked. See [Class PickNodeCallback](#).

### **Prototype:**

```
virtual void SetPickMode(PickModeCallback *pc)=0;
```

### **Remarks:**

This will set the command mode to a standard pick mode. The callback implements hit testing and a method that is called when the user actually picks an item. Note that this method, if called a second time, will cancel the pick mode and put the user into 'Select and Move' mode. This can be used to handle the case where a user clicks on a user interface control a second time to cancel to picking.

Sample code using this API is available in

**\MAXSDK\SAMPLES\OBJECTS\MORPHOBJ.CPP**. A utility plug-in that uses this API is

**\MAXSDK\SAMPLES\UTILITIES\ASCIIOUT.CPP**.

### **Parameters:**

#### **PickModeCallback \*pc**

A pointer to an instance of the class [PickModeCallback](#).

### **Prototype:**

```
virtual void ClearPickMode()=0;
```

**Remarks:**

This method is called to make sure there are no pick modes in the command stack.

**Prototype:**

```
virtual void FlashNodes(INodeTab *nodes)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to 'flash' a group of nodes. This is usually used as a confirmation of some operation (for example as an indication of the completion of a pick node operation.) The nodes are briefly erased and then redrawn in the viewport to flash them.

**Parameters:**

```
INodeTab *nodes
```

Pointer to the table of nodes to 'flash'.

**Sample Code:**

```
INodeTab flash;  
INode *node;  
for (int i=0; i<ip->GetSelNodeCount(); i++) {  
    node = ip->GetSelNode(i);  
    flash.Append(1,&node,10);  
}  
ip->FlashNodes(&flash);
```

**IObjCreate and IObjParam Pointer Casting****Prototype:**

```
virtual IObjCreate *GetIObjCreate()=0;
```

**Remarks:**

Returns this interface pointer cast as a **IObjCreate** pointer.

**Prototype:**

```
virtual IObjParam *GetIObjParam()=0;
```

**Remarks:**

Returns this interface pointer cast as a **IObjParam** pointer.

**Object Snap Methods****Prototype:**

**virtual IOsnapManager \*GetOsnapManager()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns an interface pointer to the object snap manager. See [Class IOsnapManager](#). Also see the Advanced Topics section on [Snapping](#).

**Prototype:**

**virtual MouseManager \*GetMouseManager()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is used internally by the Osnap Manager. Plug-Ins don't need to use this method.

**Prototype:**

**virtual void InvalidateOsnapdraw()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This is used internally to invalidate the osnap drawing mechanism. Plug-Ins don't need to use this method.

**Preview Creation****Prototype:**

**virtual void CreatePreview(PreviewParams \*pvp=NULL)=0;**

**Remarks:**

This method is used to render a preview image (or animation) from the currently active viewport using the real-time (viewport) renderer.

This method is available in release 2.0 and later only.

**Parameters:**

**PreviewParams \*pvp=NULL**

This class defines the way the preview is generated (via its data members). If this is passed as NULL the parameters from the preview rendering dialog box are used. See [Class PreviewParams](#).

## Progress Bar Methods

**Prototype:**

**virtual BOOL ProgressStart(TCHAR \*title, BOOL dispBar, LPTHREAD\_START\_ROUTINE fn, LPVOID arg)=0;**

**Remarks:**

This method puts up a progress bar in the status panel. The function **fn** is then called and is passed the argument **arg**. This function **fn** does the processing work of the plug-in. See the sample code below.

Note: It is not possible to use the progress bar APIs in the create or modify branches of the command panel. In the create or modify branch of the command panel, **EndEditParams()** gets called from this method. This is because most of MAX is "shut down" during a progress operation. For example, it is not appropriate for users to be moving objects during an IK calculation, or changing the camera lens while a preview is being created (all these operations use the **ProgressStart()** API). It is for this same reason that the Transform Type-in, Medit, Track View and Video Post windows are hidden during a progress operation. Since **EndEditParams()** is called, the Interface pointer a plug-in maintains is no longer valid after the operation is started. This method is useful for Utility plug-ins, and Import/Export plug-ins however.

**Parameters:**

**TCHAR \*title**

The title string for the progress bar to let the user know what is happening.

**BOOL dispBar**

If FALSE the progress bar is not displayed; if TRUE the progress bar is displayed.

## **LPTHREAD\_START\_ROUTINE fn**

This is a pointer to a function that returns a **DWORD** and takes a single argument. When **ProgressStart()** is called, this function is called with the argument **arg** passed. This function should be declared as follows:

```
DWORD WINAPI fn(LPVOID arg)
```

## **LPVOID arg**

This is the argument to the function **fn**.

## **Return Value:**

TRUE means the progress mode was entered successfully. FALSE means that there was a problem. Currently the return value is always TRUE. When compiled for multi-threading (which is turned off in the 1.0 build), FALSE is returned if the new thread could not be created.

## **Sample Code:**

This code demonstrates the use of the **ProgressStart()**, **ProgressEnd()**, **GetCancel()** and **SetCancel()** APIs. There are two ways to use the APIs. One is to use a dummy function for **fn** in **ProgressStart()**. Then just call **ProgressUpdate()** from whatever function you want to do the processing. The other way is to use **fn** to do the processing.

In this version, the **fn** function passed to **ProgressStart()** performs the work.

```
DWORD WINAPI fn(LPVOID arg) {  
    int i, percent;  
    Interface *ip = theUtility.ip;  
    for (i = 0; i < 1000; i++) {  
        percent = i/10;  
        ip->ProgressUpdate(percent);  
        if (ip->GetCancel()) {  
            switch(MessageBox(ip->GetMAXHwnd(), _T("Really Cancel"),  
                _T("Question"), MB_ICONQUESTION | MB_YESNO)) {  
                case IDYES:  
                    return(0);  
                case IDNO:  
                    ip->SetCancel(FALSE);  
            }  
        }  
    }
```

```

}
return(0);
}
void Utility::Test1() {
    Interface *ip = theUtility.ip;
    LPVOID arg;
    ip->ProgressStart(_T("Title String"), TRUE, fn, arg);
    ip->ProgressEnd();
}

```

In this version, the **fn** function passed to **ProgressStart()** is a dummy function, and the processing is done outside it.

```

DWORD WINAPI fn(LPVOID arg) {
    return(0);
}
void Utility::Test1() {
    int i, percent, retval;
    Interface *ip = theUtility.ip;
    LPVOID arg;
    ip->ProgressStart(_T("Title String"), TRUE, fn, arg);
    for (i = 0; i < 1000; i++) {
        percent = i/10;
        ip->ProgressUpdate(percent);
        if (ip->GetCancel()) {
            retval = MessageBox(ip->GetMAXHwnd(), _T("Really Cancel"),
                _T("Question"), MB_ICONQUESTION | MB_YESNO);
            if (retval == IDYES)
                break;
            else if (retval == IDNO)
                ip->SetCancel(FALSE);
        }
    }
    ip->ProgressEnd();
}

```

**Prototype:**

```

virtual void ProgressUpdate(int pct, BOOL showPct = TRUE,

```

**TCHAR \*title = NULL)=0;**

**Remarks:**

This method updates the progress bar. As the function **fn** passed in **ProcessStart()** above is working it should periodically call this method to report its progress.

**Parameters:**

**int pct**

The percentage complete (0 to 99). This is what causes the progress bar to move.

**BOOL showPct = TRUE**

If TRUE, then the **title** parameter is ignored, and a percent is displayed to the right of the progress bar. If FALSE, then the **title** parameter is displayed next to the progress bar. This is for operations that are discrete -- the title might change from "extruding" to "capping" to "welding" for example. Note that currently the Cancel button is not shown if **showPct** is set to FALSE, however the ESC key may be used to cancel.

**TCHAR \*title = NULL**

If **showPct** is FALSE, this string is displayed next to the progress bar.

**Prototype:**

**virtual void ProgressEnd()=0;**

**Remarks:**

This method removes the progress bar and frees the memory that was allocated internally to handle the processing.

**Prototype:**

**virtual BOOL GetCancel()=0;**

**Remarks:**

This method returns the progress bar cancel button status. Also see **SetCancel()** below.

**Return Value:**

TRUE if the user pressed the cancel button; otherwise FALSE.

**Prototype:**

```
virtual void SetCancel(BOOL sw)=0;
```

**Remarks:**

Sets the canceled status returned from **GetCancel()**. This may be used if you want to give the user a confirmation dialog box asking if they really want to cancel. For example, when a MAX user creates an preview animation this API is used. If the user presses cancel, the preview code reads this via

**GetCancel()**. Then a confirmation dialog is displayed asking the user if they indeed want to cancel. If the user selects that they don't want to cancel, this method is called passing FALSE. This sets the class variable that is returned by **GetCancel()**. The cancel request is ignored and processing continues.

Note that this will not cancel unless you implement code to process **GetCancel()**. It merely sets the state returned from **GetCancel()**.

**Parameters:**

**BOOL sw**

TRUE to set the cancel flag; FALSE to clear the cancel flag.

**Renderer Access**

The following APIs provide a simplistic method to call the renderer and render frames (to gain more control over the renderer, see the methods after these first three). The renderer just uses the current user specified parameters. Note that the renderer uses the width, height, and aspect of the specified bitmap so the caller can control the size of the rendered image rendered. Also Note: These methods drive the renderer and not video post.

**Prototype:**

```
virtual int OpenCurRenderer(INode *camNode,ViewExp  
*view,RenderType t = RENDTYPE_NORMAL, int w=0, int h=0)=0;
```

**Remarks:**

This method is called to open the current renderer. It must be opened before frames can be rendered. Either **camNode** or **view** must be non-NULL, but not both. Remember to close the renderer when you are done (using **CloseCurRenderer()**).

**Parameters:**

**INode \*camNode**

A pointer to the camera node to render, or NULL if a viewport should be rendered.

**ViewExp \*view**

A pointer to the view to render, or NULL if the camera should be rendered.

**RendType t = RENDTYPE\_NORMAL**

This parameter is available in release 3.0 and later only.

This provides an optional way to specify the view when opening the renderer.

This specifies the type of render. See [List of Render Types](#).

**int w=0**

This parameter is available in release 3.0 and later only.

This specifies the width of the rendering.

**int h=0**

This parameter is available in release 3.0 and later only.

This specifies the height of the rendering.

**Return Value:**

Nonzero indicates success; failure is zero.

**Prototype:**

```
virtual int OpenCurRenderer(ViewParams *vpar,RendType t =  
RENDTYPE_NORMAL, int w=0, int h=0)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to open the current renderer. It provides an optional way to specify the view when opening.

**Parameters:****ViewParams \*vpar**

This class describes the properties of a view that is being rendered. See [Class ViewParams](#).

**RendType t = RENDTYPE\_NORMAL**

This parameter is available in release 3.0 and later only.

This provides an optional way to specify the view when opening the renderer.

This specifies the type of render. See [List of Render Types](#).

**int w=0**

This parameter is available in release 3.0 and later only.

This specifies the width of the rendering.

**int h=0**

This parameter is available in release 3.0 and later only.

This specifies the height of the rendering.

**Return Value:**

Nonzero indicates success; failure is 0.

**Prototype:**

**virtual void CloseCurRenderer()=0;**

**Remarks:**

This method is called to close the renderer. The renderer must be closed when you are finished with it.

**Prototype:**

**virtual int CurRendererRenderFrame(TimeValue t,Bitmap \*bm,RendProgressCallback \*prog=NULL, float frameDur = 1.0f , ViewParams \*vp=NULL, RECT \*regionRect = NULL)=0;**

**Remarks:**

This method is called to render a frame to the given bitmap. The renderer uses the width, height, and aspect ratio of the specified bitmap to control the size of the rendered image.

**Parameters:**

**TimeValue t**

The time to render the image.

**Bitmap \*bm**

The bitmap to render to. This bitmap defines the size and aspect ratio of the render. See [Class Bitmap](#).

**RendProgressCallback \*prog=NULL**

The RendProgressCallback is an optional callback. See [Class RendProgressCallback](#).

**float frameDur = 1.0f**

This parameter should always be set to 1.0.

**ViewParams \*vp=NULL**

This parameter allows you to specify a different view transformation on each render call. For instance, you can render a given scene at a given time from many different viewpoints, without calling **Render::Open()** for each one.

**RECT \*regionRect = NULL**

This parameter is available in release 3.0 and later only.

This value, if passed, defines the region to be rendered. This only works for **RENDTYPE\_REGION** and **RENDTYPE\_REGIONCROP**.

**Return Value:**

The result of the render - Nonzero if success; otherwise 0.

**Prototype:**

**virtual IScanRenderer \*CreateDefaultScanlineRenderer()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method creates a default scanline renderer. This renderer must be deleted by calling **IScanRenderer::DeleteThis()**.

**Return Value:**

A pointer to a new IScanRenderer object.

**Prototype:**

**virtual BOOL DisplayActiveCameraViewWithMultiPassEffect() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method will draw the active view (if it is a camera view with a multi-pass effect enabled) with that effect active.

**Return Value:**

TRUE if the active view is a camera view with a multi-pass effect enabled, FALSE otherwise.

## Plug-In Renderer Access

Below is a set of functions parallel to those above to work with any `Renderer` instance.

### Prototype:

```
virtual int OpenRenderer(Renderer *pRenderer, INode  
*camNode, ViewExp *view, RendType type =  
RENDTYPE_NORMAL, int w=0, int h=0)=0;
```

### Remarks:

This method is available in release 4.0 and later only.

This method is called to open the specified renderer. It must be opened before frames can be rendered. Either **camNode** or **view** must be non-NULL, but not both. Remember to close the renderer when you are done (using **CloseRenderer()**).

### Parameters:

#### **Renderer \*pRenderer**

Points to the renderer to open.

#### **INode \*camNode**

A pointer to the camera node to render, or NULL if a viewport should be rendered.

#### **ViewExp \*view**

A pointer to the view to render, or NULL if the camera should be rendered.

#### **RendType type = RENDTYPE\_NORMAL**

This parameter is available in release 3.0 and later only.

This provides an optional way to specify the view when opening the renderer.

This specifies the type of render. See [List of Render Types](#).

#### **int w=0**

This specifies the width of the rendering.

#### **int h=0**

This specifies the height of the rendering.

### Return Value:

Nonzero indicates success; failure is zero.

**Prototype:**

```
virtual int OpenRenderer(Renderer *pRenderer, ViewParams *vpar, RendType type = RENDTYPE_NORMAL, int w=0, int h=0)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is called to open the specified renderer. It provides an optional way to specify the view when opening.

**Parameters:****Renderer \*pRenderer**

Points to the renderer to do the rendering.

**ViewParams \*vpar**

This class describes the properties of a view that is being rendered. See [Class ViewParams](#).

**RendType type = RENDTYPE\_NORMAL**

This parameter is available in release 3.0 and later only.

This provides an optional way to specify the view when opening the renderer.

This specifies the type of render. See [List of Render Types](#).

**int w=0**

This specifies the width of the rendering.

**int h=0**

This specifies the height of the rendering.

**Return Value:**

Nonzero indicates success; failure is 0.

**Prototype:**

```
virtual int RendererRenderFrame(Renderer *pRenderer, TimeValue t, Bitmap *bm, RendProgressCallback *prog=NULL, float frameDur = 1.0f, ViewParams *vp=NULL, RECT *regionRect = NULL)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method is called to render a frame with the specified renderer to the given

bitmap. The renderer uses the width, height, and aspect ratio of the specified bitmap to control the size of the rendered image.

**Parameters:**

**Renderer \*pRenderer**

Points to the renderer which will do the rendering.

**TimeValue t**

The time to render the image.

**Bitmap \*bm**

The bitmap to render to. This bitmap defines the size and aspect ratio of the render. See [Class Bitmap](#).

**RendProgressCallback \*prog=NULL**

The RendProgressCallback is an optional callback. See [Class RendProgressCallback](#).

**float frameDur = 1.0f**

This parameter should always be set to 1.0.

**ViewParams \*vp=NULL**

This parameter allows you to specify a different view transformation on each render call. For instance, you can render a given scene at a given time from many different viewpoints, without calling **Render::Open()** for each one.

**RECT \*regionRect = NULL**

This parameter is available in release 3.0 and later only.

This value, if passed, defines the region to be rendered. This only works for **RENDTYPE\_REGION** and **RENDTYPE\_REGIONCROP**.

**Return Value:**

The result of the render - Nonzero if success; otherwise 0.

**Prototype:**

**virtual void CloseRenderer(Renderer \*pRenderer)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Closes the specified renderer.

**Parameters:**

**Renderer \*pRenderer**

Points to the renderer to close.

To get more control over the renderer, the renderer can be called directly. The following methods give access to the current renderer and the user's current rendering settings. Note: These methods drive the renderer and not video post.

**Prototype:**

**virtual Renderer \*GetCurrentRenderer()=0;**

**Remarks:**

Retrieves a pointer to the renderer currently set as the active renderer. This will be either the production renderer or the draft renderer depending upon which is active. A developer can determine which renderer this is by calling the **ClassID()** method of the renderer.

**Return Value:**

A pointer to the renderer.

**Prototype:**

**virtual Renderer \*GetProductionRenderer()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves a pointer to the renderer currently set as the production renderer. A developer can determine which renderer this is by calling the **ClassID()** method of the renderer.

**Return Value:**

A pointer to the renderer.

**Prototype:**

**virtual Renderer \*GetDraftRenderer()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Retrieves a pointer to the renderer currently set as the draft renderer. A developer can determine which renderer this is by calling the **ClassID()** method of the renderer.

**Return Value:**

A pointer to the renderer.

**Prototype:**

```
virtual Renderer *GetRenderer(RenderSettingID  
renderSettingID)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the specified renderer.

**Parameters:**

**RenderSettingID renderSettingID**

One of these values: See [List of Render Setting IDs](#)

**Return Value:**

A pointer to the renderer.

**Prototype:**

```
virtual void AssignCurRenderer(Renderer *rend)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Assigns the renderer passed for use as either the draft renderer or the production renderer depending upon which is active.

**Parameters:**

**Renderer \*rend**

The renderer to assign.

**Prototype:**

```
virtual void AssignProductionRenderer(Renderer *rend)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Assigns the renderer passed as the production renderer.

**Parameters:**

**Renderer \*rend**

The renderer to assign.

**Prototype:**

**virtual void AssignDraftRenderer(Renderer \*rend)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Assigns the renderer passed as the draft renderer.

**Parameters:**

**Renderer \*rend**

The renderer to assign.

**Prototype:**

**virtual void AssignRenderer(RenderSettingID renderSettingID,  
Renderer \*rend)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Assigns the renderer passed as one of the standard MAX rendering options (Production, Draft, etc).

**Parameters:**

**RenderSettingID renderSettingID**

One of these values: See [List of Render Setting IDs](#)

**Renderer \*rend**

Points to the renderer to assign.

**Prototype:**

**virtual void SetUseDraftRenderer(BOOL b)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Specifies which renderer is active -- draft or production. Pass TRUE to use the draft renderer and FALSE to get the production renderer.

**Prototype:**

**virtual BOOL GetUseDraftRenderer()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Determines which renderer is active -- draft or production.

**Return Value:**

TRUE for the draft renderer and FALSE for the production renderer.

**Prototype:**

**virtual void ChangeRenderSetting(RenderSettingID  
renderSettingID)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Sets the specified renderer as active.

**Parameters:**

**RenderSettingID renderSettingID**

One of these values: See [List of Render Setting IDs](#).

**Prototype:**

**virtual RenderSettingID GetCurrentRenderSetting()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns a value which indicates which renderer is current. See [List of Render Setting IDs](#).

**Prototype:**

**virtual IRenderElementMgr \*GetCurRenderElementMgr()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a pointer to the current render elements manager interface.

**Prototype:**

## **virtual IRenderElementMgr**

**\*GetRenderElementMgr(RenderSettingID renderSettingID)=0;**

### **Remarks:**

This method is available in release 4.0 and later only.

This method returns a pointer to the production or draft render element manager -- passing in renderSettingID = RS\_IReshade will return NULL.

### **Parameters:**

**RenderSettingID renderSettingID**

One of these values: See [List of Render Setting IDs](#).

### **Prototype:**

**virtual void SetupRendParams(RendParams &rp, ViewExp \*vpt, RendType t = RENDTYPE\_NORMAL)=0;**

### **Remarks:**

This method is called to fill in a **RendParams** structure that can be passed to the renderer with the user's current rendering settings. This is whatever was last used, or the default settings.

In MAX 1.x note the following (this needs not be done in MAX 2.0 or later):

In order to open a renderer using this method to setup the **RendParams** class the following code should be used:

```
RendParams rp;  
SetupRendParams(rp, );  
rp.atmos = NULL;  
rp.envMap = NULL;
```

As shown above, this method does not automatically set the values for **envMap** and **atmos**. You must do this manually if you are using the **RendParams** object to initialize the renderer. Then you can call **Renderer::Open(, rp, )**. In MAX 2.0 and later, **atmos** and **envMap** are properly initialized without the above code.

### **Parameters:**

**RendParams &rp**

This is the class instance whose data is filled in. See [Class RendParams](#).

### **ViewExp \*vpt**

This pointer only needs to be passed in if the RendType is **RENDTYPE\_REGION** or **RENDTYPE\_BLOWUP**. In these cases it will set up the **RendParams regxmin, regxmax, regymin, regymax** from values stored in the viewport. See [Class ViewExp](#).

### **RendType t = RENDTYPE\_NORMAL**

See [List of Render Types](#).

### **Prototype:**

```
virtual void GetViewParamsFromNode(INode* vnode,  
ViewParams& vp, TimeValue t)=0;
```

### **Remarks:**

This method is available in release 4.0 and later only.

This method fills in the specified ViewParams structure based on type of node passed (camera or light). It can be used when instantiating a renderer and calling Open(), Render(), and Close() directly on it.

### **Parameters:**

#### **INode\* vnode**

Points to the node to initialize from.

#### **ViewParams& vp**

The ViewParams structure to initialize.

#### **TimeValue t**

The time at which to initialize the structure.

### **Prototype:**

```
virtual BOOL CheckForRenderAbort()=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

This method may be called during a rendering to check if user has cancelled the render.

### **Return Value:**

TRUE if user has cancelled; otherwise FALSE. If not rendering the method returns FALSE.

These methods give access to the individual user specified render parameters. These are either parameters that the user specifies in the render dialog or the renderer page of the preferences dialog.

**Prototype:**

**virtual int GetRendTimeType()=0;**

**Remarks:**

Retrieves the type of time range to be rendered.

**Return Value:**

One of the following values:

**REND\_TIMESINGLE**

A single frame.

**REND\_TIMESEGMENT**

The active time segment.

**REND\_TIMERANGE**

The user specified range.

**REND\_TIMEPICKUP**

The user specified frame pickup string (for example "1,3,5-12").

**Prototype:**

**virtual void SetRendTimeType(int type)=0;**

**Remarks:**

Sets the type of time range rendered.

**Parameters:**

**int type**

One of the following values:

**REND\_TIMESINGLE**

A single frame.

**REND\_TIMESEGMENT**

The active time segment.

**REND\_TIMERANGE**

The user specified range.

**REND\_TIMEPICKUP**

The user specified frame pickup string (for example "1,3,5-12").

**Prototype:**

**virtual TimeValue GetRendStart()=0;**

**Remarks:**

Retrieves the renderer's start time setting.

**Prototype:**

**virtual void SetRendStart(TimeValue start)=0;**

**Remarks:**

Sets the renderer's start time setting.

**Parameters:**

**TimeValue start**

The time to begin rendering.

**Prototype:**

**virtual TimeValue GetRendEnd()=0;**

**Remarks:**

Retrieves the renderer's end time setting.

**Prototype:**

**virtual void SetRendEnd(TimeValue end)=0;**

**Remarks:**

Sets the renderer's end time setting.

**Parameters:**

**TimeValue end**

The time to end rendering.

**Prototype:**

**virtual int GetRendNThFrame()=0;**

**Remarks:**

Returns the renderer's 'n-th' frame setting.

**Prototype:**

**virtual void SetRendNThFrame(int n)=0;**

**Remarks:**

Sets the renderer's 'n-th' frame setting.

**Parameters:**

**int n**

The n-th frame setting.

**Prototype:**

**virtual BOOL GetRendShowVFB()=0;**

**Remarks:**

Retrieves the state of the renderer's show virtual frame buffer flag. Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendShowVFB(BOOL onOff)=0;**

**Remarks:**

Sets the state of the renderer's show virtual frame buffer flag.

**Parameters:**

**BOOL onOff**

TRUE is on; FALSE is off.

**Prototype:**

**virtual BOOL GetRendSaveFile()=0;**

**Remarks:**

Retrieves the state of the renderer's save file flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendSaveFile(BOOL onOff)=0;**

**Remarks:**

Sets the state of the renderer's save file flag.

**Parameters:**

**BOOL onOff**

TRUE is on; FALSE is off.

**Prototype:**

**virtual BOOL GetRendUseDevice()=0;**

**Remarks:**

Retrieves the state of the renderer's use device flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendUseDevice(BOOL onOff)=0;**

**Remarks:**

Sets the state of the renderer's use device flag.

**Parameters:**

**BOOL onOff**

TRUE is on; FALSE is off.

**Prototype:**

**virtual BOOL GetRendUseNet()=0;**

**Remarks:**

Retrieves the state of the renderer's use net flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendUseNet(BOOL onOff)=0;**

**Remarks:**

Sets the state of the renderer's use net flag.

**Parameters:****BOOL onOff**

TRUE is on; FALSE is off.

**Prototype:**

**virtual BitmapInfo& GetRendFileBI()=0;**

**Remarks:**

Retrieves the rendering file BitmapInfo. This class describes the output file. See [Class BitmapInfo](#).

**Prototype:**

**virtual BitmapInfo& GetRendDeviceBI()=0;**

**Remarks:**

Retrieves the rendering device BitmapInfo. This class describes the output device. See [Class BitmapInfo](#).

**Prototype:**

**virtual int GetRendWidth()=0;**

**Remarks:**

Retrieves the rendering output width in pixels.

**Prototype:**

**virtual void SetRendWidth(int w)=0;**

**Remarks:**

Sets the rendering output width.

**Parameters:****int w**

The width in pixels.

**Prototype:**

**virtual int GetRendHeight()=0;**

**Remarks:**

Retrieves the rendering output height in pixels.

**Prototype:**

**virtual void SetRendHeight(int h)=0;**

**Remarks:**

Sets the rendering output height.

**Parameters:**

**int h**

The height in pixels.

**Prototype:**

**virtual float GetRendAspect()=0;**

**Remarks:**

Retrieves the renderer's pixel aspect ratio setting. Note for MAX 1.2: To get the 'Image Aspect Ratio' setting use:

**float aspectRatio =  
((float) ip->GetRendWidth())/((float) ip->GetRendHeight());**

In MAX 2.0 or later **GetRendImageAspect()** may be used:

**Prototype:**

**virtual void SetRendAspect(float a)=0;**

**Remarks:**

Sets the renderer's pixel aspect ratio setting.

**Parameters:**

**float a**

The pixel aspect ratio to set.

**Prototype:**

**virtual float GetRendImageAspect()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

**Return Value:**

Returns the image aspect ratio.

**Prototype:**

**virtual float GetRendApertureWidth()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

**Return Value:**

Returns the aperture width in millimeters (mm).

**Prototype:**

**virtual void SetRendApertureWidth(float aw)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the aperture width.

**Parameters:**

**float aw**

The width to set in millimeters (mm).

**Prototype:**

**virtual BOOL GetRendFieldRender()=0;**

**Remarks:**

Retrieves the renderer's field render flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendFieldRender(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's field render flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRenderColorCheck()=0;**

**Remarks:**

Retrieves the renderer's color check flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRenderColorCheck(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's color check flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRenderSuperBlack()=0;**

**Remarks:**

Retrieves the renderer's super black flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRenderSuperBlack(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's super black flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendHidden()=0;**

**Remarks:**

Retrieves the renderer's render hidden objects flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendHidden(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's render hidden objects flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendForce2Side()=0;**

**Remarks:**

Retrieves the renderer's force two-sided flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendForce2Side(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's force two-sided flag. TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendAtmosphere()=0;**

**Remarks:**

Retrieves the renderer's uses atmospheric effects flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendAtmosphere(BOOL onOff)=0;**

**Remarks:**

Sets if the renderer uses atmospheric effects.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendEffects()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

**Return Value:**

Returns TRUE if Rendering Effects will be used; otherwise FALSE.

**Prototype:**

**virtual void SetRendEffects(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if Rendering Effects will be used.

**Parameters:**

**BOOL onOff**

TRUE to use (on); FALSE to not use (off).

**Prototype:**

**virtual BOOL GetRendDisplacement()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

**Return Value:**

Returns TRUE if rendering displacements is enabled; otherwise FALSE.

Note: Developers should use the **flags** parameter of the **View** class which is passed into **GetRenderMesh()** to determine if Displacement Mapping is being used because the values may not be the same (for instance when rendering in the Materials Editor). See [Class View](#).

**Prototype:**

**virtual void SetRendDisplacement(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if rendering displacements are enabled.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual TSTR& GetRendPickFramesString()=0;**

**Remarks:**

Retrieves the string holding the frames the user wants to render. For example "1,3,5-12".

**Prototype:**

**virtual BOOL GetRendDitherTrue()=0;**

**Remarks:**

Retrieves the renderer's dither true color flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendDitherTrue(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's dither true color flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendDither256()=0;**

**Remarks:**

Retrieves the renderer's dither 256 color flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendDither256(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's dither 256 color flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendMultiThread()=0;**

**Remarks:**

Retrieves the renderer's multi-threaded flag.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendMultiThread(BOOL onOff)=0;**

**Remarks:**

Sets the renderer's multi-threaded flag.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetRendNThSerial()=0;**

**Remarks:**

This retrieves the output file sequencing nth serial numbering setting.

**Return Value:**

Returns TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetRendNThSerial(BOOL onOff)=0;**

**Remarks:**

This sets the output file sequencing nth serial numbering setting.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual int GetRendVidCorrectMethod()=0;**

**Remarks:**

Retrieves the video color check method.

**Return Value:**

One of the following values:

**0** is FLAG

**1** is SCALE\_LUMA

**2** is SCALE\_SAT

**Prototype:**

**virtual void SetRendVidCorrectMethod(int m)=0;**

**Remarks:**

Sets the video color check method.

**Parameters:**

**int m**

One of the following values:

**0** is FLAG

**1** is SCALE\_LUMA

**2** is SCALE\_SAT

**Prototype:**

**virtual int GetRendFieldOrder()=0;**

**Remarks:**

Retrieves the rendering field order.

**Return Value:**

One of the following values:

**0** is Even

**1** is Odd

**Prototype:**

**virtual void SetRendFieldOrder(int fo)=0;**

**Remarks:**

Sets the rendering field order to even or odd.

**Parameters:**

**int fo**

One of the following values:

**0** sets Even

**1** sets Odd

**Prototype:**

**virtual int GetRendNTSC\_PAL()=0;**

**Remarks:**

Retrieves the video color check NTSC or PAL setting.

**Return Value:**

One of the following values:

**0** is NTSC

**1** is PAL

**Prototype:**

**virtual void SetRendNTSC\_PAL(int np)=0;**

**Remarks:**

Sets the video color check NTSC or PAL setting.

**Parameters:**

**int np**

One of the following values:

**0** sets NTSC

**1** sets PAL

**Prototype:**

**virtual int GetRendSuperBlackThresh()=0;**

**Remarks:**

Returns the super black threshold setting.

**Prototype:**

**virtual void SetRendSuperBlackThresh(int sb)=0;**

**Remarks:**

Sets the super black threshold setting.

**Parameters:**

**int sb**

The super black threshold.

**Prototype:**

**virtual int GetRendFileNumberBase()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the File Number Base in the 'Common Parameters' rollup of the Render Scene dialog.

**Prototype:**

**virtual void SetRendFileNumberBase(int n)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the File Number Base in the 'Common Parameters' rollup of the Render Scene dialog.

**Parameters:**

**int n**

The number to set.

**Prototype:**

**virtual BOOL GetSkipRenderedFrames()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the skip existing rendered frames state is on; otherwise FALSE.

**Prototype:**

**virtual void SetSkipRenderedFrames(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the skip existing rendered frames state to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

## Right Click Menu Related Methods

### Prototype:

```
virtual RightClickMenuManager*  
GetRightClickMenuManager()=0;
```

### Remarks:

Using this pointer a developer can add to the menu that pops up when the user clicks the right mouse button. Example code is available in:

`\MAXSDK\SAMPLES\MODIFIERS\EDITSP.L.CPP`. See Also: [Class RightClickMenuManager](#).

### Return Value:

A pointer to the **RightClickMenuManager**.

## Rollup Page Related Methods

See [Command Panel -- Rollup Page Methods](#).

## Selection Sets (Named)

See Also: [Sub-Object Selection Sets \(Named\)](#)

### Prototype:

```
virtual void ClearCurNamedSelSet()=0;
```

### Remarks:

This method clears the current edit field of the named selection set drop down.

### Prototype:

```
virtual void SetCurNamedSelSet(TCHAR *setName)=0;
```

### Remarks:

This method is available in release 2.0 and later only.

Sets the edit field of the named selection set drop down to the set whose name is passed.

### Parameters:

**TCHAR \*setName**

The name of the selection set to make current.

**Prototype:**

**virtual void NamedSelSetListChanged()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Calling this method tells the system that the named sub-object selection sets have changed and that the drop down needs to be rebuilt. This will cause **BaseObject::SetupNamedSelDropDown()** to be called on the current item being edited. This is often called inside restore objects that undo changes to the selection set. This causes the system to check if the current item being edited is in sub-object selection mode, and if so, will cause **SetupNamedSelDropDown()** to be called. Note that restore objects can be invoked at any time and the user may not be in sub-object selection mode (for instance they might be in the Display panel). Restore objects however can simply call this method and the system will figure out if the drop down needs to be updated.

**Prototype:**

**virtual int GetNumNamedSelSets()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of named selection sets at the object level.

**Prototype:**

**virtual TCHAR \*GetNamedSelSetName(int setNum)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the name of the named selection set whose index is passed.

**Parameters:**

**int setNum**

The index of the named selection set.

**Prototype:**

**virtual int GetNamedSelSetItemCount(int setNum)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the number of items in the named selection set whose index is passed.

**Parameters:**

**int setNum**

The index of the named selection set.

**Prototype:**

**virtual INode \*GetNamedSelSetItem(int setNum,int i)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method may be used to retrieve the INode pointer of the 'i-th' item in the named selection set whose index is passed.

**Parameters:**

**int setNum**

The index of the selection set whose 'i-th' INode pointer is returned.

**int i**

The index into the selection set.

**Prototype:**

**virtual void AddNewNamedSelSet(INodeTab &nodes, TSTR &name)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Adds a new named selection set to those already available in the drop down list in the MAX toolbar.

**Parameters:**

**INodeTab &nodes**

The table of nodes making up the selection set.

**TSTR &name**

The name for the set.

**Prototype:**

**virtual void RemoveNamedSelSet(TSTR &name)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Removes the specified named selection set those already available in the drop down list in the MAX toolbar.

**Parameters:**

**TSTR &name**

The name for the set to remove.

## Scene Access

**Prototype:**

**virtual ReferenceTarget \*GetScenePointer()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer for direct access to the scene. This is primarily used for hanging AppData off the entire scene as opposed to a certain Animatable.

## Show End Result Related Methods

**Prototype:**

**virtual void EnableShowEndResult(BOOL enabled)=0;**

**Remarks:**

This method is called if a modifier wants to temporarily disable any modifiers following it. For example the edit mesh modifier does not let you edit a mesh while other modifiers later in the pipeline are affecting the result so it calls this method to disable the others temporarily.

**Parameters:**

**BOOL enabled**

TRUE is enabled; FALSE is disabled.

**Prototype:**

**virtual BOOL GetShowEndResult()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the Show End Result button is on (pressed); otherwise FALSE.

**Prototype:**

**virtual void SetShowEndResult(BOOL show)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the on/off (pressed/unpressed) state of the Show End Result button. Note that calling this method generates a redraw.

**Parameters:**

**BOOL show**

TRUE for on; FALSE for off.

## Slave / Server Mode Methods

**Prototype:**

**virtual BOOL InSlaveMode()=0;**

**Remarks:**

Returns TRUE if MAX is operating in network rendering mode and FALSE if operating in normal interactive mode. This method returns the same value as **Interface::IsNetServer()**.

**Prototype:**

**virtual BOOL IsNetServer()=0;**

**Remarks:**

Returns TRUE if MAX is operating in network rendering mode and FALSE if operating in normal interactive mode. This method returns the same value as **Interface::InSlaveMode()**.

**Prototype:**

**virtual void SetNetServer()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is for internal use only. Calling this method will not (alone) set MAX in "Server" mode. Developers should not call this method.

## **Snap Related Methods**

**Prototype:**

**virtual int InitSnapInfo(SnapInfo \*info)=0;**

**Remarks:**

This method is available in release 2.0 and later only (previously available as a global function).

Initialized the SnapInfo structure passed with the current snap settings.

**Parameters:**

**SnapInfo \*info**

Points to the SnapInfo structure to initialize. See [Structure SnapInfo](#).

**Return Value:**

Returns nonzero if snap is on; zero if off.

**Prototype:**

**virtual float SnapAngle(float angleIn, BOOL fastSnap=TRUE, BOOL forceSnap=FALSE)=0;**

**Remarks:**

Normally, with angle snap off, interactive rotation of a node uses a rate of 1/2 degree per pixel. With angle snap on, the angles are snapped to the nearest MAX angle snap value.

This method may be used when interactive rotation is taking place with the mouse to snap the angle passed to the nearest MAX angle snap value. In this method, the input value/output value snap correspondence is accelerated as the angle grows. This prevents the user from having to move the mouse too much with larger angle values. This is why this method does not return a linear relationship between the input angle and the snapped output angle.

Note that when angle snap is off, this method just returns the input value

unaltered.

Note for R3: This method formerly was set up with a single parameter, the angle to be snapped. If the angle snap toggle was on, snapping occurred. If not, it did nothing. There were two problems with this:

1) A multiplier was applied to the angle input, giving faster interactive results in object rotations, etc. This had a negative effect if you just wanted your input angle snapped to the nearest snap angle.

2) It only snapped if the angle snap toggle was on. Sometimes, you might want to snap something to the angle snap value even if the master toggle was off.

To remedy these shortcomings, the method has had two parameters added (**fastSnap** and **forceSnap**).

**Parameters:**

**float angleIn**

Angle to snap in radians.

**BOOL fastSnap=TRUE**

This parameter is available in release 3.0 and later only.

If TRUE the snapping multiplier is used; if FALSE it is not.

**BOOL forceSnap=FALSE**

This parameter is available in release 3.0 and later only.

If TRUE snapping is used even if the master angle snap toggle is off.

**Return Value:**

Angle snapped to the nearest angle snap setting (considering acceleration if specified), in radians, to be used for interactive rotation.

**Prototype:**

**virtual float SnapPercent(float percentIn)=0;**

**Remarks:**

Given a value in the range 0.0 (0%) to 1.0 (100%) this method snaps the value using the current percentage snap.

**Parameters:**

**float percentIn**

The value to snap.

**Return Value:**

The snapped value where 0.0 = 0% and 1.0 = 100%.

**Prototype:**

```
virtual BOOL GetSnapState()=0;
```

**Remarks:**

Retrieves the snap toggle state.

**Return Value:**

TRUE if snap is on; FALSE if snap is off.

**Prototype:**

```
virtual int GetSnapMode()=0;
```

**Remarks:**

Retrieves the current snap type.

**Return Value:**

One of the following values:

```
SNAPMODE_RELATIVE  
SNAPMODE_ABSOLUTE
```

**Prototype:**

```
virtual BOOL SetSnapMode(int mode)=0;
```

**Remarks:**

Set the current snap mode. Note that setting the mode to **SNAPMODE\_ABSOLUTE** will fail if the reference coordinate system is not in set to Screen.

**Parameters:**

**int mode**

One of the following values:

```
SNAPMODE_RELATIVE  
SNAPMODE_ABSOLUTE
```

**Return Value:**

Returns TRUE if succeeded; otherwise FALSE.

## Sound Object Access

### Prototype:

```
virtual SoundObj *GetSoundObject()=0;
```

### Remarks:

Returns the current sound object. See the sample code in `\MAXSDK\SAMPLES\UTILITIES\UTILTEST.CPP`.

See Also: [Class SoundObj](#), [Class IWaveSound](#).

### Prototype:

```
virtual void SetSoundObject(SoundObj *snd)=0;
```

### Remarks:

Sets the current sound object to the one specified. See [Class SoundObj](#).

### Parameters:

```
SoundObj *snd
```

The sound object to set as current.

## Sub-Object Related Methods

### Prototype:

```
virtual void RegisterSubObjectTypes(const TCHAR **types, int  
count, int startIndex=0)=0;
```

### Remarks:

This method registers the sub-object types for a given plug-in object type. See the Advanced Topics section on [sub-object selection](#) for more details.

### Parameters:

```
const TCHAR **types
```

Array of strings listing the sub object levels. The order the strings appear in the array sets the indices used for the sub-object levels. Level 0 is always object level, the first string corresponds to level 1, and the second string corresponds to level 2, etc. In the sample code below, "**Center**" is level 1 and "**Gizmo**" is level 2.

```
int count
```

The number of strings in the array.

**int startIndex=0**

This parameter is available in release 2.0 and later only.

Specifies which string to display initially in the sub-object type combo box. This is needed because the NURBS object computes its sub-object list dynamically, and sometimes it add a new sub-object level while already in a sub-object level. The default value of zero replicates the original behavior.

**Sample Code:**

```
const TCHAR *ptype[] = { _T("Center"), _T("Gizmo") };  
ip->RegisterSubObjectTypes(ptype, 2);
```

**Prototype:**

```
virtual int GetSubObjectLevel()=0;
```

**Remarks:**

Returns the state of the sub object drop-down.

**Return Value:**

0 is object level and  $\geq 1$  refers to the levels registered by the object using **RegisterSubObjectTypes()**. The value refers to the order the item appeared in the list. 1 is the first item, 2 is the second, etc.

**Prototype:**

```
virtual void SetSubObjectLevel(int level, BOOL force =  
FALSE)=0;
```

**Remarks:**

Sets the sub-object drop down. This will cause the object being edited to receive a notification that the current sub-object level has changed (via **BaseObject::ActivateSubobjSel()**).

**Parameters:**

**int level**

The level registered by the object using **RegisterSubObjectTypes()**. 0 indicates object level. Values greater than 1 refer to the order the items appeared in the list.

**BOOL force = FALSE**

If this parameter is TRUE, this method will set the level even if the current level is the same as the level requested. This is to support objects that change sub-object levels on the fly, for instance NURBS.

**Prototype:**

**virtual int GetNumSubObjectLevels()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns the number of sub object levels that the currently edited object (or modifier) has. Like the other sub-object related methods in this class, this method will only return a valid answer if the modifier panel is displayed.

**Prototype:**

**virtual void EnableSubObjectSelection(BOOL enable)=0;**

**Remarks:**

This method enables or disables sub-object selection. Note that it will already be disabled if there are no subobject levels registered. In this case, this method has no effect.

**Parameters:**

**BOOL enable**

TRUE to enable sub-object selection; FALSE to disable.

**Prototype:**

**virtual BOOL IsSubObjectSelectionEnabled()=0;**

**Remarks:**

This method returns the state that is modified by

**EnableSubObjectSelection()**. That is, it does not actually return the state of the button, but indicates the disabled state as set by **EnableSubObjectSelection()**.

**Return Value:**

TRUE if the sub-object button has been disabled by **EnableSubObjectSelection()**; otherwise FALSE.

**Prototype:**

```
virtual void PipeSelLevelChanged()=0;
```

**Remarks:**

Plug-ins call this method to notify the system that the selection level in the pipeline has changed. The selection level flows up the pipeline so if you change the selection level you affect things later in the pipeline. For example an edit modifier that changes the sub-object level from vertex to object level must call this method after making the change to notify the system. Note that it is only called for modifiers whose sub-object levels propagate up the pipeline. For example, when entering a sub-object level within the Bend modifier, **PipeSelLevelChanged()** is not called.

This method should be called from within **ActivateSubobjSel()** to notify the system that a selection level has changed in the pipeline. Note that calling this method from within **ModifyObject()** is no good since it involves re-evaluating the pipeline, which will call **ModifyObject()**, which will call **PipeSelLevelChanged()** again, etc.

**Prototype:**

```
virtual void GetPipelineSubObjLevel(DWORDTab &levels)=0;
```

**Remarks:**

Gets the sub-object selection level at the point in the pipeline just before the current place in the history.

**Parameters:**

**DWORDTab &levels**

The sub-object level. This value depends on the object. The only level defined is level 0, which means 'object' level selection.

**Prototype:**

```
virtual int SubObHitTest(TimeValue t, int type, int crossing, int flags, IPoint2 *p, ViewExp *vpt)=0;
```

**Remarks:**

This method may be called to perform a sub-object hit test. You may access the number of hits using: **vpt->NumSubObjHits()**; See [Class ViewExp](#) for

a list of the other methods that may be used to examine the results.

**Parameters:**

**TimeValue t**

The time of the hit testing.

**int type**

The hit test type. See [List of Hit Test Types](#).

**int crossing**

Nonzero for crossing selection; 0 for normal (window).

**int flags**

The flags for hit testing. See [List of Hit Test Flags](#).

**IPoint2 \*p**

Point to check in screen coordinates.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Return Value:**

Nonzero if the item was hit; otherwise 0.

## Sub-Object Selection Sets (Named)

**Prototype:**

```
virtual void AppendSubObjectNamedSelSet(const TCHAR  
*set)=0;
```

**Remarks:**

A modifier may call this method to add sub-object named selection sets to the named selection set drop down list in the MAX toolbar. This should be done whenever the selection level changes (in the Modifiers

**BaseObject::ActivateSubobjSel()** method). See [Class BaseObject](#) for additional methods associated with sub-object named selection sets.

**Parameters:**

**const TCHAR \*set**

The named selection set to add to the list.

**Prototype:**

**virtual void ClearSubObjectNamedSelSets()=0;**

**Remarks:**

This method clears the named sub-object selection sets from the drop down.

**Status Panel / Prompt Related Methods**

Generally prompts are set by the command mode and these are the methods used. The developer may use the **DisplayTempPrompt()** method below to temporarily display a prompt to the user independent of a command mode.

**Prototype:**

**virtual void PushPrompt( TCHAR \*s )=0;**

**Remarks:**

Pushes a prompt to display on the prompt stack.

**Parameters:**

**TCHAR \*s**

The string to display.

**Prototype:**

**virtual void PopPrompt()=0;**

**Remarks:**

Pops a displayed string off the prompt stack. The previous prompt will be restored.

**Prototype:**

**virtual void ReplacePrompt( TCHAR \*s )=0;**

**Remarks:**

Replaces the string on the top of the prompt stack.

**Parameters:**

**TCHAR \*s**

The string to display.

**Prototype:**

**virtual void DisplayTempPrompt( TCHAR \*s, int msec=1000)=0;**

**Remarks:**

Displays the string passed for the duration passed. After the time elapses, the string is popped from the stack. This may be used to put up a temporary error message for example.

**Parameters:**

**TCHAR \*s**

The string to display temporarily.

**int msec=1000**

The duration in milliseconds to display the string.

**Prototype:**

**virtual void RemoveTempPrompt()=0;**

**Remarks:**

Removes the temporary prompt immediately.

**Prototype:**

**virtual void DisableStatusXYZ()=0;**

**Remarks:**

Disables mouse tracking and display of coordinates to the X, Y, Z status boxes. Typically a plug-in would disable mouse tracking on mouse down and enable it on mouse up.

**Prototype:**

**virtual void EnableStatusXYZ()=0;**

**Remarks:**

Enables mouse tracking and display of coordinates to the X, Y, Z status boxes. Typically a plug-in would disable mouse tracking on mouse down and enable it on mouse up.

**Prototype:**

**virtual void SetStatusXYZ(Point3 xyz,int type)=0;**

**Remarks:**

Displays the point passed using the format passed in the X, Y, Z status boxes.

**Parameters:**

**Point3 xyz**

The point to be displayed.

**int type**

The format of the point:

**STATUS\_UNIVERSE**

Current system units.

**STATUS\_SCALE**

0=0%, 1=100%.

**STATUS\_ANGLE**

Degrees.

**STATUS\_OTHER**

Straight floating point value.

**Prototype:**

**virtual void SetStatusXYZ(AngAxis aa)=0;**

**Remarks:**

This method will convert the specified angle axis for status display.

**Parameters:**

**AngAxis aa**

The angle axis to convert and display.

## **Track Bar and Track View Related Methods**

**Prototype:**

**virtual ITrackViewNode \*GetTrackViewRootNode()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method returns a pointer to the Track View Root Node. See [Class ITrackViewNode](#).

**Prototype:**

```
virtual ITreeView* CreateTreeViewChild(ReferenceTarget* root,  
HWND hParent, DWORD style=0, ULONG id=0, int  
open=OPENTV_SPECIAL)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method will create a plain treeview window (no title, borders, etc.) as a child window of the given window. To destroy the window, delete the ITreeView pointer.

**Parameters:****ReferenceTarget\* root**

Points to the root node of the hierarchy to display in the Track View.

**HWND hParent**

The window handle of the parent for the dialog.

**DWORD style=0**

The style flags;

**TVSTYLE\_MAXIMIZEBUT**

Provide a maximize button.

**TVSTYLE\_INVIEWPORT**

Display in the viewport.

**TVSTYLE\_NAMEABLE**

The treeview is namable.

**TVSTYLE\_INMOTIONPAN**

Used in the motion panel.

**ULONG id=0**

The ID of the treeview window.

**int open=OPENTV\_SPECIAL**

One of the following values:

**OPENTV\_NEW**

Open a new treeview.

**OPENTV\_SPECIAL**

Open a special treeview.

**OPENTV\_LAST**

Open the last treeview.

**Prototype:**

**virtual ITrackBar\* GetTrackBar()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns an instance of the **ITrackBar** class. This class may be used to manipulate the track bar. See [Class ITrackBar](#).

## **Time Configuration Key Steps Settings Access**

**Prototype:**

**virtual BOOL GetKeyStepsSelOnly()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the Time Configuration / Key Steps / Selected Objects Only check box is on; otherwise FALSE.

**Prototype:**

**virtual void SetKeyStepsSelOnly(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the Time Configuration / Key Steps / Selected Objects Only check box to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetKeyStepsUseTrans()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the Time Configuration / Key Steps / Use Current Transform check box is on; otherwise FALSE.

**Prototype:**

**virtual void SetKeyStepsUseTrans(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the Time Configuration / Key Steps / Use Current Transform check box to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetKeyStepsPos()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the Time Configuration / Key Steps / Position check box is on; otherwise FALSE. This value is only meaningful if Use Current Transform is off.

**Prototype:**

**virtual void SetKeyStepsPos(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the Time Configuration / Key Steps / Position check box is to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetKeyStepsRot()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the Time Configuration / Key Steps / Rotation check box is on; otherwise FALSE. This value is only meaningful if Use Current Transform is off.

**Prototype:**

**virtual void SetKeyStepsRot(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the Time Configuration / Key Steps / Rotation check box is to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual BOOL GetKeyStepsScale()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the Time Configuration / Key Steps / Scale check box is on; otherwise FALSE. This value is only meaningful if Use Current Transform is off.

**Prototype:**

**virtual void SetKeyStepsScale(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the Time Configuration / Key Steps / Scale check box is to on or off.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:****virtual BOOL GetKeyStepsUseTrackBar()=0;****Remarks:**

This method is available in release 3.0 and later only.

Returns the state of the Time Configuration dialog 'Key Steps / Use TrackBar' checkbox. TRUE if checked; FALSE if unchecked.

**Prototype:****virtual void SetKeyStepsUseTrackBar(BOOL onOff)=0;****Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the Time Configuration dialog 'Key Steps / Use TrackBar' checkbox.

**Parameters:****BOOL onOff**

TRUE for on; FALSE for off.

**User Interface Controls and Properties****Prototype:****virtual void SetFlyOffTime(int msec)=0;****Remarks:**

This sets the custom control flyoff time to the value passed. This is the number of milliseconds the user must hold down on a flyoff button before the flyoff is activated.

**Parameters:****int msec**

The number of milliseconds the user must hold down on the button before the flyoff is activated.

**Prototype:****virtual int GetFlyOffTime()=0;****Remarks:**

Returns the number of milliseconds the user must hold down on a flyoff button before the flyoff is activated.

**Prototype:**

**virtual BOOL GetCrossing()=0;**

**Remarks:**

Returns the state of the 'crossing' preference for hit testing.

**Return Value:**

TRUE if crossing selection is on; FALSE if off.

**Prototype:**

**virtual void SetToolButtonState(int button, BOOL state )=0;**

**Remarks:**

Sets the state of one of the transform tool buttons.

**Parameters:**

**int button**

The transform tool buttons:

**MOVE\_BUTTON**

**ROTATE\_BUTTON**

**NUSCALE\_BUTTON**

**USCALE\_BUTTON**

**SQUASH\_BUTTON**

**SELECT\_BUTTON**

**BOOL state**

TRUE indicates pressed, FALSE is not pressed.

**Prototype:**

**virtual int GetAxisConstraints()=0;**

**Remarks:**

Retrieves the state of the axis constraints flyoff.

**Return Value:**

One of the following axis constraints:

**AXIS\_XY**  
**AXIS\_ZX**  
**AXIS\_YZ**  
**AXIS\_X**  
**AXIS\_Y**  
**AXIS\_Z**

**Prototype:**

**virtual void SetAxisConstraints(int c)=0;**

**Remarks:**

Sets the state of the axis constraints flyoff.

**Parameters:**

**int c**

The axis constraint to set. You may pass one of the following:

**AXIS\_XY**  
**AXIS\_ZX**  
**AXIS\_YZ**  
**AXIS\_X**  
**AXIS\_Y**  
**AXIS\_Z**

**Prototype:**

**virtual void EnableAxisConstraints(int c, BOOL enabled)=0;**

**Remarks:**

Enables or disables the specified axis constraint.

**Parameters:**

**int c**

The axis constraint. You may pass one of the following:

**AXIS\_XY**  
**AXIS\_ZX**  
**AXIS\_YZ**  
**AXIS\_X**

**AXIS\_Y**  
**AXIS\_Z**

**BOOL enabled**

TRUE to enable; FALSE to disable.

**Prototype:**

**virtual void PushAxisConstraints(int c)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Pushes the specified axis constraint. This push/pop mechanism is used so that the appropriate axis mode can be restored after the Transform Gizmo has been used. The Gizmo itself calls this Push method in response to the HitTest with certain flags.

**Parameters:**

**int c**

The axis constraint. You may pass one of the following:

**AXIS\_XY**  
**AXIS\_ZX**  
**AXIS\_YZ**  
**AXIS\_X**  
**AXIS\_Y**  
**AXIS\_Z**

**Prototype:**

**virtual void PopAxisConstraints()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Pops the active constraint. After the Transform Gizmo pushes a constraint a selection processor pops it back again after the manipulators are deactivated.

**Prototype:**

**virtual int GetCoordCenter()=0;**

**Remarks:**

Retrieves the state of the coordinate system center.

**Return Value:**

One of the following values:

**ORIGIN\_LOCAL**

Object's pivot.

**ORIGIN\_SELECTION**

Center of selection set (or center of individual object for local or parent space).

**ORIGIN\_SYSTEM**

Center of the reference coordinate system.

**Prototype:**

**virtual void SetCoordCenter(int c)=0;**

**Remarks:**

Sets the state of the coordinate system center.

**Parameters:**

**int c**

One of the following values (from **MAXAPI.H**).

**ORIGIN\_LOCAL**

Object's pivot.

**ORIGIN\_SELECTION**

Center of selection set (or center of individual object for local or parent space).

**ORIGIN\_SYSTEM**

Center of the reference coordinate system.

**Prototype:**

**virtual void EnableCoordCenter(BOOL enabled)=0;**

**Remarks:**

Enables or disables the coordinates system center.

**Parameters:**

## **BOOL enabled**

TRUE to enable; FALSE to disable.

### **Prototype:**

```
virtual int GetRefCoordSys()=0;
```

### **Remarks:**

Retrieves the reference coordinate system setting.

### **Return Value:**

One of the following reference coordinate systems:

```
COORDS_HYBRID  
COORDS_SCREEN  
COORDS_WORLD  
COORDS_PARENT  
COORDS_LOCAL  
COORDS_OBJECT
```

### **Prototype:**

```
virtual void SetRefCoordSys(int c)=0;
```

### **Remarks:**

Sets the reference coordinate system used.

### **Parameters:**

**int c**

Reference coordinate system:

```
COORDS_HYBRID  
COORDS_SCREEN  
COORDS_WORLD  
COORDS_PARENT  
COORDS_LOCAL  
COORDS_OBJECT
```

### **Prototype:**

```
virtual void EnableRefCoordSys(BOOL enabled)=0;
```

**Remarks:**

Enables or disables the reference coordinates system.

**Parameters:****BOOL enabled**

TRUE to enable; FALSE to disable.

**Prototype:**

```
virtual BOOL GetPlaybackLoop()=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the state of the "loop" checkbox in the time configuration panel. Note that the loop control is only active when "real time" is selected.

**Return Value:**

TRUE if loop is on; FALSE if off.

**Prototype:**

```
virtual void SetPlaybackLoop(BOOL loop)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the state of the "loop" checkbox in the time configuration panel. Note that the loop control is only active when "real time" is selected.

**Parameters:****BOOL loop**

TRUE to set the loop to on; FALSE to set it off.

**Video Post Related Methods****Prototype:**

```
virtual INode *GetINodeFromRenderID(UWORD id)=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the node pointer from the id in the

**BMM\_CHAN\_NODE\_RENDER\_ID** G-Buffer channel. The renderer will set the RenderID of all rendered nodes, and will set all non-rendered nodes to **0xffff**. See [List of Image Channels](#).

**Parameters:**

**UWORD id**

The id from the G Buffer channel.

**Prototype:**

**virtual int GetSelectFilter()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns your current selected select filter in the toolbar.

**Prototype:**

**virtual void SetSelectFilter(int c)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the current selected select filter in the toolbar.

**Parameters:**

**int c**

The index of the filter you wish to set.

**Prototype:**

**virtual int GetNumberSelectFilters()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the number of select filters in the drop down list.

**Prototype:**

**virtual TCHAR\* GetSelectFilterName(int index)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the name that appears in the interface for the specified filter.

**Parameters:**

**int index**

The index of the filter.

**Prototype:**

**virtual BOOL GetDisplayFilter(int index) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the state of a display filter.

**Parameters:**

**int index**

The index of the display filter that you want to check.

**Prototype:**

**virtual void SetDisplayFilter(int index, BOOL on) = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the state of a display filter.

**Parameters:**

**int index**

The index of the display filter you wish to set.

**BOOL on**

TRUE for on; FALSE for off.

**Prototype:**

**virtual int GetNumberDisplayFilters() = 0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the number of display filters in the display panel.

**Prototype:**

```
virtual TCHAR* GetDisplayFilterName(int index)=0;;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the name of the specified filter.

**Parameters:**

**int index**

The index of the filter.

**Prototype:**

```
virtual BOOL DisplayFilterIsNodeVisible(int index, int sid,  
Class_ID cid, INode *node) = 0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method checks the display filter at index, and sees if the node, class id, and super class id fail the filter check or not.

**Parameters:**

**int index**

The index of the filter

**int sid**

The super class id

**Class\_ID cid**

The class ID

**INode \*node**

The node to check.

**Return Value:**

TRUE if visible, otherwise FALSE.

**Viewport Access****Prototype:**

```
virtual void RedrawViews(TimeValue t, DWORD
```

```
vpFlags=REDRAW_NORMAL, ReferenceTarget
*change=NULL)=0;
```

**Remarks:**

This method may be called to cause the viewports to be redrawn.

**Parameters:**

**TimeValue t**

The time at which to redraw the viewports.

**DWORD vpFlags=REDRAW\_NORMAL**

You may specify one of the following:

**REDRAW\_BEGIN**

Call this before you redraw.

**REDRAW\_INTERACTIVE**

This allows the view quality to degrade to maintain interactivity.

**REDRAW\_END**

If during interactive redraw the state degraded, this will redraw the views in the undegraded state.

**REDRAW\_NORMAL**

This redraws the views in the undegraded state.

**ReferenceTarget \*change=NULL**

This parameter is not used - always let it default to NULL.

**Example:**

```
ip->RedrawViews(ip->GetTime(),REDRAW_BEGIN);
// More code ...
ip->RedrawViews(ip->GetTime(),REDRAW_INTERACTIVE);
// More code ...
ip->RedrawViews(ip->GetTime(),REDRAW_END);
```

**Prototype:**

```
virtual void ForceCompleteRedraw(BOOL doDisabled=TRUE)=0;
```

**Remarks:**

Calling this method will cause all the viewports to be completely redrawn.

Note: This method literally forces **everything** (every object, every screen rectangle, every view) to be marked invalid and then the whole scene is

regenerated. (The individual object pipeline caches are **not** flushed, however.)  
So this routine is guaranteed to be slow.

**Parameters:**

**BOOL doDisabled=TRUE**

This parameter is available in release 2.0 and later only.

If TRUE disabled viewports are redrawn; otherwise they are not.

**Prototype:**

**virtual void DisableSceneRedraw()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This turns the scene redraw off (disables it). Scene redraw should be disabled in any renderer's **Open()** method, and re-enabled in the renderer's **Close()** method. All calls to **DisableSceneRedraw()/Enable SceneRedraw()** should be in pairs, since an internal counter is used to actually do the redraw enable/disable action.

**Prototype:**

**virtual void EnableSceneRedraw()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This turns the scene redraw on (enables it). Scene redraw should be disabled in any renderer's **Open()** method, and re-enabled in the renderer's **Close()** method. All calls to **DisableSceneRedraw()/Enable SceneRedraw()** should be in pairs, since an internal counter is used to actually do the redraw enable/disable action.

**Prototype:**

**virtual int IsSceneRedrawDisabled()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns nonzero if the redraw is disabled; zero if enabled.

**Prototype:**

**virtual BOOL SetActiveViewport( HWND hwnd )=0;**

**Remarks:**

This allows you to specify the active viewport.

**Parameters:**

**HWND hwnd**

The handle of the window to activate.

**Return Value:**

TRUE if the viewport was not previously active; otherwise FALSE.

**Prototype:**

**virtual ViewExp \*GetActiveViewport()=0;**

**Remarks:**

Returns the **ViewExp** pointer of the active MAX viewport. Remember to release the **ViewExp** pointer with **Interface::ReleaseViewport()**.

**Prototype:**

**virtual ViewExp \*GetViewport( HWND hwnd )=0;**

**Remarks:**

This method gets a viewport interface given a window handle.

**Parameters:**

**HWND hwnd**

The window handle of the viewport.

**Prototype:**

**virtual void ReleaseViewport( ViewExp \*vpt )=0;**

**Remarks:**

When the developer is done with the viewport interface acquired via **GetViewport()** or **GetActiveViewport()** they should call this method to release it.

**Parameters:**

## **ViewExp \*vpt**

The viewport interface to release.

### **Prototype:**

**virtual int GetViewportLayout()=0;**

### **Remarks:**

This method may be called to retrieve a value that describes the configuration of the MAX viewports.

### **Return Value:**

The viewport layout configuration. The list below uses the following syntax:

# is the total number of viewports.

V = vertical split

H = horizontal split

L/R = left/right placement

T/B = top/bottom placement

One of the following values. Note: The bottom nibble (4-bits) is the total number of views. You may use the constant **VP\_NUM\_VIEWS\_MASK** to mask off the 4 bits that contains the total number of viewports.

**VP\_LAYOUT\_1**

**VP\_LAYOUT\_2V**

**VP\_LAYOUT\_2H**

**VP\_LAYOUT\_2HT**

**VP\_LAYOUT\_2HB**

**VP\_LAYOUT\_3VL**

**VP\_LAYOUT\_3VR**

**VP\_LAYOUT\_3HT**

**VP\_LAYOUT\_3HB**

**VP\_LAYOUT\_4**

**VP\_LAYOUT\_4VL**

**VP\_LAYOUT\_4VR**

**VP\_LAYOUT\_4HT**

**VP\_LAYOUT\_4HB**

**VP\_LAYOUT\_1C**

**Prototype:**

**virtual void SetViewportLayout(int layout)=0;**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the viewport configuration layout.

**Parameters:**

**int layout**

The layout to use. See the return values of **GetViewportLayout()** above.

**Prototype:**

**virtual BOOL IsViewportMaxed()=0;**

**Remarks:**

Returns TRUE if the current viewport is full screen; otherwise FALSE.

**Prototype:**

**virtual void SetViewportMax(BOOL max)=0;**

**Remarks:**

This method will maximize (set to a single full screen view) or minimize the current viewport.

**Parameters:**

**BOOL max**

If TRUE the viewport is maximized; otherwise it is minimized.

**Prototype:**

**virtual void ViewportZoomExtents(BOOL doAll, BOOL skipPersp=FALSE)=0;**

**Remarks:**

This method performs a zoom extents on the viewport(s). This fills the viewport(s) with the objects of the scene.

**Parameters:**

**BOOL doAll**

If TRUE all the viewports are zoomed to their extents; otherwise just the

current viewport is.

**BOOL skipPersp=FALSE**

If TRUE perspective viewports are not altered; otherwise these views are zoomed to their extents as well.

**Prototype:**

**virtual int IsCPEdgeOnInView()=0;**

**Remarks:**

This method returns nonzero if the construction plane is 'head on' in the current viewport. For example if the construction plane was XY and you were looking from the Front view, this method would return nonzero. This is used for example during object creation because this process doesn't work very well when the view is 'head on'.

**Return Value:**

Nonzero if the construction plane is 'head on' in the current viewport; otherwise 0.

For use with extended views: - make the extended viewport active (set on mouse click, for example) -put up the view type popup menu (put up on right-click, for example)

**Prototype:**

**virtual void MakeExtendedViewportActive(HWND hWnd)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used with Extended Viewports (see [Class ViewWindow](#)). It is called when the extended viewport needs to become active. It should be called whenever the user clicks in the non-3D window (so as to deactivate the current 3D window, and redirect commands like the Min/Max toggle to the non-3D viewport window).

**Parameters:**

**HWND hWnd**

The handle of the window which to made active.

**Prototype:**

```
virtual void PutUpViewMenu(HWND hWnd, POINT pt)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used with Extended Viewports (see [Class ViewWindow](#)). It is called to put up the view type popup menu (for example the right-click menu). It should be called when the user right-clicks in a dead region of the non-3D window. This brings up the view selection menu so that the user can choose to replace the current window with a 3D or other non-3D window without having to go to the Views | Viewport Config dialog directly.

**Parameters:**

**HWND hWnd**

The handle of the window the menu is to appear in.

**POINT pt**

The point at which the menu is put up.

**Sample Code:**

```
case WM_RBUTTONDOWN:
```

```
    pt.x = LOWORD(l);
```

```
    pt.y = HIWORD(l);
```

```
        GetCOREInterface()->PutUpViewMenu(h, pt);
```

**Prototype:**

```
virtual BOOL RegisterViewWindow(ViewWindow *vw)=0;
```

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to register a window that can appear in a viewport.

**Parameters:**

**ViewWindow \*vw**

The pointer to the view window to register.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual BOOL UnRegisterViewWindow(ViewWindow \*vw)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to unregister a window that can appear in a viewport.

**Parameters:**

**ViewWindow \*vw**

The pointer to the view window to unregister.

**Return Value:**

TRUE if successful, otherwise FALSE.

**Prototype:**

**virtual void ZoomToBounds(BOOL doAll, Box3 box)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to zoom the current or selected viewport to a bounding region.

**Parameters:**

**BOOL doAll**

This flag determines whether only the selected or all viewports get zoomed.

TRUE for all, FALSE for selected only.

**Box3 box**

The bounding region to zoom to.

## **Viewport Background Properties**

**Prototype:**

**virtual void SetViewportBGColor(const Point3 &color)=0;**

**Remarks:**

Sets the viewport background color to the specified color.

**Parameters:**

**const Point3 &color**

The color to set.

**Prototype:**

**virtual Point3 GetViewportBGColor()=0;**

**Remarks:**

Returns the viewport background color.

**Prototype:**

**virtual BOOL setBkgImageName(TCHAR \*name)=0;**

**Remarks:**

This method is used to specify the background image used.

**Parameters:**

**TCHAR \*name**

The name of the background image.

**Return Value:**

TRUE if the image was set; otherwise FALSE.

**Prototype:**

**virtual TCHAR \*getBkgImageName()=0;**

**Remarks:**

This method is used to retrieve the name of the background image used. The pointer returned from this method does not need to be freed.

**Prototype:**

**virtual void setBkgImageAspect(int t)=0;**

**Remarks:**

Sets the background image aspect ratio. This may match the viewport, the bitmap, or the rendering output aspect ratio.

**Parameters:**

**int t**

One of the following values:

**VIEWPORT\_BKG\_ASPECT\_VIEW**

**VIEWPORT\_BKG\_ASPECT\_BITMAP**  
**VIEWPORT\_BKG\_ASPECT\_OUTPUT**

**Prototype:**

**virtual int getBkgImageAspect()=0;**

**Remarks:**

Retrieves the background image aspect ratio. This will be the viewport, the bitmap, or the rendering output aspect ratio.

**Return Value:**

One of the following values:

**VIEWPORT\_BKG\_ASPECT\_VIEW**  
**VIEWPORT\_BKG\_ASPECT\_BITMAP**  
**VIEWPORT\_BKG\_ASPECT\_OUTPUT**

**Prototype:**

**virtual void setBkgImageAnimate(BOOL onOff)=0;**

**Remarks:**

This method sets if the background image is animated in the viewports. If TRUE the image updates to reflect the current frame. If FALSE the image remains static regardless of time.

**Parameters:**

**BOOL onOff**

TRUE to enable viewport background image animation; FALSE to disable it.

**Prototype:**

**virtual int getBkgImageAnimate()=0;**

**Remarks:**

This method determines if the background image is set to update with the current frame in the viewports.

**Prototype:**

**virtual void setBkgFrameRange(int start, int end, int step=1)=0;**

**Remarks:**

This method establishes the range of frames used for an animated background.

**Parameters:****int start**

The start frame number.

**int end**

The end frame number.

**int step=1**

The frame increment.

**Prototype:**

```
virtual int getBkgFrameRangeVal(int which)=0;
```

**Remarks:**

This method retrieves either the start or end frame number.

**Parameters:****int which**

One of the following values:

**VIEWPORT\_BKG\_START**

**VIEWPORT\_BKG\_END**

**Prototype:**

```
virtual void setBkgORTType(int which, int type)=0;
```

**Remarks:**

Sets the background Out of Range Type. This may be the start or end ORT.

**Parameters:****int which**

One of the following values:

**0** : Sets the Start Processing ORT.

**1** : Sets the End Processing ORT.

**int type**

One of the following values:

**VIEWPORT\_BKG\_BLANK**

**VIEWPORT\_BKG\_HOLD**  
**VIEWPORT\_BKG\_LOOP**

**Prototype:**

**virtual int getBkgORType(int which)=0;**

**Remarks:**

Retrieves the background Out of Range Type. This may be the start or end ORT.

**Parameters:**

**int which**

One of the following values:

**0** : Gets the Start Processing ORT.

**1** : Gets the End Processing ORT.

**Return Value:**

One of the following values:

**VIEWPORT\_BKG\_BLANK**

**VIEWPORT\_BKG\_HOLD**

**VIEWPORT\_BKG\_LOOP**

**Prototype:**

**virtual void setBkgStartTime(TimeValue t)=0;**

**Remarks:**

This sets the "Start at" parameter from the Views / Background Image... dialog.

**Parameters:**

**TimeValue t**

The time to start.

**Prototype:**

**virtual TimeValue getBkgStartTime()=0;**

**Remarks:**

This returns the "Start at" parameter from the Views / Background Image...

dialog.

**Prototype:**

**virtual void setBkgSyncFrame(int f)=0;**

**Remarks:**

Sets the background "Sync Start to Frame" setting.

**Parameters:**

**int f**

The frame number.

**Prototype:**

**virtual int getBkgSyncFrame()=0;**

**Remarks:**

Returns the background "Sync Start to Frame" setting.

**Prototype:**

**virtual int getBkgFrameNum(TimeValue t)=0;**

**Remarks:**

This method will convert the TimeValue passed to a frame number based on the background image settings (ORTs, start/end times, sync frame, etc.).

**Parameters:**

**TimeValue t**

The time to convert.

**Return Value:**

The frame number corresponding to the time passed.

## **Window Handle of MAX**

**Prototype:**

**virtual HWND GetMAXHwnd()=0;**

**Remarks:**

Returns the window handle of MAX.

## Windows Messages

### Prototype:

**virtual void TranslateAndDispatchMAXMessage(MSG &msg)=0;**

### Remarks:

If a plug-in needs to do a **PeekMessage()** and wants to actually remove the message from the queue, it can use this method to have the message translated and dispatched.

### Parameters:

**MSG &msg**

The message from **PeekMessage()**.

### Prototype:

**virtual BOOL CheckMAXMessages()=0;**

### Remarks:

This will go into a **PeekMessage()** loop until there are no more messages left. This is a way a plug-in can relieve control to the system.

There may be certain circumstances where a plug-in wants to give control back to MAX. For example a plug-in may put up a progress bar with a cancel button during a lengthy operation. However the cancel button would not receive any messages if the user was clicking on it because no messages are being dispatched.

This method will relieve control and let any messages that are in the queue get processed. If there are no messages it will return right away. This provides a way for a plug-in to yield control.

Note: A developer must be prepared to handle a lot of different conditions if this is done. For example the user could click on the delete key and delete the object that was being processed. **EndEditParams()** could be called on the plug-in. So in **EndEditParams()** there must be some logic to signal the other lengthy process that **EndEditParams()** was called.

### Return Value:

If this method returns FALSE then the user is attempting to quit MAX and the caller should return.

**Prototype:**

**virtual void RescaleWorldUnits(float f, BOOL selected)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to rescale the world units of the entire scene, or optionally the current selection set.

**Parameters:**

**float f**

The scale factor to apply to the scene.

**BOOL selected**

TRUE to scale selected objects only; otherwise the entire scene is scaled.

## Transform Gizmo Related Methods

**Prototype:**

**virtual BOOL GetUseTransformGizmo()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the state of the Transform Tools / Gizmo toggle.

**Return Value:**

TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetUseTransformGizmo(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method enables or disables the use of Transform Gizmos.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetTransformGizmoRestoreAxis(BOOL bOnOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method sets whether the TransformGizmo should restore the axis constraint when released, or if the axis constraint is permanently changed. The value is saved in the 3DSMAX.INI file for later sessions.

**Parameters:**

**BOOL bOnOff**

Enable or disable the restoration of the axis constraint.

**Prototype:**

**virtual BOOL GetTransformGizmoRestoreAxis()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Indicates if the TransformGizmo will restore the axis constraint when released. Returns TRUE if it will; FALSE if it won't.

**Prototype:**

**virtual BOOL GetConstantAxisRestriction()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the state of the Transform Tools / Constant Axis toggle.

**Return Value:**

TRUE if on; FALSE if off.

**Prototype:**

**virtual void SetConstantAxisRestriction(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the Transform Tools / Constant Axis toggle.

**Parameters:**

**BOOL onOff**

TRUE for on; FALSE for off.

**Prototype:**

```
virtual int HitTestTransformGizmo(IPoint2 *p, ViewExp *vpt, int axisFlags) = 0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to hittest gizmos for sub-objects.

