14 // ValueConverter is the interface providing the ConvertValue
15 //
16 // Various implementations of ValueConverter are provided by
17 // driver package to provide consistent implementations of c
18 // between drivers. The ValueConverters have several uses:
19 //
20 // * converting from the Value types as provided by the sql
21 //   into a database table's specific column type and makin
22 //   fits, such as making sure a particular int64 fits in a
23 //   table's uint16 column.
24 //
25 // * converting a value as given from the database into one
26 //   driver Value types.
27 //
28 // * by the sql package, for converting from a driver's Val
29 //   to a user's type in a scan.

7 // This file implements "varint" encoding of 64-bit integers
8 // The encoding is:
9 // - unsigned integers are serialized 7 bits at a time, starting
10 //   from the least significant bits
11 // - the most significant bit (msb) in each output byte indicates
12 //   whether it is a continuation byte (msb = 1)
13 // - signed integers are mapped to unsigned integers using the two's
14 //   complement encoding: Positive values x are written as 2*x + 0, negative
15 //   values are written as 2*(^x) + 1; that is, negative numbers are
16 //   written as their two's complement and whether to complement is encoded
17 //   in bit 0.
18 // Design note:
19 // At most 10 bytes are needed for 64-bit values. The encoding could
20 // be more dense: a full 64-bit value needs an extra byte just to
21 // know there can't be more than 64 bits. This is a trivial optimization
22 // that would reduce the maximum encoding length to 9 bytes. However, it is
23 // invariant that the msb is always the "continuation bit" and this
24 // format is incompatible with a varint encoding for larger numbers.

5 /*
6 Package gob manages streams of gobs - binary values exchange
7 Encoder (transmitter) and a Decoder (receiver). A typical u
8 arguments and results of remote procedure calls (RPCs) such
9 package "rpc".
10
11 A stream of gobs is self-describing. Each data item in the
12 a specification of its type, expressed in terms of a small s
13 types. Pointers are not transmitted, but the things they po
14 transmitted; that is, the values are flattened. Recursive t
15 recursive values (data with cycles) are problematic. This m
16
17 To use gobs, create an Encoder and present it with a series
18 values or addresses that can be dereferenced to values. The
19 all type information is sent before it is needed. At the re
20 Decoder retrieves values from the encoded stream and unpacks
21 variables.
22
23 The source and destination values/types need not correspond
24 fields (identified by name) that are in the source but absen
25 variable will be ignored. Fields that are in the receiving
26 from the transmitted type or value will be ignored in the de
27 with the same name is present in both, their types must be c
28 receiver and transmitter will do all necessary indirection a
29 convert between gobs and actual Go values. For instance, a
30 schematically,
31
32     struct { A, B int }
33
34 can be sent from or received into any of these Go types:
35
36     struct { A, B int }      // the same
37     *struct { A, B int }    // extra indirection of the
38     struct { *A, **B int }  // extra indirection of the
39     struct { A, B int64 }   // different concrete value
40
41 It may also be received into any of these:
```

```

42
43     struct { A, B int }      // the same
44     struct { B, A int }      // ordering doesn't matter;
45     struct { A, B, C int }   // extra field (C) ignored
46     struct { B int }         // missing field (A) ignored
47     struct { B, C int }      // missing field (A) ignored
48

```

49 Attempting to receive into these types will draw a decode error

```

50
51     struct { A int; B uint } // change of signedness
52     struct { A int; B float } // change of type for B
53     struct { }               // no field names in struct
54     struct { C, D int }      // no field names in struct
55

```

56 Integers are transmitted two ways: arbitrary precision signed and
57 arbitrary precision unsigned integers. There is no int8, in
58 discrimination in the gob format; there are only signed and
59 described below, the transmitter sends the value in a variable
60 the receiver accepts the value and stores it in the destination
61 Floating-point numbers are always sent using IEEE-754 64-bit
62 below).

63
64 Signed integers may be received into any signed integer variable
65 unsigned integers may be received into any unsigned integer
66 point values may be received into any floating point variable
67 the destination variable must be able to represent the value
68 operation will fail.

69
70 Structs, arrays and slices are also supported. Strings and
71 supported with a special, efficient representation (see below)
72 decoded, if the existing slice has capacity the slice will be
73 if not, a new array is allocated. Regardless, the length of
74 reports the number of elements decoded.

75
76 Functions and channels cannot be sent in a gob. Attempting
77 to encode a value that contains one will fail.

78
79 The rest of this comment documents the encoding, details that
80 for most users. Details are presented bottom-up.

81
82 An unsigned integer is sent one of two ways. If it is less
83 as a byte with that value. Otherwise it is sent as a minimal
84 (high byte first) byte stream holding the value, preceded by
85 byte count, negated. Thus 0 is transmitted as (00), 7 is transmitted
86 256 is transmitted as (FE 01 00).

87
88 A boolean is encoded within an unsigned integer: 0 for false

89
90 A signed integer, i, is encoded within an unsigned integer,
91 upward contain the value; bit 0 says whether they should be

