The MoonScript installation comes with a small kernel of functions that can do various common things.

The entire library is currently contained in a single object. We can bring this in by requiring `"moon"`.

```
require "moon"  
-- `moon.p` is the debug printer  
moon.p { hello: "world" }
```

If you prefer to just inject all of the functions into the current scope, you can do the following. The following has the same effect as above:

```
require "moon.all"  
p { hello: "world" }
```

All of the functions are compatible with Lua in addition to MoonScript, but they are not in the same sense in the context of MoonScript.

MoonScript Standard Library

This is an overview of all the included functions. All of the examples assured has been included with `require "moon.all"`.

Printing Functions

`p(arg)`

Prints a formatted version of an object. Excellent for inspecting the conten

Table Functions

```
run_with_scope(fn, scope, [args...])
```

Mutates the environment of function `fn` and runs the function with any ex
Returns the result of the function.

The environment of the function is set to a new table whose metatable will
values. `scope` must be a table. If `scope` does not have an entry for a value,
original environment.

```
my_env = {  
  secret_function: -> print "shhh this is secret"  
  say_hi: -> print "hi there!"  
}  
  
say_hi = -> print "I am a closure"  
  
fn = ->  
  secret_function!  
  say_hi!  
  
run_with_scope fn, my_env
```

Note that any closure values will always take precedence against global n
environment. In the example above, the `say_hi` in the environment has be
variable `say_hi`.

```
defaulttbl([tbl,] fn)
```

Sets the `__index` of table `tbl` to use the function `fn` to generate table val
looked up.

```
extend(arg1, arg2, [rest...])
```

Chains together a series of tables by their metatable's `__index` property. On all objects except for the last with a new table whose `__index` is set to the

Returns the first argument.

```
a = { hello: "world" }  
b = { okay: "sure" }  
  
extend a, b  
  
print a.okay
```

`copy(tbl)`

Creates a shallow copy of a table, equivalent to:

```
copy = (arg) -> {k,v for k,v in pairs self}
```

Class/Object Functions

```
is_object(value)
```

Returns true if `value` is an instance of a MoonScript class, false otherwise

```
type(value)
```

If `value` is an instance of a MoonScript class, then return it's class object.
of calling Lua's `type` method.

```
class MyClass
  nil

x = MyClass!
assert type(x) == MyClass
```

```
bind_methods(obj)
```

Takes an instance of an object, returns a proxy to the object whose method providing self as the first argument.

```
obj = SomeClass!

bound_obj = bind_methods obj

-- following have the same effect
obj\hello!
bound_obj.hello!
```

It lazily creates and stores in the proxy table the bound methods when the

```
mixin(obj, class, [args...])
```

Copies the methods of a class `cls` into the table `obj`, then calls the constant `obj` as the receiver.

In this example we add the functionality of `First` to an instance of `Second` via `mix_in!`.

```
class First
  new: (@var) =>
  show_var: => print "var is:", @var

class Second
  new: =>
    mixin self, First, "hi"

a = Second!
a.show_var!
```

Be wary of name collisions when mixing in other classes, names will be overwritten.

```
mixin_object(obj, other_obj, method_names)
```

Inserts into `obj` methods from `other_obj` whose names are listed in `method_names`. The methods are bound methods that will run with `other_obj` as the receiver.

```
class List
  add: (item) => print "adding to", self
  remove: (item) => print "removing from", self

class Encapsulation
  new: =>
    @list = List!
    mixin_object self, @list, {"add", "remove"}

e = Encapsulation!
e.add "something"
```

```
mixin_table(a, b, [names])
```

Copies the elements of table `b` into table `a`. If names is provided, then o

Misc Functions

```
fold(items, fn)
```

Calls function `fn` repeatedly with the accumulated value and the current value `items`. The accumulated value is the result of the last call to `fn`, or, in the first call, the first element of `items`. The current value is the value being iterated over starting with the second element of `items`.

`items` is a normal array table.

For example, to sum all numbers in a list:

```
numbers = {4, 3, 5, 6, 7, 2, 3}
sum = fold numbers, (a, b) -> a + b
```

Debug Functions

```
debug.upvalue(fn, key[, value])
```

Gets or sets the value of an upvalue for a function by name.