**Parameters:**

**IPoint2 \*p**

Point to check in screen coordinates.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**int axisFlags**

One or more of the following values:

**HIT\_TRANSFORMGIZMO**

This flag is passed in on a **MOUSE\_FREEMOVE** message so that the axis is hit tested and it highlights if it is hit, but it doesn't actually switch the transform mode.

**HIT\_SWITCH\_GIZMO**

In case of a **MOUSE\_POINT**, this flag is used, and if the axis is hit, the 'hit' transform mode will be pushed on the transform mode stack.

**Return Value:**

Nonzero if the item was hit; otherwise 0.

## **Add / Delete Class Methods**

**Prototype:**

```
virtual int AddClass(ClassDesc *cd)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to dynamically add a plug-in class. This method will

update the control panel in the Create or Modify branches dynamically.

**Parameters:**

**ClassDesc \*cd**

Points to the Class Descriptor to add. See [Class ClassDesc](#).

**Return Value:**

Returns -1 if the superclass was unknown, 0 if the class already exists, or 1 if the class was added successfully.

**Prototype:**

**virtual int DeleteClass(ClassDesc \*cd)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to dynamically delete a plug-in class. This method will update the control panel in the Create or Modify branches dynamically.

**Parameters:**

**ClassDesc \*cd**

Points to the Class Descriptor to add. See [Class ClassDesc](#).

**Return Value:**

Returns -1 if the superclass was unknown, 0 if the class does not exist, or 1 if the class was deleted successfully.

## **Property Set Access**

The following methods provide developer access to the property set data stored by MAX. A MAX user can enter this data via the File Properties dialog. There are three tabs to this dialog which correspond to the options which may be specified for the **PropertySet** parameter used in the methods below. The **PROPSPEC** and **PROPVARIANT** structures used below are part of the Windows API. Developers can find sample code using these methods in **\MAXSDK\SAMPLES\UTILITIES\PROPERTYTEST\PROPERTYT**

**Prototype:**

**virtual int GetNumProperties(int PropertySet)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of properties of the specified property set. See the note at the start of this group of methods above for info on property sets.

**Parameters:**

**int PropertySet**

See [List of PropertySet Options](#).

**Prototype:**

```
virtual int FindProperty(int PropertySet, const PROPSPEC*  
propspec)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Return the index of the specified property or -1 if it is not found. See the note at the start of this group of methods above for info on property sets.

**Parameters:**

**int PropertySet**

See [List of PropertySet Options](#).

**const PROPSPEC\* propspec**

Points to a PROPSPEC structure of the property to find. The Windows API PROPSPEC structure is used by many of the methods of IPropertyStorage to specify a property either by its property identifier or the associated string name. See the Windows API for details on this structure.

**Return Value:**

The zero based index of the specified property or -1 if not found.

**Prototype:**

```
virtual const PROPVARIANT* GetPropertyVariant(int  
PropertySet, int idx)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Return the value of the property at this index, in PROPVARIANT form. See the note at the start of this group of methods above for info on property sets.

**Parameters:****int PropertySet**See [List of PropertySet Options](#).**int idx**

The zero based index of the property variant to get.

**Return Value:**

Points to a **PROPVARIANT** structure. This Windows API structure is used in most of the methods of IPropertyStorage to define the type tag and the value of a property in a property set. See the Windows API for details on this structure.

**Prototype:**

```
virtual const PROPSPEC* GetPropertySpec(int PropertySet, int idx)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Return the name of the property at this index, in PROPSPEC form. See the note at the start of this group of methods above for info on property sets.

**Parameters:****int PropertySet**See [List of PropertySet Options](#).**int idx**

The zero based index of the property name to get.

**Return Value:**

Points to a PROPSPEC structure. The Windows API PROPSPEC structure is used by many of the methods of IPropertyStorage to specify a property either by its property identifier or the associated string name. See the Windows API for details on this structure.

**Prototype:**

```
virtual void AddProperty(int PropertySet, const PROPSPEC* propspec, const PROPVARIANT* propvar)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

This method adds a property to the specified property set. See the sample code in

`\MAXSDK\SAMPLES\UTILITIES\PROPERTYTEST\PROPERTY`

See the note at the start of this group of methods above for info on property sets.

**Parameters:**

**int PropertySet**

See [List of PropertySet Options](#).

**const PROPSPEC\* propspec**

Points to a PROPSPEC structure.

**const PROPVARIANT\* propvar**

Points to a PROPVARIANT structure.

**Prototype:**

**virtual void DeleteProperty(int PropertySet, const PROPSPEC\* propspec)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Deletes the specified property. The property will be removed and the memory freed. See the note at the start of this group of methods above for info on property sets.

**Parameters:**

**int PropertySet**

See [List of PropertySet Options](#).

**const PROPSPEC\* propspec**

Points to a PROPSPEC structure to delete.

## **XRef Methods**

**Prototype:**

**virtual void SetIncludeXRefsInHierarchy(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows a plug-in to specify whether scene XRef objects are hidden from the hierarchy when it is traversed. Normally this parameter is set to FALSE except during rendering. If a plug-in wants access to XRef scene objects then it should set this to TRUE and traverse the scene and then set it back to FALSE when it's done.

Most of the time the XRef trees (whose root node is a child of the client scene's root node) are skipped when traversing the hierarchy. When this option is turned on, all root nodes will include child XRef scene root nodes in any traversal related functions such as **NumberOfChildren()** and **GetChildNode(i)**.

This option is turned on automatically before rendering and turned off after so that scene XRefs appear in the production renderer. **Note: This option should not be left on if it is turned on since it would cause scene XRef objects to be accessible to the user in the client scene.**

Note that plug-ins can also access XRef objects using the [Class INode XRef methods](#).

**Parameters:**

**BOOL onOff**

TRUE to include XRefs in the hierarchy; FALSE to not include them.

**Prototype:**

**virtual BOOL GetIncludeXRefsInHierarchy()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if XRefs are included in the traversal of the scene hierarchy; otherwise FALSE. See the method above for details.

**Prototype:**

**virtual BOOL IsXRefAutoUpdateSuspended()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the automatic updating of XRefs is suspended; otherwise

FALSE. When an XRef file is changed and that causes an XRef object to update, the old XRef object gets deleted from memory which can cause problems for some plug-ins. For example, the Dynamics system would have a problem if an update occurred while a solution was solving. This method is used to disable the automatic updating to prevent the problem.

**Prototype:**

**virtual void SetXRefAutoUpdateSuspended(BOOL onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the automatic updating of XRefs is suspended or not. See the note in **IsXRefAutoUpdateSuspended()** for details.

**Parameters:**

**BOOL onOff**

TRUE to suspend; FALSE to restore automatic updating.

**Prototype:**

**virtual BOOL IsSceneXRefNode(INode \*node)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the specified node is part of a scene XRef or FALSE if the node is a regular modifiable node in the current scene.

**Parameters:**

**INode \*node**

The node to check.

## **Licensing Methods**

**Prototype:**

**virtual bool IsTrialLicense()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the application is running under a trial license, as opposed to

a full, authorized license; otherwise FALSE.

**Prototype:**

**virtual bool IsNetworkLicense()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

As of R4 this method will always return false as R4 does not have network licencing.

**Prototype:**

**virtual bool IsEmergencyLicense()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

As of R4 this method is no longer supported and always returns false.

Returns TRUE if the application is running under an emergency license, while the full license is exported; otherwise FALSE.

**Prototype:**

**virtual int GetProductVersion()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the product version which is one of the following values:

**PRODUCT\_VERSION\_DEVEL** -- A debug build, or licensed in-house.

**PRODUCT\_VERSION\_TRIAL** -- A trial license.

**PRODUCT\_VERSION\_ORDINARY** -- A commercial license.

**PRODUCT\_VERSION\_NFR** -- Not for resale.

**PRODUCT\_VERSION\_EDU** -- Educational or student license.

**Prototype:**

**virtual int GetLicenseBehavior()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns one of the following values which indicates the liscence behaviour:

**LICENSE\_BEHAVIOR\_PERMANENT** -- A permanent license, or hardware lock.

**LICENSE\_BEHAVIOR\_EXTENDABLE** -- A term license which can be extended.

**LICENSE\_BEHAVIOR\_NONEXTENDABLE** -- A term license which cannot be extended.

**Prototype:**

**virtual int GetLicenseDaysLeft()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns an integer indicating the number of full days left in the term of the license. A value of 0 means that today is the last day of validity. For permanent licenses, a fixed value is returned indicating greater than 10 years are left.

**Prototype:**

**virtual bool IsFeatureLicensed(int subNum)=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method is not currently supported and always returns false. In the future it will be used for returning true or false as the license subgroup designated by the argument is or is not enabled.

**Return Value:**

TRUE if licensed; FALSE if not licensed.

**Deferred Loading Related Methods****Prototype:**

**virtual void EnableDeferredPluginLoading(bool onOff)=0;**

**Remarks:**

This method is available in release 3.0 and later only.

In the Preferences dialog / General Tab / Plug-In Loading section there is a Checkbox labelled 'Load Plug-Ins when Used'. This method sets the state of this toggle. See the Advanced Topics section [Deferred Loading of Plug-Ins](#).

**Parameters:****bool onOff**

TRUE for on; FALSE for off.

**Prototype:**

**virtual bool DeferredPluginLoadingEnabled()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

In the Preferences dialog / General Tab / Plug-In Loading section there is a Checkbox labelled 'Load Plug-Ins when Used'. This method returns the state of this toggle.. See the Advanced Topics section [Deferred Loading of Plug-Ins](#).

**Return Value:**

TRUE if on; FALSE if off.

**Undo / Redo Related Methods****Prototype:**

**virtual void FlushUndoBuffer()=0;**

**Remarks:**

This method is available in release 3.0 and later only.

This function will flush the undo buffer. See the Advanced Topics section [Undo / Redo](#).

## Class List by Category

See Also: [Plug-In Types Overview](#).

This section provides a list of all the main classes in the SDK organized by category. Hyperlinks are provided to the reference section of each class. You may also use the Search function in the on-line help toolbar. When using search note that all the classes in the SDK are named beginning with **Class**, so they are grouped together and appear in alphabetical order. To find a particular method or function by name, choose Search, select the Find tab, then enter the name in the 'Type the word(s) you want to find' field.

## Sparks Addin for MS VC++ 6 IDE

**See Also:** [Sparks Developer Program](#), [Sparks Developer Knowledgebase](#), [Sparks Addin for MS VC++ 7 IDE](#)

## Overview

New for 3ds max 5.1 is the Sparks Addin for use with the MS VC++ 6 IDE. Its functionality allows 3ds max developers to search the sparks knowledgebase for the text that's selected in the IDE.

**The Sparks Addin is available to the public.**

## Installation

1. Open VC++ 6, and go to Tools: Customize: Add-ins and Macro Files.
2. Click on the 'browse' button and locate SparksAddin.dll in the maxsdk help directory. Click 'open'.
3. Check the checkbox next to its entry in the 'Add-ins and macro files:' list box.
4. The toolbar should now be visible in your environment.

## Usage

1. With the addin toolbar enabled, select a string of text in the IDE.
2. Click a button on the toolbar to launch the sparks knowledgebase with the selected string.
  - a. (3ds max icon): Searches the entire knowledgebase.
  - b. (letter icon): Searches all webboard support threads, legacy support threads, developer techdocs, and solutions.
  - c. (class icon): Searches the latest 3ds max SDK documentation only. Very useful for class/method lookup.
3. Once inside the sparks knowledgebase, you can alter your search as well as use 'and/or' keywords to refine your search.

## **Local Address**

The addin can be found in the maxsdk help directory of the 5.1 install. Please read the SparksAddinReadme therein for usage and installation instructions.

## Internet Address

[http://sparks.discreet.com/downloads/downloadshome.cfm?  
f=2&wf\\_id=87](http://sparks.discreet.com/downloads/downloadshome.cfm?f=2&wf_id=87)

## Sparks Addin for MS VC++ 7 IDE

See Also: [Sparks Developer Program](#), [Sparks Developer Knowledgebase](#)

## Overview

New for 3ds max 6 is the Sparks Addin for use with the MS VC++ 7 IDE. Its functionality allows 3ds max developers to search the sparks knowledgebase for the text that's selected in the IDE.

**The Sparks Addin is available to the public.**

## **Installation**

- 1. Follow the installation instructions in the included installer.**

## Usage

1. With the addin toolbar enabled, select a string of text in the IDE.
2. Click the 'Search 3ds max SDK Knowledgebase' button to launch the search. Below are descriptions for items in the Collection dropdown
  - a. Entire Knowledgebase:** Searches the entire knowledgebase.
  - b. Support Threads:** Searches all webboard support threads, legacy support threads, developer techdocs, and solutions.
  - c. SDK Documentation:** Searches the latest 3ds max SDK documentation only. Very useful for class/method lookup.
3. Once inside the sparks knowledgebase, you can alter your search as well as use 'and/or' keywords to refine your search.

**Internet Address**

[http://sparks.discreet.com/downloads/downloadshome.cfm?f=2&wf\\_id=105](http://sparks.discreet.com/downloads/downloadshome.cfm?f=2&wf_id=105)

## Class GeomObject

See Also: [Class Object](#), [Class Mesh](#).

class GeomObject : public Object

### Description:

This is the base class for the creation of Geometric Object plug-ins. This class represents an object that has geometry and is renderable.

### Methods:

#### Prototype:

**virtual int IsInstanceDependent()**

#### Remarks:

Implemented by the Plug-In.

If an object creates different meshes depending on the particular instance (view-dependent) it should return nonzero; otherwise 0.

#### Default Implementation:

**{ return 0; }**

#### Prototype:

**virtual Mesh\* GetRenderMesh(TimeValue t, INode \*inode, View& view, BOOL& needDelete);**

#### Remarks:

Implemented by the Plug-In.

This method should be implemented by all renderable GeomObjects. It provides a mesh representation of the object for use by the renderer. Primitives that already have a mesh cached can just return a pointer to it (and set **needDelete** to FALSE).

In release 3.0 and later, any implementations of this method which take a long time should periodically call **View::CheckForRenderAbort()** to see if the user has canceled the render. If canceled, the function can either return NULL, or return a non null pointer with the appropriate value for **needDelete**. (If **needDelete** is TRUE a non-null mesh will be deleted.)

#### Parameters:

**TimeValue t**

The time to get the mesh.

**INode \*inode**

The node in the scene.

**View& view**

If the renderer calls this method it will pass the view information here. See [Class View](#).

**BOOL& needDelete**

Set to TRUE if the renderer should delete the mesh, FALSE otherwise.

**Return Value:**

A pointer to the mesh object.

**Prototype:**

```
virtual PatchMesh* GetRenderPatchMesh(TimeValue, INode  
*inode, View& view, BOOL& needDelete);
```

**Remarks:**

Implemented by the Plug-In.

This method provides a patch mesh representation of the object for use by the renderer. If this method returns NULL, then **GetRenderMesh()** will be called.

**Parameters:****TimeValue t**

The time to get the patch mesh.

**INode \*inode**

The node in the scene.

**View& view**

If the renderer calls this method it will pass the view information here. See [Class View](#).

**BOOL& needDelete**

Set to TRUE if the renderer should delete the patch mesh, FALSE otherwise.

**Return Value:**

A pointer to the patch mesh. See [Class PatchMesh](#).

**Prototype:**

```
virtual int NumberOfRenderMeshes();
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

Objects may supply multiple render meshes ( e.g. particle systems). If this method returns a positive number, then **GetMultipleRenderMesh** and **GetMultipleRenderMeshTM** will be called for each mesh, instead of calling **GetRenderMesh**.

**Return Value:**

The number of render meshes, or 0 to indicate that multiple meshes aren't supported.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual Mesh* GetMultipleRenderMesh(TimeValue t, INode  
*inode, View& view, BOOL& needDelete, int meshNumber);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

For multiple render meshes, this method must be implemented. set **needDelete** to TRUE if the render should delete the mesh, FALSE otherwise.

**Parameters:**

**TimeValue t**

The time at which to obtain the mesh.

**INode \*inode**

The pointer to the node.

**View& view**

A reference to the view.

**BOOL& needDelete**

TRUE if the mesh needs to be deleted, otherwise FALSE.

**int meshNumber**

Specifies which of the multiple meshes is being asked for.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void GetMultipleRenderMeshTM(TimeValue t, INode  
*inode, View& view, int meshNumber, Matrix3& meshTM,  
Interval& meshTMValid);
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the Plug-In.

For multiple render meshes, this method must be implemented.

**Parameters:**

**TimeValue t**

The time at which to obtain the mesh.

**INode \*inode**

The pointer to the node.

**View& view**

A reference to the view.

**int meshNumber**

Specifies which of the multiple meshes is being asked for.

**Matrix3& meshTM**

Should be returned with the transform defining the offset of the particular mesh in object space.

**Interval& meshTMValid**

Should contain the validity interval of **meshTM**.

**Default Implementation:**

```
{ return; }
```

**Prototype:**

```
virtual BOOL CanDoDisplacementMapping();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if this object can do displacement mapping; otherwise FALSE.

**Default Implementation:**

```
{ return 0; }
```

## Class SimpleObject

See Also: [Class GeomObject](#), [Class IParamBlock](#), [Class Mesh](#).

```
class SimpleObject : public GeomObject
```

### Description:

This is a base class for creating procedural objects. This class implements many of the methods required to create a procedural object. The only limitation for a procedural object using **SimpleObject** as a base class is that it must represent itself with a mesh.

### Data Members:

Note: Methods of the base class refer to these data members. For example the base class implementations of the bounding box methods use the **mesh** data member. Therefore the plug-in derived from SimpleObject must use these same data members.

public:

#### **IParamBlock \*pblock;**

The parameter block for managing the object's parameters.

#### **Mesh mesh;**

The mesh object that is built by **BuildMesh()**.

#### **Interval ivalid;**

The validity interval for the **mesh**. This interval is used to determine how **BuildMesh()** is called. If this interval is not set **BuildMesh()** will be called over and over as the system won't know when the mesh is valid or not. Make sure you set this interval to accurately reflect the validity interval for the mesh.

#### **BOOL suspendSnap;**

If TRUE, this causes no snapping to occur. This is commonly used to prevent an object from snapping to itself when it is creating. For example, in the mouse proc used to create an object, the following code is often used when snapping mouse points:

```
ob->suspendSnap = TRUE;
```

```
p0 = vpt->SnapPoint(m,m,NULL,SNAP_IN_PLANE);
```

This disables snapping temporarily to keep the object from snapping to itself.

Procedural Object plug-ins which subclass off SimpleObject must implement

these methods. The default implementations are noted.

**Methods:**

**Prototype:**

**virtual void BuildMesh(TimeValue t)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to build the mesh representation of the object using its parameter settings at the time passed. The plug-in should use the data member **mesh** to store the built mesh.

**Parameters:**

**TimeValue t**

The time at which to build the mesh.

**Prototype:**

**virtual ParamDimension \*GetParameterDim(int pbIndex)**

**Remarks:**

Implemented by the Plug-In.

This method returns the parameter dimension of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter to return the dimension of.

**Return Value:**

Pointer to a ParamDimension.

**Example:**

**return stdNormalizedDim;**

**Default Implementation:**

The default implementation returns **defaultDim**.

See Also: [ParamDimension](#)

**Prototype:**

```
virtual TSTR GetParameterName(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

This method returns the name of the parameter whose index is passed.

**Parameters:**

```
int pbIndex
```

The index of the parameter to return the name of.

**Return Value:**

The name of the parameter.

**Default Implementation:**

```
The default implementation returns TSTR(_T("Parameter"))
```

**Prototype:**

```
virtual void InvalidateUI()
```

**Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

**Example:**

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **pmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that ip and pblock are assumed to be initialized interface and parameter block pointers

```
(IObjParam *ip, IParamBlock *pblock).
```

```
float newval;
```

```
Interval valid=FOREVER;
```

```
TimeValue t=ip->GetTime();
```

```
// Get the value from the parameter block at the current time.  
pblock->GetValue( PB_ANGLE, t, newval, valid );  
// Set the value. Note that the notify argument is passed as  
FALSE.  
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Prototype:**

```
virtual BOOL OKtoDisplay(TimeValue t)
```

**Remarks:**

Implemented by the Plug-In.

This method returns a BOOL to indicate if it is okay to draw the object at the time passed. Normally it is always OK to draw the object, so the default implementation returns TRUE. However for certain objects it might be a degenerate case to draw the object at a certain time (perhaps the size went to zero for example), so these objects could return FALSE.

**Parameters:**

**TimeValue t**

The time at which the object would be displayed.

**Default Implementation:**

```
{ return TRUE; }
```

**Return Value:**

TRUE if the object may be displayed; otherwise FALSE.

## Class ParticleObject

See Also: [Class GeomObject](#), [Class ForceField](#), [Class CollisionObject](#), [Class ShadeContext](#).

```
class ParticleObject : public GeomObject
```

### Description:

This is the base class for creating particle system plug-ins.

Many particle systems may be derived from class **SimpleParticle** instead of this class. See [Class SimpleParticle](#) for more details.

Note: This class is derived from GeomObject and still has **GEOMOBJECT\_CLASS\_ID** as its super class. To determine if an object is a ParticleObject, call:

**Animatable::GetInterface()** with the ID **I\_PARTICLEOBJ** or use the macro:

**GetParticleInterface(anim)** where **anim** is the object in question. This will return a **ParticleObject\*** or **NULL**. See [Class Animatable](#) .

Note: See the method **Animatable::GetProperty()** for details on choosing the method used to evaluate the particle system during motion blur rendering. See [Class Animatable](#) .

### Methods:

#### Prototype:

```
virtual void ApplyForceField(ForceField *ff)=0;
```

#### Remarks:

Implemented by the Plug-In.

This method is called to add the force field object passed to the list of force field objects operating on this particle system.

#### Parameters:

**ForceField \*ff**

Points to an instance of a ForceField object.

#### Sample Code:

```
void SimpleParticle::ApplyForceField(ForceField *ff) {  
    fields.Append(1,&ff);  
}
```

```
}
```

**Prototype:**

```
virtual BOOL ApplyCollisionObject(CollisionObject *co)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to add the collision object passed to the list of collision objects operating on this particle system.

**Parameters:**

**CollisionObject \*co**

Points to an instance of a collision object.

**Return Value:**

If a particle does not support this method it should return FALSE; otherwise return TRUE.

**Sample Code:**

```
BOOL SimpleParticle::ApplyCollisionObject(CollisionObject *co)
{
    cobjs.Append(1,&co);
    return TRUE;
}
```

**Prototype:**

```
int IsDeformable();
```

**Remarks:**

Implemented by the System.

This method returns TRUE to indicate it is deformable. A particle object is deformable, but does not let itself be deformed using the usual **GetPoint()** / **SetPoint()** methods. Instead a space warp must apply a force field to deform the particle system.

**Prototype:**

```
BOOL CanCacheObject();
```

**Remarks:**

Implemented by the System.

This method returns FALSE to indicate the object cannot be cached. Particle objects don't perform a shallow copy and therefore cannot be cached.

**Prototype:**

```
virtual BOOL NormalAlignVector(TimeValue t,Point3 &pt, Point3 &norm);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

This method is inherited from [Class Object](#). This is a default implementation provided for particle systems.

**Parameters:**

**TimeValue t**

The time to compute the normal align vector.

**Point3 &pt**

The point of intersection.

**Point3 &norm**

The normal at the point of intersection.

**Return Value:**

TRUE if this method is implemented to return the normal align vector; otherwise FALSE.

**Default Implementation:**

```
{pt=Point3(0,0,0);norm=Point3(0,0,-1);return TRUE;}
```

**Prototype:**

```
virtual Point3 ParticlePosition(TimeValue t,int i);
```

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

Returns the position of the specified particle in world space at the time passed.

The Particle Age texture map and the Particle Motion Blur texture map use this method.

**Parameters:**

**TimeValue t**

The time to return the particle position.

**int i**

The index of the particle.

Note: When a texture map calls these methods, the particle index **i** is passed to the texmap in the data member **ShadeContext::mtlNum**. The particle systems encode the index of the particle associated with the face of the particle mesh being shaded into the **mtlNum**. For instance, once the particle system generates a mesh to be rendered, every face of the mesh corresponds to a particle. This isn't a one-to-one correspondance because there are more faces than particles (if the particles are represented as tetrahedrons there are four faces per particle). When a texture map or material that is shading a mesh generated by a particle system wants to know which particle the face is associated with it gets this info out of the **ShadeContext::mtlNum**.

For example, here is a fragment of the code from the Particle Age texture map where it evaluates the color of the point being shaded:

```
AColor PartAgeTex::EvalColor(ShadeContext& sc)  
{  
  ...  
  // Evaluate...  
  Object *ob = sc.GetEvalObject();  
  if (ob && ob->IsParticleSystem()) {  
    ParticleObject *obj = (ParticleObject*)ob;  
    TimeValue t = sc.CurTime();  
    TimeValue age = obj->ParticleAge(t,sc.mtlNum);  
    TimeValue life = obj->ParticleLife(t,sc.mtlNum);  
    ...etc.  
  }
```

**Default Implementation:**

```
{return Point3(0,0,0);}
```

**Prototype:**

```
virtual Point3 ParticleVelocity(TimeValue t,int i);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns the velocity of the specified particle at the time passed (in 3ds max units per tick). This is specified as a vector. The Particle Age texture map and the Particle Motion Blur texture map use this method.

**Parameters:**

**TimeValue t**

The time to return the particle velocity.

**int i**

The index of the particle.

**Default Implementation:**

```
{return Point3(0,0,0);};
```

**Prototype:**

```
virtual float ParticleSize(TimeValue t,int i);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns the world space size of the specified particle in at the time passed.

The Particle Age texture map and the Particle Motion Blur texture map use this method.

**Parameters:**

**TimeValue t**

The time to return the particle size.

**int i**

The index of the particle.

**Default Implementation:**

```
{return 0.0f;};
```

**Prototype:**

```
virtual int ParticleCenter(TimeValue t,int i);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns a value indicating where the particle geometry (mesh) lies in relation to the particle position.

This is used by Particle Motion Blur for example. It gets the point in world space of the point it is shading, the size of the particle from **ParticleSize()**, and the position of the mesh from **ParticleCenter()**. Given this information, it can know where the point is, and it makes the head and the tail more transparent.

**Parameters:**

**TimeValue t**

The time to return the particle center.

**int i**

The index of the particle.

**Return Value:**

One of the following:

**PARTCENTER\_HEAD**

The particle geometry lies behind the particle position.

**PARTCENTER\_CENTER**

The particle geometry is centered around particle position.

**PARTCENTER\_TAIL**

The particle geometry lies in front of the particle position.

**Default Implementation:**

```
{return PARTCENTER_CENTER;}
```

**Prototype:**

```
virtual TimeValue ParticleAge(TimeValue t, int i);
```

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

Returns the age of the specified particle -- the length of time it has been 'alive'.

The Particle Age texture map and the Particle Motion Blur texture map use this method.

**Parameters:**

**TimeValue t**

Specifies the time to compute the particle age.

**int i**

The index of the particle.

**Default Implementation:**

```
{return -1;}
```

**Prototype:**

```
virtual TimeValue ParticleLife(TimeValue t, int i);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns the life of the particle -- the length of time the particle will be 'alive'.

The Particle Age texture map and the Particle Motion Blur texture map use this method.

**Parameters:**

**TimeValue t**

Specifies the time to compute the particle life span.

**int i**

The index of the particle.

**Default Implementation:**

```
{return -1;}
```

**Prototype:**

```
virtual BOOL HasConstantTopology();
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

If a particle system has a fixed number of particles of fixed topology, then it can return TRUE for this method, and the renderer will then compute the image motion blur velocities based on the vertex motions, giving motion blur for rotating particles etc. If the particle system is topology-varying it should return FALSE.

**Default Implementation:**

```
{return FALSE;}
```

## Class SimpleParticle

See Also: [Class ParticleObject](#), [Marker Types](#), [Class Mesh](#), [Class ParticleSys](#), [Class Interval](#), [Template Class Tab](#), [Class ParamDimension](#).

```
class SimpleParticle : public ParticleObject
```

### Description:

This class provides a base class from which you may derive Particle System plug-ins. This class may be used by particle systems that fit within its form. The form is primarily dictated by the data members maintain by the class. The class maintains an instance of class ParticleSys that describes the particles. It also has a table of force fields and collision objects. The emitter for the particles is represented by a mesh. There is also a parameter block pointer available.

Particle system plug-ins that don't fit this form may derive from a base class without any constraints. See [Class ParticleObject](#) for more details.

### Data Members:

public:

#### **IParamBlock \*pblock;**

The parameter block pointer.

#### **ParticleSys parts;**

This is a description of the particles themselves (their count, position, velocities, ...).

#### **TimeValue tvalid;**

A particle system derived from SimpleParticle is valid at a particular time only (it does not have a validity interval). It is assumed to be always changing. This data member holds the time at which it is valid (when **tvalid** is TRUE).

#### **BOOL valid;**

This flag indicates if the particle system is valid. If TRUE, **tvalid** should contain the time it is valid for.

#### **Tab<ForceField\*> fields;**

The table of force fields affecting the particles.

#### **Tab<CollisionObject\*> cobjs;**

The table of collision objects affecting the particles.

#### **Mesh mesh;**

The mesh object that represents the emitter.

**Interval mvalid;**

The validity interval for the emitter mesh. If the mesh is invalid

**BuildEmitter()** will be called.

**static SimpleParticle \*editOb;**

The SimpleParticle object that is being edited between **BeginEditParams()** and **EndEditParams()**.

**static IObjParam \*ip;**

Storage for the interface pointer passed into **BeginEditParams()**. This pointer is only valid between **BeginEditParams()** and **EndEditParams()**.

**Methods:**

**Prototype:**

**SimpleParticle();**

**Remarks:**

Constructor. The **pblock** is initialized to NULL, the **mvalid** interval is set to empty, and **valid** is set to FALSE.

**Prototype:**

**virtual void UpdateParticles(TimeValue t, INode \*node)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called so the particle system can update its state to reflect the current time passed. This may involve generating new particle that are born, eliminating old particles that have expired, computing the impact of collisions or force field effects, and modify the positions and velocities of the particles.

**Parameters:**

**TimeValue t**

The particles should be updated to reflect this time.

**INode \*node**

This is the emitter node. Particles system are world space objects so they are not instanced. This means that the particle system can depend on the node's world space position.

**Sample Code:**

For example code see `\MAXSDK\SAMPLES\OBJECTS\RAIN.CPP`.

**Prototype:**

```
void SetParticlePosition(TimeValue t, int i, Point3 pos);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the position of the specified particle at the specified time.

**Parameters:****TimeValue t**

The time at which to set the particle position.

**int i**

The zero based index of the particle to set.

**Point3 pos**

The position to set.

**Prototype:**

```
void SetParticleVelocity(TimeValue t, int i, Point3 vel);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the velocity of the specified particle at the specified time (in 3ds max units per tick).

**Parameters:****TimeValue t**

The time at which to set the particle velocity.

**int i**

The zero based index of the particle to set.

**Point3 vel**

The velocity to set.

**Prototype:**

```
void SetParticleAge(TimeValue t, int i, TimeValue age);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the age of the specified particle at the specified time.

**Parameters:****TimeValue t**

The time at which to set the particle age.

**int i**

The zero based index of the particle to set.

**TimeValue age**

The age to set.

**Prototype:**

**virtual void BuildEmitter(TimeValue t, Mesh& amesh)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to allow the plug-in to provide a representation of its emitter in the 3D viewports.

**Parameters:****TimeValue t**

Specifies the time to build the emitter.

**Mesh& amesh**

Store the built mesh representation here.

**Prototype:**

**virtual Interval GetValidity(TimeValue t)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to retrieve the validity time of the particle system emitter.

**Parameters:****TimeValue t**

The time to compute the validity interval.

**Return Value:**

The validity interval of the particle system emitter at the specified time.

**Prototype:**

```
virtual MarkerType GetMarkerType();
```

**Remarks:**

Implemented by the Plug-In.

Returns one of the defined marker types to use when displaying particles.

**Return Value:**

One of the following values:

See [Marker Types](#).

**Default Implementation:**

```
{return POINT_MRKR;}
```

**Prototype:**

```
virtual BOOL OKtoDisplay(TimeValue t);
```

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the particle emitter is okay to display at the specified time. If at certain times it is not okay to display this method should return FALSE. This might occur if a size goes to 0. Normally however it is always okay to display so the default implementation returns TRUE.

**Parameters:**

**TimeValue t**

The time to display the emitter.

**Return Value:**

TRUE if it is okay to display, FALSE otherwise.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual BOOL EmitterVisible();
```

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the particle emitter is visible in the viewports. If the plug-in provides a UI control to toggle the emitter on and off, this method should return the state of this control.

**Return Value:**

TRUE if the emitter is visible; otherwise FALSE.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual void InvalidateUI();
```

**Remarks:**

Implemented by the Plug-In.

It is important the user interface controls display values that reflect the current time. This method is called if the user interface parameters needs to be updated because the user moved to a new time.

**Example:**

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **pmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that ip and pblock are assumed to be initialized interface and parameter block pointers (**IObjParam \*ip, IParamBlock \*pblock**).

```
float newval;
```

```
Interval valid=FOREVER;
```

```
TimeValue t=ip->GetTime();
```

```
// Get the value from the parameter block at the current time.
```

```
pblock->GetValue( PB_ANGLE, t, newval, valid );
```

```
// Set the value. Note that the notify argument is passed as  
FALSE.
```

```
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Prototype:**

```
virtual ParamDimension *GetParameterDim(int pbIndex);
```

**Remarks:**

Implemented by the Plug-In.

This method returns the parameter dimension of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter to return the dimension of.

**Return Value:**

Pointer to a ParamDimension.

**Example:**

```
return stdNormalizedDim;
```

**Default Implementation:**

The default implementation returns **defaultDim**.

See Also: [ParamDimension](#)

**Prototype:**

```
virtual TSTR GetParameterName(int pbIndex);
```

**Remarks:**

Implemented by the Plug-In.

This method returns the name of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index of the parameter to return the name of.

**Return Value:**

The name of the parameter.

**Default Implementation:**

The default implementation returns **TSTR(\_T("Parameter"))**

## Class PatchObject

See Also: [Class GeomObject](#), [Class IPatchOps](#), [Class IPatchSelect](#), [Class IPatchSelectData](#), [Class ISubMtlAPI](#), [Class AttachMatDlgUser](#), [Class PatchMesh](#), [Class Patch](#), [Class Mesh](#), [Class TessApprox](#), [Working with Patches](#).

```
class PatchObject : public GeomObject, IPatchOps, IPatchSelect,  
IPatchSelectData, ISubMtlAPI, AttachMatDlgUser
```

### Description:

This class is the base class for the creation of Patch objects. This class stores an instance of a **PatchMesh** that holds all the Patches that make up this patch object. This class also maintains a **Mesh** cache. All methods of this class are implemented by the system.

### Data Members:

public:

#### **PatchMesh patch;**

The patch mesh for this patch object.

#### **Mesh mesh;**

The Mesh cache.

#### **BOOL meshValid;**

Indicates if the mesh cache is valid.

#### **BOOL showMesh;**

Indicates if the mesh is shown in the viewports

#### **GenericNamedSelSetList vselSet;**

This data member is available in release 3.0 and later only.

Vertex level named selection sets.

#### **GenericNamedSelSetList eselSet;**

This data member is available in release 3.0 and later only.

Edge level named selection sets.

#### **GenericNamedSelSetList pselSet;**

This data member is available in release 3.0 and later only.

Patch level named selection sets.

#### **int patchSelSubType;**

This data member is available in release 4.0 and later only.

The sub-object selection level, defined by;

### **PO\_PATCH**

Patch sub-object level. When SetSubobjectLevel(PO\_PATCH) is called, both the PatchMesh selection level and patchSelSubType are set to PO\_PATCH.

### **PO\_ELEMENT**

Element sub-object level. When SetSubobjectLevel(PO\_ELEMENT) is called, the PatchMesh selection level is set to PO\_PATCH and patchSelSubType is set to PO\_ELEMENT.

### **Methods:**

#### **Prototype:**

**PatchObject();**

#### **Remarks:**

Constructor.

#### **Prototype:**

**~PatchObject();**

#### **Remarks:**

Destructor.

#### **Prototype:**

**void UpdatePatchMesh(TimeValue t);**

#### **Remarks:**

This method is available in release 2.0 and later only.

This should be implemented by classes derived from PatchObject whose patches change over time.

#### **Parameters:**

**TimeValue t**

The time to update the patch mesh.

#### **Default Implementation:**

**{}**

**Prototype:**

**void PrepareMesh(TimeValue t);**

**Remarks:**

This method checks to see if the mesh cache is up to date, and if not, it generates it.

**Parameters:**

**TimeValue t**

This parameter is available in release 2.0 and later only.

The mesh cache should be generated to reflect this time.

**Prototype:**

**BOOL ShowLattice();**

**Remarks:**

Returns TRUE if the patch lattice is displayed; otherwise FALSE.

**Prototype:**

**BOOL ShowVerts();**

**Remarks:**

Returns TRUE if the patch vertices are shown; otherwise FALSE.

**Prototype:**

**void SetShowLattice(BOOL sw);**

**Remarks:**

Sets the state of the lattice display switch.

**Parameters:**

**BOOL sw**

TRUE to turn on the lattice display; FALSE to turn it off.

**Prototype:**

**void SetShowVerts(BOOL sw);**

**Remarks:**

Sets the state of the vertex display switch

**Parameters:**

**BOOL sw**

TRUE to turn on the vertex display; FALSE to turn it off.

**Prototype:**

**void SetMeshSteps(int steps);**

**Remarks:**

Sets the number of mesh steps (viewport).

**Parameters:**

**int steps**

The number of steps to set.

**Prototype:**

**int GetMeshSteps();**

**Remarks:**

Returns the number of mesh steps (viewport).

**Prototype:**

**void SetMeshStepsRender(int steps);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the Surface Render Steps setting.

**Parameters:**

**int steps**

The value to set.

**Prototype:**

**int GetMeshStepsRender();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the Surface Render Steps setting.

**Prototype:**

**void SetShowInterior(BOOL si);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the 'Show Interior Edges' value.

**Parameters:**

**BOOL si**

TRUE for on; FALSE for off.

**Prototype:**

**BOOL GetShowInterior();**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the 'Show Interior Edge' setting; TRUE if on; FALSE if off.

**Prototype:**

**void SetAdaptive(BOOL sw);**

**Remarks:**

Sets the state of the adaptive switch.

**Parameters:**

**BOOL sw**

TRUE to turn on; FALSE to turn off.

**Prototype:**

**BOOL GetAdaptive();**

**Remarks:**

Returns the state of the adaptive switch. TRUE is on; FALSE is off.

**Prototype:**

**void SetViewTess(TessApprox tess);**

**Remarks:**

Sets the tessellation approximation object used for viewport rendering.

**Parameters:**

**TessApprox tess**

The tessellation approximation object to be used for viewport rendering.

**Prototype:**

**TessApprox GetViewTess();**

**Remarks:**

Returns the tessellation approximation object used for rendering in the viewports.

**Prototype:**

**void SetProdTess(TessApprox tess);**

**Remarks:**

Sets the tessellation approximation object used for production rendering.

**Parameters:**

**TessApprox tess**

The tessellation approximation object to be used for production rendering.

**Prototype:**

**TessApprox GetProdTess();**

**Remarks:**

Returns the tessellation approximation object used for production rendering.

**Prototype:**

**void SetDispTess(TessApprox tess);**

**Remarks:**

Sets the tessellation approximation object used for display in the viewports.

**Parameters:**

## **TessApprox tess**

The tessellation approximation object to be used for the viewports.

### **Prototype:**

**TessApprox GetDispTess();**

### **Remarks:**

Returns the tessellation approximation object used for display in the viewports.

### **Prototype:**

**BOOL GetViewTessNormals();**

### **Remarks:**

Returns TRUE if normals are used from the viewport tesselator; otherwise FALSE.

### **Prototype:**

**void SetViewTessNormals(BOOL use);**

### **Remarks:**

Sets if normals are used from the viewport tesselator.

### **Parameters:**

**BOOL use**

TRUE to use normals; FALSE to not use them.

### **Prototype:**

**BOOL GetProdTessNormals();**

### **Remarks:**

Returns TRUE if normals are used from the production renderer tesselator; otherwise FALSE.

### **Prototype:**

**void SetProdTessNormals(BOOL use);**

### **Remarks:**

Sets if normals are used from the production renderer tesselator.

**Parameters:**

**BOOL use**

TRUE to use normals; FALSE to not use them.

**Prototype:**

**BOOL GetViewTessWeld();**

**Remarks:**

Returns TRUE if the viewport mesh is welded after tessellation; otherwise FALSE.

**Prototype:**

**void SetViewTessWeld(BOOL weld);**

**Remarks:**

Sets if the viewport mesh is welded after tessellation; otherwise FALSE.

**Parameters:**

**BOOL weld**

TRUE to weld; FALSE to not weld.

**Prototype:**

**BOOL GetProdTessWeld();**

**Remarks:**

Returns TRUE if the production renderer mesh is welded after tessellation; otherwise FALSE.

**Prototype:**

**void SetProdTessWeld(BOOL weld);**

**Remarks:**

Sets if the production renderer mesh is welded after tessellation; otherwise FALSE.

**Parameters:**

**BOOL weld**

TRUE to weld; FALSE to not weld.

**Prototype:**

**void InvalidateMesh();**

**Remarks:**

Invalidates the mesh cache.

**Prototype:**

**void SetFlag(DWORD fl, BOOL val=TRUE);**

**Remarks:**

This method is available in release 4.0 and later only.

This method sets or clears the status of the Show End Result flag.

**Parameters:**

**DWORD fl**

The flag you wish to set or clear. Currently the only flag defined is the Show End Result flag **EP\_DISP\_RESULT**.

**BOOL val**

Specifies if the given flag should be set or cleared.

**Prototype:**

**void ClearFlag (DWORD fl);**

**Remarks:**

This method is available in release 4.0 and later only.

This method clears the status of the Show End Result flag.

**Parameters:**

**DWORD fl**

The flag you wish to set or clear. Currently the only flag defined is the Show End Result flag **EP\_DISP\_RESULT**.

**Prototype:**

**bool GetFlag(DWORD fl);**

**Remarks:**

This method is available in release 4.0 and later only.

This methods allows you to obtain the status of the Show End Result flag.

**Parameters:**

**DWORD fl**

The flag you wish to set or clear. Currently the only flag defined is the Show End Result flag **EP\_DISP\_RESULT**.

**Prototype:**

**void ShowEndResultChanged(BOOL showEndResult);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called by the system then the status of the Show End Result function changes (ie. the Show End Results button has been toggled on or off).

Note that setting the state of the Show End Result is done through the

**Interface::SetShowEndResult()** method.

**Parameters:**

**BOOL showEndResult**

This flag specifies the Show End Result status, which is TRUE if on; FALSE if off.

**Prototype:**

**int Display(TimeValue t, INode\* inode, ViewExp \*vpt, int flags, ModContext \*mc);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is used to display the gizmo version of the patch mesh.

**Parameters:**

**TimeValue t**

The time to display the object.

**INode\* inode**

The node to display.

**ViewExp\* vpt**

An interface pointer that may be used to call methods associated with the

viewports.

**int flags**

The display flags. See the [List of Display Flags](#) for more information.

**ModContext\* mc**

A pointer to the modifiers ModContext.

**Prototype:**

**void GetWorldBoundingBox (TimeValue t, INode \* inode, ViewExp\* vp, Box3& box, ModContext \*mc);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the world space bounding box for the gizmo version of the patch mesh.

**Parameters:**

**TimeValue t**

The time to compute the bounding box.

**INode\* inode**

The node to calculate the bounding box for.

**ViewExp\* vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Box3& box**

The bounding box which was computed.

**ModContext\* mc**

A pointer to the modifiers ModContext.

**Prototype:**

**int GetSubobjectType();**

**Remarks:**

This method is available in release 4.0 and later only.

This method goes hand-in-hand with **GetSubobjectLevel()**, except that this method returns the type of geometry that is actually being acted upon.

**Return Value:**

The sub-object type, either **PO\_PATCH** or **PO\_ELEMENT**.

**Prototype:**

**Color GetVertColor(int mp=0, bool \*differs=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the common color for all selected vertices. If no vertices are selected then white (1,1,1) will be returned, however, if multiple vertices with different colors are selected, then black (0,0,0) will be returned.

**Parameters:**

**int mp=0**

The map channel.

**bool \*differs=NULL**

This parameter is returned to indicate if there were any differences.

**Prototype:**

**void SetVertColor(Color clr, int mp=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will set all selected vertices to the specified color.

**Parameters:**

**Color clr**

The color you wish to apply to all the selected vertices.

**int mp=0**

The map channel.

**Prototype:**

**Color GetPatchColor(int mp=0, bool \*differs=NULL);**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the common color for all selected patches. If no patches are selected then white (1,1,1) will be returned, however, if different vertex colors are present in the selected patches, then black (0,0,0) will be returned.

**Parameters:**

**int mp=0**

The map channel.

**bool \*differs=NULL**

This parameter is returned to indicate if there were any differences.

**Prototype:**

**void SetPatchColor(Color clr, int mp=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will set all selected patches to the specified color.

**Parameters:**

**Color clr**

The color you wish to apply to all the selected patches.

**int mp=0**

The map channel.

**Prototype:**

**void SelectVertByColor(VertColor clr, int deltaR, int deltaG, int deltaB, BOOL add, BOOL sub, int mp=0);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will select all vertices which fall into a specified color range.

**Parameters:**

**VertColor clr**

The starting color of the vertices you wish to select by color.

**int deltaR**

The difference range for the red color component.

**int deltaG**

The difference range for the green color component.

**int deltaB**

The difference range for the blue color component.

**BOOL add**

This flag adds vertices to the selection that fall into the color range.

**BOOL sub**

This flag subtracts vertices from the selection that fall into the color range.

**int mp=0**

The map channel.

**Prototype:**

```
void SelectOpenEdges();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method examines the patch mesh and selects any edges used by only one single patch.

**Prototype:**

```
void DoBevel(TimeValue t);
```

**Remarks:**

When called with the *Animate* state active and on a nonzero *TimeValue*, this method will prepare the controllers for the geometry that is being created. The program can then fill in the animated vertex values later.

**Parameters:****TimeValue t**

This parameter is available in release 4.0 and later only.

The time at which to prepare and execute the bevel operation.

**Prototype:**

```
void DoExtrude(TimeValue t);
```

**Remarks:**

When called with the Animate state active and on a nonzero TimeValue, this method will prepare the controllers for the geometry that is being created. The program can then fill in the animated vertex values later.

**Parameters:**

**TimeValue t**

This parameter is available in release 4.0 and later only.

The time at which to prepare and execute the extrude operation.

**Prototype:**

**void DoCreateShape();**

**Remarks:**

This method is available in release 4.0 and later only.

This method will create a bezier spline shape from the selected edges of the patch mesh. Each edge will become a separate spline in the output shape. The user will be prompted to enter a name for the new editable spline object that will be created.

**Prototype:**

**void DoEdgeWeld();**

**Remarks:**

This method is available in release 4.0 and later only.

This method will perform the edge weld function on the patch object. Note that this does not take into account any threshold but welds edges only if they use the same two vertices as endpoints. When two or more edges are welded, the locations of the edge vectors are averaged to create the new edge.

**Prototype:**

**void DoFlipNormals(int patchIndex = -1);**

**Remarks:**

This method is available in release 4.0 and later only.

This method flips the normals of a specified patch or all selected patches. This method will save undo information and displays a prompt if **patchIndex < 0** while there are no patches selected.

**Parameters:****int patchIndex**

The index of the patch for which to flip the normal. If this parameter is  $< 0$ , the normals of all selected patches will be flipped (if there are any selected).

Any vertices set to **PVERT\_COPLANAR** that lie on the boundary between flipped and unflipped patches will have their type set to

**PVERT\_CORNER**. This is because attempting to compute normals of neighboring patches with opposite normals in order to get a proper plane often results in invalid normals being generated. Making the vertex a corner type prevents the problem. Any vertices not on the boundary between flipped and unflipped patches are left as is.

**Prototype:**

**void DoUnifyNormals();**

**Remarks:**

This method is available in release 4.0 and later only.

This method examines the selected patch set and attempts to make them all face the same direction. Preferred direction is arbitrary; the first selected patch encountered in each contiguous group determines the direction all patches in that group will attain.

Any vertices set to **PVERT\_COPLANAR** that lie on the boundary between flipped and unflipped patches will have their type set to

**PVERT\_CORNER**. This is because attempting to compute normals of neighboring patches with opposite normals in order to get a proper plane often results in invalid normals being generated. Making the vertex a corner type prevents the problem. Any vertices not on the boundary between flipped and unflipped patches are left as is.

**Prototype:**

**void DoBreak(BOOL interactive = TRUE);**

**Remarks:**

This method is available in release 4.0 and later only.

In vertex mode, this method examines selected vertices, and if any of the vertices that are part of the selection set are used by more than one patch,

those vertices (and any attached vectors) are duplicated into separate geometry for each patch using it.

In edge mode, this method examines the selected edges and any vectors on the selected edges that are used by more than one patch are duplicated into separate geometry for each patch using them. Any vertices used by more than one selected edge are duplicated as well for patches on opposite sides of the edge.

Note: If the vertices and vectors involved have controllers attached, they are removed by this operation.

**Parameters:**

**BOOL interactive**

If this parameter is set to TRUE it will cause the method to display the appropriate prompts, create an undo object, and notifies the dependents.

**Prototype:**

**void DoDeleteSelected(BOOL interactive = TRUE);**

**Remarks:**

This method is available in release 3.0 and later only.

This method will delete the selected patches, exactly like the DeleteMesh modifier does.

**Parameters:**

**BOOL interactive**

This parameter is available in release 4.0 and later only.

If this parameter is set to TRUE it will cause the method to display the appropriate prompts, create an undo object, and notifies the dependents.

**Prototype:**

**void ChangeMappingTypeLinear(BOOL linear);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will change the mapping type of the selected patches to linear or curved.

**Parameters:**

## **BOOL linear**

If TRUE the mapping type will be changed to linear. FALSE will change the mapping type to curved.

### **Prototype:**

```
virtual void GetUIParam(patchUIParam uiCode, int &ret);
```

### **Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit patch parameters from the command panel. Currently not in use.

### **Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**int &ret**

The returned value.

### **Default Implementation:**

```
{ }
```

### **Prototype:**

```
virtual void SetUIParam(patchUIParam uiCode, int val);
```

### **Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit patch parameters from the command panel. Currently not in use.

### **Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**int val**

The value to set.

### **Default Implementation:**

```
{ }
```

**Prototype:**

**virtual void GetUIParam(patchUIParam uiCode, float &ret);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to get the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**float &ret**

The returned value.

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual void SetUIParam(patchUIParam uiCode, float val);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows you to set the edit patch parameters from the command panel. Currently not in use.

**Parameters:**

**patchUIParam uiCode**

This enum is currently empty.

**float val**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

**bool Editing();**

**Remarks:**

This method is available in release 4.0 and later only.

This method will return TRUE if the SplineShape object or Edit Spline modifier is active in the command panel.

**Default Implementation:**

```
{ return (ip && (editObj==this)) ? TRUE : FALSE; }
```

## Class HelperObject:

See Also: [Class Object](#), [Class Animatable](#).

class HelperObject : public Object

### Description:

This is used as a base class to create helper object plug-ins. It simply provides implementations for a few of the methods of Animatable and Object.

### Methods:

#### Prototype:

**SClass\_ID SuperClassID();**

#### Remarks:

Implemented by the System.

Returns the super class ID of this plug-in type: **HELPER\_CLASS\_ID**

#### Prototype:

**int IsRenderable();**

#### Remarks:

Implemented by the System.

Returns 0 to indicate this object type may not be rendered.

#### Prototype:

**virtual void InitNodeName(TSTR& s);**

#### Remarks:

Implemented by the System.

Sets the default node name to "**Helper**".

#### Prototype:

**virtual int UsesWireColor();**

#### Remarks:

Implemented by the System.

Returns TRUE to indicate the object color is used for display.

## Class ConstObject

See Also: [Class HelperObject](#), [Class INode](#), [Class Object](#), [Class ViewExp](#), [Class Matrix3](#).

```
class ConstObject : public HelperObject
```

### Description:

This is a base class used to create construction grid objects. It implements a few of the methods of Animatable and Object and provides a few for working with construction grids.

### Methods:

#### Prototype:

```
int IsConstObject();
```

#### Remarks:

Implemented by the System.

Returns 1 to indicate this object is a construction grid object.

#### Prototype:

```
virtual void GetConstructionTM( TimeValue t, INode* inode,  
    ViewExp *vp, Matrix3 &tm ) = 0;
```

#### Remarks:

Implemented by the Plug-In.

This method returns the construction grid transformation matrix. This is the world space orientation and position of the construction plane.

#### Parameters:

##### **TimeValue t**

The time to retrieve the matrix.

##### **INode\* inode**

The node in the scene corresponding to the construction grid object.

##### **ViewExp \*vp**

The viewport the TM is being returned for. Certain construction grid objects might have a different plane for different viewports.

##### **Matrix3 &tm**

The transform matrix for this view is returned here.

**Prototype:**

**virtual Point3 GetSnaps(TimeValue t) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is specific to construction grids. The system calls this method to retrieve the snap dimension of the grid. In the 3ds max user interface for the construction grid helper object there is a spinner for 'Spacing'. This is the spacing for the grid. When **GetSnaps()** is called the Point3 returned will have this value in all three axes. This value is used, for example, when you create a box or other primitive and are setting the height dimension.

Note: In release 3.0 and later this method was changed to return a Point3 (not a Point3&).

**Parameters:**

**TimeValue t**

The time to retrieve the snap values.

## Class SimpleSpline

See Also: [Class ShapeObject](#).

```
class SimpleSpline : public ShapeObject
```

### Description:

Defines a simple spline object class to make spline primitives easier to create. This class provides default implementations for most of the **ShapeObject** methods. The plug-in derived from **SimpleSpline** must only implement a handful of methods to create a shape plug-in.

SimpleSpline plug-ins use a Super Class ID of **SHAPE\_CLASS\_ID**.

### Data Members:

public:

**IParamBlock \*ipblock;**

Interpolation parameter block (handled by **SimpleSpline**).

**IParamBlock \*pblock;**

User's parameter block. See [Class IParamBlock](#).

**static IParamMap \*ipmapParam;**

The parameter map. See [Class IParamMap](#).

**static int dlgSteps;**

The dialog steps settings.

**static BOOL dlgOptimize;**

The dialog Optimize toggle.

**static BOOL dlgAdaptive;**

The dialog Adaptive toggle.

**BezierShape shape;**

The Spline cache.

**Interval ivalid;**

The validity interval for the spline. See [Class Interval](#).

**BOOL suspendSnap;**

Flag to suspend snapping used during creation.

**static SimpleSpline \*editOb;**

This is the spline being edited in the command panel.

**Methods:**

**Prototype:**

**SimpleSpline();**

**Remarks:**

Constructor. The validity interval is set to empty, and the pblocks are set to NULL.

**Prototype:**

**~SimpleSpline();**

**Remarks:**

Destructor.

Clients of SimpleSpline need to implement these methods:

**Prototype:**

**virtual TCHAR \*GetObjectName() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the name that will appear in the history browser.

**Prototype:**

**virtual void InitNodeName(TSTR& s) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method retrieves the default name of the node when it is created.

**Parameters:**

**TSTR& s**

The name is stored here.

**Prototype:**

**virtual Class\_ID ClassID() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the unique Class\_ID of the plug-in. See [Class Class\\_ID](#) for more details.

**Prototype:**

**virtual void GetClassName(TSTR& s) = 0;**

**Remarks:**

Implemented by the Plug-In.

Retrieves the name of the plug-in class. This is used internally for debugging purposes.

**Parameters:**

**TSTR& s**

The name is stored here.

**Prototype:**

**virtual void BuildShape(TimeValue t,BezierShape& ashape) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to build the shape at the specified time and store the results in **ashape**.

**Parameters:**

**TimeValue t**

The time to build the shape.

**BezierShape& ashape**

The created shape is store here.

**Prototype:**

**virtual RefTargetHandle Clone(RemapDir& remap = NoRemap()) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to have the plug-in clone itself. The plug-in should clone

all its references as well.

**Parameters:**

**RemapDir &remap = NoRemap()**

This class is used for remapping references during a Clone. See [Class RemapDir](#).

**Return Value:**

A pointer to the cloned item.

**Prototype:**

**virtual void EndEditParams(IObjParam \*ip, ULONG flags, Animatable \*next) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called when the user is finished editing object's parameters. The system passes a flag into the **EndEditParams()** method to indicate if the rollup page should be removed. If this flag is TRUE, the plug-in must unregister the rollup page, and delete it from the panel.

**Parameters:**

**IObjParam \*ip**

This is an interface pointer passed in. The developer may use the interface pointer to call methods such as **DeleteRollupPage()**.

**ULONG flags**

The following flag may be set:

**END\_EDIT\_REMOVEUI**

If TRUE, the item's user interface should be removed.

**Animatable \*next**

This parameter may be used in the motion and hierarchy branches of the command panel. This pointer allows a plug-in to look at the ClassID of the next item that was being edited, and if it is the same as this item, to not replace the entire UI in the command panel. Note that for items that are edited in the modifier branch this field can be ignored.

**Prototype:**

**virtual CreateMouseButton\* GetCreateMouseButton() = 0;**

**Remarks:**

Implemented by the Plug-In.

This method allows the system to retrieve a callback object used in creating the shape in the 3D viewports. This method returns a pointer to an instance of a class derived from **CreateMouseButton**. This class has a method **proc()** which is where the developer defines the user/mouse interaction used during the shape creation phase.

**Return Value:**

A pointer to an instance of a class derived from [CreateMouseButton](#).

**Prototype:**

**virtual BOOL ValidForDisplay(TimeValue t) = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if it is okay to display the shape at the time passed; otherwise FALSE. Certain shapes may not want to be displayed at a certain time, for example if their size goes to zero at some point.

**Parameters:**

**TimeValue t**

The time to check.

**Prototype:**

**virtual void InvalidateUI();**

**Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **ipmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner

controls. This will cause the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that **ip** and **pblock** are assumed to be initialized interface and parameter block pointers (**IObjParam \*ip, IParamBlock \*pblock**).

```
float newval;  
Interval valid=FOREVER;  
TimeValue t=ip->GetTime();  
// Get the value from the parameter block at the current time.  
pblock->GetValue( PB_ANGLE, t, newval, valid );  
// Set the value. Note that the notify argument is passed as  
FALSE.  
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Prototype:**

```
virtual ParamDimension *GetParameterDim(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

This method returns the parameter dimension of the parameter whose index is passed.

**Parameters:**

```
int pbIndex
```

The index of the parameter to return the dimension of.

**Return Value:**

Pointer to a ParamDimension. See [Class ParamDimension](#).

**Default Implementation:**

```
{return defaultDim;}
```

**Prototype:**

```
virtual TSTR GetParameterName(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

Returns the name of the parameter whose index is passed.

**Parameters:**

**int pbIndex**

The index into the parameter block of the parameter to return the name of.

**Default Implementation:**

```
{return TSTR(_T("Parameter"));} 
```

**Prototype:**

```
virtual BOOL DisplayVertTicksDuringCreation();
```

**Remarks:**

Returns TRUE if the Simple Spline should display vertex ticks during its creation; otherwise FALSE.

**Default Implementation:**

```
{ return TRUE; }
```

## Class SimpleShape

See Also: [Class ShapeObject](#), [Class IParamBlock](#), [Class PolyShape](#), [Class Interval](#), [Working with Shapes and Splines](#).

```
class SimpleShape : public ShapeObject
```

### Description:

This class defines a simple shape object to make procedural shape primitives easier to create. For example, the 3ds max Helix plug-in is derived from this class. There are a set of mandatory and optional methods to implement.

Revised for 3ds max 2.0 SimpleShape-based objects have a new 'General' rollup, which contains renderable shape options: Renderable checkbox, Thickness spinner, and a Mapping coords checkbox. These are supported automatically. To support the new features of the renderable splines, the derived class of SimpleShape needs to work with a few new methods -- see **SimpleShapeClone()** and **ReadyGeneralParameters()** below for details.

### Data Members:

public:

**IParamBlock \*pblock;**

The parameter block for managing the shape's parameters.

**static IObjParam \*ip;**

This data member is available in release 2.0 and later only.

This is the interface pointer stored by the class.

**static HWND hGenParams;**

This data member is available in release 2.0 and later only.

The window handle to the 'General' rollup.

**static BOOL dlgRenderable;**

This data member is available in release 2.0 and later only.

The 'Renderable' flag in the 'General' rollup.

**static float dlgThickness;**

This data member is available in release 2.0 and later only.

The 'Thickness' setting in the 'General' rollup.

**static BOOL dlgGenUVs;**

This data member is available in release 2.0 and later only.  
The 'Generate Mapping Coords' flag in the 'General' rollup.

**PolyShape shape;**

The shape cache.

**Interval ivalid;**

The validity interval for the shape cache.

**BOOL suspendSnap;**

A flag to suspend snapping used during the creation process.

**static SimpleShape \*editOb;**

The shape that is currently being edited in the command panel.

**static ISpinnerControl \*thickSpin;**

Points to the spinner control used for the thickness parameter.

**Methods:**

**Prototype:**

**SimpleShape();**

**Remarks:**

Constructor.

**Prototype:**

**~SimpleShape();**

**Remarks:**

Destructor.

Clients of SimpleShape need to implement these methods:

**Prototype:**

**virtual void BuildShape(TimeValue t, PolyShape& ashape) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to build the shape at the specified time and store the result into the PolyShape passed.

**Parameters:**

**TimeValue t**

The time to build the shape.

**PolyShape& ashape**

The built shape is stored here.

**Prototype:**

**virtual BOOL ValidForDisplay(TimeValue t) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method indicates if the shape may be displayed at the time passed. At certain times, for certain shapes, the shape may not be in a displayable form. For example, the size of the shape may go to zero at a certain point and would be inappropriate to display.

**Parameters:****TimeValue t**

The time to check.

**Return Value:**

TRUE if the shape may be displayed at the specified time; otherwise FALSE.

**Prototype:**

**virtual void InvalidateUI()**

**Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **ipmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that **ip** and **pblock** are assumed to be initialized interface and parameter block pointers

```
(IObjParam *ip, IParamBlock *pblock).  
float newval;  
Interval valid=FOREVER;  
TimeValue t=ip->GetTime();  
// Get the value from the parameter block at the current time.  
pblock->GetValue( PB_ANGLE, t, newval, valid );  
// Set the value. Note that the notify argument is passed as  
FALSE.  
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual ParamDimension *GetParameterDim(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

This method returns the parameter dimension of the parameter whose index is passed.

**Parameters:**

```
int pbIndex
```

The index of the parameter to return the dimension of.

**Return Value:**

Pointer to a ParamDimension. See [Class ParamDimension](#).

**Default Implementation:**

```
{return defaultDim;}
```

**Prototype:**

```
virtual TSTR GetParameterName(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

Returns the name of the parameter whose index is passed.

**Parameters:****int pbIndex**

The index into the parameter block of the parameter to return the name of.

**Default Implementation:**

```
{return TSTR(_T("Parameter"));} 
```

**For procedural shapes the following methods must be implemented:**

**Prototype:**

```
virtual Point3 InterpCurve3D(TimeValue t, int curve, float param,  
int ptype = PARAM_SIMPLE) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method returns a point interpolated on the entire curve.

**Parameters:****TimeValue t**

The time to evaluate.

**int curve**

The index of the curve to evaluate.

**float param**

The 'distance' along the curve where 0 is the start and 1 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The interpolated point on the curve.

**Prototype:**

```
virtual Point3 TangentCurve3D(TimeValue t, int curve, float  
param, int ptype = PARAM_SIMPLE) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method returns a tangent vector interpolated on the entire curve.

**Parameters:**

**TimeValue t**

The time at which to evaluate the curve.

**int curve**

The index of the curve to evaluate.

**float param**

The 'distance' along the curve where 0.0 is the start and 1.0 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The tangent vector.

**Prototype:**

**virtual float LengthOfCurve(TimeValue t, int curve) = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the length of the specified curve.

**Parameters:**

**TimeValue t**

The time at which to compute the length.

**int curve**

The index of the curve.

**The following methods are optional.**

You should strongly consider implementing these, because the default implementations just do the bare-minimum job. It is often best to break up a curve into several smaller pieces than to have one single long curve. For example, the user may use a step setting of 10, and will expect to see a reasonable approximation of the shape using such a step setting. A curve that is

too long will not be accurately represented by such a steps setting as it will be too course. Chopping your curve up into manageable pieces will make things look better.

**Prototype:**

**virtual int NumberOfPieces(TimeValue t, int curve)**

**Remarks:**

Implemented by the Plug-In.

Returns the number of sub-curves in a curve.

**Parameters:**

**TimeValue t**

The time at which to check.

**int curve**

The index of the curve.

**Default Implementation:**

```
{ return 1; }
```

**Prototype:**

**virtual Point3 InterpPiece3D(TimeValue t, int curve, int piece,  
float param, int ptype=PARAM\_SIMPLE)**

**Remarks:**

Implemented by the Plug-In.

This method returns the interpolated point along the specified sub-curve.

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The curve to evaluate.

**int piece**

The sub-curve (segment) to evaluate.

**float param**

The position along the sub-curve to return where 0.0 is the start and 1.0 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The point in world space.

**Default Implementation:**

```
{ return InterpCurve3D(t, curve, param); }
```

**Prototype:**

```
virtual Point3 TangentPiece3D(TimeValue t, int curve,  
    int piece, float param, int ptype=PARAM_SIMPLE)
```

**Remarks:**

Implemented by the Plug-In.

Returns the tangent vector on a sub-curve at the specified 'distance' along the curve.

**Parameters:**

**TimeValue t**

The time to evaluate the sub-curve.

**int curve**

The curve to evaluate.

**int piece**

The sub-curve (segment) to evaluate.

**float param**

The position along the sub-curve to return where 0.0 is the start and 1.0 is the end.

**int ptype=PARAM\_SIMPLE**

The parameter type for spline interpolation. See [List of Parameter Types for Shape Interpolation](#).

**Return Value:**

The tangent vector.

**Default Implementation:**

```
{ return TangentCurve3D(t, curve, param, ptype); }
```

**Prototype:****void ReadyGeneralParameters();****Remarks:**

This method is available in release 2.0 and later only.

To support the new features of the renderable splines, in the derived class's constructor, call ReadyGeneralParameters(). This will set up the general parameters in the base class to the proper defaults. Failure to make this call will cause SimpleShape-based objects to be created with default general parameters rather than those of the previously-created object.

**Prototype:****void SimpleShapeClone(SimpleShape \*sshpSource);****Remarks:**

This method is available in release 2.0 and later only.

To support the new features of the renderable splines, the derived class of SimpleShape needs to, in the Clone method, call this method. This will insure that the base class parameters are copied to the cloned object. Failure to make this call will cause cloned SimpleShape-based objects to revert to the default rendering parameters.

**Parameters:****SimpleShape \*sshpSource**

The source shape for the clone.

**Prototype:****virtual MtlID GetMatID(TimeValue t, int curve, int piece);****Remarks:**

This method is available in release 3.0 and later only.

Returns the material ID of the specified segment of the specified curve or the shape.

**Parameters:****TimeValue t**

The time at which to return the material ID

**int curve**

The zero based index of the curve.

**int piece**

The zero based index of the segment of the curve.

## Class LightObject

See Also: [Class Object](#), [Class ObjLightDesc](#), [Class Interval](#), [Class Texmap](#).

```
class LightObject : public Object
```

### Description:

This is the base class from which plug-in lights may be derived.

### Methods:

#### Prototype:

```
virtual RefResult EvalLightState(TimeValue time, Interval&  
valid, LightState *ls)=0;
```

#### Remarks:

Implemented by the Plug-In.

This method is called to update the passed **LightState** and validity interval of the light.

#### Parameters:

##### **TimeValue time**

The time to evaluate the light state.

##### **Interval& valid**

The validity interval of the light about the specified time. This interval should be updated to reflect the validity interval of the light.

##### **LightState \*ls**

A pointer to the **LightState** structure which describes the properties of the light. This function updates the data in the structure to reflect the properties of the light at the specified time. See [Structure LightState](#).

#### Return Value:

**REF\_SUCCEED** if the **LightState** was updated; otherwise **REF\_FAIL**.

#### Prototype:

```
virtual ObjLightDesc *CreateLightDesc(INode *n, BOOL  
forceShadowBuffer  
)
```

**Remarks:**

Implemented by the Plug-In.

When the renderer goes to render the scene it asks all of the lights to create an **ObjectLightDesc** object. This is the method that is called to return this object.

**Parameters:**

**INode \*n**

The node pointer of the light.

**BOOL forceShadowBuffer**

Forces the creation of a shadow buffer.

**Return Value:**

An instance of **ObjectLightDesc**. See [Class ObjectLightDesc](#).

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void SetUseLight(int onOff)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets if the light is on or off.

**Parameters:**

**int onOff**

TRUE for on; FALSE for off.

**Prototype:**

```
virtual BOOL GetUseLight()=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the light is on; otherwise FALSE.

**Prototype:**

**virtual void SetHotspot(TimeValue time, float f)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the hotspot to the specified angle at the specified time.

**Parameters:**

**TimeValue time**

The time to set the hotspot angle.

**float f**

The angle to set in degrees.

**Prototype:**

**virtual float GetHotspot(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Implemented by the Plug-In.

Retrieves the hotspot angle.

**Parameters:**

**TimeValue t**

The time to retrieve the angle.

**Interval& valid = Interval(0,0)**

The validity interval that this method will update to reflect the hotspot setting.

**Return Value:**

The hotspot angle (in degrees).

**Prototype:**

**virtual void SetFalloffsize(TimeValue time, float f)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the falloff setting of the light.

**Parameters:**

**TimeValue time**

The time to set the falloff.

**float f**

The falloff angle in degrees.

**Prototype:**

```
virtual float GetFallsizes(TimeValue t, Interval& valid = Interval(0,0))=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the falloff angle of the light in radians.

**Parameters:**

**TimeValue t**

The time to retrieve the falloff angle.

**Interval& valid = Interval(0,0)**

The validity interval that this method will update to reflect the falloff setting.

**Return Value:**

The falloff angle of the light in degrees.

**Prototype:**

```
virtual void SetAtten(TimeValue time, int which, float f)=0;
```

**Remarks:**

Implemented by the Plug-In.

Sets the specified attenuation range distance at the time passed.

**Parameters:**

**TimeValue time**

The time to set the attenuation distance.

**int which**

Indicates which distance to set. One of the following values:

**LIGHT\_ATTEN\_START** - The start range radius.

**LIGHT\_ATTEN\_END** - The end range radius.

**float f**

The distance to set.

**Prototype:**

**virtual float GetAtten(TimeValue t, int which, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the specified attenuation range distance at the time passed.

**Parameters:**

**TimeValue t**

The time to retrieve the attenuation distance.

**int which**

Indicates which distance to retrieve. One of the following values:

**LIGHT\_ATTEN\_START** - The start range radius.

**LIGHT\_ATTEN\_END** - The end range radius.

**Interval& valid = Interval(0,0)**

The validity interval that this method will update to reflect the attenuation setting.

**Return Value:**

The specified attenuation range distance.

**Prototype:**

**virtual void SetTDist(TimeValue time, float f)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the light's target distance.

**Parameters:**

**TimeValue time**

The time to set the distance.

**float f**

The distance to set.

**Prototype:**

**virtual float GetTDist(TimeValue t, Interval& valid =**

**Interval(0,0)=0;**

**Remarks:**

Implemented by the Plug-In.  
Retrieves the light's target distance.

**Parameters:**

**TimeValue t**

The time to retrieve the distance.

**Interval& valid = Interval(0,0)**

The validity interval that this method will update to reflect the target distance setting.

**Return Value:**

The light's target distance.

**Prototype:**

**virtual void SetConeDisplay(int s, int notify=TRUE)=0;**

**Remarks:**

Implemented by the Plug-In.  
Sets the light's cone display flag. This controls if the cone is depicted graphically in the viewports.

**Parameters:**

**int s**

Indicates if the cone display should be on or off. If nonzero, the cone should be displayed; otherwise it should be turned off.

**int notify=TRUE**

If notify is TRUE the plug-in should call **NotifyDependents()** to notify its dependents.

**Prototype:**

**virtual BOOL GetConeDisplay()=0;**

**Remarks:**

Implemented by the Plug-In.  
Retrieves the light's cone display setting. This indicates if the cone is depicted

graphically in the viewports.

**Return Value:**

TRUE to indicate the cone is displayed; FALSE to indicate it is turned off.

**Prototype:**

**virtual int GetShadowMethod();**

**Remarks:**

Implemented by the Plug-In.

Returns the type of shadows used by the light.

**Return Value:**

One of the following values:

**LIGHTSHADOW\_NONE**

**LIGHTSHADOW\_MAPPED**

**LIGHTSHADOW\_RAYTRACED**

**Default Implementation:**

```
{return LIGHTSHADOW_NONE;}
```

**Prototype:**

**virtual void SetRGBColor(TimeValue t, Point3& rgb);**

**Remarks:**

Implemented by the Plug-In.

Sets the color of the light at the specified time.

**Parameters:**

**TimeValue t**

The time to set the color.

**Point3& rgb**

The color to set.

**Prototype:**

**virtual Point3 GetRGBColor(TimeValue t, Interval &valid = Interval(0,0));**

**Remarks:**

Implemented by the Plug-In.