```

92 receipt. The encode algorithm looks like this:
93
94     uint u;
95     if i < 0 {
96         u = (^i << 1) | 1      // complement i, bit
97     } else {
98         u = (i << 1)         // do not complement i, bit
99     }
100     encodeUnsigned(u)
101

```

102 The low bit is therefore analogous to a sign bit, but making
103 instead guarantees that the largest negative integer is not
104 example, $-129 = \wedge 128 = (\wedge 256 \gg 1)$ encodes as (FE 01 01).

105
106 Floating-point numbers are always sent as a representation o
107 That value is converted to a uint64 using math.Float64bits.
108 byte-reversed and sent as a regular unsigned integer. The b
109 exponent and high-precision part of the mantissa go first.
110 often zero, this can save encoding bytes. For instance, 17.
111 three bytes (FE 31 40).

112
113 Strings and slices of bytes are sent as an unsigned count fo
114 uninterpreted bytes of the value.

115
116 All other slices and arrays are sent as an unsigned count fo
117 elements using the standard gob encoding for their type, rec

118
119 Maps are sent as an unsigned count followed by that man key,
120 pairs. Empty but non-nil maps are sent, so if the sender has
121 a map, the receiver will allocate a map even no elements are
122 transmitted.

123
124 Structs are sent as a sequence of (field number, field value
125 value is sent using the standard gob encoding for its type,
126 field has the zero value for its type, it is omitted from th
127 field number is defined by the type of the encoded struct: t
128 encoded type is field 0, the second is field 1, etc. When e
129 field numbers are delta encoded for efficiency and the field
130 order of increasing field number; the deltas are therefore u
131 initialization for the delta encoding sets the field number
132 integer field 0 with value 7 is transmitted as unsigned delt
133 = 7 or (01 07). Finally, after all the fields have been sen
134 denotes the end of the struct. That mark is a delta=0 value
135 representation (00).

136
137 Interface types are not checked for compatibility; all inter
138 treated, for transmission, as members of a single "interface
139 int or []byte - in effect they're all treated as interface{}
140 are transmitted as a string identifying the concrete type be

141 that must be pre-defined by calling Register), followed by a
142 length of the following data (so the value can be skipped if
143 stored), followed by the usual encoding of concrete (dynamic
144 the interface value. (A nil interface value is identified b
145 and transmits no value.) Upon receipt, the decoder verifies
146 concrete item satisfies the interface of the receiving varia
147

148 The representation of types is described below. When a type
149 connection between an Encoder and Decoder, it is assigned a
150 id. When Encoder.Encode(v) is called, it makes sure there i
151 the type of v and all its elements and then it sends the pai
152 where typeid is the type id of the encoded type of v and enc
153 encoding of the value v.

154

155 To define a type, the encoder chooses an unused, positive ty
156 pair (-type id, encoded-type) where encoded-type is the gob
157 description, constructed from these types:

158

```
159     type wireType struct {
160         ArrayT *ArrayType
161         SliceT *SliceType
162         StructT *StructType
163         MapT *MapType
164     }
165     type arrayType struct {
166         CommonType
167         Elem typeId
168         Len int
169     }
170     type CommonType struct {
171         Name string // the name of the struct type
172         Id int // the id of the type, repeated s
173     }
174     type sliceType struct {
175         CommonType
176         Elem typeId
177     }
178     type structType struct {
179         CommonType
180         Field []*fieldType // the fields of the stru
181     }
182     type fieldType struct {
183         Name string // the name of the field.
184         Id int // the type id of the field, whi
185     }
186     type mapType struct {
187         CommonType
188         Key typeId
189         Elem typeId
```

```

190     }
191
192 If there are nested type ids, the types for all inner type i
193 before the top-level type id is used to describe an encoded-
194
195 For simplicity in setup, the connection is defined to unders
196 priori, as well as the basic gob types int, uint, etc. Thei
197
198     bool        1
199     int         2
200     uint        3
201     float       4
202     []byte      5
203     string      6
204     complex     7
205     interface   8
206     // gap for reserved ids.
207     wireType    16
208     ArrayType   17
209     CommonType  18
210     SliceType   19
211     StructType  20
212     FieldType   21
213     // 22 is slice of fieldType.
214     MapType     23
215
216 Finally, each message created by a call to Encode is precede
217 unsigned integer count of the number of bytes remaining in t
218 the initial type name, interface values are wrapped the same
219 interface value acts like a recursive invocation of Encode.
220
221 In summary, a gob stream looks like
222
223     (byteCount (-type id, encoding of a wireType)* (type
224
225 where * signifies zero or more repetitions and the type id c
226 be predefined or be defined before the value in the stream.

280
281 /*
282 For implementers and the curious, here is an encoded example
283     type Point struct {X, Y int}
284 and the value
285     p := Point{22, 33}
286 the bytes transmitted that encode p will be:
287     1f ff 81 03 01 01 05 50 6f 69 6e 74 01 ff 82 00
288     01 02 01 01 58 01 04 00 01 01 59 01 04 00 00 00

```

```

289         07 ff 82 01 2c 01 42 00
290 They are determined as follows.
291
292 Since this is the first transmission of type Point, the type
293 for Point itself must be sent before the value. This is the
294 we've sent on this Encoder, so it has type id 65 (0 through
295 reserved).
296
297         1f          // This item (a type descriptor) is 31 bytes
298         ff 81      // The negative of the id for the type we're
299                  // This is one byte (indicated by FF = -1) f
300                  // ^-65<<1 | 1. The low 1 bit signals to co
301                  // rest upon receipt.
302
303         // Now we send a type descriptor, which is itself a
304         // The type of wireType itself is known (it's built
305         // all its components), so we just need to send a *v
306         // that represents type "Point".
307         // Here starts the encoding of that value.
308         // Set the field number implicitly to -1; this is do
309         // of every struct, including nested structs.
310         03          // Add 3 to field number; now 2 (wireType.st
311                  // structType starts with an embedded Common
312                  // as a regular structure here too.
313         01          // add 1 to field number (now 0); start of e
314         01          // add 1 to field number (now 0, the name of
315         05          // string is (unsigned) 5 bytes long
316         50 6f 69 6e 74 // wireType.structType.CommonType.na
317         01          // add 1 to field number (now 1, the id of t
318         ff 82      // wireType.structType.CommonType._id = 65
319         00          // end of embedded wireType.structType.Commo
320         01          // add 1 to field number (now 1, the field a
321         02          // There are two fields in the type (len(str
322         01          // Start of first field structure; add 1 to
323         01          // 1 byte
324         58          // structType.field[0].name = "X"
325         01          // Add 1 to get field number 1: field[0].id
326         04          // structType.field[0].typeId is 2 (signed i
327         00          // End of structType.field[0]; start structT
328         01          // Add 1 to get field number 0: field[1].nam
329         01          // 1 byte
330         59          // structType.field[1].name = "Y"
331         01          // Add 1 to get field number 1: field[0].id
332         04          // struct.Type.field[1].typeId is 2 (signed
333         00          // End of structType.field[1]; end of struct
334         00          // end of wireType.structType structure
335         00          // end of wireType structure
336
337 Now we can send the Point value. Again the field number res

```