Returns the color of the light at the specified time and updates the validity interval to reflect this parameters validity interval.

**Parameters:****TimeValue t**

The time to retrieve the value.

**Interval &valid = Interval(0,0)**

The validity interval to intersect with this parameters interval.

**Return Value:**

The color of the light at the specified time.

**Default Implementation:**

```
{return Point3(0,0,0);}
```

**Prototype:**

```
virtual void SetIntensity(TimeValue time, float f);
```

**Remarks:**

Implemented by the Plug-In.

Sets the intensity of the light to the value passed.

**Parameters:****TimeValue time**

The time to set the value.

**float f**

The value to set.

**Prototype:**

```
virtual float GetIntensity(TimeValue t, Interval& valid =  
Interval(0,0));
```

**Remarks:**

Implemented by the Plug-In.

Retrieves the intensity of the light at the specified time and updates the validity interval passed to reflect the validity interval of this parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the value.

**Interval &valid = Interval(0,0)**

The validity interval to intersect with this parameters interval.

**Return Value:**

The intensity of the light at the specified time

**Default Implementation:**

```
{return 0.0f;}
```

**Prototype:**

```
virtual void SetAspect(TimeValue t, float f);
```

**Remarks:**

Implemented by the Plug-In.

Sets the aspect ratio of the light at the specified time.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Prototype:**

```
virtual float GetAspect(TimeValue t, Interval& valid =  
Interval(0,0));
```

**Remarks:**

Implemented by the Plug-In.

Retrieves the aspect ratio of the light at the specified time and updates the validity interval passed to reflect the validity interval of this parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the value.

**Interval &valid = Interval(0,0)**

The validity interval to intersect with this parameters interval.

**Return Value:**

The aspect ratio of the light at the specified time

**Default Implementation:**

```
{return 0.0f;}
```

**Prototype:**

```
virtual void SetUseAtten(int s);
```

**Remarks:**

Implemented by the Plug-In.

Sets the flag to indicate if the light is attenuated.

**Parameters:**

**int s**

Nonzero to indicate the light is attenuated; otherwise 0.

**Prototype:**

```
virtual BOOL GetUseAtten();
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE to indicate the light is attenuated; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void SetAttenDisplay(int s);
```

**Remarks:**

Implemented by the Plug-In.

Sets the flag to indicate if the light attenuation ranges are displayed.

**Parameters:**

**int s**

Nonzero to indicate the light attenuation ranges are displayed; otherwise 0.

**Prototype:**

**virtual BOOL GetAttenDisplay();**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the light attenuation ranges are displayed; otherwise FALSE.

**Default Implementation:**

**{return FALSE;}**

**Prototype:**

**virtual void Enable(int enab);**

**Remarks:**

Implemented by the Plug-In.

Sets the light to enabled or disables (on or off).

**Parameters:**

**int enab**

Nonzero to set the light to on; zero to turn the light off.

**Prototype:**

**virtual void SetMapBias(TimeValue t, float f);**

**Remarks:**

Implemented by the Plug-In.

Sets the map bias setting at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The map bias value to set. The 3ds max lights use a range of 0.0 to 100.0.

**Prototype:**

**virtual float GetMapBias(TimeValue t, Interval& valid = Interval(0,0));**

**Remarks:**

Implemented by the Plug-In.

Returns the map bias setting at the time passed and updates the validity interval to reflect the validity interval of this parameter.

**Parameters:****TimeValue t**

The time to retrieve the value.

**Interval& valid = Interval(0,0)**

The validity interval to update to reflect this parameters validity interval.

**Return Value:**

The map bias setting at the time passed.

**Default Implementation:**

```
{return 0.0f;}
```

**Prototype:**

```
virtual void SetMapRange(TimeValue t, float f);
```

**Remarks:**

Implemented by the Plug-In.

Sets the map sample range setting to the value passed at the time passed.

**Parameters:****TimeValue t**

The time to set the value.

**float f**

The value to set. The 3ds max lights use a range of 0.0 to 20.0.

**Prototype:**

```
virtual float GetMapRange(TimeValue t, Interval& valid = Interval(0,0));
```

**Remarks:**

Implemented by the Plug-In.

Retrieves the lights map sample range setting at the specified time and updates the validity interval to reflect the validity interval of this parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the value.

**Interval& valid = Interval(0,0)**

The validity interval to update to reflect this parameters validity interval.

**Return Value:**

The lights map sample range setting.

**Default Implementation:**

```
{return 0.0f;}
```

**Prototype:**

```
virtual void SetMapSize(TimeValue t, int f);
```

**Remarks:**

Implemented by the Plug-In.

Sets the lights map size parameter to the value passed at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**int f**

The value to set.

**Prototype:**

```
virtual int GetMapSize(TimeValue t, Interval& valid =  
Interval(0,0))
```

**Remarks:**

Implemented by the Plug-In.

Returns the lights map size parameter at the specified time and updates the validity interval passed to reflect the validity interval of this parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the value.

**Interval& valid = Interval(0,0)**

The validity interval to update to reflect this parameters validity interval.

**Return Value:**

The lights map size parameter.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetRayBias(TimeValue t, float f);
```

**Remarks:**

Implemented by the Plug-In.

Sets the raytrace bias setting to the value passed at the specified time.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Prototype:**

```
virtual float GetRayBias(TimeValue t, Interval& valid =  
Interval(0,0));
```

**Remarks:**

Implemented by the Plug-In.

Returns the lights raytrace bias setting at the specified time and updates the validity interval passed to reflect the validity interval of this parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the value.

**Interval& valid = Interval(0,0)**

The validity interval to update to reflect this parameters validity interval.

**Return Value:**

The lights raytrace bias setting at the specified time.

**Default Implementation:**

```
{return 0.0f;}
```

**Prototype:**

```
virtual int GetUseGlobal()
```

**Remarks:**

Implemented by the Plug-In.

Returns the Use Global Settings flag setting.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetUseGlobal(int a);
```

**Remarks:**

Implemented by the Plug-In.

Sets the lights Use Global Settings flag.

**Parameters:**

**int a**

Nonzero indicates the light uses the global settings; zero indicates the light uses its own settings.

**Prototype:**

```
virtual int GetShadow()
```

**Remarks:**

Implemented by the Plug-In.

Returns the lights Cast Shadows flag.

**Return Value:**

Nonzero indicates the light casts shadows; otherwise 0.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

**virtual void SetShadow(int a);**

**Remarks:**

Implemented by the Plug-In.

Sets the lights Cast Shadows flag.

**Parameters:**

**int a**

Nonzero indicates the light casts shadows; zero indicates the light does not cast shadows.

**Prototype:**

**virtual int GetShadowType()**

**Remarks:**

Implemented by the Plug-In.

Retrieves the type of shadows used by the light - mapped or raytraced.

**Return Value:**

One of the following values:

**-1:** if the Shadow Generator is NULL. (R3 only).

**0:** if the light uses Shadow Maps.

**1:** if the light uses Raytraced Shadows.

**0xffff:** for any other Shadow Generators. (R3 only).

**Default Implementation:**

**{return 0;}**

**Prototype:**

**virtual void SetShadowType(int a);**

**Remarks:**

Implemented by the Plug-In.

Sets the type of shadows used by the light - mapped or raytraced.

**Parameters:**

**int a**

One of the following values:

**0:** This value plugs in a Shadow Map Generator  
**1:** This value plugs in a Raytraced Shadow Generator.  
Any other value is a NOOP.

**Prototype:**

**virtual void SetShadowGenerator(ShadowType \*s);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the shadow generator used by the light.

**Parameters:**

**ShadowType \*s**

The shadow plug-in to use. See [Class ShadowType](#).

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual ShadowType \*GetShadowGenerator();**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns a pointer to the shadow generator plug-in in use by the light. See [Class ShadowType](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual int GetAbsMapBias()**

**Remarks:**

Implemented by the Plug-In.  
Returns the lights Absolute Map Bias setting.

**Return Value:**

Nonzero indicates Absolute Map Bias is on; zero indicates it is off.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetAbsMapBias(int a);
```

**Remarks:**

Implemented by the Plug-In.

Sets the lights Absolute Map Bias setting.

**Parameters:**

**int a**

Nonzero indicates Absolute Map Bias is on; zero indicates it is off.

**Prototype:**

```
void SetAtmosShadows(TimeValue t, int onOff);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the atmospheric shadowing shadows on / off toggle for the light.

**Parameters:**

**TimeValue t**

The time at which to set the state.

**int onOff**

Nonzero for on; zero for off.

**Prototype:**

```
int GetAtmosShadows(TimeValue t);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the state of the atmospheric shadowing shadows on / off toggle for the light.

**Parameters:**

**TimeValue t**

The time at which to retrieve the state.

**Prototype:**

**void SetAtmosOpacity(TimeValue t, float f);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the atmospheric shadowing opacity for the light to the specified value at the time specified.

**Parameters:**

**TimeValue t**

The time at which to set the value.

**float f**

The value to set.

**Prototype:**

**float GetAtmosOpacity(TimeValue t, Interval& valid=FOREVER);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the atmospheric shadowing opacity for the light at the specified time.

**Parameters:**

**TimeValue t**

The time at which to retrieve the value.

**Interval& valid=FOREVER**

The validity interval which is updated to reflect the validity of the opacity setting.

**Prototype:**

**void SetAtmosColAmt(TimeValue t, float f);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the atmospheric shadowing color amount to the specified value at the

time passed.

**Parameters:**

**TimeValue t**

The time at which to set the value.

**float f**

The value to set.

**Prototype:**

**float GetAtmosColAmt(TimeValue t, Interval& valid=FOREVER);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the atmospheric shadowing color amount setting at the specified time.

**Parameters:**

**TimeValue t**

The time at which to retrieve the value.

**Interval& valid=FOREVER**

The validity interval which is updated to reflect the validity of the color amount setting.

**Prototype:**

**virtual int GetOvershoot()**

**Remarks:**

Implemented by the Plug-In.

Returns the lights Overshoot on / off setting. Nonzero indicates overshoot is on; otherwise 0.

**Default Implementation:**

**{return 0;}**

**Prototype:**

**virtual void SetOvershoot(int a);**

**Remarks:**

Implemented by the Plug-In.

Sets the lights Overshoot on / off setting.

**Parameters:**

**int a**

Nonzero indicates overshoot is on; otherwise 0.

**Prototype:**

**virtual int GetProjector()**

**Remarks:**

Implemented by the Plug-In.

Returns the lights Projector on / off setting. Nonzero indicates this light projects an image; otherwise 0.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

**virtual void SetProjector(int a);**

**Remarks:**

Implemented by the Plug-In.

Sets the lights projector on / off setting.

**Parameters:**

**int a**

Nonzero indicates this light projects an image; otherwise 0.

**Prototype:**

**virtual ExclList\* GetExclList();**

**Remarks:**

Implemented by the Plug-In.

Returns the list of names of items included or excluded by this light. See [Class NameTab](#).

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL Include();
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the light's name list is of items to be included by the light.

Returns FALSE if the list is of items to exclude from the light.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual Texmap* GetProjMap()
```

**Remarks:**

Implemented by the Plug-In.

Returns the map used by a projector light.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual void SetProjMap(Texmap* pmap);
```

**Remarks:**

Implemented by the Plug-In.

Sets the image(s) used by the projector light.

**Parameters:**

**Texmap\* pmap**

The map to use.

**Prototype:**

```
virtual void UpdateTargDistance(TimeValue t, INode* inode);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Updates the display of the light's target distance in the light's rollup page.

**Parameters:**

**TimeValue t**

The time to retrieve the distance.

**INode\* inode**

The light node.

**Default Implementation:**

```
{
```

## Class GenLight

See Also: [Class LightObject](#), [Class NameTab](#), [Class Control](#), [Class Interval](#), [Class Point3](#), [Class ObjLightDesc](#).

```
class GenLight : public LightObject
```

### Description:

This class describes a generic light object. It is used as a base class for creating plug-in lights. Methods of this class are used to get and set properties of the light. All methods of this class are implemented by the plug-in.

### Methods:

#### Prototype:

```
virtual GenLight *NewLight(int type)=0;
```

#### Remarks:

Creates a new light object of the specified type.

#### Parameters:

**int type**

One of the following values:

**OMNI\_LIGHT** -- Omnidirectional light.

**TSPOT\_LIGHT** -- Targeted spot light.

**DIR\_LIGHT** -- Directional light.

**FSPOT\_LIGHT** -- Free spot light.

**TDIR\_LIGHT** -- Targeted directional light.

#### Return Value:

A pointer to a new instance of the specified light type.

#### Prototype:

```
virtual int Type()=0;
```

#### Remarks:

This method is available in release 2.0 and later only.

Returns the type of light this is.

#### Return Value:

One of the following values:

**OMNI\_LIGHT** -- Omnidirectional light.

**TSPOT\_LIGHT** -- Targeted spot light.

**DIR\_LIGHT** -- Directional light.

**FSPOT\_LIGHT** -- Free spot light.

**TDIR\_LIGHT** -- Targeted directional light.

**Prototype:**

**virtual BOOL IsSpot()=0;**

**Remarks:**

Returns TRUE if the light is a spotlight; otherwise FALSE.

**Prototype:**

**virtual BOOL IsDir()=0;**

**Remarks:**

Returns TRUE if the light is directional; otherwise FALSE.

**Prototype:**

**virtual void SetUseLight(int onOff)=0;**

**Remarks:**

Sets the light on or off.

**Parameters:**

**int onOff**

Nonzero sets the light on; zero sets it off.

**Prototype:**

**virtual BOOL GetUseLight(void)=0;**

**Remarks:**

Returns TRUE if the light is on; otherwise FALSE.

**Prototype:**

**virtual void SetSpotShape(int s)=0;**

**Remarks:**

Sets the shape used for a spotlight, either rectangular or circular.

**Parameters:**

**int s**

One of the following values:

**RECT\_LIGHT**

**CIRCLE\_LIGHT**

**Prototype:**

**virtual int GetSpotShape(void)=0;**

**Remarks:**

Retrieves the shape used for a spotlight.

**Return Value:**

One of the following values:

**RECT\_LIGHT**

**CIRCLE\_LIGHT**

**Prototype:**

**virtual void SetHotspot(TimeValue time, float f)=0;**

**Remarks:**

Sets the hotspot to the specified angle at the specified time.

**Parameters:**

**TimeValue time**

The time to set the value.

**float f**

The angle in degrees.

**Prototype:**

**virtual float GetHotspot(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the hotspot angle in degrees at the specified time and updates the interval to reflect the validity of the hotspot controller.

**Parameters:**

**TimeValue t**

The time to get the angle.

**Interval& valid = Interval(0,0)**

The interval which is updated.

**Prototype:**

**virtual void SetFalloffsize(TimeValue time, float f)=0;**

**Remarks:**

Sets the falloff angle at the specified time.

**Parameters:**

**TimeValue time**

The time to set the angle.

**float f**

The angle to set in degrees.

**Prototype:**

**virtual float GetFalloffsize(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the falloff angle in degrees at the specified time and updates the interval passed to reflect the validity of the falloff controller.

**Parameters:**

**TimeValue t**

The time to return the value.

**Interval& valid = Interval(0,0)**

The interval which is updated.

**Prototype:**

**virtual void SetAtten(TimeValue time, int which, float f)=0;**

**Remarks:**

Sets the specified attenuation range distance at the time passed.

**Parameters:****TimeValue time**

The time to set the attenuation distance.

**int which**

Indicates which distance to set. One of the following values:

**ATTEN1\_START**

The near start range.

**ATTEN1\_END**

The near end range.

**ATTEN\_START**

The far start range.

**ATTEN\_END**

The far end range.

**float f**

The distance to set.

**Prototype:**

```
virtual float GetAtten(TimeValue t, int which, Interval& valid =  
Interval(0,0))=0;
```

**Remarks:**

Returns the specified attenuation distance at the time passed and updates the interval to reflect the validity of the attenuation controller.

**Parameters:****TimeValue t**

The time to get the attenuation distance.

**int which**

Indicates which distance to get. One of the following values:

**ATTEN1\_START**

The near start range.

**ATTEN1\_END**

The near end range.

**ATTEN\_START**

The far start range.

**ATTEN\_END**

The far end range.

**Interval& valid = Interval(0,0)**

The interval which is updated.

**Prototype:**

```
virtual void SetTDist(TimeValue time, float f)=0;
```

**Remarks:**

Sets the light's target distance.

**Parameters:****TimeValue time**

The time to set the distance.

**float f**

The distance to set.

**Prototype:**

```
virtual float GetTDist(TimeValue t, Interval& valid =  
Interval(0,0))=0;
```

**Remarks:**

Returns the light's target distance at the specified time and updates the interval passed to reflect the validity of the target distance.

**Parameters:****TimeValue t**

The time to retrieve the distance.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

```
virtual ObjLightDesc *CreateLightDesc(INode *n,BOOL  
forceShadowBuffer=false)=0;
```

**Remarks:**

When the renderer goes to render the scene it asks all of the lights to create an ObjLighDesc object. This is the method that is called to return a pointer to this object.

**Parameters:****INode \*n**

The node pointer of the light.

**BOOL forceShadowBuffer**

Forces the creation of a shadow buffer.

**Prototype:****virtual void SetRGBColor(TimeValue t, Point3& rgb)=0;****Remarks:**

Sets the color of the light at the specified time.

**Parameters:****TimeValue t**

The time to set the color.

**Point3& rgb**

The color to set.

**Prototype:****virtual Point3 GetRGBColor(TimeValue t, Interval &valid = Interval(0,0))=0;****Remarks:**

Returns the color of the light at the specified time and updates the validity interval to reflect this parameters validity interval.

**Parameters:****TimeValue t**

The time to get the color.

**Interval &valid = Interval(0,0)**

The interval which is updated.

**Prototype:**

```
virtual void SetHSVColor(TimeValue t, Point3& hsv)=0;
```

**Remarks:**

Sets the HSV color of the light at the specified time.

**Parameters:****TimeValue t**

The time to set the color.

**Point3& hsv**

The color.

**Sample Code:**

The following sample shows how the RGB value can be converted to HSV.

```
{  
  int h, s, v;  
  Point3 rgbf = GetRGBColor(t, valid);  
  DWORD rgb = RGB((int)(rgbf[0]*255.0f),  
    (int)(rgbf[1]*255.0f), (int)(rgbf[2]*255.0f));  
  RGBtoHSV (rgb, &h, &s, &v);  
  return Point3(h/255.0f, s/255.0f, v/255.0f);  
}
```

**Prototype:**

```
virtual Point3 GetHSVColor(TimeValue t, Interval &valid =  
  Interval(0,0))=0;
```

**Remarks:**

Retrieves the HSV color of the light at the specified time and updates the validity interval to reflect the color parameter.

**Parameters:****TimeValue t**

The time to retrieve the color.

**Interval &valid = Interval(0,0)**

The interval to update.

**Return Value:**

The color of the light (as a Point3).

**Prototype:**

**virtual void SetIntensity(TimeValue time, float f)=0;**

**Remarks:**

Sets the intensity (multiplier value) of the light at the specified time.

**Parameters:**

**TimeValue time**

The time to set the intensity.

**float f**

The value to set.

**Prototype:**

**virtual float GetIntensity(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the intensity (multiplier value) of the light at the specified time and updates the interval passed to reflect the validity of the controller.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval is updated.

**Prototype:**

**virtual void SetContrast(TimeValue time, float f)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the light's contrast setting.

**Parameters:**

**TimeValue time**

The time to set the contrast value.

**float f**

The new contrast value in the range of 0.0 to 100.0.

**Prototype:**

**virtual float GetContrast(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the light's contrast setting in the range 0.0 to 100.0.

**Parameters:**

**TimeValue t**

The time to get the light's contrast setting.

**Interval& valid = Interval(0,0)**

This interval is updated to reflect the interval of the light's contrast setting.

**Prototype:**

**virtual void SetAspect(TimeValue t, float f)=0;**

**Remarks:**

Set the aspect property to the specified value.

**Parameters:**

**TimeValue t**

The time at which to set the aspect ratio.

**float f**

Specifies the aspect ratio setting.

**Prototype:**

**virtual float GetAspect(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the aspect property (for rectangular lights) at the specified time and updates the interval passed to reflect the validity of the aspect controller.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

```
virtual void SetConeDisplay(int s, int notify=TRUE)=0;
```

**Remarks:**

Sets the spotlight cone display to on or off. This controls if the cone is depicted graphically in the viewports.

**Parameters:****int s**

Indicates if the cone display should be on or off. Nonzero indicates the cone should be displayed; otherwise it will be turned off.

**int notify=TRUE**

If notify is TRUE the plug-in should call **NotifyDependents()** to notify its dependents.

**Prototype:**

```
virtual BOOL GetConeDisplay()=0;
```

**Remarks:**

Returns the cone display property. TRUE if the spotlight cone is on; FALSE if off.

**Prototype:**

```
virtual void SetUseAtten(int s)=0;
```

**Remarks:**

Sets the far attenuation state to on or off.

**Parameters:****int s**

Nonzero for on; zero for off.

**Prototype:**

**virtual BOOL GetUseAtten()=0;**

**Remarks:**

Returns nonzero if far attenuation is on; zero if off.

**Prototype:**

**virtual void SetAttenDisplay(int s)=0;**

**Remarks:**

Establishes if the light far attenuation range is displayed in the viewports.

**Parameters:**

**int s**

Nonzero for on; zero for off.

**Prototype:**

**virtual BOOL GetAttenDisplay()=0;**

**Remarks:**

Returns TRUE if the far attenuation range is displayed; otherwise FALSE.

**Prototype:**

**virtual void SetUseAttenNear(int s)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Sets if the light uses near attenuation.

**Parameters:**

**int s**

Nonzero to use near attenuation; otherwise zero.

**Prototype:**

**virtual BOOL GetUseAttenNear(void)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the light has near attenuation on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetAttenNearDisplay(void)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the light near attenuation range is displayed in the viewports; otherwise FALSE.

**Prototype:**

**virtual void SetAttenNearDisplay(int s)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Establishes if the light near attenuation range is displayed in the viewports.

**Parameters:**

**int s**

TRUE to turn on the display; otherwise FALSE.

**Prototype:**

**virtual void Enable(int enab)=0;**

**Remarks:**

Sets the light to enabled or disables (on or off).

**Parameters:**

**int enab**

Nonzero for on; zero for off.

**Prototype:**

**virtual void SetMapBias(TimeValue t, float f)=0;**

**Remarks:**

Sets the map bias value at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Prototype:**

```
virtual float GetMapBias(TimeValue t, Interval& valid =  
Interval(0,0))=0;
```

**Remarks:**

Returns the map bias setting at the specified time and updates the interval passed to reflect the validity of the map bias.

**Parameters:****TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

```
virtual void SetMapRange(TimeValue t, float f)=0;
```

**Remarks:**

Sets the map range value at the time passed.

**Parameters:****TimeValue t**

The time to set the value.

**float f**

The value to set.

**Prototype:**

```
virtual float GetMapRange(TimeValue t, Interval& valid =  
Interval(0,0))=0;
```

**Remarks:**

Returns the map range setting at the specified time and updates the interval

passed to reflect the validity of the map range.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

**virtual void SetMapSize(TimeValue t, int f)=0;**

**Remarks:**

Sets the map size value at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**int f**

The value to set.

**Prototype:**

**virtual int GetMapSize(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the map size setting at the specified time and updates the interval passed to reflect the validity of the map size.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

**virtual void SetRayBias(TimeValue t, float f)=0;**

**Remarks:**

Sets the map raytrace bias value at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Prototype:**

**virtual float GetRayBias(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Returns the raytrace bias setting at the specified time and updates the interval passed to reflect the validity of the bias.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid = Interval(0,0)**

The interval to update.

**Prototype:**

**virtual int GetUseGlobal()=0;**

**Remarks:**

Returns TRUE if the use global setting is on; otherwise FALSE.

**Prototype:**

**virtual void SetUseGlobal(int a)=0;**

**Remarks:**

Set the use global setting to on or off.

**Parameters:**

**int a**

TRUE for on; FALSE for off.

**Prototype:**

```
virtual int GetShadow();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the lights Cast Shadows flag. Nonzero indicates the light casts shadows; otherwise 0.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetShadow(int a);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the lights Cast Shadows flag.

**Parameters:**

**int a**

Nonzero indicates the light casts shadows; zero indicates the light does not cast shadows.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int GetShadowType();
```

**Remarks:**

This method is available in release 3.0 and later only.

Retrieves the type of shadows used by the light - mapped or raytraced.

**Return Value:**

One of the following values:

**-1:** if the Shadow Generator is NULL. (R3 only).

**0:** if the light uses Shadow Maps.

**1:** if the light uses Raytraced Shadows.

**0xffff**: for any other Shadow Generators. (R3 only).

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SetShadowType(int a);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the type of shadows used by the light - mapped or raytraced.

**Parameters:**

**int a**

The shadow type. One of the following values:

**0**: This value plugs in a Shadow Map Generator.

**1**: This value plugs in a Raytraced Shadow Generator.

Any other value is a NO-OP.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetShadowGenerator(ShadowType *s);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the shadow generator used by the light.

**Parameters:**

**ShadowType \*s**

The shadow plug-in to use. See [Class ShadowType](#).

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual ShadowType *GetShadowGenerator();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the shadow generator plug-in in use by the light. See [Class ShadowType](#).

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetAtmosShadows(TimeValue t, int onOff);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the atmospheric shadow flag to on or off at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the value.

**int onOff**

TRUE for on; FALSE for off.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual int GetAtmosShadows(TimeValue t);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the atmospheric shadow setting at the specified time.

**Parameters:**

**TimeValue t**

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

**virtual void SetAtmosOpacity(TimeValue t, float f);**

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the atmospheric opacity value at the time passed.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual float GetAtmosOpacity(TimeValue t, Interval& valid=FOREVER);**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the atmospheric opacity value at the specified time and updates the validity interval to reflect the validity of the opacity controller.

**Parameters:**

**TimeValue t**

The time to get the value.

**Interval& valid=FOREVER**

The interval to update.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

**virtual void SetAtmosColAmt(TimeValue t, float f);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the atmospheric shadow color amount at the specified time.

**Parameters:**

**TimeValue t**

The time to set the value.

**float f**

The value to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual float GetAtmosColAmt(TimeValue t, Interval& valid=FOREVER);
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the atmospheric shadow color amount at the specified time and updates the interval passed to reflect the validity of the amount.

**Parameters:**

**TimeValue t**

The time to get.

**Interval& valid=FOREVER**

The interval to update.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

```
virtual int GetOvershoot()=0;
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the overshoot setting. Nonzero is on; zero is off.

**Prototype:**

**virtual void SetOvershoot(int a)=0;**

**Remarks:**

This method is available in release 2.0 and later only.  
Sets the overshoot setting.

**Parameters:**

**int a**

Nonzero for on; zero for off.

**Prototype:**

**virtual ExclList& GetExclusionList()=0;**

**Remarks:**

Returns the exclusion list for the light.

**Prototype:**

**virtual void SetExclusionList(ExclList &list)=0;**

**Remarks:**

Sets the exclusion list for the light.

**Parameters:**

**ExclList &list**

The exclusion list.

**Prototype:**

**virtual BOOL SetHotSpotControl(Control \*c)=0;**

**Remarks:**

Sets the controller for the hot spot parameter.

**Parameters:**

**Control \*c**

The controller to set.

**Return Value:**

TRUE if the controller was set; otherwise FALSE.

**Prototype:**

**virtual BOOL SetFalloffControl(Control \*c)=0;**

**Remarks:**

Sets the controller for the falloff parameter.

**Parameters:**

**Control \*c**

The controller to set.

**Return Value:**

TRUE if the controller was set; otherwise FALSE.

**Prototype:**

**virtual BOOL SetColorControl(Control \*c)=0;**

**Remarks:**

Sets the controller for the color parameter.

**Parameters:**

**Control \*c**

The controller to set.

**Return Value:**

TRUE if the controller was set; otherwise FALSE.

**Prototype:**

**virtual Control\* GetHotSpotControl()=0;**

**Remarks:**

Returns the controller for the hot spot parameter.

**Prototype:**

**virtual Control\* GetFalloffControl()=0;**

**Remarks:**

Returns the controller for the falloff parameter.

**Prototype:**

**virtual Control\* GetColorControl()=0;**

**Remarks:**

Returns the controller for the color parameter.

**Prototype:**

**virtual void SetAffectDiffuse(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Establishes if the light affects the diffuse color of objects.

**Parameters:**

**BOOL onOff**

TRUE to have the light affect the diffuse color; otherwise FALSE.

**Prototype:**

**virtual BOOL GetAffectDiffuse()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the light affects the diffuse color of objects; otherwise FALSE.

**Prototype:**

**virtual void SetAffectSpecular(BOOL onOff)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Establishes if the light affects the specular color of objects.

**Parameters:**

**BOOL onOff**

TRUE to have the light affect the specular color; otherwise FALSE.

**Prototype:**

**virtual BOOL GetAffectSpecular()=0;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns TRUE if the light affects the specular color of objects; otherwise FALSE.

**Prototype:**

**virtual void SetDecayType(BOOL onOff);**

**Remarks:**

This method is available in release 2.0 and later only.

Sets the decay state of the light.

**Parameters:**

**BOOL onOff**

This boolean works as an integer where **0** is None, **1** is Inverse and **2** is Inverse Square.

**Default Implementation:**

```
{}
```

**Prototype:**

**virtual BOOL GetDecayType();**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the decay state of the light.

**Return Value:**

This boolean works as an integer where **0** is None, **1** is Inverse and **2** is Inverse Square.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

**virtual void SetDecayRadius(TimeValue time, float f);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the decay radius (i.e. falloff) of the light.

**Parameters:**

**TimeValue time**

The time at which to set the radius.

**float f**

The radius to set.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual float GetDecayRadius(TimeValue t, Interval& valid =  
Interval(0,0));
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the decay radius of the light and updates the validity interval to reflect the validity of the radius controller.

**Parameters:**

**TimeValue t**

The time at which to return the radius.

**Interval& valid = Interval(0,0)**

The validity interval which is updated.

**Default Implementation:**

```
{ return 0.0f;}
```

**Prototype:**

```
virtual void SetDiffuseSoft(TimeValue time, float f);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the state of the 'Soften Diffuse Edge' parameter.

**Parameters:**

**TimeValue time**

The time at which to set the value.

**float f**

The value to set in the range of 0.0 to 100.0.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual float GetDiffuseSoft(TimeValue t, Interval& valid =  
Interval(0,0));
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns the state of the 'Soften Diffuse Edge' parameter.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Interval& valid = Interval(0,0)**

The validity interval that is updated to reflect the state of this parameter.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

```
virtual void SetShadColor(TimeValue t, Point3& rgb);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the shadow color to the specified value at the time passed.

**Parameters:**

**TimeValue t**

The time at which to set the shadow color.

**Point3& rgb**

The color to set.

**Default Implementation:**

```
}
```

**Prototype:**

```
virtual Point3 GetShadColor(TimeValue t, Interval &valid =  
Interval(0,0));
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the shadow color at the time passed and updates the validity interval passed to reflect the validity of the shadow color controller.

**Parameters:**

**TimeValue t**

The time at which to return the shadow color.

**Interval &valid = Interval(0,0)**

The validity interval which is updated.

**Default Implementation:**

```
{ return Point3(0,0,0); }
```

**Prototype:**

```
virtual BOOL GetLightAffectsShadow();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the Light Affects Shadow Color flag is set; otherwise FALSE.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void SetLightAffectsShadow(BOOL b);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the state of the Light Affects Shadow Color flag to the value passed.

**Parameters:**

**BOOL b**

TRUE for set; FALSE for off.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void SetShadMult(TimeValue t, float m);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the shadow color multiplier (density) to the value passed at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the value.

**float m**

The value to set.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual float GetShadMult(TimeValue t, Interval &valid =  
Interval(0,0));
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the shadow color multiplier (density) at the specified time and updates the interval passed to reflect the validity of the multiplier controller.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Interval &valid = Interval(0,0)**

The interval which is updated.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual Texmap* GetProjMap();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the texmap used as the projector image or NULL if not set.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetProjMap(Texmap* pmap);
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the texmap to use as the light's projector image.

**Parameters:**

**Texmap\* pmap**

Points to the texmap to set or NULL to clear it.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual Texmap* GetShadowProjMap();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns a pointer to the texmap used as the shadow projector or NULL if not set.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetShadowProjMap(Texture* pmap);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the texmap to use as the light's shadow projector.

**Parameters:**

```
Texture* pmap
```

Points to the texmap to set or NULL to clear it.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual void SetAmbientOnly(BOOL onOff);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Sets the ambient only flag to on or off.

**Parameters:**

```
BOOL onOff
```

TRUE for on; FALSE for off.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual BOOL GetAmbientOnly();
```

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the state of the ambient only flag. TRUE is on; FALSE is off.

**Default Implementation:**

```
{ return FALSE; }
```

# Class CameraObject

See Also: [Class Object](#).

class CameraObject : public Object

## Description:

This is a base class from which camera plug-ins may be derived. Methods of this class are used to get and set properties of the camera. All methods of this class are implemented by the plug-in.

## Methods:

### Prototype:

```
virtual RefResult EvalCameraState(TimeValue time,  
Interval& valid, CameraState* cs)=0;
```

### Remarks:

Implemented by the Plug-In.

This method is called to update the CameraState and validity interval at the specified time.

### Parameters:

#### **TimeValue time**

Specifies the time to evaluate the camera.

#### **Interval& valid**

The plug-in computes the validity interval of the camera at the specified time and stores the result here.

#### **CameraState\* cs**

The camera state to update. See [Structure CameraState](#). Note: The view vector and 'up' vector for the camera are stored with the matrix transform for the node. Cameras can be multiple-instanced so it must work this way. To get at this matrix use the following method from [Class INode](#):

```
virtual Matrix3 GetObjTMAfterWSM(TimeValue time,  
Interval* valid=NULL)=0;
```

The scaling of this matrix may be removed by normalizing each of the rows.

### Return Value:

**REF\_SUCCEEDED** if the camera state was updated successfully; otherwise **REF\_FAIL**.

**Prototype:**

**virtual void SetOrtho(BOOL b)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets whether the camera is on ortho mode or not.

**Parameters:**

**BOOL b**

Pass TRUE for ortho and FALSE for not ortho.

**Prototype:**

**virtual BOOL IsOrtho()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the camera is in ortho mode and FALSE if it is not.

**Prototype:**

**virtual void SetFOV(TimeValue time, float f)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the field-of-view of the camera at the specified time.

**Parameters:**

**TimeValue t**

The time at which to set the field-of-view.

**float f**

The value to set in radians.

**Prototype:**

**virtual float GetFOV(TimeValue t, Interval& valid = Interval(0,0))=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the field-of-view setting of the camera at the specified time and adjusts the validity interval of the camera at this time to reflect the field-of-view parameter.

**Parameters:****TimeValue t**

The time to retrieve the field-of-view setting.

**Interval& valid = Interval(0,0)**

The validity interval to set.

**Return Value:**

The field-of-view of the camera in radians.

**Prototype:**

```
virtual void SetTDist(TimeValue time, float f)=0;
```

**Remarks:**

Implemented by the Plug-In.

Sets the target distance setting (for free cameras) at the specified time.

**Parameters:****TimeValue t**

The time at which to set the target distance.

**float f**

The value to set.

**Prototype:**

```
virtual float GetTDist(TimeValue t, Interval& valid =  
Interval(0,0))=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the target distance setting of the camera at the specified time and adjusts the validity interval of the camera to reflect the target distance parameter.

**Parameters:**

**TimeValue t**

The time to retrieve the target distance setting.

**Interval & valid = Interval(0,0)**

This validity interval is intersected with the validity interval of the target distance parameter.

**Return Value:**

The target distance of the camera.

**Prototype:**

**virtual int GetManualClip()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the manual clip flag. This indicates the camera will perform clipping at its hither and yon distances.

**Return Value:**

Nonzero if manual clipping is enabled; otherwise 0.

**Prototype:**

**virtual void SetManualClip(int onOff)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the manual clip flag. This indicates the camera will perform clipping at its hither and yon distances.

**Parameters:**

**int onOff**

The state of the manual clipping flag to set. Nonzero indicates clipping will be performed.

**Prototype:**

**virtual float GetClipDist(TimeValue t, int which,  
Interval &valid=Interval(0,0))=0;**

**Remarks:**

Implemented by the Plug-In.

Retrieves the clipping distance of the specified plane at the specified time and modifies the validity interval to reflect the setting of the clipping distance parameter.

**Parameters:****TimeValue t**

The time to retrieve the clipping distance.

**int which**

Indicates which distance to return. One of the following values:

**CAM\_HITHER\_CLIP** - The hither distance

**CAM\_YON\_CLIP** - The yon distance.

**Interval &valid=Interval(0,0)**

The validity interval that this method will update to reflect the clipping distance interval.

**Return Value:**

The clipping distance.

**Prototype:**

```
virtual void SetClipDist(TimeValue t, int which, float val)=0;
```

**Remarks:**

Implemented by the Plug-In.

Sets the clipping distance of the specified plane at the specified time.

**Parameters:****TimeValue t**

The time to set the clipping distance.

**int which**

Indicates which distance to set. One of the following values:

**CAM\_HITHER\_CLIP** - The hither distance

**CAM\_YON\_CLIP** - The yon distance.

**float val**

The distance to set.

**Prototype:**

**virtual void SetEnvRange(TimeValue time, int which, float f)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the environment range distance at the specified time.

**Parameters:****TimeValue time**

The time to set the environment range.

**int which**

Indicates which distance to set. One of the following values:

**ENV\_NEAR\_RANGE** - The near distance.

**ENV\_FAR\_RANGE** - The far distance.

**float f**

The distance to set.

**Prototype:**

**virtual float GetEnvRange(TimeValue t, int which,  
Interval& valid = Interval(0,0))=0;**

**Remarks:**

Implemented by the Plug-In.

Retrieves the environment range distance at the specified time and intersects the specified validity interval with the interval of the environment range parameter.

**Parameters:****TimeValue time**

The time to retrieve the environment range.

**int which**

Indicate which distance to set. One of the following values:

**ENV\_NEAR\_RANGE** - The near distance.

**ENV\_FAR\_RANGE** - The far distance.

**Interval& valid = Interval(0,0)**

The validity interval that this method will update to reflect the environment

range setting.

**Return Value:**

The environment range distance at the specified time.

**Prototype:**

**virtual void SetEnvDisplay(BOOL b, int notify=TRUE)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the environment range display flag. This indicates if the camera will display its range settings.

**Parameters:**

**BOOL b**

The flag state to set.

**int notify=TRUE**

If notify is TRUE, dependents of this message are sent the

**REFMSG\_CHANGE** message, via:

**NotifyDependents(FOREVER, PART\_OBJ,  
REFMSG\_CHANGE);**

Otherwise no notification is sent.

**Prototype:**

**virtual BOOL GetEnvDisplay()=0;**

**Remarks:**

Implemented by the Plug-In.

Retrieves the environment range display setting.

**Return Value:**

TRUE if ranges are displayed; otherwise FALSE.

**Prototype:**

**virtual void RenderApertureChanged(TimeValue t)=0;**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on all cameras when the render aperture width has changed.

**Parameters:**

**TimeValue t**

The time of the change.

**Prototype:**

**virtual void UpdateTargDistance(TimeValue t, INode \*inode);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on all target cameras when the target distance has changed. For instance, a distance shown in the user interface may be updated in this method.

**Parameters:**

**TimeValue t**

The time of the change.

**INode \*inode**

The camera node.

**Default Implementation:**

**{**

**Prototype:**

**virtual void SetIMultiPassCameraEffect(IMultiPassCameraEffect \*pIMultiPassCameraEffect);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the plug-in.

The **IMultiPassCameraEffect** should be checked to see if compatible with the camera before being assigned.

**Parameters:**

**IMultiPassCameraEffect \*pIMultiPassCameraEffect**

The IMultiPassCameraEffect to assign.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void SetMultiPassEffectEnabled(TimeValue t, BOOL  
enabled);
```

**Remarks:**

This method is available in release 4.0 and later only.  
Enables or disables the multi-pass effect.

**Parameters:**

**TimeValue t**

The time at which to enable the effect.

**BOOL enabled**

TRUE for enabled; FALSE for disabled.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL GetMultiPassEffectEnabled(TimeValue t, Interval&  
valid);
```

**Remarks:**

This method is available in release 4.0 and later only.  
Returns the enabled or disabled state of the multi-pass effect setting for the camera.

**Parameters:**

**TimeValue t**

The time at which to get the setting.

**Interval& valid**

The validity interval for the setting.

**Return Value:**

TRUE for enabled; FALSE for disabled.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual IMultiPassCameraEffect *GetIMultiPassCameraEffect();
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the current multi-pass camera effect. See [Class IMultiPassCameraEffect](#).

**Default Implementation:**

```
{ return NULL; }
```

## Class GenCamera

See Also: [Class CameraObject](#), [Class Interval](#), [Class Control](#).

```
class GenCamera : public CameraObject
```

### Description:

This class describes a generic camera object. It is used as a base class for creating plug-in cameras. Methods of this class are used to get and set properties of the camera. All methods of this class are implemented by the plug-in.

### Methods:

#### Prototype:

```
virtual GenCamera *NewCamera(int type)=0;
```

#### Remarks:

Creates a new generic camera object.

#### Parameters:

**int type**

Nonzero if the camera has a target; otherwise 0.

#### Return Value:

A pointer to a new instance of the specified light type.

#### Prototype:

```
virtual void SetConeState(int s)=0;
```

#### Remarks:

Sets if the camera cone is displayed in the viewports.

#### Parameters:

**int s**

Nonzero to display the camera cone; otherwise 0.

#### Prototype:

```
virtual int GetConeState()=0;
```

#### Remarks:

Returns TRUE if the camera cone is displayed in the viewports; otherwise

FALSE.

**Prototype:**

**virtual void SetHorzLineState(int s)=0;**

**Remarks:**

Sets if the camera has a horizon line displayed.

**Parameters:**

**int s**

Nonzero to display the horizon line; otherwise 0.

**Prototype:**

**virtual int GetHorzLineState()=0;**

**Remarks:**

Returns TRUE if the camera has a horizon line displayed; otherwise FALSE.

**Prototype:**

**virtual void Enable(int enab)=0;**

**Remarks:**

Enables or disables the camera. If enabled the camera may be displayed, hit tested, etc.

**Parameters:**

**int enab**

Nonzero to enable; zero to disable.

**Prototype:**

**virtual BOOL SetFOVControl(Control \*c)=0;**

**Remarks:**

Sets the controller for the field-of-view parameter.

**Parameters:**

**Control \*c**

Points to the controller to set.

**Return Value:**

Returns TRUE if set; otherwise FALSE.

**Prototype:**

```
virtual Control *GetFOVControl()=0;
```

**Remarks:**

Returns the controller for the field-of-view parameter.

**Prototype:**

```
virtual void SetFOVType(int ft)=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Sets the Field-Of-View type of the camera.

**Parameters:****int ft**

One of the following values:

**FOV\_W**

Width-related FOV

**FOV\_H**

Height-related FOV

**FOV\_D**

Diagonal-related FOV

**Prototype:**

```
virtual int GetFOVType()=0;
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the Field-Of-View type of the camera. One of the following values:

**FOV\_W**

Width-related FOV

**FOV\_H**

Height-related FOV

## **FOV\_D**

Diagonal-related FOV

### **Prototype:**

```
virtual int Type()=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Returns one of the following values to indicate the camera type:

**FREE\_CAMERA** (No Target)

**TARGETED\_CAMERA** (Target / Look At Controller)

**PARALLEL\_CAMERA** (Orthographic Camera)

### **Prototype:**

```
virtual void SetType(int tp)=0;
```

### **Remarks:**

This method is available in release 3.0 and later only.

Sets the type of camera.

### **Parameters:**

**int tp**

One of the following types:

**FREE\_CAMERA** (No Target)

**TARGETED\_CAMERA** (Target / Look At Controller)

**PARALLEL\_CAMERA** (Orthographic Camera)

## Class Modifier

See Also: [Class BaseObject](#), [Class ObjectState](#), [Class ModContext](#), [Class ModContextEnumProc](#), [Class Interval](#), [Class ISave](#), [Class ILoad](#), [Class Class\\_ID](#).

```
class Modifier : public BaseObject
```

### Description:

This is the class from which you may derive Object Space and Space Warp (World Space) Modifier plug-ins. This class is subclassed off of **BaseObject** so the modifier can put up a graphical representation in the viewport to use as a gizmo.

### Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Modifier Name Access](#)

[InputType, ChannelsUsed, ChannelsChanged.](#)

[Object Modification Methods](#)

[Topology Dependence](#)

[Loading and Saving Methods](#)

[Notification of Change](#)

[Modifier Stack Enable/Disable Methods](#)

[ModContext Enumeration](#)

[Validity Intervals](#)

### Methods:

#### Modifier Name Access

#### Prototype:

```
virtual TSTR GetName();
```

#### Remarks:

Implemented by the System.

Returns the name of the modifier.

**Prototype:**

**virtual void SetName(TSTR n);**

**Remarks:**

Implemented by the System.

Sets the name of the modifier to the name passed.

**Parameters:**

**TSTR n**

Specifies the name to set.

**InputType, ChannelsUsed, ChannelsChanged.****Prototype:**

**virtual Class\_ID InputType()=0;**

**Remarks:**

Implemented by the Plug-In.

This is the type of object that the modifier knows how to modify. Simple modifiers that just modify points of an object can operate on generic 'Deformable' objects. Deformable objects are any type of object that has points. A modifier could also work on a particular type of object such as a TriObject or PatchObject.

**Return Value:**

The Class\_ID of the item. You can request any Class\_ID for your input type. For example, **Class\_ID(OMNI\_LIGHT\_CLASS\_ID, 0)**. See [List of Class IDs](#).

**Prototype:**

**virtual ChannelMask ChannelsUsed()=0;**

**Remarks:**

Implemented by the Plug-In.

These are channels that the modifier needs in order to perform its modification. This should at least include the channels specified in

**ChannelsChanged()** but may include more.

Note that **ChannelsUsed()** is called many times but the channels returned

should not change on the fly.

**Return Value:**

The channels required. See [List of Channel Bits](#).

**Sample Code:**

```
{ return GEOM_CHANNEL|TOPO_CHANNEL; }
```

**Prototype:**

```
virtual ChannelMask ChannelsChanged()=0;
```

**Remarks:**

Implemented by the Plug-In.

These are the channels that the modifier actually modifies. Note that **ChannelsChanged()** is called many times but the channels returned should not change on the fly.

**Return Value:**

The channels that are changed. See [List of Channel Bits](#).

**Prototype:**

```
ChannelMask TotalChannelsUsed();
```

**Remarks:**

Returns the same value as **ChannelsUsed()** above except **GFX\_DATA\_CHANNEL** will be ORed in if the **TOPO\_CHANNEL** or the **TEXMAP\_CHANNEL** are being used.

**Prototype:**

```
ChannelMask TotalChannelsChanged();
```

**Remarks:**

Returns the same value as **ChannelsChanged()** above except **GFX\_DATA\_CHANNEL** will be ORed in if the **TOPO\_CHANNEL**, the **TEXMAP\_CHANNEL**, or the **VERTCOLOR\_CHANNEL** are being changed.

**Prototype:**

**virtual bool ChangesSelType();**

**Remarks:**

This method is available in release 4.0 and later only.

If a modifier want to make it possible to switch dynamically between changing the selection type that flows up the stack, or leaving it like it is, it can overwrite this. The default implementation indicates that it changes the selection type, if the **SUBSEL\_TYPE\_CHANNEL** is part of **ChannelsChanged()**. Note that **ChannelsChanged()** can not dynamically changed for various reasons.

**Default Implementation:**

```
{ return ChannelsChanged() & SUBSEL_TYPE_CHANNEL ? true  
: false; }
```

## Object Modification

**Prototype:**

**virtual void ModifyObject(TimeValue t, ModContext &mc,  
ObjectState\* os, INode \*node)=0;**

**Remarks:**

Implemented by the Plug-In.

This is the method that actually modifies the input object. This method is responsible for altering the object and then updating the validity interval of the object to reflect the validity of the modifier.

**Parameters:**

**TimeValue t**

The time at which the modification is being done.

**ModContext &mc**

A reference to the ModContext.

**ObjectState\* os**

The object state flowing through the pipeline. This contains a pointer to the object to modify.

**INode \*node**

The node the modifier is applied to. This parameter is always NULL for

Object Space Modifiers and non-NULL for World Space Modifiers (Space Warps). This is because a given WSM is only applied to a single node at a time whereas an OSM may be applied to several nodes. This may be used for example by particle system space warps to get the transformation matrix of the node at various times.

See Also: Advanced Topics section on [Object Modification](#).

## Validity Intervals

### Prototype:

**virtual Interval LocalValidity(TimeValue t);**

### Remarks:

Implemented by the Plug-In.

This method returns the validity interval of a modifier. It is simply the combination of the validity of all the modifier's parameters. It's used to determine when to cache in the pipeline, but is not directly responsible for determining when **ModifyObject()** is called. **ModifyObject()** is called when the pipeline needs to be evaluated either because someone sent a **REFMSG\_CHANGE** message or the validity of the object does not include the current time.

If a modifier is not animated it's OK to simply return **FOREVER** from this method. In the case where the modifier changes because a user changes a non-animated control in the user interface (for instance a check box), you can cause reevaluation by notifying your dependents of the change, i.e.:

**NotifyDependents(FOREVER, PART\_ALL,  
REFMSG\_CHANGE);**

### Parameters:

**TimeValue t**

The time to calculate the Interval.

See Also: Advanced Topics on [Intervals](#).

## Topology Dependence

### Prototype:

## **virtual BOOL DependOnTopology(ModContext &mc)**

### **Remarks:**

Implemented by the Plug-In.

Modifiers that place a dependency on topology should return TRUE for this method. An example would be a modifier that stores a selection set base on vertex indices. This modifier depends on the indices being intact for it to operate correctly.

### **Parameters:**

#### **ModContext &mc**

Reference to the ModContext.

### **Default Implementation:**

```
{ returns FALSE; }
```

### **Return Value:**

TRUE if the modifier depends on topology; otherwise FALSE.

## **Modifier Stack Access**

### **Prototype:**

```
void DisableMod()
```

### **Remarks:**

Implemented by the System.

This disables the modifier in the history browser (modifier stack).

### **Prototype:**

```
void EnableMod()
```

### **Remarks:**

Implemented by the System.

This enables the modifier in the history browser (modifier stack).

### **Prototype:**

```
int IsEnabled()
```

### **Remarks:**

Implemented by the System.

This returns the status (enabled or disabled) of the modifier in the history browser.

**Return Value:**

Nonzero if enabled; otherwise 0.

**Prototype:**

**void DisableModInRender()**

**Remarks:**

Implemented by the System.

This turns off the modifier in the renderer

**Prototype:**

**void EnableModInRender()**

**Remarks:**

Implemented by the System.

This turns on the modifier in the renderer

**Prototype:**

**int IsEnabledInRender()**

**Remarks:**

Implemented by the System.

This returns the status (enabled or disabled) of the modifier in the renderer.

**Return Value:**

Nonzero if enabled; otherwise 0.

**Prototype:**

**void DisableModInViews();**

**Remarks:**

Implemented by the System.

Disables the modifier in the viewports (it remains active in the renderer unless **DisableMod()** above is used).

**Prototype:**

```
void EnableModInViews();
```

**Remarks:**

Implemented by the System.

Enables the modifier in the viewports.

**Prototype:**

```
int IsEnabledInViews();
```

**Remarks:**

Implemented by the System.

Returns nonzero if the modifier is enabled in the viewports; otherwise zero.

**Prototype:**

```
void DisableModApps()
```

**Remarks:**

This method is used internally.

**Prototype:**

```
void EnableModApps()
```

**Remarks:**

This method is used internally.

**Notification of Input Changed****Prototype:**

```
virtual void NotifyInputChanged(Interval changeInt, PartID  
partID, RefMessage message, ModContext *mc)
```

## Remarks:

Implemented by the Plug-In.

This method is called when an item in the modifier stack before this modifier sends a **REFMSG\_CHANGE** message via **NotifyDependents()**.

Consider the following example: Assume the modifier stack contains a Sphere Object, then a Bend, then a Edit Mesh. The Edit Mesh modifier does not have a reference to the Bend or the Sphere because it does not officially depend on these items. However it does depend on them in a certain sense, because it modifies the data that these items produce. So, if they change it may affect the modifier. A modifier may build a cache based on its input object. The modifier needs a way to know when to discard this cache because the input object has changed. Whenever one of the items before this modifier in the stack sends out a **REFMSG\_CHANGE** message via **NotifyDependents()** to indicate it has changed this method is called. The modifier may respond in a way appropriate to it, for example by discarding its cache of the input object.

It is not legal, to issue a **NotifyDependent()**'s in the **NotifyInputChanged()** method of a modifier, without checking for reentrancy. Imagine, you have an instanced modifier applied to the same object in the stack. Sending a refmsg from the **NotifyInputChanged** method will casue an endles loop. Simply putting a guard in, that checks for reentrancy should get rid of the problem.

## Parameters:

### **Interval changeInt**

This is the interval from the message. It is reserved for future use - now it will always be FOREVER.

### **PartID partID**

This is the partID from the message.

### **RefMessage message**

This is the message sent.

### **ModContext \*mc**

The ModContext for the pipeline that changed. If a modifier is applied to multiple objects, then there are ModApps in each pipeline that it is applied to. These ModApps are pointing to the same modifier. Consider the following example: Say you apply a Bend modifier to a Sphere, a Cylinder and a Box object. There are three ModApps but only one Bend modifier. Then you go to

the Sphere and adjust its Radius. This will cause **NotifyInputChanged()** to be called on the Bend because the Bend's input changed. However only one of its inputs changed - only the Sphere changed and not the Cylinder or the Box. Therefore **NotifyInputChanged()** will be called once, and the ModContext passed in will be for the Sphere's changed pipeline. It is possible that all three objects could change at the same time. If an instanced float controller was assigned to the radius, width, and height - one parameter for each object - then the controller was adjusted in the function curve editor, all three items would change. In this case **NotifyInputChanged()** would be called three times on the Bend. Once for each pipeline, once with each ModContext.

## Loading and Saving Methods

### Prototype:

```
IOResult Save(ISave *isave);
```

### Remarks:

Implemented by the System.

This method handles saving the modifier name. This method should be called by the derived class BEFORE it saves any chunks. See the sample code below.

### Parameters:

```
ISave *isave
```

You may use this pointer to call methods of ISave to write data.

### Return Value:

One of the following values: **IO\_OK, IO\_ERROR.**

### Sample Code:

```
IOResult DispMod::Save(ISave *isave)  
{  
// First save the modifier name by  
// calling the base class version.  
Modifier::Save(isave);  
// Then save this modifiers data.  
isave->BeginChunk(BMIO_CHUNK);  
bi.Save(isave);  
isave->EndChunk();
```

```
return IO_OK;
}
```

**Prototype:**

**IOResult Load(ILoad \*iLoad);**

This method handles loading the modifier name. It should be called by the derived class BEFORE it loads any chunks.

**Remarks:**

Implemented by the System.

**Parameters:**

**ILoad \*iLoad**

You may use this pointer to call methods of ILoad to read data.

**Return Value:**

One of the following values: **IO\_OK, IO\_ERROR.**

**Prototype:**

**virtual IOResult LoadLocalData(ILoad \*iLoad, LocalModData \*\*pLd)**

**Remarks:**

Implemented by the Plug-In.

When a 3ds max file is being loaded, this method is called so that the modifier can load the LocalModData structure that is hung off each ModContext. If the modifier doesn't store any data in the ModContext it can ignore this method.

**Parameters:**

**ILoad \*iLoad**

You may use this pointer to call methods of ILoad to read data.

**LocalModData \*\*pLd**

A pointer to a pointer in the ModContext. The modifier must set this pointer to point at a new LocalModData derived class.

**Return Value:**

One of the following values: **IO\_OK, IO\_ERROR.**

**Prototype:**

**virtual IOResult SaveLocalData(ISave \*isave, LocalModData \*ld)**

**Remarks:**

Implemented by the Plug-In.

When a 3ds max file is being saved, this method is called so that the modifier can save the localData structure that is hung off each ModContext. If the modifier doesn't store any data in the ModContext it can ignore this method.

**Parameters:**

**ISave \*isave**

You may use this pointer to call methods of ISave to write data.

**LocalModData \*ld**

Pointer to the LocalModData for the modifier.

**Return Value:**

One of the following values: **IO\_OK**, **IO\_ERROR**.

## **ModContext Enumeration**

**Prototype:**

**void EnumModContexts(ModContextEnumProc \*proc);**

**Remarks:**

Implemented by the System.

This method will call the callback object proc method once for each application of the modifier.

**Parameters:**

**ModContextEnumProc \*proc**

The callback object whose proc method is called.

See Also: [Class ModContextEnumProc](#).

**Prototype:**

**void GetIDerivedObject(ModContext \*mc, IDerivedObject  
\*&derObj, int &modIndex);**

**Remarks:**

This method is available in release 4.0 and later only.

This method will retrieve the IDerivedObject and index of this modifier for a given modifier context.

**Parameters:**

**ModContext \*mc**

Points to the ModContext for the modifier.

**IDerivedObject \*&derObj**

A pointer to the IDerivedObject is returned here.

**int &modIndex**

The zero based index of the modifier in the derived object is returned here.

**Prototype:**

**virtual void CopyAdditionalChannels(Object \*fromObj, Object \*toObj);**

**Remarks:**

This method is available in release 4.0 and later only.

In case the modifier changes the object type (basically the os->obj pointer in ModifyObject) \*and\* changes the ExtensionChannel, it has to overwrite this method and copy only the channels that it doesn't modify/added already to the new object.

**Parameters:**

**Object \*fromObj**

**Object \*toObj**

**Default Implementation:**

**{ toObj->CopyAdditionalChannels(fromObj);}**

**Prototype:**

**virtual int NeedUseSubselButton();**

**Remarks:**

This method is no longer used.

## Class SimpleMod

See Also: [Class Modifier](#).

class SimpleMod : public Modifier

### Description:

The **SimpleMod** class supplies most of the methods needed to implement an object space modifier.

To be a 'Simple' modifier, the following assumptions are made:

The modifier only modifies the geometry channel.

The modifier uses an instance of a class derived from Deformer to do the modifying.

The modifier's gizmo is represented as a 3D box that has had the modifier applied to it.

This class maintains a pointer to a parameter block. If the client of **SimpleMod** uses a single parameter block then **SimpleMod** can manage all the methods associated with SubAnims and References for the client.

If the client of **SimpleMod** maintains several parameter blocks then the client must implement the methods **NumSubs()**, **SubAnim(i)**, **SubAnimName(i)**, **NumRefs()**, **GetReference(i)** and **SetReference(i)** and call the **SimpleMod** methods when 'i' refers to the parameters maintained by **SimpleMod**.

When clients of **SimpleMod** are cloning themselves, they should call this method on the clone to copy **SimpleMod**'s data.

```
void SimpleModClone(SimpleMod *smodSource);
```

Clients of **SimpleMod** probably want to override these. If they do they should call these from within their implementation of these methods.

```
void BeginEditParams(IObjParam *ip, ULONG flags,Animatable *prev);
```

```
void EndEditParams(IObjParam *ip, ULONG flags,Animatable *next);
```

### Data Members:

public:

```
Control *tmControl;
```

Points to the transform controller for the Gizmo.

**Control \*posControl;**

Points to the position controller for the Center.

**IParamBlock \*pblock;**

Pointer to a parameter block. Clients of SimpleMod should use the following value as the reference index of this parameter block. **#define**

**SIMPMOD\_PBLOCKREF 2**

**static IObjParam \*ip;**

Storage for the interface pointer.

**static MoveModBoxCMode \*moveMode;**

Storage for the move modifier box command mode.

**static RotateModBoxCMode \*rotMode;**

Storage for the rotate modifier box command mode.

**static UScaleModBoxCMode \*uscaleMode;**

Storage for the uniform scale modifier box command mode.

**static NUScaleModBoxCMode \*nuscaleMode;**

Storage for the non-uniform scale modifier box command mode.

**static SquashModBoxCMode \*squashMode;**

Storage for the squash modifier box command mode.

**static SimpleMod \*editMod;**

Storage for the instance of SimpleMod that is being edited in the command panel.

**Methods:**

**Prototype:**

**virtual Deformer& GetDeformer(TimeValue t,ModContext &mc,Matrix3& mat,Matrix3& invmat)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is used to retrieve the callback object that will handle the deformation.

**Parameters:**

**TimeValue t**

Specifies the time the modification is being performed.

### **ModContext &mc**

A reference to the ModContext.

### **Matrix3& mat**

A reference to a matrix that describes the space the modification is supposed to happen in. This is computed from the ModContext matrix and the controllers controlling the gizmo and center of the modifier. The plug-in developers job is simply to transform each point to be deformed by this matrix before it performs its own deformation to the point. After the modifier applies its own deformation to the point, the developer transforms the point by the inverse of this matrix (passed below).

### **Matrix3& invmat**

This is the inverse of the matrix above. See the comment above for how this is used.

### **Return Value:**

A C++ reference to the deformer callback object.

### **Prototype:**

**virtual void InvalidateUI()**

### **Remarks:**

Implemented by the Plug-In.

This is called if the user interface parameters needs to be updated because the user moved to a new time. The UI controls must display values for the current time.

### **Example:**

If the plug-in uses a parameter map for handling its UI, it may call a method of the parameter map to handle this: **pmapParam->Invalidate();**

If the plug-in does not use parameter maps, it should call the **SetValue()** method on each of its controls that display a value, for example the spinner controls. This will cause to the control to update the value displayed. The code below shows how this may be done for a spinner control. Note that ip and pblock are assumed to be initialized interface and parameter block pointers

**float newval;**

```
Interval valid=FOREVER;  
TimeValue t=ip->GetTime();  
// Get the value from the parameter block at the current time.  
pblock->GetValue( PB_ANGLE, t, newval, valid );  
// Set the value. Note that the notify argument is passed as  
FALSE.  
// This ensures no messages are sent when the value changes.  
angleSpin->SetValue( newval, FALSE );
```

**Prototype:**

```
virtual Interval GetValidity(TimeValue t)
```

**Remarks:**

Implemented by the Plug-In.

The SimpleMod class calls this method to retrieve the validity interval of the modifier. The modifier provides this interval by starting an interval at FOREVER and intersecting it with each of its parameters validity intervals.

**Parameters:**

**TimeValue t**

The time to compute the validity interval.

**Default Implementation:**

```
{return FOREVER;}
```

**Return Value:**

The validity interval of the modifier.

See Also: The Advanced Topics section on [Intervals](#).

**Prototype:**

```
virtual ParamDimension *GetParameterDim(int pbIndex)
```

**Remarks:**

Implemented by the Plug-In.

Returns the dimension of the parameter whose index is passed. See Class [ParamDimension](#).

**Parameters:****int pbIndex**

The index of the parameter.

**Default Implementation:****{return defaultDim;}****Return Value:**

A pointer to the dimension of the parameter.

**Prototype:****virtual TSTR GetParameterName(int pbIndex)****Remarks:**

Implemented by the Plug-In.

Returns the name of the parameter whose index is passed.

**Parameters:****int pbIndex**

Index of the parameter.

**Default Implementation:****{return TSTR(\_T("Parameter"))};}****Return Value:**

The name of the parameter.

**Prototype:****virtual BOOL GetModLimits(TimeValue t,float &zmin, float &zmax, int &axis)****Remarks:**

Implemented by the Plug-In.

If the effect can be limited (like the way bend/taper/twist/etc. can be limited) then it should specify the min and max limits and the axis that it is limited along. SimpleMod will then display the limits as part of the Gizmo. If it does not support limits then it should return FALSE or simply not implement this method.

**Parameters:**

**TimeValue t**

The time to get the limits.

**float &zmin**

The min limit.

**float &zmax**

The max limit.

**int &axis**

The axis that it is limited along: x=0, y=1, z=2.

**Return Value:**

TRUE if limits are supported; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

# Class Control

See Also: [Class ReferenceTarget](#), [Class IKeyControl](#), [Class IKDeriv](#), [Class IKEnumCallback](#), [Class StdControl](#), [List of Additional Controller Related Functions](#), [Class AngAxis](#), [Class Quat](#), [Class Interval](#), [Class Matrix3](#), [Class Point3](#), [Class ScaleValue](#), [Class JointParams](#), [Class SetXFormPacket](#).

```
class Control : public ReferenceTarget
```

## Description:

Control is the class from which you may derived controller objects. Controllers are the objects in 3ds max that control animation. Controllers come in different types based on the type of data they control. For example, Transform controllers control the 4x3 matrices used to define the position of nodes in the scene while float controllers control simple floating point values.

Note: Many controller plug-ins may be able to subclass from StdControl rather than Control. This simplifies the developers job. StdControl handles the processing of Out of Range Types, Ease Curves, and Multiplier Curves. See [Class StdControl](#) for more information.

Plug-In Information:

Class Defined In CONTROL.H

Super Class ID CTRL\_FLOAT\_CLASS\_ID - Used by float controllers.

CTRL\_POINT3\_CLASS\_ID - Used by Point3 controllers.

CTRL\_MATRIX3\_CLASS\_ID - Used by Matrix3 controllers.

CTRL\_POSITION\_CLASS\_ID - Used by position controllers.

CTRL\_ROTATION\_CLASS\_ID - Used by rotation controllers.

CTRL\_SCALE\_CLASS\_ID - Used by scale controllers.

CTRL\_MORPH\_CLASS\_ID - Used by morph controllers.

Standard File Name Extension DLC

Extra Include File Needed None

### **Methods:**

### **Prototype:**

```
virtual void GetValue(TimeValue t, void *val, Interval &valid,  
    GetSetMethod method=CTRL_ABSOLUTE)=0;
```

### **Remarks:**

Implemented by the Plug-In.

Retrieves the value of the controller at the specified time, and updates the validity interval passed in to reflect the interval of the controller. This method is responsible for handling Out of Range Types, Ease Curves and Multiplier Curves. See the sample code below.

### **Parameters:**

#### **TimeValue t**

Specifies the time to retrieve the value.

#### **void \*val**

This points to a variable to hold the computed value of the controller at the specified time. What the plug-in needs to do to store the value of the controller depends on the controller type. There are six controller types: **float**, **Point3**, **Position**, **Rotation**, **Scale**, and **Transform**. The way the value is stored also depends on the **GetSetMethod** parameter **method**. Below is list of the possible cases and how the value should be stored in each case.

#### **float**

If **method == CTRL\_ABSOLUTE**

**\*val** points to a float

The controller should simply store the value.

If **method == CTRL\_RELATIVE**

**\*val** points to a float

The controller should add its value to the existing floating point value.

### **Point3**

If **method == CTRL\_ABSOLUTE**

**\*val** points to a **Point3**

The controller should simply store the value.

If **method == CTRL\_RELATIVE**

**\*val** points to a **Point3**

The controller should add its value to the existing **Point3** value.

### **Position**

If **method == CTRL\_ABSOLUTE**

**\*val** points to a **Point3**

The controller should simply store the value.

If **method == CTRL\_RELATIVE**

**\*val** points to a **Matrix3**

The controller should apply its value to the matrix by pre-multiplying its position.

**Matrix3 \*mat = (Matrix3\*)val;**

**Point3 v = the computed value of the controller...**

**mat->PreTranslate(v);**

### **Rotation**

If **method == CTRL\_ABSOLUTE**

**\*val** points to a **Quat**

The controller should simply store the value.

If **method == CTRL\_RELATIVE**

**\*val** points to a **Matrix3**

The controller should apply its value to the matrix by pre-multiplying its rotation.

**Matrix3 \*mat = (Matrix3\*)val;**

**Quat q** = the computed value of the controller...

**PreRotateMatrix(\*mat,q);**

## Scale

If **method == CTRL\_ABSOLUTE**

**\*val** points to a **ScaleValue**

The controller should simply store the value.

If **method == CTRL\_RELATIVE**

**\*val** points to a **Matrix3**

The controller should apply its value to the matrix by pre-multiplying its scale.

**Matrix3 \*mat = (Matrix3\*)val;**

**ScaleValue s** = the computed value of the controller...

**ApplyScaling(\*mat,s);**

## Transform (Matrix3)

If **method == CTRL\_ABSOLUTE**

**\*val** points to a **Matrix3**

The controller should simply store the value.

**Important Note: Developers should only pass**

**CTRL\_RELATIVE when getting the value of a Matrix3 controller. This is because the controller may use the matrix as input to compute the value. Therefore it is not acceptable to use CTRL\_ABSOLUTE to get the value.**

If **method == CTRL\_RELATIVE**

**\*val** points to a **Matrix3**.

The controller should apply its value to the matrix by pre-multiplying. When **GetValue()** is called on a transform controller the method is **CTRL\_RELATIVE** and the matrix passed is usually the **parent** of the node.

**Important Note for Matrix3 Controllers:** when **SetValue()** is called **\*val** points to an instance of [Class SetXFormPacket](#). See that class for more details on how it is used.

### **Interval &valid**

The validity interval to update. The controllers validity interval should be intersected with this interval. This updates the interval to reflect the interval of the controller.

### **GetSetMethod method=CTRL\_ABSOLUTE**

One of the following values:

#### **CTRL\_RELATIVE**

Indicates the plug-in should apply the value of the controller to **\*val**. See Above.

#### **CTRL\_ABSOLUTE**

Indicates the controller should simply store its value in **\*val**. See Above.

### **Sample Code:**

The following code is from the StdControl implementation of this method. It demonstrates how the out of range and multiplier curves are handled.

```
void StdControl::GetValue(TimeValue t, void *val, Interval &valid,
GetSetMethod method)
{
    Interval range = GetTimeRange(TIMERANGE_ALL);
    Interval wvalid = FOREVER, cvalid = FOREVER;
    void *ptr = val;
    int ort;
    float m;
    TimeValue oldTime = t;

    if (method==CTRL_RELATIVE) {
        ptr = CreateTempValue();
    }

    // Grab the multiplier before the time warp.
    m = GetMultVal(t,valid);
```

```

// Apply the time warp.
t = ApplyEase(t,wvalid);

if (t<=range.Start()) {
    ort = GetORT(ORT_BEFORE);
} else {
    ort = GetORT(ORT_AFTER);
}

if (/*ort==ORT_CONSTANT*/TestAFlag(A_ORT_DISABLED) ||
    range.Empty() || range.InInterval(t)) {

    GetValueLocalTime(t,ptr,cvalid);
} else {
    switch (ort) {
    case ORT_CONSTANT:
        if (t<range.Start()) {
            GetValueLocalTime(range.Start(),ptr,cvalid,CTRL_ABSOLUTE);
            cvalid.Set(TIME_NegInfinity,range.Start());
        } else {
            GetValueLocalTime(range.End(),ptr,cvalid,CTRL_ABSOLUTE);
            cvalid.Set(range.End(),TIME_PosInfinity);
        }
        break;

    case ORT_LOOP:
    case ORT_CYCLE:
        GetValueLocalTime(CycleTime(range,t),ptr,
            cvalid,CTRL_ABSOLUTE);
        break;

    case ORT_OSCILLATE: {
        int cycles = NumCycles(range,t);
        TimeValue tp = CycleTime(range,t);
        if (cycles&1) {
            tp = range.End()-(tp-range.Start());
        }
    }
    }
}

```

```

    GetValueLocalTime(tp,ptr,cvalid,CTRL_ABSOLUTE);
    break;
}

case ORT_RELATIVE_REPEAT:
case ORT_IDENTITY:
case ORT_LINEAR:
    Extrapolate(range,t,ptr,cvalid,ort);
    break;
}
}

if (m!=1.0f) {
    MultiplyValue(ptr,m);
}
if (method==CTRL_RELATIVE) {
    ApplyValue(val,ptr);
    DeleteTempValue(ptr);
}

if (ort!=ORT_CONSTANT) {
    cvalid.Set(oldTime,oldTime);
}
valid &= cvalid;
valid &= wvalid;
// Time warps can cause this to happen.
if (valid.Empty()) valid.Set(oldTime,oldTime);
}

```

**Prototype:**

```

virtual void SetValue(TimeValue t, void *val, int commit=1,
    GetSetMethod method=CTRL_ABSOLUTE)=0;

```

**Remarks:**

Implemented by the Plug-In.

This method sets the value of the controller at the specified time. This method is responsible for handling Out of Range Types, Ease Curves and Multiplier

Curves. See the sample code below.

Note: Developers who want to create keys for a keyframe controller by calling **SetValue()** directly can do so, but the animate button should be turned on using the following code:

```
SuspendAnimate();  
AnimateOn();  
// Call SetValue() -- make sure commit=1  
ResumeAnimate();
```

#### Parameters:

##### **TimeValue t**

Specifies the time to save the value.

##### **void \*val**

Points to an instance of a data type that corresponds with the controller type. These are the same as **GetValue()** above with the following exceptions:

For rotation controllers, if the **GetSetMethod** is **CTRL\_RELATIVE**, **\*val** points to an **AngAxis**, while if it is **CTRL\_ABSOLUTE** it points to a **Quat**.

For **Matrix3** controllers **\*val** points to an instance of class **SetXFormPacket**. See [Class SetXFormPacket](#).

##### **int commit=1**

When **SetValue()** is called the controller should store its value (usually into a cache it maintains), and if this parameter is set, also 'commit' its value (usually by calling **CommitValue()**).

For example, consider a 3ds max keyframe controller: If **commit==1** and if the Animate button is on, then the cache should be updated and a key should be created. If the Animate button is off then the cache should be updated and the keys should all be offset. If **commit==0** then the cache value is set and its validity interval is set to the current time. If later **commit==1** then a key would be created from that cached value. If **SetValue()** is never called with **commit=1** then the key is never set. For instance with Inverse Kinematics, **SetValue()** is called many times over and over at the same **TimeValue** with **commit=0**. The controller doesn't create a key, it just changes its cached value. When an IK solution is finally reached, **SetValue()** is called with

**commit=1** and a key is created.

Note that calling **SetValue()** with **commit=0** and then calling **CommitValue()** should have the same effect as calling **SetValue()** with **commit=1**.

See the methods **CommitValue()** and **RestoreValue()** below.

**GetSetMethod method=CTRL\_ABSOLUTE**

One of the following values:

**CTRL\_RELATIVE**

Indicates the plug-in should add the value to the existing value **\*val** (i.e. Move/Rotate/Scale)

**CTRL\_ABSOLUTE**

Indicates the plug-in should just set the value.