```

338
339     07      // this value is 7 bytes long
340     ff 82   // the type number, 65 (1 byte (-FF) followe
341     01      // add one to field number, yielding field 0
342     2c      // encoding of signed "22" (0x22 = 44 = 22<<
343     01      // add one to field number, yielding field 1
344     42      // encoding of signed "33" (0x42 = 66 = 33<<
345     00      // end of structure
346
347 The type encoding is long and fairly intricate but we send i
348 If p is transmitted a second time, the type is already known
349 output will be just:
350
351     07 ff 82 01 2c 01 42 00
352
353 A single non-struct value at top level is transmitted like a
354 delta tag 0. For instance, a signed integer with value 3 pr
355 the argument to Encode will emit:
356
357     03 04 00 06
358
359 Which represents:
360
361     03      // this value is 3 bytes long
362     04      // the type number, 2, represents an integer
363     00      // tag delta 0
364     06      // value 3
365
366 */

```

23 // Unmarshal parses the JSON-encoded data and stores the res
24 // in the value pointed to by v.
25 //
26 // Unmarshal uses the inverse of the encodings that
27 // Marshal uses, allocating maps, slices, and pointers as ne
28 // with the following additional rules:
29 //
30 // To unmarshal JSON into a pointer, Unmarshal first handles
31 // the JSON being the JSON literal null. In that case, Unma
32 // the pointer to nil. Otherwise, Unmarshal unmarshals the
33 // the value pointed at by the pointer. If the pointer is n
34 // allocates a new value for it to point to.
35 //
36 // To unmarshal JSON into an interface value, Unmarshal unma
37 // the JSON into the concrete value contained in the interfa
38 // If the interface value is nil, that is, has no concrete v
39 // Unmarshal stores one of these in the interface value:
40 //
41 //     bool, for JSON booleans
```

```

42 //      float64, for JSON numbers
43 //      string, for JSON strings
44 //      []interface{}, for JSON arrays
45 //      map[string]interface{}, for JSON objects
46 //      nil for JSON null
47 //
48 // If a JSON value is not appropriate for a given target typ
49 // or if a JSON number overflows the target type, Unmarshal
50 // skips that field and completes the unmarshalling as best
51 // If no more serious errors are encountered, Unmarshal retu
52 // an UnmarshalTypeError describing the earliest such error.

25
26 // Marshal returns the JSON encoding of v.
27 //
28 // Marshal traverses the value v recursively.
29 // If an encountered value implements the Marshaler interface
30 // and is not a nil pointer, Marshal calls its MarshalJSON method
31 // to produce JSON. The nil pointer exception is not strict
32 // but mimics a similar, necessary exception in the behavior
33 // of UnmarshalJSON.
34 //
35 // Otherwise, Marshal uses the following type-dependent default
36 // encodings:
37 // Boolean values encode as JSON booleans.
38 //
39 // Floating point and integer values encode as JSON numbers.
40 //
41 // String values encode as JSON strings, with each invalid U
```

```

42 // replaced by the encoding of the Unicode replacement chara
43 // The angle brackets "<" and ">" are escaped to "\u003c" an
44 // to keep some browsers from misinterpreting JSON output as
45 //
46 // Array and slice values encode as JSON arrays, except that
47 // []byte encodes as a base64-encoded string, and a nil slic
48 // encodes as the null JSON object.
49 //
50 // Struct values encode as JSON objects. Each exported struc
51 // becomes a member of the object unless
52 //   - the field's tag is "-", or
53 //   - the field is empty and its tag specifies the "omitempty"
54 // The empty values are false, 0, any
55 // nil pointer or interface value, and any array, slice, map
56 // length zero. The object's default key string is the struc
57 // but can be specified in the struct field's tag value. The
58 // struct field's tag value is the key name, followed by an
59 // and options. Examples:
60 //
61 //   // Field is ignored by this package.
62 //   Field int `json:"- "`
63 //
64 //   // Field appears in JSON as key "myName".
65 //   Field int `json:"myName"`
66 //
67 //   // Field appears in JSON as key "myName" and
68 //   // the field is omitted from the object if its value is
69 //   // as defined above.
70 //   Field int `json:"myName,omitempty"`
71 //
72 //   // Field appears in JSON as key "Field" (the default),
73 //   // the field is skipped if empty.
74 //   // Note the leading comma.
75 //   Field int `json:",omitempty"`
76 //
77 // The "string" option signals that a field is stored as JSO
78 // JSON-encoded string. This extra level of encoding is som
79 // used when communicating with JavaScript programs:
80 //
81 //   Int64String int64 `json:",string"`
82 //
83 // The key name will be used if it's a non-empty string cons
84 // only Unicode letters, digits, dollar signs, percent signs
85 // underscores and slashes.
86 //
87 // Map values encode as JSON objects.
88 // The map's key type must be string; the object keys are us
89 // as map keys.
90 //
91 // Pointer values encode as the value pointed to.

```

```

92 // A nil pointer encodes as the null JSON object.
93 //
94 // Interface values encode as the value contained in the int
95 // A nil interface value encodes as the null JSON object.
96 //
97 // Channel, complex, and function values cannot be encoded i
98 // Attempting to encode such a value causes Marshal to retur
99 // an InvalidTypeError.
100 //

25 // Marshal returns the XML encoding of v.
26 //
27 // Marshal handles an array or slice by marshalling each of
28 // Marshal handles a pointer by marshalling the value it poi
29 // pointer is nil, by writing nothing. Marshal handles an i
30 // marshalling the value it contains or, if the interface va
31 // writing nothing. Marshal handles all other data by writi
32 // elements containing the data.
33 //
34 // The name for the XML elements is taken from, in order of
35 // - the tag on the XMLName field, if the data is a stru
36 // - the value of the XMLName field of type xml.Name
37 // - the tag of the struct field used to obtain the data
38 // - the name of the struct field used to obtain the dat
39 // - the name of the marshalled type
40 //
41 // The XML element for a struct contains marshalled elements
```

```

42 // exported fields of the struct, with these exceptions:
43 //   - the XMLName field, described above, is omitted.
44 //   - a field with tag "-" is omitted.
45 //   - a field with tag "name,attr" becomes an attribute with
46 //     the given name in the XML element.
47 //   - a field with tag ",attr" becomes an attribute with
48 //     field name in the in the XML element.
49 //   - a field with tag ",chardata" is written as character data
50 //     not as an XML element.
51 //   - a field with tag ",innerxml" is written verbatim, not
52 //     to the usual marshalling procedure.
53 //   - a field with tag ",comment" is written as an XML comment,
54 //     subject to the usual marshalling procedure. It must contain
55 //     the "--" string within it.
56 //   - a field with a tag including the "omitempty" option
57 //     if the field value is empty. The empty values are a
58 //     nil pointer or interface value, and any array, slice, or
59 //     string of length zero.
60 //   - a non-pointer anonymous struct field is handled as if
61 //     fields of its value were part of the outer struct.
62 //
63 // If a field uses a tag "a>b>c", then the element c will be

21 // to data structures.
22
23 // Unmarshal parses the XML-encoded data and stores the resu
24 // the value pointed to by v, which must be an arbitrary str
25 // slice, or string. Well-formed data that does not fit into
26 // discarded.
27 //
28 // Because Unmarshal uses the reflect package, it can only a
29 // to exported (upper case) fields. Unmarshal uses a case-s
30 // comparison to match XML element names to tag values and s
31 // field names.
32 //
33 // Unmarshal maps an XML element to a struct using the follo
34 // In the rules, the tag of a field refers to the value asso
35 // key 'xml' in the struct field's tag (see the example abov
36 //
37 // * If the struct has a field of type []byte or string wi
38 //     ",innerxml", Unmarshal accumulates the raw XML neste
39 //     element in that field. The rest of the rules still
40 //
41 // * If the struct has a field named XMLName of type xml.N
```

```
42 //      Unmarshal records the element name in that field.
43 //
44 //      * If the XMLName field has an associated tag of the for
45 //      "name" or "namespace-URL name", the XML element must
46 //      the given name (and, optionally, name space) or else
47 //      returns an error.
48 //
49 //      * If the XML element has an attribute whose name matches
50 //      struct field name with an associated tag containing
51 //      the explicit name in a struct field tag of the form
52 //      Unmarshal records the attribute value in that field.
53 //
54 //      * If the XML element contains character data, that data
55 //      accumulated in the first struct field that has tag "
56 //      The struct field may have type []byte or string.
57 //      If there is no such field, the character data is discarded.
58 //
59 //      * If the XML element contains comments, they are accumulated in
60 //      the first struct field that has tag ",comments". The
61 //      field may have type []byte or string. If there is no such
62 //      field, the comments are discarded.
63 //
64 //      * If the XML element contains a sub-element whose name matches
65 //      the prefix of a tag formatted as "a" or "a>b>c", unmarshal
66 //      will descend into the XML structure looking for elements with
67 //      given names, and will map the innermost elements to the struct
68 //      field. A tag starting with ">" is equivalent to one
69 //      with the field name followed by ">".
70 //
71 //      * If the XML element contains a sub-element whose name matches
72 //      a struct field's XMLName tag and the struct field has an
73 //      explicit name tag as per the previous rule, unmarshal maps
74 //      the sub-element to that struct field.
75 //
76 //      * If the XML element contains a sub-element whose name matches a
77 //      field without any mode flags ("attr", "chardata", "comment", "text"),
78 //      maps the sub-element to that struct field.
79 //
80 //      * If the XML element contains a sub-element that hasn't matched
81 //      any of the above rules and the struct has a field with tag "-"
82 //      unmarshal maps the sub-element to that struct field.
83 //
84 //      * A non-pointer anonymous struct field is handled as if it had
85 //      fields of its value were part of the outer struct.
86 //
87 //      * A struct field with tag "-" is never unmarshalled into.
88 //
89 //      Unmarshal maps an XML element to a string or []byte by saving the
90 //      concatenation of that element's character data in the struct field.
91 //      []byte. The saved []byte is never nil.
```

```

92 //
93 // Unmarshal maps an attribute value to a string or []byte b
94 // the value in the string or slice.
95 //
96 // Unmarshal maps an XML element to a slice by extending the
97 // the slice and mapping the element to the newly created va
98 //
99 // Unmarshal maps an XML element or attribute value to a boo
100 // setting it to the boolean value represented by the string
101 //
102 // Unmarshal maps an XML element or attribute value to an in
103 // floating-point field by setting the field to the result o

4
5 /*
6     Package flag implements command-line flag parsing.
7
8     Usage:
9
10    Define flags using flag.String(), Bool(), Int(), etc
11
12    This declares an integer flag, -flagname, stored in
13        import "flag"
14        var ip = flag.Int("flagname", 1234, "help me
15    If you like, you can bind the flag to a variable using
16        var flagvar int
17        func init() {
18            flag.IntVar(&flagvar, "flagname", 12
19        }
20    Or you can create custom flags that satisfy the Value
21    interface (and couple them to flag parsing by using
22        flag.Var(&flagVal, "name", "help message for
23    For such flags, the default value is just the initial
24
25    After all flags are defined, call
26        flag.Parse()
27    to parse the command line into the defined flags.
28
29    Flags may then be used directly. If you're using the Value
30    interface they are all pointers; if you bind to variables, the
31        fmt.Println("ip has value ", *ip)
32        fmt.Println("flagvar has value ", flagvar)
33
34    After parsing, the arguments after the flag are available as a
35    slice flag.Args() or individually as flag.Arg(i).
36    The arguments are indexed from 0 up to flag.NArg().
37
38    Command line flag syntax:
39        -flag
40        -flag=x
41        -flag x // non-boolean flags only
42    One or two minus signs may be used; they are equivalent.
43    The last form is not permitted for boolean flags because of the
44    meaning of the command
```

```

45         cmd -x *
46     will change if there is a file called 0, false, etc.
47     use the -flag=false form to turn off a boolean flag.
48
49     Flag parsing stops just before the first non-flag ar
50     ("- " is a non-flag argument) or after the terminator
51
52     Integer flags accept 1234, 0664, 0x1234 and may be n
53     Boolean flags may be 1, 0, t, f, true, false, TRUE,
54     Duration flags accept any input valid for time.Parse
55
56     The default set of command-line flags is controlled
57     top-level functions. The FlagSet type allows one to
58     independent sets of flags, such as to implement subc
59     in a command-line interface. The methods of FlagSet
60     analogous to the top-level functions for the command
61     flag set.

5 /*
6     Package fmt implements formatted I/O with functions
7     to C's printf and scanf. The format 'verbs' are der
8     are simpler.
9
10
11     Printing
12
13     The verbs:
14
15     General:
16         %v          the value in a default format.
17                    when printing structs, the plus flag
18         %#v        a Go-syntax representation of the va
19         %T          a Go-syntax representation of the ty
20         %%          a literal percent sign; consumes no
21
22     Boolean:
23         %t          the word true or false
24
25     Integer:
26         %b          base 2
27         %c          the character represented by the cor
28         %d          base 10
29         %o          base 8
30         %q          a single-quoted character literal sa
31         %x          base 16, with lower-case letters for
32         %X          base 16, with upper-case letters for
33         %U          Unicode format: U+1234; same as "U+%
34
35     Floating-point and complex constituents:
36         %b          decimalless scientific notation with
37                    in the manner of strconv.FormatFloat
38                    e.g. -123456p-78
39         %e          scientific notation, e.g. -1234.456e
40         %E          scientific notation, e.g. -1234.456E
41         %f          decimal point but no exponent, e.g.
42         %g          whichever of %e or %f produces more
43         %G          whichever of %E or %f produces more
44
45     String and slice of bytes:
46         %s          the uninterpreted bytes of the strin
47         %q          a double-quoted string safely escape
```