**Important Note for Matrix3 Controllers:** When **SetValue()** is called this **method** parameter is ignored. The **\*val** pointer passed to **SetValue()** points to an instance of [Class SetXFormPacket](#).

See that class for more details on how it is used.

#### Sample Code:

The following code is from the StdControl implementation of this method. It demonstrates how the out of range and multiplier curves are handled.

```
void StdControl::SetValue(TimeValue t, void *val, int commit,
GetSetMethod method)
{
    Interval range = GetTimeRange(TIMERANGE_ALL);
    Interval wvalid, mvalid;
    int ort;
    float m;

    // Grab the multiplier before the time warp.
    m = GetMultVal(t,mvalid);
    if (m!=1.0f && m!=0.0f) {
        MultiplyValue(val,1.0f/m);
    }

    // Apply the time warp.
```

```

t = ApplyEase(t,wvalid);
if (range.Empty()) {
    SetValueLocalTime(t,val,commit,method);
    return;
}

if (t<=range.Start()) {
    ort = GetORT(ORT_BEFORE);
} else {
    ort = GetORT(ORT_AFTER);
}
if (TestAFlag(A_ORT_DISABLED)) ort = ORT_CONSTANT;

switch (ort) {
case ORT_LOOP:
case ORT_CYCLE:
    SetValueLocalTime(CycleTime(range,t),val,commit,method);
    break;

case ORT_OSCILLATE: {
    int cycles = NumCycles(range,t);
    if (cycles&1) {
        t = range.Duration() - CycleTime(range,t);
    } else {
        t = CycleTime(range,t);
    }
    SetValueLocalTime(t,val,commit,method);
    break;
}

// These ORTs aren't cyclic so we just set the value out of range.
case ORT_RELATIVE_REPEAT:
case ORT_CONSTANT:
case ORT_IDENTITY:
case ORT_LINEAR:
    SetValueLocalTime(t,val,commit,method);
    break;
}

```

```
}  
}
```

**Prototype:**

```
virtual bool GetLocalTMComponents(TimeValue t,  
TMComponentsArg& cmpts, Matrix3Indirect& parentMatrix);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the PRS components of the local matrix. In general, controller cannot decide on the local matrix without knowing the parent matrix. However, many controllers, such as default controllers, are well defined without the parent matrix. In these cases, it is more efficient to compute the local components directly without going through the world matrix.

Therefore, the argument `parentMatrix` is a reference to `Matrix3Indirect`. This would allow clients to supply a "delayed parent matrix," which will be computed only if it is necessary. It returns true for Matrix3, Position, Rotation, or Scale controllers, and return false otherwise.

The PRS components will be put in argument `cmpts` in the respective fields with corresponding validity intervals. NULL pointer, of `TMComponentsArg::position` for example, indicates that the client is not concerned about the component. When it is not NULL, the corresponding pointer to the validity interval MUST NOT be NULL. When it is not NULL, `TMComponentsArg::rotation` is a float[4]. `rotRep` tells what the numbers mean.

Position, Rotation, or Scale, controllers will put results at the respective component when the corresponding pointer is not NULL.

Upon entry, `parentMatrix` should represent the parent matrix up to the first requested components. For Matrix3 controllers, for example, if `cmpts.position==NULL && cmpts.rotation!=NULL`, then `parentMatrix` should be matrix that includes the parent node matrix plus the position of this node.

Upon return, this matrix may be modified.

**Parameters:****TimeValue t**

The time at which to get the local TM components.

## TMComponentsArg& cmpts

See [Structure TMComponentsArgs](#).

## Matrix3Indirect& parentMatrix

The parent matrix. Note the definition:  $\text{LocalMatrix} = \text{WorldMatrix} * \text{ParentWorldMatrix}^{-1}$

## Post Clone Notification

### Prototype:

**virtual void PostCloneNode();**

### Remarks:

This method is available in release 2.0 and later only.

This method is called on a transform controller after a node is cloned and the clone process has finished. This allows the controller to do any work it needs to after the clone is complete.

### Default Implementation:

```
{}
```

## Undo / Redo methods

Controllers, like objects and modifiers, need to be able to undo and redo themselves. Whenever a controller is about to modify its data, it checks the state of the global Hold object to see if it is holding. If so it must register a RestoreObject with the hold (see the Advanced Topics section [Undo/Redo](#)). Controllers also support another type of undo and redo through two methods: **CommitValue()** and **RestoreValue()**.

The purpose of this 'inner' hold and restore buffer is not to hold and restore the entire state of the controller, but to hold and restore the value of the controller at a single instant in time. When **SetValue()** is called on a controller with the **commit** parameter equal to zero, the controller records the new value, but does not necessarily modify any data. For example, a keyframe controller doesn't actually generate a new key -- it just updates a cache it maintains. Then, if the controller is asked to evaluate itself at the exact same **TimeValue** for which the controller was just set, it can just return the cached value.

The **RestoreValue()** method will simply throw out the temporary value

whereas the **CommitValue()** method will cause the value to be actually committed (a key generated in the case of a keyframe controller).

The purpose of this inner hold and restore is for iterative procedures that need to set values many times at a single **TimeValue** and don't want to incur the overhead of things like recalculating the tangents at adjacent keys. Some examples of these types of procedures are inverse kinematics and collision detection.

**Prototype:**

**virtual void CommitValue(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

This method, along with **RestoreValue()**, comprise an "inner" hold and restore mechanism (see above). When the controller's **SetValue()** method is called, if the **commit** parameter is nonzero, then the controller should save the value of the controller at the current time into its cache and also 'commit' the value. For example, this stores a key in the case of a keyframe controller. If the set value was not committed then **RestoreValue()** may be called to restore the previous value.

**Parameters:**

**TimeValue t**

Specifies the time to save the value.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void RestoreValue(TimeValue t)**

**Remarks:**

Implemented by the Plug-In.

This method is the other half of the "inner" hold and restore mechanism. This method is called to restore a previously saved value. This method restores the current cache value to the value that was set before **SetValue()** was last called. The way the standard 3ds max controllers handle this is as follows: When **SetValue()** is called a temporary hold mechanism (**TempStore** define

in **CONTROL.H**) is used to hold the current value. Then the new value is set. If **RestoreValue()** is later called then it restores the current value from the temporary storage. Note that in addition to restoring from the **TempStore**, another way a controller may restore the current value is to re-interpolate the keys.

**Parameters:**

**TimeValue t**

Specifies the time to restore the value.

**Default Implementation:**

**{**

## **New Controller Assignment**

**Prototype:**

**virtual void Copy(Control \*from)=0;**

**Remarks:**

Implemented by the Plug-In.

When a controller is assigned to a track in the track view, the new controller is plugged into the parameter and this method is called on the new controller. A pointer to the old controller is passed in to this method. The new controller can attempt to copy any data that it can from the old controller. At the very least it should initialize itself to the value of the old controller at frame 0.

**Parameters:**

**Control \*from**

A pointer to the previous controller.

**Prototype:**

**virtual BOOL IsReplaceable()**

**Remarks:**

Implemented by the Plug-In.

This method determines if another controller can replace this one. A controller can return FALSE from this method to not allow the user to assign a new controller in its place. This will also prevent the controller from being replaced

by a paste controller operation.

**Return Value:**

TRUE to allow the controller to be replaced; otherwise FALSE.

**Default Implementation:**

```
{return TRUE;}
```

## **Lookat Controller methods**

The following two methods work with lookat controllers. If the controller is not a lookat controller, these methods should be ignored.

**Prototype:**

```
virtual INode* GetTarget()
```

**Remarks:**

Implemented by the Plug-In.

This method retrieves a lookat controller's target.

**Return Value:**

The lookat controllers target node.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual RefResult SetTarget(INode *targ)
```

**Remarks:**

Implemented by the Plug-In.

This method stores a lookat controller's target.

**Parameters:**

**INode \*targ**

The target node to store.

**Return Value:**

One of the following values:

**REF\_SUCCEED**

Indicates the target was set.

## **REF\_FAIL**

Indicates the target was not set.

### **Default Implementation:**

```
{return REF_SUCCEED;}
```

## **Sub-Controllers**

### **Prototype:**

```
virtual Control *GetPositionController()
```

### **Remarks:**

Implemented by the Plug-In.

Implemented by transform controllers that have a position controller that can be edited in the motion branch. This method returns a pointer to the position controller of the transform controller.

### **Default Implementation:**

```
{return NULL;}
```

### **Prototype:**

```
virtual Control *GetRotationController()
```

### **Remarks:**

Implemented by the Plug-In.

Implemented by transform controllers that have a rotation controller that can be edited in the motion branch. This method returns a pointer to the rotation controller of the transform controller.

### **Return Value:**

### **Default Implementation:**

```
{return NULL;}
```

### **Prototype:**

```
virtual Control *GetScaleController()
```

### **Remarks:**

Implemented by the Plug-In.

Implemented by transform controllers that have a scale controller that can be edited in the motion branch. This method returns the a pointer to the scale controller of the transform controller.

**Return Value:**

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual Control *GetRollController()
```

**Remarks:**

Implemented by the Plug-In.

Implemented by lookat controllers that have a float valued roll controller so that the roll can be edited via the transform type-in. This method returns a pointer to the roll controller of the lookat controller.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL SetPositionController(Control *c);
```

**Remarks:**

Implemented by the Plug-In.

This method assigns a new position controller. Plug-Ins don't need to be concerned with freeing the previous controller if this method is called. Any previous controller assigned will be deleted by 3ds max if it is not used elsewhere in the scene.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL SetRotationController(Control *c);
```

**Remarks:**

Implemented by the Plug-In.

This method assigns a new rotation controller. Plug-Ins don't need to be concerned with freeing the previous controller if this method is called. Any previous controller assigned will be deleted by 3ds max if it is not used elsewhere in the scene.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL SetScaleController(Control *c);
```

**Remarks:**

Implemented by the Plug-In.

This method assigns a new scale controller. Plug-Ins don't need to be concerned with freeing the previous controller if this method is called. Any previous controller assigned will be deleted by 3ds max if it is not used elsewhere in the scene.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL SetRollController(Control *c);
```

**Remarks:**

Implemented by the Plug-In.

This method assigns a new roll controller. Plug-Ins don't need to be concerned with freeing the previous controller if this method is called. Any previous controller assigned will be deleted by 3ds max if it is not used elsewhere in the scene.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual Control *GetXController();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the 'X' sub-controller of this controller. If a controller has an 'X', 'Y', or 'Z' controller, it can implement this set of methods so that its sub-controllers can respect track view filters. Examples of controllers that have XYZ sub-controllers are the Euler angle controller or the Position XYZ controller.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual Control *GetYController();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the 'Y' sub-controller of this controller. If a controller has an 'X', 'Y', or 'Z' controller, it can implement this set of methods so that its sub-controllers can respect track view filters. Examples of controllers that have XYZ sub-controllers are the Euler angle controller or the Position XYZ controller.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual Control *GetZController();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a pointer to the 'Z' sub-controller of this controller. If a controller has an 'X', 'Y', or 'Z' controller, it can implement this set of methods so that its sub-controllers can respect track view filters. Examples of controllers that have XYZ sub-controllers are the Euler angle controller or the Position XYZ controller.

**Default Implementation:**

```
{return NULL;}
```

## Transform Controller methods

### Prototype:

**virtual BOOL ChangeParents(TimeValue t,const Matrix3& oldP,  
const Matrix3& newP,const Matrix3& tm)**

### Remarks:

Implemented by the Plug-In.

This method is called on transform, position, rotation, and scale controllers when their input matrix is about to change. This happens when the user links an object (either from one object to another or when the user links an object for the first time). Because a controller's transformation is relative to its parent, when the user changes parents, the transform controller will need to change itself. If a plug-in returns FALSE the node will calculate a change and call **SetValue()** to make the necessary adjustments at the specific time passed.

Consider the following example of a position controller:

If a node in the scene that is NOT animated, is linked to another node, this method would be called. If the method returned FALSE then the node would calculate a change and call **SetValue()** to make the adjustment and this would be okay. If however the node was animated there would be a problem. Say for example that an unlinked node was bouncing up and down along the world Z axis. If this node is then linked to a node that was rotated such that its Z axis was pointed in the direction of the world X axis (so the object is flipped over on its side) the linked node (whose animation keys are stored relative to its previous parent (the world)) would then begin to bounce up and down along the world X axis instead. This is because it is still moving along its parent's Z axis, but its parent's Z axis is really the world X axis. Thus the object needs to be counter-rotated to compensate. Additionally, all the animation keys for the object also need to be counter-rotated. A position keyframe controller would need to implement this method to handle the correction of the object and its keyframes. See the sample code below.

### Parameters:

#### **TimeValue t**

The time of the change.

#### **const Matrix3& oldP**

The old parent matrix.

**const Matrix3& newP**

The new parent matrix.

**const Matrix3& tm**

The nodes current world transformation.

**Return Value:**

If FALSE the node will call **SetValue()** to make the necessary adjustments.

**Default Implementation:**

```
{return FALSE;}
```

**Sample Code:**

This is the code used inside 3ds max' position controller. It takes the difference between the two parents and transforms the position track by that amount. It computes the relative transformation which is the old parent times the inverse of the new parent.

A plug-in could provide an implementation for this method using a similar concept.

**INTERP\_CONT\_TEMPLATE**

**BOOL**

```
InterpControl<INTERP_CONT_PARAMS>::ChangeParents(  
    TimeValue t,  
    const Matrix3& oldP,const Matrix3& newP,const Matrix3& tm)  
{  
    if (SuperClassID()==CTRL_POSITION_CLASS_ID) {  
        HoldTrack();  
        // Position controllers need their path counter rotated to  
        // account for the new parent.  
        Matrix3 rel = oldP * Inverse(newP);  
        // Modify the controllers current value (the controllers cache)  
        *((Point3*)&curval) = *((Point3*)&curval) * rel;  
        // Then modify the keys...  
        for (int i=0; i<keys.Count(); i++) {  
            // All this casting keeps the compiler happy  
            // for non-Point3 versions of this template.  
            *((Point3*)&keys[i].val) =
```

```
        *((Point3*)&keys[i].val) * rel;
    }
    keys.KeysChanged(FALSE);
    ivalid.SetEmpty();
    return TRUE;
} else {
    return FALSE;
}
}
```

**Prototype:**

```
virtual RefResult PinNodeChanged(RefMessage message,Interval
changeInt, PartID &partID);
```

**Remarks:**

This method is available in release 2.0 and later only.

If a node is pinned to another node, and the node gets a **NotifyRefChanged()** message that its pinned node has changed, then this method is called on the transform controller of the node. Otherwise the controller wouldn't get notified since the controller doesn't have a reference to the pin node (but the node does). Most controllers don't really care, but the IK controller does.

**Parameters:**

**RefMessage message**

The message that was sent.

**Interval changeInt**

This is the interval of time over which the message is active. Currently, all controllers will receive **FOREVER** for this interval.

**PartID &partID**

This contains information specific to the message passed in. Some messages don't use the **partID** at all. See the section [List of Reference Messages](#) for more information about the meaning of the **partID** for some common messages.

**Return Value:**

The return value from this method is of type **RefResult**. This is usually **REF\_SUCCEED** indicating the message was processed. Sometimes, the return value may be **REF\_STOP**. This return value is used to stop the message from being propagated to the dependents of the item.

**Default Implementation:**

```
{return REF_SUCCEED;}
```

**Prototype:**

```
virtual void NodeIKParamsChanged();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on a transform controller when one of the node level IK parameters has been changed.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL InheritsParentTransform()
```

**Remarks:**

Implemented by the Plug-In.

This method is only implemented by transform controllers. Transform controllers that do not inherit their parent's transform should override this method.

When a transform controller is evaluated, the parent transform is passed in to the controller and the controller typically applies its value to the parent transform. However, some controllers (for example Biped) may choose to control the TM in an absolute manner and therefore ignore the incoming parent's TM. The system needs to know about this because normally if an object and its parent are selected and the user attempts to move them only the parent transform is modified because it is assumed that the child will inherit its parents TM.

Note: This method may still return TRUE even if all the bits returned from **GetInheritanceFlags()** are SET to indicate that nothing is inherited from

the parent. This is simply because these methods don't have the same level of 'granularity'. This method deals with the overall inheritance of the parent's transform whereas the inheritance flags relate to individual parts.

**Return Value:**

TRUE if the controller inherits its parents TM; otherwise FALSE. Returning FALSE will cause **SetValue()** to be called even in the case when the parent is also being transformed.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

```
virtual DWORD GetInheritanceFlags();
```

**Remarks:**

Implemented by the Plug-In.

This method should be implemented by TM controllers that support filtering out inheritance. It returns the state of the transform inheritance flags. These are the values that show up in the Hierarchy branch, under the Link Info section, in the Inheritance rollup.

**Return Value:**

One or more of the following values:

Note: Each bit is used to represent a single inheritance. If the bit is **CLEAR (OFF)** it means inherit (checked in the 3ds max UI). If the bit is **SET** it means **DON'T** inherit (unchecked in the 3ds max UI).

- INHERIT\_POS\_X**
- INHERIT\_POS\_Y**
- INHERIT\_POS\_Z**
- INHERIT\_ROT\_X**
- INHERIT\_ROT\_Y**
- INHERIT\_ROT\_Z**
- INHERIT\_SCL\_X**
- INHERIT\_SCL\_Y**
- INHERIT\_SCL\_Z**
- INHERIT\_ALL**

**Default Implementation:**

```
{return INHERIT_ALL;}
```

**Prototype:**

```
virtual BOOL SetInheritanceFlags(DWORD f, BOOL keepPos);
```

**Remarks:**

Implemented by the Plug-In.

This method should be implemented by TM controllers that support filtering out inheritance.

Note: Each bit is used to represent a single inheritance. This method expects the bits of the flags passed to be **CLEAR (OFF)** to mean DON'T inherit (unchecked in the 3ds max UI). If they are **SET** it means inherit (checked in the 3ds max UI).

**Parameters:****DWORD f**

The inheritance flags. One or more of the following values:

```
INHERIT_POS_X  
INHERIT_POS_Y  
INHERIT_POS_Z  
INHERIT_ROT_X  
INHERIT_ROT_Y  
INHERIT_ROT_Z  
INHERIT_SCL_X  
INHERIT_SCL_Y  
INHERIT_SCL_Z  
INHERIT_ALL
```

**BOOL keepPos**

If TRUE the position of the node should remain the same; otherwise the node may move.

**Return Value:**

Return TRUE if TM controller supports inheritance; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

## **IsLeaf / IsKeyable / IsColor**

### **Prototype:**

**virtual BOOL IsLeaf()**

### **Remarks:**

Implemented by the Plug-In.

Indicates whether the controller is a leaf controller. If a controller is a leaf controller, then it **MUST NOT BY DEFINITION** have any sub-controllers or references. The controller should return **TRUE** if it has no sub-controllers. For example, a PRS controller is not a leaf controller (because it has sub-controllers for Position, Rotation and Scale), but a simple keyframed float controller is a leaf controller.

### **Return Value:**

**TRUE** if the controller is a leaf controller; **FALSE** otherwise.

### **Default Implementation:**

```
{return TRUE;}
```

### **Prototype:**

**virtual int IsKeyable()**

### **Remarks:**

Implemented by the Plug-In.

Indicates if the controller is a keyframe controller. This means the controller stores keys at certain frames and interpolates between keys at other times.

### **Return Value:**

Nonzero if the controller is a keyframe controller; zero otherwise.

### **Default Implementation:**

```
{return 1;}
```

### **Prototype:**

**virtual BOOL IsColorController()**

### **Remarks:**

Implemented by the Plug-In.

Implemented by any Point3 controller that wishes to indicate that it is intended to control floating point RGB color values. Returns TRUE to indicate that it controls float color values; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Ease / Multiplier Curve and ORT methods**

The following methods involve ease and multiplier curves. See the sample code after the methods **GetValue()** and **SetValue()** to see how these methods are used.

**Prototype:**

```
virtual BOOL CanApplyEaseMultCurves()
```

**Remarks:**

Implemented by the Plug-In.

This method determines if a controller may have ease or multiplier curves applied to it. This method defaults to returning TRUE, but can be implemented to return FALSE by a controller that does not wish to let ease or multiplier curves be applied to it.

**Return Value:**

TRUE to allow the application of ease and multiplier curves; otherwise FALSE.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
TimeValue ApplyEase(TimeValue t,Interval &valid);
```

**Remarks:**

Implemented by the System.

The controller calls this method to pipe the TimeValue passed through the ease curve to get the modified TimeValue.

**Parameters:**

**TimeValue t**

The time to have modified by the ease curve.

**Interval &valid**

The validity interval of the TimeValue returned.

**Return Value:**

The modified TimeValue.

**Prototype:**

**void AppendEaseCurve(Control \*cont);**

**Remarks:**

Implemented by the System.

Adds an ease curve to the specified controller.

**Parameters:**

**Control \*cont**

The controller that the ease curve will be applied to.

**Prototype:**

**int NumEaseCurves();**

**Remarks:**

Implemented by the System.

Returns the number of ease curves applied to the controller.

**Prototype:**

**void DeleteEaseCurve(int i);**

**Remarks:**

Implemented by the System.

Deletes the 'i-th' ease curve from the controller.

**Parameters:**

**int i**

The index of the ease curve to delete.

**Prototype:**

**float GetMultVal(TimeValue t,Interval &valid);**

**Remarks:**

Implemented by the System.

Retrieves a floating point value that is the product of all the multiplier curves at the specified time.

**Parameters:**

**TimeValue t**

The time to retrieve the

**Interval &valid**

The validity interval of the value.

**Return Value:**

The product of all the multiplier curves applied to the controller.

**Prototype:**

**void AppendMultCurve(Control \*cont);**

**Remarks:**

Implemented by the System.

Adds a multiplier curve to the specified controller.

**Parameters:**

**Control \*cont**

The controller to have the multiplier curve added.

**Prototype:**

**int NumMultCurves();**

**Remarks:**

Implemented by the System.

Returns the number of multiplier curves assigned to the controller.

**Prototype:**

**void DeleteMultCurve(int i);**

**Remarks:**

Implemented by the System.

Deletes the 'i-th' multiplier curve from this controller.

**Parameters:**

**int i**

The index of the curve to delete.

**When a user brings up the track view and sets the out of range types for the controller the following two methods are called.**

**Prototype:**

**virtual int GetORT(int type)**

**Remarks:**

Implemented by the System.

Returns the specified Out of Range Type used by the controller. The system handles this method but the controller needs to process the ORT in its implementation of **GetValue()** and **SetValue()**.

**Parameters:**

**int type**

One of the following values:

**ORT\_BEFORE** - leading up to the pattern

**ORT\_AFTER** - beyond the key pattern

**Return Value:**

One of the following values:

See [List of Out of Range Types](#).

**Prototype:**

**virtual void SetORT(int ort,int type);**

**Remarks:**

Implemented by the System.

Sets the specified Out of Range Type to be used by the controller. The system handles this method but the controller needs to process the ORT in its implementation of **GetValue()** and **SetValue()**.

**Parameters:**

**int ort**

See [List of Out of Range Types](#).

**int type**

One of the following values:

**ORT\_BEFORE** - leading up to the pattern

**ORT\_AFTER** - beyond the key pattern

**Prototype:**

**virtual void EnableORTs(BOOL enable);**

**Remarks:**

Implemented by the System.

Sets the enabled/disabled state for Out of Range Types. If disabled, this temporarily causes the Out of Range Types to behave as if set to constant. This can be used if you want to modify a controller but don't want ORT mapping for ORT\_LOOP, ORT\_CYCLE, or ORT\_OSCILLATE.

**Parameters:**

**BOOL enable**

TRUE to enable ORTs; FALSE to disable.

**The methods below are used with Inverse Kinematics. The following is an overview of the control flow of the system calling these IK methods on the controller during IK calculations:**

First the system calls **EnumIKParams()** once to get the number of IK parameters (degrees of freedom) from the plug-in. This lets the system know how many parameters the controller has. This happens only once when the entire chain is set up. For example during interactive IK, when the user presses the mouse button down the chain is set up. In applied IK when the user presses the Apply IK button the chain is set up.

Next the IK task is defined. For example, if the user is doing interactive IK they press the mouse button down and the IK chain is set up. Next they move the mouse a few pixels. This results in a delta for the end effector. This defines the task for the end effector. The end effector wants to move some delta or rotate some amount. This has defined a task to be solved.

In order to solve the task the system must iterate towards a solution.

To do this it first needs to compute the derivatives of all the parameters. The system calls **CompDerivs()** on the controller. The controller computes the derivative and tells the system by calling methods on the **IKDeriv** argument passed to the method. It provides its derivative for each of the parameters.

Next the system uses this derivative information to formulate a change in the parameter that will get closer to the solution. The system then computes an amount to change the parameter and then calls **IncIKParams()**. The delta passed to this method is the amount of change it wants in the parameter. The controller then applies this change (perhaps not all of it due to constraints it might have) and returns the amount that was applied.

This has completed a single iteration. All the parameters have been adjusted a bit and hopefully we have move closer to a solution. At this point the system calls **CompDerivs()** again because just moving the parameters a small amount may have actually changed the derivative. The cycle begins again.

When the IK solver has reached its solution the IK task is finished. Below are the methods that must be implemented to participate in this process.

**Prototype:**

**virtual void EnumIKParams(IKEnumCallback &callback)**

**Remarks:**

Implemented by the Plug-In.

This tells the system how many parameters the controller has. A controller can have as many IK parameters as it wants. An IK parameter corresponds to a degree of freedom in IK. The parameter is a floating point scalar value. For example a position controller has three degrees of freedom (X, Y, Z) and thus three parameters that IK can vary in its solution. The path controller has only a single parameter (degree of freedom) - the position along the path. The 3ds max user may set the number of degrees of freedom. For example, a user can specify that a rotation controller cannot rotate about one or more axes. These are then no longer degrees of freedom or IK parameters.

This method is called by the system so the plug-in can specify how many IK parameters it has. It does this by calling the provided callback object **proc()** method once for each parameter it has. It passes a pointer to itself and the index of the IK parameter. For example a position controller with three degrees of freedom (and thus three IK parameters) would call the **callback.proc()** three time passing an index of 0, then 1, then 2. See the sample code below.

**Parameters:**

**IKEnumCallback &callback**

This callback is provided by the system and should be called by the plug-in once for each IK parameter the plug-in has. See [Class IKEnumCallback](#).

**Default Implementation:**

```
{
```

**Sample Code:**

```
void QuatEnumIKParams(Control *cont,IKEnumCallback
&callback)
{
    JointParams *jp = (JointParams*)cont-
>GetProperty(PROPID_JOINTPARAMS);
    for (int i=0; i<3; i++) {
        if (!jp || jp->Active(i)) {
            callback.proc(cont,i);
        }
    }
}
```

**Prototype:**

```
virtual BOOL CompDeriv(TimeValue t,Matrix3& ptm,
    IKDeriv& derivs,DWORD flags)
```

**Remarks:**

Implemented by the Plug-In.

This method is used to determine what effect a change in the parameter has on the end effector. This is the derivative of the end effector with respect to the parameter. What the derivative means in this case is what happens to the end effector if the parameter is changed by some small delta.

The plug-in provides the derivatives to the system calling **derivs.DP()** and **derivs.DR()**. It should call **derivs.DP()** and **derivs.DR()** in the same order as the **callback.proc()** was called in the **NumIKParams()** method implementation.

When the controller computes the derivative it should apply itself to the parent matrix. For example a position controller would compute its derivative based on the parent and the position of the end effector and then apply itself to the

parent matrix. If it does apply itself to the parent it should return TRUE. If it does not apply itself it should return FALSE.

**Parameters:**

**TimeValue t**

Specifies the time to compute the derivative.

**Matrix3& ptm**

The parents transformation.

**IKDeriv& derivs**

This class provides methods the plug-in calls to set the derivatives. See [Class IKDeriv](#).

**DWORD flags**

One of the following values:

**POSITION\_DERIV**

Indicates that **derivs.DP()** should be called.

**ROTATION\_DERIV**

Indicates that **derivs.DR()** should be called.

**Return Value:**

If a controller isn't participating in IK then it should return FALSE and the client (usually PRS) will apply the controller's value to the parent TM.

**Default Implementation:**

```
{return FALSE;}
```

**Sample Code:**

The following sample code shows how the quaternion controller has implemented this method. Note that the method loops based on the number of end effectors, and calls **derivs.NextDOF()** after each iteration.

```
BOOL QuatCompDeriv(Control *cont,TimeValue t,Matrix3& ptm,
```

```
IKDeriv& derivs,DWORD flags)
```

```
{
```

```
JointParams *jp = (JointParams*)cont-
```

```
>GetProperty(PROPID_JOINTPARAMS);
```

```
Quat q;
```

```
Interval valid;
```

```

for (int i=0; i<3; i++) {
  if (!jp || jp->Active(i)) {
    for (int j=0; j<derivs.NumEndEffectors(); j++) {
      Point3 r = derivs.EndEffectorPos(j) - ptm.GetRow(3);
      if (flags&POSITION_DERIV) {
        derivs.DP(CrossProd(ptm.GetRow(i),r),j);
      }
      if (flags&ROTATION_DERIV) {
        derivs.DR(ptm.GetRow(i),j);
      }
    }
    derivs.NextDOF();
  }
}
return FALSE;
}

```

**Prototype:**

**virtual float IncIKParam(TimeValue t,int index,float delta);**

**Remarks:**

Implemented by the Plug-In.

When the system has computed a change in the parameter it will call this method. The controller should increment the specified parameter by the specified delta. The controller can increment the parameter less than this delta if it needs to. This could be for several reasons:

- 1 Its parameter may be constrained to lie within a specific interval. It would not want to add a delta that took the parameter outside of this interval.
- 2 It was asked to calculate a constant partial derivative for a linkage that could be nonlinear. Therefore the derivative may have only been an instantaneous approximation. Due to the locality of the IK solution, the controller might not want to allow a delta that was too large.

After the controller has applied the delta, it needs to indicate to the system how much of the delta was used.

**Parameters:**

**TimeValue t**

The time of the increment.

**int index**

Specifies the IK parameter to increment.

**float delta**

The delta to apply to the parameter. The controller can increment the parameter less than this delta if it needs to in order to accommodate a limit it has. This methods returns the amount that was actually incremented.

**Return Value:**

The amount the parameter was actually incremented. This allows the IK solver to know the value was not incremented the full amount.

**Default Implementation:**

```
{return 0.0f;}
```

**Sample Code:**

```
float QuatIncIKParam(Control *cont,TimeValue t,int index,float
delta)
{
    JointParams *jp = (JointParams*)cont-
>GetProperty(PROPID_JOINTPARAMS);
    if ((float)fabs(delta)>MAX_IKROT) delta = MAX_IKROT *
SGN(delta);
    if (jp) {
        float v=0.0f;
        if (jp->Limited(index)) {
            Quat q;
            Interval valid;
            cont->GetValue(t,&q,valid,CTRL_ABSOLUTE);
            v = GetRotation(q,index);
        }
        delta = jp->ConstrainInc(index,v,delta);
    }
    Point3 a(0,0,0);
    a[index] = 1.0f;
    AngAxis aa(a,-delta);
```

```

cont->SetValue(t,&aa,FALSE,CTRL_RELATIVE);
return delta;
}
static float GetRotation(Quat& q,int axis)
{
Matrix3 tm;
q.MakeMatrix(tm);
MRow* t = tm.GetAddr();
int n = (axis+1)%3, nn = (axis+2)%3;
if (fabs(t[n][axis]) < fabs(t[nn][axis])) {
return (float)atan2(t[n][nn],t[n][n]);
} else {
return -(float)atan2(t[nn][n],t[nn][nn]);
}
}
}

```

**Prototype:**

**virtual void ClearIKParam(Interval iv,int index)**

**Remarks:**

Implemented by the Plug-In.

This method is called to have the controller delete its keys. If the user has the 'Clear Keys' check box checked when they press the 'Apply IK' button, this method is called to have the controller deletes keys in the given interval for the specified degree of freedom.

**Parameters:**

**Interval iv**

The interval over which the keys should be deleted.

**int index**

Specified the degree of freedom (parameter) that the keys should be deleted for.

**Default Implementation:**

**{return;}**

**Prototype:**

**virtual void InitIKJoints(InitJointData \*posData,InitJointData \*rotData)**

**Remarks:**

Implemented by the Plug-In.

This is an optional method that can be implemented by controllers that support IK to initialize their joint parameters based on data loaded from 3D Studio R4/DOS files.

**Parameters:**

**InitJointData \*posData**

The position data from the 3DS file. See [Class InitJointData](#).

**InitJointData \*rotData**

The rotation data from the 3DS file.

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual void InitIKJoints2(InitJointData2 \*posData, InitJointData2 \*rotData);**

**Remarks:**

Implemented by the Plug-In.

This method is available in release 4.0 and later only.

This is an optional method that can be implemented by controllers that support IK to initialize their joint parameters based on data loaded from 3D Studio R4/DOS files.

**Parameters:**

**InitJointData2 \*posData**

The position data from the 3DS file. See [Class InitJointData2](#).

**InitJointData2 \*rotData**

The rotation data from the 3DS file.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL GetIKJoints(InitJointData *posData,InitJointData *rotData);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method retrieves the IK joint parameter data from the UI.

**Parameters:**

**InitJointData \*posData**

Points to the object to hold the position data. See [Class InitJointData](#).

**InitJointData \*rotData**

Points to the object to hold the rotation data.

**Return Value:**

TRUE if the data was retrieved; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual BOOL GetIKJoints2(InitJointData2 *posData, InitJointData2 *rotData);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method retrieves the IK joint parameter data from the UI.

**Parameters:**

**InitJointData2 \*posData**

Points to the object to hold the position data. See [Class InitJointData2](#).

**InitJointData2 \*rotData**

Points to the object to hold the rotation data.

**Return Value:**

TRUE if the data was retrieved; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

**virtual BOOL GetDOFParams(TimeValue t, Matrix3 &ptm,  
DOFParams &dofs, BOOL nodeSel);**

**Remarks:**

This method is available in release 2.0 and later only.

The new IK system has some axes gizmos which show the degrees of freedom, etc. This method is called by the system

**Parameters:**

**TimeValue t**

The current time.

**Matrix3 &ptm**

The parent matrix.

**DOFParams &dofs**

This is the structure to be filled in. See [Class DOFParams](#).

**BOOL nodeSel**

TRUE if the node is currently selected; otherwise FALSE.

**Return Value:**

TRUE if the method is implemented; FALSE otherwise.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

**virtual BOOL CreateLockKey(TimeValue t, int which);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to create a locking key. This is a key that looks back to the previous key and creates a new key at the specified time which matches the previous key in value. It also adjusts the parameters for the key such that the value stays constant from the previous key to this key. For instance, the TCB controller will set the previous and new continuity to 0. The Bezier controller sets the out tangent type of the previous key to linear and the in tangent type of the new key to linear.

**Parameters:****TimeValue t**

The time to create the key.

**int which**

Specifies which type of key to create: **0** for position, **1** for rotation.

**Return Value:**

TRUE if the method is implemented; FALSE otherwise.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void MirrorIKConstraints(int axis, int which, BOOL  
pasteMirror=FALSE);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to mirror the specified IK constraints about the specified axis. When IK constraints are mirrored they need to be updated to reflect the new orientation. For instance, if you set the constraints for a left arm to bend only +90 degrees along one axis and then copied these to a right arm the joint would bend backwards. What you need to do is provides the appropriate compensation so the orientation is kept proper.

**Parameters:****int axis**

Specifies the axis of reflection: **0** for X, **1** for Y, **2** for Z.

**int which**

Specifies which type of constraints are being mirrored: **0** for position, **1** for rotation.

**BOOL pasteMirror=FALSE**

TRUE if the mirror is being done as part of a paste operation; otherwise FALSE (for example if the mirror was being done with the mirror tool).

**Return Value:**

TRUE if the method is implemented; FALSE otherwise.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL TerminateIK();
```

**Remarks:**

This method is available in release 2.0 and later only.

User can specify a node as a terminator. This method gives the associated controller the chance to specify that it's terminated.

**Return Value:**

TRUE if the method is implemented; FALSE otherwise.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void NodeIKParamsChanged();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on a transform controller when one of the node level IK parameters has been changed

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void TMInvalidated();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called in a transform controller when a node invalidates its TM cache

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL OKToBindToNode(INode *node);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method lets a TM controller determine if it's OK to IK bind to a particular node.

**Parameters:**

```
INode *node
```

Points to the node to check.

**Return Value:**

TRUE if it's okay to bind; FALSE if it's not.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual BOOL PreventNodeDeletion();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on TM controllers so that system slave controllers can prevent the **Interface::DeleteNode()** API from deleting them. Note that **DeleteNode()** has an optional parameter to override this so master controllers can easily delete slave nodes if they want to.

**Return Value:**

TRUE to prevent deletion; FALSE to allow it.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual float EvalVisibility(TimeValue t, View &view, Box3 pbox,  
Interval &valid);
```

**Remarks:**

This method is available in release 2.0 and later only.

The Level of Detail utility lets you construct an object that alters its geometric complexity (or level of detail) based on its size in the rendered image. You do this by creating several versions of the same object -- each with different levels of detail, grouping them as one, and then assigning the Level of Detail utility, which automatically creates a special LOD controller as a Visibility track. The LOD controller then hides and unhides the various objects in the group, depending on their size in the rendered scene.

This method is called on visibility float controllers with view related parameters. This is used by the Level of Detail controller to allow view dependent visibility.

**Parameters:**

**TimeValue t**

The time at which to evaluate.

**View &view**

This class contains information about the view being rendered. This includes information such as the image width and height, the projection type, and matrices to convert between world to view and world to camera. See [Class View](#).

**Box3 pbox**

The bounding box of the node that's being evaluated.

**Interval &valid**

This interval should be updated to reflect the validity of the visibility controller.

**Return Value:**

The visibility of the object at the specified time.

**Default Implementation:**

The default implementation will simply call **GetValue()**.

**Prototype:**

**virtual BOOL VisibleInViewports();**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called on visibility controllers. This gives them the option to

completely hide an object in the viewports.

**Return Value:**

TRUE if the object is visible in the viewport; FALSE if invisible.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual BOOL CanInstanceController();
```

**Remarks:**

This method is available in release 2.0 and later only.

Called on transform controllers or visibility controllers when a node is cloned and the user has chosen to instance

**Return Value:**

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
void CloneControl(Control *ctrl,RemapDir &remap);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is implemented by the System. It should be called by any leaf controller's **Clone()** method so that ease and multiplier curves are cloned.

**Parameters:**

**Control \*ctrl**

Points to the cloned controller (the new one).

**RemapDir &remap**

The **RemapDir** passed to this controller's **Clone()** method.

**Sample Code:**

```
RefTargetHandle Clone(RemapDir& remap=NoRemap()) {  
    ExprControl *ctrl = new ExprControl(this->type, *this);  
    CloneControl(ctrl,remap);  
}
```

```
return ctrl;  
}
```

The following functions are not part of class Control but are provided for use. These functions are for use by Position or Rotation controllers. Position controllers would use the Point3 versions and Rotation controllers would use the Quat versions

```
void QuatEnumIKParams(Control *cont,IKEnumCallback  
&callback);
```

```
BOOL QuatCompDeriv(Control *cont,TimeValue t,Matrix3&  
ptm,  
IKDeriv& derivs,DWORD flags);
```

```
float QuatIncIKParam(Control *cont,TimeValue t,int index,float  
delta);
```

```
void QuatBeginIKParams(Control *cont,IObjParam *ip,  
ULONG flags,  
Animatable *prev);
```

```
void Point3EnumIKParams(Control *cont,IKEnumCallback  
&callback);
```

```
BOOL Point3CompDeriv(Control *cont,TimeValue t,Matrix3&  
ptm,  
IKDeriv& derivs,DWORD flags);
```

```
float Point3IncIKParam(Control *cont,TimeValue t,int  
index,float delta);
```

```
void Point3BeginIKParams(Control *cont,IObjParam *ip,  
ULONG flags,Animatable *prev);
```

**The methods below deal with copying and pasting IK parameters in the Hierarchy branch.**

**Prototype:**

**virtual BOOL CanCopyIKParams(int which)**

**Remarks:**

Implemented by the Plug-In.

This method returns TRUE if the controller has IK parameters it can copy and FALSE otherwise.

**Parameters:**

**int which**

One of the following values:

**COPYPASTE\_IKPOS  
COPYPASTE\_IKROT**

**Return Value:**

TRUE if the controller can copy the specified IK parameters; otherwise FALSE.

**Default Implementation:**

**{return FALSE;}**

**Prototype:**

**virtual IKClipObject \*CopyIKParams(int which)**

**Remarks:**

Implemented by the Plug-In.

This method is called to have the controller copy the specified IK parameters to an IKClipObject and return a pointer to it. The plug-in should derive a class from the IKClipObject, put its data in the class, and return a new instance of it. See [Class IKClipObject](#).

**Parameters:**

**int which**

One of the following values:

**COPYPASTE\_IKPOS  
COPYPASTE\_IKROT**

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL CanPasteIKParams(IKClipObject *co,int which)
```

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the controller can paste the specified IK parameters; otherwise FALSE.

**Parameters:**

**IKClipObject \*co**

A pointer to the current **IKClipObject** in the clipboard. This class identifies the creator of the clip object. See [Class IKClipObject](#). The plug-in should look at the IDs in the **IKClipObject** to make sure it matches this controller. If it does not, the plug-in should return FALSE.

**int which**

One of the following values:

**COPYPASTE\_IKPOS**

**COPYPASTE\_IKROT**

**Return Value:**

TRUE if the controller can paste the specified IK parameters; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual void PasteIKParams(IKClipObject *co,int which)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to have the controller paste the specified IK parameters from the specified IKClipObject to itself.

**Parameters:**

**IKClipObject \*co**

A pointer to an IKClipObject. See [Class IKClipObject](#).

**int which**

One of the following values:

**COPYPASTE\_IKPOS**

**COPYPASTE\_IKROT**

**Default Implementation:**

```
{}
```

**Controllers that wish to have an gizmo (apparatus) available in the scene will implement these methods.**

**Prototype:**

```
virtual int Display(TimeValue t, INode* inode,  
ViewExp *vpt, int flags);
```

**Remarks:**

Implemented by the Plug-In.

This is called by the system to have the controller display its gizmo. When a controller is being edited in the Motion branch, this method is called to allow it to display any apparatus it may have in the scene. Note that **Display()** is only called on Transform Controllers. It is not called on any sub-controllers, for example it wouldn't be called on the position controller of a PRS transform controller.

In R4 and higher however the display method **WILL** be called on Position, Rotation and scale controllers as well

**Parameters:**

**TimeValue t**

The time to display the object.

**INode\* inode**

The node to display.

**ViewExp \*vpt**

An interface pointer that exposes methods the plug-in may call related to the viewports.

**int flags**

See [List of Display Flags](#).

**Return Value:**

Nonzero if the item was displayed; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual int HitTest(TimeValue t, INode* inode, int type,  
int crossing, int flags, IPoint2 *p, ViewExp *vpt)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to determine if the specified screen point intersects the controller gizmo. The method returns nonzero if the gizmo was hit; otherwise 0.

**Parameters:**

**TimeValue t**

The time to perform the hit test.

**INode\* inode**

A pointer to the node whose gizmo should be tested.

**int type**

The type of hit testing to perform. See [Hit Test Types](#) for details.

**int crossing**

The state of the crossing setting. If TRUE crossing selection is on.

**int flags**

The hit test flags. See [Hit Test Flags](#) for details.

**IPoint2 \*p**

The screen point to test.

**ViewExp \*vpt**

An interface pointer that may be used to call methods associated with the viewports.

**Return Value:**

Nonzero if the controller gizmo was hit; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void GetWorldBoundingBox(TimeValue t,INode* inode,  
ViewExp *vpt, Box3& box)
```

**Remarks:**

Implemented by the Plug-In.

This is the world space bounding box of the controllers gizmo.

**Parameters:**

**TimeValue t**

The time to retrieve the bounding box.

**INode \* inode**

The node to calculate the bounding box for.

**ViewExp\* vp**

An interface pointer that exposes portions of View3D that are exported for use by plug-ins.

**Box3& box**

The bounding box is returned through **box**.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual void ActivateSubobjSel(int level, XFormModes& modes)
```

**Remarks:**

Implemented by the Plug-In.

When the user changes the selection of the sub-object drop down, this method is called to notify the plug-in. This method should provide instances of a class derived from **CommandMode** to support move, rotate, non-uniform scale, uniform scale, and squash modes. These modes replace their object mode counterparts however the user still uses the move/rotate/scale tool buttons in

the toolbar to activate them. If a certain level of sub-object selection does not support one or more of the modes NULL may be passed. If NULL is specified the corresponding toolbar button will be grayed out.

**Parameters:**

**int level**

The sub-object selection level the command modes should be set to support. A level of 0 indicates object level selection. If level is greater than or equal to 1 the index refers to the types registered by the object in the order they appeared in the list when registered by **Interface::RegisterSubObjectTypes()**. See [Class Interface](#).

**XFormModes& modes**

The command modes to support. See [Class XFormModes](#).

**Default Implementation:**

{ }

**Prototype:**

**virtual void SelectSubComponent(CtrlHitRecord \*hitRec,  
BOOL selected, BOOL all, BOOL invert=FALSE)**

**Remarks:**

Implemented by the Plug-In.

This method is called to change the selection state of the component identified by **hitRec**.

**Parameters:**

**CtrlHitRecord \*hitRec**

Identifies the component whose selected state should be modified. See [Class CtrlHitRecord](#).

**BOOL selected**

TRUE if the item should be selected; FALSE if the item should be de-selected.

**BOOL all**

TRUE if the entire object should be selected; FALSE if only the portion of the identified by **hitRec**.

**BOOL invert=FALSE**

This is set to TRUE when **all** is also set to TRUE and the user is holding down

the Shift key while region selecting in select mode. This indicates the items hit in the region should have their selection state inverted

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void ClearSelection(int selLevel)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to clear the selection for the given sub-object level. All sub-object elements of this type should be deselected.

**Parameters:**

**int selLevel**

Specifies the selection level to clear.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual int SubObjectIndex(CtrlHitRecord *hitRec)
```

**Remarks:**

Implemented by the System.

Returns the index of the sub-object element identified by the CtrlHitRecord **hitRec**. The sub-object index identifies a sub-object component. The relationship between the index and the component is established by the controller. For example a controller may allow the user to select a group of footprints and these groups may be identified as group 0, group 1, group 2, etc. Given a hit record that identifies a footprint, the controller's implementation of this method would return the group index that the footprint belonged to.

**Parameters:**

**CtrlHitRecord \*hitRec**

Identifies the component whose index should be returned. See [Class](#)

[CtrlHitRecord](#).

**Return Value:**

The index of the sub-object element.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual void SelectAll(int selLevel);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to select every element of the given sub-object level.

This will be called when the user chooses Select All from the 3ds max Edit menu.

**Parameters:**

**int selLevel**

Specifies the selection level to select.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void InvertSelection(int selLevel);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is called to invert the specified sub-object level. If the element is selected it should be deselected. If it's deselected it should be selected. This will be called when the user chooses Select Invert from the 3ds max Edit menu.

**Parameters:**

**int selLevel**

Specifies the selection level to invert.

**Default Implementation:**

```
{}
```

**When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current controller being edited so that it can display the axis.**

Two methods allows the system to do this:

**Prototype:**

```
virtual void GetSubObjectCenters(SubObjAxisCallback *cb,  
    TimeValue t,INode *node)
```

**Remarks:**

Implemented by the Plug-In.

When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current controller being edited so that it can display the axes. This method specifies the position of the center. The plug-in enumerates its centers and calls the callback **cb** once for each. See [Sub-Object Coordinate Systems](#).

**Parameters:**

**SubObjAxisCallback \*cb**

The callback object whose methods may be called. See [Class SubObjAxisCallback](#).

**TimeValue t**

The time to enumerate the centers.

**INode \*node**

A pointer to the node.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void GetSubObjectTMs(SubObjAxisCallback *cb,  
    TimeValue t,INode *node)
```

**Remarks:**

Implemented by the Plug-In.

When the user is in a sub-object selection level, the system needs to get the reference coordinate system definition from the current controller being edited

so that it can display the axes. This method returns the axis system of the reference coordinate system. The plug-in enumerates its TMs and calls the callback **cb** once for each. See [Sub-Object Coordinate Systems](#).

**Parameters:**

**SubObjAxisCallback \*cb**

The callback object whose methods may be called. See [Class SubObjAxisCallback](#).

**TimeValue t**

The time to enumerate the TMs.

**Inode \*node**

A pointer to the node.

**Default Implementation:**

**{**

## Modify sub-object apparatuses

### Prototype:

```
virtual void SubMove( TimeValue t, Matrix3& partm,  
    Matrix3& tmAxis, Point3& val,  
    BOOL localOrigin=FALSE )
```

### Remarks:

Implemented by the Plug-In.

When this method is called the plug-in should respond by moving its selected sub-object components.

### Parameters:

#### **TimeValue t**

The time of the transformation.

#### **Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the controller's space and convert them into world space points.

#### **Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

#### **Point3& val**

This value is a vector with X, Y, and Z representing the movement along each axis.

#### **BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local origin.

### Default Implementation:

```
{}
```

### Prototype:

```
virtual void SubRotate( TimeValue t, Matrix3& partm,  
    Matrix3& tmAxis, Quat& val, BOOL localOrigin=FALSE ){}
```

**Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by rotating its selected sub-object components.

**Parameters:****TimeValue t**

The time of the transformation.

**Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the controller's space and convert them into world space points.

**Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

**Quat& val**

The amount to rotate the selected components.

**BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local origin. Note: This information may be passed onto a transform controller (if there is one) so they may avoid generating 0 valued position keys for rotation and scales. For example if the user is rotating an item about anything other than its local origin then it will have to translate in addition to rotating to achieve the result. If a user creates an object, turns on the animate button, and rotates the object about the world origin, and then plays back the animation, the object does not do what the was done interactively. The object ends up in the same position, but it does so by both moving and rotating. Therefore both a position and a rotation key are created. If the user performs a rotation about the local origin however there is no need to create a position key since the object didn't move (it only rotated). So a transform controller can use this information to avoid generating 0 valued position keys for rotation and scales.

**Prototype:**

```
virtual void SubScale(TimeValue t, Matrix3& partm, Matrix3& tmAxis, Point3& val, BOOL localOrigin=FALSE)
```

**Remarks:**

Implemented by the Plug-In.

When this method is called the plug-in should respond by scaling its selected sub-object components.

**Parameters:****TimeValue t**

The time of the transformation.

**Matrix3& partm**

The 'parent' transformation matrix. This matrix represents a transformation that would take points in the modifier's space and convert them into world space points.

**Matrix3& tmAxis**

The matrix that represents the axis system. This is the space in which the transformation is taking place.

**Point3& val**

This value is a vector with X, Y, and Z representing the scale along X, Y, and Z respectively.

**BOOL localOrigin=FALSE**

When TRUE the transformation is occurring about the sub-object's local origin. See the note above in the Rotate method.

**Prototype:**

**virtual BOOL RescaleTime(Interval oseg, Interval nseg);**

**Remarks:**

This method is available in release 3.0 and later only.

This method is called when the user rescales time in the time configuration dialog. If FALSE is returned from this method then

**Animatable::MapKeys()** will be used to perform the scaling. Controllers can override this method to handle things like rescaling tagents that

**MapKeys()** won't affect and return TRUE if they don't want **MapKeys()** to be called.

**Parameters:**

**Interval oseg**

The old time segment.

### **Interval nseg**

The new time segment.

#### **Default Implementation:**

```
{return FALSE;}
```

#### **Prototype:**

```
virtual int GetDrawPixelStep();
```

#### **Remarks:**

This method is available in release 4.0 and later only.

Prior to R4 TrackView was using static defines to determines the number samples/pixel it used to draw and compute curve extents. Now a controller can override these defaults by implementing GetDrawPixelStep() and GetExtentTimeStep().

This method allows a control to get sampled at a different rate than what trackview does by default so the controller can speed up redraws. It returns the pixel sample rate for when the curve is drawn.

#### **Default Implementation:**

```
{return 5;}
```

#### **Prototype:**

```
virtual int GetExtentTimeStep();
```

#### **Remarks:**

This method is available in release 4.0 and later only.

Prior to R4 TrackView was using static defines to determines the number samples/pixel it used to draw and compute curve extents. Now a controller can override these defaults by implementing GetDrawPixelStep() and GetExtentTimeStep().

This method returns the ticks sample rate used when the curve is checked for its Y extents.

#### **Default Implementation:**

```
{return 40;}
```

## Load / Save

### Prototype:

**IOResult Save(ISave \*isave);**

### Remarks:

Implemented by the System.

The default implementation of **Save()** handles the saving of the out of range types. The plug-in should call this method from its implementation of **Save()**. The plug-in should call this method before it saves any of its chunks.

The out of range types are saved in these chunks:

**CONTROLBASE\_CHUNK**

**INORT\_CHUNK**

**OUTORT\_CHUNK**

### Parameters:

**ISave \*isave**

This pointer may be used to call methods to write data to disk. See [Class ISave](#).

### Return Value:

One of the following values:

**IO\_OK** - The result was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

### Prototype:

**IOResult Load(ILoad \*iload);**

### Remarks:

Implemented by the System.

The default implementation of **Load()** handles the loading of the out of range types. The plug-in should call this method from its implementation of **Load()**. The plug-in should call this method before it loads any of its chunks.

The out of range types are saved in these chunks:

**CONTROLBASE\_CHUNK**

**INORT\_CHUNK**

**OUTORT\_CHUNK**

**Parameters:****ILoad \*iLoad**

This pointer may be used to call methods to load data from disk. See [Class ILoad](#).

**Return Value:**

One of the following values:

**IO\_OK** - The result was acceptable - no errors.

**IO\_ERROR** - This is returned if an error occurred.

**These are implemented to handle ease curves.**

If a controller is a leaf controller, then it MUST NOT BY DEFINITION have any sub-controllers or references. If it is a leaf controller, then these are implemented to handle the ease curve list. If it is NOT a leaf controller, then these can be overridden.

From ReferenceMaker. See this class for details on these methods.

**int NumRefs();**

**RefTargetHandle GetReference(int i);**

**void SetReference(int i, RefTargetHandle rtarg);**

From Animatable. See this class for details on these methods.

**int NumSubs();**

**Animatable\* SubAnim(int i);**

**TSTR SubAnimName(int i);**

Default implementations of some Animatable methods:

**void\* GetInterface(ULONG id);**

**int PaintFCurves(ParamDimensionBase \*dim,**

**HDC hdc, Rect& rcGraph, Rect& rcPaint,**

**float tzoom, int tscroll, float vzoom, int vscroll, DWORD flags );**

**int GetFCurveExtents(ParamDimensionBase \*dim,**

**float &min, float &max, DWORD flags);**

## Class StdControl

See Also: [Class Control](#), [Class Interval](#), [Class Matrix3](#), [Class Point3](#), [Class Quat](#), [Class ScaleValue](#), [List of Additional Control Related Functions](#)

```
class StdControl : public Control
```

### Description:

StdControl is a class from which you may derived controller objects. Controllers are the objects in 3ds max that control animation. Any controller that does not evaluate itself as a function of its input can subclass off this class.

The purpose of this class is to simplify some aspects of implementing controllers. The only restriction when using this class is that the controller can not evaluate itself as a function of its input. For example, position, rotation, and scale controllers are passed a TM when they are evaluated. They are supposed to calculate their value and apply it to the TM (pre-multiply). It is possible that the controller could calculate its value as some function of this input matrix. For example, a rotation controller could look at the position of the matrix and the position of some other node in the scene and calculate the rotation such that the object is looking at the other node. Most controllers don't do this so they can subclass off this class which handles processing ORTs (Out of Range Types), ease curves and multiplier curves.

This class implements **GetValue()** and **SetValue()** but requires the derived class to implement two new methods: **GetValueLocalTime()** and **SetValueLocalTime()**.

The implementations of **GetValue()** and **SetValue()** handle processing the ORTs and ease and multiplier curves.

Plug-In Information:

Class Defined In CONTROL.H

Super Class ID CTRL\_FLOAT\_CLASS\_ID - Used by float controllers.

CTRL\_POINT3\_CLASS\_ID - Used by Point3 controllers.

CTRL\_MATRIX3\_CLASS\_ID - Used by Matrix3 controllers.

CTRL\_POSITION\_CLASS\_ID - Used by position controllers.

CTRL\_ROTATION\_CLASS\_ID - Used by rotation controllers.

CTRL\_SCALE\_CLASS\_ID - Used by scale controllers.

CTRL\_MORPH\_CLASS\_ID - Used by morph controllers.

Standard File Name Extension DLC

Extra Include File Needed None

### Methods:

#### Prototype:

```
virtual void GetValueLocalTime(TimeValue t, void *val,  
Interval &valid, GetSetMethod method=CTRL_ABSOLUTE)=0;
```

#### Remarks:

Implemented by the Plug-In.

This method is called to have the controller evaluate itself at the given time. In this class the system implements the method **GetValue()**. **GetValue()** calls this method to retrieve the value of the controller at the specified time. The implementation of **GetValue()** then takes care of handling the ORTs, ease curves and multiplier curves. The plug-in must only return the value of the controller.

#### Parameters:

##### **TimeValue t**

The time to retrieve the value.

##### **void \*val**

This points to a variable to hold the computed value of the controller at the specified time. What the plug-in needs to do to store the value of the controller depends on the controller type. There are six controller types: **float, Point3, Position, Rotation, Scale, and Transform.**

##### **float**

**\*val** points to a float

##### **Point3**

**\*val** points to a Point3

##### **Position**

**\*val** points to a Point3

##### **Rotation**

**\*val** points to a Quat

##### **Scale**

**\*val** points to a ScaleValue

## **Transform**

**\*val** points to a Matrix3

## **Interval & valid**

The interval to update. The controllers validity interval should be intersected with this interval. This updates the interval to reflect the interval of the controller.

## **GetMethod method=CTRL\_ABSOLUTE**

This will always be: **CTRL\_ABSOLUTE**

This indicates the controller should simply store its value in **\*val**.

## **Prototype:**

```
virtual void SetValueLocalTime(TimeValue t, void *val,  
    int commit=1, GetSetMethod method=CTRL_ABSOLUTE)=0;
```

## **Remarks:**

Implemented by the Plug-In.

In this class the system implements the method **SetValue()**. **SetValue()** calls this method to store the value of the controller at the specified time. The system takes care of handling the ORTs and multiplier curves. The plug-in must only store the value of the controller.

## **Parameters:**

### **TimeValue t**

The time to store the value.

### **void \*val**

Storage for the value to set. See **\*val** in **Control::SetValue()** for the possible data types passed here.

### **int commit=1**

If this parameter is zero, the controller should save the value at the given time before setting the value. If commit is nonzero, the controller doesn't need to actually update its keys or tangents. See Control methods **CommitValue()** and **RestoreValue()**.

## **GetMethod method=CTRL\_ABSOLUTE**

One of the following values:

**CTRL\_RELATIVE**

Indicates the plug-in should add the value to the existing value **\*val** (i.e. Move/Rotate/Scale)

### **CTRL\_ABSOLUTE**

Indicates the plug-in should just set the value.

#### **Prototype:**

```
void GetValue(TimeValue t, void *val, Interval &valid,  
GetSetMethod method=CTRL_ABSOLUTE);
```

#### **Remarks:**

This method is implemented by the system. Controller that subclass from StdControl only need to implement **GetValueLocalTime()**. See above.

#### **Prototype:**

```
void SetValue(TimeValue t, void *val, int commit=1,  
GetSetMethod method=CTRL_ABSOLUTE);
```

#### **Remarks:**

This method is implemented by the system. Controller that subclass from StdControl only need to implement **SetValueLocalTime()**. See above.

#### **Prototype:**

```
virtual void Extrapolate(Interval range, TimeValue t,  
void *val, Interval &valid, int type)=0;
```

#### **Remarks:**

Implemented by the Plug-In.

This method is used to calculate some of the Out of Range Types (ORTs). There are several kinds of extrapolations that need to be done based on the ORT type. There are template functions implemented in **CONTROL.H** to do them. See [List of Miscellaneous Controller Functions](#) for a description of those available.

#### **Parameters:**

##### **Interval range**

The range that must be extrapolated.

## **TimeValue t**

The time outside the range to extrapolate.

## **void \*val**

Storage for the extrapolated value. See **\*val** in **GetValueLocalTime()** for the possible data types passed here.

## **Interval &valid**

The validity interval of the extrapolated value.

## **int type**

See [List of Out of Range Types](#).

### **Sample Code:**

The following sample code shows the use of the template functions to implement this method to calculate the ORTs.

#### **INTERP\_CONT\_TEMPLATE**

```
void InterpControl<INTERP_CONT_PARAMS>::Extrapolate(Interval  
range,TimeValue t,void *val,
```

```
    Interval &valid,int type)
```

```
{
```

```
    T val0, val1, val2, res;
```

```
    switch (type) {
```

```
        case ORT_LINEAR:
```

```
            if (t<range.Start()) {
```

```
                GetValueLocalTime(range.Start(),&val0,valid);
```

```
                GetValueLocalTime(range.Start()+1,&val1,valid);
```

```
                res = LinearExtrapolate(range.Start(),t,val0,val1,val0);
```

```
            } else {
```

```
                GetValueLocalTime(range.End()-1,&val0,valid);
```

```
                GetValueLocalTime(range.End(),&val1,valid);
```

```
                res = LinearExtrapolate(range.End(),t,val0,val1,val1);
```

```
            }
```

```
            break;
```

```
        case ORT_IDENTITY:
```

```
            if (t<range.Start()) {
```

```
                GetValueLocalTime(range.Start(),&val0,valid);
```

```
                res = IdentityExtrapolate(range.Start(),t,val0);
```

```
            } else {
```

```

    GetValueLocalTime(range.End(),&val0,valid);
    res = IdentityExtrapolate(range.End(),t,val0);
    }
    break;

case ORT_RELATIVE_REPEAT:
    GetValueLocalTime(range.Start(),&val0,valid);
    GetValueLocalTime(range.End(),&val1,valid);
    GetValueLocalTime(CycleTime(range,t),&val2,valid);
    res = RepeatExtrapolate(range,t,val0,val1,val2);
    break;
    }
valid.Set(t,t);
*((T*)val) = res;
}

```

**Prototype:**

**virtual void \*CreateTempValue()=0;**

**Remarks:**

Implemented by the Plug-In.

When processing the ORTs the system might need a temporary variable to hold an intermediate value. Since the system doesn't know the type of the data that the controller is controlling it can't allocate the right amount of temporary storage. It calls this method to do so. The plug-in's implementation of this method should allocate storage to hold its type of data and return a pointer to it.

**Prototype:**

**virtual void DeleteTempValue(void \*val)=0;**

**Remarks:**

Implemented by the Plug-In.

This method simply deletes the memory allocated by **CreateTempValue()**.

**Parameters:**

**void \*val**

Points to the memory allocated by **CreateTempValue()**.

**Prototype:**

**virtual void ApplyValue(void \*val, void \*delta)=0;**

**Remarks:**

Implemented by the Plug-In.

Applies the given value to the given input value. For position, rotation, and scale controllers, the input value will be a matrix and the value being applied will be a Point3, Quaternion, or ScaleValue, respectively. For other controllers the input value is the same type as the value being applied.

**Parameters:**

**void \*val**

The value to update.

**void \*delta**

The value to apply.

**Prototype:**

**virtual void MultiplyValue(void \*val, float m)=0;**

**Remarks:**

Implemented by the Plug-In.

If the controller has multiplier curves then the system will calculate the factor from all the multiplier curves and then ask the controller to multiply the scalar value to the particular data type.

**Parameters:**

**void \*val**

The value to update.

**float m**

The scalar value to multiply **\*val** by.

# Class SceneImport

See Also: [Class ImpInterface](#), [Class Interface](#).

class SceneImport

## Description:

This is a base class for creating file import plug-ins. The plug-in implements methods of this class to describe the properties of the import plug-in and a method that handles the actual import process.

## Methods:

### Prototype:

**SceneImport();**

### Remarks:

Constructor.

### Prototype:

**virtual ~SceneImport();**

### Remarks:

Destructor.

### Prototype:

**virtual int ExtCount() = 0;**

### Remarks:

Implemented by the Plug-In.

Returns the number of file name extensions supported by the plug-in.

### Prototype:

**virtual const TCHAR \*Ext(int i) = 0;**

### Remarks:

Implemented by the Plug-In.

Returns the 'i-th' file name extension (i.e. "3DS").

### Parameters:

**int i**

The index of the file name extension to return.

**Prototype:**

**virtual const TCHAR \*LongDesc() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns a long ASCII description of the file type being imported (i.e. "Autodesk 3D Studio File").

**Prototype:**

**virtual const TCHAR \*ShortDesc() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns a short ASCII description of the file type being imported (i.e. "3D Studio").

**Prototype:**

**virtual const TCHAR \*AuthorName() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Author name.

**Prototype:**

**virtual const TCHAR \*CopyrightMessage() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Copyright message for the plug-in.

**Prototype:**

**virtual const TCHAR \*OtherMessage1() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the first message string that is displayed.

**Prototype:**

**virtual const TCHAR \*OtherMessage2() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the second message string that is displayed.

**Prototype:**

**virtual unsigned int Version() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the version number of the import plug-in. The format is the version number \* 100 (i.e. v3.01 = 301).

**Prototype:**

**virtual void ShowAbout(HWND hWnd) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to have the plug-in display its "About..." box.

**Parameters:**

**HWND hWnd**

The parent window handle for the dialog.

**Prototype:**

**virtual int DoImport(const TCHAR \*name, ImpInterface \*ii, Interface \*i, BOOL suppressPrompts=FALSE) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method actually performs the file import.

**Parameters:**

**const TCHAR \*name**

The file name chosen by the user to import.

**ImpInterface \*ii**

An import interface pointer that may be used to create objects and nodes in the scene.

**Interface \*i**

Pass the 3ds max interface pointer here.

**BOOL suppressPrompts=FALSE**

This parameter is available in release 2.0 and later only.

When TRUE, the plug-in must not display any dialogs requiring user input. It is up to the plug-in as to how to handle error conditions or situations requiring user input. This is an option set up for the 3ds max API in order for plug-in developers to create batch import plugins which operate unattended. See

**Interface::ImportFromFile().****Return Value:**

One of the following three values should be returned

```
#define IMPEXP_FAIL 0
```

```
#define IMPEXP_SUCCESS 1
```

```
#define IMPEXP_CANCEL 2
```

**Prototype:**

```
virtual int ZoomExtents();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to control the zoom extents done after the import is accomplished. It returns a value that indicates if the plug-in should override the user preference setting.

Also see the method **Interface::GetImportZoomExtents()** which returns the state of the system zoom extents flag.

**Return Value:**

One of the following values:

```
ZOOMEXT_NOT_IMPLEMENTED
```

Indicates to use the preference setting.

## **ZOOMEXT\_YES**

Indicates to do a zoom extents after import regardless of the preference setting.

## **ZOOMEXT\_NO**

Indicates to **not** do a zoom extents regardless of the preference setting.

### **Default Implementation:**

```
{ return ZOOMEXT_NOT_IMPLEMENTED; }
```

# Class SceneExport

See Also: [Class ExpInterface](#), [Class Interface](#).

class SceneExport

## Description:

This is a base class for creating file export plug-ins. The plug-in implements methods of this class to describe the properties of the export plug-in and a method that handles the actual export process.

## Methods:

### Prototype:

**SceneExport();**

### Remarks:

Constructor.

### Prototype:

**virtual ~SceneExport();**

### Remarks:

Destructor.

### Prototype:

**virtual int ExtCount() = 0;**

### Remarks:

Implemented by the Plug-In.

Returns the number of file name extensions supported by the plug-in.

### Prototype:

**virtual const TCHAR \*Ext(int i) = 0;**

### Remarks:

Implemented by the Plug-In.

Returns the 'i-th' file name extension (i.e. "3DS").

### Parameters:

**int i**

The index of the file name extension to return.

**Prototype:**

**virtual const TCHAR \*LongDesc() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns a long ASCII description of the file type being exported (i.e. "Autodesk 3D Studio File").

**Prototype:**

**virtual const TCHAR \*ShortDesc() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns a short ASCII description of the file type being exported (i.e. "3D Studio").

**Prototype:**

**virtual const TCHAR \*AuthorName() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Author name.

**Prototype:**

**virtual const TCHAR \*CopyrightMessage() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Copyright message for the plug-in.

**Prototype:**

**virtual const TCHAR \*OtherMessage1() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the first message string that is displayed.

**Prototype:**

**virtual const TCHAR \*OtherMessage2() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the second message string that is displayed.

**Prototype:**

**virtual unsigned int Version() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the version number of the export plug-in. The format is the version number \* 100 (i.e. v3.01 = 301).

**Prototype:**

**virtual void ShowAbout(HWND hWnd) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to have the plug-in display its "About..." box.

**Parameters:**

**HWND hWnd**

The parent window handle for the dialog.

**Prototype:**

**virtual int DoExport(const TCHAR \*name,ExpInterface \*ei,Interface \*i, BOOL suppressPrompts=FALSE, DWORD options=0) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called for the plug-in to perform its file export.

**Parameters:****const TCHAR \*name**

The export file name.

**ExpInterface \*ei**

A pointer the plug-in may use to call methods to enumerate the scene.

**Interface \*i**

An interface pointer the plug-in may use to call methods of 3ds max.

**BOOL suppressPrompts=FALSE**

This parameter is available in release 2.0 and later only.

When TRUE, the plug-in must not display any dialogs requiring user input. It is up to the plug-in as to how to handle error conditions or situations requiring user input. This is an option set up for the 3ds max API in order for plug-in developers to create batch export plugins which operate unattended. See

**Interface::ExportToFile().****DWORD options=0**

This parameter is available in release 3.0 and later only.

In order to support export of selected objects (as well as future enhancements), this method now has this additional parameter. The only currently defined option is:

**SCENE\_EXPORT\_SELECTED**

When this bit is set the export module should only export the selected nodes.

**Return Value:**

One of the following three values should be returned

**#define IMPEXP\_FAIL 0****#define IMPEXP\_SUCCESS 1****#define IMPEXP\_CANCEL 2****Prototype:****virtual BOOL SupportsOptions(int ext, DWORD options);****Remarks:**

This method is available in release 3.0 and later only.

This method is called by 3ds max to determine if one or more export options are supported by a plug-in for a given extension. It should return TRUE if all

option bits set are supported for this extension; otherwise FALSE.

Note that the method has a default implementation defined in order to provide easy backward compatibility. It returns FALSE, indicating that no options are supported.

**Parameters:**

**int ext**

This parameter indicates which extension the options are being queried for, based on the number of extensions returned by the

**SceneExport::ExtCount()** method. This index is zero based.

**DWORD options**

This parameter specifies which options are being queried, and may have more than one option specified. At present, the only export option is

**SCENE\_EXPORT\_SELECTED**, but this may change in the future. If

more than one option is specified in this field, the plugin should only return

TRUE if all of the options are supported. If one or more of the options are not supported, the plugin should return FALSE.

**Default Implementation:**

```
{return FALSE;}
```

## Class Atmospheric

See Also: [Class SpecialFX](#), [Class SFXParamDlg](#), [Class IRendParams](#), [Class ShadeContext](#), [Class Point3](#), [Class Color](#), [Class Interval](#).

```
class Atmospheric : public SpecialFX
```

### Description:

This is the base class for the creation of Atmospheric plug-ins. Developers may look to the text below for information on the techniques used to create these types of effects:

Kenton Musgrave, Darwyn Peachey, Ken Perlin, Steven Worley, Texturing and Modeling A Procedural Approach (Cambridge, MA: Academic Press, Inc., 1994). ISBN: 0-12-228760-6.

Chapter 6 on Hypertexture, particularly the section on 'Raymarching', describes essentially the method 3ds max uses.

### Methods:

#### Prototype:

```
virtual AtmosParamDlg *CreateParamDialog(IRendParams *ip)
```

#### Remarks:

Implemented by the Plug-In.

This method creates and returns a new instance of a class derived from **AtmosParamDlg** to manage the user interface. This put up a modal dialog that lets the user edit the plug-ins parameters.

#### Parameters:

```
IRendParams *ip
```

This is the interface given to the atmospheric effect so it may display its parameters.

#### Return Value:

A new instance of a class derived from **AtmosParamDlg**.

Note: **typedef SFXParamDlg AtmosParamDlg;**

#### Default Implementation:

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL SetDlgThing(AtmosParamDlg* dlg);
```

**Remarks:**

This method is available in release 3.0 and later only.

You should implement this if you are using the ParamMap2 AUTO\_UI system and the effect has secondary dialogs that have something other than the incoming effect as their 'thing'. Called once for each secondary dialog for you to install the correct thing. Return TRUE if you process the dialog, FALSE otherwise, in which case the incoming effect will be set into the dialog.

Note: Developers needing more information on this method can see the remarks for [MtlBase::CreateParamDlg\(\)](#) which describes a similar example of this method in use (in that case it's for use by a texture map plug-in).

**Parameters:**

```
AtmosParamDlg* dlg
```

Points to the ParamDlg.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual void Shade(ShadeContext& sc,const Point3& p0,const  
Point3& p1,Color& color,Color& trans, BOOL isBG=FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

This is the function that is called to apply the atmospheric effect. The line segment defined by the world space points **p0** and **p1** represent a segment of volume that needs to be shaded. This line segment is a line along the ray defined by the line between the viewer's eye (the camera) and the pixel being rendered in the image plane and continuing through world space. This ray is broken up into segments, with the boundaries defined by surfaces. If there are no surfaces, there will just be a single segment from the eye point going off into space (**p1** will be a large number). If there is a surface that is hit, and the surface is opaque, there will still be one segment from the eye to the surface. If the surface is transparent there may be two segments, the segment before and the segment after. Therefore the ray may be broken up into many segments

depending on the number of transparent surfaces hit.

The shader does not need to be directly concerned with this however. It only knows it's shading the segment between **p0** and **p1**. It will get called repeatedly for different pixels and different segments.

The output of this method is the computed **color** and **transparency**.

An example implementation of this method is 3ds max's Simple Fog. It takes the distance of the line segment and essentially interpolates towards the fog color based on the distance. This is a very simple effect.

3ds max's Volume Fog traverses along the segment and evaluates its 3D noise function. It integrates the density across the segment, and uses the density to compute the fog color.

### **Parameters:**

#### **ShadeContext& sc**

The ShadeContext.