45 %x base 16, lower-case, two characters
46 %X base 16, upper-case, two characters
47 Pointer:
48 %p base 16 notation, with leading 0x
49

50 There is no 'u' flag. Integers are printed unsigned
51 Similarly, there is no need to specify the size of t
52

53 The width and precision control formatting and are i
54 code points. (This differs from C's printf where th
55 of bytes.) Either or both of the flags may be replac
56 character '*', causing their values to be obtained f
57 operand, which must be of type int.
58

59 For numeric values, width sets the width of the fiel
60 sets the number of places after the decimal, if appr
61 example, the format %6.2f prints 123.45.
62

63 For strings, width is the minimum number of characte
64 padding with spaces if necessary, and precision is t
65 number of characters to output, truncating if necess
66

67 Other flags:

68 + always print a sign for numeric valu
69 guarantee ASCII-only output for %q (
70 - pad with spaces on the right rather
71 # alternate format: add leading 0 for
72 0X for hex (%#X); suppress 0x for %p
73 print a raw (backquoted) string if p
74 write e.g. U+0078 'x' if the charact
75 ' ' (space) leave a space for elided sig
76 put spaces between bytes printing st
77 0 pad with leading zeros rather than s
78

79 For each Printf-like function, there is also a Print
80 that takes no format and is equivalent to saying %v
81 operand. Another variant Println inserts blanks bet
82 operands and appends a newline.
83

84 Regardless of the verb, if an operand is an interfac
85 the internal concrete value is used, not the interfa
86 Thus:

```
87                    var i interface{} = 23  
88                    fmt.Printf("%v\n", i)
```

89 will print 23.
90

91 If an operand implements interface Formatter, that i
92 can be used for fine control of formatting.
93

94 If the format (which is implicitly %v for Println et

95 for a string (%s %q %v %x %X), the following two rul
96
97 1. If an operand implements the error interface, the
98 will be used to convert the object to a string, whic
99 be formatted as required by the verb (if any).
100
101 2. If an operand implements method String() string,
102 will be used to convert the object to a string, whic
103 be formatted as required by the verb (if any).
104
105 To avoid recursion in cases such as
106 type X string
107 func (x X) String() string { return Sprintf(
108 convert the value before recurring:
109 func (x X) String() string { return Sprintf(
110
111 Format errors:
112
113 If an invalid argument is given for a verb, such as
114 a string to %d, the generated string will contain a
115 description of the problem, as in these examples:
116
117 Wrong type or unknown verb: %!verb(type=valu
118 Printf("%d", hi): %!d(strin
119 Too many arguments: %!(EXTRA type=value)
120 Printf("hi", "guys"): hi%!(EXTR
121 Too few arguments: %!verb(MISSING)
122 Printf("hi%d"): hi %!d(MI
123 Non-int for width or precision: %!(BADWIDTH)
124 Printf("%*s", 4.5, "hi"): %!(BADWID
125 Printf("%. *s", 4.5, "hi"): %!(BADPRE
126
127 All errors begin with the string "%!" followed somet
128 by a single character (the verb) and end with a pare
129 description.
130
131
132 Scanning
133
134 An analogous set of functions scans formatted text t
135 values. Scan, Scanf and Scanln read from os.Stdin;
136 Fscanf and Fscanln read from a specified io.Reader;
137 Sscanf and Sscanln read from an argument string. Sc
138 Fscanln and Sscanln stop scanning at a newline and r
139 the items be followed by one; Sscanf, Fscanf and Ssc
140 newlines in the input to match newlines in the forma
141 routines treat newlines as spaces.
142
143 Scanf, Fscanf, and Sscanf parse the arguments accord

```
144     format string, analogous to that of Printf. For exa
145 will scan an integer as a hexadecimal number, and %v
146 the default representation format for the value.
147
148     The formats behave analogously to those of Printf wi
149 following exceptions:
150
151         %p is not implemented
152         %T is not implemented
153         %e %E %f %F %g %G are all equivalent and sca
154         %s and %v on strings scan a space-delimited
155
156     The familiar base-setting prefixes 0 (octal) and 0x
157 (hexadecimal) are accepted when scanning integers wi
158 format or with the %v verb.
159
160     Width is interpreted in the input text (%5s means at
161 five runes of input will be read to scan a string) b
162 is no syntax for scanning with a precision (no %5.2f
163 %5f).
164
165     When scanning with a format, all non-empty runs of s
166 characters (except newline) are equivalent to a sing
167 space in both the format and the input. With that p
168 text in the format string must match the input text;
169 stops if it does not, with the return value of the f
170 indicating the number of arguments scanned.
171
172     In all the scanning functions, if an operand impleme
173 Scan (that is, it implements the Scanner interface)
174 method will be used to scan the text for that operan
175 if the number of arguments scanned is less than the
176 arguments provided, an error is returned.
177
178     All arguments to be scanned must be either pointers
179 types or implementations of the Scanner interface.
180
181     Note: Fscan etc. can read one character (rune) past
182 they return, which means that a loop calling a scan
183 may skip some of the input. This is usually a probl
184 when there is no space between input values. If the
185 provided to Fscan implements ReadRune, that method w
186 to read characters. If the reader also implements U
187 that method will be used to save the character and s
188 calls will not lose data. To attach ReadRune and Un
189 methods to a reader without that capability, use
190 bufio.NewReader.

6 //
7 // Go Path
8 //
9 // The Go path is a list of directory trees containing Go so
10 // It is consulted to resolve imports that cannot be found i
11 // Go tree. The default path is the value of the GOPATH env
12 // variable, interpreted as a path list appropriate to the o
13 // (on Unix, the variable is a colon-separated string;
14 // on Windows, a semicolon-separated string;
15 // on Plan 9, a list).
16 //
17 // Each directory listed in the Go path must have a prescrib
18 //
19 // The src/ directory holds source code. The path below 'sr
20 // the import path or executable name.
21 //
22 // The pkg/ directory holds installed package objects.
23 // As in the Go tree, each target operating system and
24 // architecture pair has its own subdirectory of pkg
25 // (pkg/GOOS_GOARCH).
26 //
27 // If DIR is a directory listed in the Go path, a package wi
28 // source in DIR/src/foo/bar can be imported as "foo/bar" an
29 // has its compiled form installed to "DIR/pkg/GOOS_GOARCH/f
30 // (or, for gccgo, "DIR/pkg/gccgo/foo/libbar.a").
31 //
32 // The bin/ directory holds compiled commands.
33 // Each command is named for its source directory, but only
34 // using the final element, not the entire path. That is, t
35 // command with source in DIR/src/foo/quux is installed into
36 // DIR/bin/quux, not DIR/bin/foo/quux. The foo/ is stripped
37 // so that you can add DIR/bin to your PATH to get at the
38 // installed commands.
39 //
40 // Here's an example directory layout:
41 //
42 //     GOPATH=/home/user/gocode
43 //
44 //     /home/user/gocode/
```

```

45 //          src/
46 //              foo/
47 //                  bar/                (go code in package b
48 //                      x.go

57 //
58 // Build Constraints
59 //
60 // A build constraint is a line comment beginning with the d
61 // that lists the conditions under which a file should be in
62 // Constraints may appear in any kind of source file (not ju
63 // they must be appear near the top of the file, preceded
64 // only by blank lines and other line comments.
65 //
66 // A build constraint is evaluated as the OR of space-separa
67 // each option evaluates as the AND of its comma-separated t
68 // and each term is an alphanumeric word or, preceded by !,
69 // That is, the build constraint:
70 //
71 //          // +build linux,386 darwin,!cgo
72 //
73 // corresponds to the boolean formula:
74 //
75 //          (linux AND 386) OR (darwin AND (NOT cgo))
76 //
77 // During a particular build, the following words are satisf
78 //
79 //          - the target operating system, as spelled by runtime
80 //          - the target architecture, as spelled by runtime.GOARCH
81 //          - "cgo", if ctxt.CgoEnabled is true
82 //          - any additional words listed in ctxt.BuildTags
83 //
84 // If a file's name, after stripping the extension and a pos
85 // matches *_GOOS, *_GOARCH, or *_GOOS_GOARCH for any known
86 // system and architecture values, then the file is consider
87 // build constraint requiring those terms.
88 //
89 // To keep a file from being considered for the build:
90 //
91 //          // +build ignore
92 //
93 // (any other unsatisfied word will work as well, but ``igno
94 //

```

```
95 // To build a file only when using cgo, and only on Linux an
96 //
97 //      // +build linux,cgo darwin,cgo
98 //
99 // Such a file is usually paired with another file implement
100 // default functionality for other systems, which in this ca
101 // carry the constraint:
102 //
103 //      // +build !linux !darwin !cgo
104 //
105 // Naming a file dns_windows.go will cause it to be included
106 // building the package for Windows; similarly, math_386.s w
107 // only when building the package for 32-bit x86.
108 //
109 package build

6 Package template (html/template) implements data-driven temp
7 generating HTML output safe against code injection. It provi
8 same interface as package text/template and should be used i
9 text/template whenever the output is HTML.
10
11 The documentation here focuses on the security features of t
12 For information about how to program the templates themselve
13 documentation for text/template.
14
15 Introduction
16
17 This package wraps package text/template so you can share it
18 to parse and execute HTML templates safely.
19
20     tmpl, err := template.New("name").Parse(...)
21     // Error checking elided
22     err = tmpl.Execute(out, data)
23
24 If successful, tmpl will now be injection-safe. Otherwise, e
25 defined in the docs for ErrorCode.
26
27 HTML templates treat data values as plain text which should
28 can be safely embedded in an HTML document. The escaping is
29 actions can appear within JavaScript, CSS, and URI contexts.
30
31 The security model used by this package assumes that templat
32 trusted, while Execute's data parameter is not. More details
33 provided below.
34
35 Example
36
37     import "text/template"
38     ...
39     t, err := template.New("foo").Parse(`{{define "T"}}Hello,
40     err = t.ExecuteTemplate(out, "T", "<script>alert('you have
41
```

```

92     <a href="?q={{.}}">                                O&#39;Reilly%3a%20How%20a
93     <a onx='f("{{.}}")'>                                O\x27Reilly: How are \x3c
94     <a onx='f({{.}})'>                                  "O\x27Reilly: How are \x3
95     <a onx='pattern = /{{.}}/;'>                        O\x27Reilly: How are \x3c
96
97 If used in an unsafe context, then the value might be filter
98
99 Context                                                {{.}} After
100 <a href="{{.}}">                                        #ZgotmplZ
101
102 since "O'Reilly:" is not an allowed protocol like "http:".
103
104
105 If {{.}} is the innocuous word, `left`, then it can appear r
106
107 Context                                                {{.}} After
108 {{.}}                                                  left
109 <a title='{{.}}'>                                       left
110 <a href='{{.}}'>                                         left
111 <a href='/{{.}}'>                                       left
112 <a href='?dir={{.}}'>                                       left
113 <a style="border-{{.}}: 4px">                                       left
114 <a style="align: {{.}}">                                       left
115 <a style="background: '{{.}}'>                                       left
116 <a style="background: url('{{.}}')> left
117 <style>p.{{.}} {color:red}</style> left
118
119 Non-string values can be used in JavaScript contexts.
120 If {{.}} is
121
122     []struct{A,B string}{ "foo", "bar" }
123
124 in the escaped template
125
126     <script>var pair = {{.}};</script>
127
128 then the template output is
129
130     <script>var pair = {"A": "foo", "B": "bar"};</script>
131
132 See package json to understand how non-string content is mar
133 embedding in JavaScript contexts.
134
135
136 Typed Strings
137
138 By default, this package assumes that all pipelines produce
139 It adds escaping pipeline stages necessary to correctly and
140 plain text string in the appropriate context.