#### **const Point3& p0**

The start point of the segment to shade. This point (and **p1**) are in an undefined 'internal' space specific to the renderer (which for the 3ds max renderer is in fact is camera space). To get to world space the plug-in would call **sc.PointTo(p0,REF\_WORLD)**.

#### **const Point3& p1**

The end point of the segment to shade.

#### **Color& color**

This method shades the volume between p0 and p1 and modifies this color.

#### **Color& trans**

This method shades the volume between p0 and p1 and modifies this transparency.

#### **BOOL isBG=FALSE**

TRUE if the background is being shaded; otherwise FALSE. If TRUE then p1 will be infinity (a large number). This is used when the option to not fog the background is on.

### **Prototype:**

```
IOResult Save(ISave *isave);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the system.

To facilitate naming atmospheric effects, a 'name' string has been added to the base class. This method should be called from the developers sub-classed Atmospheric plug-in to save the name.

**Prototype:**

**IOResult Load(ILoad \*iload);**

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the system.

To facilitate naming atmospheric effects, a 'name' string has been added to the base class. This method should be called from the developers sub-classed Atmospheric plug-in to load the name.

# Class Mtl

See Also: [Class MtlBase](#), [Class Texmap](#), [Class ShadeContext](#), [ShadeOutput](#), [Class Interval](#), [Class Color](#).

```
class Mtl : public MtlBase
```

## Description:

This is the base class for the creation of material plug-ins. This class provides methods to do things such as compute the properties of the material for a given location, return the number of sub-materials and access the properties of the material for the interactive renderer.

## Plug-In Information:

Class Defined In IMTL.H

Super Class ID MATERIAL\_CLASS\_ID

Standard File Name Extension DLT

Extra Include File Needed IMTL.H

## Method Groups:

The following hyperlinks take you to the start of groups of related methods within the class:

[Naming Methods](#)

[Shade](#)

[Get/SetActiveTexmap](#)

[Get Property Methods](#)

[Set Property Methods](#)

[Sub-Mtl Access Methods](#)

[Dynamic Properties Methods](#)

[Displacement Mapping](#)

[Replace Material Dialog](#)

## Methods:

## Prototype:

```
Mtl();
```

## Remarks:

Constructor. The active texture map is set to NULL.

## Naming Methods

### Prototype:

**virtual TSTR GetSubMtlSlotName(int i);**

### Remarks:

Implemented by the Plug-In.

This method returns the slot name of the 'i-th' sub-material. This name appears in the materials editor dialog. For instance, if you are in a material and then you go down into a sub-material, this is the name that appears just below the 'Get Material' icon. For example, in the Multi/Sub-Object material when you choose one of the sub-materials, the map name appears to let you know which slot you are working on. For the Multi/Sub-Object material, this is the number of the slot, i.e. "#1:", "#2:", "#3:", etc.

### Parameters:

**int i**

The index of the sub-materials whose slot name should be returned.

### Prototype:

**TSTR GetSubMtlTVName(int i);**

### Remarks:

Implemented by the Plug-In.

Returns the name of the 'i-th' sub-material that should appear in track view.

### Parameters:

**int i**

The index of the sub-materials whose track view name should be returned.

## Shade

### Prototype:

**virtual void Shade(ShadeContext& sc)=0;**

### Remarks:

Implemented by the Plug-In.

This is the main method of the material. This is called by the renderer to compute the color and transparency output returned in **sc.out**.

**Parameters:**

**ShadeContext& sc**

Describes properties of the pixel to be shaded. The result of this method is returned in the **ShadeOutput** data member of **sc**.

## Get/SetActiveTexmap

**Prototype:**

**MtlBase\* GetActiveTexmap();**

**Remarks:**

Implemented by the System.

Returns a pointer to the active texture map used in the interactive renderer.

**Prototype:**

**void SetActiveTexmap(MtlBase \*txm);**

**Remarks:**

Implemented by the System.

Stores the pointer to the active texture map used in the interactive renderer.

Note that this method does not do everything required to update the viewports with the new texmap. To accomplish that call

**Interface::ActivateTexture()**.

## Get Properties Methods

The following methods are used for displaying materials in the 3ds max viewports.

**Prototype:**

**virtual Color GetAmbient(int mtlNum=0, BOOL  
backFace=FALSE)=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ambient color of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

```
virtual Color GetDiffuse(int mtlNum=0, BOOL  
backFace=FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the diffuse color of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

```
virtual Color GetSpecular(int mtlNum=0, BOOL  
backFace=FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the specular color of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

**virtual float GetShininess(int mtlNum=0, BOOL  
backFace=FALSE)=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the shininess value of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

**virtual float GetShinStr(int mtlNum=0, BOOL  
backFace=FALSE)=0;**

**Remarks:**

Implemented by the Plug-In.

Returns the shininess strength value of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

```
virtual float GetXParency(int mtlNum=0, BOOL  
backFace=FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the transparency value of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Prototype:**

```
virtual float GetSelfIllum(int mtlNum=0, BOOL  
backFace=FALSE);
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the Plug-In.

Returns the self illumination value of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

**virtual BOOL GetSelfIllumColorOn(int mtlNum=0, BOOL backFace=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the Self Illumination Color is on (checked) for the specified material; otherwise FALSE.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

**virtual Color GetSelfIllumColor(int mtlNum=0, BOOL backFace=FALSE);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the Self Illumination Color of the specified material for use in the interactive renderer.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Default Implementation:**

```
{ Color c( .0f,.0f,.0f); return c; }
```

**Prototype:**

**virtual float WireSize(int mtlNum=0, BOOL backFace=FALSE)**

**Remarks:**

Implemented by the Plug-In.  
Returns the wire size of the material.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual Sampler *GetPixelSampler(int mtlNum=0, BOOL  
backFace=FALSE);
```

**Remarks:**

This method is available in release 3.0 and later only.  
Returns a pointer to the Sampler used for the specified sub-material.

**Parameters:**

**int mtlNum=0**

This is the material index for mult-materials.

**BOOL backFace=FALSE**

If the surface normal of the face is pointing away from the viewer this will be TRUE; otherwise FALSE.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual RenderData *GetRenderData();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns the auxiliary data attached to the material by the renderer.

**Default Implementation:**

```
{ return renderData; }
```

**Prototype:**

```
virtual BOOL IsOutputConst(ShadeContext& sc, int stdID);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns TRUE if the evaluated color/value (output) is constant over all possible inputs described by the shade context. If it cannot determine the correct answer, it returns FALSE.

**Parameters:**

**ShadeContext& sc**

This describes the context of the question.

**int stdID**

The ID of the channel in question. See [List of Texture Map Indices](#)

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual BOOL EvalColorStdChannel(ShadeContext& sc, int stdID,  
Color&  
outClr);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method evaluates the material on a single standard texmap channel over an area described in the ShadeContext. A return value of FALSE indicates that the color could not be evaluated.

If there's no texmap defined for a channel or the output of the texmap is not "meaningful", the raw color stored by the material or shader is returned. (The output of a texmap is meaningful in a given ShadeContext if it is the same as when the scene is rendered. If the map cannot determine whether the output value is the same as when rendered, it should not be meaningful.)

Note that the output color is not clamped. If the method is called with a monochrome channel ID, the result value is copied in the R, G and B components of the Color structure.

As a default implementation, this method sets the output color to black and returns FALSE.

**Parameters:**

**ShadeContext& sc**

This describes the context in which the material should be evaluated.

**int stdID**

The ID of the channel to perform evaluation on. See [List of Texture Map Indices](#)

**Color& outClr**

The result of the evaluation.

**Default Implementation:**

```
{ return FALSE; }
```

## Set Properties Methods

**Prototype:**

```
virtual void SetAmbient(Color c, TimeValue t)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method saves the specified color at the specified time.

**Parameters:**

**Color c**

The color to store.

**TimeValue t**

The time to set this color.

**Prototype:**

```
virtual void SetDiffuse(Color c, TimeValue t)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method saves the specified color at the specified time.

**Parameters:**

**Color c**

The color to store.

**TimeValue t**

The time to set this color.

**Prototype:**

**virtual void SetSpecular(Color c, TimeValue t)=0;**

**Remarks:**

Implemented by the Plug-In.

This method saves the specified color at the specified time.

**Parameters:**

**Color c**

The color to store.

**TimeValue t**

The time to set this color.

**Prototype:**

**virtual void SetShininess(float v, TimeValue t)=0;**

**Remarks:**

Implemented by the Plug-In.

This method saves the specified shininess at the specified time.

**Parameters:**

**float v**

The shininess value to store.

**TimeValue t**

The time to set this color.

**Prototype:**

**virtual void SetRenderData(RenderData \*rdata);**

**Remarks:**

This method is available in release 4.0 and later only.

This method allows the renderer to attach auxiliary data to each material.

**Parameters:**

**RenderData \*rdata**

The auxiliary data you wish to attach.

**Default Implementation:**

```
{ renderData = rdata; }
```

**Sub-material Access Methods****Prototype:**

```
virtual int NumSubMtls()
```

**Remarks:**

Implemented by the Plug-In.

Returns the number of sub-materials managed by this material.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual Mtl* GetSubMtl(int i)
```

**Remarks:**

Implemented by the Plug-In.

Returns a pointer to the 'i-th' sub-material of this material.

**Parameters:**

**int i**

The index of the material to return.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual void SetSubMtl(int i, Mtl *m)
```

**Remarks:**

Implemented by the Plug-In.

Stores the 'i-th' sub-material of this material.

**Parameters:****int i**

The index of the material to store.

**Mtl \*m**

The material pointer to store.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual int SubMtlOn(int i);
```

**Remarks:**

This method is not currently used.

**Prototype:**

```
virtual int VPDisplaySubMtl();
```

**Remarks:**

This method is available in release 4.0 and later only.

This method returns which sub-mtl is to display in the viewport, a return value of:-1 indicates not implemented.

Note that when a material, such as Blend, has a method of selecting which sub-map is to be shown in the viewport, and implements this method, the materials editor lets you turn on Show Map In Viewport (SMIV) in all the sub maps at once. When the material, such as top-bottom, doesn't have a selector, and doesn't implement this method, then the materials editor will only let you turn on SMIV for one map/mtl in the entire sub-tree of the material.

**Default Implementation:**

```
{ return -1; }
```

**Dynamic Properties Methods**

**Prototype:**

```
float GetDynamicsProperty(TimeValue t, int mtlNum, int propID);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method returns the specified dynamics property of the material at the specified time.

**Parameters:****TimeValue t**

The time to return the dynamics property.

**int mtlNum**

The index of the sub-material or zero if this is a base material.

**int propID**

Specifies the type of property. One of the following values:

**DYN\_BOUNCE**

The bounce coefficient. Values in the range 0.0 to 1.0.

**DYN\_STATIC\_FRICTION**

The static friction property. Values in the range 0.0 to 1.0.

**DYN\_SLIDING\_FRICTION**

The sliding friction property. Values in the range 0.0 to 1.0.

**Default Implementation:**

The default implementation for Mtl will handle all multi-materials. All root level materials (for instance Standard) need to implement this method.

**Prototype:**

```
void SetDynamicsProperty(TimeValue t, int mtlNum, int propID, float value);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method sets the specified dynamics property of the material at the specified time.

**Parameters:**

## **TimeValue t**

The time at which to set the value.

## **int mtlNum**

The sub-material number for a multi-material.

## **int propID**

Specifies the type of property. One of the following values:

### **DYN\_BOUNCE**

The bounce coefficient. Values in the range 0.0 to 1.0.

### **DYN\_STATIC\_FRICTION**

The static friction property. Values in the range 0.0 to 1.0.

### **DYN\_SLIDING\_FRICTION**

The sliding friction property. Values in the range 0.0 to 1.0.

## **float value**

The value to set.

### **Default Implementation:**

The default implementation for Mtl will handle all multi-materials. All root level materials (for instance Standard) need to implement this method.

## **Displacement Mapping**

### **Prototype:**

```
virtual float EvalDisplacement(ShadeContext& sc);
```

### **Remarks:**

This method is available in release 2.0 and later only.

Returns the amount of displacement along the normal of the surface at the point as specified by the **ShadeContext**.

### **Parameters:**

**ShadeContext& sc**

This contains the details of the point being displaced.

### **Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:****virtual Interval DisplacementValidity(TimeValue t);****Remarks:**

This method is available in release 2.0 and later only.

Returns the validity interval of the displacement mapping around the specified time.

**Parameters:****TimeValue t**

The Interval returned reflects the validity around this time.

**Default Implementation:****{ return FOREVER; }****Replace Material Dialog****Prototype:****virtual BOOL DontKeepOldMtl();****Remarks:**

This method is available in release 3.0 and later only.

Return TRUE to prevent the Replace Material (Discard old material? / Keep old material as sub-material?) dialog from being presented to the user; FALSE to allow it to be presented. This allows a plug-in to control the display of this dialog when being created in a Material Editor slot.

**Default Implementation:****{ return FALSE; }****Prototype:****virtual BOOL SupportsShaders();****Remarks:**

This method is available in release 4.0 and later only.

This method returns TRUE if the material supports shaders, otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

## Class Texmap

See Also: [Class MtlBase](#), [Class ShadeContext](#), [Class UVGen](#), [Class XYZGen](#), [Class TexHandleMaker](#), [Class NameAccum](#), [Class AColor](#), [Class Matrix3](#), [List of Procedural Texture Clamping, Noise and Misc Functions](#).

```
class Texmap: public MtlBase
```

### Description:

This is the base class for the creation of texture map plug-ins. It provides methods for things such as calculating the color of the map for a given location, and computing a perturbation to apply to a normal for bump mapping.

Note: Developers creating procedural textures should be aware that these textures may appear less than perfect when a 3ds max user is using the "Quick Renderer" in the Materials Editor. This is not the fault of the plug-in texture, it is simply that the "Quick Renderer" uses an algorithm that is quicker but less accurate than the standard scanline renderer. Therefore, don't be concerned if your texture does not show up perfectly when using "Quick Renderer".

### Plug-In Information:

Class Defined In IMTL.H

Super Class ID TEXMAP\_CLASS\_ID

Standard File Name Extension DLT

Extra Include Files Needed IMTL.H (and optionally TEXUTIL.H)

### Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Eval Methods](#)

[Output Level](#)

[Texture Display in the Viewports](#)

[Loading Map Files](#)

[Slot Type](#)

[Get UV Transform / Texture Tiling](#)

[UVGen and XYZGen Access](#)

[Additional Details related to Bump Mapping](#)

**Methods:****Prototype:**

**Texmap();**

**Remarks:**

Constructor. The number of active uses of this texture is set to 0.

**Eval Methods****Prototype:**

**virtual AColor EvalColor(ShadeContext& sc)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called to evaluate the color of the texture map for the context.

This is for channels that have a color such as diffuse, specular, ambient, etc.

This method is called for every pixel of the texture.

**Parameters:**

**ShadeContext& sc**

Describes the properties of the pixel to evaluate.

**Return Value:**

An **AColor** object which stores the **r, g, b, a** values. Note: The alpha is premultiplied, and the alpha value goes into **AColor::a**.

**Prototype:**

**virtual float EvalMono(ShadeContext& sc);**

**Remarks:**

Implemented by the Plug-In.

Evaluate the map for a "mono" channel. Mono channels are those that don't have a color, but rather a single value. This is for things like shininess, transparency, etc. This just permits a bit of optimization.

**Parameters:**

**ShadeContext& sc**

Describes the properties of the pixel to evaluate.

**Return Value:**

A floating point value for the mono channel.

**Default Implementation:**

```
{return Intens(EvalColor(sc));}
```

**Prototype:**

```
virtual BOOL EvalColorMonoChannel(ShadeContext& sc, int  
stdID, Color&  
outClr);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method evaluates the material on a single standard texmap channel over an area described in the ShadeContext. A return value of FALSE indicates that the value could not be evaluated.

If there's no texmap defined for a channel or the output of the texmap is not "meaningful", the raw value stored by the material or shader is returned. For the definition of the term "meaningful" see

**Texmap::IsOutputMeaningful()**.

Note that the output value is not clamped. If the method is called on a color channel, the intensity of the RGB value is returned. The intensity is computed as defined by the global helper method Interns in the 3ds max SDK.

As a default implementation, this calls **EvalColorStdChannel()** method and sets the result to the intensity of the color.

**Parameters:**

**ShadeContext& sc**

This describes the context in which the material should be evaluated.

**int stdID**

The ID of the channel to perform evaluation on. See List of Texture Map Indices *\*\*aztodo\*\** [link this](#)

**Color& outClr**

The result of the evaluation.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual Point3 EvalNormalPerturb(ShadeContext& sc)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is used for bump mapping to retrieve a perturbation to apply to a normal.

**Parameters:**

```
ShadeContext& sc
```

Describes the properties of the pixel to evaluate.

**Return Value:**

A deflection vector for perturbing the normal.

**Prototype:**

```
virtual BOOL HandleOwnViewPerturb();
```

**Remarks:**

This method is available in release 2.0 and later only.

This query is made of maps plugged into the Reflection or Refraction slots: Normally the view vector is replaced with a reflected or refracted one before calling the map: if the plugged in map doesn't need this, it should return TRUE.

**Default Implementation:**

```
{ return FALSE; }
```

## Output Level

**Prototype:**

```
virtual void SetOutputLevel(TimeValue t, float v)
```

**Remarks:**

Implemented by the Plug-In.

Sets the output level at the specified time. It is used to set the output level of the imbedded Texout object, principally by importing plug-ins. It is implemented in all Texmaps.

**Parameters:**

**TimeValue t**

The time to set the output level.

**float v**

The value to set.

**Default Implementation:**

```
{
```

**Prototype:**

```
void RecursInitSlotType(int sType);
```

**Remarks:**

Implemented by the System.

This method is used internally to set the slot type for all subtexmaps in a tree.

**Prototype:**

```
virtual BITMAPINFO* GetVPDisplayDIB(TimeValue t,  
TexHandleMaker& thmaker, Interval &valid, BOOL  
mono=FALSE, int forceW=0, int forceH=0);
```

**Remarks:**

This method is available in release 4.0 and later only.

This gets the viewport display bitmap in DIB format, useful when combining several maps for hardware-supported multiple texture display. If **mono** is TRUE, the map should do a mono evaluation and place the result in RGB.

**forceW** and **forceH**, if non-zero, override dimensions specified by **thmaker**.

**Parameters:****TimeValue t**

The time to get the bitmap at.

**TexHandleMaker& thmaker**

This class provides methods for creating a texture handle from a 3ds max bitmap and a Windows DIB. It also has a method to retrieve the required size of the texture map. See [Class TexHandleMaker](#).

**Interval &valid**

The validity interval of the returned bitmap.

**BOOL mono**

Indicates whether a map should do mono evaluation.

**int forceW**

Overrides the bitmap width usually supplied by **thmaker**.

**int forceH**

Overrides the bitmap height usually supplied by **thmaker**.

**Get UV Transform / Texture Tiling****Prototype:**

**virtual void GetUVTransform(Matrix3 &uvtrans)**

**Remarks:**

Implemented by the Plug-In.

This method is called to retrieve the UV transformation matrix for use in the viewports. If a developer is using an instance of UVGen, a method of that class may be called to retrieve the value:

(i.e. **{ uvGen->GetUVTransform(uvtrans); }** ).

**Parameters:****Matrix3 &uvtrans**

The transformation matrix is returned here.

**Default Implementation:**

**{ }**

**Prototype:**

**virtual int GetTextureTiling()**

**Remarks:**

Implemented by the Plug-In.

This method is called to get the tiling state of the texture for use in the viewports. This is described by a set of symmetry flags that may be ORed together. If you are using an instance of UVGen to handle the UV user interface you may simply call a method of UVGen to handle this.

For example: **{ return uvGen->GetTextureTiling(); }**

**Return Value:**

See [List of Texture Symmetry Flags](#).

**Default Implementation:**

```
{ return U_WRAP|V_WRAP; }
```

**Prototype:**

```
virtual int GetUVWSource();
```

**Remarks:**

This method is available in release 2.0 and later only.

Returns a value indicating where to get the texture vertices for the Texmap.

**Return Value:**

One of the following values:

**UVWSRC\_EXPLICIT**

Use explicit mesh texture vertices from one of the mapping channels (see **GetMapChannel()** below to determine which one). This uses the UVW coordinates assigned to the object, either through the Generate Mapping Coordinates option in the object's creation parameters, or through mapping modifiers, such as UVW Map.

**UVWSRC\_EXPLICIT2**

Use explicit mesh texture vertices from the Vertex Color Channel.

**UVWSRC\_OBJXYZ**

Generate planar UVW mapping coordinates from the object local XYZ on-the-fly. This corresponds to the "Planar from Object XYZ" option.

**UVWSRC\_WORLDXYZ**

This value is available in release 3.0 and later only.

Generate planar UVW mapping coordinates from the world XYZ on-the-fly. This corresponds to the "Planar From World XYZ" option. Note: this value used for the UVW is the world XYZ, taken directly, with out normalization to the objects bounding box. This differs from "Planar from Object XYZ", where the values are normalized to the object's bounding box.

**Default Implementation:**

```
{ return UVWSRC_EXPLICIT; }
```

**Prototype:**

```
virtual int GetMapChannel();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the map channel being used by the texmap if **GetUVWSource()** returns **UVWSRC\_EXPLICIT**. The return value should be at least 1. A value of 0 is not acceptable.

**Default Implementation:**

```
{ return 1; }
```

## UVGen and XYZGen Access

**Prototype:**

```
virtual UVGen *GetTheUVGen();
```

**Remarks:**

This method is available in release 2.0 and later only.

Texture maps that use a UVGen should implement this method to return a pointer to it.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

```
virtual XYZGen *GetTheXYZGen();
```

**Remarks:**

This method is available in release 2.0 and later only.

Texture maps that use a XYZGen should implement this method to return a pointer to it.

**Default Implementation:**

```
{ return NULL; }
```

## Loading Bitmap Files

**Prototype:**

## **virtual int LoadMapFiles(TimeValue t)**

### **Remarks:**

Implemented by the Plug-In.

This method is called prior to rendering to allow the plug-in to load any bitmap files it requires.

Note that **LoadMapFiles()** is called to load map files only, not to list the missing files. The missing files are listed using the **EnumAuxFiles()** method, which allows enumerating them without loading them.

Also Note: There is currently not an **UnloadMapFiles()** method. There are a couple of ways to do this however. One is to call

**Interface::FreeAllBitmaps()**. That method traverses the scene reference hierarchy and calls **Animatable::FreeAllBitmaps()** on each item. Another approach is to evaluate the Material / TextureMap hierarchy on each material.

Then call **Animatable::FreeAllBitmaps()** yourself in the

**MtlEnum::proc()** shown below.

```
class MtlEnum {  
public:  
    virtual void proc(MtlBase *m) = 0;  
};  
  
void EnumMtlTree(MtlBase *mb, MtlEnum &tenum) {  
    tenum.proc(mb);  
    for (int i=0; i<mb->NumSubTexmaps(); i++) {  
        Texmap *st = mb->GetSubTexmap(i);  
        if (st)  
            EnumMtlTree(st,tenum);  
        }  
    if (IsMtl(mb)) {  
        Mtl *m = (Mtl *)mb;  
        for (i=0; i<m->NumSubMtls(); i++) {  
            Mtl *sm = m->GetSubMtl(i);  
            if (sm)  
                EnumMtlTree(sm,tenum);  
            }  
    }
```

```
}  
}
```

Now just define a subclass of MtlEnum that does what you want, and call EnumMtlTree. In this particular case it is more efficient than enumerating the entire reference hierarchy. If you do want to enumerate the entire reference hierarchy, here's how

```
class RefEnumProc {  
    public:  
    virtual void proc(ReferenceMaker *rm)=0;  
};  
  
void EnumRefs(ReferenceMaker *rm, RefEnumProc &proc)  
{  
    proc.proc(rm);  
    for (int i=0; i<rm->NumRefs(); i++) {  
        ReferenceMaker *srm = rm->GetReference(i);  
        if (srm) EnumRefs(srm,proc);  
    }  
}
```

Just define a subclass of RefEnumProc that does what you want, and call EnumRefs on the part of the reference hierarchy you want to enumerate. For example

```
class MyEnum: public RefEnumProc {  
    void proc(ReferenceMaker *rm) { /* do something */ }  
}  
  
void afunction(Mtl* m) {  
    MyEnum enumer;  
    EnumRefs(m,&enumer);  
}
```

**Parameters:**

**TimeValue t**

The time the maps are being loaded.

**Return Value:**

Always return nonzero from this method.

**Default Implementation:**

```
{ return 1; }
```

**Prototype:**

```
virtual void RenderBitmap(TimeValue t, Bitmap *bm, float  
scale3D=1.0f, BOOL filter = FALSE);
```

**Remarks:**

This method is available in release 2.0 and later only.

This method is used to render a 2D bitmap version of this texmap.

**Parameters:**

**TimeValue t**

The time at which to render the texmap to the bitmap.

**Bitmap \*bm**

A pointer to a bitmap to render to. This bitmap must be created at the resolution you wish to render to.

**float scale3D=1.0f**

This is a scale factor applied to 3D Texmaps. This is the scale of the surface in 3d space that is mapped to UV. This controls how much of the texture appears in the bitmap representation.

**BOOL filter = FALSE**

If TRUE the bitmap is filtered. It is quite a bit slower to rescale bitmaps with filtering on.

## Slot Type

**Prototype:**

```
virtual void InitSlotType(int sType)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to initialize the slot type. This sets the proper button in the coordinate user interface rollup page. If you are using an instance of UVGen to handle the UV user interface you may simply call a method of

UVGen to handle this. For example: **{ if (uvGen) uvGen->InitSlotType(sType); }**

**Parameters:**

**int sType**

See [List of Map Slot Types](#).

**Default Implementation:**

**{ }**

**Prototype:**

**virtual void RenderBitmap(TimeValue t, Bitmap \*bm, float scale3D=1.0f, BOOL filter = FALSE);**

**Remarks:**

This method is available in release 2.0 and later only.

Renders the texmap to the specified bitmap.

**Parameters:**

**TimeValue t**

The time at which to render the bitmap.

**Bitmap \*bm**

The result is stored in this bitmap. The properties of this bitmap define the resolution, color depth, etc.

**float scale3D=1.0f**

This is the scale of the surface in 3d space that is mapped to UV.

**BOOL filter = FALSE**

If TRUE the bitmap is filtered. It is quite a bit slower to rescale bitmaps with filtering on.

**Default Implementation:**

The default implementation calls **Interface::RenderTexmap()**.

**Prototype:**

**virtual BOOL IsOutputMeaningful(ShadeContext& sc);**

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the system.

Returns TRUE only if all submaps and itself have a meaningful output.

Returns FALSE if at least one sub-texmap or itself does not have a meaningful output

The output of a texmap is meaningful in a given ShadeContext if it is the same as when the scene is rendered. If the map cannot determine whether the output value is the same as when rendered, it should not be meaningful. This method can be called before **EvalColor()** or **EvalMono()** on a texmap in order to decide whether to call these methods at all or if their return values should be used in further calculations.

**Parameters:**

**ShadeContext& sc**

This describes the context of the question.

**Prototype:**

**virtual BOOL IsLocalOutputMeaningful(ShadeContext& sc);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns TRUE if the output of **this** texmap is meaningful for the given context; it should not take into account subtexmaps. This method is called by **IsOutputMeaningful()**.

**Parameters:**

**ShadeContext& sc**

This describes the context of the question.

**Default Implementation:**

**{ return FALSE; }**

**Prototype:**

**virtual int IsHighDynamicRange( ) const;**

**Remarks:**

This method is available in release 4.0 and later only.

Returns nonzero if the texture is returning high dynamic range data; otherwise zero.

### Default Implementation:

```
{ return false; }
```

### Additional Details related to Bump Mapping

Note the following information concerning bump mapping:

The following function evaluates the normal perturbation vector in the Bitmap texture.

```
Point3 BMTex::EvalNormalPerturb(ShadeContext& sc) {
    Point3 dPdu, dPdv;
    Point2 dM;
    if (gbufID) sc.SetGBufferID(gbufID);
    if (thebm==NULL)
        return Point3(0,0,0);
    uvGen->GetBumpDP(sc,dPdu,dPdv); // get bump basis vectors
    if (alphaAsMono)
        dM=(.01f)*uvGen-
>EvalDeriv(sc,&alphasamp,filterType!=FILTER_NADA);
    else
        dM=(.01f)*uvGen-
>EvalDeriv(sc,&mysamp,filterType!=FILTER_NADA);
    return texout->Filter(dM.x*dPdu+dM.y*dPdv);
}
```

The function **GetBumpDP()** returns the "bump basis vectors". These are the gradient vectors of the UVW mapping in the object coordinate space.

The following function is used to compute the U and V bump basis vectors for a triangle given the texture coordinates at the three vertices of the triangle ( tv[] ) and the 3D coordinates at the vertices ( v[] ). It is simply a solution using linear algebra for the U and V axes in terms of the XYZ coordinates. It returns

**b[0] = DP/DU**

**b[1] = DP/DV**

This function does not compute DP/DW (the W bump basis vector), which at present is a shortcoming of the scanline renderer.

```
void ComputeBumpVectors(const Point3 tv[3], const Point3 v[3],
```

```

Point3 bvec[3]) {
float uva,uvb,unc,uvd,uvk;
Point3 v1,v2;
uva = tv[1].x-tv[0].x;
uvb = tv[2].x-tv[0].x;
unc = tv[1].y-tv[0].y;
uvd = tv[2].y-tv[0].y;
uvk = uvb*unc - uva*uvd;
v1 = v[1]-v[0];
v2 = v[2]-v[0];
if (uvk!=0) {
    bvec[0] = (unc*v2-uvd*v1)/uvk;
    bvec[1] = (uva*v2-uvb*v1)/uvk;
}
else {
    if (uva!=0)
        bvec[0] = v1/uva;
    else if (uvb!=0)
        bvec[0] = v2/uvb;
    else
        bvec[0] = Point3(0.0f,0.0f,0.0f);
    if (unc!=0)
        bvec[1] = v1/unc;
    else if (uvd!=0)
        bvec[1] = v2/uvd;
    else
        bvec[1] = Point3(0.0f,0.0f,0.0f);
}
bvec[2] = Point3(0,0,1); // TBD- How to compute this ??
}

```

The three Point3's returned in bvec are stored away, and then simply returned in the function **SContext::GetBumpDP()**;

The function **UVGen::EvalDeriv()** evaluates the local derivative of the texture map in the U and V directions, taking into account symmetry and scaling.

The resulting derivative,  $dM$ , is scaled down from the value returned by `EvalDeriv` to keep the bump perturbations in a more reasonable range.

The perturbation vector is calculated as:

$$dM.x * dPdu + dM.y * dPdv$$

And then passed through the `texout->Filter` function, which is just the following:

```
Point3 Texout::Filter(Point3 c) {  
if (outAmt!=1.0f) c *= outAmt;  
if (flags&TEXOUT_INVERT) c = -c;  
return c;  
}
```

## Class Tex3D

See Also: [Class Texmap](#), [Working with Materials and Textures](#).

```
class Tex3D : public Texmap
```

### Description:

Developers that have created a 3D Studio/DOS SXP and a corresponding 3ds max texture plug-in may want to subclass from this class. It provides a way to have an instance of your 3ds max texture plug-in created automatically when the corresponding SXP is found in a 3DS file being imported.

This works as follows:

In the 3ds max texture plug-in's implementation of **DllMain()** the following function is called:

```
void RegisterSXPReader(TCHAR *sxpName, Class_ID cid);
```

The plug-in passes its own SXP name (i.e. "MARBLE\_I.SXP") and its own Class\_ID.

The system then remembers this. When the 3DStudio import plug-ins is loading a .3DS file and it encounters an SXP with this name, it will create an instance of the plug-in class (using the Class\_ID) and call the method of this class **ReadSXPData()**. The plug-in can then initialize itself with proper values by reading the old SXP data.

A sample plug-in that uses this technique is the 3ds max Marble texture. It imports the settings from the 3D Studio Marble SXP. See the sample code in **\MAXSDK\SAMPLES\MATERIALS\MARBLE.CPP**.

### Methods:

#### Prototype:

```
virtual void ReadSXPData(TCHAR *name, void *sxpdata)=0;
```

#### Remarks:

This method is called when the 3D Studio/DOS import plug-in encounters an SXP with the name registered by **RegisterSXPReader()**.

#### Parameters:

```
TCHAR *name
```

The name of the SXP.

**void \*sxpdata**

This is the SXP's initialization data. The plug-in can look at this data to see what numbers it was initialized to in the .3DS file being imported. It can then set its initial value to match the SXP settings.

## Class ImageFilter

See Also: [Class ImageFilterInfo](#), [Class Bitmap](#), [Class ITrackViewNode](#), [Class TimeChange](#), [Class UndoNotify](#), [Working with Bitmaps](#).

class ImageFilter

### Description:

Image processing filter plug-ins are derived from **ImageFilter**. This class has virtual methods the developer implements to provide information about the plug-in version, and description. The developer also implements the **Capability()** method to indicate the properties of the plug-in such as if it is a one pass filter or compositor, and whether it has a control dialog to be displayed.

The **Render()** method is the one that actually alters the source image to perform the work of the application.

Filter plug-ins have access to several bitmaps associated with the video post data stream. All filter plug-ins will have at least a pointer to data member **srcmap**.

This is Video Post's main image pipeline. Composition and transition (layer) filters will also receive a second bitmap (**frgmap**) which should be composited above the main bitmap (**srcmap**). If **mskmap** is not NULL, it will contain a pointer to a grayscale image to be used as a mask for the process. Note that developers should not delete these bitmaps as they are maintained by 3ds max.

If a plug-in is both a filter and a compositor, the plug-in can tell if it is running as a filter when the **frgmap** pointer is NULL.

Note: If changes are made to an **ImageFilter** plug-in, the system will not automatically put up the 'The scene has been modified. Do you want to save your changes?' dialog if the user attempts to exit without saving. So that your plug-in does not go unsaved, you should call the following global function if you make changes. This will indicate to the system that the save requester needs to be brought up:

**void SetSaveRequired(int b=TRUE);**

Sets the 'save dirty bit'. This will indicate to the system that the save requester needs to be presented to the user.

### Method Groups:

The hyperlinks below jump to beginning of related methods within the class:

[Channels](#)  
[Filter Control Dialog Interactivity](#)  
[Track View Node Methods](#)

### **Data Members:**

protected:

#### **BOOL interactive;**

This data member is available in release 2.0 and later only.  
TRUE if the setup dialog is interactive; otherwise FALSE.

#### **HWND vpSetuphWnd;**

The window handle of the video post setup dialog.

#### **HWND vphWnd;**

The window handle of the Video Post dialog.

#### **HWND dlghWnd;**

The window handle of the filter's setup dialogue when in "Interactive" mode.

#### **Bitmap \*srcmap**

The Source Bitmap (background). Note: The Video Post output resolution may be retrieved using this pointer. The width is **srcmap->Width()** and the height is **srcmap->Height()**.

#### **Bitmap \*mskmap**

The Image Mask Bitmap (for grayscale masking). This bitmap is at the Video Post output resolution size when the developer needs to access it in the **Render()** method.

#### **Bitmap \*frgmap**

The Foreground Bitmap (for layering/transitions). This bitmap is at the Video Post output resolution size when the developer needs to access it in the

**Render()** method.

**ImageFilterInfo \*ifi**

A pointer to an instance of the class that provides information about this filter and the video post queue.

public:

**TimeChange timeChange;**

This data member is available in release 2.0 and later only.

This class maintains this time change object so it may send

**FLT\_TIMECHANGED** messages.

**UndoNotify\* undonotify;**

This data member is available in release 2.0 and later only.

Points to an instance of the class that can be used so an **ImageFilter** plug-in can get notified on a change to its Track View Node.

**Methods:**

**Constructor / Destructor**

**Prototype:**

**ImageFilter();**

**Remarks:**

Constructor. The **srcmap**, **mskmap** and **frgmap** are set to NULL. The undo notify pointer is set to NULL and the interactive flag is set to FALSE.

**Prototype:**

**virtual ~ImageFilter();**

**Remarks:**

Destructor.

**Max Interface Pointer**

**Prototype:**

**virtual Interface \*Max();**

**Remarks:**

Implemented by the System.

This method returns an interface pointer for calling methods implemented in 3ds max. See [Class Interface](#).

**Description/Copyright/Author/Version****Prototype:**

```
virtual const TCHAR *Description() = 0;
```

**Remarks:**

Implemented by the Plug-In.

Returns an ASCII description of the filter plug-in (i.e. "Convolution Filter").

**Prototype:**

```
virtual const TCHAR *AuthorName() = 0
```

**Remarks:**

Implemented by the Plug-In.

Returns the name of the plug-in's author.

**Prototype:**

```
virtual const TCHAR *CopyrightMessage() = 0
```

**Remarks:**

Implemented by the Plug-In

Returns the plug-in ASCII Copyright message.

**Prototype:**

```
virtual UINT Version() = 0;
```

**Remarks:**

Implemented by the Plug-In.

Returns the plug-in version number \* 100 (i.e. v3.01 = 301).

**Capabilities**

**Prototype:**

**virtual DWORD Capability() = 0**

**Remarks:**

Implemented by the Plug-In.

This method returns a set of flags that describe the capabilities of this filter plug-in. These capabilities indicate if the plug-in is a filter, compositor, or has a control panel. To create a flag, "OR" the capabilities together, ie.

**(IMGFLT\_CONTROL | IMGFLT\_COMPOSITOR)**. Note: It is valid for a plug-in to both a Filter and a Compositor. If both flags are set, the user will be able to select it from both the Filter list and from the Compositor list. The plug-in will know it is running as a filter when the foreground map pointer, **frgmap**, is NULL.

**Return Value:**

See [List of Image Filter Capability Flags](#).

## Dialogs

**Prototype:**

**virtual void ShowAbout(HWND hWnd) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called by the system to display the About Box of the plug-in. This dialog is mandatory so the developer must implement this method.

**Parameters:**

**HWND hWnd**

The parent window handle of the dialog.

**Prototype:**

**virtual BOOL ShowControl(HWND hWnd)**

**Remarks:**

Implemented by the Plug-In.

This method is called by the system to display the control panel for the plug-in. This control panel is optional and its existence should be flagged by the

capability flag returned from **Capability()** (**IMGFLT\_CONTROL**). If a plug-in does not have a control panel, don't implement this method and let it default to FALSE.

**Parameters:**

**HWND hWnd**

The parent window handle of the dialog.

**Return Value:**

TRUE if the user selects OK to exit the dialog, and FALSE if the user selects Cancel.

**Default Implementation:**

```
{ return FALSE; }
```

## Rendering

**Prototype:**

```
virtual BOOL Render(HWND hWnd) = 0
```

**Remarks:**

Implemented by the Plug-In.

This is the method the plug-in implements to alter the image. This method performs the work of the filter or compositor.

**Parameters:**

**HWND hWnd**

The window handle to which the plug-in will be sending progress and abort check messages.

**Return Value:**

TRUE if the render was completed; otherwise FALSE (error or canceled by user).

**Sample Code:**

Below is an example of a render loop through each horizontal band of the image demonstrating the posting of messages. At the start of the loop the progress and check abort messages are sent. The progress message updates the Execute Video Post dialog with how much of the image has been processed. The check abort message allows the plug-in to detect if the user has canceled the operation.

```

BOOL result = TRUE;
BOOL abort = FALSE;
for (int iy = 0; iy < srcmap->Height(); iy++) {
    // Progress Report
    SendMessage(hWnd,FLT_PROGRESS,iy,srcmap->Height()-1);
    // Check for Abort
    SendMessage(hWnd,FLT_CHECKABORT,0,(LPARAM)(BOOL
*)&abort);
    if (abort) {
        result = FALSE;
        break;
    }
}
return(result);

```

Messages are sent via the Window API **SendMessage()** function. See [List of ImageFilter Related Messages](#).

## **Parameter Block Configuration Data**

Parameter Block Load and Save. A 'parameter block' is really nothing more than data a developer wants to load and save. See the sample code below to see how these methods are used to save the data in the UserSettable structure.

```

typedef struct userSettable {
int data1;
float data2;
} UserSettable;

```

```

DWORD MyFilter::EvaluateConfigure () {
return sizeof (UserSettable);
}

```

```

BOOL MyFilter::LoadConfigure (void *ptr) {
UserSettable *buf = (UserSettable *) ptr;
memcpy (&userSettings, ptr, sizeof(UserSettable));
return TRUE;

```

```
}
```

```
BOOL MyFilter::SaveConfigure (void *ptr) {  
if (ptr) {  
memcpy (ptr, &userSettings, sizeof(UserSettable));  
return TRUE;  
} else  
return FALSE;  
}
```

**Prototype:**

```
virtual DWORD EvaluateConfigure()
```

**Remarks:**

Implemented by the Plug-In.

The system will call this method to determine the buffer size required by the plug-in. The plug-in can save its parameter block in this buffer by implementing the **SaveConfigure()** method.

**Return Value:**

The number of bytes required by the plug-in's parameter block.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual BOOL LoadConfigure(void *ptr)
```

**Remarks:**

Implemented by the Plug-In.

This method will be called so the plug-in can load its parameter block.

Memory management is performed by 3ds max using standard **LocalAlloc()** and **LocalFree()**.

**Parameters:**

```
void *ptr
```

A pre-allocated buffer.

**Return Value:**

TRUE if the data was loaded OK; otherwise FALSE.

**Default Implementation:**

```
{ return (FALSE) };
```

**Prototype:**

```
virtual BOOL SaveConfigure(void *ptr)
```

**Remarks:**

Implemented by the Plug-In.

This method will be called so the plug-in can transfer its parameter block to the host.

**Parameters:**

```
void *ptr
```

A pre-allocated buffer the plug-in may write to.

**Return Value:**

TRUE if the data was saved OK; otherwise FALSE.

**Default Implementation:**

```
{ return (FALSE); }
```

**Linear Interpolation****Prototype:**

```
virtual int Lerp(int a, int b, int l);
```

**Remarks:**

This method is used internally.

**Prototype:**

```
virtual int Lerp(int a, int b, float f);
```

**Remarks:**

This method is used internally.

**Preview**

**Prototype:**

```
virtual BOOL CreatePreview(HWND hWnd, Bitmap **back, int
frame, int width, int height, float aspect, Bitmap **fore = NULL,
DWORD flag = PREVIEW_UP);
```

**Remarks:**

Implemented by the System.

This method provides a preview facility for use by plug-ins. This can be used by plug-ins that want to have a preview bitmap while displaying a control dialog.

Note: When you add a new Video Post event, an event object is created and it is added to the event queue when you hit the OK button. However, because the event is added to the queue only when you exit the dialogue, you cannot create a preview at that stage. Later, when you "Edit" the event, it is part of the queue and you can create a preview. Internally, there is no way for 3ds max to tell if the "Setup" button was called from an "Add" event or from an "Edit" event. Plug-In developers can tell if they are in the "Add" event mode by looking at the return value from this method. It will be FALSE if in "Add" mode since the call will fail.

**Parameters:****HWND hWnd**

This window handle will receive progress notification messages. The messages are defined in both BITMAP.H and FILTERS.H:

**FLT\_PROGRESS**

wParam: Current

lParam: Total

**FLT\_CHECKABORT**

wParam: 0

lParam: BOOL\*

**FLT\_TEXTMSG**

wParam: 0

lParam: LPCTSTR

**BMM\_PROGRESS**

wParam: Current

lParam: Total

### **BMM\_CHECKABORT**

wParam: 0

lParam: \*BOOL

### **BMM\_TEXTMSG**

wParam: 0

lParam: LPCTSTR

### **Bitmap \*\*back**

A pointer to the Bitmap Pointer (the Background). If the Bitmap pointer is NULL, a new bitmap is created using the given dimensions. This pointer must be NULL the first time this function is called as the bitmap must be created by Video Post. Once this function is called and a bitmap is returned, it is OK to call it again using this map. In this case, Video Post will simply use it instead of creating a new one. Note: You must NOT delete the bitmap when done -- Video Post will take care of it.

### **int frame**

The desired frame in TICKS. Note that this is the position of the Video Post frame slider (in TICKS) and not the main 3ds max frame slider. See the Advanced Topics section on [Time](#) for details on ticks.

### **int width**

The desired width of the preview.

### **int height**

The desired height of the preview.

### **Float aspect**

The desired aspect ratio of the preview.

### **Bitmap \*\*fore = NULL**

A pointer to the Bitmap Pointer (the Foreground). For layer plug-ins, this points to the foreground image. This is only valid if flag is set to **PREVIEW\_BEFORE**. In this case **back** will hold Video Post main queue and **fore** will have the foreground image to be composited. This is useful if you, a layer plug-in, want to collect the images and run a realtime preview. If flag is not **PREVIEW\_BEFORE**, **fore** will be a NULL pointer indicating there is no bitmap.

## **DWORD flag = PREVIEW\_UP**

The flag controls how much of the queue to run. The options are:

### **PREVIEW\_BEFORE**

The queue is run up to the event before the filter calling it.

### **PREVIEW\_UP**

The queue is run up to the event (filter) calling this function.

### **PREVIEW\_WHOLE**

The whole queue is run including events after this filter.

### **Return Value:**

TRUE if the creation was successful; otherwise FALSE.

## **Channels**

### **Prototype:**

```
virtual DWORD ChannelsRequired();
```

### **Remarks:**

Implemented by the Plug-In.

If a filter wants to work with the G-buffer (geometry/graphics buffer) it implements this method. It is used to indicate what image channels this plug-in requires. Prior to rendering 3ds max will scan the plug-ins in the chain of events and find out all the channels being requested. At the time the plug-in's **Render()** method is called, it will have access to these channels. The methods of class Bitmap may be used to access the channels.

Note: The generation of these channels should not normally be a default setting for the plug-in. These channels are memory intensive and if the plug-in won't use the channel it should not ask for it. Normally the plug-in would ask the user which channels to use and only then set the proper flags.

### **Return Value:**

See [List of Image Channels](#).

### **Default Implementation:**

```
{ return BMM_CHAN_NONE; }
```

## **Filter Control Dialog Interactivity**

**Prototype:**

```
void MakeDlgInteractive(HWND hWnd);
```

**Remarks:**

Implemented by the System.

This method is available in release 2.0 and later only.

This method may be used to allow a filter's dialog to operate interactively.

This means that a user can have the filter's control dialog up and still operate 3ds max and Track View at the same time. This method should be called from the filter's **Control()** method as part of the **WM\_INITDIALOG** code.

Note that even though this method can be called safely for any reason, developers should only call it when using animated parameters. It doesn't make sense to use it for filters with non-animated or no parameters. For sample code using this method see

**\MAXSDK\SAMPLES\POSTFILTERS\NEGATIVE\NEGATIVE.C**

**Parameters:**

**HWND hWnd**

The parent window handle.

**Sample Code:**

```
BOOL ImageFilter_Negative::Control(HWND hWnd,UINT  
message,WPARAM wParam,LPARAM lParam) {  
  switch (message) {  
    case WM_INITDIALOG: {  
      //-- Make Dialogue Interactive  
      MakeDlgInteractive(hWnd);  
      ...
```

**Prototype:**

```
virtual void FilterUpdate();
```

**Remarks:**

This method is available in release 2.0 and later only.

Whenever a filter instance is created or updated (i.e. the user went through the Filter Edit Control dialog) this method is called. The filter may use it to create or update its node controls. For an example see

**\MAXSDK\SAMPLES\POSTFILTERS\NEGATIVE\NEGATIVE.C**

**Default Implementation:**

```
{}
```

**Track View Node Methods**

**Prototype:**

```
BOOL IsInteractive();
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

Returns TRUE if the control dialog is interactive; otherwise FALSE. This means a user can have the filter's control dialog up and still operate 3ds max and Track View at the same time.

**Prototype:**

```
virtual ITrackViewNode *CreateNode();
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

This method may be called to create a new Track View Node.

**Prototype:**

```
virtual ITrackViewNode *Node();
```

**Remarks:**

This method is available in release 2.0 and later only.

Implemented by the System.

This method is used to return the Track View node for this filter.

## Class GBuffer

See Also: [Class GBufReader](#), [Class GBufWriter](#), [List of Image Channels](#), [List of GBuffer Channel Types](#), [Class Bitmap](#).

```
class GBuffer : public InterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This class is used by Bitmaps to implement an enhanced G-Buffer (providing more functionality than the 2.x G-Buffer). The new G-Buffer stores multiple layers at each pixel. The Virtual Frame Buffer includes a new spinner to the right of the "channels" drop down which lets you look at the different layers. (It only appears when there are G-Buffer channels present).

The multiple layers of the G-Buffer allow rendering effects to do better antialiasing and handling of transparency. The frontmost layer is still stored in the G-Buffer as full, screen-sized arrays, one for each channel. The subsequent layers are stored in a variable number of "layer records" all of which are the same size (which depends on which channels have been requested via the **GBuffer::CreateChannels()** function). Even scenes with no transparency can have more than one layer at a given pixel. This can occur along the edges of an object, where the object partially covers some pixels, and another object (or objects) is visible in the remaining part of the pixel. Each visible face in the pixel will be represented by a fragment. A given object will not always appear on the same layer. If it is the only object in a pixel it will be in the frontmost layer, but where it is partially occluded it will lie in a layer behind the occluding object.

Another way multiple layers can occur (aside from transparency) is when objects are given the "Render Occluded Objects" property in the object properties dialog. When an object has this property, it acts as if it were transparent, and objects behind it, though invisible, are rendered and stored in the G-Buffer.

Another G-Buffer layer is added to contain the background color in its color channel for any pixel which is not empty and on which the background gets evaluated. This means the background layer will be present behind transparent objects or objects with "render occluded" turned on. It will also be present along the edges of objects where the background is partially visible in the pixel. Note: This does not depend at all on having the **GB\_BG** flag set. It is necessary to have the **GB\_COLOR** channel, however.

All methods of this class are implemented by the System.

**Note on RPF files:** The following information relates to the layer storage scheme used in the 3ds max RPF files.

The layer information for each scan line is stored as a series of run-encoded channels, each containing the same number of data elements, one per layer record. The first channel is a “psuedo-channel” that contains the x value for each layer record. If there are multiple layers for a given x, this will be reflected as several identical x values in a row.

For instance, if the x channel contained

5,6,7,7,8,8,8,9,10

And the Z channel contained

100, 100, 100,200, 100,200,300, 100, 100

This would mean at pixel 7 there are 2 layers, and pixel 8 there are 3 layers.

Pixel depths

5 100

6 100

7 100, 200

8 100, 200, 300

9 100

10. 100

As an extra note regarding RPF files, a new data member was added to [class RenderInfo](#), which is saved with the RPF (and RLA) files. In order to avoid getting out of sync with previous file format implementations a “version” word preceding the RenderInfo record has been added into the format. The version is set to a value that will distinguish it from the first word of the RenderInfo data, enabling it to determine the version. If we make further additions to RenderInfo in the future, the version will allow us to keep it straight. To load both older and newer RPF and RLA files correctly, the code that loads the RenderInfo been modified, and therefore any plugins and 3rd party code that read these files need to be changed. Here's my the code:

```

#define RENDINFO_VERS1 1000
int RLARender::ReadRenderInfo(RenderInfo *ri) {
short vers;
if (fread(&vers,sizeof(short),1,fd)!=1) return 0;
int size = sizeof(RenderInfo);
if (vers != RENDINFO_VERS1) {
// the old version didn't start with a version word, but
// with projType which is 0 or 1.
size -= sizeof(Rect); // The old record didn't have the region Rect.
fseek(fd,-sizeof(short),SEEK_CUR); // Undo the version read
}
if (ri) {
if (fread(ri,size,1,fd)!=1) return 0;
}
else
fseek(fd, size, SEEK_CUR);
return 1;
}

```

**The following functions are not part of this class but are available for use:**

**Function:**

**GBuffer \*NewDefaultGBuffer();**

**Remarks:**

Creates and returns a pointer to a new default G-Buffer. The buffer is essentially created empty.

A 'default' G-Buffer is one that 3ds max itself creates. See

**GBuffer::IsDefaultGBuffer()** below.

**Function:**

**void SetMaximumGBufferLayerDepth(int m);**

**Remarks:**

Sets the maximum GBuffer layer depth.

**Parameters:**

**int m**

The number to set.

**Function:**

**int GetMaximumGBufferLayerDepth();**

**Remarks:**

Returns the maximum GBuffer layer depth.

**Function:**

**int GBDataSize(int i);**

**Remarks:**

Returns the number of bytes per pixel for the specified channel.

**Parameters:**

**int i**

The index of the channel. See [List of G-Buffer Channel Indexes](#).

**Function:**

**TCHAR \*GBChannelName(int i);**

**Remarks:**

Returns the name of the specified channel.

**Parameters:**

**int i**

The index of the channel. See [List of G-Buffer Channel Indexes](#).

**Return Value:**

The name returned for the specified index:

GB\_Z (0): "Z"

GB\_MTL\_ID (1): "Material Effects"

GB\_NODE\_ID (2): "**Object**"  
GB\_UV (3): "**UV Coordinates**"  
GB\_NORMAL (4): "**Normal**"  
GB\_REALPIX (5): "**Non-Clamped Color**"  
GB\_COVERAGE (6): "**Coverage**"  
GB\_BG (7): "**Coverage Background**"  
GB\_NODE\_RENDER\_ID (8): "**Node Render ID**"  
GB\_COLOR (9): "**Color**"  
GB\_TRANSP10): "**Transparency**"  
GB\_VELOC (11): "**Velocity**"  
GB\_WEIGHT (12): "**Sub-Pixel Weight**"  
GB\_MASK (2): "**Sub-Pixel Coverage Mask**"

**Methods:**

public:

**Prototype:**

**virtual void SetRasterSize(int ww, int hh)=0;**

**Remarks:**

This method is used internally to set the size of the G-Buffer.

**Parameters:**

**int ww**

The width to set in pixels.

**int hh**

The height to set in pixels.

**Prototype:**

**virtual int Width()=0;**

**Remarks:**

Returns the width of the GBuffer.

**Prototype:**

**virtual int Height()=0;**

**Remarks:**

Returns the height of the GBuffer.

**Prototype:**

**virtual int InitBuffer()=0;**

**Remarks:**

Initializes the GBuffer. Call this method before writing to the buffer. If present, the GB\_Z channels is set to -BIGFLOAT and the GB\_NODE\_RENDER\_ID channel is set to 0xffff. The Render ID Name Table is cleared.

**Return Value:**

Nonzero on success; otherwise zero.

**Sample Code:**

```
GBuffer *gbuf = tobm->GetGBuffer();  
if (gbuf) gbuf->InitBuffer();
```

**Prototype:**

**virtual ULONG CreateChannels(ULONG channelMask)=0;**

**Remarks:**

This method creates the specified channels in this G-Buffer.

**Parameters:**

**ULONG channelMask**

Specifies the channels to create. See [List of Image Channels](#).

**Return Value:**

The channels that are currently present.

**Prototype:**

**virtual void DeleteChannels(ULONG channelMask)=0;**

**Remarks:**

This method delete specified channels.

**Parameters:**

## **ULONG channelMask**

Specifies the channels to create. See [List of Image Channels](#).

### **Return Value:**

The channels that are currently present.

### **Prototype:**

```
virtual ULONG ChannelsPresent()=0;
```

### **Remarks:**

Returns the channels that are currently present. See [List of Image Channels](#).

### **Prototype:**

```
virtual void *GetChannel(ULONG channelId, ULONG&  
chanType)=0;
```

### **Remarks:**

Returns a pointer to the specified channel of the G-Buffer, and determines its type in terms of bits per pixel. NULL is returned if the channel can't be found.

### **Parameters:**

**ULONG channelId**

The channel to get. See [List of Image Channels](#).

**ULONG& chanType**

The channel type. See [List of G-Buffer Channel Types](#).

### **Prototype:**

```
virtual GBufReader *CreateReader()=0;
```

### **Remarks:**

Creates and returns a pointer to a **GBufReader** object.

### **Prototype:**

```
virtual void DestroyReader(GBufReader *pRdr)=0;
```

### **Remarks:**

Deletes the specified **GBufReader** object.

### **Parameters:**

**GBufReader \*pRdr**

Points to the reader to delete.

**Prototype:**

**virtual GBufWriter \*CreateWriter()=0;**

**Remarks:**

Creates and returns a pointer to a **GBufWriter** object.

**Prototype:**

**virtual void DestroyWriter(GBufWriter \*pRdr)=0;**

**Remarks:**

Deletes the specified **GBufWriter** object.

**Parameters:**

**GBufWriter \*pRdr**

Points to the writer to delete.

**Prototype:**

**virtual BOOL IsDefaultGBuffer();**

**Remarks:**

Returns TRUE if this is a default G-Buffer; otherwise FALSE. A 'default' G-Buffer is one that 3ds max itself creates. Since GBuffer is a virtual class a plug-in developer could create their own G-Buffers (for some very special purpose). In that case it would not be a 'default' G-Buffer and this method would return FALSE.

**Prototype:**

**virtual void DeleteThis()=0;**

**Remarks:**

Deletes this G-Buffer.

**Prototype:**

**virtual void Copy(GBuffer \*gbfrom)=0;**

**Remarks:**

Copies the data from the specified G-Buffer to this one. This method maintains the multi-layer data correctly. The channels present in each G-Buffer must match.

**Parameters:**

**GBuffer \*gbfrom**

Points to the source of the copy.

**Prototype:**

**virtual void CopyScale(GBuffer \*gbfrom, int cw=-1, int ch=-1)=0;**

**Remarks:**

Copies the data from the specified G-Buffer and optionally scales its size while maintaining the multi-layer data correctly. This is used in Video Post whenever there is an input bitmap that is a different size than the current Video Post image dimensions.

**Parameters:**

**GBuffer \*gbfrom**

Points to the source of the copy.

**int cw=-1**

The width for the copy. If -1 is specified the copy is the same size as the original.

**int ch=-1**

The height for the copy. If -1 is specified the copy is the same size as the original.

**Prototype:**

**virtual void Position(int srcy, int trgy, int srcx, int trgx, int trgw, int trgh)=0;**

**Remarks:**

This method is used internally and is something that normally a developer shouldn't call directly. It is used inside the Bitmap routines for manipulating bitmaps. It takes a sub rectangle of the G-Buffer which has an upper left corner at (srcx,srcy), and dimensions of (trgw,trgh), and moves it to be

positioned at (trgx,trgy). Portions of the G-Buffer outside of this rectangle are discarded.

**Parameters:**

**int srcy**

The source y location.

**int trgy**

The target y location.

**int srcx**

The source x location.

**int trgx**

The target x location.

**int trgw**

The target width.

**int trgh**

The target height.

**Prototype:**

**virtual int NumberLayerRecords(int y)=0;**

**Remarks:**

Returns the total number of layer records for the specified scan line. On each scan line there is a single array of layer records. Each layer record contains an x value which tells at what pixel it is located, and then all of the G-Buffer data that is being stored in this particular G-Buffer. The layer records for a given pixel all have the same x value, and are ordered front-to-back in scene depth.

This method is used by the RLA and RPF writer code. See **\MAXSDK\SAMPLES\IO\RLA\RLA.CPP** for an example.

**Parameters:**

**int y**

The zero based index of the scan line.

**Prototype:**

**virtual int GetLayerChannel(int y, int ichan, char \*data)=0;**

**Remarks:**

This method goes through all the layer records and pulls out the values for a particular channel into an array, which is handy for run-encoding when saving to a file.

**Parameters:**

**int y**

The zero based index of the scan line.

**int ichan**

The channel to check. See [List of G-Buffer Channel Indexes](#). When **ichan=-1**, it gives an array of the x values from each of the layer records.

**char \*data**

Points to storage for the layer data.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual int CreateLayerRecords(int y, int num)=0;**

**Remarks:**

This method creates the specified number of layer records for the scan line passed.

**Parameters:**

**int y**

The zero based index of the scan line.

**int num**

The number of records to create.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual int SetLayerChannel(int y, int ichan, char \*data)=0;**

**Remarks:**

Sets the layer record data for the specified channel for the scan line passed.

**Parameters:**

**int y**

The zero based index of the scan line.

**int ichan**

The channel to set. See [List of G-Buffer Channel Indexes](#). When **ichan=-1**, it sets an array of the x values from each of the layer records.

**char \*data**

Points to storage for the layer data.

**Return Value:**

TRUE on success; otherwise FALSE.

**Prototype:**

**virtual void UpdateChannelMinMax()**=0**;**

**Remarks:**

This method searches the G-Buffer Z, UV and VELOC channels and stores the minimum and maximum values. This enables the **GetChannelMin()** and **GetChannelMax()** methods to work. This is called internally when 3ds max generates a G-Buffer. When developers get one from the renderer this method will already have been called.

**Prototype:**

**virtual BOOL GetChannelMin(int chan, void \*data)**=0**;**

**Remarks:**

Retrieves the minimum value in the specified channel.

**Parameters:**

**int chan**

The channel to check. One of the following (the other channels are not supported):

**GB\_Z**

Z-Buffer depth - **float**

**GB\_UV**

UV coordinates - **Point2**

**GB\_VELOC**

Velocity - **Point2**

**void \*data**

Points to storage for the value to get.

**Return Value:**

TRUE if **chan** was valid and the value could be stored in **data**; otherwise FALSE.

**Prototype:**

**virtual BOOL GetChannelMax(int chan, void \*data)=0;**

**Remarks:**

Retrieves the maximum value in the specified channel.

**Parameters:**

**int chan**

The channel to check. One of the following (the other channels are not supported):

**GB\_Z**

Z-Buffer depth - **float**

**GB\_UV**

UV coordinates - **Point2**

**GB\_VELOC**

Velocity - **Point2**

**void \*data**

Points to storage for the value to get.

**Return Value:**

TRUE if **chan** was valid and the value could be stored in **data**; otherwise FALSE.

**Prototype:**

**virtual NameTab &NodeRenderIDNameTab()=0;**

**Remarks:**

This method returns a reference to the table of node names indexed by their **NodeRenderId**. See [Class NameTab](#).

**Prototype:**

**virtual Tab<float> &ImageBlurMultiplierTab()=0;**

**Remarks:**

This method is available in release 4.0 and later only.

This method returns a reference to a table of floats. These are image blur multipliers indexed by NodeRenderID.

**Prototype:**

**INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0);**

**Remarks:**

This is a general purpose function that allows the API to be extended in the future. The 3ds max development team can assign new **cmd** numbers and continue to add functionality to this class without having to 'break' the API. This is currently reserved for future use.

**Parameters:**

**int cmd**

The command to execute.

**ULONG arg1=0**

Optional argument 1 (defined uniquely for each **cmd**).

**ULONG arg2=0**

Optional argument 2.

**ULONG arg3=0**

Optional argument 3.

**Return Value:**

An integer return value (defined uniquely for each **cmd**).

## Class Effect

See Also: [Class SpecialFX](#), [Class SFXParamDlg](#), [Class IRendParams](#), [Class RenderGlobalContext](#), [Class Bitmap](#), [Class ISave](#), [Class ILoad](#), [Class INode](#), [Class Interface](#).

```
class Effect : public SpecialFX
```

### Description:

This class is available in release 3.0 and later only.

This is the base class used in the creation of Rendering Effect plug-ins. In 3ds max 3.0 these plug-in are added in sequence after a rendering is complete without the use of Video Post. A developer creates a sub-class of this class and implements or calls the methods shown below.

### Plug-In Information:

Class Defined In RENDER.H

Super Class ID RENDER\_EFFECT\_CLASS\_ID

Standard File Name Extension DLV

Extra Include File Needed None

There are also methods in the Interface class for manipulating the Effects List:

```
virtual int NumEffects()=0;  
virtual Effect *GetEffect(int i)=0;  
virtual void SetEffect(int i,Effect *e)=0;  
virtual void AddEffect(Effect *eff)=0;  
virtual void DeleteEffect(int i)=0;
```

### Methods:

public:

### Prototype:

```
virtual EffectParamDlg *CreateParamDialog(IRendParams *ip);
```

### Remarks:

Implemented by the Plug-In.

This method creates and returns a new instance of a class derived from **EffectParamDlg** to manage the user interface. This put up a modal dialog that lets the user edit the plug-ins parameters.

**Parameters:****IRendParams \*ip**

This is the interface given to the rendering effect so it may display its parameters.

**Return Value:**

A new instance of a class derived from **EffectParamDlg**.

Note: **typedef SFXParamDlg EffectParamDlg;**

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL SetDlgThing(EffectParamDlg* dlg);
```

**Remarks:**

You should implement this if you are using the ParamMap2 AUTO\_UI system and the effect has secondary dialogs that have something other than the incoming effect as their 'thing'. Called once for each secondary dialog for you to install the correct thing. Return TRUE if you process the dialog, FALSE otherwise, in which case the incoming effect will be set into the dialog.

Note: Developers needing more information on this method can see the remarks for [MtlBase::CreateParamDlg\(\)](#) which describes a similar example of this method in use (in that case it's for use by a texture map plug-in).

**Parameters:****EffectParamDlg\* dlg**

Points to the ParamDlg.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual DWORD GBufferChannelsRequired(TimeValue t);
```

**Remarks:**

Implemented by the Plug-In.

Returns a DWORD that indicates the channels that this Effect requires in the

output bitmap.

**Parameters:**

**TimeValue t**

The time at which the channels are required.

**Return Value:**

The required channels. See [List of Image Channels](#).

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void Apply(TimeValue t, Bitmap *bm,  
RenderGlobalContext *gc, CheckAbortCallback *cb)=0;
```

**Remarks:**

Implemented by the Plug-In.

This is the method that is called to apply the effect to the bitmap passed.

**Parameters:**

**TimeValue t**

The time at which to apply the effect.

**Bitmap \*bm**

The bitmap the effect modifies and stores the result in.

**RenderGlobalContext \*gc**

This can be used to retrieve information about the global rendering environment.

**CheckAbortCallback \*cb**

Points to an object whose **Check()** method may be called to determine if the user wants to abort. See [Class CheckAbortCallback](#).

**Prototype:**

```
IOResult Save(ISave *isave);
```

**Remarks:**

Implemented by the System.

To facilitate naming rendering effects a 'name' string exists in the base class.

This method should be called at the start of the developer's sub-classed Effect plug-in to save the name.

**Parameters:**

**ISave \*isave**

An interface for saving data.

**Prototype:**

**IOResult Load(ILoad \*iload);**

**Remarks:**

Implemented by the System.

To facilitate naming rendering effects a 'name' string exists in the base class.

This method should be called at the start of the developer's sub-classed Effect plug-in to load the name.

**Parameters:**

**ILoad \*iload**

An interface for loading data.

## Class Osnap

See Also: [Class OsnapHit](#), [Class IOsnapManager](#), [Class OsnapMarker](#), [Structure SnapInfo](#) The Advanced Topics section on [Snapping](#).

```
class Osnap
```

### Description:

This class is available in release 2.0 and later only.

This is the base class for the derivation of a new object snap plug-ins.

Conceptually, the osnap class represents a "rule" for locating points in an object's local space. Typically, an instance of this class will only make sense for certain object types. It's the job of the **ValidInput()** method to filter out uninteresting nodes in the scene. When the scene is traversed, each object which passes the input test will be passed into the **Snap()** method. This method is the workhorse of object snap plug-ins and is responsible for computing, allocating and recording its hits.

For convenience, an object snap plug-in may encompass multiple sub-rules. For example, the shape snap contains rules for computing both tangents and perpendicular points on splines. Therefore many of the methods have an index argument which identifies which sub-snap it applies to.

For sample code see

```
\MAXSDK\SAMPLES\SNAPS\SPHERE\SPHERE.CPP.
```

### Friend Classes:

```
friend class OsnapHit;  
friend class OsnapManager;
```

### Methods:

#### Prototype:

```
Osnap();
```

#### Remarks:

Constructor. The **OsnapManger** interface pointer is initialized.

#### Prototype:

```
virtual ~Osnap();
```

**Remarks:**

Destructor. Internal data structure to the class are freed.

**Prototype:**

```
virtual int numsubs();
```

**Remarks:**

Returns the number of sub-snaps this plug-in provides.

**Default Implementation:**

```
{return 1;}
```

**Prototype:**

```
virtual BOOL IsActive();
```

**Remarks:**

Implemented by the system.

Returns TRUE if any of the sub-snaps are active; otherwise FALSE.

**Prototype:**

```
virtual BOOL GetActive(int index);
```

**Remarks:**

Implemented by the system.

Returns TRUE if any of the indexed sub-snap is active.

**Prototype:**

```
virtual void SetActive(int index, BOOL state);
```

**Remarks:**

Implemented by the system.

Sets the indexed sub-snap to the specified state.

**Prototype:**

```
virtual TCHAR *Category();
```

**Remarks:**

Returns the category string for this plug-in. If the plug-in fails to override this

method, the snap will be added to the "standard" page of the UI.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual Class_ID ClassID();
```

**Remarks:**

Returns the Class\_ID for this plug-in.

**Default Implementation:**

```
{ return Class_ID( 0, 0); }
```

**Prototype:**

```
virtual boolean ValidInput(SClass_ID scid, Class_ID cid)=0;
```

**Remarks:**

This method is used to check if the object whose super class ID and class ID are passed is valid input for this object snap plug-in to snap to.

**Parameters:**

**SClass\_ID scid**

The Super Class ID to check.

**Class\_ID cid**

The Class ID to check.

**Return Value:**

Returns TRUE if the object is OK to snap to; otherwise FALSE.

**Sample Code:**

```
boolean SphereSnap::ValidInput(SClass_ID scid, Class_ID cid){  
    boolean c_ok = FALSE, sc_ok = FALSE;  
    sc_ok |= (scid == GEOMOBJECT_CLASS_ID)? TRUE : FALSE;  
    c_ok |= (cid == Class_ID(SPHERE_CLASS_ID,0))? TRUE :  
    FALSE;  
    return sc_ok && c_ok;  
}
```

**Prototype:**

```
virtual void Snap(Object* pObj, IPoint2 *p, TimeValue t);
```

**Remarks:**

Implemented by the Plug-In.

This is the workhorse of a snap plug-in. This method should compute and record hits on the given object.

**Parameters:****Object\* pObj**

A pointer to an object which passed the valid input test. Note that if this method is called, you can make certain assumption about the class of the object and do appropriate casting as needed.

**IPoint2 \*p**

The cursor position.

**TimeValue t**

The time at which to check.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual BOOL UseCallbacks();
```

**Remarks:**

Developers have the option of placing all their code in a single **Snap()** method or of breaking it up into multiple callbacks. Developers wishing to use callbacks should override this method to return TRUE. Note: if callbacks are used, the **Snap()** method is **not** called.

**Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual int NumCallbacks();
```

**Remarks:**

Returns the number of callbacks used.

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual SnapCallback GetSnapCallback(int sub);
```

**Remarks:**

Returns the specified callback to be used for snapping.

**Parameters:**

**int sub**

The sub-snap index.

**Return Value:**

Note the following typedef -- a **SnapCallback** is simply a pointer to a function passed two arguments:

```
typedef void (*SnapCallback) (Object* pObj, IPoint2 *p) ;
```

**Default Implementation:**

```
{ return NULL;}
```

**Prototype:**

```
virtual BOOL GetSupportedObject(INode *iNode, TimeValue t,  
ObjectState *os);
```

**Remarks:**

This method is provided for future use so that snaps can evaluate the object at arbitrary points in the pipeline. Returns TRUE if the object associated with the node passed is supported; otherwise FALSE. The default implementation calls **ValidInput()** and fills the storage pointed to by os with the object state at the end of the geometry pipeline. This is the same object state returned by EvalWorldState.

**Parameters:**

**INode \*iNode**

The node whose object being checked.

**TimeValue t**

The time at which to check the object.

## **ObjectState \*os**

This pointer should be updated to the **ObjectState** of the object associated with the node by calling **INode::EvalWorldState()**.

### **Default Implementation:**

```
BOOL Osnap::GetSupportedObject(INode *inode, TimeValue t, ObjectState *os) {  
    *os = inode->EvalWorldState(t);  
    assert(os);  
    Class_ID thistype = os->obj->ClassID();  
    unsigned long supertype = os->obj->SuperClassID();  
    return ValidInput(supertype,thistype)?TRUE:FALSE;  
}
```

### **Prototype:**

```
virtual TSTR *snapname(int index)=0;
```

### **Remarks:**

Returns a pointer to the snap's name to be displayed in the user interface.

### **Parameters:**

**int index**

The index of the sub-snap whose name is returned.

### **Prototype:**

```
virtual TSTR *tooltip(int index);
```

### **Remarks:**

Reserved for future use.

### **Parameters:**

**int index**

The index of the sub-snap whose name is returned.

### **Default Implementation:**

```
{return NULL;}
```

**Prototype:**

**virtual OsnapMarker \*GetMarker(int index)=0;**

**Remarks:**

Implemented by the Plug-In.

This method should return a pointer to a (typically static) OsnapMarker. These markers define the identifying markers which get displayed in the viewports.

**Parameters:**

**int index**

The subsnap whose marker the system requires.

**Return Value:**

A pointer to an OsnapMarker. If this method returns NULL, a default marker will be displayed.

**Prototype:**

**virtual WORD HiliteMode();**

**Remarks:**

Implemented by the Plug-In.

Returns a value to indicate the type of highlighting to be done for this snap.

Typically, some part of the objects geometry is illuminated. In some cases it is desirable to illuminate the objects bounding box and occasionally to draw a world space crosshair. The default implementations should normally be used.

**Return Value:**

One or more of the following values:

**HILITE\_NORMAL**

This is the default and indicates that some part of the objects geometry will be hilited. The description of this geometry is recorded in the hitmesh member of the class OsnapHit.

**HILITE\_BOX**

This is return value indicates that the objects bounding box should be drawn as the result of a hit on this object.

**HILITE\_CROSSHAIR**

Reserved for grid snapping. This return value indicates that a world space crosshair should be drawn through the hitpoint.

**Default Implementation:**

```
{return HILITE_NORMAL;}
```

**Prototype:**

```
virtual boolean BeginUI(HWND hwnd);
```

**Remarks:**

This method is reserved for future use.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual void EndUI(HWND hwnd);
```

**Remarks:**

This method is reserved for future use.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual HBITMAP getTools()=0;
```

**Remarks:**

Returns a handle to a bitmap that contains the icons to be displayed for this snap. If there are N subsnaps, this bitmap should contain N icons. The size of an individual icon is 16x15.

**Prototype:**

```
virtual HBITMAP getMasks()=0;
```

**Remarks:**

Returns a handle to a bitmap that contains the masks for the UI icons for this snap plug-in.

**Prototype:**

```
virtual BOOL HitTest(Object* pObj, IPoint2 *p, TimeValue t);
```

**Remarks:**

Implemented by the Plug-In.

Developers may override this method to do additional hit testing on each object as an additional rejection criteria. The default implementation returns TRUE and consequently filters nothing. Note that if this method returns FALSE for a given object, the snap method will never be called for it.

Note: Nodes are always trivially rejected if the cursor position does not fall within the screen space bounding box of the node.

**Parameters:****Object\* pObj**

A pointer to the object returned by GetSupportedObject.

**IPoint2 \*p**

The cursor position.

**TimeValue t**

The time at which to hittest.

**Return Value:**

Returns TRUE if the object is being hit and should be considered for snapping.

**Default Implementation:**

```
{return TRUE;}
```

**Prototype:**

```
virtual WORD AccelKey(int index)=0;
```

**Remarks:**

This method is no longer used.

# Class BitmapIO

See Also: [Class Bitmap](#), [Class BitmapStorage](#), [Class BitmapInfo](#), [Working with Bitmaps](#).

```
class BitmapIO : public BaseInterfaceServer
```

## Description:

This is the base class used by developers creating image loader / saver plug-ins. Developers implement pure virtual methods of this class to load the image, open it for output, write to it, close it, and to provide information about the image loader/saver they are creating. These are properties such as the author name, copyright, image format description, filename extension(s) used, and the capabilities of the image loader / saver.

When a BitmapIO derived image reader reads an image, it creates a storage class that makes sense to it. For example, a paletted 8 bit is perfect for loading GIF's but not for loading 32 bit Targas. The inverse is also true. There is no point in creating a TRUE\_64 storage to load a GIF. Because this is how image buffers are managed, it is also important to note that if a developer writes an image loader that creates images from scratch (a gradient generator for instance), there is no need to have any real memory allocated. The plug-in would simply derive a new type of **BitmapStorage** and provide the pixels through the common methods (virtual buffer), creating them as they are requested.

## Data Members:

protected:

**float gamma;**

The gamma setting.

**Bitmap \*map;**

The Bitmap using this OUTPUT handler.

**BitmapStorage \*storage;**

The storage used by this INPUT handler.

**int openMode;**

The mode that the IO module is open for. See [List of Bitmap Open Mode Types](#).

**BitmapIO \*prevIO;**

A linked list pointer to the previous IO module for multiple outputs of a single bitmap.

**BitmapIO \*nextIO;**

A linked list pointer to the next IO module for multiple outputs of a single bitmap.

public:

**BitmapInfo bi;**

Describes the properties of the bitmap being handled by the instance of this class.

## Methods:

### Output Pixels

public:

#### Prototype:

```
int GetOutputPixels(int x,int y,int pixels,BMM_Color_64  
*ptr,BOOL preMultAlpha=TRUE);
```

**Remarks:**

Implemented by the System.

This method is used by the subclassed BitmapIO to get pixels for output with the appropriate output gamma correction.

**Parameters:****int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**BMM\_Color\_64 \*ptr**

Pointer to storage for the retrieved pixels. See [Structure BMM\\_Color\\_64](#).

**BOOL preMultAlpha=TRUE**

This parameter is available in release 3.0 and later only.

Setting this parameter to FALSE will cause pixels with non-premultiplied alpha to be returned.

**Return Value:**

Nonzero if the pixels were retrieved; otherwise zero.

**Prototype:**

```
int GetDitheredOutputPixels(int x,int y,int pixels,BMM_Color_32 *ptr,BOOL preMultAlpha=TRUE);
```

**Remarks:**

Implemented by the System.

This method is used by the subclassed BitmapIO to get 32 bit pixels for output with the appropriate output gamma correction and dither. Note that this method works on only a single scanline of pixels at a time.

**Parameters:****int x**

Source x location.

**int y**

Source y location.

**int pixels**

Number of pixels to retrieve.

**BMM\_Color\_32 \*ptr**

Pointer to storage for the retrieved pixels. See [Structure BMM\\_Color\\_32](#).

**BOOL preMultAlpha=TRUE**

This parameter is available in release 3.0 and later only.

Setting this parameter to FALSE will cause pixels with non-premultiplied alpha to be returned.

**Return Value:**

Nonzero if the pixels were retrieved; otherwise zero.

**DIB Access****Prototype:**

**PBITMAPINFO GetOutputDib(int depth = 24);**

**Remarks:**

Implemented by the System.

This method is used by the subclassed BitmapIO to get a DIB for output with the appropriate output gamma correction.

**Parameters:**

**int depth = 24**

Specifies the depth of the DIB. This may be either 24 or 32.

**Prototype:**

**PBITMAPINFO GetDitheredOutputDib(int depth = 24);**

**Remarks:**

Implemented by the System.

This methods is used by the subclassed BitmapIO to get a DIB for output with the appropriate output gamma correction and dither.

**Parameters:**

**int depth = 24**

Specifies the depth of the DIB. This may be either 24 or 32.

## Output Gamma Setting

### Prototype:

**float OutputGamma();**

### Remarks:

Implemented by the System.  
Returns the output gamma setting.

## Dithering

### Prototype:

**BOOL DitherTrueColor();**

### Remarks:

Implemented by the System.  
If a BitmapIO wants to do its own dithering, it should call this method to find out if dithering is wanted for true color images. If it is a 24 bit or 32 bit format, it would usually just call **GetDitheredOutputPixels()** instead.

### Return Value:

TRUE if dithering is desired; otherwise FALSE.

### Prototype:

**BOOL DitherPaletted();**

### Remarks:

Implemented by the System.  
If a BitmapIO wants to do its own dithering, it should call this method to find out if dithering is wanted for paletted images.

### Return Value:

TRUE if dithering is desired; otherwise FALSE.

## Palette Computation

### Prototype:

**int CalcOutputPalette(int palsize, BMM\_Color\_48 \*pal);**

**Remarks:**

Calculate a color palette for output color packing for the map that is using this output handler (this is the map pointed at by the protected data member **Bitmap \*map**). This method performs gamma correction. See [Class ColorPacker](#), [Class Quantizer](#).

**Parameters:****int palsize**

The size of the palette to compute.

**BMM\_Color\_48 \*pal**

Storage for the palette.

**Return Value:**

Nonzero if the palette was computed; otherwise zero.

## Open Mode Setting

**Prototype:****inline int OpenMode()****Remarks:**

Implemented by the System.

Returns the open mode setting. See [Bitmap Open Mode Types](#).

## Storage / Bitmap Access

**Prototype:****BitmapStorage \*Storage()****Remarks:**

Implemented by the System.

Returns a pointer to the BitmapStorage for this image input handler.

**Prototype:****inline Bitmap \*Map()****Remarks:**

Implemented by the System.

Returns a pointer to the Bitmap using this output handler.

## Filename Extensions

### Prototype:

```
virtual int ExtCount() = 0
```

### Remarks:

Implemented by the Plug-In.

Returns the number of filename extensions supported by this IO module. For example the EPS plug-in supports "EPS" and "PS", and thus returns 2.

### Prototype:

```
virtual const TCHAR *Ext( int n ) = 0;
```

### Remarks:

Implemented by the Plug-In.

The extensions are accessed using a virtual array. This method returns the 'i-th' filename extension supported by the IO module, (i.e. "EPS").

### Parameters:

**int i**

Specifies which filename extension to return.

## Author/Desc/Copyright/Version

### Prototype:

```
virtual const TCHAR *LongDesc( ) = 0
```

### Remarks:

Implemented by the Plug-In.

Returns a long ASCII description of the image format (i.e. "Targa 2.0 Image File").

### Prototype:

```
virtual const TCHAR *ShortDesc() = 0
```

### Remarks:

Implemented by the Plug-In.

Returns a short ASCII description of the image format (i.e. "Targa").

**Prototype:**

**virtual const TCHAR \*AuthorName() = 0**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Author name of the IO module.

**Prototype:**

**virtual const TCHAR \*CopyrightMessage() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the ASCII Copyright message for the IO module.

**Prototype:**

**virtual UINT Version() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the IO module version number \* 100 (i.e. v3.01 = 301)

## Capabilities

**Prototype:**

**virtual int Capability() = 0;**

**Remarks:**

Implemented by the Plug-In.

Returns the IO module capability flags. These describe the capabilities of the plug-in such as if it supports reading images, writing images, multiple files, and whether it has its own information and control dialog boxes. See

[BitmapIO Capability Flags](#).

## **ShowAbout / ShowImage / ShowControl**

### **Prototype:**

**virtual void ShowAbout( HWND hWnd ) = 0;**

### **Remarks:**

Implemented by the Plug-In.

This method is called to show the plug-in's "About" box. This is called, for example, from the About button of the Add Image Input Event dialog in Video Post.

### **Parameters:**

**HWND hWnd**

The handle of the owner window.

### **Prototype:**

**virtual BOOL ShowImage(HWND hWnd, BitmapInfo \*bi)**

### **Remarks:**

Implemented by the Plug-In.

If the **BMMIO\_OWN\_VIEWER** flag is set in the flags returned from the **Capability()** method, this method will be called whenever the user wants to view an image for this device. This is for devices which can "play" image sequences such as AVIs, FLCs, etc.

### **Parameters:**

**HWND hWnd**

The handle of the owner window.

**BitmapInfo \*bi**

The bitmap to view.

### **Return Value:**

TRUE if the viewing the image was successful; otherwise FALSE.

### **Default Implementation:**

```
{ return FALSE; }
```

### **Prototype:**

## **virtual BOOL ShowControl( HWND hWnd, DWORD flag )**

### **Remarks:**

Implemented by the Plug-In.

Displays the Control Panel of the IO module. This function is only called if the plug-in has defined it supports it (through the Capability flag returned from **Capability()**, ie. **BMMIO\_CONTROLREAD**, etc.). See [BitmapIO Capability Flags](#).

### **Parameters:**

#### **HWND hWnd**

The handle of the owner window.

#### **DWORD flag**

Indicates to the plug-in what operation the control is for (read, write, or generic). See [BitmapIO Capability Flags](#)

### **Return Value:**

If the user exits the box through an OK, this function should return TRUE. If the user cancels out, it will should FALSE. FALSE indicates nothing has changed so the system won't bother asking the plug-in if it wants to save data.

### **Default Implementation:**

```
{ return FALSE; }
```

## **Parameter Block Methods**

The following methods (**EvaluateConfigure()**, **LoadConfigure()**, **SaveConfigure()**) deal with parameter block loading and saving. See the sample code below to see how the EPS BitmapIO plug-in uses these methods.

```
typedef struct userSettable {  
    int units; // Inches or MM  
    int binary; // Whether want binary image data or not  
    int preview; // Whether want TIFF preview in file  
    int orientation; // Options are portrait or landscape  
    int colorType; // Whether image is output as rgb or gray  
    float paperHeight; // Height of output (for centering image)  
    float paperWidth; // Width of output (for centering image)  
    float xResolution; // In dots per inch
```

```
float yResolution; // In dots per inch
} UserSettable;
```

```
DWORD BitmapIO_EPS::EvaluateConfigure () {
return sizeof (UserSettable);
}
```

```
BOOL BitmapIO_EPS::LoadConfigure (void *ptr) {
UserSettable *buf = (UserSettable *) ptr;
memcpy (&userSettings, ptr, sizeof(UserSettable));
return TRUE;
}
```

```
BOOL BitmapIO_EPS::SaveConfigure (void *ptr) {
if (ptr) {
memcpy (ptr, &userSettings, sizeof(UserSettable));
return TRUE;
} else
return FALSE;
}
```

**Prototype:**

```
virtual DWORD EvaluateConfigure( ) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called by 3ds max to determine the buffer size required by the plug-in. The plug-in implements this method and returns the number of bytes of configuration data it needs to save.

**Return Value:**

The buffer size required by the plug-in (in bytes).

**Prototype:**

```
virtual BOOL LoadConfigure( void *ptr ) = 0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called by 3ds max to allow the plug-in to load any configuration data.

**Parameters:**

**void \*ptr**

Pointer initialized to point to the previously saved configuration data.

**Return Value:**

Returns TRUE if the data was loaded properly; otherwise FALSE.

**Prototype:**

**virtual BOOL SaveConfigure( void \*ptr ) = 0;**

**Remarks:**

Implemented by the Plug-In.

This method is called by 3ds max to allow the plug-in to save any configuration data.

**Parameters:**

**void \*ptr**

Pointer initialized to a pre-allocated buffer where the plug-in may save data.

**Return Value:**

Returns TRUE if the data was saved; otherwise FALSE.

**Silent Mode Setting****Prototype:**

**BOOL SilentMode()**

**Remarks:**

Implemented by the System.

Returns the state of the silent mode flag. If this flag is TRUE the plug-in should NOT post a dialog displaying any error messages.

**Prototype:**

## **BMMRES GetFrame(BitmapInfo \*fbi, int \*frame);**

### **Remarks:**

Implemented by the System.

This method is for use with multi-frame sequences. It processes the desired frame based on the user options. For example the user can tell the system to hold on the last frame of the sequence, loop back to the beginning, or return an error. This method does all the checking automatically based on the BitmapInfo object passed and computes the proper frame number.

### **Parameters:**

#### **BitmapInfo \*fbi**

A pointer to the BitmapInfo that contains the user options. This is the instance passed to **Load()**.

#### **int \*frame**

A pointer to an integer to receive the frame number

### **Return Value:**

One of the following values:

**BMMRES\_SUCCESS**

**BMMRES\_BADFRAME**

## Critical Error Handling

### Prototype:

**BMMRES ProcessImageIOError(BitmapInfo \*bi, TCHAR \*string = NULL);**

### Remarks:

Implemented by the System.

This method may be called to present the user with the 3ds max Image IO Error dialog box. The dialog displays the bitmap file name or device name, and the specified error message. The user may choose Cancel or Retry from the dialog. An appropriate value is returned based on the users selection.

This method is used to handle hardware I/O errors automatically or display the given string.

In this method, if Silent Mode is on (for example network rendering is being done), no dialog is presented and **BMMRES\_ERRORTAKENCARE** is returned.

### Parameters:

#### **BitmapInfo \*bi**

A pointer to the BitmapInfo. This is used to retrieve the file or device name (using **bi->Name()** or **bi->Device()**).

#### **TCHAR \*string = NULL**

The error message to present in the dialog. If NULL this method will query the operating system for the last I/O error and give its own interpretation of the error. This will work for all "File Not Found", "Permission Denied", etc. type errors.

### Return Value:

One of the following values:

#### **BMMRES\_ERRORTAKENCARE**

Returned if the user selected OK from the dialog or the error was taken care of (silent mode was on).

#### **BMMRES\_ERRORRETRY**

The user has selected Retry from the dialog.

### Prototype:

## **BMMRES ProcessImageIOError(BitmapInfo \*bi, int errorcode);**

### **Remarks:**

Implemented by the System.

This method may be called to present the user with the 3ds max Image IO Error dialog box displaying the specified error message based on the error code passed. The user may choose Cancel or Retry from the dialog. An appropriate value is returned based on the users selection. If Silent Mode is on (for example network rendering is being done) no dialog is presented and **BMMRES\_ERRORTAKENCARE** is returned.

### **Parameters:**

#### **BitmapInfo \*bi**

A pointer to the BitmapInfo. This is used to retrieve the file or device name (using **bi->Name()** or **bi->Device()**).

#### **int errorcode**

The error code. Pass one of the following values and the string shown to its right will be presented.

**BMMRES\_INTERNALERROR** - Internal Error

**BMMRES\_NUMBEREDFILENAMEERROR** - Error Creating  
Numbered File Name.

**BMMRES\_BADFILEHEADER** - Invalid Image File Header

**BMMRES\_CANTSTORAGE** - Error Creating Image Storage

**BMMRES\_MEMORYERROR** - Memory Error

**BMMRES\_BADFRAME** - Invalid Frame Requested

Any other values produce - Unknown Error

### **Return Value:**

One of the following values:

**BMMRES\_ERRORTAKENCARE**

Returned if the user selected Cancel from the dialog or the error was taken care of (silent mode was on).

**BMMRES\_ERRORRETRY**

The user has selected Retry from the dialog.

### **Sample Code:**

```
BMMRES BitmapIO_JPEG::Write(int frame) {  
    //-- If we haven't gone through an OpenOutput(), leave
```

```

if (openMode != BMM_OPEN_W)
    return (ProcessImageIOError(&bi,BMMRES_INTERNALERROR));
/-- Resolve Filename -----
TCHAR filename[MAX_PATH];
if (frame == BMM_SINGLEFRAME) {
    _tcscpy(filename,bi.Name());
} else {
    if (!BMMCreateNumberedFilename(bi.Name(),frame,filename)) {
        return
(ProcessImageIOError(&bi,BMMRES_NUMBEREDFILENAMEERRO
    }
}

```

## G-Buffer Channels Required

### Prototype:

```
virtual DWORD ChannelsRequired()
```

### Remarks:

Implemented by the Plug-In.

These are the channels required for output. By setting this flag, the plug-in can request that 3ds max generate the given channels. Prior to rendering, 3ds max will scan the plug-ins in the chain of events and list all types of channels being requested. The plug-in, at the time of the **Write()** method, will have access to these channels through the channel interface described in **BitmapStorage**.

### Return Value:

See [List of Image Channels](#).

### Default Implementation:

```
{ return BMM_CHAN_NONE; }
```

## Image Information

### Prototype:

```
virtual BMMRES GetImageInfoDlg( HWND hWnd, BitmapInfo
*bi, const TCHAR *filename = NULL )
```

**Remarks:**

Implemented by the Plug-In.

This method will display a dialog with information about the given bitmap (either defined in **bi.Name()/bi.Device()** or explicitly in the filename passed). The default method will retrieve image information using the mandatory **GetImageInfo()** and display a generic information dialog. If an image loader / writer wants to show its own info dialog, perhaps showing an image property not found in the generic dialog, it can implement its own function (and notify the system using the **BMM\_INFODLG** flag in the capabilities flag).

**Parameters:**

**HWND hWnd**

The parent window handle calling the dialog.

**BitmapInfo \*bi**

Defines the name of the bitmap or device (unless specified below).

**const TCHAR \*filename = NULL**

Specifies the filename to use explicitly.

**Return Value:**

The result of the operation. See [Bitmap Error Codes](#).

**Prototype:**

**virtual BMMRES GetImageInfo( BitmapInfo \*bi ) = 0;**

**Remarks:**

Implemented by the Plug-In.

The BitmapIO module implements this method to initialize the **BitmapInfo** instance passed in with information about the image. This information might be obtained from read the image header for example. The BitmapInfo passed contains the name of the image to get the information about.

**Parameters:**

**BitmapInfo \*bi**

A pointer to an instance of the class **BitmapInfo**.

**Return Value:**

If an error occurs, the plug-in should process the error (display a message if

appropriate) and return **BMMRES\_ERRORTAKENCARE**. If everything went OK, the plug-in should return **BMMRES\_SUCCESS**.

**Sample Code:**

```
bi->SetWidth(640);  
bi->SetHeight(480);  
bi->SetType(BMM_TRUE_24);  
bi->SetAspect(1.0f);  
bi->SetGamma(1.0f);  
bi->SetFirstFrame(0);  
bi->SetLastFrame(0);  
return BMM_SUCCESS;
```

**Prototype:**

```
virtual BMMRES GetImageName( BitmapInfo *bi, TCHAR  
*filename)
```

**Remarks:**

Implemented by the Plug-In.

This method is implemented by image file loaders (IFL handlers). It is called to update the filename passed based on the properties of the BitmapInfo passed. See the implementation of this method in **\MAXSDK\SAMPLES\IO\IFL.CPP**.

**Parameters:**

**BitmapInfo \*bi**

Specifies the properties of the IFL sequence.

**TCHAR \*filename**

The filename to update based on the properties of **bi**.

**Return Value:**

See [Bitmap Error Codes](#).

**Prototype:**

```
virtual void EvalMatch(TCHAR *matchString);
```

**Remarks:**

This method is available in release 2.0 and later only.

The bitmap manager caches images in order to speed its process. When a new image is requested, if it's

already loaded, a pointer to it is passed around as opposed to loading an entire new copy of it. It does so by comparing the image name and the frame number requested (in case of multiframe files and/or devices).

This works fine in most cases, however consider the following scenario. The Accom device generates images just as if you were loading Targa files. The comparison explained above works fine. The problem however, is that within the Accom private setup, you can determine where in the Accom to start reading frames. In other words, you may have a sequence of images recorded in the Accom starting at frame 300 for instance. Once in the Accom setup, you define your starting frame at 300 and whenever 3ds max requests a frame, the Accom driver offsets the requested frame number by 300. For example, when 3ds max is rendering its 10th frame and requests a frame from the Accom (for a Map or for a background, etc.), the Accom will see that 3ds max wants frame 10 and the user had setup the starting frame at 300. After computing the offset the Accom driver returns frame 310. Now, if two or more maps are used in a scene, the cache match mechanism explained above fails as it does not take in consideration the "starting frame" parameter of the Accom driver. For it, the name matches (Accom) and the frame number matches (frame 10 in the example above). If two or more maps start at different positions within the Accom, the first one defined will be used as it satisfies the match.

To handle this condition this new method saves extra information (driver private information) about a frame. Basically, part of the match process is now handled by those drivers that implement this method.

If a driver has some private data (handled by its own setup dialogue) that defines anything in how images are returned (in other words, if different images are returned because of those private settings being different), it must define the **BMMIO\_EVALMATCH** return flag and must also implement this method. The flag is necessary to avoid wasting time setting up instances of the driver just to call the (possibly unimplemented) method.

#### **Parameters:**

**TCHAR \*matchString**

The match string. The driver simply builds a string made of its own "per frame" parameters and returns it so 3ds max can compare it with another

instance of the driver.

## Loading

### Prototype:

```
virtual BitmapStorage *Load( BitmapInfo *bi, Bitmap *map,  
    BMMRES *status ) = 0;
```

### Remarks:

Implemented by the Plug-In.

This is the method that is called to actually load and store the image. This method usually creates the storage for the image data, allocates storage space, and puts the image to the storage one scanline at a time. This method also usually sets the **BitmapIO::openMode** flag to **BMM\_OPEN\_R** to indicate the image is loaded and open for reading.

### Parameters:

#### **BitmapInfo \*bi**

Points to an instance of class BitmapInfo. This has the name of the bitmap / device to load.

#### **Bitmap \*map**

This points to the bitmap to be loaded.

#### **BMMRES \*status**

The result of the bitmap load operation. See [Bitmap Error Codes](#).

### Return Value:

The BitmapStorage created to manages this bitmap.

### Sample Code:

See the **Load()** method of  
**\MAXSDK\SAMPLES\IO\JPEG\JPEG.CPP**.

## Output / Write / Close

### Prototype:

```
virtual int OpenOutput(BitmapInfo *bi, Bitmap *map);
```

### Remarks:

Implemented by the Plug-In.

This method opens the image for output and prepare to write to it. This is the time that the plug-in receives the information about what to write, the flags, etc. When the **Write()** method is called the only thing passed is the frame number.

**Parameters:**

**BitmapInfo \*bi**

The image information.

**Bitmap \*map**

Points to the bitmap to save.

**Return Value:**

Returns nonzero if everything was OK; otherwise 0.

**Sample Code:**

See the **OpenOutput()** method of

**\MAXSDK\SAMPLES\IO\JPEG\JPEG.CPP.**

**Prototype:**

**virtual int Write(int frame);**

**Remarks:**

Implemented by the Plug-In.

This method is called to write the image from the **BitmapStorage** to disk.

The data member **bi** contains the relevant information (for example **bi.Name()** contains the name of the file to write).

**Parameters:**

**DWORD frame**

Specifies the frame to write. For single image formats this will be **BMM\_SINGLEFRAME.**

**Return Value:**

Returns nonzero if everything was OK; otherwise 0.

**Sample Code:**

See the **Write()** method of

**\MAXSDK\SAMPLES\IO\JPEG\JPEG.CPP.**

**Prototype:**

```
virtual int Close(int flag);
```

**Remarks:**

Implemented by the Plug-In.

Closes the output file and saves or discards the changes based on the flag passed.

**Parameters:**

```
int flag
```

See [List of Bitmap Close Types](#).

**Return Value:**

Returns nonzero if output was closed successfully; otherwise 0.

**Sample Code:**

See the **Close()** method of

```
\MAXSDK\SAMPLES\IO\WSD\WSD.CPP.
```

**Internal use****Prototype:**

```
void InitOutputGammaTable(BitmapInfo*bi);
```

**Remarks:**

Implemented by the System.

This method is used internally to build the output gamma table.

**Prototype:**

```
virtual PAVIFILE GetPaviFile();
```

**Remarks:**

Implemented by the System.

This method is used internally.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**inline void SetPrev(BitmapIO \*prev)**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**inline void SetNext(BitmapIO \*next);**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**inline BitmapIO \*Prev();**

**Remarks:**

Implemented by the System.

This method is used internally.

**Prototype:**

**inline BitmapIO \*Next();**

**Remarks:**

Implemented by the System.

This method is used internally.

## Class UtilityObj

See Also: [Class Interface](#), [Class IUtil](#).

class UtilityObj

### Description:

3ds max utility plug-ins are derived from this class. Methods are provided for editing the utilities parameters and responding to changes in the current selection set. An interface pointer is provided for calling the utility methods provided by MAX.

Note: Utility plug-ins are not a direct participant in the geometry pipeline system of 3ds max in the same way modifiers or space warps are. For this reason,

**UtilityObj** plug-ins are not suitable for modifying objects flowing down the pipeline. Use **Modifier** or **WSModifier** plug-ins for this purpose.

Also note: It is possible to create a utility plug-in that uses a modeless dialog box. When 3ds max itself uses modeless dialogs, it disables input to the other open windows such as the Track View, the Materials Editor, etc. In this way, the user cannot perform some action that could disturb the operation of the modeless dialog. For example using Track View, a user could assign a different controller to a node, and a utility plug-in might be accessing keys from the node's previous controller. Since utility plug-ins cannot currently prevent the user from operating these other parts of MAX, developers need to be careful about the use of modeless dialogs.

### Methods:

### Prototype:

```
virtual void BeginEditParams(Interface *ip,IUtil *iu)=0;
```

### Remarks:

Implemented by the Plug-In.

This method is called when the utility plug-in may be used in the Utility branch of the command panel. The plug-in may add rollup pages to the command panel in this method for example.

### Parameters:

#### **Interface \*ip**

An interface pointer you may use to call methods of the Interface class.

**IUtil \*iu**

An interface pointer you may use to close the current utility in the command panel.

**Prototype:**

**virtual void EndEditParams(Interface \*ip,IUtil \*iu)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called when the utility plug-in is done being used in the Utility branch of the command panel (for example if the user changes to the Create branch).

**Parameters:****Interface \*ip**

An interface pointer you may use to call methods of the Interface class.

**IUtil \*iu**

An interface pointer you may use to close the current utility in the command panel.

**Prototype:**

**virtual void SelectionSetChanged(Interface \*ip,IUtil \*iu);**

**Remarks:**

Implemented by the Plug-In.

This method is called when the selection set changes. A plug-in may implement this method to respond to this condition.

**Parameters:****Interface \*ip**

An interface pointer you may use to call methods of the Interface class.

**IUtil \*iu**

An interface pointer you may use to close the current utility in the command panel.

**Prototype:**

**virtual void SetStartupParam(TSTR param);**

**Remarks:**

This method is available in release 2.0 and later only.

This method is called after **BeginEditParams()** when the user starts the utility from the command line with the option **-U** and passes an argument to the utility.

**Parameters:****TSTR param**

The command line argument is passed here.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void DeleteThis()=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to delete the utility object allocated by **ClassDesc::Create()**.

For example if the developer has used the **new** operator to allocate memory for their plug-in class they should implement this method as **{ delete this; }** to delete the plug-in object.

In some cases it may be better to use a single static instance of the plug-in class and not allocate and deallocate memory. For example some of the sample utility plug-ins use a single static instance of their plug-in class. This is done so that if the user moves between branches in the command panel (goes into the Create branch and then returns to the Utility branch) all the utility plug-in parameters remain intact. If the memory was allocated and deallocated each time the parameter would be 'forgotten'. The samples that use a single static instance implement this method as **{ }** (NULL). See the sample code in **\MAXSDK\SAMPLES\UTILITIES\COLCLIP.CPP** for an example.

## Class GUP

See Also: [Class Interface](#), [Class DllDir](#), [Class BitmapManager](#), [Class ITreeEnumProc](#), [Class ILoad](#), [Class ISave](#).

```
class GUP : public InterfaceServer
```

### Description:

This class is available in release 3.0 and later only.

This is the base class for the creation of Global Utility Plug-Ins.

These plug-ins work as follows: At 3ds max startup time, before 3ds max begins its message loop and after all its subsystems are initialized, the GUP Manager will scan the plug-in directory and load all plug-ins with the **"\*.gup"** extension. One by one, the GUP Manager will call the plug-in's **Start()** method. At that point the plug-in would do its initialization and decide if it wants to remain loaded or if it can be discarded. As an option, it is also possible for a GUP plug-in for make 3ds max fail and abort all together. If a plug-in wishes to remain loaded (after returning a **GUPRESULT\_KEEP** result code from the **Start()** method described below), it should start a new thread for its code as there is no other call from 3ds max.

Unlike other 3ds max plug-ins, GUP's do not provide a user interface. If developers of GUP plug-ins desire to present an interface, they can develop a standard 3ds max utility plug-in to do so. See [Class UtilityObj](#). There is some sample code using this technique available in **\MAXSDK\SAMPLES\GUP\COMSRV\MSCOM.CPP**. This Utility plug-in (**COMSRV.DLU**) accesses the COM/DCOM plug-in and allows the user to "register" or "unregister" the COM interface. See the Advanced Topics section [COM/DCOM Interface](#).

### Plug-In Information:

Class Defined In GUP.H

Super Class ID GUP\_CLASS\_ID

Standard File Name Extension GUP

Extra Include File Needed None

**Methods:**

public:

**Prototype:**

**GUP();**

**Remarks:**

Constructor.

**Prototype:**

**virtual ~GUP();**

**Remarks:**

Destructor.

**Prototype:**

**virtual HINSTANCE MaxInst();**

**Remarks:**

Implemented by the System.

Returns the application instance handle of 3ds max itself.

**Prototype:**

**virtual HWND MaxWnd();**

**Remarks:**

Implemented by the System.

Returns the window handle of 3ds max's main window.

**Prototype:**

**virtual DllDir\* MaxDllDir();**

**Remarks:**

Implemented by the System.

Returns a pointer to an instance of a class which provides access to the DLL Directory. This is a list of every DLL loaded in 3ds max

**Prototype:**

**virtual Interface\* Max();**

**Remarks:**

Implemented by the System.

Returns an interface pointer for calling methods provided by 3ds max.

**Prototype:**

**virtual BitmapManager\* Bmi();**

**Remarks:**

Implemented by the System.

Returns a pointer to the bitmap manager which may be used to manage the use of bitmaps within 3ds max.

**Prototype:**

**virtual int EnumTree(ITreeEnumProc \*proc);**

**Remarks:**

Implemented by the System.

This may be called to enumerate every INode in the scene.

**Parameters:**

**ITreeEnumProc \*proc**

This callback object is called once for each INode in the scene.

**Return Value:**

Nonzero if the process was aborted by the callback (**TREE\_ABORT**); otherwise 0.

**Prototype:**

**virtual bool ExecuteStringScript(TCHAR \*string);**

**Remarks:**

Implemented by the System.

This method will execute the specified MAXScript command. If a developer needs to ask 3ds max to do something and this "something" is not implemented within the COM interface, it is possible to send MAXScript

commands through this method (and **ExecuteFileScript()** below). This method will execute whatever string is specified, for instance **ExecuteStringScript("open \"MyScene.max\")**.

**Parameters:**

**TCHAR \*string**

Points to the MAXScript command to execute.

**Return Value:**

TRUE indicates if the command was successfully sent to MAXScript; FALSE if it was not sent. Note that this does not reflect the success of the embedded command.

**Prototype:**

**virtual bool ExecuteFileScript(TCHAR \*file);**

**Remarks:**

Implemented by the System.

This method will execute the specified MAXScript file.

**Parameters:**

**TCHAR \*file**

The file name for the script file.

**Return Value:**

TRUE indicates if the script was successfully sent to MAXScript; FALSE if it was not sent. Note that this does not reflect the result of the script.

**Prototype:**

**virtual DWORD Start()=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called at boot time. At that point the plug-in should do its initialization and decide if it wants to remain loaded or if it can be discarded. As an option, it is also possible for a GUP plug-in for make 3ds max fail and abort all together. Obviously this should be used with caution and plenty of documentation from the part of the developer of the plug-in. If a plug-in wishes to remain loaded (after returning a **GUPRESULT\_KEEP** result

code), it should start a new thread for its code as there is no other call from 3ds max.

**Return Value:**

One of the following values:

**GUPRESULT\_KEEP**

Return this value to have the plug-in remain loaded.

**GUPRESULT\_NOKEEP**

Return this value to discard.

**GUPRESULT\_ABORT**

Return this value to cause 3ds max to shut down.

**Prototype:**

**virtual void Stop()=0;**

**Remarks:**

Implemented by the Plug-In.

The **Stop()** method is called when 3ds max is going down. The GUP Manager will call this methods for all GUP plug-ins that were maintained in memory right before it discards them. This method is called only for plug-ins that returned **GUPRESULT\_KEEP** for the **Start()** method above.

**Prototype:**

**virtual DWORD Control(DWORD parameter);**

**Remarks:**

Implemented by the Plug-In.

This method is an entry point for external access to GUP plug-in. For instance, Utility plug-ins can invoke their GUP plugin counterpart and have direct access to them.

**Parameters:**

**DWORD parameter**

The meaning of this parameter is defined by the plug-in.

**Return Value:**

The return value meaning is also defined by the plug-in.

**Default Implementation:**

```
{ return 0;}
```

**Prototype:**

```
virtual IOResult Save(ISave *isave);
```

**Remarks:**

This method is called to save any data the plug-in may have into the 3ds max file.

**Parameters:**

**ISave \*isave**

An interface used for saving data.

**Prototype:**

```
virtual IOResult Load(ILoad *iload);
```

**Remarks:**

This method is called to load any data the plug-in may have from the 3ds max file.

**Parameters:**

**ILoad \*iload**

An interface used for loading data.

# Class TrackViewUtility

See Also: [Class ITVUtility](#), [Class Interface](#), [Class Control](#).

class TrackViewUtility

## Description:

This class is available in release 2.0 and later only.

This is the base class for Track View Utility plug-ins. These plug-ins are launched via the 'Track View Utility' icon just to the left of the track view name field in the toolbar. Clicking on this button brings up a dialog of all the track view utilities currently installed in the system. Most utilities will probably be modeless floating dialogs, however modal utilities may be created as well.

The developer will derive their classes from this class. Methods are provided to bracket the beginning and ending of parameter editing, and responding to various changes in Track View (such as key selection, time selection, node selection, etc.). There is also a method to delete this instance of the plug-in class.

Sample code is available in

**\MAXSDK\SAMPLES\UTILITIES\RANDKEYS.CPP, ORTKEYS.CPP and SELKEYS.CPP.**

## Plug-In Information:

Class Defined In	TVUTIL.H
Super Class ID	TRACKVIEW_UTILITY_CLASS_ID
Standard File Name Extension	DLU
Extra Include File Needed	None

## Methods:

### Prototype:

**virtual void DeleteThis()=0;**

### Remarks:

This method is called to delete this instance of the plug-in class. This method should free the memory allocated in **ClassDesc::Create()**. See the Advanced Topics section on [Memory Management](#) for more details.

### Prototype:

**virtual void BeginEditParams(Interface \*ip,ITVUtility \*iu);**

**Remarks:**

This method is called to begin editing of the Track View utility plug-in's parameters.

**Parameters:**

**Interface \*ip**

An interface for calling functions provided by 3ds max.

**ITVUtility \*iu**

An interface for allowing track view utilities to access the Track View they are launched from.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void EndEditParams(Interface \*ip,ITVUtility \*iu);**

**Remarks:**

This method is called when the user has closed the Track View utility or Track View itself.

**Parameters:**

**Interface \*ip**

An interface for calling functions provided by 3ds max.

**ITVUtility \*iu**

An interface for allowing track view utilities to access the Track View they are launched from.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void TrackSelectionChanged();**

**Remarks:**

This method is called when the selection of tracks has changed.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void NodeSelectionChanged();
```

**Remarks:**

This method is called when the selection of nodes has changed.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void KeySelectionChanged();
```

**Remarks:**

This method is called when the selection of keys has changed.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void TimeSelectionChanged();
```

**Remarks:**

This method is called when the amount of time selected changes in Edit Time mode. See **ITVUtility::GetTimeSelection()**.

**Default Implementation:**

```
{}
```

**Prototype:**

```
virtual void MajorModeChanged();
```

**Remarks:**

This method is called if the current mode of Track View changes. These are the modes such as Edit Keys, Edit Time, Edit Ranges, Position Ranges, and Edit Function Curves. See **ITVUtility::GetMajorMode()**.

**Default Implementation:**

```
{
```

**Prototype:**

```
virtual void TrackListChanged();
```

**Remarks:**

This method is called when the Track View list is rebuild. This is the list of items that are visible (currently open).

**Default Implementation:**

```
{
```

# Class Renderer

See Also: [Class ReferenceTarget](#), [Class FrameRenderParams](#), [Class RendProgressCallback](#), [Class IRendParams](#), [Class INode](#), [Class ViewParams](#), [Class RendParamDlg](#), [Class RendParams](#), [Class DefaultLight](#).

class Renderer : public ReferenceTarget

## Description:

This is the base class for the creation of plug-in renderers. There are five methods that need to be implemented: **Open()**, **Render()**, **Close()**, **CreateParamDialog()** and **ResetParams()**.

In 3ds max 2.0 and later developers must also implement **ReferenceTarget::Clone()** to support the new Production/Draft renderer capability.

## Methods:

### Prototype:

```
virtual int Open(INode *scene, INode *vnode, ViewParams  
*viewPar, RendParams &rp, HWND hwnd, DefaultLight*  
defaultLights=NULL, int numDefLights=0)=0;
```

### Remarks:

Implemented by the Plug-In.

This method is called once per render. It gives the renderer a chance to build up any data structures which it will use over the course of the render.

### Parameters:

#### **INode \*scene**

The root node of the scene to render. Note: If you are rendering in the Materials Editor, you'll instead get a pointer to the INode that is in the sample slot -- not the root node.

#### **INode \*vnode**

The view node. This may be a camera, a light, or NULL.

#### **ViewParams \*viewPar**

View parameters for rendering orthographic or user viewports. This is used if **\*vnode** is NULL.

## **RendParams &rp**

This class contains a set of common renderer parameters.

### **HWND hwnd**

The owner window for messages.

### **DefaultLight\* defaultLights=NULL**

An array of default lights if there are no user created lights in the scene.

### **int numDefLights=0**

Number of lights in **defaultLights** array.

### **Return Value:**

Nonzero for success, zero for failure.

### **Prototype:**

```
virtual int Render(TimeValue t, Bitmap *tobm,  
FrameRendParams &frp, HWND hwnd, RendProgressCallback  
*prog=NULL, ViewParams *viewPar=NULL)=0;
```

### **Remarks:**

Implemented by the Plug-In.

This method is called to render a frame. It should use the camera or view passed to the **Open()** method. This is called once per frame, and the resulting rendered image is written to **tobm**.

### **Parameters:**

#### **TimeValue t**

The frame to render.

#### **Bitmap \*tobm**

This is the target bitmap. The properties of the bitmap define the render width, height and aspect. See [Class Bitmap](#).

#### **FrameRendParams &frp**

A set of time dependent parameters.

#### **HWND hwnd;**

The owner window handle.

#### **RendProgressCallback \*prog=NULL**

A callback used to allow the renderer to update the rendering dialog. The

renderer may call methods of this class.

**ViewParams \*viewPar=NULL**

This parameter is available in release 2.0 and later only.

This parameter allows you to specify a different view transformation on each render call. For example, you can render a given scene at a given time from many different viewpoints, without calling **Render::Open()** for each one.

**Return Value:**

Nonzero for success, zero for failure.

**Prototype:**

**virtual void Close (HWND hwnd)=0;**

**Remarks:**

Implemented by the Plug-In.

This method is called once when rendering is done. This is where the renderer frees any data structures being held on to. This includes things such as shadow buffers, render-ready meshes, lists of materials, etc.

**Parameters:**

**HWND hwnd**

The owner window handle.

**Prototype:**

**virtual bool ApplyRenderEffects(TimeValue t, Bitmap \*pBitmap, bool updateDisplay=true);**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called to apply the render effects at the specified time value. It should be called between the **Open()** and **Close()** methods.

This can be used during a multi-pass rendering, in order to apply the render effects to the final, blended bitmap.

**Parameters:**

**TimeValue t**

The time to apply the render effects.

**Bitmap \*pBitmap**

Points to the bitmap.

**bool updateDisplay=true**

Passing true indicates that Bitmap's display should be refreshed by the renderer; false indicates it should not be.

**Return Value:**

Returns true if the effects were successfully applied; otherwise false.

**Default Implementation:**

```
{ return false; }
```

**Prototype:**

```
virtual RendParamDlg *CreateParamDialog(IRendParams  
*ir,BOOL prog=FALSE)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to create and return a pointer to an instance of the **RendParamDlg** class. The renderer can add rollup page(s) to the renderer configuration dialog using the **IRendParams** interface passed into this method.

**Parameters:****IRendParams \*ir**

An interface that provides methods for use in displaying parameters, for example this class has methods for adding rollup pages.

**BOOL prog=FALSE**

If TRUE then the rollup page should just display the parameters so the user has them for reference while rendering, they should not be editable.

**Return Value:**

A pointer to an instance of the **RendParamDlg** class. This class will be deleted using **RendParamDlg::DeleteThis()**.

**Prototype:**

```
virtual void ResetParams()=0;
```

**Remarks:**

Implemented by the Plug-In.

This method simply sets all the parameters to their default values.

# Class Shader

See Also: [Class BaseShader](#), [Class MacroRecorder](#).

```
class Shader : public BaseShader
```

## Description:

This class is available in release 3.0 and later only.

This is the class that developers use to create Shader plug-ins. Developers must implement the methods of this class to provide data to the 3ds max interactive renderer so it can properly reflect the look of the shader in the viewports. The methods associated with the actual Shader illumination code are from the base class **BaseShader**.

There are various Get and Set methods defined in this class. Plug-in developers provide implementations for the 'Get' methods which are used by the interactive renderer. The implementations of the 'Set' methods are used when switching between shaders types in the Materials Editor. This is used to transfer the corresponding colors between the old Shader and the new one.

Note that some shaders may not have the exact parameters as called for in the methods. In those case an approximate value may be returned from the 'Get' methods. For example, the Strauss Shader doesn't have an Ambient channel. In that case the Diffuse color is taken and divided by 2 and returned as the Ambient color. This gives the interactive renderer something to work with that might not be exact but is somewhat representative.

## Methods:

```
public:
```

## Prototype:

```
virtual void CopyStdParams(Shader* pFrom)=0;
```

## Remarks:

This method copies the standard shader parameters from **pFrom** to this object. Note that plug-ins typically disable the macro recorder during this operation as the Get and Set methods are called. See the sample code for examples.

## Parameters:

```
Shader* pFrom
```

The source parameters.

**Prototype:**

**virtual BOOL GetLockDS()=0;**

**Remarks:**

Returns TRUE if the Diffuse / Specular lock is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetLockAD()=0;**

**Remarks:**

Returns TRUE if the Ambient / Diffuse lock is on; otherwise FALSE.

**Prototype:**

**virtual BOOL GetLockADTex()=0;**

**Remarks:**

Returns TRUE if the Ambient / Diffuse Texture lock is on; otherwise FALSE.

**Prototype:**

**virtual Color GetAmbientClr(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Ambient Color.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual Color GetDiffuseClr(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Diffuse Color.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual Color GetSpecularClr(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Specular Color.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual Color GetSelfIllumClr(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Self Illumination Color.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual float GetSelfIllum(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Self Illumination Amount.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual float GetGlossiness(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Glossiness Level.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual float GetSpecularLevel(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Specular Level.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual float GetSoftenLevel(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns the Soften Level as a float.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual BOOL IsSelfIllumClrOn(int mtlNum, BOOL backFace)=0;**

**Remarks:**

Returns TRUE if the Self Illumination Color setting is on (checked); FALSE if off.

**Parameters:**

The parameters to this method are not applicable and may safely be ignored.

**Prototype:**

**virtual BOOL IsSelfIllumClrOn()=0;**

**Remarks:**

Returns TRUE if the Self Illumination Color setting is on (checked); FALSE if off.

**Prototype:**

**virtual Color GetAmbientClr(TimeValue t)=0;**

**Remarks:**

Returns the Ambient Color at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the color.

**Prototype:**

**virtual Color GetDiffuseClr(TimeValue t)=0;**

**Remarks:**

Returns the Diffuse Color at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the color.

**Prototype:**

**virtual Color GetSpecularClr(TimeValue t)=0;**

**Remarks:**

Returns the Specular Color at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the color.

**Prototype:**

**virtual float GetGlossiness(TimeValue t)=0;**

**Remarks:**

Returns the Glossiness value at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Prototype:**

**virtual float GetSpecularLevel(TimeValue t)=0;**

**Remarks:**

Returns the Specular Level at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Prototype:**

**virtual float GetSoftenLevel(TimeValue t)=0;**

**Remarks:**

Returns the Soften Specular Highlights setting at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Prototype:**

**virtual float GetSelfIllum(TimeValue t)=0;**

**Remarks:**

Returns the Self Illumination Amount at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the value.

**Prototype:**

**virtual Color GetSelfIllumClr(TimeValue t)=0;**

**Remarks:**

Returns the Self Illumination Color at the specified time.

**Parameters:**

**TimeValue t**

The time at which to return the color.

**Prototype:**

**virtual void SetLockDS(BOOL lock)=0;**

**Remarks:**

Sets the state of the Diffuse / Specular lock to on or off.

**Parameters:**

**BOOL lock**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetLockAD(BOOL lock)=0;**

**Remarks:**

Sets the state of the Ambient / Diffuse lock to on or off.

**Parameters:**

**BOOL lock**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetLockADTex(BOOL lock)=0;**

**Remarks:**

Sets the state of the Ambient / Diffuse Texture lock to on or off.

**Parameters:**

**BOOL lock**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetSelfIllum(float v, TimeValue t)=0;**

**Remarks:**

Sets the Self Illumination parameter to the specified value at the time passed.

**Parameters:**

**float v**

The value to set.

**TimeValue t**

The time to set the value.

**Prototype:**

**virtual void SetSelfIllumClrOn(BOOL on)=0;**

**Remarks:**

Sets the Self Illumination Color On/Off state.

**Parameters:**

**BOOL on**

TRUE for on; FALSE for off.

**Prototype:**

**virtual void SetSelfIllumClr(Color c, TimeValue t)=0;**

**Remarks:**

Sets the Self Illumination Color at the specified time.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time to set the color.

**Prototype:**

**virtual void SetAmbientClr(Color c, TimeValue t)=0;**

**Remarks:**

Sets the Ambient Color at the specified time.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time to set the color.

**Prototype:**

**virtual void SetDiffuseClr(Color c, TimeValue t)=0;**

**Remarks:**

Sets the Diffuse Color at the specified time.

**Parameters:****Color c**

The color to set.

**TimeValue t**

The time to set the color.

**Prototype:**

**virtual void SetSpecularClr(Color c, TimeValue t)=0;**

**Remarks:**

Sets the Specular Color at the specified time.

**Parameters:**

**Color c**

The color to set.

**TimeValue t**

The time to set the color.

**Prototype:**

**virtual void SetGlossiness(float v, TimeValue t)=0;**

**Remarks:**

Sets the Glossiness parameter to the specified value at the time passed.

**Parameters:**

**float v**

The value to set.

**TimeValue t**

The time to set the value.

**Prototype:**

**virtual void SetSpecularLevel(float v, TimeValue t)=0;**

**Remarks:**

Sets the Specular Level parameter to the specified value at the time passed.

**Parameters:**

**float v**

The value to set.

**TimeValue t**

The time to set the value.

**Prototype:**

**virtual void SetSoftenLevel(float v, TimeValue t)=0;**

**Remarks:**

Sets the Soften Specular Highlights Level to the specified value at the time passed.

**Parameters:**

**float v**

The value to set.

**TimeValue t**

The time to set the value.

**Prototype:**

**virtual float EvalHiliteCurve(float x);**

**Remarks:**

This method is called to evaluate the highlight curve that appears in the Shader user interface.

Note: This gets called from the **DrawHilite()** function which is available to developers in

**\MAXSDK\SAMPLES\MATERIALS\SHADER\SHADERUTIL.CP**

**DrawHilite()** get called from the window proc **HiliteWndProc()** in the same file. This code is available to developers to use in their Shader dialog procs.

**Parameters:**

**float x**

The input value.

**Return Value:**

The output value on the curve. A value of 1.0 represents the top of the curve as it appears in the UI. Values greater than 1.0 are okay and simply appear off the top of the graph.

**Default Implementation:**

```
{ return 0.0f; }
```

**Prototype:**

**virtual float EvalHiliteCurve2(float x, float y, int level = 0);**

**Remarks:**

This is the highlight curve function for the two highlight curves which intersect and appear in the UI, for instance in the Anisotropic shader.

**Parameters:****float x**

The x input value.

**float y**

The y input value.

**int level = 0**

This is used by multi-layer shaders to indicate which layer to draw. The draw highlight curve routines use this when redrawing the graph.

**Return Value:**

The output value of the curve.

**Default Implementation:**

```
{ return 0.0f; }
```

## Class Sampler

See Also: [Class SpecialFX](#), [Class SamplingCallback](#), [Class SFXParamDlg](#), [Class ShadeContext](#), [Class Point3](#), [Class Point2](#), [Class ILoad](#), [Class ISave](#).

```
class Sampler : public SpecialFX
```

### Description:

This class is available in release 3.0 and later only.

This is the base class for the creation of Sampler plug-ins which work with the Standard material. These appear in the Super Sampling rollout in the Sampler dropdown. They have an Enable checkbox and a Quality spinner for their user interface. An optional modal dialog may also be presented.

A Sampler is a plug-in that determines where inside a single pixel the shading and texture samples are computed. For some Samplers this pattern is the same for each pixel, for others a different pattern is chosen for each pixel. After determining the sample locations, the sampler calls back to the renderer to compute the shading values. It then averages the resulting shading values and returns its estimate of the final color.

Some Samplers are adaptive. This means that the Sampler decides on-the-fly how many samples to take to achieve its goal. There are many subtleties to adaptive Samplers and many ways to define the adaptive mechanism. The adaptive mechanism used by the R3 Samplers is very simple: take 4 samples, look for the maximum change in any of the color channels, if it's greater than the threshold, then sample the entire pixel according to the given quality. Threshold is an optional parameter that may, but need not be used by adaptive Samplers.

The transfer of control from 3ds max to the Sampler plug-in is as follows: A Sampler is responsible for the sampling loop. It samples until it is done and computes the sum of its samples upon completion. Once the Sampler's **DoSample()** method is called 3ds max no longer has control. This is how adaptive samplers are handled. The **DoSample()** routine will determine how often and where it samples, then it calls the provided **SamplingCallback::SampleAtOffset()** method to have 3ds max compute the shading value.

### Plug-In Information:

Class Defined In SAMPLER.H

Super Class ID SAMPLER\_CLASS\_ID

Standard File Name Extension DLH

Extra Include File Needed None

### Methods:

public:

### Prototype:

```
virtual void DoSamples(Color& c, Color& t, SamplingCallback*  
cb, ShadeContext* sc, MASK mask=NULL)=0;
```

### Remarks:

This is the method where the Sampler plug-in does its sampling loop. Upon completion it returns the color and transparency back to 3ds max in **c** and **t**.

A sampler samples a range of 0.0 to 1.0. For a pixel sampler this range gets mapped to a single pixel. The sampler doesn't need to be concerned with this however. It just works within the 0.0 to 1.0 space determining where to put the samples. Essentially, this method generates a set of points and calls **SamplingCallback::SampleAtOffset()** for each one. Then it sums up the results of the values returned from **SampleAtOffset()**, divides by the number of samples, and stores the results in **c** and **t**.

### Parameters:

#### **Color& c**

This is the output color.

#### **Color& t**

This is the output transparency.

#### **SamplingCallback\* cb**

This is the callback provided by 3ds max which the sampler uses to actually do the sampling.

#### **ShadeContext\* sc**

The Shade Context which provides information about the pixel being sampled.

#### **MASK mask=NULL**

The 64 bit pixel mask. This mask corresponds to the 8x8 sub-pixel area grid. The actual geometry covers only some portion of these bits. This is essentially an 8x8 raster for the inside of the pixel where bits are set over the polygon

being rendered and bits are off for areas not over the polygon. Developers typically only want to sample where the geometry is and thus when the bits are on. If not the results are very poor visually.

Note: Most polygons are quite small in a typically complex scene being rendered. In other words, most polygons that need to get sampled will only have a small number of these mask bits on since the polygons are very small relative to the pixel. For instance, edge on polygons may project down to only a few bits within the pixel. Consequently it is quite possible that there may be zero samples, i.e. no geometry in the mask. Developers need to check for this zero samples condition. If this is the case then a method of **ShadeContext** called **SurfacePtScreen()** is used. This method returns a point which is guaranteed to be on the fragment no matter how small it is. This point can then be used for at least a single sample.

### **Sample Code:**

The following is a brief analysis of the **DoSamples()** method from the Uniform Sampler of 3ds max. This sampler sub-divides the sample area into a grid and samples the pixel at the center point of each grid unit.

This code is from the file

**\\MAXSDK\\SAMPLES\\RENDER\\SAMPLERS\\STDSAMPLERS.CPI**

The complete code is shown below and then a code fragment analysis follows:

```
void UniformSampler::DoSamples(Color& clr, Color&trans,  
SamplingCallback* cb, ShadeContext* sc, MASK mask )
```

```
{
```

```
int sideSamples = GetSideSamples();
```

```
int numSamples = sideSamples * sideSamples;
```

```
DbgAssert( sideSamples > 0 );
```

```
// we map 0...sideSz into 0..1
```

```
float sideSzInv = 1.0f / float(sideSamples);
```

```
float sampleScale = sideSzInv;
```

```
Point2 sample;
```

```
float nSamples = 0.0f;
```

```
clr.r = clr.g = clr.b = trans.r = trans.g = trans.b = 0;
```

```

// Sampling loop
for( int y = 0; y < sideSamples; ++y ) {
    sample.y = (float(y) + 0.5f) * sideSzInv;

    for( int x = 0; x < sideSamples; ++x ) {
        sample.x = (float(x) + 0.5f) * sideSzInv;

        if ( sampleInMask( sample, mask ) ) {
            Color c, t;
            // NB, returns true for unclipped samples
            if (cb->SampleAtOffset( c, t, sample, sampleScale )) {
                clr += c;
                trans += t;
                nSamples += 1.0f;
            }
        }
    }
}

// Check for 0 samples
if ( nSamples == 0.0f ){
    // use frag center if no other samples
    sample = sc->SurfacePtScreen();
    sample.x = frac(sample.x ); sample.y = frac( sample.y );

    cb->SampleAtOffset( clr, trans, sample, 1.0f );
} else {
    clr /= nSamples;
    trans /= nSamples;
}
}

```

The above code is broken into smaller fragments to look at below:

```

int sideSamples = GetSideSamples();

```

Here the sampler is just getting the number of sides in the sampling grid. This is computed based on the Quality spinner in the user interface. In this sampler this results in a number between 2 and 6 (developers can look at the **UniformSampler::GetSideSamples()** method to see this). Thus the resulting sampling grid is 2x2 or 3x3, up to 6x6. Then the number of samples is computed by multiplying the number of sides times itself.

```
int numSamples = sideSamples * sideSamples;
```

Next the side size inverse is computed to know how big the step size is. This is the amount to step along each time.

The sample scale is how large is the piece that's being sampled. For example, if the grid is 2x2 then each sample is scaled by 1/2

```
float sideSzInv = 1.0f / float(sideSamples);
```

```
float sampleScale = sideSzInv;
```

Next the number of samples, and the color and transparency are initialized to zero:

```
Point2 sample;
```

```
float nSamples = 0.0f;
```

```
clr.r = clr.g = clr.b = trans.r = trans.g = trans.b = 0;
```

Then the sampling loop begins. Here the positions of individual sampling points are computed. Each point is then checked to see if it corresponds to a point in the mask (is over a polygon). (The **sampleInMask** function is defined in

```
\MAXSDK\SAMPLES\RENDER\SAMPLERS\SAMPLERUTIL.CI
```

If it is a point that's over a polygon then **SampleAtOffset()** is called. What **SampleAtOffset()** does is turn the passed 2D sample into a 3D sample and returns a color and transparency. These returned values are summed up over the sampling loop (**clr += c; trans += t;**).

```
// Sampling loop
```

```
for( int y = 0; y < sideSamples; ++y ) {  
sample.y = (float(y) + 0.5f) * sideSzInv;
```

```
for( int x = 0; x < sideSamples; ++x ) {  
sample.x = (float(x) + 0.5f) * sideSzInv;
```

```
if ( sampleInMask( sample, mask ) ) {
```

```

Color c, t;
// NB, returns true for unclipped samples
if (cb->SampleAtOffset( c, t, sample, sampleScale )) {
    clr += c;
    trans += t;
    nSamples += 1.0f;
}
}
}
}

```

At the end of the sampling loop a check is done to see if there were zero samples. This is the case if the geometry is very small relative to the pixel. There are two approaches that one might take when there are zero samples. One is to simply return black. A strict 'jitter-type' sampler might do this since, in fact, no samples were hit. This will result in artifacts to the image however. A better approach is to use the **ShadeContext** method **SurfacePtScreen()** to return a point which is guaranteed to be at the center of the fragment. Then this point is passed to **SampleAtOffset()** so a single sample which is on the fragment is used.

If a single sample point was used, **DoSamples()** is finished. The results are in **clr** and **trans** as returned from **SampleAtOffset()**.

If a number of samples was taken, the Colors **clr** and **trans** are divided by the number of samples (**nSamples**) to get the final colors.

```

// Check for 0 samples
if ( nSamples == 0.0f ){
    // use frag center if no other samples
    sample = sc->SurfacePtScreen();
    sample.x = frac(sample.x ); sample.y = frac( sample.y );

    cb->SampleAtOffset( clr, trans, sample, 1.0f );
} else {
    clr /= nSamples;
    trans /= nSamples;
}

```

**Prototype:****virtual int GetNSamples()=0;****Remarks:**

This methods returns the integer number of samples given the current quality setting. If doing adaptive sampling (where the number of samples may vary) return the maximum number of samples possible.

**Prototype:****virtual float GetQuality()=0;****Remarks:**

Returns the sampling quality in the range of 0.0 to 1.0. Quality means how many samples are taken to compute the shade in a pixel. Higher quality is of course achieved by more samples. Quality 0.0 means "minimal", Quality 1.0 means "best", and Quality 0.5 means "good, the default ". Some samplers do not have adjustable quality (like 3ds max 2.5 Star), in which case the quality spinner is disabled and this method is ignored.

**Prototype:****virtual void SetQuality(float value)=0;****Remarks:**

Sets the sampling quality. This is the one default parameter.

**Parameters:****float value**

Quality is nominal with a range of 0.0 to 1.0.

**Prototype:****virtual int SupportsQualityLevels()=0;****Remarks:**

This method returns 0 on "unchangeable", otherwise the number of quality levels.

**Prototype:****virtual BOOL GetEnable()=0;**

**Remarks:**

Returns TRUE if sampling is enabled; otherwise FALSE.

**Prototype:**

**virtual void SetEnable(BOOL samplingOn)=0;**

**Remarks:**

Sets the Enable Sampler state to on or off.

**Parameters:**

**BOOL samplingOn**

TRUE for on; FALSE for off.

**Prototype:**

**virtual TCHAR\* GetDefaultComment()=0;**

**Remarks:**

Returns a comment string for the Sampler which appears in the Materials Editor user interface.

**Prototype:**

**virtual SamplerParamDlg \*CreateParamDialog(HWND hWndParent);**

**Remarks:**

This method creates and puts up a pop-up modal dialog that allows editing the sampler extended parameters (if any).

**Parameters:**

**HWND hWndParent**

The window handle of the parent.

**Return Value:**

Points to the object to manage the dialog. Note: **typedef SFXParamDlg SamplerParamDlg;**

See [Class SFXParamDlg](#).

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

```
virtual BOOL SetDlgThing(EffectParamDlg* dlg);
```

**Remarks:**

You should implement this method if you are using the ParamMap2 AUTO\_UI system and the sampler has secondary dialogs that have something other than the incoming effect as their 'thing'. Called once for each secondary dialog for you to install the correct thing. Return TRUE if you process the dialog, FALSE otherwise, in which case the incoming effect will be set into the dialog.

Note: Developers needing more information on this method can see the remarks for [MtlBase::CreateParamDlg\(\)](#) which describes a similar example of this method in use (in that case it's for use by a texture map plug-in).

**Parameters:**

```
EffectParamDlg* dlg
```

Points to the ParamDlg.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
IOResult Save(ISave *isave);
```

**Remarks:**

Implemented by the System.

This method saves the name of the sampler. This should be called at the start of a plug-in's save methods.

**Parameters:**

```
ISave *isave
```

An interface for saving data.

**Prototype:**

```
IOResult Load(ILoad *iload);
```

**Remarks:**

Implemented by the System.

This method loads the name of the sampler. This should be called at the start of a plug-in's load methods.

**Parameters:****ILoad \*iload**

An interface for loading data.

**Optional Adaptive Sampling Methods (with default implementations)****Prototype:**

```
virtual BOOL SupportsAdaptive();
```

**Remarks:**

Returns TRUE if the sampler is adaptive; otherwise FALSE. If this method returns TRUE the Adaptive On checkbox appears along with the Threshold spinner.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

```
virtual ULONG SupportsStdParams();
```

**Remarks:**

This method determines which of the various optional parameters are displayed. Zero or more of the following values (which may be added together):

**IS\_ADAPTIVE** -- Samples is adaptive in some way.

**ADAPTIVE\_CHECK\_BOX** -- Enable the Adaptive check box.

**ADAPTIVE\_THRESHOLD** -- Enable the adaptive Threshold spinner.

**SUPER\_SAMPLE\_TEX\_CHECK\_BOX** -- Enable the texture Super Sampling check box.

**ADVANCED\_DLG\_BUTTON** -- Enable the Advanced button. This allows an additional popup dialog to be presented to the user. See the

method **ExecuteParamDialog()**.

**OPTIONAL\_PARAM\_0** -- Enable optional spinner 0. See the methods **GetOptionalParamName()**, **GetOptionalParamMax()**, etc.

**OPTIONAL\_PARAM\_1** -- Enable optional spinner 1.

The following option is simply a set of these:

```
R3_ADAPTIVE =  
(IS_ADAPTIVE+ADAPTIVE_CHECK_BOX+ADAPTIVE_THR
```

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void SetTextureSuperSampleOn(BOOL on);
```

**Remarks:**

This method is called on the Sampler to reflect the change in the 'Supersamp. Tex.' checkbox state. This determines whether to cut down the texture sample size of each sample, or whether to always use 1 pixel texture sample size.

**Parameters:**

**BOOL on**

TRUE for on; FALSE for off.

**Default Implementation:**

```
{ }
```

**Prototype:**

```
virtual BOOL GetTextureSuperSampleOn();
```

**Remarks:**

Returns TRUE if Super Sampling is on; otherwise FALSE. See **SetTextureSuperSampleOn()** above.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual void SetAdaptiveOn(BOOL on);**

**Remarks:**

This method is called on the Sampler to reflect the change in the 'Adaptive' checkbox state.

**Parameters:**

**BOOL on**

TRUE for on; FALSE for off.

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual BOOL IsAdaptiveOn();**

**Remarks:**

Returns TRUE if Adaptive is on (checked in the user interface); otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual void SetAdaptiveThreshold(float value);**

**Remarks:**

This method is called on the Sampler to reflect the change in the 'Threshold' spinner.

**Parameters:**

**float value**

The value to set. Range 0-1.

**Default Implementation:**

```
{ }
```

**Prototype:**

**virtual float GetAdaptiveThreshold();**

**Remarks:**

Returns the adaptive threshold setting.

**Default Implementation:**

```
{ return 0.0f; }
```

**Optional Parameter Related Methods****Prototype:**

```
virtual long GetNOOptionalParams();
```

**Remarks:**

Samplers plug-ins support two optional parameter which may be used by the plug-in for its own needs. This methods returns the number of parameters it supports. Note that the max value is 2.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual TCHAR *GetOptionalParamName(long nParam);
```

**Remarks:**

Returns the name of the specified parameter.

**Parameters:**

**long nParam**

The zero based index of the optional parameter: 0 for the first one, 1 for the second.

**Default Implementation:**

```
{ return _T(""); }
```

**Prototype:**

```
virtual float GetOptionalParamMax(long nParam);
```

**Remarks:**

Returns the maximum value of the specified optional parameter.

**Parameters:**

### **long nParam**

The zero based index of the optional parameter: 0 for the first one, 1 for the second.

#### **Default Implementation:**

```
{ return 1.0f; }
```

#### **Prototype:**

```
virtual float GetOptionalParam(long nParam);
```

#### **Remarks:**

Returns the value of the specified optional parameter.

#### **Parameters:**

### **long nParam**

The zero based index of the optional parameter: 0 for the first one, 1 for the second.

#### **Default Implementation:**

```
{ return 0.0f; }
```

#### **Prototype:**

```
virtual void SetOptionalParam(long nParam, float val);
```

#### **Remarks:**

Sets the value of the specified optional parameter.

#### **Parameters:**

### **long nParam**

The zero based index of the optional parameter: 0 for the first one, 1 for the second.

### **float val**

The value to set.

#### **Default Implementation:**

```
{ }
```

#### **Prototype:**

**virtual void ExecuteParamDialog(HWND hWndParent, StdMat2\* mtl);**

**Remarks:**

This method is called to put up a modal dialog which allows editing of the extended parameters. The rest of the operation of 3ds max should be disabled by this modal dialog (which is why you should use **GetMAXHwnd()**). This method is called when the Advanced button is pressed (which is enabled by using the **ADVANCED\_DLG\_BUTTON** flag returned from **SupportsStdParams()**).

**Parameters:**

**HWND hWndParent**

The parent window handle. Use **Interface::GetMAXHwnd()**.

**StdMat2\* mtl**

Points to the owning Standard material.

**Default Implementation:**

**{}**

## Class FilterKernel

See Also: [Class SpecialFX](#), [Class SFXParamDlg](#).

```
class FilterKernel : public SpecialFX
```

### Description:

This class is available in release 3.0 and later only.

This is the plug-in class from which developers sub-class their Anti-aliasing filters. These filters appear in the Render Scene dialog in the Anti-Aliasing section in the Filter dropdown list.

Filter are a very simple plug-in as there are only a few methods that define them. The **KernelFn()** method is the one that does the filtering. The other methods are simply informational.

A filter kernel is nothing but a curve that starts (usually at 0) at some distance R from a center pole. This curve is swept around the center pole forming a volume that is centered at the center of a pixel (0.5,0.5) and extends to cover some of the near neighboring pixels. The height of this filter "hat" gives the weight for each pixel under the filter. To achieve high resolution and good quality this convolution is done at full 8x8 sub-pixel resolution: each subpixel is weighted by the height of the curve above it. This is what the KernelFn() method returns. It is given the distance from the center pole and it returns the weight. This is the only method that computes anything.

Note: When things get rasterized in 3ds max it is done so at a resolution higher than that of the final output raster. 3ds max actually rasterizes the geometry to an 8x8 raster **within each** pixel. This mask is used do hiding and shading operations properly **inside** each pixel. Each of these 64 inside-a-pixel pixels is called a subpixel.

Theoretically, the **KernelFn()** function could get called once for each sub-pixel with the distance of the center of that subpix to the center pole. Of course that would take a great deal of time. Instead 3ds max builds a table at the beginning of a render. This table is slow to build (it requires many calls to **KernelFn()**) but fast to use and gives **exactly** the same answer as doing the computationally intense approach at the sub-pixel level. Thus the **KernelFn()** function can be fairly slow yet the render still happens relatively fast.

### Plug-In Information:

Class Defined In RENDER.H

Super Class ID FILTER\_KERNEL\_CLASS\_ID

Standard File Name Extension DLK

Extra Include File Needed None

**Methods:**

public:

**Prototype:**

**virtual double KernelFn(double x, double y = 0.0)=0;**

**Remarks:**

This is the function that is called to sample the kernel values. This returns the weight of the filtering curve at the specified distance from the center pole of the curve.

**Parameters:**

**double x**

The distance from the center pole of the curve.

**double y = 0.0**

The distance from the center pole of the curve in y (for 2D filters).

**Prototype:**

**virtual bool Is2DKernel()=0;**

**Remarks:**

Most kernels are 1D and hence circularly symmetric about the center pole, but some are 2D like a box or diamond. This method returns true if the filter is 2D and false if 1D.

A 2D kernel uses both parameters of the methods GetKernelSz() and SetKernelSz(). A 1D kernel only uses x; y need not be included in the set. Note that GetKernelSz() always requires both x & y since they are return parameters while a 1D kernel ignores y. Also note that a 2D filter provides a filter function that uses both the x and y parameters.

**Prototype:**

**virtual long GetKernelSupport()=0;**

**Remarks:**

This method returns the kernel 'support'. Support is the integer number of pixels **beyond** the center pixel that are touch in some part by the kernel. Support of 0 is 1x1: the area filter. A support value of 1 is a 3x3 filter, one pixel on all sides of the center. A support of 2 is 5x5. The size of a side of the block is always  $2*Support+1$ . Support confides how many pixels might be touched, but not the exact size of the filter.

**Prototype:**

**virtual long GetKernelSupportY()=0;**

**Remarks:**

For 2D kernels returns the Y support. See **GetKernelSupport()** above.

**Prototype:**

**virtual bool IsVariableSz()=0;**

**Remarks:**

Returns true if the filter is variable size; otherwise false. Size means the distance from the center pole where the filter function becomes essentially 0. In non-variable size filters this width is returned in **GetKernelSz()** and is usually displayed in the greyed out Size box in the user interface. In variable size filters get & set size control the bluriness.

**Prototype:**

**virtual void GetKernelSz(double& x, double& y)=0;**

**Remarks:**

Retrieves the kernel size. A 2D kernel uses both parameters of this method. A 1D kernel only uses x (y is set to 0).

**Parameters:**

**double& x**

The x size is returned here.

**double& y**

The y size is returned here.

**Prototype:****virtual void SetKernelSz(double x, double y = 0.0)=0;****Remarks:**

Stores the kernel size. A 2D kernel stores both parameters of this method. A 1D kernel stores only x.

**Parameters:****double x**

The x value to store.

**double y = 0.0**

The y value to store.

**Prototype:****virtual bool IsNormalized();****Remarks:**

Returning true from this method will disable the built-in normalizer.

Normalized means that if you have some solid color and you filter it, you get the same color out; it is not brighter or darker than the original. With positive only filters this is always possible, but with some negative lobe filters the colors overflow, so they are toned down (produce a slightly darker image, but don't overflow).

The normalizer computes the positive and negative volumes of an arbitrary filter and scales all the filter values by  $1/\text{volume}$  where  $\text{volume} = (\text{posVolume} - \text{abs}(\text{negVolume}))$ . This whole process is turned off and the filter values direct from the plug-in have already been scaled internally when this method returns true.

**Default Implementation:****{ return FALSE; }****Prototype:****virtual bool HasNegativeLobes()=0;****Remarks:**

This method tells the filtering code that it can speed things up potentially by dealing with the positive common only case. Currently this is not taken

advantage of.

**Prototype:**

**virtual TCHAR\* GetDefaultComment()=0;**

**Remarks:**

Returns a pointer to a string which describes the filter. This string is displayed in the static text box in the user interface.

**Prototype:**

**virtual long GetNFilterParams()=0;**

**Remarks:**

There are two optional parameters that may be used by the filter (besides Filter Size). This method returns the number used. If two parameters are used both hidden spinners appear in the Anti-aliasing section of the Render Scene dialog. If only one parameter is used just the top spinner appears. If this method returns nonzero then the methods below are used to supply the names for the parameter(s) and to provide and receive the values.

**Prototype:**

**virtual TCHAR \*GetFilterParamName(long nParam)=0;**

**Remarks:**

Returns a pointer to the string containing the name of the specified parameter.

**Parameters:**

**long nParam**

The index of the parameter (0 or 1).

**Prototype:**

**virtual double GetFilterParam(long nParam)=0;**

**Remarks:**

Returns the specified parameter value.

**Parameters:**

**long nParam**

The index of the parameter (0 or 1).

**Prototype:**

**virtual void SetFilterParam(long nParam, double val)=0;**

**Remarks:**

Stores the value passed for the specified parameter.

**Parameters:**

**long nParam**

The index of the parameter (0 or 1).

**double val**

The value to set.

**Prototype:**

**IOResult Save(ISave \*isave);**

**Remarks:**

Saves the filter name. This should be called at the start of a plug-in's save method.

**Prototype:**

**IOResult Load(ILoad \*iload);**

**Remarks:**

Loads the filter name. This should be called at the start of a plug-in's load method.

## Class ShadowType

### Description:

**This class is only available in release 5 or later.**

The user of GetAreaShadowType() is a linear or area light.

The usage is:

```
void AreaShadowLightObjDesc::createShadowGenerator(
    AreaLight*  light,
    bool        forceShadowBuf
)
{
    ShadowType* shad = light->ActiveShadowType();
    IAreaShadowType* area = shad->GetAreaShadowType();

    // If we aren't forcing Shadow Map and the shadow generator
    // supports area shadows, then create the area shadow generator.
    // The flags are the same as for CreateShdowGenerator
    if (!forceShadowBuf && area != NULL) {
        _areaShadGen = area->CreateAreaShadowGenerator(light, this,
            SHAD_2SIDED)
    } else {
        _shadGen = shad->CreateShadowGenerator(light, this,
SHAD_2SIDED);
    }
}
```

Sampling the area shadows is a little tricky to allow for some optimizaton.

This is an example of the code needed in AreaShadowLightObjDesc::Illuminate.

The variable, sampler, should be local to allow multithreading.