```

141
142 When a data value is not plain text, you can make sure it is
143 by marking it with its type.
144
145 Types HTML, JS, URL, and others from content.go can carry sa
146 exempted from escaping.
147
148 The template
149 Hello, {{.}}!
151
152 can be invoked with
153 tmpl.Execute(out, HTML(`**World**`))
155
156 to produce
157 Hello, **World**!
159
160 instead of the
161 Hello, World!
163
164 that would have been produced if {{.}} was a regular string.
165
166
167 Security Model
168
169 <http://js-quasis-libraries-and-repl.googlecode.com/svn/trunk>
170
171 This package assumes that template authors are trusted, that
172 parameter is not, and seeks to preserve the properties below
173 of untrusted data:
174
175 Structure Preservation Property:
176 "... when a template author writes an HTML tag in a safe tem
177 the browser will interpret the corresponding portion of the
178 regardless of the values of untrusted data, and similarly fo
179 such as attribute boundaries and JS and CSS string boundarie
180
181 Code Effect Property:
182 "... only code specified by the template author should run a
183 injecting the template output into a page and all code speci
184 template author should run as a result of the same."
185
186 Least Surprise Property:
187 "A developer (or code reviewer) familiar with HTML, CSS, and
188 knows that contextual autoescaping happens should be able to
189 and correctly infer what sanitization happens."

```
190 */  
191 package template

5 // This algorithm is based on "Faster Suffix Sorting"
6 //   by N. Jesper Larsson and Kunihiko Sadakane
7 // paper: http://www.larsson.dogma.net/ssrev-tr.pdf
8 // code:  http://www.larsson.dogma.net/qsufsort.c
9
10 // This algorithm computes the suffix array sa by computing
11 // Consecutive groups of suffixes in sa are labeled as sorted
12 // unsorted groups. For a given pass of the sorter, all suffixes
13 // up to their first h characters, and sa is h-ordered. Suffixes
14 // final positions and unambiguously sorted in h-order are i
15 // Consecutive groups of suffixes with identical first h characters
16 // unsorted group. In each pass of the algorithm, unsorted groups
17 // according to the group number of their following suffix.
18
19 // In the implementation, if sa[i] is negative, it indicates
20 // the first element of a sorted group of length -sa[i], and
21 // An unsorted group sa[i:k] is given the group number of the
22 // last element, k-1. The group numbers are stored in the inverse
23 // and when all groups are sorted, this slice is the inverse

21 //
22 // __ieee754_atanh(x)
23 // Method :
24 //     1. Reduce x to positive by atanh(-x) = -atanh(x)
25 //     2. For x>=0.5
26 //           1           2x
27 //     atanh(x) = --- * log(1 + -----) = 0.5 * log1p(2 *
28 //                2           1 - x
29 //
30 //     For x<0.5
31 //     atanh(x) = 0.5*log1p(2x+2x*x/(1-x))
32 //
33 // Special cases:
34 //     atanh(x) is NaN if |x| > 1 with signal;
35 //     atanh(NaN) is that NaN with no signal;
36 //     atanh(+/-1) is +/-INF with signal.
37 //
38
39 // Atanh(x) calculates the inverse hyperbolic tangent of x.
40 //
41 // Special cases are:
42 //     Atanh(1) = +Inf
43 //     Atanh(±0) = ±0
44 //     Atanh(-1) = -Inf
```

```

45 //      Atanh(x) = NaN if x < -1 or x > 1
46 //      Atanh(NaN) = NaN
47 func Atanh(x float64) float64 {

30 // exp(x)
31 // Returns the exponential of x.
32 //
33 // Method
34 // 1. Argument reduction:
35 //     Reduce x to an r so that |r| <= 0.5*ln2 ~ 0.34658.
36 //     Given x, find r and integer k such that
37 //
38 //         x = k*ln2 + r, |r| <= 0.5*ln2.
39 //
40 //     Here r will be represented as r = hi-lo for better
41 //     accuracy.
42 //
43 // 2. Approximation of exp(r) by a special rational functi
44 // the interval [0,0.34658]:
```

```

45 // Write
46 //     R(r**2) = r*(exp(r)+1)/(exp(r)-1) = 2 + r*r/6 -
47 // We use a special Remes algorithm on [0,0.34658] to g
48 // a polynomial of degree 5 to approximate R. The maxim
49 // of this polynomial approximation is bounded by 2**-5
50 // other words,
51 //     R(z) ~ 2.0 + P1*z + P2*z**2 + P3*z**3 + P4*z**4
52 // (where z=r*r, and the values of P1 to P5 are listed
53 // and
54 //     | 2.0+P1*z+...+P5*z5 - R(z) | <= 2-59
55 //     |
56 // The computation of exp(r) thus becomes
57 //
58 //     2*r
59 //     exp(r) = 1 + -----
60 //                   R - r
61 //                   r*R1(r)
62 //     = 1 + r + ----- (for better acc
63 //                   2 - R1(r)
64 // where
65 //
66 //     2      4      10
67 //     R1(r) = r - (P1*r  + P2*r  + ... + P5*r  ).
68 // 3. Scale back to obtain exp(x):
69 // From step 1, we have
70 //     exp(x) = 2**k * exp(r)
71 //
72 // Special cases:
73 //     exp(INF) is INF, exp(NaN) is NaN;
74 //     exp(-INF) is 0, and
75 //     for finite argument, only exp(0)=1 is exact.
76 //
77 // Accuracy:
78 //     according to an error analysis, the error is always
79 //     1 ulp (unit in the last place).
80 //
81 // Misc. info.
82 //     For IEEE double
83 //         if x > 7.09782712893383973096e+02 then exp(x) o

9 // The go code is a simplified version of the original C.
10 //
11 //      tgamma.c
12 //
13 //      Gamma function
14 //
15 // SYNOPSIS:
16 //
17 // double x, y, tgamma();
18 // extern int signgam;
19 //
20 // y = tgamma( x );
21 //
22 // DESCRIPTION:
23 //
24 // Returns gamma function of the argument. The result is
25 // correctly signed, and the sign (+1 or -1) is also
26 // returned in a global (extern) variable named signgam.
27 // This variable is also filled in by the logarithmic gamma
28 // function lgamma().
29 //
30 // Arguments |x| <= 34 are reduced by recurrence and the fun
31 // approximated by a rational function of degree 6/7 in the
32 // interval (2,3). Large arguments are handled by Stirling'
33 // formula. Large negative arguments are made positive using
34 // a reflection formula.
35 //
36 // ACCURACY:
37 //
38 //                                     Relative error:
39 // arithmetic      domain      # trials      peak      rms
40 //      DEC         -34, 34      10000        1.3e-16    2.5e-17
41 //      IEEE        -170, -33    20000        2.3e-15    3.3e-16
42 //      IEEE         -33, 33     20000        9.4e-16    2.2e-16
43 //      IEEE          33, 171.6  20000        2.3e-15    3.2e-16
44 //
```

```

45 // Error for arguments outside the test range will be larger
46 // owing to error amplification by the exponential function.
47 //

25 // __ieee754_jn(n, x), __ieee754_yn(n, x)
26 // floating point Bessel's function of the 1st and 2nd kind
27 // of order n
28 //
29 // Special cases:
30 //      y0(0)=y1(0)=yn(n,0) = -inf with division by zero signal
31 //      y0(-ve)=y1(-ve)=yn(n,-ve) are NaN with invalid signal
32 // Note 2. About jn(n,x), yn(n,x)
33 //      For n=0, j0(x) is called,
34 //      for n=1, j1(x) is called,
35 //      for n<x, forward recursion is used starting
36 //      from values of j0(x) and j1(x).
37 //      for n>x, a continued fraction approximation to
38 //      j(n,x)/j(n-1,x) is evaluated and then backward
39 //      recursion is used starting from a supposed value
40 //      for j(n,x). The resulting value of j(0,x) is
41 //      compared with the actual value to correct the
42 //      supposed value of j(n,x).
43 //
44 //      yn(n,x) is similar in all respects, except
```

```

45 //      that forward recursion is used for all
46 //      values of n>1.
47
48 // Jn returns the order-n Bessel function of the first kind.

26 // Reentrant version of the logarithm of the Gamma function
27 // with user provided pointer for the sign of Gamma(x).
28 //
29 // Method:
30 // 1. Argument Reduction for  $0 < x \leq 8$ 
31 //    Since  $\gamma(1+s) = s \cdot \gamma(s)$ , for  $x$  in  $[0, 8]$ , we may
32 //    reduce  $x$  to a number in  $[1.5, 2.5]$  by
33 //     $\lgamma(1+s) = \log(s) + \lgamma(s)$ 
34 //    for example,
35 //     $\lgamma(7.3) = \log(6.3) + \lgamma(6.3)$ 
36 //     $= \log(6.3 \cdot 5.3) + \lgamma(5.3)$ 
37 //     $= \log(6.3 \cdot 5.3 \cdot 4.3 \cdot 3.3 \cdot 2.3) + \lgamma(2.3)$ 
38 // 2. Polynomial approximation of  $\lgamma$  around its
39 //    minimum ( $y_{\min} = 1.461632144968362245$ ) to maintain monotonicity
40 //    On  $[y_{\min} - 0.23, y_{\min} + 0.27]$  (i.e.,  $[1.23164, 1.73163]$ ),
41 //    Let  $z = x - y_{\min}$ ;
42 //     $\lgamma(x) = -1.214862905358496078218 + z^{**2} \cdot$ 
43 //     $\text{poly}(z)$  is a 14 degree polynomial.
44 // 2. Rational approximation in the primary interval  $[2, 3]$ 
```

```

45 // We use the following approximation:
46 //     s = x-2.0;
47 //     lgamma(x) = 0.5*s + s*P(s)/Q(s)
48 // with accuracy
49 //     |P/Q - (lgamma(x)-0.5s)| < 2**-61.71
50 // Our algorithms are based on the following observatio
51 //
52 //     zeta(2)-1    2    zeta(3)-1
53 // lgamma(2+s) = s*(1-Euler) + ----- * s - ----- *
54 //                                2                                3
55 //
56 //     where Euler = 0.5772156649... is the Euler constant,
57 //     is very close to 0.5.
58 //
59 // 3. For x>=8, we have
60 //     lgamma(x)~(x-0.5)log(x)-x+0.5*log(2pi)+1/(12x)-1/(36
61 // (better formula:
62 //     lgamma(x)~(x-0.5)*(log(x)-1)-.5*(log(2pi)-1) + ..
63 // Let z = 1/x, then we approximation
64 //     f(z) = lgamma(x) - (x-0.5)(log(x)-1)