```
AreaShadowSampler* sampler = _areaShadGen->InitializeSampler(  
    alloca(_areaShadGen->GetSamplerSize()));
```

Once the sampler has been initialized, you can calculate the visibility between any point on the light and the point being shaded by using:

```
float atten = sampler->(sc, pointOnLight, shadedNormal,  
lightColor);
```

The value of pointOnLight depends on the type of light we are sampling. If the light is parallel, then pointOnLight needs to be in the local light coordinates. If the light is not parallel, then pointOnLight needs to be in camera coordinates.

## Class ShadowGenerator

See Also: [Class ShadowType](#), [Class ShadBufRenderer](#), [Class RendContext](#), [Class RenderGlobalContext](#), [Class ShadeContext](#), [Class Matrix3](#), [Class Point3](#), [Class Color](#).

class ShadowGenerator

### Description:

This class is available in release 3.0 and later only.

This class is used by a Shadow Type plug-in to generate the shadows. It only exists during a render, with one per instance of the light. Methods of this class perform the shadow buffer creation and sampling.

The ShadowGenerator API allows for two methods of sampling: A generator can use either a "generic" sampling method:

**float Sample(ShadeContext &sc, Point3 &norm, Color& color);**

Or, if it the generator is to work with Volumetric lights, it must use the following sampling shadow-map style interface:

**float Sample(ShadeContext &sc, float x, float y, float z, float xslope, float yslope);**

**BOOL QuickSample(int x, int y, float z);**

**FiltSample(int x, int y, float z, int level);**

**LineSample(int x1, int y1, float z1, int x2, int y2, float z2);**

To indicate that the latter interface is used, the method

**ShadowType::SupportStdMapInterface()** must return TRUE;

**The following functions are not part of this class but are available for use:**

**Function:**

**ShadowType \*NewDefaultShadowMapType();**

**Remarks:**

This global function returns a new default shadow-map shadow generator.

**Function:**

**ShadowType \*NewDefaultRayShadowType();**

**Remarks:**

This global function returns a new default ray-trace shadow generator.

**Methods:**

public:

**Prototype:**

**virtual int Update(TimeValue t, const RendContext& rendCntxt, RenderGlobalContext \*rgc, Matrix3& lightToWorld, float aspect, float param, float clipDist = DONT\_CLIP)=0;**

**Remarks:**

This is called on every frame to create a new shadow buffer for that frame. For example, the objects in the scene will have moved to different position, etc., so a new shadow buffer will need to be set up. See [Class ShadBufRenderer](#) for a helper class used for generating shadow map buffers.

**Parameters:**

**TimeValue t**

The time for the update.

**const RendContext& rendCntxt**

The render context -- this is used for the progress bar.

**RenderGlobalContext \*rgc**

This is used to get an instance list.

**Matrix3& lightToWorld**

The light to world space transformation matrix. This is not necessarily the same as that of the light.

**float aspect**

This is the aspect ratio for non-square buffers. The aspect gives the height/width ratio of the shadow rectangle. The shadow buffer bitmap is always the same number of pixels wide as it is high, but it can be mapped into a non-square rectangle.

**float param**

This is the field-of-view of the light in radians for perspective projections or the width in world coordinates for parallel projections.

### **float clipDist = DONTCLIP**

This parameter specifies the far clipping distance for the light. This is used when the far distance attenuation is turned on, and can result in much more efficient shadow buffer creation. If you have a small scene in the middle of a large complex scene, and the small scene is lit by, for instance, a shadow-casting omni, if you don't use far attenuation the omni has to take into account the entire large scene in its shadow map. Using far attenuation will clip all this outside stuff. Also omnies free up any of their 6 shadow buffer that end up being empty, so this can save memory usage.

#### **Return Value:**

Nonzero on success; otherwise zero.

#### **Prototype:**

```
virtual int UpdateViewDepParams(const Matrix3&  
worldToCam)=0;
```

#### **Remarks:**

If things such as automatic cubic maps or mirror are used, the rendering is done from several different points of view. This method is called to allow the view matrix to be computed and cached so it won't have to be computed over and over again. The shadow buffer caches the matrix that does the transformation from the current view coordinates into its coordinates.

#### **Parameters:**

```
const Matrix3& worldToCam
```

This is the direction the view is looking from. Object coordinates are relative to this 'camera'. This is not always a 'camera', it is just world to whatever view is needed, for example from a mirror.

#### **Return Value:**

Nonzero on success; otherwise zero.

#### **Prototype:**

```
virtual void FreeBuffer()=0;
```

#### **Remarks:**

This method is used to delete the memory associated with the buffer.

**Prototype:**

```
virtual void DeleteThis()=0;
```

**Remarks:**

Call this to destroy the ShadowGenerator.

**Prototype:**

```
virtual float Sample(ShadeContext &sc, Point3 &norm, Color&  
color);
```

**Remarks:**

Generic shadow sampling function. Implement this when **ShadowType::SupportStdMapInterface()** returns FALSE.

This is the Sample method used for ray traced shadows, for example. It takes the color that would illuminate the surface if there were no shadows, and returns a modified value. The shade context provides the point on the surface (**sc.P()**) and **norm** is the normal to the surface.

**Parameters:**

**ShadeContext &sc**

The shade context provides the point on the surface (**sc.P()**).

**Point3 &norm**

This is the normal to the surface.

**Color& color**

The input color.

**Return Value:**

It returns an attenuation, where 1.0 indicates it is not in shadow, and 0.0 indicates it is in shadow.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual float Sample(ShadeContext &sc, float x, float y, float z,  
float xslope, float yslope);
```

**Remarks:**

Implement this method when **ShadowType::SupportStdMapInterface()** returns TRUE. This interface allows illuminated atmospheric.

This method is called to determine how much the point (x, y, z) is in shadow. It returns an attenuation, where 1.0 indicates it is not in shadow, and 0.0 indicates it is in shadow, and potentially a small negative number. A small negative number should be returned when the sample falls outside of the buffer (this is needed in order to fix a problem occurring with Omni Lights when using shadow maps). All shadow generators that implement this function need to do this. The value itself isn't important, as long as it is negative and very small (for instance (-float(1.0e-30))).

**Parameters:**

**ShadeContext &sc**

The shade context.

**float x**

The x coordinate of the point to check. This point is normalized into shadow buffer space. For example if the shadow buffer was 256x256 a point at the center would be 128, 128.

**float y**

The y coordinate of the point to check. This point is normalized into shadow buffer space.

**float z**

The z coordinate of the point to check. This is the distance perpendicular to the light where 0.0 is right at the light.

**float xslope**

This indicates the slope of the surface relative to the shadow buffer in x.

**float yslope**

This indicates the slope of the surface relative to the shadow buffer in y.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual BOOL QuickSample(int x, int y, float z);
```

**Remarks:**

Implement this method when **ShadowType::SupportStdMapInterface()** returns TRUE. This interface allows illuminated atmospheric.

This method determines if the given point is in a shadow. It samples a single pixel in the shadow map.

**Parameters:**

**int x**

The x coordinate of the point to check. This point is normalized into shadow buffer space. For example if the shadow buffer was 256x256 a point at the center would be 128, 128.

**int y**

The y coordinate of the point to check. This point is normalized into shadow buffer space.

**float z**

The z coordinate of the point to check. This is the distance perpendicular to the light where 0.0 is right at the light.

**Return Value:**

TRUE if the point is in shadow; otherwise FALSE.

**Default Implementation:**

```
{ return 1; }
```

**Prototype:**

```
virtual float FiltSample(int x, int y, float z, int level);
```

**Remarks:**

Implement this method when **ShadowType::SupportStdMapInterface()** returns TRUE. This interface allows illuminated atmospheric.

This method is called to determine how much the point (x, y, z) is in shadow. It returns an attenuation, where 1.0 indicates it is not in shadow, and 0.0 indicates it is in shadow. The method **QuickSample()** above looks at a single pixel in the shadow buffer. This method looks at either 4 or 8 pixels (based on the level parameter) to compute the result. The center pixel is given the highest weighting, while the other pixels are given lesser weightings. However this method is still fairly quick, since it doesn't base the weighting on the location within the pixel. This is in contrast to the **Sample()** method above, where the blending of the adjacent pixels is weighted by the position within

the sub-pixel.

**Parameters:**

**int x**

The x coordinate of the point to check. This point is normalized into shadow buffer space. For example if the shadow buffer was 256x256 a point at the center would be 128, 128.

**int y**

The y coordinate of the point to check. This point is normalized into shadow buffer space.

**float z**

The z coordinate of the point to check. This is the distance perpendicular to the light where 0.0 is right at the light.

**int level**

This may be 0 or 1. If 0, four neighboring pixels are blended in. If 1, eight neighboring pixels are blended in.

**Return Value:**

A value in the range 0.0 to 1.0.

**Default Implementation:**

```
{ return 1.0f; }
```

**Prototype:**

```
virtual float LineSample(int x1, int y1, float z1, int x2, int y2, float z2);
```

**Remarks:**

Implement this method when **ShadowType::SupportStdMapInterface()** returns TRUE. This interface allows illuminated atmospherics.

This method is called to sample the shadow map along a line segment. It uses a line between x1, y1 and x2, y2. The z values are interpolated between z1 and z2 and compared to the z value in the shadow map for that pixel.

**Parameters:**

**int x1**

The start x coordinate of the line. This point is normalized into shadow buffer space. For example if the shadow buffer was 256x256 a point at the center

would be 128, 128.

**int y1**

The start y coordinate of the line. This point is normalized into shadow buffer space.

**float z1**

The start z coordinate of the line. This is the distance perpendicular to the light where 0.0 is right at the light.

**int x2**

The end x coordinate of the line. This point is normalized into shadow buffer space.

**int y2**

The end y coordinate of the line. This point is normalized into shadow buffer space.

**float z2**

The end z coordinate of the line. This is the distance perpendicular to the light where 0.0 is right at the light.

**Return Value:**

A value in the range 0.0 to 1.0 which represents how much of the ray was inside the light and how much was outside the light.

**Default Implementation:**

```
{ return 1.0f; }
```

## Class ShadBufRenderer

See Also: [Class ShadowGenerator](#), [Class RendContext](#), [Class RenderGlobalContext](#), [Class ObjLightDesc](#), [Class Matrix3](#).

```
class ShadBufRenderer
```

### Description:

This class is available in release 3.0 and later only.

This class is used to generate a Shadow Buffer which may be used to determine if a point is in shadow or not. The 3ds max shadow maps use this object internally, for example.

There is a global function that creates one of these **ShadBufRenderer** objects. With one of these developers can call its **Render()** method to generate (render) a Shadow Buffer.

The rendered shadow buffer stores a Z distance at every point in the buffer. This can then be used to determine if something is in shadow. To check a certain point you simply see if the Z value is behind the one in the buffer. That is, a shadow buffer tells one, from the point of view of a light, how far it is to the first object for each pixel in the buffer. If the Z point of the thing being shadowed is farther than (behind) the corresponding Z value in the buffer then the thing is in shadow. If it's closer than it is not in shadow.

The main **Render()** method is typically called from the **Update()** method of class **ShadowGenerator** which is called on every frame to create a new shadow buffer.

To use this class you basically do the following:

Allocate an array of floating point values, one float for each point in the shadow buffer:

```
buffer = new float[shadsize*shadsize];
```

Then create a default Shadow Buffer Renderer using the global function provided:

```
ShadBufRenderer *sbr = NewDefaultShadBufRenderer();
```

Then you setup all the parameters for the view, etc prior to calling the **Render()** method to render the buffer. (These parameters are passed in to the **ShadowGenerator::Update()** method).

```
int nRendered = sbr->Render(rc, RGC, buffer, parallel, shadsize,
```

**param, aspect, clipDist, ltDesc, worldToLight);**

You can check the return value to determine if any objects were intersected by the shadow volume. If none were, the shadow buffer can be freed.

```
if (nRendered==0) {  
    delete [] buffer;  
    sbr->DeleteThis();  
    buffer = NULL;  
    return 1;  
}
```

All methods of this class are implemented by the system.

**The following global function is not a member of this class but is available for use:**

**Function:**

```
ShadBufRenderer *NewDefaultShadBufRenderer();
```

**Remarks:**

This global function creates and returns a pointer to a new default shadow buffer renderer.

**Methods:**

public:

**Prototype:**

```
virtual int Render(RendContext &rc, RenderGlobalContext  
*RGC, float *buf, BOOL parallel, int shadsize, float param, float  
aspect, float clipDist, ObjLightDesc *ltDesc, Matrix3  
worldToLight)=0;
```

**Remarks:**

Compute a shadow Z buffer for the current scene from the viewpoint of the light. NOTE: The computed shadow buffer has positive Z values as you go away from the light, which is the reverse of the 3ds max coordinate system.

**Parameters:**

```
RendContext &rc
```

The RendContext which is used for the progress bar API.

**RenderGlobalContext \*RGC**

Points to the RenerGlobalContext which is used to retireve information about the global rendering enviornment (to get an instance list).

**float \*buf**

This is the buffer to render to. This is a pre-allocated array of floats (**shadsize\*shadsize**).

**BOOL parallel**

The projection type. TRUE if parallel projection; FALSE if perspective projection.

**int shadsize**

The size of the buffer (shadsize by shadsize pixels).

**float param**

The view parameter. For a perspective this is the:field-of-view (in radians). For a parallel view this is the width in world coordinates.

**float aspect**

This is the aspect ratio of the buffer projection.

**float clipDist**

The clipping distance. This tells the shadow buffer renderer to not consider objects farther than this distance from light.

**ObjLightDesc \*ltDesc**

This is the descriptor for light that was passed in to CreateShadowGenerator().

**Matrix3 worldToLight**

The world to light transformation matrix for the light.

**Return Value:**

Returns the number of objects that the shadow volume intersected. If this value is 0, the shadow buffer can be freed to save memory.

**Prototype:**

**virtual float Furthest()=0;**

**Remarks:**

After a render, this method returns the farthest Z in the shadow buffer.

**Prototype:**

**virtual float Closest()=0;**

**Remarks:**

After a render, this method returns the closest Z in the shadow buffer.

**Prototype:**

**virtual void DeleteThis()=0;**

**Remarks:**

Deletes this **ShadowBufRenderer** object.

## Class SoundObj

See Also: [Class ReferenceTarget](#), [Class Animatable](#).

```
class SoundObj : public ReferenceTarget
```

### Description:

This is the base class for the creation of sound plug-ins. The 3ds max user may choose a sound plug-in using the File / Preferences... Animation Tab / Sound Plug-In option.

There is always one sound object in the scene. A sound object's primary purpose is to provide a sound track for the scene. The sound object also serves as a clock that controls timing when an animation is played. This ensure the animation is synched to the sound object. This class has methods to start and stop the sound playing, play a specified range of the sound, and toggle the sound on and off.

A sound plug-in can participate in Track View by implementing the methods of Animatable such as **PaintTrack()**. See the Advanced Topics section [Track View](#) for details.

Sound Object plug-ins use a Super Class ID of **SOUNDOBJ\_CLASS\_ID**.

### Methods:

#### Prototype:

```
virtual BOOL Play(TimeValue tStart,TimeValue t0,TimeValue t1,TimeValue frameStep)=0;
```

#### Remarks:

Implemented by the Plug-In.

When the system calls this method the plug-in should loop the playing of sound from time **t0** to **t1** beginning at time **tStart**. It should continue to loop until **Stop()** is called.

#### Parameters:

**TimeValue tStart**

The time to start playing the sound.

**TimeValue t0**

The loop begin range.

**TimeValue t1**

The loop end range.

**TimeValue frameStep**

The frame increment.

**Return Value:**

TRUE if the sound was played; FALSE otherwise.

**Prototype:**

**virtual void Scrub(TimeValue t0,TimeValue t1)=0;**

**Remarks:**

Implemented by the Plug-In.

Implementation of this method is optional. The plug-in should play the amount of sound between time **t0** and **t1**. The sound should only be played once.

**Parameters:**

**TimeValue t0**

The start time for playback.

**TimeValue t1**

The end time for playback.

**Prototype:**

**virtual TimeValue Stop()=0;**

**Remarks:**

Implemented by the Plug-In.

This stops the sound from playing.

**Return Value:**

The time at which the sound was stopped.

**Prototype:**

**virtual TimeValue GetTime()=0;**

**Remarks:**

Implemented by the Plug-In.

This returns the current time as managed by the **SoundObj**.

**Return Value:**

The current time.

**Prototype:**

**virtual BOOL Playing()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the sound is playing; otherwise FALSE.

**Prototype:**

**virtual void SaveSound(PAVIFILE pfile,TimeValue t0,TimeValue t1)=0;**

**Remarks:**

Implemented by the Plug-In.

This saves the sound between the specified times to the specified file.

**Parameters:**

**PAVIFILE pfile**

The file to save the sound track to.

**TimeValue t0**

The start of the time range to save.

**TimeValue t1**

The end of the time range to save.

**Prototype:**

**virtual void SetMute(BOOL mute)=0;**

**Remarks:**

Implemented by the Plug-In.

Sets the sound to mute or toggles it back on. This will be called if the Active checkbox is toggled for example.

**Parameters:**

**BOOL mute**

Specifies if the sound should be muted. TRUE indicates the sound should be

muted; FALSE indicates the sound should be enabled.

**Prototype:**

**virtual BOOL IsMute()=0;**

**Remarks:**

Implemented by the Plug-In.

Returns TRUE if the sound is muted; otherwise FALSE.

**The following function is not a method of class SoundObj but is used by the system internally:**

**Function:**

**SoundObj \*NewDefaultSoundObj();**

**Remarks:**

Implemented by the System.

Returns a new default sound object. This is the standard one provided by 3ds max.

# Class ColPick

See Also: [Class ColorPicker](#), [Class HSVCallback](#), [Class Class\\_ID](#), [Class IPoint2](#), [DWORD--COLORREF Color Format..](#)

class ColPick : public InterfaceServer

## Description:

This class is available in release 3.0 and later only.

This is the base class for the creation of plug-in color selectors. The list of available color pickers appear in the 3ds max user interface in the General page of the Preferences dialog. The chosen picker will be called whenever a user clicks on a 3ds max color swatch control.

## Plug-In Information:

Class Defined In HSV.H

Super Class ID COLPICK\_CLASS\_ID

Standard File Name Extension DLU

Extra Include File Needed HSV.H

## Functions:

These global functions are not part of this class but are used internally by 3ds max to plug in the current color picker. Developers should not need to access these.

## Function:

**ColPick \*SetCurColPick(ColPick \*colpick);**

## Remarks:

This function is available in release 3.0 and later only.

This global function is used internally to establish the current color picker used.

## Parameters:

**ColPick \*colpick**

Points to the color picker to use.

## Return Value:

A pointer to the current color picker.

**Function:**

**ColPick \*GetCurColPick();**

**Remarks:**

This function is available in release 3.0 and later only.

Returns a pointer to the current color picker.

**Methods:**

public:

**Prototype:**

**virtual INT\_PTR ModalColorPicker(HWND hwndOwner,  
DWORD \*lpc, IPoint2 \*spos, HSVCallback \*callBack, TCHAR  
\*name)=0;**

**Remarks:**

Implemented by the Plug-In

This method is called to bring up the modal color picker.

**Parameters:**

**HWND hwndOwner**

The owning window handle

**DWORD \*lpc**

A pointer to the color to be edited. See [DWORD COLORREF Format](#).

**IPoint2 \*spos**

The starting position of the dialog. This is set to ending position on return.

**HSVCallback \*callBack**

This callback is called whenever color changes.

**TCHAR \*name**

The name of color being edited

**Return Value:**

TRUE if the user pressed OK; FALSE on cancel.

**Prototype:**

**virtual ColorPicker \*CreateColorPicker(HWND  
hwndOwner, DWORD initColor, IPoint2\* spos, HSVCallback  
\*pcallback, TCHAR \*name, BOOL isObjectColor=FALSE)=0;**

**Remarks:**

Implemented by the Plug-In

This method is called to create and return a ColorPicker object for the modeless color picker.

**Parameters:****HWND hwndOwner**

The owning window handle.

**DWORD initColor**

The initial value of the color. See [DWORD COLORREF Format](#).

**IPoint2\* spos**

The starting position of dialog.

**HSVCallback \*pcallback**

This callback is called whenever color changes.

**TCHAR \*name**

The name of color being edited.

**BOOL isObjectColor=FALSE**

This indicates the color picker is being used for the object color in the command panel, and the color picker then displays the Add Color button

**Prototype:**

```
virtual const TCHAR *ClassName()=0;
```

**Remarks:**

Implemented by the Plug-In

Returns the name of the class. This name appears in the drop down list of color picker choices.

**Prototype:**

```
virtual Class_ID ClassID()=0;
```

**Remarks:**

Implemented by the Plug-In

Returns the unique ClassID of this plug-in. The Class\_ID for the default color picker is **Class\_ID(DEFAULT\_COLPICK\_CLASS\_ID,0)**.

**Prototype:**

**virtual void DeleteThis()=0;**

**Remarks:**

Implemented by the Plug-In

This method is called to delete this instance of the plug-in class.

**Prototype:**

**virtual INT\_PTR Execute(int cmd, ULONG arg1=0, ULONG arg2=0, ULONG arg3=0)=0;**

**Remarks:**

Implemented by the Plug-In

This method is used for future expansion and is currently not used.

## **Class FrontEndController**

This class and its former purpose has been replaced by the [CUIFrameMgr](#).

## Class MCInputDevice

See Also: [Class MCDeviceBinding](#), [Class IMCapManager](#), [Time](#), [Character Strings](#).

```
class MCInputDevice
```

### Description:

This class is available in release 2.0 and later only.

This is the base class for an input device plug-in. All methods of this class are implemented by the plug-in.

In terms of the motion capture system, the basic item that is plug-able is the motion capture device. This is something like a mouse, joystick, or midi device. Developers implement two classes, this one, **MCInputDevice**, and **MCDeviceBinding**. There is usually only one instance of **MCInputDevice**. This is like the virtual mouse, or the joystick. This represents the actual device. An instance of the device binding represents an instance where a motion capture controller has been bound to a device, i.e. the user has picked the device and assigned it to a parameter. Thus there may be many instances of the device binding. The device binding is part of the reference hierarchy. The device itself doesn't usually have any parameters for the user to adjust -- these are rather part of the device binding.

Some simple sample code for the mouse motion capture device is available in **\MAXSDK\SAMPLES\MOCAP\MCDEVICE.CPP**.

### Methods:

#### Prototype:

```
virtual TSTR DeviceName()=0;
```

#### Remarks:

Returns the name for the input device.

#### Prototype:

```
virtual MCDeviceBinding *CreateBinding()=0;
```

#### Remarks:

The motion capture utility creates a list of all the MCInputDevices in the system. When the user wants to pick one it will call this method. It returns a

new instance of the **MCDeviceBinding** class.

**Prototype:**

**virtual void UtilityStarted(IMCapManager \*im);**

**Remarks:**

This method is called when the user enters the utility.

**Parameters:**

**IMCapManager \*im**

This is an interface into the motion capture manager.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void UtilityStopped(IMCapManager \*im);**

**Remarks:**

This method is called when the user leaves the utility.

**Parameters:**

**IMCapManager \*im**

This is an interface into the motion capture manager.

**Default Implementation:**

**{}**

**Prototype:**

**virtual void Cycle(UINT tick);**

**Remarks:**

This method is called when the user is in 'Record' (capture) mode or 'Test' mode. It is called once per millisecond. For instance the joystick device uses this method. To understand this method consider the following example:

With MIDI you don't call a function to see if a key has been pressed or not -- rather it is a message based system where you're notified if something happens. In contrast to this is the joystick. If the user moves the joystick the program is not notified. Rather a developer must poll the joystick to get its

current position. During motion capture one could poll the joystick at every frame to get its current position. However this approach leads to jittering (aliasing). The problem is that, on average, the joystick is providing a smooth series of values, but instantaneously, the values jump around a bit. So, the joystick motion capture plug-in implements this method to stores the values returned at every millisecond. Then later, when needing to sample the joystick at a certain time, the stored table of values can be averaged and this provides a level of smoothing.

**Parameters:**

**UINT tick**

The time of this call in milliseconds.

**Default Implementation:**

```
{
```

## Class ViewFile

class ViewFile

### Description:

This class allows a developer to replace the file viewer used by 3ds max (This is the "View File" option in 3ds max's File menu). By creating a DLL from this class, and replacing the standard 3ds max ViewFile. DLL the system will always use the developer defined version. Note: To execute this plug-in, put the DLL in the same directory as the 3DSMAX.EXE executable.

The following two functions are called by the system to create and delete the instance of this class that handles the file viewing.

### **void \*ViewFileCreate();**

This function is implemented by the plug-in to create a new instance of this class. For example:

```
void *ViewFileCreate() {  
    return new ViewFile;  
}
```

### **void ViewFileDestroy(ViewFile \*v);**

This function is implemented by the plug-in to delete the instance of this class created above. For example:

```
void ViewFileDestroy(ViewFile *v) {  
    if (v)  
        delete v;  
}
```

### Methods:

### Prototype:

```
void View(HWND hWnd)
```

### Remarks:

Implemented by the Plug-In.

This method is called by the system to bring up the file viewer.

### Parameters:

```
HWND hWnd
```

The parent window handle.

See Also: `\MAXSDK\SAMPLES\VIEWFILE\VIEWFILE.CPP` for an example of the standard 3ds max file viewer.

## Interface Class Overview

See Also: [Links to Interface Classes](#), [Class Interface](#), [Class ViewExp](#), [Class INode](#).

3ds max provides a large number of functions for plug-ins to use. There are two approaches plug-ins may use to call these functions in MAX:

- 1 Plug-Ins can directly call functions in **CORE.DLL**
- 2 They may call methods on an interface pointer.

The primary purpose of **CORE.DLL** is that it contains implementations for some of the methods of the base classes that plug-ins derive their classes from. Plug-Ins generally don't call these methods directly, but instead inherit them as part of their derived class. **CORE.DLL** also has other miscellaneous functions that it exports. Plug-ins link to **CORE.LIB** so they can simply call these methods like any other function.

Unlike **CORE.DLL**, **3DSMAX.EXE** does not export any methods. Instead, a plug-in calls functions in 3ds max through a pointer to an interface class. An interface class is simply a class with no data members and all pure virtual methods. These classes are essentially just a table of function pointers.

Some of these interfaces are general. For example, the class **Interface** provides methods to do things like redraw the viewports, work with standard 3ds max dialog boxes, and work with MAX's coordinate systems. Other interfaces have specific contexts. For instance, the **ViewExp** interface class provides an interface to a viewport. Methods of this interface refer to a specific viewport.

Most interfaces have a specific life time outside of which they must not be used. For instance, when a modifier becomes active in the modify branch of the command panel, its **BeginEditParams()** method is called and an **IObjParams** interface is passed in. This interface pointer is defined to be valid until (and including) the modifier's **EndEditParams()** method is called. If a plug-in were to hang on to the pointer outside of this interval and then call one of its methods, the result would be undefined. Another example is the **INode** interface pointer, which when passed in to **Object::Display()**, is valid for only the duration of the function call.

For a list of all the interfaces into 3ds max see the section [Interface Classes](#).

Note: Developer will often see the storage class attributes **CoreExport** and

**DllExport** in the source code. These attributes are simply Microsoft-specific extensions to the C++ language used to enable 3ds max to export functions, data, and objects from a DLL so that plug-ins may call them.

# Class Point2

See Also: [Class IPoint2](#).

class Point2

## Description:

This class describes a 2D point using float x and y coordinates. Methods are provided to add and subtract points, multiply and divide by scalars, normalize and compute the dot product of two Point2s. All methods are implemented by the system.

## Data Members:

public:

**float x,y;**

The x and y components of the point.

**static const Point2 Origin;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point2(0.0f, 0.0f);**

**static const Point2 XAxis;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point2(1.0f, 0.0f);**

**static const Point2 YAxis;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point2(0.0f, 1.0f);**

## Methods:

Constructors

## Prototype:

**Point2()**

## Remarks:

Constructor. No initialization is performed by this constructor.

## Prototype:

## **Point2(float X, float Y)**

### **Remarks:**

Constructor. Data members are initialized to X and Y.

### **Prototype:**

## **Point2(double X, double Y)**

### **Remarks:**

Constructor. Data members are initialized to X and Y cast as floats.

### **Prototype:**

## **Point2(const Point2& a)**

### **Remarks:**

Constructor. Data members are initialized to a.x and a.y.

### **Prototype:**

## **Point2(float af[2])**

### **Remarks:**

Constructor. Data members are initialized as  $x = af[0]$  and  $y = af[1]$ .

### **Prototype:**

## **Point2& Set(float X, float Y);**

### **Remarks:**

This method is available in release 3.0 and later only.

Sets the x and y coordinate to the values passed and returns a reference to this Point2.

### **Parameters:**

#### **float X**

The new x value.

#### **float Y**

The new y value.

### **Return Value:**

A reference to this **Point2**.

**Prototype:**

**float DotProd(const Point2&) const**

**Remarks:**

Returns the dot product of two Point2's. This is the sum of both x values multiplied together and both y values multiplied together.

**Prototype:**

**float Length() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the length of the point. This is **sqrt(v.x\*v.x+v.y\*v.y)**;

**Prototype:**

**int MaxComponent() const;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns the component with the maximum absolute value.

**Return Value:**

0 for X, 1 for Y, 2 for Z.

**Prototype:**

**int MinComponent() const;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns the component with the minimum absolute value.

**Return Value:**

0 for X, 1 for Y, 2 for Z.

**Prototype:**

**Point2 Normalize() const;**

**Remarks:**

This method is available in release 3.0 and later only.

This method returns a normalized version of this Point2. This method is more accurate than **\*this/Length()** (internal computations are done in double precision).

**Prototype:**

```
int Equals(const Point2& p, float epsilon = 1E-6f);
```

**Remarks:**

This method is available in release 3.0 and later only.

Compares this Point2 and the specified one to see if the x and y values are within plus or minus the specified tolerance.

**Parameters:**

**const Point2& p**

The point to compare.

**float epsilon = 1E-6f**

The tolerance to use in the comparison.

**Return Value:**

Nonzero if the points are 'equal'; otherwise zero.

**Prototype:**

```
Point2& Unify();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to unify (or normalize) this Point2 (in place) and return the result. Internal computations are done in double precision.

**Prototype:**

```
float LengthUnify();
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to unify (or normalize) this Point2 (in place) and return the previous length. Internal computations are done in double precision.

**Operators:**

**Prototype:**

**float& operator[](int i)  
const float& operator[](int i) const**

**Remarks:**

Allows access to x, y using the subscript operator.

**Return Value:**

A value for **i** of 0 will return x, 1 will return y.

**Prototype:**

**operator float\*()**

**Remarks:**

Returns the address of the Point2.x

**Prototype:**

**Point2 operator-() const**

**Remarks:**

Unary -. Negates both x and y.

**Return Value:**

A Point2 with -x, -y.

**Prototype:**

**Point2 operator+() const**

**Remarks:**

Unary +. Returns the point unaltered.

**Return Value:**

Returns the Point2 unaltered.

**Prototype:**

**Point2& operator-=(const Point2&)**

**Remarks:**

Subtracts a Point2 from this Point2.

**Return Value:**

A Point2 that is the difference between two Point2s.

**Prototype:**

**Point2& operator+=(const Point2&)**

**Remarks:**

Adds a Point2 to this Point2.

**Return Value:**

A Point2 that is the sum of two Point2's.

**Prototype:**

**Point2& operator\*=(float)**

**Remarks:**

Multiplies this Point2 by a floating point value.

**Return Value:**

A Point2 multiplied by a float.

**Prototype:**

**Point2& operator/=(float)**

**Remarks:**

Divides this Point2 by a floating point value.

**Return Value:**

A Point2 divided by a float.

**Prototype:**

**Point2 operator-(const Point2&) const**

**Remarks:**

Subtracts a Point2 from a Point2.

**Return Value:**

A Point2 that is the difference between two Point2's.

**Prototype:**

**Point2 operator+(const Point2&) const**

**Remarks:**

Adds a Point2 to a Point2.

**Return Value:**

The sum of two Point2's.

**Prototype:**

**float operator\*(const Point2&) const**

**Remarks:**

Returns the dot product of two Point2's. This is the sum of both x values multiplied together and both y values multiplied together.

**Prototype:**

**int operator==(const Point2& p) const**

**Remarks:**

Equality operator. Compares two Point2's.

**Return Value:**

Nonzero if the Point2's are equal; otherwise 0.

The following functions are not methods of class Point2 but are available for use:

**Prototype:**

**Point2 operator\*(float, const Point2&)**  
**Point2 operator\*(const Point2&, float)**

**Remarks:**

Each returns a Point2 multiplied by a scalar.

**Prototype:**

**Point2 operator/(const Point2&, float)**

**Remarks:**

Returns a Point2 whose x and y members are divided by a scalar.

**Prototype:**

**ostream &operator<<(ostream&, const Point2&)**

**Remarks:**

Formats the Point2 for output as in:

**(x, y)**

**Function:**

**float Length(const Point2& v)**

**Remarks:**

Returns the length of the Point2, ie:

**sqrt(v.x\*v.x+v.y\*v.y);**

**Function:**

**int MaxComponent(const Point2&)**

**Remarks:**

Returns the component with the maximum absolute value. 0=x, 1=y.

**Function:**

**int MinComponent(const Point2&)**

**Remarks:**

Returns the component with the minimum absolute value. 0=x, 1=y.

**Function:**

**Point2 Normalize(const Point2&)**

**Remarks:**

Returns a unit vector. This is a Point2 with each component divided by the point **Length()**.

# Class Point3

See Also: [Class IPoint3](#), [Class DPoint3](#), [Class Matrix3](#).

class Point3

## Description:

This class describes a 3D point using float x, y and z coordinates. Methods are provided to add and subtract points, multiply and divide by scalars, and element by element multiply and divide two points.

This class is also frequently used to simply store three floating point values that may not represent a point. For example, a color value where x=red, y=green, and z=blue. For color, the range of values is 0.0 to 1.0, where 0 is 0 and 1.0 is 255. All methods are implemented by the system.

Note: In 3ds max, all vectors are assumed to be row vectors. Under this assumption, multiplication of a vector with a matrix can be written either way (Matrix\*Vector or Vector\*Matrix), for ease of use, and the result is the same -- the (row) vector transformed by the matrix.

## Data Members:

public:

**float x, y, z;**

The x, y and z components of the point.

**static const Point3 Origin;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point3(0.0f, 0.0f, 0.0f);**

**static const Point3 XAxis;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point3(1.0f, 0.0f, 0.0f);**

**static const Point3 YAxis;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point3(0.0f, 1.0f, 0.0f);**

**static const Point3 ZAxis;**

This data member is available in release 3.0 and later only.

This is equivalent to **Point3(0.0f, 0.0f, 1.0f);**

**Methods:**

**Prototype:**

**Point3()**

**Remarks:**

Constructor. No initialization is performed.

**Prototype:**

**Point3(float X, float Y, float Z)**

**Remarks:**

Constructor. x, y, and z are initialized to the values specified.

**Prototype:**

**Point3(double X, double Y, double Z)**

**Remarks:**

Constructor. x, y, and z are initialized to the specified values (cast as floats).

**Prototype:**

**Point3(int X, int Y, int Z)**

**Remarks:**

Constructor. x, y, and z are initialized to the specified values (cast as floats).

**Prototype:**

**Point3(const Point3& a)**

**Remarks:**

Constructor. x, y, and z are initialized to the specified Point3.

**Prototype:**

**Point3(float af[3])**

**Remarks:**

Constructor. x, y, and z are initialized to af[0], af[1], and af[2] respectively.

**Operators:**

**Prototype:**

```
float& operator[](int i)
const float& operator[](int i) const
```

**Remarks:**

Allows access to x, y and z using the subscript operator.

**Return Value:**

An value for **i** of 0 will return x, 1 will return y, 2 will return z.

**Prototype:**

```
operator float*()
```

**Remarks:**

Conversion function. Returns the address of the Point3.x

**Prototype:**

```
Point3 operator-() const
```

**Remarks:**

Unary - operator. Negates x, y and z.

**Prototype:**

```
Point3 operator+() const
```

**Remarks:**

Unary +. Returns the Point3.

**Prototype:**

```
inline Point3& operator--=(const Point3&);
```

**Remarks:**

Subtracts a Point3 from this Point3.

**Prototype:**

```
inline Point3& operator+=(const Point3&);
```

**Remarks:**

Adds a Point3 to this Point3.

**Prototype:**

**inline Point3& operator\*=(float);**

**Remarks:**

Multiplies this Point3 by a floating point value.

**Prototype:**

**inline Point3& operator/=(float);**

**Remarks:**

Divides this Point3 by a floating point value.

**Prototype:**

**inline Point3& operator\*=(const Point3&);**

**Remarks:**

Element-by-element multiplication of two Point3s:  
(**x\*x, y\*y, z\*z**).

**Prototype:**

**int operator==(const Point3& p) const**

**Remarks:**

Equality operator. Test for equality between two Point3's.

**Return Value:**

Nonzero if the Point3's are equal; otherwise 0.

**Prototype:**

**inline Point3 operator-(const Point3&) const;**

**Remarks:**

Subtracts a Point3 from a Point3.

**Prototype:**

**inline Point3 operator+(const Point3&) const;**

**Remarks:**

Adds a Point3 to a Point3.

**Prototype:**

**inline Point3 operator/(const Point3&) const;**

**Remarks:**

Divides a Point3 by a Point3 element by element.

**Prototype:**

**inline Point3 operator\*(const Point3&) const;**

**Remarks:**

Multiplies a Point3 by a Point3 element by element.  
(**x\*x, y\*y, z\*z**).

**Prototype:**

**Point3 operator^(const Point3&) const;**

**Remarks:**

The cross product of two Point3's (vectors).

**Return Value:**

The cross product of two Point3's.

**The following functions are not methods of Point3 but are available for use:**

**Prototype:**

**inline float Length(const Point3& v)**

**Remarks:**

Returns the 'Length' of the point (vector). This is:  
**sqrt(v.x\*v.x+v.y\*v.y+v.z\*v.z)**

**Prototype:**

**inline float FLength(const Point3& v)**

**Remarks:**

Returns the 'Length' of the point (vector) using a faster assembly language implementation for square root. This is:

**Sqrt(v.x\*v.x+v.y\*v.y+v.z\*v.z)**

**Prototype:**

**inline float LengthSquared(const Point3& v)**

**Remarks:**

The 'Length' squared of the point. This is **v.x\*v.x+v.y\*v.y+v.z\*v.z**.

**Prototype:**

**int MaxComponent(const Point3&);**

**Remarks:**

Returns the component with the maximum absolute value. 0=x, 1=y, 2=z.

**Prototype:**

**int MinComponent(const Point3&);**

**Remarks:**

Returns the component with the minimum absolute value. 0=x, 1=y, 2=z.

**Prototype:**

**Point3 Normalize(const Point3&);**

**Remarks:**

Returns a normalized unit vector. This is a Point3 with each component divided by the point **Length()**.

**Prototype:**

**Point3 FNormalize(const Point3&);**

**Remarks:**

Returns a normalized unit vector using faster assembly language code than that used by **Normalize()**. This is a Point3 with each component divided by

the point **Length()**.

**Prototype:**

**inline Point3 operator\*(float f, const Point3& a)**

**Remarks:**

Returns a Point3 that is the specified Point3 multiplied by the specified float.

**Prototype:**

**inline Point3 operator\*(const Point3& a, float f)**

**Remarks:**

Returns a Point3 that is the specified Point3 multiplied by the specified float.

**Prototype:**

**inline Point3 operator/(const Point3& a, float f)**

**Remarks:**

Returns a Point3 that is the specified Point3 divided by the specified float.

**Prototype:**

**inline Point3 operator+(const Point3& a, float f)**

**Remarks:**

Returns a Point3 that is the specified Point3 with the specified floating point valued added to each component x, y, and z.

**Prototype:**

**inline float DotProd(const Point3& a, const Point3& b);**

**Remarks:**

Returns the dot product of two Point3s. This is the sum of each of the components multiplied together, element by element

**$a.x*b.x+a.y*b.y+a.z*b.z$**

The dot product has the property of equaling the product of the magnitude (length) of the two vector times the cosine of the angle between them.

**Prototype:**

**Point3 CrossProd(const Point3& a, const Point3& b);**

**Remarks:**

This returns the cross product of the specified Point3's (vectors). The cross product of two vectors is a third vector, perpendicular to the plane formed by the two vectors.

**Prototype:**

**ULONG CompressNormal(Point3 p);**

**Remarks:**

This function will compress a normal vector from 12 bytes to 4 bytes. The vector has to be  $\leq 1.0$  in length.

**Prototype:**

**Point3 DeCompressNormal(ULONG n);**

**Remarks:**

This function may be used to decompress a surface normal from the G-Buffer (ie the **BMM\_CHAN\_NORMAL** channel). The Point3 returned is normalized. The decompressed vector has absolute error  $<.001$  in each component.

## Class Matrix3

See Also: [Class Point3](#), [Matrix Representations of 3D Transformations](#), [Class Quat](#), [Class AngAxis](#), [Structure AffineParts](#), [Class BigMatrix](#).

class Matrix3

### Description:

This class implements a 4x3 3D transformation matrix object. Methods are provided to zero the matrix, set it to the identity, compute its inverse, apply incremental translation, rotation and scaling, and build new X, Y and Z rotation matrices. Operators are provided for matrix addition, subtraction, and multiplication. All methods are implemented by the system.

Note: In 3ds max, all vectors are assumed to be row vectors. Under this assumption, multiplication of a vector with a matrix can be written either way (Matrix\*Vector or Vector\*Matrix), for ease of use, and the result is the same -- the (row) vector transformed by the matrix.

### Data Members:

private:

**float m[4][3];**

Matrix storage.

**DWORD flags;**

Matrix Identity Flags.

**POS\_IDENT**

Indicates the translation row of the matrix is the identity.

**ROT\_IDENT**

Indicates the rotation elements of the matrix are the identity.

**SCL\_IDENT**

Indicates the scale elements of the matrix are the identity.

**MAT\_IDENT**

Indicates the matrix is the identity matrix. This is equivalent to **(POS\_IDENT|ROT\_IDENT|SCL\_IDENT)**.

public:

**static const Matrix3 Identity;**

This data member is available in release 3.0 and later only.

An instance of an identity matrix.

**Methods:**

**Prototype:**

**Matrix3()**

**Remarks:**

Constructor. Note that no initialization is done. Use **Zero()** or **Identity()**, or the constructors below.

**Prototype:**

**Matrix3(BOOL init)**

**Remarks:**

Constructor. If TRUE is passed to the method the matrix is set to the identity.

**Parameters:**

**BOOL init**

Specifies if the Matrix3 should be initialized to the identity.

**Prototype:**

**Matrix3(float (\*fp)[3]);**

**Remarks:**

Constructor. The matrix is initialized to **fp**.

**Parameters:**

**float (\*fp)[3]**

Specifies the initial values for the matrix.

**Prototype:**

**Matrix3(const Point3& U, const Point3& V, const Point3& N,  
const Point3& T);**

**Remarks:**

This method is available in release 3.0 and later only.

Constructor. Initializes the matrix with the row data passed and validates the matrix flags.

**Parameters:**

**const Point3& U**

The data for row 0.

**const Point3& V**

The data for row 1.

**const Point3& N**

The data for row 2.

**const Point3& T**

The data for row 3.

**Prototype:**

**void SetNotIdent()**

**Remarks:**

This clears the **MAT\_IDENT** flag to indicate the matrix is not the identity. If any changes are made to components directly via **GetAddr()**, this method must be called.

**Prototype:**

**Remarks:**

**void SetIdentFlags(DWORD f)**

**Remarks:**

This sets the specified identity flag(s).

**Parameters:**

**DWORD f**

Specifies the identity flag bit(s) to set. See Matrix Identity Flags above.

**Prototype:**

**DWORD GetIdentFlags() const**

**Remarks:**

Returns the identity flags.

**Prototype:**

## **void ClearIdentFlag(DWORD f)**

### **Remarks:**

Clears the specified identity flag(s). See Matrix Identity Flags above.

### **Parameters:**

#### **DWORD f**

Specifies the identity flag bit(s) to clear.

### **Prototype:**

#### **BOOL IsIdentity() const**

### **Remarks:**

Returns TRUE if the matrix is the identity matrix (based on the flags); otherwise FALSE.

### **Prototype:**

#### **void ValidateFlags();**

### **Remarks:**

This method is available in release 2.0 and later only.

This method may be used to recompute the \*\_IDENT flags for this matrix.

For instance, if you call a method, such as

**INode::GetObjTMAfterWSM()**, and it returns a matrix, you cannot use the **IsIdentity()** method to check if the matrix is indeed the identity. This is because the flags that method checks are not initialized by the INode method. What you can do however is call this method first. This will validate the flags in the matrix so they accurately reflect the properties of the matrix. If after calling this method, and then calling **IsIdentity()**, the proper result would be returned.

### **Prototype:**

#### **MRow\* GetAddr()**

### **Remarks:**

Returns the address of this Matrix3.

The Matrix3 class keeps flags indicating identity for rotation, scale, position, and the matrix as a whole, and thus the direct access via the [] operator is

restricted to prevent developers from modifying the matrix without updating the flags. This method, `GetAddr()`, still lets you get at the matrix itself and then you can use the `[]` operator on the result. Note: If you change the matrix via this pointer, you **MUST** clear the proper IDENT flags!

Also Note: **`typedef float MRow[3];`**

**Return Value:**

The address of the `Matrix3`.

**Prototype:**

**`const MRow* GetAddr() const;`**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the address of this `Matrix3`.

The `Matrix3` class keeps flags indicating identity for rotation, scale, position, and the matrix as a whole, and thus the direct access via the `[]` operator is restricted to prevent developers from modifying the matrix without updating the flags. This method, `GetAddr()`, still lets you get at the matrix itself and then you can use the `[]` operator on the result. Note: If you change the matrix via this pointer, you **MUST** clear the proper IDENT flags!

Also Note: **`typedef float MRow[3];`**

**Prototype:**

**`void IdentityMatrix();`**

**Remarks:**

Set this matrix to the Identity Matrix.

**Prototype:**

**`void Zero();`**

**Remarks:**

This method sets all elements of the matrix to 0.0f

**Prototype:**

**`Matrix3& Set(const Point3& U, const Point3& V, const Point3&`**

**N, const Point3& T);**

**Remarks:**

This method is available in release 3.0 and later only.

Initializes the matrix with the row data passed and validates the matrix flags.

**Parameters:**

**const Point3& U**

The data for row 0.

**const Point3& V**

The data for row 1.

**const Point3& N**

The data for row 2.

**const Point3& T**

The data for row 3.

**Return Value:**

A reference to this matrix.

**Prototype:**

**int Equals(const Matrix3& M, float epsilon = 1E-6f) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Compares the elements of this matrix and the one specified element by element for equality within the specified tolerance **epsilon**. Returns nonzero if they are 'equal'; otherwise zero.

**Parameters:**

**const Matrix3& M**

The matrix to compare against.

**float epsilon = 1E-6f**

The tolerance for comparison. If the values in the matrix are within this value (+ **epsilon** or - **epsilon**) they are considered equal.

**Prototype:**

**Point3 GetRow(int i) const**

**Remarks:**

Returns the specified row of this matrix.

**Parameters:**

**int i**

Specifies the row to retrieve.

**Prototype:**

**void SetRow(int i, Point3 p);**

**Remarks:**

Sets the specified row of this matrix to the specified values.

**Parameters:**

**int i**

Specifies the row to set.

**Point3 p**

The values to set.

**Prototype:**

**Point4 GetColumn(int i) const;**

**Remarks:**

Returns the 'i-th' column of this matrix.

**Parameters:**

**int i**

Specifies the column to get (0-2).

**Prototype:**

**void SetColumn(int i, Point4 col);**

**Remarks:**

Sets the 'i-th' column of this matrix to the specified values.

**Parameters:**

**int i**

Specifies the column to set (0-2).

### **Point4 col**

The values to set.

#### **Prototype:**

**Point3 GetColumn3(int i) const;**

#### **Remarks:**

Returns the upper three entries in the specified column.

#### **Parameters:**

**int i**

Specifies the partial column to get (0-2).

#### **Prototype:**

**void NoTrans();**

#### **Remarks:**

This method zeros the translation portion of this matrix.

#### **Prototype:**

**void NoRot();**

#### **Remarks:**

This method zeros the rotation portion of this matrix.

#### **Prototype:**

**void NoScale();**

#### **Remarks:**

The method zeros the scale portion of this matrix without orthogonalization. If the matrix was sheared (skewed) then the method is not able to remove scale component completely. Use Orthogonalize() method first, and then NoScale() to remove scale component entirely. Read SCL\_IDENT flag to check if NoScale() method was enough to make the matrix to be orthogonal (with perpendicular axes of unit length).Prototype:

**void Orthogonalize();**

**Remarks:**

This is an "unbiased" orthogonalization of this matrix. The algorithm seems to take a maximum of 4 iterations to converge. An orthogonal matrix has an axis system where each axis is 90 degrees from the others (it's not skewed).

**Prototype:**

**void SetTrans(const Point3 p)**

**Remarks:**

Sets the translation row of this matrix to the specified values. The **POS\_IDENT** flag is cleared.

**Parameters:**

**const Point3 p**

Specifies the values for the translation row.

**Prototype:**

**void SetTrans(int i, float v)**

**Remarks:**

Sets the specified component of the translation row of this matrix to the specified value. The **POS\_IDENT** flag is cleared.

**Parameters:**

**int i**

Specifies the component of the translation row of this matrix to set.

**float v**

The value to set.

**Prototype:**

**Point3 GetTrans() const**

**Remarks:**

Returns the translation row of this matrix.

**Return Value:**

The translation row of this matrix.

**Prototype:**

**void SetScale(const Point3 p);**

**Remarks:**

This method is not currently implemented.

**Prototype:**

**void Translate(const Point3& p);**

**Remarks:**

Apply an incremental translation transformation to this matrix. This is equivalent to multiplying on the RIGHT by the transform.

**Parameters:**

**const Point3& p**

Specifies the translation.

**Prototype:**

**void RotateX(float angle);**

**Remarks:**

Apply an incremental X rotation transformation to this matrix. This is equivalent to multiplying on the RIGHT by the transform.

**Parameters:**

**float angle**

Specifies the X rotation in radians.

**Prototype:**

**void RotateY(float angle);**

**Remarks:**

Apply an incremental Y rotation transformation to this matrix. This is equivalent to multiplying on the RIGHT by the transform.

**Parameters:**

**float angle**

Specifies the Y rotation in radians.

**Prototype:**

**void RotateZ(float angle);**

**Remarks:**

Apply an incremental Z rotation transformation to this matrix. This is equivalent to multiplying on the RIGHT by the transform.

**Parameters:**

**float angle**

Specifies the Z rotation in radians.

**Prototype:**

**void Scale(const Point3& s, BOOL trans = FALSE);**

**Remarks:**

Apply an incremental scaling transformation to this matrix. This is equivalent to multiplying on the RIGHT by the transform.

**Parameters:**

**const Point3& s**

The scale values.

**BOOL trans = FALSE**

If set to **TRUE**, the translation component is scaled. If **trans = FALSE** the translation component is unaffected. When 3ds max was originally written there was a bug in the code for this method where the translation portion of the matrix was not being scaled. This meant that when a matrix was scaled the bottom row was not scaled. Thus it would always scale about the local origin of the object, but it would scale the world axes. When this bug was discovered, dependencies existed in the code upon this bug. Thus it could not simply be fixed because it would break the existing code that depended upon it working the incorrect way. To correct this the **trans** parameter was added. If this is set to **TRUE**, the translation component will be scaled correctly. The existing plug-ins don't use this parameter, it defaults to **FALSE**, and the code behaves the old way.

**Prototype:**

**void PreTranslate(const Point3& p);**

**Remarks:**

Apply an incremental translation transformation to this matrix. This is equivalent to multiplying on the LEFT by the transform.

**Parameters:**

**const Point3& p**

Specifies the translation distance.

**Prototype:**

**void PreRotateX(float angle);**

**Remarks:**

Apply an incremental X rotation transformation to this matrix. This is equivalent to multiplying on the LEFT by the transform.

**Parameters:**

**float angle**

Specifies the X rotation in radians.

**Prototype:**

**void PreRotateY(float angle);**

**Remarks:**

Apply an incremental Y rotation transformation to this matrix. This is equivalent to multiplying on the LEFT by the transform.

**Parameters:**

**float angle**

Specifies the Y rotation in radians.

**Prototype:**

**void PreRotateZ(float angle);**

**Remarks:**

Apply an incremental Z rotation transformation to this matrix. This is equivalent to multiplying on the LEFT by the transform.

**Parameters:**

**float angle**

Specifies the Z rotation in radians.

**Prototype:**

**void PreScale(const Point3& s, BOOL trans = FALSE);**

**Remarks:**

Apply an incremental scaling transformation to this matrix. This is equivalent to multiplying on the LEFT by the transform.

**Parameters:**

**const Point3& s**

The scale values.

**BOOL trans = FALSE**

If trans = FALSE the translation component is unaffected.

**Prototype:**

**void SetTranslate(const Point3& p);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets this matrix to the identity and the translation components to the specified values.

**Parameters:**

**const Point3& p**

The translation values to store.

**Prototype:**

**void SetRotateX(float angle);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets this matrix to the identity and the rotation components to the specified X rotation.

**Parameters:**

**float angle**

The angle for X rotation (in radians).

**Prototype:**

**void SetRotateY(float angle);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets this matrix to the identity and the rotation components to the specified Y rotation.

**Parameters:**

**float angle**

The angle for Y rotation (in radians).

**Prototype:**

**void SetRotateZ(float angle);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets this matrix to the identity and the rotation components to the specified Z rotation.

**Parameters:**

**float angle**

The angle for Z rotation (in radians).

**Prototype:**

**void SetRotate(const Quat& q);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the rotation components of the matrix as specified by the quaternion. The translation and scale components will match the identity matrix.

**Parameters:**

**const Quat& q**

Specifies the rotation to use for the matrix.

**Prototype:**

**void SetRotate(const AngAxis& aa);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the rotation components of the matrix as specified by the AngAxis. The translation and scale components will match the identity matrix.

**Parameters:**

**const AngAxis& aa**

Specifies the rotation to use for the matrix.

**Prototype:**

**void SetRotate(float yaw, float pitch, float roll);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the rotation components of this matrix using yaw, pitch and roll angles.

There are many different conventions for specifying a rotation by means of three Euler angles. This function uses the convention of rotating around the world Z axis, then the X axis, then the Y axis; the three arguments are given in the order Y, X, Z.

This one is equivalent to:

M.IdentityMatrix();

M.RotateZ(roll);

M.RotateX(pitch);

M.RotateY(yaw);

--Which presupposes Y is vertical, X is sideways, Z is forward

**Parameters:**

**float yaw**

The yaw angle in radians.

**float pitch**

The pitch angle in radians.

**float roll**

The roll angle in radians.

**Prototype:**

**void SetAngleAxis();**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the rotation portion of the matrix to the rotation specified by the angle and axis and sets the translation portion to zeros.

**Parameters:**

**const Point3& axis**

The axis of rotation.

**float angle**

The angle of rotation about the axis in radians.

**Prototype:**

**void SetScale(const Point3& s);**

**Remarks:**

This method is available in release 3.0 and later only.

Sets the scale components of this matrix to the specified values. The other components to this matrix will match the identity.

**Parameters:**

**const Point3& s**

The scale factors for the matrix.

**Prototype:**

**void SetFromToUp(const Point3& from, const Point3& to, const Point3& up);**

**Remarks:**

This method is available in release 3.0 and later only.

This creates a matrix describing a viewpoint which is at the 'from' location, looking toward the 'to' location; the viewpoint is tilted so that the 'up' vector points to the top of the view.

**Parameters:**

**const Point3& from**

This specifies the viewpoint source location.

**const Point3& to**

This vector specifies the direction of view.

**const Point3& up**

This vector points to the top of the view.

**Prototype:**

**void Invert();**

**Remarks:**

This method is available in release 3.0 and later only.

This method inverts this matrix. An inverted matrix, when multiplied by the original, yields the identity.

**Prototype:**

**BOOL Parity() const;**

**Remarks:**

This method is available in release 2.0 and later only.

Returns the 'parity' of the matrix. If one axis of the matrix is scaled negatively this switches the 'parity'. However if you scale two axes it will flip it back.

Three times switches it again.

When rendering a mesh, if you scale something along one axis, it turns 'inside out'. That is the direction when the normals are reversed. This method may be used to detect that case and then reverse the normals. The 3ds max renderer does this -- if this method returns TRUE it flips all the normals so it won't turn inside out.

**Sample Code:**

```
BOOL Matrix3::Parity() const {  
    if (flags&SCL_IDENT) return FALSE;  
    Point3 cp = CrossProd(GetRow(0),GetRow(1));  
    if (DotProd(cp,GetRow(2)) < 0.0) return TRUE;  
    return FALSE;  
}
```

**Prototype:**

**Point3 PointTransform(const Point3& p) const;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the specified point transformed by this matrix.

**Parameters:**

**const Point3& p**

The point to transform by this matrix.

**Prototype:**

**Point3 VectorTransform(const Point3& p) const;**

**Remarks:**

This method is available in release 3.0 and later only.  
Returns the specified vector transformed by this matrix.

**Parameters:**

**const Point3& p**

The vector to transform by this matrix.

**Prototype:**

**void TransformPoints(Point3 \*array, int n, int stride =  
sizeof(Point3));**

**Remarks:**

This method is available in release 3.0 and later only.  
Transforms the specified list of points with this matrix.

**Parameters:**

**Point3 \*array**

The array of points to transform with this matrix.

**int n**

The number of points in the array.

**int stride = sizeof(Point3)**

The size of the increment used when moving to the next point. If you wish to transform an array of data objects which contain x, y, and z coordinates in order (such as a **Point4**, or a structure containing a **Point3** as a member) you can specify a 'stride' value (for instance **sizeof(data\_object)**).

**Prototype:**

```
void TransformPoints(const Point3 *array, Point3 *to, int n, int stride = sizeof(Point3), int strideTo = sizeof(Point3));
```

**Remarks:**

This method is available in release 3.0 and later only.

Transforms the specified list of points with this matrix and stores the resulting transformed points in the storage passed.

**Parameters:**

**const Point3 \*array**

The array of points to transform (the source).

**Point3 \*to**

The array to store the transformed points (the destination).

**int n**

The number of points in the source array.

**int stride = sizeof(Point3)**

**int strideTo = sizeof(Point3)**

The size increment used when moving to the next storage location.

**Prototype:**

```
void TransformVectors(Point3 *array, int n, int stride = sizeof(Point3));
```

**Remarks:**

This method is available in release 3.0 and later only.

Transforms the specified list of vectors with this matrix.

**Parameters:**

**Point3 \*array**

The array of vectors to transform with this matrix.

**int n**

The number of vectors in the array.

**int stride = sizeof(Point3)**

The size of the increment used when moving to the next vector. If you wish to transform an array of data objects which contain x, y, and z coordinates in order (such as a **Point4**, or a structure containing a **Point3** as a member) you

can specify a 'stride' value (for instance **sizeof(data\_object)**).

**Prototype:**

```
void TransformVectors(const Point3 *array, Point3 *to, int n, int stride = sizeof(Point3), int strideTo = sizeof(Point3));
```

**Remarks:**

This method is available in release 3.0 and later only.

Transforms the specified list of vectors with this matrix and stores the resulting transformed vectors in the storage passed.

**Parameters:**

**const Point3 \*array**

The array of vectors to transform (the source).

**Point3 \*to**

The array to store the transformed vectors (the destination).

**int n**

The number of vectors in the source array.

**int stride = sizeof(Point3)**

The size increment used when moving to the next source location.

**int strideTo = sizeof(Point3)**

The size increment used when moving to the next storage location.

**Prototype:**

```
void GetYawPitchRoll(float *yaw, float *pitch, float *roll);
```

**Remarks:**

This method is available in release 3.0 and later only.

Retrieves the yaw, pitch and roll angles represented by the rotation in this matrix.

**Parameters:**

**float \*yaw**

The yaw rotation angle is stored here (in radians).

**float \*pitch**

The pitch rotation angle is stored here (in radians).

**float \*roll**

The roll rotation angle is stored here (in radians).

**Operators:**

**Prototype:**

**int operator==(const Matrix3& M) const;**

**Remarks:**

This method is available in release 3.0 and later only.

Compares the elements of this matrix and the one specified element by element for exact equality. Returns nonzero if they are equal; otherwise zero.

**Parameters:**

**const Matrix3& M**

The matrix to compare against.

**Prototype:**

**Matrix3& operator-=(const Matrix3& M);**

**Remarks:**

Subtracts a **Matrix3** from this **Matrix3**.

**Prototype:**

**Matrix3& operator+=(const Matrix3& M);**

**Remarks:**

Adds a **Matrix3** to this **Matrix3**.

**Prototype:**

**Matrix3& operator\*=(const Matrix3& M);**

**Remarks:**

Multiplies this Matrix3 by the specified Matrix3 (**\*this = (\*this)\*M;**).

**Prototype:**

**Matrix3 operator\*(const Matrix3&) const;**

**Remarks:**

Perform matrix multiplication.

**Prototype:**

**Matrix3 operator+(const Matrix3&) const;**

**Remarks:**

Perform matrix addition.

**Prototype:**

**Matrix3 operator-(const Matrix3&) const;**

**Remarks:**

Perform matrix subtraction.

**Prototype:**

**const Point3& operator[](int i) const;**

**Remarks:**

Returns a reference to the 'i-th' Point3 of the matrix.

The following functions are not methods of **Matrix3** but are available for use:

**Function:**

**Matrix3 RotateXMatrix(float angle);**

**Remarks:**

Builds a new matrix for use as a X rotation transformation.

**Parameters:**

**float angle**

Specifies the angle of rotation in radians.

**Return Value:**

A new X rotation **Matrix3**.

**Function:**

**Matrix3 RotateYMatrix(float angle);**

**Remarks:**

Builds a new matrix for use as a Y rotation transformation.

**Parameters:**

**float angle**

Specifies the angle of rotation in radians.

**Return Value:**

A new Y rotation **Matrix3**.

**Function:**

**Matrix3 RotateZMatrix(float angle);**

**Remarks:**

Builds a new matrix for use as a Z rotation transformation.

**Parameters:**

**float angle**

Specifies the angle of rotation in radians.

**Return Value:**

A new Z rotation **Matrix3**.

**Function:****Matrix3 TransMatrix(const Point3& p);****Remarks:**

Builds a new matrix for use as a translation transformation.

**Parameters:****const Point3& p**

Specifies the translation values.

**Return Value:**

A new translation **Matrix3**.

**Function:****Matrix3 ScaleMatrix(const Point3& s);****Remarks:**

Builds a new matrix for use as a scale transformation.

**Parameters:****const Point3& p**

Specifies the scale values.

**Return Value:**

A new scale **Matrix3**.

**Function:****Matrix3 RotateYPRMatrix(float Yaw, float Pitch, float Roll);****Remarks:**

Builds a new matrix for use as a rotation transformation by specifying yaw, pitch and roll angles.

This definition will depend on what our coordinate system is. This one is equivalent to:

**M.IdentityMatrix();****M.RotateZ(roll);****M.RotateX(pitch);****M.RotateY(yaw);**

Which presupposes Y is vertical, X is sideways, Z is forward

**Parameters:**

**float Yaw**

Specifies the yaw angle in radians.

**float Pitch**

Specifies the pitch angle in radians.

**float Roll**

Specifies the roll angle in radians.

**Return Value:**

A new rotation **Matrix3**.

**Function:**

**Matrix3 RotAngleAxisMatrix(Point3& axis, float angle);**

**Remarks:**

Builds a new matrix for use as a rotation transformation by specifying an angle and axis.

**Parameters:**

**Point3& axis**

Specifies the axis of rotation. Note that this angle is expected to be normalized.

**float angle**

Specifies the angle of rotation. Note: The direction of the angle in this method is opposite of that in **AngAxisFromQ()**.

**Return Value:**

A new rotation **Matrix3**.

**Function:**

**Matrix3 Inverse(const Matrix3& M);**

**Remarks:**

Return the inverse of the matrix

**Parameters:**

**const Matrix3& M**

The matrix to compute the inverse of.

**Function:**

**Point3 VectorTransform(const Matrix3& M, const Point3& V);**

**Remarks:**

Transform the vector (Point3) with the specified matrix.

**Parameters:**

**const Matrix3& A**

The matrix to transform the vector with.

**const Point3& V**

The vector to transform.

**Return Value:**

The transformed vector (as a Point3).

**Function:**

**Matrix3 XFormMat(const Matrix3& xm, const Matrix3& m);**

**Remarks:**

This method is used to build a matrix that constructs a transformation in a particular space. For example, say you have a rotation you want to apply, but you want to perform the rotation in another coordinate system. To do this, you typically transform into the space of the coordinate system, then apply the transformation, and then transform out of that coordinate system. This method constructs a matrix that does just this. It transforms matrix **m** so it is applied in the space of matrix **xm**. It returns a **Matrix3** that is **xm\*m\*Inverse(xm)**.

**Parameters:**

**const Matrix3& xm**

Specifies the coordinate system you want to work in.

**const Matrix3& m**

Specifies the transformation matrix.

**Return Value:**

Returns a **Matrix3** that is **xm\*m\*Inverse(xm)**.

**Function:**

**Point3 operator\*(const Matrix3& A, const Point3& V);**  
**Point3 operator\*(const Point3& V, const Matrix3& A);**

**Remarks:**

These transform a **Point3** with a **Matrix3**. These two versions of transforming a point with a matrix do the same thing, regardless of the order of operands (linear algebra rules notwithstanding).

**Parameters:**

**const Point3& V**

The point to transform.

**const Matrix3& A**

The matrix to transform the point with.

**Return Value:**

The transformed **Point3**.

## Class Quat

See Also: [Class Point3](#), [Class Matrix3](#), [Class AngAxis](#).

class Quat

### Description:

This class provides a compact representation for orientation in three space and provides methods to perform Quaternion algebra.

Quaternions provide an alternative representation for orientation in three-space. To reduce computing, you can substitute quaternion multiplication for rotation-matrix composition.

A quaternion is made up of four terms: a real scalar part which specifies the amount of rotation and an imaginary vector part which defines the axis of rotation. If the quaternion is normalized, the scalar term equals the cosine of half the angle of rotation, the vector term is the axis of rotation, and the magnitude of the vector term equals the sine of half the angle of rotation.

Interpolation between two key frame orientations is much easier using quaternions and produces smooth and natural motion. Unlike Euler angles, no numerical integration is necessary; quaternions provide an analytic result (no approximations).

The rotation convention in the 3ds max API is the left-hand-rule. Note that this is different from the right-hand-rule used in the 3ds max user interface.

For additional information see: Quaternion operations:

From "Quaternion Calculus and Fast Animation",  
by Ken Shoemake, in notes for SIGGRAPH 1987 Course # 10,  
"Computer Animation: 3-D Motion Specification and Control".

All methods of this class are implemented by the system.

### Data Members:

public:

**float x,y,z,w;**

The **x**, **y**, **z** values make up the vector portion. **w** is the angle of rotation about the vector (see remarks above for details).

### Methods:

**Prototype:**

**Quat()**

**Remarks:**

Constructor. No initialization is performed.

**Prototype:**

**Quat(float X, float Y, float Z, float W)**

**Remarks:**

Constructor. The data members are initialized to the values passed.

**Prototype:**

**Quat(double X, double Y, double Z, double W)**

**Remarks:**

Constructor. The data members are initialized to the values passed (cast as floats).

**Prototype:**

**Quat(const Quat& a)**

**Remarks:**

Constructor. The data members are initialized to the Quat passed.

**Prototype:**

**Quat(float af[4])**

**Remarks:**

Constructor. The data members are initialized to the values passed.  
**x = af[0]; y = af[1]; z = af[2]; w = af[3];**

**Prototype:**

**Quat(const Matrix3& mat);**

**Remarks:**

Constructor. Convert the specified 3x3 rotation matrix to a unit quaternion.

**Prototype:**

**Quat(const AngAxis& aa);**

**Remarks:**

Constructor. The Quat is initialized to the AngAxis passed.

**Prototype:**

**Quat(const Point3& V, float W);**

**Remarks:**

This method is available in release 3.0 and later only.

Constructor. The quaternion is initialized from the vector **V** and angle **W** passed. The quaternion is then normalized.

**Prototype:**

**Quat Inverse() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the inverse of this quaternion (1/q).

**Prototype:**

**Quat Conjugate() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the conjugate of a quaternion.

**Prototype:**

**Quat LogN() const;**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the natural logarithm of a UNIT quaternion.

**Prototype:**

## **Quat Exp() const;**

### **Remarks:**

This method is available in release 3.0 and later only.  
Returns the exponentiate quaternion (where  $\mathbf{q.w}=0$ ).

### **Operators:**

### **Prototype:**

**float& operator[](int i)**

### **Remarks:**

Array access operator. Valid **i** values: 0=x, 1=y, 2=z, 3=w.

### **Prototype:**

**const float& operator[](int i) const**

### **Remarks:**

Array access operator. Valid **i** values: 0=x, 1=y, 2=z, 3=w.

### **Prototype:**

**operator float\*()**

### **Remarks:**

Returns the address of the Quaternion.

Unary operators

### **Prototype:**

**Quat operator-() const**

### **Remarks:**

Unary negation. Returns **Quat(-x,-y,-z,-w)**.

### **Prototype:**

**Quat operator+() const**

### **Remarks:**

Unary +. Returns the Quat unaltered.

## Assignment operators

### **Prototype:**

**Quat& operator-=(const Quat&);**

### **Remarks:**

This operator is the same as the /= operator.

### **Prototype:**

**Quat& operator+=(const Quat&);**

### **Remarks:**

This operator is the same as the \*= operator..

### **Prototype:**

**Quat& operator\*=(const Quat&);**

### **Remarks:**

Multiplies this quaternion by a quaternion.

### **Prototype:**

**Quat& operator\*=(float);**

### **Remarks:**

Multiplies this quaternion by a floating point value.

### **Prototype:**

**Quat& operator/=(float);**

### **Remarks:**

Divides this quaternion by a floating point value.

### **Prototype:**

**int operator==(const Quat& a) const;**

### **Remarks:**

Returns nonzero if the quaternions are equal; otherwise 0.

**Prototype:**

**void Identity()**

**Remarks:**

Sets this quaternion to the identity quaternion (**x=y=z=0.0; w=1.0**).

**Prototype:**

**int IsIdentity() const;**

**Remarks:**

Returns nonzero if the quaternion is the identity; otherwise 0.

**Prototype:**

**void Normalize();**

**Remarks:**

Normalizes this quaternion, dividing each term by a scale factor such that the resulting sum of the squares of all parts equals unity.

**Prototype:**

**Quat& MakeClosest(const Quat& qto);**

**Remarks:**

Modifies **q** so it is on same side of hypersphere as **qto**.

**Prototype:**

**void MakeMatrix(Matrix3 &mat, bool b=FALSE) const;**

**Remarks:**

Converts the quaternion to a 3x3 rotation matrix. The quaternion need not be unit magnitude.

**Parameters:**

**Matrix3 &mat**

The matrix.

**BOOL b=FALSE**

This parameter is available in release 4.0 and later only.

When this argument is set to false (or omitted), each function performs as it

did before version 4.0. When the boolean is TRUE, the matrix is made with its terms transposed. When this transposition is specified, **EulerToQuat()** and **QuatToEuler()** are consistent with one another. (In 3ds max 3, they have opposite handedness).

**Prototype:**

**Quat operator+(const Quat&) const;**

**Remarks:**

This operator is the same as the \* operator.

**Prototype:**

**Quat operator-(const Quat&) const;**

**Remarks:**

This operator is the same as the / operator.

**Prototype:**

**Quat operator\*(const Quat&) const;**

**Remarks:**

Returns the product of two quaternions.

**Prototype:**

**Quat operator/(const Quat&) const;**

**Remarks:**

Returns the ratio of two quaternions: This creates a result quaternion  $r = p/q$ , such that  $q*r = p$ . (Order of multiplication is important)

The following operators and functions are not part of class Quat but are available for use.

**Prototype:**

**Quat operator\*(float, const Quat&);**

**Remarks:**

Multiplies the quaternion by a scalar.

**Prototype:**

**Quat operator\*(const Quat&, float);**

**Remarks:**

Multiplies the quaternion by a scalar.

**Prototype:**

**Quat operator/(const Quat&, float);**

**Remarks:**

Divides the quaternion by a scalar.

**Prototype:**

**Quat Inverse(const Quat& q);**

**Remarks:**

Returns the inverse of the quaternion ( $1/\mathbf{q}$ ).

**Prototype:**

**Quat Conjugate(const Quat& q);**

**Remarks:**

Returns the conjugate of a quaternion.

**Prototype:**

**Quat LogN(const Quat& q);**

**Remarks:**

Returns the natural logarithm of UNIT quaternion.

**Prototype:**

**Quat Exp(const Quat& q);**

**Remarks:**

Exponentiate quaternion (where  $\mathbf{q}.\mathbf{w}==0$ ).

**Prototype:**

**Quat Slerp(const Quat& p, const Quat& q, float t);**

**Remarks:**

Spherical linear interpolation of UNIT quaternions.

As t goes from 0 to 1, qt goes from p to q.

$\text{slerp}(p,q,t) = (p*\sin((1-t)*\omega) + q*\sin(t*\omega)) / \sin(\omega)$

**Prototype:**

**Quat LnDif(const Quat& p, const Quat& q);**

**Remarks:**

Computes the "log difference" of two quaternions,  $\mathbf{p}$  and  $\mathbf{q}$ , as  $\ln(\mathbf{q}\text{inv}(\mathbf{p})*\mathbf{q})$ .

**Prototype:**

**Quat QCompA(const Quat& qprev,const Quat& q, const Quat& qnext);**

**Remarks:**

Compute a, the term used in Boehm-type interpolation.

$\mathbf{a}[n] = \mathbf{q}[n]*\mathbf{q}\text{exp}(-(1/4)*(\ln(\mathbf{q}\text{inv}(\mathbf{q}[n])*q[n+1]) + \ln(\mathbf{q}\text{inv}(\mathbf{q}[n])*q[n-1] )))$

**Prototype:**

**Quat Squad(const Quat& p, const Quat& a, const Quat &b, const Quat& q, float t);**

**Remarks:**

$\text{Squad}(p,a,b,q; t) = \text{Slerp}(\text{Slerp}(p,q;t), \text{Slerp}(a,b;t); 2(1-t)t)$ .

**Prototype:**

**Quat qorthog(const Quat& p, const Point3& axis);**

**Remarks:**

Rotate **p** by 90 degrees (quaternion space metric) about the specified **axis**.

**Prototype:**

**Quat squadrev(float angle,const Point3& axis,const Quat& p,  
const Quat& a,const Quat& b,const Quat& q,float t);**

**Remarks:**

Quaternion interpolation for angles > 2PI.

**Parameters:**

**float angle**

Angle of rotation

**const Point3& axis**

The axis of rotation

**const Quat& p**

Start quaternion

**const Quat& a**

Start tangent quaternion

**const Quat& b**

End tangent quaternion

**const Quat& q**

End quaternion

**float t**

Parameter, in range [0.0,1.0]

**Prototype:**

**void RotateMatrix(Matrix3& mat, const Quat& q);**

**Remarks:**

Converts the quaternion to a matrix and multiples it by the specified matrix.  
The result is returned in **mat**.

**Prototype:**

**void PreRotateMatrix(Matrix3& mat, const Quat& q);**

**Remarks:**

Converts the quaternion to a matrix and multiplies it on the left by the specified matrix. . The result is returned in **mat**.

**Prototype:**

**Quat QFromAngAxis(float ang, const Point3& axis);**

**Remarks:**

Converts the [angle,axis] representation to the equivalent quaternion.

**Prototype:**

**void AngAxisFromQ(const Quat& q, float \*ang, Point3& axis);**

**Remarks:**

Converts the quaternion to the equivalent [angle,axis] representation.

**Prototype:**

**float QangAxis(const Quat& p, const Quat& q, Point3& axis);**

**Remarks:**

Compute the [angle,axis] corresponding to the rotation from **p** to **q**. Returns angle, sets axis.

**Prototype:**

**void DecomposeMatrix(const Matrix3& mat, Point3& p,  
Quat& q, Point3& s);**

**Remarks:**

Decomposes a matrix into a rotation, scale, and translation (to be applied in that order). This only will work correctly for scaling which was applied in the rotated axis system. For more general decomposition see the function **decomp\_affine()**. See [Structure AffineParts](#).

**Prototype:**

**Quat TransformQuat(const Matrix3 &m, const Quat&q );**

**Remarks:**

Returns the transformation of the specified quaternion by the specified matrix.

**Prototype:**

**inline Quat IdentQuat()**

**Remarks:**

Returns the identity quaternion (**Quat(0.0,0.0,0.0,1.0)**).

**Function:**

**void QuatToEuler(Quat &q, float \*ang);**

**Remarks:**

Converts the quaternion to Euler angles. When converting a quaternion to Euler angles using this method, the correct order of application of the resulting three rotations is X, then Y, then Z. The angles are returned as **ang[0]=x, ang[1]=y, ang[2]=z**.

**Function:**

**void EulerToQuat(float \*ang, Quat &q, int order);**

**Remarks:**

Converts Euler angles to a quaternion. The angles are specified as **ang[0]=x, ang[1]=y, ang[2]=z**. This method is implemented as:

```
void EulerToQuat(float *ang, Quat &q, int order)  
{  
  Matrix3 mat(1);  
  for (int i=0; i<3; i++) {  
    switch (orderings[order][i]) {  
      case 0: mat.RotateX(ang[i]); break;  
      case 1: mat.RotateY(ang[i]); break;  
      case 2: mat.RotateZ(ang[i]); break;  
    }  
  }
```

```
    q = Quat(mat);  
}
```

**Prototype:**

```
ostream &operator<<(ostream&, const Quat&);
```

**Remarks:**

Output on an ostream.

## Class Color

See Also: [Class AColor](#), [Structure BMM\\_Color\\_24](#), [Structure BMM\\_Color\\_32](#), [Structure BMM\\_Color\\_48](#), [Structure BMM\\_Color\\_64](#), [Structure BMM\\_Color\\_fl](#), [Structure RealPixel](#).

class Color

### Description:

This class represents color as three floating point values: r, g, and b. All methods of this class are implemented by the system.

### Data Members:

public:

**float r,g,b;**

These values are in the range 0.0 to 1.0.

### Methods:

### Prototype:

**Color()**

### Remarks:

Constructor. The resulting object should be initialized with one of the initialization methods.

### Prototype:

**Color(float R, float G, float B)**

### Remarks:

Constructor. Initializes the Color to the RGB color values passed.

### Parameters:

**float R**

Specifies the red component of the color.

**float G**

Specifies the green component of the color.

**float B**

Specifies the blue component of the color.

**Prototype:**

**Color(double R, double G, double B)**

**Remarks:**

Constructor. Initializes the Color to the RGB color values passed.

**Parameters:**

**double R**

Specifies the red component of the color.

**double G**

Specifies the green component of the color.

**double B**

Specifies the blue component of the color.

**Prototype:**

**Color(int R, int G, int B)**

**Remarks:**

Constructor. Initializes the Color to the RGB color values passed.

**Parameters:**

**int R**

Specifies the red component of the color.

**int G**

Specifies the green component of the color.

**int B**

Specifies the blue component of the color.

**Prototype:**

**Color(const Color& a)**

**Remarks:**

Constructor. Initializes the Color to the Color passed.

**Parameters:**

**Color& a**

Specifies the initial color.

**Prototype:**

**Color(DWORD rgb)**

**Remarks:**

Constructor. Initializes the color to the Windows RGB value.

**Parameters:**

**DWORD rgb**

Specifies the initial color via a Windows RGB value.

**Prototype:**

**Color(Point3 p)**

**Remarks:**

Constructor. Initializes the Color to the value of the Point3 passed.

**Parameters:**

**Point3 p**

Specifies the color. r=x, g=y, b=z.

**Prototype:**

**Color(float af[3])**

**Remarks:**

Constructor. Initializes the color to the value passed.

**Parameters:**

**float af[3]**

Specifies the color. r=af[0], g=af[1], b=af[2].

**Prototype:**

**Color(const BMM\_Color\_24& c);**

**Remarks:**

This method is available in release 4.0 and later only.

Constructor. Initializes this Color from the 24 bit color value passed.

**Parameters:**

**const BMM\_Color\_24& c**

The 24 bit color to initialize from.

**Prototype:**

**Color(const BMM\_Color\_32& c);**

**Remarks:**

This method is available in release 4.0 and later only.

Constructor. Initializes this Color from the 32 bit color value passed.

**Parameters:**

**const BMM\_Color\_32& c**

The 32 bit color to initialize from.

**Prototype:**

**Color(const BMM\_Color\_48& c);**

**Remarks:**

This method is available in release 4.0 and later only.

Constructor. Initializes this Color from the 48 bit color value passed.

**Parameters:**

**const BMM\_Color\_48& c**

The 48 bit color to initialize from.

**Prototype:**

**Color(const BMM\_Color\_64& c);**

**Remarks:**

This method is available in release 4.0 and later only.

Constructor. Initializes this Color from the 64 bit color value passed.

**Parameters:**

**const BMM\_Color\_64& c**

The 64 bit color to initialize from.

**Prototype:**

**Color(const BMM\_Color\_fl& c);**

**Remarks:**

This method is available in release 4.0 and later only.

Constructor. Initializes this Color from the floating point color passed.

**Parameters:**

**const BMM\_Color\_fl& c**

The floating point color to initialize from. No conversion or scaling is done.

**Prototype:**

**Color(RealPixel rp);**

**Remarks:**

Constructor. Initializes the color to the RealPixel structure passed.

**Parameters:**

**RealPixel rp**

Specifies the RealPixel format to convert.

**Prototype:**

**void Black()**

**Remarks:**

Sets the Color to black.  $r = g = b = 0.0f$

**Prototype:**

**void White()**

**Remarks:**

Sets the Color to white.  $r = g = b = 1.0f$

**Prototype:**

**void ClampMax()**

**Remarks:**

Makes all the components of the Color  $\leq 1.0$

**Prototype:**

## **void ClampMin()**

### **Remarks:**

Makes all the components of the Color  $\geq 0.0$

### **Prototype:**

**void ClampMinMax()**

### **Remarks:**

Makes all the components fall in the range  $[0,1]$

### **Prototype:**

**int MaxComponent(const Color&)**

### **Remarks:**

Returns the index of the component with the maximum absolute value.

### **Parameters:**

**const Color&**

The color to check.

### **Return Value:**

The index of the component with the maximum absolute value. r=0, g=1, b=2.

### **Prototype:**

**int MinComponent(const Color&)**

### **Remarks:**

Returns the index of the component with the minimum absolute value

### **Parameters:**

**const Color&**

The color to check.

### **Return Value:**

The index of the component with the minimum absolute value. r=0, g=1, b=2.

### **Prototype:**

**float MaxVal(const Color&)**

**Remarks:**

Returns the value of the component with the maximum absolute value.

**Parameters:**

**const Color&**

The color to check.

**Return Value:**

The value of the component with the maximum absolute value.

**Prototype:**

**float MinVal(const Color&)**

**Remarks:**

The value of the component with the minimum absolute value.

**Parameters:**

**const Color&**

The color to check.

**Return Value:****Prototype:**

**inline float Length(const Color& v)**

**Remarks:**

Returns the 'length' of the color, i.e.

```
return (float)sqrt(v.r*v.r+v.g*v.g+v.b*v.b);
```

**Parameters:**

**const Color& v**

The color to return the length of.

**Return Value:**

The length of the color.

**Operators:****Prototype:**

**float& operator[](int i)**

**Remarks:**

Access operator.

**Parameters:**

**int i**

The index of the component to return.

**Return Value:**

0=r, 1=g, 2=b.

**Prototype:**

**const float& operator[](int i) const**

**Remarks:**

Access operator.

**Parameters:**

**int i**

The index of the component to return.

**Return Value:**

0=r, 1=g, 2=b.

**Prototype:**

**operator float\*()**

**Remarks:**

Returns a pointer to the red component of the color. This may be used to treat the Color as an array of three floats.

**Prototype:**

**operator DWORD()**

**Remarks:**

Convert the Color to a Windows RGB color. See [COLORREF](#).

**Prototype:**

**operator Point3()**

**Remarks:**

Convert the Color to a Point3. x=r, y=g, z=b.

**Prototype:**

**operator RealPixel()**

**Remarks:**

Convert the Color to the RealPixel format.

**Prototype:**

**operator BMM\_Color\_24();**

**Remarks:**

This method is available in release 4.0 and later only.

Converts this Color to the BMM\_Color\_24 format.

**Prototype:**

**operator BMM\_Color\_32();**

**Remarks:**

This method is available in release 4.0 and later only.

Converts this Color to the BMM\_Color\_32 format.

**Prototype:**

**operator BMM\_Color\_48();**

**Remarks:**

This method is available in release 4.0 and later only.

Converts this Color to the BMM\_Color\_48 format.

**Prototype:**

**operator BMM\_Color\_64();**

**Remarks:**

This method is available in release 4.0 and later only.

Converts this Color to the BMM\_Color\_64 format.

**Prototype:**

**operator BMM\_Color\_fl();**

**Remarks:**

This method is available in release 4.0 and later only.

Converts this Color to the BMM\_Color\_fl format.

**Prototype:**

**Color operator-() const**

**Remarks:**

Unary - operator.

**Return Value:**

The Color with the components negated, i.e.

**{ return(Color(-r,-g,-b)); }**

**Prototype:**

**Color operator+() const**

**Remarks:**

Unary + operator.

**Return Value:**

The Color itself.

## Assignment operators.

**Prototype:**

**inline Color& operator-=(const Color&);**

**Remarks:**

Subtracts a Color from this Color.

**Return Value:**

A Color that is the difference between two Colors.

**Prototype:**

**inline Color& operator+=(const Color&);**

**Remarks:**

Adds a Color to this Color.

**Return Value:**

A Color that is the sum of two Colors.

**Prototype:**

**inline Color& operator\*=(float);**

**Remarks:**

Multiplies the components of this Color by a float.

**Return Value:**

A Color multiplied by a float.

**Prototype:**

**inline Color& operator/=(float);**

**Remarks:**

Divides the components of a Color by a float.

**Return Value:**

A Color divided by a float.

**Prototype:**

**inline Color& operator\*=(const Color&);**

**Remarks:**

Performs element-by-element multiplying between two Colors.

**Return Value:**

A Color element-by-element multiplied by another Color.

**Prototype:**

**int operator==(const Color& p) const**

**Remarks:**

Test for equality between two Colors.

**Return Value:**

Nonzero if the Colors are equal; otherwise 0.

**Prototype:**

**int operator!=(const Color& p) const**

**Remarks:**

Tests for inequality between two Colors.

**Return Value:**

Nonzero if the Colors are not equal; otherwise 0.

**Prototype:**

**inline Color operator-(const Color&) const;**

**Remarks:**

Subtracts a Color from a Color.

**Return Value:**

A Color that is the difference between two Colors.

**Prototype:**

**inline Color operator+(const Color&) const;**

**Remarks:**

Adds a Color to a Color.

**Return Value:**

A Color that is the difference between two Colors.

**Prototype:**

**inline Color operator/(const Color&) const;**

**Remarks:**

Divides a Color by a Color.

**Return Value:**

A Color divided by a Color. r/r, g/g, b/b.

**Prototype:**

**inline Color operator\*(const Color&) const;**

**Remarks:**

Multiplies a Color by a Color.

**Return Value:**

A Color multiplied by a Color. r\*r, g\*g, b\*b.

## Class WSMModifier

See Also: [Class Modifier](#), [SimpleWSMMod](#).

class WSMModifier : public Modifier

### Description:

This is a base class for creating world space modifiers. It simply provides a default implementation of **SuperClassID()**.

World Space Modifier plug-ins use a Super Class ID of **WSM\_CLASS\_ID**.

### Methods:

### Prototype:

**SClass\_ID SuperClassID();**

### Remarks:

Implemented by the System.

Returns the Super Class ID of this plug-in type: **WSM\_CLASS\_ID**.

## Class IKeyControl

See Also: [Class Animatable](#), [Class IKey](#), [Class Control](#), [List of SuperClass IDs](#), [Keyframe and Procedural Controller Data Access](#).

class IKeyControl

### Description:

This is an interface into the TCB, Linear, and Bezier keyframe controllers. It allows a developer to add, delete, retrieve and store the keys of the controller. This is for controllers that have made their keys accessible using this interface. 3ds max has done this for its keyframe controllers. It is up to other third party developers to decide if they wish to make their keys available through this interface as well. See below for more details.

It is up to the developer to make sure that the **IKey\*** points to a key of the appropriate derived class based on the **ClassID()** of the controller. For the details of using these APIs see the Advanced Topics section [Keyframe and Procedural Cotroller Data Access](#).

All methods of this class are implemented by the system.

To get a pointer to this interface given a pointer to a controller, use the following macro (defined in **ANIMTBL.H** ). Using this macro, given any Animatable, it is easy to ask for the control interface.

```
#define GetKeyControlInterface(anim)  
((IKeyControl*)anim->GetInterface(I_KEYCONTROL))
```

A plug-in developer may use this macro as follows:

```
IKeyControl *ikc = GetKeyControlInterface(anim);
```

This return value will either be NULL or a pointer to a valid controller interface. Here is an example of getting the controller interface from a node in the scene. First get the position controller from the node (see [Class INode](#)) and then get the controller interface.

```
Control *c;  
c = node->GetTMController()->GetPositionController();  
IKeyControl *ikeys = GetKeyControlInterface(c);
```

With this controller interface you can use its methods to get information about the keys.

```
int num = ikeys->GetNumKeys();
```

Developers should note that the values that are retrieved from this class may differ from the values that appear in Key Info in the 3ds max user interface. For instance, the Intan and Outtan values are multiplied by the global function **GetFrameRate()** when displayed. Additionally, the sign of angles (+ or -) may be reversed from the what is found in the UI. For example, the following shows the values shown in Key Info versus the values retrieved from **GetKey()**:

Motion branch Key Info:

**Key#1**

**X: -1.0**

**Y: 0.0**

**Z: 0.0**

**Ang: 0.0**

**Key#2**

**X: 0.0**

**Y: 1.0**

**Z: 0.0**

**Ang: 90.0**

**Key#3**

**X: 0.0**

**Y: 0.0**

**Z: 1.0**

**Ang: 90.0**

```
ITCBRotKey key;
```

```
ikc->GetKey(i, &key);
```

**Key#1**

**X: 1.0**

**Y: 0.0**

**Z: 0.0**

**Ang: 0.0**

**Key#2**  
**X: 0.0**  
**Y: -1.0**  
**Z: 0.0**  
**Ang: 1.57**

**Key#3**  
**X: 0.0**  
**Y: 0.0**  
**Z: -1.0**  
**Ang: 1.57**

Sample code in the SDK that makes use of this interface is the 3D Studio Export plug-in. See `\MAXSDK\SAMPLES\IMPEXP\3DSEXP.CPP`.

**The following classes are available for keyframe data storage:**

**Tension/Continuity/Bias:**

[Class ITCBKey](#)

[Class ITCBFloatKey](#)

[Class ITCBPoint3Key](#),

[Class ITCBRotKey](#)

[Class ITCBScaleKey](#)

**Bezier:**

[Class IBezFloatKey](#)

[Class IBezPoint3Key](#)

[Class IBezQuatKey](#)

[Class IBezScaleKey](#)

**Linear:**

[Class ILinFloatKey](#)

[Class ILinPoint3Key](#)

[Class ILinRotKey](#)

[Class ILinScaleKey](#)

Note: Developers creating controller plug-ins may wish to make their keys accessible to others through this interface. The way 3ds max does this is by deriving the controllers from this class (**IKeyControl**) in addition to class **Control**. So, multiple inheritance is used, and 3ds max then implements the methods of this class to provide the interface.

Below is the code from 3ds max implementation of **Animatable::GetInterface()** (as part of a template). Note the cast of the **this** pointer to **IKeyControl**.

```
INTERP_CONT_TEMPLATE
void*
InterpControl<INTERP_CONT_PARAMS>::GetInterface(ULC
id)
{
if (id==I_KEYCONTROL) {
return (IKeyControl*)this;
} else {
return Control::GetInterface(id);
}
}
```

**Methods:****Prototype:**

```
virtual int GetNumKeys()=0;
```

**Remarks:**

Returns the total number of keys.

**Prototype:**

```
virtual void SetNumKeys(int n)=0;
```

**Remarks:**

Sets the number of keys allocated. This may add blank keys or delete existing keys. It is more efficient to set a large number of keys using this method and then calling **SetKey()** to store the values rather than calling **AppendKey()** over and over for each key.

**Parameters:****int n**

The new number of keys.

**Prototype:****virtual void GetKey(int i,IKey \*key)=0;****Remarks:**

Retrieves the 'i-th' key and stores the result in key.

**Parameters:****int i**

The index of the key to retrieve.

**IKey \*key**

Storage for the key data.

**Prototype:****virtual void SetKey(int i,IKey \*key)=0;****Remarks:**

Sets the 'i-th' key. The 'i-th' key must exist.

**Parameters:****int i**

The index of the key to set.

**IKey \*key**

Pointer to the key data.

**Prototype:****virtual int AppendKey(IKey \*key)=0;****Remarks:**

This method will append a new key onto the end of the key list. Note that the key list will ultimately be sorted by time.

**Parameters:**

**IKey \*key**

Pointer to the key data to append.

**Return Value:**

The key's index.

**Prototype:**

**virtual void SortKeys()=0;**

**Remarks:**

This method should be called if any changes are made that would require the keys to be sorted. The keys are stored in order by TimeValue.

**Prototype:**

**virtual DWORD &GetTrackFlags()=0;**

**Remarks:**

Retrieves the track flags.

**Return Value:**

One or more of the following values:

**TFLAG\_CURVESEL**

Determines if the curve is selected in the track view in the function curve editor.

**TFLAG\_RANGE\_UNLOCKED**

Determines if the range is locked to the first key and the last key. If a user goes into Position Ranges mode and moves the range bar, the range becomes unlocked.

**TFLAG\_LOOPEDIN**

This is set if the in out of range type is set to loop.

**TFLAG\_LOOPEDOUT**

This is set if the out of range type is set to loop.

**TFLAG\_COLOR**

Set for Bezier Point3 controllers that are color controllers.

## **TFLAG\_HSV**

Set for color controls that interpolate in HSV rather than RGB.

# Class Object

See Also: [Class BaseObject](#), [Class Deformer](#), [Class Interval](#), [Class GraphicsWindow](#), [Template Class Tab](#), [Geometry Pipeline System](#).

```
class Object: public BaseObject , public IXTCAccess
```

## Description:

The object class is the base class for all objects. An object is one of two things: A procedural object or a derived object. Derived objects are part of the system and may not be created by plug-ins. They are containers for modifiers.

Procedural objects can be many different things such as cameras, lights, helper objects, geometric objects, etc. Methods of this class are responsible for things such as allowing the object to be deformed (changing its points), retrieving a deformed bounding box, converting the object between different types (to a mesh or patch for example), texture mapping the object (if appropriate) and interacting with the system regarding mapping. There are other methods involved in validity intervals for the object and its channels, and a method used to return the sub-object selection state of the object.

## Method Groups:

The hyperlinks below jump to the start of groups of related methods within the class:

[Viewport Rectangle Enlargement](#)

## Methods:

## Deformable Object Methods

### Prototype:

```
virtual int IsDeformable()
```

### Remarks:

Implemented by the Plug-In.

Indicates whether this object is deformable. A deformable object is simply an object with points that can be modified. Deformable objects must implement the generic deformable object methods (**NumPoints()**, **GetPoint(i)**, **SetPoint(i)**, **Deform()**).

A deformable object is simply an object with points that can be modified. These points can be stored in any form the object wants. They are accessed through a virtual array interface with methods to get and set the 'i-th' point. If an object has tangents for instance, it would convert them to and from points as necessary. For example, a simple Bezier spline object that stored its control handles relative to the knot would convert them to be absolute when **GetPoint()** was called with 'i' specifying one of the control points. When the control point is later set, the object can convert it back to be relative to its knot. At this point it could also apply any constraints that it may have, such as maintaining a degree of continuity. The idea is that the entity calling **GetPoint(i)** and **SetPoint(i)** doesn't care what the point represents. It will simply apply some function to the point.

### Return Value:

Return nonzero if the object is deformable and implements the generic deformable object methods; otherwise 0.

### Default Implementation:

```
{ return 0; }
```

Deformable object methods. These only need to be implemented if the object

returns TRUE from the **IsDeformable()** method.

**Prototype:**

**virtual int NumPoints()**

**Remarks:**

Implemented by the Plug-In.

The points of a deformable object are accessed through a virtual array interface. This method specifies the number of points in the object. The meaning of 'points' is defined by the object. A TriObject uses the vertices as the points for example.

**Default Implementation:**

**{ return 0;}**

**Return Value:**

The number of points in the object.

**Prototype:**

**virtual Point3 GetPoint(int i)**

**Remarks:**

Implemented by the Plug-In.

The points of a deformable object are accessed through a virtual array interface. This method returns the 'i-th' point of the object.

Note: If your plug-in is a modifier and you want to operate on the selected points of the object you are modifying, you can't tell which points are selected unless you know the type of object. If it is a generic deformable object there is no way of knowing since the way the object handles selection is up to it.

Therefore, if you want to operate on selected points of a generic deformable object, use a Deformer.

**Parameters:**

**int i**

Specifies which point should be returned.

**Default Implementation:**

**{ return Point3(0,0,0); }**

**Return Value:**

The 'i-th' point of the object.

**Prototype:**

**virtual void SetPoint(int i, const Point3& p)**

**Remarks:**

Implemented by the Plug-In.

The points of a deformable object are accessed through a virtual array interface. This method stores the 'i-th' point of the object.

**Parameters:**

**int i**

The index of the point to store.

**const Point3& p**

The point to store.

**Prototype:**

**virtual BOOL IsPointSelected(int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns TRUE if the 'i-th' point is selected; otherwise FALSE.

**Parameters:**

**int i**

The zero based index of the point to check.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual float PointSelection(int i);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns a floating point weighted point selection if the object supports it. The default implementation just returns 1.0f if selected and 0.0f if not.

**Parameters:****int i**

The zero based index of the point to check.

**Default Implementation:**

```
{ return IsPointSelected(i) ? 1.0f : 0.0f; }
```

**Prototype:**

```
virtual void PointsWereChanged();
```

**Remarks:**

Implemented by the Plug-In.

Informs the object that its points have been deformed, so it can invalidate its cache. A developer who uses the **GetPoint()** / **SetPoint()** approach to modifying an object will call **PointsWereChanged()** to invalidate the object's cache. For example, if a modifier calls **SetPoint()**, when it is finished it should call this method so the object can invalidate and/or update its bounding box and any other data it might cache.

**Prototype:**

```
virtual void Deform(Deformer *defProc, int useSel=0);
```

**Remarks:**

Implemented by the Plug-In.

This is the method used to deform the object with a deformer. The developer should loop through the object's points calling the **defProc** for each point (or each selected point if **useSel** is nonzero).

The **Deform()** method is mostly a convenience. Modifiers can implement a 'Deformer' callback object which is passed to the **Deform()** method. The object then iterates through its points calling their deformer's callback for each point. The only difference between using the **Deform()** method as opposed to iterating through the points is that the **Deform()** method should respect sub-object selection. For example, the TriObject's implementation of **Deform()** iterates through its vertices, if the TriObject's selection level is set to vertex then it only calls the Deformer's callback for vertices that are selected. This way modifiers can be written that can be applied only to selection sets without

any specific code to check selected points. The default implementation of this method just iterates through all points using **GetPoint(i)** and **SetPoint(i)**. If an object supports sub-object selection sets then it should override this method.

**Parameters:**

**Deformer \*defProc**

A pointer to an instance of the Deformer class. This is the callback object that actually performs the deformation.

**int useSel=0**

A flag to indicate if the object should use the selected points only. If nonzero the selected points are used; otherwise all the points of the object are used.

**Default Implementation:**

```
void Object::Deform(Deformer *defProc,int useSel) {
    int nv = NumPoints();
    for (int i=0; i<nv; i++)
        SetPoint(i,defProc->Map(i,GetPoint(i)));
    PointsWereChanged();
}
```

**Sample Code:**

This code shows the **TriObject** implementation of this method. Note how it looks at the **useSel** parameter to only call the selected points if required.

```
void TriObject::Deform(Deformer *defProc,int useSel) {
    int nv = NumPoints();
    int i;
    if ( useSel ) {
        BitArray sel = mesh.VertexTempSel();
        float *vssel = mesh.getVSelectionWeights ();
        if (vssel) {
            for (i=0; i<nv; i++) {
                if(sel[i]) {
                    SetPoint(i,defProc->Map(i,GetPoint(i)));
                    continue;
                }
                if (vssel[i]==0) continue;
            }
        }
    }
}
```

```

    Point3 & A = GetPoint(i);
    Point3 dir = defProc->Map(i,A) - A;
    SetPoint(i,A+vssel[i]*dir);
}
} else {
    for (i=0; i<nv; i++) if (sel[i]) SetPoint(i,defProc-
>Map(i,GetPoint(i)));
}
} else {
    for (i=0; i<nv; i++)
        SetPoint(i,defProc->Map(i,GetPoint(i)));
}
PointsWereChanged();
}

```

## NURBS Relational Weights

### Prototype:

```
virtual BOOL HasWeights();
```

### Remarks:

This method is available in release 2.0 and later only.

Returns TRUE if the object has weights for its points that can be set; otherwise FALSE.

### Default Implementation:

```
{ return FALSE; }
```

### Prototype:

```
virtual double GetWeight(int i);
```

### Remarks:

This method is available in release 2.0 and later only.

Returns the weight of the specified point of the object.

### Parameters:

```
int i
```

The point to return the weight of.

**Default Implementation:**

```
{ return 1.0; }
```

**Prototype:**

```
virtual void SetWeight(int i, const double w);
```

**Remarks:**

This method is available in release 2.0 and later only.

Sets the weight of the specified point.

**Parameters:**

**int i**

The point whose weight to set.

**const double w**

The value to set.

**Default Implementation:**

```
{ }
```

## **Bounding Box Method**

**Prototype:**

```
virtual void GetDeformBBox(TimeValue t, Box3& box, Matrix3  
*tm=NULL, BOOL useSel=FALSE );
```

**Remarks:**

Implemented by the Plug-In.

This method computes the bounding box in the objects local coordinates or the optional space defined by **tm**.

Note: If you are looking for a precise bounding box, use this method and pass in the node's object TM (**INode::GetObjectTM()**) as the matrix.

**Parameters:**

**TimeValue t**

The time to compute the box.

**Box3& box**

A reference to a box the result is stored in.

**Matrix3 \*tm=NULL**

This is an alternate coordinate system used to compute the box. If the **tm** is not NULL this matrix should be used in the computation of the result.

**BOOL useSel=FALSE**

If TRUE, the bounding box of selected sub-elements should be computed; otherwise the entire object should be used.

## Type Conversion Methods

### Prototype:

**virtual int CanConvertToType(Class\_ID obtype)**

### Remarks:

Implemented by the Plug-In.

Indicates whether the object can be converted to the specified type. If the object returns nonzero to indicate it can be converted to the specified type, it must handle converting to and returning an object of that type from

**ConvertToType()**.

Also see [Class ObjectConverter](#) for additional details on converting objects between types.

### Parameters:

**Class\_ID obtype**

The Class\_ID of the type of object to convert to. See [Class Class\\_ID](#), [List of Class\\_IDs](#).

### Return Value:

Nonzero if the object can be converted to the specified type; otherwise 0.

### Default Implementation:

```
{ return 0; }
```

### Prototype:

**virtual Object\* ConvertToType(TimeValue t, Class\_ID obtype)**

### Remarks:

Implemented by the Plug-In.

This method converts this object to the type specified and returns a pointer to it. Note that if `ConvertToType()` returns a new object it should be a completely different object with no ties (pointers or references) to the original.

Also see [Class ObjectConverter](#) for additional details on converting objects between types.

The following is an issue that developers of world space modifiers need to be aware of if the world space modifier specifies anything but generic deformable objects as its input type. In other words, if a world space modifier, in its implementation of **Modifier::InputType()**, doesn't specifically return **defObjectClassID** then the following issue regarding the 3ds max pipeline needs to be considered. Developers of other plug-ins that don't meet this condition don't need to be concerned with this issue.

World space modifiers that work on anything other than generic deformable objects are responsible for transforming the points of the object they modify into world space using the ObjectState TM. To understand why this is necessary, consider how 3ds max applies the node transformation to the object flowing down the pipeline.

In the geometry pipeline architecture, the node in the scene has its transformation applied to the object in the pipeline at the transition between the last object space modifier and the first world space modifier. The node transformation is what places the object in the scene -- thus this is what puts the object in world space. The system does this by transforming the points of the object in the pipeline by the node transformation. This is only possible however for deformable objects. Deformable objects are those that support the **Object::IsDeformable()**, **NumPoints()**, **GetPoint()** and **SetPoint()** methods. These deformable objects can be deformed by the system using these methods, and thus the system can modify the points to put them in world space itself.

If a world space modifier does not specify that it works on deformable objects, the system is unable to transform the points of the object into world space. What it does instead is apply the transformation to the ObjectState TM. In this case, a world space modifier is responsible for transforming the points of the object into world space itself, and then setting the ObjectState TM to the identity. There is an example of this in the sample code for the Bomb space warp. The Bomb operates on **TriObjects** and implements **InputType()** as `{ return Class_ID(TRIOBJ_CLASS_ID,0); }`. Since

it doesn't specifically return **defObjectClassID**, it is thus responsible for transforming the points of the object into world space itself. It does this in its implementation of **ModifyObject()** as follows:

```
if (os->GetTM()) {  
    Matrix3 tm = *(os->GetTM());  
    for (int i=0; i<triOb->mesh.getNumVerts(); i++) {  
        triOb->mesh.verts[i] = triOb->mesh.verts[i] * tm;  
    }  
    os->obj->UpdateValidity(GEOM_CHAN_NUM,os->tmValid());  
    os->SetTM(NULL,FOREVER);  
}
```

As the code above shows, the Bomb checks if the ObjectState TM is non-NULL. If it is, the points of the object are still not in world space and thus must be transformed. It does this by looping through the points of the **TriObject** and multiplying each point by the ObjectState TM. When it is done, it sets the ObjectState TM to NULL to indicate the points are now in world space. This ensure that any later WSMs will not transform the points with this matrix again.

For the Bomb world space modifier this is not a problem since it specifies in its implementation of **ChannelsChanged()** that it will operate on the geometry channel (**PART\_GEOM**). Certain world space modifiers may not normally specify **PART\_GEOM** in their implementation of **ChannelsChanged()**. Consider the camera mapping world space modifier. Its function is to apply mapping coordinates to the object it is applied to. Thus it would normally only specify **PART\_TEXMAP** for **ChannelsChanged()**. However, since it operates directly on **TriObjects**, just like the Bomb, the system cannot transform the points into world space, and therefore the camera mapping modifier must do so in its implementation of **ModifyObject()**. But since it is actually altering the points of the object by putting them into world space it **is** altering the geometry channel. Therefore, it should really specify **PART\_GEOM | PART\_TEXMAP** in its implementation of **ChannelsChanged()**. If it didn't do this, but went ahead and modified the points of the object anyway, it would be transforming not copies of the points, but the original points stored back in an earlier cache or even the base object.

This is the issue developers need to be aware of. To state this in simple terms then: Any world space modifier that needs to put the points of the object into world space (since it doesn't implement **InputType()** as **defObjectClassID**) needs to specify **PART\_GEOM** in its implementation of **ChannelsChanged()**.

**Parameters:**

**TimeValue t**

The time at which to convert.

**Class\_ID obtype**

The Class\_ID of the type of object to convert to. See [Class Class\\_ID](#), [List of Class IDs](#).

**Return Value:**

A pointer to an object of type **obtype**.

**Default Implementation:**

```
{ return NULL; }
```

**Sample Code:**

The following code shows how a **TriObject** can be retrieved from a node. Note on the code that if you call **ConvertToType()** on an object and it returns a pointer other than itself, you are responsible for deleting that object.

```
// Retrieve the TriObject from the node
int deleteIt;
TriObject *triObject = GetTriObjectFromNode(ip->GetSelNode(0),
    deleteIt);
// Use the TriObject if available
if (!triObject) return;
// ...
// Delete it when done...
if (deleteIt) triObject->DeleteMe();

// Return a pointer to a TriObject given an INode or return NULL
// if the node cannot be converted to a TriObject
TriObject *Utility::GetTriObjectFromNode(INode *node, int
&deleteIt) {
    deleteIt = FALSE;
```

```

Object *obj = node->EvalWorldState(0).obj;
if (obj->CanConvertToType(Class_ID(TRIOBJ_CLASS_ID, 0))) {
    TriObject *tri = (TriObject *) obj->ConvertToType(0,
        Class_ID(TRIOBJ_CLASS_ID, 0));
    // Note that the TriObject should only be deleted
    // if the pointer to it is not equal to the object
    // pointer that called ConvertToType()
    if (obj != tri) deleteIt = TRUE;
    return tri;
}
else {
    return NULL;
}
}

```

## Face and Vertex Count Calculations

### Prototype:

```

virtual BOOL PolygonCount(TimeValue t, int& numFaces, int&
numVerts);

```

### Remarks:

This method is available in release 3.0 and later only.

Retrieves the number of faces and vertices of the polyginal mesh representation of this object. If this method returns FALSE then this functionality is not supported.

Note: Plug-In developers should use the global function

**GetPolygonCount(Object\*, int&, int&)** to retrieve the number of vertices and faces in an arbitrary object.

### Parameters:

#### **TimeValue t**

The time at which to compute the number of faces and vertices.

#### **int& numFaces**

The number of faces is returned here.

#### **int& numVerts**

The number of vertices is returned here.

**Return Value:**

TRUE if the method is fully implemented; otherwise FALSE.

**Default Implementation:**

```
{ return FALSE; }
```

## Collapse Stack Methods

**Prototype:**

```
virtual Class_ID PreferredCollapseType();
```

**Remarks:**

This method is available in release 2.0 and later only.

This method allows objects to specify the class that is the best class to convert to when the user collapses the stack. The main base classes have default implementations. For example, `GeomObject` specifies `TriObjects` as its preferred collapse type and `shapes` specify `splines` as their preferred collapse type

**Default Implementation:**

```
{return Class_ID(0,0);}
```

**Return Value:**

The `Class_ID` of the preferred object type. See [List of Class IDs](#).

**Prototype:**

```
virtual void GetCollapseTypes(Tab<Class_ID>  
&clist, Tab<TSTR*> &nlist);
```

**Remarks:**

This method is available in release 2.0 and later only.

When the user clicks on the Edit Stack button in the modify branch a list of 'Convert To:' types is presented. The user may click on one of these choices to collapse the object into one of these types (for instance, an Editable Mesh or an Editable NURBS object). This method returns a list of `Class_IDs` and descriptive strings that specify the allowable types of objects that this object may be collapsed into.

Note: Most plug-ins call the base class method in **Object** in their implementation of this method. The base class implementation provided by

**Object** checks if the object can convert to both an editable mesh and an editable spline. If it can, these are added to the allowable types.

**Parameters:**

**Tab<Class\_ID> &clist**

The table of allowable Class\_IDs.

**Tab<TSTR\*> &nlist**

The table of pointers to strings that correspond to the table of Class\_IDs above.

**Sample Code:**

```
void SphereObject::GetCollapseTypes(Tab<Class_ID>
&clist, Tab<TSTR*> &nlist)
{
    Object::GetCollapseTypes(clist, nlist);
    Class_ID id = EDITABLE_SURF_CLASS_ID;
    TSTR *name = new TSTR(GetString(IDS_SM_NURBS_SURFACE));
    clist.Append(1, &id);
    nlist.Append(1, &name);
}
```

**Prototype:**

**virtual Object \*CollapseObject();**

**Remarks:**

This method is available in release 4.0 and later only.

This method is called on the world space cache object when the stack gets collapsed, that lets the pipeline object decide, if it wants to return a different object than itself. The default implementation simply returns this. A PolyObject e.g. can create and return an EditablePolyObject in this method, so that the collapsed object has a UI. I only implemented this method for PolyObject, but this can potentially be implemented that way for all pipeline objects, that currently pass up the editable version.

It is important, that all places, that collapse the stack are calling this method after evaluating the stack.

It also is important, that the editable version implements this method to simply return this, otherwise you'll get a non-editable object when you collapse an

editable polyobject.

**Return Value:**

A pointer to the resulting object.

**Default Implementation:**

```
{ return this;}
```

## Mapping Methods

**Prototype:**

```
virtual int IsMappable()
```

**Remarks:**

This method lets you know if the **ApplyUVWMap()** method is available for this object. This is used by things like the UVW mapping modifier, so that it can determine which objects can have their mapping modified. Returns nonzero if the object is mappable; otherwise zero.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual int NumMapChannels();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the maximum number of channels supported by this type of object.

TriObjects for instance return **MAX\_MESHMAPS** which is currently set to 100.

**Default Implementation:**

```
{ return IsMappable(); }
```

**Prototype:**

```
virtual int NumMapsUsed();
```

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of maps currently used by this object. This is at least 1+ (highest channel in use). This is used so a plug-in that does something to all map channels doesn't always have to do it to every channel up to **MAX\_MESHMAPS** but rather only to this value.

**Default Implementation:**

```
{ return NumMapChannels(); }
```

**Prototype:**

```
void ApplyUVWMap(int type,float utile, float vtile, float wtile,int  
uflip, int vflip, int wflip, int cap,const Matrix3 &tm, int  
channel=1);
```

**Remarks:**

This method may be called to map the object with UVW mapping coordinates. If the object returns nonzero from **IsMappable()** then this method should be implemented.

**Parameters:**

**int type**

The mapping type. One of the following values:

**MAP\_PLANAR**

**MAP\_CYLINDRICAL**

**MAP\_SPHERICAL**

**MAP\_BALL**

**MAP\_BOX**

**float utile**

Number of tiles in the U direction.

**float vtile**

Number of tiles in the V direction.

**float wtile**

Number of tiles in the W direction.

**int uflip**

If nonzero the U values are mirrored.

**int vflip**

If nonzero the V values are mirrored.

**int wflip**

If nonzero the W values are mirrored.

**int cap**

This is used with **MAP\_CYLINDRICAL**. If nonzero, then any face normal that is pointing more vertically than horizontally will be mapped using planar coordinates.

**const Matrix3 &tm**

This defines the mapping space. As each point is mapped, it is multiplied by this matrix, and then it is mapped.

**int channel=1**

This parameter is available in release 2.0 and later only.

This indicates which channel the mapping is applied to. See [List of Mapping Channel Index Values](#).

## Object Name, Properties, Display, and IntersectRay Methods

**Prototype:**

```
virtual int IsRenderable()=0;
```

**Remarks:**

Implemented by the Plug-In.

Indicates whether the object may be rendered. Some objects such as construction grids and helpers should not be rendered and can return zero.

**Return Value:**

Nonzero if the object may be rendered; otherwise 0.

**Prototype:**

```
virtual int IsConstObject()
```

**Remarks:**

Implemented by the Plug-In.

This is called to determine if this is a construction object or not.

**Return Value:**

Nonzero if the object is a construction object; otherwise 0.

**Default Implementation:**

```
{ return 0; }
```

**Prototype:**

```
virtual void InitNodeName(TSTR& s)=0;
```

**Remarks:**

Implemented by the Plug-In.

This is the default name of the node when it is created.

**Parameters:**

**TSTR& s**

The default name of the node is stored here.

**Prototype:**

```
virtual int UsesWireColor()
```

**Remarks:**

Implemented by the Plug-In.

This method determines if the object color is used for display.

**Return Value:**

TRUE if the object color is used for display; otherwise FALSE.

**Default Implementation:**

```
{ return TRUE; }
```

**Prototype:**

```
virtual int DoOwnSelectHilite()
```

**Remarks:**

Implemented by the Plug-In.

If an object wants to draw itself in the 3D viewports in its selected state in some custom manner this method should return nonzero. If this item returns nonzero, the **BaseObject::Display()** method should respect the selected state of the object when it draws itself. If this method returns zero the system will use its standard method of showing the object as selected.

**Default Implementation:**

```
{ return 0; }
```

**Return Value:**

Nonzero if the object will draw itself in the selected state; otherwise 0. If nonzero, the plug-in developer is responsible for displaying the object in the selected state as part of its **Display()** method.

**Prototype:**

```
virtual int IntersectRay(TimeValue t, Ray& r, float& at, Point3& norm)
```

**Remarks:**

Implemented by the Plug-In.

This method is called to compute the intersection point and surface normal at this intersection point of the ray passed and the object.

**Parameters:****TimeValue t**

The time to compute the intersection.

**Ray& r**

Ray to intersect. See [Class Ray](#).

**float& at**

The point of intersection.

**Point3& norm**

Surface normal at the point of intersection.

**Default Implementation:**

```
{return FALSE;}
```

**Return Value:**

Nonzero if a point of intersection was found; otherwise 0.

See Also: The [Mesh class](#) implementation of this method.

**Prototype:**

```
virtual BOOL NormalAlignVector(TimeValue t,Point3 &pt, Point3 &norm);
```

**Remarks:**

This method is available in release 2.0 and later only.

Objects that don't support the **IntersectRay()** method (such as helper objects) can implement this method to provide a default vector for use with the normal align command in 3ds max.

**Parameters:**

**TimeValue t**

The time to compute the normal align vector.

**Point3 &pt**

The point of intersection.

**Point3 &norm**

The normal at the point of intersection.

**Return Value:**

TRUE if this method is implemented to return the normal align vector; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

## Validity Interval Methods

**Prototype:**

```
virtual Interval ObjectValidity(TimeValue t)
```

**Remarks:**

Implemented by the Plug-In.

This method returns the validity interval of the object as a whole at the specified time.

**Parameters:**

**TimeValue t**

The time to compute the validity interval.

**Default Implementation:**

```
{ return FOREVER; }
```

**Return Value:**

The validity interval of the object.

**Prototype:**

```
void UpdateValidity(int nchan, Interval v);
```

**Remarks:**

Implemented by the Plug-In.

When a modifier is applied to an object, it needs to include its own validity interval in the interval of the object. To do this, a modifier calls the **UpdateValidity()** method of an object. This method intersects interval **v** to the **nchan** channel validity of the object.

**Parameters:****int nchan**

The validity interval of the modifier is intersected with this channel of the object. See [List of Object Channel Numbers](#).

**Interval v**

The interval to intersect.

## Shapes Within Objects

Shape viewports can reference shapes contained within objects, so the system needs to be able to access the shapes within an object. The following four methods provide this access. These methods are used by the loft object. Since loft objects are made up of shapes, this gives the system the ability to query the object to find out if it is a shape container. Most objects don't contain shapes so they can just use the default implementations.

**Prototype:**

```
virtual int NumberOfContainedShapes();
```

**Remarks:**

Implemented by the Plug-In.

Returns the number of shapes contained inside this object. A shape container may return zero if it doesn't currently have any shapes.

**Return Value:**

The number of shapes. A return value of -1 indicates this is not a container.

**Default Implementation:**

```
{ return -1; }
```

**Prototype:**

**virtual ShapeObject \*GetContainedShape(TimeValue t, int index)**

**Remarks:**

Implemented by the Plug-In.

This method returns the **ShapeObject** specified by the index passed at the time specified. See [Class ShapeObject](#).

**Parameters:**

**TimeValue t**

The time to return the shape.

**int index**

The index of the shape.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual void GetContainedShapeMatrix(TimeValue t, int index, Matrix3 &mat)**

**Remarks:**

Implemented by the Plug-In.

Returns the matrix associated with the shape whose index is passed. This matrix contains the offset within the object used to align the shape viewport to the shape.

**Parameters:**

**TimeValue t**

The time to return the matrix.

**int index**

The index of the shape whose matrix to return.

**Matrix3 &mat**

The matrix is returned here.

**Default Implementation:**

```
{ }
```

**Prototype:****virtual BitArray ContainedShapeSelectionArray()****Remarks:**

Implemented by the Plug-In.

This is used by the lofter. The lofter can have several shapes selected, and the bit array returned here will have a bit set for each selected shape. See [Class BitArray](#).

**Return Value:****Default Implementation:****{ return BitArray(); }**

## Object Integrity Checking

**Prototype:****virtual BOOL CheckObjectIntegrity()****Remarks:**

Implemented by the Plug-In.

This method is used for debugging only. The TriObject implements this method by making sure its face's vert indices are all valid.

**Return Value:**

TRUE if valid; otherwise FALSE.

**Default Implementation:****{return TRUE;}**

## Sub-Object Selection

**Prototype:****virtual DWORD GetSubselState()****Remarks:**

Implemented by the Plug-In.

For objects that have sub selection levels, this method returns the current selection level of the object. For example, a TriObject has the following selection levels: object, vertex, face, edge. Other object types may have

different selection levels. The only standard is that a value of 0 indicates object level.

**Default Implementation:**

```
{return 0;}
```

**Return Value:**

The current selection level of the object.

## **Data Flow Evaluation Methods**

Most plug-in procedural objects do not need to be concerned with the following methods associated with locks, channels and shallow copies. The only type of plug-ins that needs to be concerned with these methods are objects that actually flow down the pipeline. Most procedural plug-ins don't go down the pipeline, instead they convert themselves to a TriObject or PatchObject, and these goes down the pipeline. It is these TriObjects or PatchObject that deal with these methods. However plug-in objects that actually flow down the pipeline will use these methods. For more information see the Advanced Topics section on the [Geometry Pipeline System](#).

**Prototype:**

```
virtual ObjectState Eval(TimeValue t)=0;
```

**Remarks:**

Implemented by the Plug-In.

This method is called to evaluate the object and return the result as an ObjectState. When the system has a pointer to an object it doesn't know if it's a procedural object or a derived object. So it calls **Eval()** on it and gets back an ObjectState. A derived object managed by the system may have to call **Eval()** on its input for example. A plug-in (like a procedural object) typically just returns itself.

A plug-in that does not just return itself is the Morph Object (`\MAXSDK\SAMPLES\OBJECTS\MORPHOBJ.CPP`). This object uses a morph controller to compute a new object and fill in an ObjectState which it returns.

**Parameters:**

**TimeValue t**

Specifies the time to evaluate the object.

**Return Value:**

The result of evaluating the object as an ObjectState.

**Sample Code:**

Typically this method is implemented as follows:

```
{ return ObjectState(this); }
```

**Prototype:**

```
void LockObject()
```

**Remarks:**

Implemented by the System.

This method locks the object as a whole. The object defaults to not modifiable.

**Prototype:**

```
void UnlockObject()
```

**Remarks:**

Implemented by the System.

This method unlocks the object as a whole.

**Prototype:**

```
int IsObjectLocked()
```

**Remarks:**

Implemented by the System.

Returns nonzero if the object is locked; otherwise 0.

**Prototype:**

```
void LockChannels(ChannelMask channels)
```

**Remarks:**

Implemented by the System.

Locks the specified channels of the object.

**Parameters:**

## **ChannelMask channels**

The channels to lock.

### **Prototype:**

**void UnlockChannels(ChannelMask channels)**

### **Remarks:**

Implemented by the System.

Unlocks the specified channel(s) of the object.

### **Parameters:**

**ChannelMask channels**

Specifies the channels to unlock.

### **Prototype:**

**ChannelMask GetChannelLocks()**

### **Remarks:**

Implemented by the System.

Returns the locked status of the channels.

### **Return Value:**

The channels of the object that are locked.

### **Prototype:**

**void SetChannelLocks(ChannelMask channels)**

### **Remarks:**

Implemented by the System.

Sets the locked status of the object's channels.

### **Parameters:**

**ChannelMask channels**

The channel to set to locked.

### **Prototype:**

**ChannelMask GetChannelLocks(ChannelMask m)**

**Remarks:**

Implemented by the System.  
Returns the locked status of the channels.

**Parameters:****ChannelMask m**

Not used.

**Return Value:**

The channels of the object that are locked.

**Prototype:**

```
void CopyChannelLocks(Object *obj, ChannelMask  
needChannels);
```

**Remarks:**

Implemented by the System.  
Copies the specified channels from the object passed.

**Parameters:****Object \*obj**

The source object.

**ChannelMask needChannels**

Indicates the channels to copy.

**Prototype:**

```
virtual Interval ChannelValidity(TimeValue t, int nchan);
```

**Remarks:**

Implemented by the Plug-In.  
Retrieve the current validity interval for the **nchan** channel of the object.  
Note that most procedural objects won't implement this method since they don't have individual channels. Developers wanting to get the validity interval for a procedural object should use **Object::ObjectValidity()** instead.

**Parameters:****TimeValue t**

The time to retrieve the validity interval of the channel.

**int nchan**

Specifies the channel to return the validity interval of. See [List of Object Channel Numbers](#).

**Return Value:**

The validity interval of the specified channel.

**Default Implementation:**

**return FOREVER;**

**Prototype:**

**virtual void SetChannelValidity(int nchan, Interval v);**

**Remarks:**

Implemented by the Plug-In.

Sets the validity interval of the specified channel.

**Parameters:****int nchan**

Specifies the channel. See [List of Object Channel Numbers](#).

**Interval v**

The validity interval for the channel.

**Prototype:**

**virtual void InvalidateChannels(ChannelMask channels)**

**Remarks:**

Implemented by the Plug-In.

This method invalidates the intervals for the given channel mask. This just sets the validity intervals to empty (calling **SetEmpty()** on the interval) .

**Parameters:****ChannelMask channels**

Specifies the channels to invalidate.

**Prototype:**

**void ReadyChannelsForMod(ChannelMask channels);**

**Remarks:**

Implemented by the System.

If the requested channels are locked, this method will replace their data with a copy and unlock them, otherwise it leaves them alone.

**Parameters:****ChannelMask channels**

The channels to ready for modification.

**Prototype:**

**virtual Object \*MakeShallowCopy(ChannelMask channels)**

**Remarks:**

Implemented by the Plug-In.

This method must make a copy of its "shell" and then shallow copy (see below) only the specified channels. It must also copy the validity intervals of the copied channels, and invalidate the other intervals.

**Parameters:****ChannelMask channels**

The channels to copy.

**Return Value:**

A pointer to the shallow copy of the object.

**Default Implementation:**

```
{ return NULL; }
```

**Prototype:**

**virtual void ShallowCopy(Object\* fromOb, ChannelMask channels)**

**Remarks:**

Implemented by the Plug-In.

This method copies the specified channels from the **fromOb** to **this** and copies the validity intervals.

A plug-in needs to copy the specified channels from the specified object **fromOb** to itself by just copying pointers (not actually copying the data). No

new memory is typically allocated, this method is just copying the pointers.

**Parameters:**

**Object\* fromOb**

Object to copy the channels from.

**ChannelMask channels**

Channels to copy.

**Prototype:**

**virtual void NewAndCopyChannels(ChannelMask channels)**

**Remarks:**

Implemented by the Plug-In.

This method replaces the locked channels with newly allocated copies. It will only be called if the channel is locked.

**Parameters:**

**ChannelMask channels**

The channels to be allocate and copy.

**Prototype:**

**virtual void FreeChannels(ChannelMask channels)**

**Remarks:**

Implemented by the Plug-In.

This method deletes the memory associated with the specified channels and set the intervals associated with the channels to invalid (empty).

**Parameters:**

**ChannelMask channels**

Specifies the channels to free.

**Prototype:**

**Interval GetNoEvalInterval()**

**Remarks:**

This method is used internally.

**Prototype:****void SetNoEvalInterval(Interval iv);****Remarks:**

This method is used internally.

**Prototype:****virtual void ReduceCaches(TimeValue t);****Remarks:**

Implemented by the Plug-In.

This method give the object the chance to reduce its caches.

**Parameters:****TimeValue t**

The time to discard any caches the object has.

**Modifier Stack Branching Methods.****Prototype:****virtual int NumPipeBranches(bool selected = true)****Remarks:**

Implemented by the Plug-In.

This method returns the number of pipeline branches combined by the object.

This is not the total number of branches, but rather the number that are active.

For example in the boolean object, if the user does not have any operands selected, this methods would return zero. If they have one selected it would return one.

**Parameters:****bool selected = true**

This parameter is available in release 4.0 and later only.

This parameter must be supported by all compound objects. In case the selected parameter is true the object should only return the number of pipebranches, that are currently selected in the UI (this is the way it worked in R3 and before. In case this parameter is false, the object has to return the number of all branches, no matter if they are selected or not

**Default Implementation:**

```
{return 0;}
```

**Prototype:**

```
virtual Object *GetPipeBranch(int i, bool selected = true)
```

**Remarks:**

Implemented by the Plug-In.

Retrieves sub-object branches from an object that supports branching. Certain objects combine a series of input objects (pipelines) into a single object. These objects act as a multiplexer allowing the user to decide which branch(s) they want to see the history for.

It is up to the object how they want to let the user choose. For example the object may use sub-object selection to allow the user to pick a set of objects for which the common history will be displayed.

When the history changes for any reason, the object should send a notification (**REFMSG\_BRANCHED\_HISTORY\_CHANGED**) via **NotifyDependents()**.

**Parameters:**

**int i**

The branch index.

**bool selected = true**

This parameter is available in release 4.0 and later only.

This parameter must be supported by all compound objects. In case the selected parameter is true the object should only return the number of pipebranches, that are currently selected in the UI (this is the way it worked in R3 and before. In case this parameter is false, the object has to return the number of all branches, no matter if they are selected or not

**Return Value:**

The 'i-th' sub-object branch.

**Default Implementation:**

```
{return NULL;}
```

**Prototype:**

**virtual INode \*GetBranchINode(TimeValue t, INode \*node, int i, bool selected = true)**

**Remarks:**

Implemented by the Plug-In.

When an object has sub-object branches, it is likely that the sub-objects are transformed relative to the object. This method gives the object a chance to modify the node's transformation so that operations (like edit modifiers) will work correctly when editing the history of the sub object branch. An object can implement this method by returning a pointer to a new

**INodeTransformed** that is based on the node passed into this method. See [Class INodeTransformed](#).

**Parameters:**

**TimeValue t**

The time to get the INode.

**INode \*node**

The original INode pointer.

**int i**

The branch index.

**bool selected = true**

This parameter is available in release 4.0 and later only.

This parameter must be supported by all compound objects. In case the selected parameter is true the object should only return the number of pipebranches, that are currently selected in the UI (this is the way it worked in R3 and before. In case this parameter is false, the object has to return the number of all branches, no matter if they are selected or not

**Return Value:**

A pointer to an INode. This can be the original passed in (the default implementation does this) or a new **INodeTransformed**.

**Default Implementation:**

```
{return node;}
```

## Particle System Methods

**Prototype:**

## **virtual BOOL CanCacheObject()**

### **Remarks:**

Implemented by the Plug-In.

This method determines if this object can have channels cached. Particle objects flow up the pipeline without making shallow copies of themselves and therefore cannot be cached. Objects other than particle system can just use the default implementation.

### **Return Value:**

TRUE if the object can be cached; otherwise FALSE.

### **Default Implementation:**

```
{return TRUE;}
```

### **Prototype:**

```
virtual void WSStateInvalidate()
```

### **Remarks:**

Implemented by the Plug-In.

This is called by a node when the node's world space state has become invalid. Normally an object does not (and should not) be concerned with this, but in certain cases like particle systems an object is effectively a world space object and needs to be notified.

### **Default Implementation:**

```
{}
```

### **Prototype:**

```
virtual BOOL IsWorldSpaceObject()
```

### **Remarks:**

Implemented by the Plug-In.

Returns TRUE if the object is a world space object; otherwise FALSE. World space objects (particles for example) can not be instanced because they exist in world space not object space. Objects other than particle system can just use the default implementation.

### **Default Implementation:**

```
{return FALSE;}
```

**Prototype:**

```
virtual Object *FindObject();
```

**Remarks:**

Implemented by the Plug-In.

This method moved from **IDerivedObject** where it was in release 1.x.

It is called to return a pointer to the base object (an object that is not a derived object). This method is overridden by DerivedObjects to search down the pipeline for the base object. The default implementation just returns **this**. This function is still implemented by derived objects and WSM's to search down the pipeline. This allows you to just call it on a nodes ObjectRef without checking for type.

**Default Implementation:**

```
{ return this; }
```

## **Parametric Surface Access**

**Prototype:**

```
virtual BOOL IsParamSurface();
```

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

There are several methods used to access a parametric position on the surface of the object. If this method returns TRUE then

**Object::GetSurfacePoint()** will be called to return a point on the surface that corresponds to the **u** and **v** parameters passed to it. If this method returns FALSE then it is assumed the object does not support returning a point on the surface based on parameteric values. For sample code see

**\MAXSDK\SAMPLES\OBJECTS\SPHERE.CPP**. If the object has several parametric surfaces then a second version of **GetSurfacePoint()** with an integer which specifies which surface will be called.

**Default Implementation:**

```
{ return FALSE; }
```

**Prototype:**

**virtual int NumSurfaces(TimeValue t);**

**Remarks:**

This method is available in release 3.0 and later only.

Returns the number of parametric surfaces within the object. Prior to release 3.0 only one parametric object could be accessed.

**Parameters:**

**TimeValue t**

The time at which to check.

**Default Implementation:**

**{return 1;}**

**Prototype:**

**virtual Point3 GetSurfacePoint(TimeValue t, float u, float v,Interval &iv);**

**Remarks:**

Implemented by the Plug-In.

This method is available in release 2.0 and later only.

This method needs to be implemented if **Object::IsParamSurface()** returns TRUE. This method is used to retrieve a point on the surface of the object based on two parameters of the surface, **u** and **v**.

Note: This method assumes there is a single parametric surface. If there is more than 1 (**NumSurfaces()** returns > 1, use the **GetSurface()** method below which allows for multiple surfaces.

**Parameters:**

**TimeValue t**

The time to retrieve the point.

**float u**

The parameter along the horizontal axis of the surface.

**float v**

The parameter along the vertical axis of the surface.

**Interval &iv**

This interval is updated based on the interval of the surface parameter.

**Default Implementation:**

```
{return Point3(0,0,0);}
```

**Prototype:**

```
virtual Point3 GetSurfacePoint(TimeValue t, int surface, float u,  
float v,Interval &iv);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method is used to retrieve a point on the specified surface of the object based on two parameters of the surface, **u** and **v**.

**Parameters:**

**TimeValue t**

The time to retrieve the point.

**int surface**

The zero based index of the surface. This number is  $\geq 0$  and  $< \text{NumSurfaces}()$ .

**float u**

The parameter along the horizontal axis of the surface.

**float v**

The parameter along the vertical axis of the surface.

**Interval &iv**

This interval is updated based on the interval of the surface parameter.

**Default Implementation:**

```
{return Point3(0,0,0);}
```

**Prototype:**

```
virtual void SurfaceClosed(TimeValue t, int surface, BOOL  
&uClosed, BOOL &vClosed);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method allows the object to return flags that indicate whether the parametric surface is closed in the U and V dimensions. Set the appropriate closure variables to TRUE if the surface is closed in that direction, FALSE if it is not. A torus, for example, is closed in both directions.

**Parameters:**

**TimeValue t**

The time to check the surface.

**int surface**

The zero based index of the surface. This number is  $\geq 0$  and  $< \text{NumSurfaces}()$ .

**BOOL &uClosed**

Set to TRUE if the surface is closed in U; otherwise to FALSE.

**BOOL &vClosed**

Set to TRUE if the surface is closed in V; otherwise to FALSE.

**Default Implementation:**

**{uClosed = vClosed = TRUE;}**

## **Viewport Rectangle Enlargement**

**Prototype:**

**virtual void MaybeEnlargeViewportRect(GraphicsWindow \*gw, Rect &rect);**

**Remarks:**

This method is available in release 3.0 and later only.

This method allows the object to enlarge its viewport rectangle, if it wants to. The system will call this method for all objects when calculating the viewport rectangle; the object can enlarge the rectangle if desired. This is used by the Editable Spline code to allow extra room for vertex serial numbers, which can extend outside the normal bounding rectangle.

**Parameters:**

**GraphicsWindow \*gw**

Points to the GraphicsWindow associated with the viewport.

**Rect &rect**

The enlarged rectangle is returned here.

**Default Implementation:**

```
{
```

**Sample Code:**

```
void SplineShape::MaybeEnlargeViewportRect(GraphicsWindow
*gw, Rect &rect) {
    if(!showVertNumbers)
        return;
    TCHAR dummy[256];
    SIZE size;
    int maxverts = -1;
    for(int i = 0; i < shape.splineCount; ++i) {
        int verts = shape.splines[i]->KnotCount();
        if(verts > maxverts)
            maxverts = verts;
    }
    sprintf(dummy,"%d",maxverts);
    gw->getTextExtents(dummy, &size);
    rect.SetW(rect.w() + size.cx);
    rect.SetY(rect.y() - size.cy);
    rect.SetH(rect.h() + size.cy);
}
```

**Prototype:**

```
virtual BOOL GetExtendedProperties(TimeValue t, TSTR
&prop1Label, TSTR &prop1Data, TSTR &prop2Label, TSTR
&prop2Data);
```

**Remarks:**

This method is available in release 3.0 and later only.

This method allows an object to return extended Properties fields. It is called when the Object Properties dialog is being prepared. If you don't want to

display any extended properties, simply return FALSE.

To display extended property fields, place the field label in the appropriate label string and the display value in a formatted string. Two fields are supplied, each with a label and a data string; if only using one, make the second label field and data field blank (""). Return TRUE to indicate you have filled in the fields. The properties dialog will display your returned values.

**Parameters:**

**TimeValue t**

The time at which the strings are requested.

**TSTR &prop1Label**

The string for the property 1 label.

**TSTR &prop1Data**

The formatted data string to appear as property 1.

**TSTR &prop2Label**

The string for the property 2 label.

**TSTR &prop2Data**

The formatted data string to appear as property 2.

**Return Value:**

TRUE if this method is implemented and the fields are filled in; otherwise FALSE.

**Default Implementation:**

```
{return FALSE;}
```

**ExtensionChannel Access :**

**Prototype:**

```
void AddXTCObject(XTCObject *pObj, int priority = 0, int  
branchID = -1);
```

**Remarks:**

This method is available in release 4.0 and later only.

This method adds an extension object into the pipeline.

Implemented by the System.

**Parameters:**

**XTCObject \*pObj**

Points to the extension object to add.

**int priority = 0**

The priority of the object. The methods (XTCObject::Display(), PreChanChangedNotify() etc) of higher priority XTCObjects will be called before those of lower priority XTCObjects.

**int branchID = -1**

The branch identifier of the object.

**Prototype:****int NumXTCObjects();****Remarks:**

This method is available in release 4.0 and later only.

Returns the number of extension objects maintained by this Object.

Implemented by the System.

**Prototype:****XTCObject \*GetXTCObject(int index);****Remarks:**

This method is available in release 4.0 and later only.

Returns a pointer to the specified extension object.

Implemented by the System.

**Parameters:****int index**

The zero based index of the extension object to return.

**Prototype:****void RemoveXTCObject(int index);****Remarks:**

This method is available in release 4.0 and later only.

Removes the extension object as indicated by the index.

Implemented by the System.

**Parameters:****int index**

The zero based index of the extension object to remove.

**Prototype:**

```
void SetXTCObjectPriority(int index,int priority);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the priority for the extension object whose index is passed.

Implemented by the System.

**Parameters:****int index**

The zero based index of the extension object to remove.

**int priority**

The new priority to assign.

**Prototype:**

```
int GetXTCObjectPriority(int index);
```

**Remarks:**

This method is available in release 4.0 and later only.

Returns the integer priority number of the extension object whose index is passed.

Implemented by the System.

**Parameters:****int index**

The zero based index of the extension object to check.

**Prototype:**

```
void SetXTCObjectBranchID(int index,int branchID);
```

**Remarks:**

This method is available in release 4.0 and later only.

Sets the branch ID of the extension object whose index is passed.

Implemented by the System.

**Parameters:**

**int index**

The zero based index of the extension object whose branch ID is set.

**int branchID**

The branch identifier to set.

**Prototype:**

**int GetXTCObjectBranchID(int index);**

**Remarks:**

This method is available in release 4.0 and later only.

Returns the integer branch ID of the extension object whose index is passed.

Implemented by the System.

**Parameters:**

**int index**

The zero based index of the extension object whose branch ID is to be returned.

**Prototype:**

**void MergeAdditionalChannels(Object \*from, int branchID);**

**Remarks:**

This method is available in release 4.0 and later only.

This method has to be called whenever the CompoundObject updates a branch (calling **Eval()** on it). Object **\*from** is the object returned from

**Eval(os.obj)**. The branchID is an integer that specifies that branch. The extension channel will get a callback to

**XTCObject::RemoveXTCObjectOnMergeBranches()** and

**XTCObject::MergeXTCObject()**. By default it returns true to

**RemoveXTCObjectOnMergeBranches** which means that the existing XTCObjects with that branchID will be deleted. The method

**MergeXTCObject** simply copies the XTCObjects from the incoming branch into the compound object.

Implemented by the System.

**Parameters:**

**Object \*from**

The object to merge additional channels from.

**int branchID**

The branch identifier to set.

**Prototype:**

**void BranchDeleted(int branchID, bool reorderChannels);**

**Remarks:**

This method is available in release 4.0 and later only.

This method has to be called on the CompoundObject so it can delete the XTCTObjects for the specified branch. The XTCTObject will again have the final decision if the XTCTObject gets really deleted or not in a callback to **XTCTObject::RemoveXTCTObjectOnBranchDeleted()** which will return true if the XTCTObject should be removed.

Implemented by the System.

**Parameters:**

**int branchID**

Specifies which branch of the compound object the extension objects are deleted from.

**bool reorderChannels**

TRUE to reorder the channels, otherwise FALSE.

**Prototype:**

**void CopyAdditionalChannels(Object \*from, bool deleteOld = true, bool bShallowCopy = false);**

**Remarks:**

This method is available in release 4.0 and later only.

This method copies all extension objects from the "from" object into the current object. In case deleteOld is false the objects will be appended. If it is true the old XTCTObjects will be deleted.

Implemented by the System.

**Parameters:**

**Object \*from**

The source object which contains extension objects.

**bool deleteOld = true**

If true the original objects are deleted after the copy; if false they remain after the copy.

**bool bShallowCopy = false**

If true only a ShallowCopy() is performed; if false a complete copy of the objects is done.

**Prototype:**

```
void DeleteAllAdditionalChannels();
```

**Remarks:**

This method is available in release 4.0 and later only.

Implemented by the System.

This method will delete all additional channels.

**The following function is not part of this class but is available for use:**

**Function:**

```
void GetPolygonCount(TimeValue t, Object* pObj, int&  
numFaces, int& numVerts);
```

**Remarks:**

This global function is available in release 3.0 and later only.

This global function (not part of class Object) may be used to count the number of faces and vertices in an object. It uses **Object::PolygonCount()** if it is supported, and converts to **TriObject** and counts faces and vertices otherwise.

**Parameters:****TimeValue t**

The time at which to compute the number of faces and vertices.

**Object\* pObj**

Points to the object to check.

**int& numFaces**

The number of faces is returned here.

**int& numVerts**

The number of vertices is returned here.

```
class Mesh : public BaseInterfaceServer
```

## Description:

The Mesh class is provided for use by plug-ins and is used by the system. It is the data structure for meshes in the system and maintains pointers to the vertices, faces, texture vertices, etc. It provides methods to handle most of the functionality that procedural objects must implement. All methods of this class are implemented by the system.

Note: There is a set of classes for working with parts of a mesh such as its face structure, element structure, and cluster structure. For details see: [Class AdjEdgeList](#), [Class AdjFaceList](#), [Class FaceElementList](#), [Class FaceClusterList](#).

## [Operators](#)

### **Data Members:**

private:

**MeshMap hmaps[NUM\_HIDDENMAPS];**

The "Hidden Maps". Eventually these will be supported by Patches and PolyMeshes, as well as in the general object interface. The purpose is to use a separate, private array for a fixed number of these maps (unlike the allocable regular map array). This allows us to reserve and support as many map channels as we need for features such as vertex alpha, vertex illumination, possible vertex normals, or other needs that may arise.

The interface for accessing these channels uses the usual map methods, with negative indices. For instance, **hmaps[0]** is indexed as

**MAP\_SHADING**, -1. **hmaps[1]** is indexed as **MAP\_ALPHA=-2**. So now methods like **Mesh::mapVerts (int mp)** have a range of -**NUM\_HIDDENMAPS** to **getNumMaps()**, instead of 0 to **getNumMaps()** as before.

**NUM\_HIDDENMAPS**: The number of "Hidden" or negative-indexed maps in objects which support hidden maps. (Currently set to 2.)

**MAP\_SHADING**: The shading (or illumination) map. Set to -1.

**MAP\_ALPHA**: The Alpha channel map. Note that only the x (or u) coordinate of the map vertices is currently used. Set to -2.

public:

## **Topology Data**

**int numVerts;**

Number of vertices.

**int numFaces;**

Number of faces.

**Face \*faces;**

Array of faces.

## Geometry Data

**Point3 \*verts;**

Array of vertex coordinates.

## Texture Coordinate Data

### **int numTVerts;**

Number of texture vertices.

### **UVVert \*tVerts;**

The array of texture vertices. This stores the UVW coordinates. For a 2D mapping only two of them are used, i.e. UV, VW, or WU. This just provides greater flexibility so the user can choose to use UV, VW, or WU.

Note: **typedef Point3 UVVert;**

### **TVFace \*tvFace;**

The array of texture faces. There needs to be one **TVFace** for every face, but there can be three indices into the UVVert array that are any UVs. Each face of the object can have its own mapping.

### **int numMaps;**

This data member is available in release 3.0 and later only.

The number of maps supported by the mesh. By default this is 2 but may be changed with the multiple map methods listed below.

### **MeshMap \*maps;**

This data member is available in release 3.0 and later only.

When the number of mapping channels is set to a value greater than 1 then an instance of this class is allocated for each channel up to **numMaps**. An instance maintains the mapping information for a single channel.

### **BitArray vdSupport;**

This data member is available in release 3.0 and later only.

This bit array indicates if a particular vertex data channel is supported in this mesh. If the bit is set the channel is supported.

### **PerData \*vData;**

This data member is available in release 3.0 and later only.

The array of PerData objects which maintain and provide access to the floating point vertex data. There is one of these for each supported channel. The first two PerData objects in this array are used internally by 3ds max.

## Color Per Vertex Data

**int numCVerts;**

Number of color vertices.

**VertColor \*vertCol;**

Array of color vertices.

**TVFace \*vcFace;**

Array of color per vertex faces.

**VertColor \*curVCArray;**

This data member is available in release 4.0 and later only.

Points to storage for a possible external color array (default = NULL). This can be either an external array or one of the mapping channels. See the method **Mesh::setVCDisplayData()**;

**int curVCChan;**

This data member is available in release 4.0 and later only.

Storage for the current mapping channel to use for vertex colors (default = 0).

**VertColor \*vertColArray;**

This data member is available in release 4.0 and later only.

When 3ds max is rendering the color values come from this variable. This array defaults to the internal **vertCol** but can be set to an external array, or a map channel. See the method **Mesh:: setVCDisplayData ()**;

**TVFace \*vcFaceData;**

This data member is available in release 4.0 and later only.

When 3ds max is rendering the vertex color lookup comes from this structure. This defaults to the **vcFace** data but if a mapping channel is used for color lookup, its **TVFace** structure is used.

## Selection Data

### **BitArray vertSel;**

Indicates the selected vertices. There is one bit for each vertex. Bits that are 1 indicate the vertex is selected.

### **BitArray faceSel;**

Indicates the selected faces. There is one bit for each face. Bits that are 1 indicate the face is selected.

### **BitArray edgeSel;**

Indicates the selected edges. There is one bit for each edge of each face. Bits that are 1 indicate the edge is selected. The edge is identified by  **$3*\text{faceIndex} + \text{edgeIndex}$** .

### **BitArray vertHide;**

Hidden flags for vertices.

## Display attribute flags

### **DWORD dispFlags;**

These control various aspect of the Mesh objects display and may be one or more of the following values:

**DISP\_VERTTICKS** - Display vertices as small tick marks.

**DISP\_SELVERTS** - Display selected vertices.

**DISP\_SELFACES** - Display selected faces.

**DISP\_SELEDGES** - Display selected edges.

**DISP\_SELPOLYS** - Display selected polygons. Polygons are defined as adjacent triangles with hidden edges. A selected face would show all edges regardless of if they were hidden edges. A polygon would only show the edges of the polygon that were not hidden.

## **Selection level**

### **DWORD selLevel;**

This is the current level of selection. When all the bits are 0, the object is at object level selection. The selection level bits are:

**MESH\_OBJECT** - Object level.

**MESH\_VERTEX** - Vertex level.

**MESH\_FACE** - Face level.

**MESH\_EDGE** - Edge level.

## **Normals**

**int normalsBuilt;**

Nonzero if normals have been built for the current mesh; otherwise 0.

## Render Data

**MeshRenderData \*renderData;**

Points to the render data used by the renderer.

## Methods:

### Prototype:

**Mesh();**

### Remarks:
