Go is an expressive, concurrent, garbage-collected programming language.

The [Go home page](#) is the primary source of information about Go. It contains [installation instructions](#), [a tutorial](#), and more.

This repository holds the gc compilers and Go packages. Changes to the code are [reviewed](#) before being committed.

The gccgo front end for GCC is hosted as a branch on the GCC Subversion server. See [the gccgo installation instructions](#).

Getting Started

Introduction

Go is an open source project with a BSD-style license. There are two official Go compiler toolchains: the gc Go compiler and the gccgo compiler that is part of the GNU C Compiler (GCC).

The gc compiler is the more mature and well-tested of the two. This page is about installing a binary distribution of the gc compiler.

For information about installing the gc compiler from source, see [Installing Go from source](#). For information about installing gccgo, see [Setting up and using gccgo](#).

Download the Go tools

Visit the [Go project's downloads page](#) and select the binary distribution that matches your operating system and processor architecture.

Official binary distributions are available for the FreeBSD, Linux, Mac OS X (Snow Leopard/Lion), and Windows operating systems and the 32-bit (386) and 64-bit (amd64) x86 processor architectures.

If a binary distribution is not available for your OS/arch combination you may want to try [installing from source](#) or [installing gccgo instead of gc](#).

Install the Go tools

The Go binary distributions assume they will be installed in `/usr/local/go` (or `c:\Go` under Windows), but it is possible to install them in a different location. If you do this, you will need to set the `GOROOT` environment variable to that directory when using the Go tools.

For example, if you installed Go to your home directory you should add the following commands to `$HOME/.profile`:

```
export GOROOT=$HOME/go
export PATH=$PATH:$GOROOT/bin
```

Windows users should read the section about [setting environment variables under Windows](#).

FreeBSD and Linux

On FreeBSD and Linux, if you are upgrading from an older version of Go you must first remove the existing version from `/usr/local/go`:

```
rm -r /usr/local/go
```

Extract [the archive](#) into `/usr/local`, creating a Go tree in `/usr/local/go`:

```
tar -C /usr/local -xzf go.release.go1.tar.gz
```

(Typically these commands must be run as root or through `sudo`.)

Add `/usr/local/go/bin` to the `PATH` environment variable. You can do this by adding this line to your `/etc/profile` (for a system-wide installation) or `$HOME/.profile`:

```
export PATH=$PATH:/usr/local/go/bin
```

Mac OS X

Open the [package file](#) and follow the prompts to install the Go tools. The package installs the Go distribution to `/usr/local/go`.

The package should put the `/usr/local/go/bin` directory in your `PATH` environment variable. You may need to restart any open Terminal sessions for the change to take effect.

Windows

The Go project provides two installation options for Windows users (besides [installing from source](#)): a zip archive that requires you to set some environment variables and an experimental MSI installer that configures your installation automatically.

Zip archive

Extract the [zip file](#) to the directory of your choice (we suggest `c:\Go`).

If you chose a directory other than `c:\Go`, you must set the `GOROOT` environment variable to your chosen path.

Add the `bin` subdirectory of your Go root (for example, `c:\Go\bin`) to to your `PATH` environment variable.

MSI installer (experimental)

Open the [MSI file](#) and follow the prompts to install the Go tools. By default, the installer puts the Go distribution in `c:\Go`.

The installer should put the `c:\Go\bin` directory in your `PATH` environment variable. You may need to restart any open command prompts for the change to take effect.

Setting environment variables under Windows

Under Windows, you may set environment variables through the "Environment Variables" button on the "Advanced" tab of the "System" control panel. Some versions of Windows provide this control panel through the "Advanced System Settings" option inside the "System" control panel.

Test your installation

Check that Go is installed correctly by building a simple program, as follows.

Create a file named `hello.go` and put the following program in it:

```
package main

import "fmt"

func main() {
    fmt.Printf("hello, world\n")
}
```

Then run it with the go tool:

```
$ go run hello.go
hello, world
```

If you see the "hello, world" message then your Go installation is working.

How to Write Go Code

Introduction

This document demonstrates the development of a simple Go package and introduces the [go command](#), the standard way to fetch, build, and install Go packages and commands.

Code organization

GOPATH and workspaces

One of Go's design goals is to make writing software easier. To that end, the `go` command doesn't use Makefiles or other configuration files to guide program construction. Instead, it uses the source code to find dependencies and determine build conditions. This means your source code and build scripts are always in sync; they are one and the same.

The one thing you must do is set a `GOPATH` environment variable. `GOPATH` tells the `go` command (and other related tools) where to find and install the Go packages on your system.

`GOPATH` is a list of paths. It shares the syntax of your system's `PATH` environment variable. A typical `GOPATH` on a Unix system might look like this:

```
GOPATH=/home/user/ext:/home/user/mygo
```

(On a Windows system use semicolons as the path separator instead of colons.)

Each path in the list (in this case `/home/user/ext` or `/home/user/mygo`) specifies the location of a *workspace*. A workspace contains Go source files and their associated package objects, and command executables. It has a prescribed structure of three subdirectories:

- `src` contains Go source files,
- `pkg` contains compiled package objects, and
- `bin` contains executable commands.

Subdirectories of the `src` directory hold independent packages, and all source files (`.go`, `.c`, `.h`, and `.s`) in each subdirectory are elements of that subdirectory's package.

When building a program that imports the package "widget" the `go` command looks for `src/pkg/widget` inside the Go root, and then—if the package source isn't found there—it searches for `src/widget` inside each workspace in order.

Multiple workspaces can offer some flexibility and convenience, but for now we'll concern ourselves with only a single workspace.

Let's work through a simple example. First, create a `$HOME/mygo` directory and its `src` subdirectory:

```
$ mkdir -p $HOME/mygo/src # create a place to put source code
```

Next, set it as the `GOPATH`. You should also add the `bin` subdirectory to your `PATH` environment variable so that you can run the commands therein without specifying their full path. To do this, add the following lines to `$HOME/.profile` (or equivalent):

```
export GOPATH=$HOME/mygo
export PATH=$PATH:$HOME/mygo/bin
```

Import paths

The standard packages are given short import paths such as `"fmt"` and `"net/http"` for convenience. For your own projects, it is important to choose a base import path that is unlikely to collide with future additions to the standard library or other external libraries.

The best way to choose an import path is to use the location of your version control repository. For instance, if your source repository is at `example.com` or `code.google.com/p/example`, you should begin your package paths with that URL, as in `"example.com/foo/bar"` or `"code.google.com/p/example/foo/bar"`. Using this convention, the `go` command can automatically check out and build the source code by its import path alone.

If you don't intend to install your code in this way, you should at least use a unique prefix like `"widgets/"`, as in `"widgets/foo/bar"`. A good rule is to use a prefix such as your company or project name, since it is unlikely to be used by another group.

We'll use `example/` as our base import path:

```
$ mkdir -p $GOPATH/src/example
```

Package names

The first statement in a Go source file should be

```
package name
```

where *name* is the package's default name for imports. (All files in a package must use the same *name*.)

Go's convention is that the package name is the last element of the import path: the package imported as "crypto/rot13" should be named rot13. There is no requirement that package names be unique across all packages linked into a single binary, only that the import paths (their full file names) be unique.

Create a new package under example called newmath:

```
$ cd $GOPATH/src/example  
$ mkdir newmath
```

Then create a file named \$GOPATH/src/example/newmath/sqrt.go containing the following Go code:

```
// Package newmath is a trivial example package.  
package newmath  
  
// Sqrt returns an approximation to the square root of x.  
func Sqrt(x float64) float64 {  
    // This is a terrible implementation.  
    // Real code should import "math" and use math.Sqrt.  
    z := 0.0  
    for i := 0; i < 1000; i++ {  
        z -= (z*z - x) / (2 * x)  
    }  
    return z  
}
```

This package is imported by the path name of the directory it's in, starting after the src component:

```
import "example/newmath"
```

See [Effective Go](#) to learn more about Go's naming conventions.

Building and installing

The `go` command comprises several subcommands, the most central being `install`. Running `go install importpath` builds and installs a package and its dependencies.

To "install a package" means to write the package object or executable command to the `pkg` or `bin` subdirectory of the workspace in which the source resides.

Building a package

To build and install the `newmath` package, type

```
$ go install example/newmath
```

This command will produce no output if the package and its dependencies are built and installed correctly.

As a convenience, the `go` command will assume the current directory if no `import path` is specified on the command line. This sequence of commands has the same effect as the one above:

```
$ cd $GOPATH/src/example/newmath
$ go install
```

The resulting workspace directory tree (assuming we're running Linux on a 64-bit system) looks like this:

```
pkg/
  linux_amd64/
    example/
      newmath.a # package object
src/
  example/
    newmath/
      sqrt.go # package source
```

Building a command

The `go` command treats code belonging to package `main` as an executable

command and installs the package binary to the GOPATH's bin subdirectory.

Add a command named `hello` to the source tree. First create the `example/hello` directory:

```
$ cd $GOPATH/src/example
$ mkdir hello
```

Then create the file `$GOPATH/src/example/hello/hello.go` containing the following Go code.

```
// Hello is a trivial example of a main package.
package main

import (
    "example/newmath"
    "fmt"
)

func main() {
    fmt.Printf("Hello, world.  Sqrt(2) = %v\n", newmath.Sqrt(2))
}
```

Next, run `go install`, which builds and installs the binary to `$GOPATH/bin` (or `$GOBIN`, if set; to simplify presentation, this document assumes `GOBIN` is unset):

```
$ go install example/hello
```

To run the program, invoke it by name as you would any other command:

```
$ $GOPATH/bin/hello
Hello, world.  Sqrt(2) = 1.414213562373095
```

If you added `$HOME/mygo/bin` to your `PATH`, you may omit the path to the executable:

```
$ hello
Hello, world.  Sqrt(2) = 1.414213562373095
```

The workspace directory tree now looks like this:

```
bin/
  hello          # command executable
pkg/
  linux_amd64/
```

```
    example/  
        newmath.a # package object  
src/  
    example/  
        hello/  
            hello.go # command source  
        newmath/  
            sqrt.go # package source
```

The `go` command also provides a `build` command, which is like `install` except it builds all objects in a temporary directory and does not install them under `pkg` or `bin`. When building a command an executable named after the last element of the import path is written to the current directory. When building a package, `go build` serves merely to test that the package and its dependencies can be built. (The resulting package object is thrown away.)

Testing

Go has a lightweight test framework composed of the `go test` command and the `testing` package.

You write a test by creating a file with a name ending in `_test.go` that contains functions named `TestXXX` with signature `func (t *testing.T)`. The test framework runs each such function; if the function calls a failure function such as `t.Error` or `t.Fail`, the test is considered to have failed.

Add a test to the `newmath` package by creating the file `$GOPATH/src/example/newmath/sqrt_test.go` containing the following Go code.

```
package newmath

import "testing"

func TestSqrt(t *testing.T) {
    const in, out = 4, 2
    if x := Sqrt(in); x != out {
        t.Errorf("Sqrt(%v) = %v, want %v", in, x, out)
    }
}
```

Now run the test with `go test`:

```
$ go test example/newmath
ok      example/newmath 0.165s
```

Run [go help test](#) and see the [testing package documentation](#) for more detail.

Remote packages

An import path can describe how to obtain the package source code using a revision control system such as Git or Mercurial. The `go` command uses this property to automatically fetch packages from remote repositories. For instance, the examples described in this document are also kept in a Mercurial repository hosted at Google Code, code.google.com/p/go.example. If you include the repository URL in the package's import path, `go get` will fetch, build, and install it automatically:

```
$ go get code.google.com/p/go.example/hello
$ $GOPATH/bin/hello
Hello, world.  Sqrt(2) = 1.414213562373095
```

If the specified package is not present in a workspace, `go get` will place it inside the first workspace specified by `GOPATH`. (If the package does already exist, `go get` skips the remote fetch and behaves the same as `go install`.)

After issuing the above `go get` command, the workspace directory tree should now look like this:

```
bin/
  hello          # command executable
pkg/
  linux_amd64/
    code.google.com/p/go.example/
      newmath.a  # package object
    example/
      newmath.a  # package object
src/
  code.google.com/p/go.example/
    hello/
      hello.go   # command source
    newmath/
      sqrt.go    # package source
      sqrt_test.go # test source
  example/
    hello/
      hello.go   # command source
    newmath/
      sqrt.go    # package source
      sqrt_test.go # test source
```

The `hello` command hosted at Google Code depends on the `newmath` package within the same repository. The imports in `hello.go` file use the same import path convention, so the `go get` command is able to locate and install the dependent package, too.

```
import "code.google.com/p/go.example/newmath"
```

This convention is the easiest way to make your Go packages available for others to use. The [Go Project Dashboard](#) is a list of external Go projects including programs and libraries.

For more information on using remote repositories with the `go` command, see [go help remote](#).

Effective Go

Introduction

Go is a new language. Although it borrows ideas from existing languages, it has unusual properties that make effective Go programs different in character from programs written in its relatives. A straightforward translation of a C++ or Java program into Go is unlikely to produce a satisfactory result—Java programs are written in Java, not Go. On the other hand, thinking about the problem from a Go perspective could produce a successful but quite different program. In other words, to write Go well, it's important to understand its properties and idioms. It's also important to know the established conventions for programming in Go, such as naming, formatting, program construction, and so on, so that programs you write will be easy for other Go programmers to understand.

This document gives tips for writing clear, idiomatic Go code. It augments the [language specification](#), the [Tour of Go](#), and [How to Write Go Code](#), all of which you should read first.

Examples

The [Go package sources](#) are intended to serve not only as the core library but also as examples of how to use the language. If you have a question about how to approach a problem or how something might be implemented, they can provide answers, ideas and background.

Formatting

Formatting issues are the most contentious but the least consequential. People can adapt to different formatting styles but it's better if they don't have to, and less time is devoted to the topic if everyone adheres to the same style. The problem is how to approach this Utopia without a long prescriptive style guide.

With Go we take an unusual approach and let the machine take care of most formatting issues. The `gofmt` program (also available as `go fmt`, which operates at the package level rather than source file level) reads a Go program and emits the source in a standard style of indentation and vertical alignment, retaining and if necessary reformatting comments. If you want to know how to handle some new layout situation, run `gofmt`; if the answer doesn't seem right, rearrange your program (or file a bug about `gofmt`), don't work around it.

As an example, there's no need to spend time lining up the comments on the fields of a structure. `gofmt` will do that for you. Given the declaration

```
type T struct {
    name string // name of the object
    value int // its value
}
```

`gofmt` will line up the columns:

```
type T struct {
    name    string // name of the object
    value   int    // its value
}
```

All Go code in the standard packages has been formatted with `gofmt`.

Some formatting details remain. Very briefly,

Indentation

We use tabs for indentation and `gofmt` emits them by default. Use spaces only if you must.

Line length

Go has no line length limit. Don't worry about overflowing a punched card. If a line feels too long, wrap it and indent with an extra tab.

Parentheses

Go needs fewer parentheses: control structures (`if`, `for`, `switch`) do not have parentheses in their syntax. Also, the operator precedence hierarchy is shorter and clearer, so

```
x<<8 + y<<16
```

means what the spacing implies.

Commentary

Go provides C-style `/* */` block comments and C++-style `//` line comments. Line comments are the norm; block comments appear mostly as package comments and are also useful to disable large swaths of code.

The program `godoc` and web server `godoc` processes Go source files to extract documentation about the contents of the package. Comments that appear before top-level declarations, with no intervening newlines, are extracted along with the declaration to serve as explanatory text for the item. The nature and style of these comments determines the quality of the documentation `godoc` produces.

Every package should have a *package comment*, a block comment preceding the package clause. For multi-file packages, the package comment only needs to be present in one file, and any one will do. The package comment should introduce the package and provide information relevant to the package as a whole. It will appear first on the `godoc` page and should set up the detailed documentation that follows.

```
/*
    Package regexp implements a simple library for
    regular expressions.

    The syntax of the regular expressions accepted is:

    regexp:
        concatenation { '|' concatenation }
    concatenation:
        { closure }
    closure:
        term [ '*' | '+' | '?' ]
    term:
        '^'
        '$'
        '.'
        character
        '[' [ '^' ] character-ranges '['
        '(' regexp ')'
*/
package regexp
```

If the package is simple, the package comment can be brief.

```
// Package path implements utility routines for
// manipulating slash-separated filename paths.
```

Comments do not need extra formatting such as banners of stars. The generated output may not even be presented in a fixed-width font, so don't depend on spacing for alignment—`godoc`, like `gofmt`, takes care of that. The comments are uninterpreted plain text, so HTML and other annotations such as `_this_` will reproduce *verbatim* and should not be used. Depending on the context, `godoc` might not even reformat comments, so make sure they look good straight up: use correct spelling, punctuation, and sentence structure, fold long lines, and so on.

Inside a package, any comment immediately preceding a top-level declaration serves as a *doc comment* for that declaration. Every exported (capitalized) name in a program should have a doc comment.

Doc comments work best as complete sentences, which allow a wide variety of automated presentations. The first sentence should be a one-sentence summary that starts with the name being declared.

```
// Compile parses a regular expression and returns, if successful, a
// object that can be used to match against text.
func Compile(str string) (regexp *Regexp, err error) {
```

Go's declaration syntax allows grouping of declarations. A single doc comment can introduce a group of related constants or variables. Since the whole declaration is presented, such a comment can often be perfunctory.

```
// Error codes returned by failures to parse an expression.
var (
    ErrInternal          = errors.New("regexp: internal error")
    ErrUnmatchedLpar    = errors.New("regexp: unmatched '('")
    ErrUnmatchedRpar    = errors.New("regexp: unmatched ')'")
    ...
)
```

Even for private names, grouping can also indicate relationships between items, such as the fact that a set of variables is protected by a mutex.

```
var (
    countLock    sync.Mutex
    inputCount   uint32
    outputCount  uint32
    errorCount   uint32
)
```

Names

Names are as important in Go as in any other language. In some cases they even have semantic effect: for instance, the visibility of a name outside a package is determined by whether its first character is upper case. It's therefore worth spending a little time talking about naming conventions in Go programs.

Package names

When a package is imported, the package name becomes an accessor for the contents. After

```
import "bytes"
```

the importing package can talk about `bytes.Buffer`. It's helpful if everyone using the package can use the same name to refer to its contents, which implies that the package name should be good: short, concise, evocative. By convention, packages are given lower case, single-word names; there should be no need for underscores or mixedCaps. Err on the side of brevity, since everyone using your package will be typing that name. And don't worry about collisions *a priori*. The package name is only the default name for imports; it need not be unique across all source code, and in the rare case of a collision the importing package can choose a different name to use locally. In any case, confusion is rare because the file name in the import determines just which package is being used.

Another convention is that the package name is the base name of its source directory; the package in `src/pkg/encoding/base64` is imported as `"encoding/base64"` but has name `base64`, not `encoding_base64` and not `encodingBase64`.

The importer of a package will use the name to refer to its contents (the `import .` notation is intended mostly for tests and other unusual situations and should be avoided unless necessary), so exported names in the package can use that fact to avoid stutter. For instance, the buffered reader type in the `bufio` package is called `Reader`, not `BufReader`, because users see it as `bufio.Reader`, which is a clear, concise name. Moreover, because imported entities are always addressed with their package name, `bufio.Reader` does not conflict with `io.Reader`. Similarly, the function to make new instances of `ring.Ring`—which is the

definition of a *constructor* in Go—would normally be called `NewRing`, but since `Ring` is the only type exported by the package, and since the package is called `ring`, it's called just `New`, which clients of the package see as `ring.New`. Use the package structure to help you choose good names.

Another short example is `once.Do`; `once.Do(setup)` reads well and would not be improved by writing `once.DoOrwaitUntilDone(setup)`. Long names don't automatically make things more readable. If the name represents something intricate or subtle, it's usually better to write a helpful doc comment than to attempt to put all the information into the name.

Getters

Go doesn't provide automatic support for getters and setters. There's nothing wrong with providing getters and setters yourself, and it's often appropriate to do so, but it's neither idiomatic nor necessary to put `Get` into the getter's name. If you have a field called `owner` (lower case, unexported), the getter method should be called `Owner` (upper case, exported), not `GetOwner`. The use of upper-case names for export provides the hook to discriminate the field from the method. A setter function, if needed, will likely be called `SetOwner`. Both names read well in practice:

```
owner := obj.Owner()
if owner != user {
    obj.SetOwner(user)
}
```

Interface names

By convention, one-method interfaces are named by the method name plus the `-er` suffix: `Reader`, `Writer`, `Formatter` etc.

There are a number of such names and it's productive to honor them and the function names they capture. `Read`, `Write`, `Close`, `Flush`, `String` and so on have canonical signatures and meanings. To avoid confusion, don't give your method one of those names unless it has the same signature and meaning. Conversely, if your type implements a method with the same meaning as a method on a well-known type, give it the same name and signature; call your string-converter method `String` not `ToString`.

MixedCaps

Finally, the convention in Go is to use `MixedCaps` or `mixedCaps` rather than underscores to write multiword names.

Semicolons

Like C, Go's formal grammar uses semicolons to terminate statements; unlike C, those semicolons do not appear in the source. Instead the lexer uses a simple rule to insert semicolons automatically as it scans, so the input text is mostly free of them.

The rule is this. If the last token before a newline is an identifier (which includes words like `int` and `float64`), a basic literal such as a number or string constant, or one of the tokens

```
break continue fallthrough return ++ -- ) }
```

the lexer always inserts a semicolon after the token. This could be summarized as, “if the newline comes after a token that could end a statement, insert a semicolon”.

A semicolon can also be omitted immediately before a closing brace, so a statement such as

```
go func() { for { dst <- <-src } }()
```

needs no semicolons. Idiomatic Go programs have semicolons only in places such as `for` loop clauses, to separate the initializer, condition, and continuation elements. They are also necessary to separate multiple statements on a line, should you write code that way.

One caveat. You should never put the opening brace of a control structure (`if`, `for`, `switch`, or `select`) on the next line. If you do, a semicolon will be inserted before the brace, which could cause unwanted effects. Write them like this

```
if i < f() {  
    g()  
}
```

not like this

```
if i < f() // wrong!  
{ // wrong!  
    g()
```

}

Control structures

The control structures of Go are related to those of C but differ in important ways. There is no `do` or `while` loop, only a slightly generalized `for`; `switch` is more flexible; `if` and `switch` accept an optional initialization statement like that of `for`; and there are new control structures including a type switch and a multiway communications multiplexer, `select`. The syntax is also slightly different: there are no parentheses and the bodies must always be brace-delimited.

If

In Go a simple `if` looks like this:

```
if x > 0 {
    return y
}
```

Mandatory braces encourage writing simple `if` statements on multiple lines. It's good style to do so anyway, especially when the body contains a control statement such as a `return` or `break`.

Since `if` and `switch` accept an initialization statement, it's common to see one used to set up a local variable.

```
if err := file.Chmod(0664); err != nil {
    log.Print(err)
    return err
}
```

In the Go libraries, you'll find that when an `if` statement doesn't flow into the next statement `return` that is, the body ends in `break`, `continue`, `goto`, or `return` the unnecessary `else` is omitted.

```
f, err := os.Open(name)
if err != nil {
    return err
}
codeUsing(f)
```

This is an example of a common situation where code must guard against a

sequence of error conditions. The code reads well if the successful flow of control runs down the page, eliminating error cases as they arise. Since error cases tend to end in return statements, the resulting code needs no else statements.

```
f, err := os.Open(name)
if err != nil {
    return err
}
d, err := f.Stat()
if err != nil {
    f.Close()
    return err
}
codeUsing(f, d)
```

Redeclaration

An aside: The last example in the previous section demonstrates a detail of how the := short declaration form works. The declaration that calls os.Open reads,

```
f, err := os.Open(name)
```

This statement declares two variables, f and err. A few lines later, the call to f.Stat reads,

```
d, err := f.Stat()
```

which looks as if it declares d and err. Notice, though, that err appears in both statements. This duplication is legal: err is declared by the first statement, but only *re-assigned* in the second. This means that the call to f.Stat uses the existing err variable declared above, and just gives it a new value.

In a := declaration a variable v may appear even if it has already been declared, provided:

- this declaration is in the same scope as the existing declaration of v (if v is already declared in an outer scope, the declaration will create a new variable),
- the corresponding value in the initialization is assignable to v, and
- there is at least one other variable in the declaration that is being declared anew.

This unusual property is pure pragmatism, making it easy to use a single `err` value, for example, in a long `if-else` chain. You'll see it used often.

For

The Go `for` loop is similar to—but not the same as—C's. It unifies `for` and `while` and there is no `do-while`. There are three forms, only one of which has semicolons.

```
// Like a C for
for init; condition; post { }
```

```
// Like a C while
for condition { }
```

```
// Like a C for(;;)
for { }
```

Short declarations make it easy to declare the index variable right in the loop.

```
sum := 0
for i := 0; i < 10; i++ {
    sum += i
}
```

If you're looping over an array, slice, string, or map, or reading from a channel, a range clause can manage the loop.

```
for key, value := range oldMap {
    newMap[key] = value
}
```

If you only need the first item in the range (the key or index), drop the second:

```
for key := range m {
    if expired(key) {
        delete(m, key)
    }
}
```

If you only need the second item in the range (the value), use the *blank identifier*, an underscore, to discard the first:

```
sum := 0
```

```
for _, value := range array {
    sum += value
}
```

For strings, the range does more work for you, breaking out individual Unicode characters by parsing the UTF-8. Erroneous encodings consume one byte and produce the replacement rune U+FFFD. The loop

```
for pos, char := range "000Z" {
    fmt.Printf("character %c starts at byte position %d\n", char, po
}
```

prints

```
character 00 starts at byte position 0
character 00 starts at byte position 3
character 0Z starts at byte position 6
```

Finally, Go has no comma operator and ++ and -- are statements not expressions. Thus if you want to run multiple variables in a for you should use parallel assignment.

```
// Reverse a
for i, j := 0, len(a)-1; i < j; i, j = i+1, j-1 {
    a[i], a[j] = a[j], a[i]
}
```

Switch

Go's switch is more general than C's. The expressions need not be constants or even integers, the cases are evaluated top to bottom until a match is found, and if the switch has no expression it switches on true. It's therefore possible—and idiomatic—to write an if-else-if-else chain as a switch.

```
func unhex(c byte) byte {
    switch {
    case '0' <= c && c <= '9':
        return c - '0'
    case 'a' <= c && c <= 'f':
        return c - 'a' + 10
    case 'A' <= c && c <= 'F':
        return c - 'A' + 10
    }
    return 0
}
```

There is no automatic fall through, but cases can be presented in comma-separated lists.

```
func shouldEscape(c byte) bool {
    switch c {
    case ' ', '?', '&', '=', '#', '+', '%':
        return true
    }
    return false
}
```

Here's a comparison routine for byte arrays that uses two switch statements:

```
// Compare returns an integer comparing the two byte arrays,
// lexicographically.
// The result will be 0 if a == b, -1 if a < b, and +1 if a > b
func Compare(a, b []byte) int {
    for i := 0; i < len(a) && i < len(b); i++ {
        switch {
        case a[i] > b[i]:
            return 1
        case a[i] < b[i]:
            return -1
        }
    }
    switch {
    case len(a) < len(b):
        return -1
    case len(a) > len(b):
        return 1
    }
    return 0
}
```

A switch can also be used to discover the dynamic type of an interface variable. Such a *type switch* uses the syntax of a type assertion with the keyword `type` inside the parentheses. If the switch declares a variable in the expression, the variable will have the corresponding type in each clause.

```
switch t := interfaceValue.(type) {
default:
    fmt.Printf("unexpected type %T", t) // %T prints type
case bool:
    fmt.Printf("boolean %t\n", t)
case int:
    fmt.Printf("integer %d\n", t)
case *bool:
```

```
    fmt.Printf("pointer to boolean %t\n", *t)
case *int:
    fmt.Printf("pointer to integer %d\n", *t)
}
```

Functions

Multiple return values

One of Go's unusual features is that functions and methods can return multiple values. This form can be used to improve on a couple of clumsy idioms in C programs: in-band error returns (such as -1 for EOF) and modifying an argument.

In C, a write error is signaled by a negative count with the error code secreted away in a volatile location. In Go, `write` can return a count *and* an error: “Yes, you wrote some bytes but not all of them because you filled the device”. The signature of `File.Write` in package `os` is:

```
func (file *File) Write(b []byte) (n int, err error)
```

and as the documentation says, it returns the number of bytes written and a non-nil error when `n != len(b)`. This is a common style; see the section on error handling for more examples.

A similar approach obviates the need to pass a pointer to a return value to simulate a reference parameter. Here's a simple-minded function to grab a number from a position in a byte array, returning the number and the next position.

```
func nextInt(b []byte, i int) (int, int) {
    for ; i < len(b) && !isDigit(b[i]); i++ {
    }
    x := 0
    for ; i < len(b) && isDigit(b[i]); i++ {
        x = x*10 + int(b[i])-'0'
    }
    return x, i
}
```

You could use it to scan the numbers in an input array a like this:

```
for i := 0; i < len(a); {
    x, i = nextInt(a, i)
    fmt.Println(x)
}
```

Named result parameters

The return or result "parameters" of a Go function can be given names and used as regular variables, just like the incoming parameters. When named, they are initialized to the zero values for their types when the function begins; if the function executes a return statement with no arguments, the current values of the result parameters are used as the returned values.

The names are not mandatory but they can make code shorter and clearer: they're documentation. If we name the results of `nextInt` it becomes obvious which returned int is which.

```
func nextInt(b []byte, pos int) (value, nextPos int) {
```

Because named results are initialized and tied to an unadorned return, they can simplify as well as clarify. Here's a version of `io.ReadFull` that uses them well:

```
func ReadFull(r Reader, buf []byte) (n int, err error) {
    for len(buf) > 0 && err == nil {
        var nr int
        nr, err = r.Read(buf)
        n += nr
        buf = buf[nr:]
    }
    return
}
```

Defer

Go's `defer` statement schedules a function call (the *deferred* function) to be run immediately before the function executing the `defer` returns. It's an unusual but effective way to deal with situations such as resources that must be released regardless of which path a function takes to return. The canonical examples are unlocking a mutex or closing a file.

```
// Contents returns the file's contents as a string.
func Contents(filename string) (string, error) {
    f, err := os.Open(filename)
    if err != nil {
        return "", err
    }
    defer f.Close() // f.Close will run when we're finished.
```

```

var result []byte
buf := make([]byte, 100)
for {
    n, err := f.Read(buf[0:])
    result = append(result, buf[0:n]...) // append is discussed
    if err != nil {
        if err == io.EOF {
            break
        }
        return "", err // f will be closed if we return here.
    }
}
return string(result), nil // f will be closed if we return here
}

```

Deferring a call to a function such as `close` has two advantages. First, it guarantees that you will never forget to close the file, a mistake that's easy to make if you later edit the function to add a new return path. Second, it means that the `close` sits near the `open`, which is much clearer than placing it at the end of the function.

The arguments to the deferred function (which include the receiver if the function is a method) are evaluated when the *defer* executes, not when the *call* executes. Besides avoiding worries about variables changing values as the function executes, this means that a single deferred call site can defer multiple function executions. Here's a silly example.

```

for i := 0; i < 5; i++ {
    defer fmt.Printf("%d ", i)
}

```

Deferred functions are executed in LIFO order, so this code will cause 4 3 2 1 0 to be printed when the function returns. A more plausible example is a simple way to trace function execution through the program. We could write a couple of simple tracing routines like this:

```

func trace(s string) { fmt.Println("entering:", s) }
func untrace(s string) { fmt.Println("leaving:", s) }

// Use them like this:
func a() {
    trace("a")
    defer untrace("a")
    // do something....
}

```

We can do better by exploiting the fact that arguments to deferred functions are evaluated when the defer executes. The tracing routine can set up the argument to the untracing routine. This example:

```
func trace(s string) string {
    fmt.Println("entering:", s)
    return s
}

func un(s string) {
    fmt.Println("leaving:", s)
}

func a() {
    defer un(trace("a"))
    fmt.Println("in a")
}

func b() {
    defer un(trace("b"))
    fmt.Println("in b")
    a()
}

func main() {
    b()
}
```

prints

```
entering: b
in b
entering: a
in a
leaving: a
leaving: b
```

For programmers accustomed to block-level resource management from other languages, defer may seem peculiar, but its most interesting and powerful applications come precisely from the fact that it's not block-based but function-based. In the section on panic and recover we'll see another example of its possibilities.

Data

Allocation with `new`

Go has two allocation primitives, the built-in functions `new` and `make`. They do different things and apply to different types, which can be confusing, but the rules are simple. Let's talk about `new` first. It's a built-in function that allocates memory, but unlike its namesakes in some other languages it does not *initialize* the memory, it only *zeros* it. That is, `new(T)` allocates zeroed storage for a new item of type `T` and returns its address, a value of type `*T`. In Go terminology, it returns a pointer to a newly allocated zero value of type `T`.

Since the memory returned by `new` is zeroed, it's helpful to arrange when designing your data structures that the zero value of each type can be used without further initialization. This means a user of the data structure can create one with `new` and get right to work. For example, the documentation for `bytes.Buffer` states that "the zero value for `Buffer` is an empty buffer ready to use." Similarly, `sync.Mutex` does not have an explicit constructor or `Init` method. Instead, the zero value for a `sync.Mutex` is defined to be an unlocked mutex.

The zero-value-is-useful property works transitively. Consider this type declaration.

```
type SyncedBuffer struct {  
    lock    sync.Mutex  
    buffer  bytes.Buffer  
}
```

Values of type `SyncedBuffer` are also ready to use immediately upon allocation or just declaration. In the next snippet, both `p` and `v` will work correctly without further arrangement.

```
p := new(SyncedBuffer) // type *SyncedBuffer  
var v SyncedBuffer     // type SyncedBuffer
```

Constructors and composite literals

Sometimes the zero value isn't good enough and an initializing constructor is

necessary, as in this example derived from package `os`.

```
func NewFile(fd int, name string) *File {
    if fd < 0 {
        return nil
    }
    f := new(File)
    f.fd = fd
    f.name = name
    f.dirinfo = nil
    f.nepipe = 0
    return f
}
```

There's a lot of boiler plate in there. We can simplify it using a *composite literal*, which is an expression that creates a new instance each time it is evaluated.

```
func NewFile(fd int, name string) *File {
    if fd < 0 {
        return nil
    }
    f := File{fd, name, nil, 0}
    return &f
}
```

Note that, unlike in C, it's perfectly OK to return the address of a local variable; the storage associated with the variable survives after the function returns. In fact, taking the address of a composite literal allocates a fresh instance each time it is evaluated, so we can combine these last two lines.

```
    return &File{fd, name, nil, 0}
```

The fields of a composite literal are laid out in order and must all be present. However, by labeling the elements explicitly as *field:value* pairs, the initializers can appear in any order, with the missing ones left as their respective zero values. Thus we could say

```
    return &File{fd: fd, name: name}
```

As a limiting case, if a composite literal contains no fields at all, it creates a zero value for the type. The expressions `new(File)` and `&File{}` are equivalent.

Composite literals can also be created for arrays, slices, and maps, with the field labels being indices or map keys as appropriate. In these examples, the

initializations work regardless of the values of `Enone`, `Eio`, and `Einval`, as long as they are distinct.

```
a := [...]string {Enone: "no error", Eio: "Eio", Einval: "invalid"}
s := []string     {Enone: "no error", Eio: "Eio", Einval: "invalid"}
m := map[int]string{Enone: "no error", Eio: "Eio", Einval: "invalid"}
```

Allocation with `make`

Back to allocation. The built-in function `make(τ , args)` serves a purpose different from `new(τ)`. It creates slices, maps, and channels only, and it returns an *initialized* (not *zeroed*) value of type τ (not $*\tau$). The reason for the distinction is that these three types are, under the covers, references to data structures that must be initialized before use. A slice, for example, is a three-item descriptor containing a pointer to the data (inside an array), the length, and the capacity, and until those items are initialized, the slice is `nil`. For slices, maps, and channels, `make` initializes the internal data structure and prepares the value for use. For instance,

```
make([]int, 10, 100)
```

allocates an array of 100 ints and then creates a slice structure with length 10 and a capacity of 100 pointing at the first 10 elements of the array. (When making a slice, the capacity can be omitted; see the section on slices for more information.) In contrast, `new([]int)` returns a pointer to a newly allocated, zeroed slice structure, that is, a pointer to a `nil` slice value.

These examples illustrate the difference between `new` and `make`.

```
var p *[]int = new([]int) // allocates slice structure; *p == nil
var v []int = make([]int, 100) // the slice v now refers to a new array

// Unnecessarily complex:
var p *[]int = new([]int)
*p = make([]int, 100, 100)

// Idiomatic:
v := make([]int, 100)
```

Remember that `make` applies only to maps, slices and channels and does not return a pointer. To obtain an explicit pointer allocate with `new`.

Arrays

Arrays are useful when planning the detailed layout of memory and sometimes can help avoid allocation, but primarily they are a building block for slices, the subject of the next section. To lay the foundation for that topic, here are a few words about arrays.

There are major differences between the ways arrays work in Go and C. In Go,

- Arrays are values. Assigning one array to another copies all the elements.
- In particular, if you pass an array to a function, it will receive a *copy* of the array, not a pointer to it.
- The size of an array is part of its type. The types `[10]int` and `[20]int` are distinct.

The value property can be useful but also expensive; if you want C-like behavior and efficiency, you can pass a pointer to the array.

```
func Sum(a *[3]float64) (sum float64) {
    for _, v := range *a {
        sum += v
    }
    return
}

array := [...]float64{7.0, 8.5, 9.1}
x := Sum(&array) // Note the explicit address-of operator
```

But even this style isn't idiomatic Go. Slices are.

Slices

Slices wrap arrays to give a more general, powerful, and convenient interface to sequences of data. Except for items with explicit dimension such as transformation matrices, most array programming in Go is done with slices rather than simple arrays.

Slices are *reference types*, which means that if you assign one slice to another, both refer to the same underlying array. For instance, if a function takes a slice argument, changes it makes to the elements of the slice will be visible to the caller, analogous to passing a pointer to the underlying array. A Read function

can therefore accept a slice argument rather than a pointer and a count; the length within the slice sets an upper limit of how much data to read. Here is the signature of the Read method of the File type in package os:

```
func (file *File) Read(buf []byte) (n int, err error)
```

The method returns the number of bytes read and an error value, if any. To read into the first 32 bytes of a larger buffer *b*, *slice* (here used as a verb) the buffer.

```
n, err := f.Read(buf[0:32])
```

Such slicing is common and efficient. In fact, leaving efficiency aside for the moment, the following snippet would also read the first 32 bytes of the buffer.

```
var n int
var err error
for i := 0; i < 32; i++ {
    nbytes, e := f.Read(buf[i:i+1]) // Read one byte.
    if nbytes == 0 || e != nil {
        err = e
        break
    }
    n += nbytes
}
```

The length of a slice may be changed as long as it still fits within the limits of the underlying array; just assign it to a slice of itself. The *capacity* of a slice, accessible by the built-in function *cap*, reports the maximum length the slice may assume. Here is a function to append data to a slice. If the data exceeds the capacity, the slice is reallocated. The resulting slice is returned. The function uses the fact that *len* and *cap* are legal when applied to the *nil* slice, and return 0.

```
func Append(slice, data[]byte) []byte {
    l := len(slice)
    if l + len(data) > cap(slice) { // reallocate
        // Allocate double what's needed, for future growth.
        newSlice := make([]byte, (l+len(data))*2)
        // The copy function is predeclared and works for any slice
        copy(newSlice, slice)
        slice = newSlice
    }
    slice = slice[0:l+len(data)]
    for i, c := range data {
        slice[l+i] = c
    }
}
```

```
    }
    return slice
}
```

We must return the slice afterwards because, although `Append` can modify the elements of `slice`, the slice itself (the run-time data structure holding the pointer, length, and capacity) is passed by value.

The idea of appending to a slice is so useful it's captured by the `append` built-in function. To understand that function's design, though, we need a little more information, so we'll return to it later.

Maps

Maps are a convenient and powerful built-in data structure to associate values of different types. The key can be of any type for which the equality operator is defined, such as integers, floating point and complex numbers, strings, pointers, interfaces (as long as the dynamic type supports equality), structs and arrays. Slices cannot be used as map keys, because equality is not defined on them. Like slices, maps are a reference type. If you pass a map to a function that changes the contents of the map, the changes will be visible in the caller.

Maps can be constructed using the usual composite literal syntax with colon-separated key-value pairs, so it's easy to build them during initialization.

```
var timeZone = map[string] int {
    "UTC":  0*60*60,
    "EST": -5*60*60,
    "CST": -6*60*60,
    "MST": -7*60*60,
    "PST": -8*60*60,
}
```

Assigning and fetching map values looks syntactically just like doing the same for arrays except that the index doesn't need to be an integer.

```
offset := timeZone["EST"]
```

An attempt to fetch a map value with a key that is not present in the map will return the zero value for the type of the entries in the map. For instance, if the map contains integers, looking up a non-existent key will return `0`. A set can be implemented as a map with value type `bool`. Set the map entry to `true` to put the

value in the set, and then test it by simple indexing.

```
attended := map[string] bool {
    "Ann": true,
    "Joe": true,
    ...
}

if attended[person] { // will be false if person is not in the map
    fmt.Println(person, "was at the meeting")
}
```

Sometimes you need to distinguish a missing entry from a zero value. Is there an entry for "UTC" or is that zero value because it's not in the map at all? You can discriminate with a form of multiple assignment.

```
var seconds int
var ok bool
seconds, ok = timeZone[tz]
```

For obvious reasons this is called the “comma ok” idiom. In this example, if `tz` is present, `seconds` will be set appropriately and `ok` will be true; if not, `seconds` will be set to zero and `ok` will be false. Here's a function that puts it together with a nice error report:

```
func offset(tz string) int {
    if seconds, ok := timeZone[tz]; ok {
        return seconds
    }
    log.Println("unknown time zone:", tz)
    return 0
}
```

To test for presence in the map without worrying about the actual value, you can use the blank identifier (`_`). The blank identifier can be assigned or declared with any value of any type, with the value discarded harmlessly. For testing just presence in a map, use the blank identifier in place of the usual variable for the value.

```
_, present := timeZone[tz]
```

To delete a map entry, use the `delete` built-in function, whose arguments are the map and the key to be deleted. It's safe to do this even if the key is already absent from the map.

```
delete(timeZone, "PDT") // Now on Standard Time
```

Printing

Formatted printing in Go uses a style similar to C's `printf` family but is richer and more general. The functions live in the `fmt` package and have capitalized names: `fmt.Printf`, `fmt.Fprintf`, `fmt.Sprintf` and so on. The string functions (`Sprintf` etc.) return a string rather than filling in a provided buffer.

You don't need to provide a format string. For each of `Printf`, `Fprintf` and `Sprintf` there is another pair of functions, for instance `Print` and `Println`. These functions do not take a format string but instead generate a default format for each argument. The `Println` versions also insert a blank between arguments and append a newline to the output while the `Print` versions add blanks only if the operand on neither side is a string. In this example each line produces the same output.

```
fmt.Printf("Hello %d\n", 23)
fmt.Fprint(os.Stdout, "Hello ", 23, "\n")
fmt.Println("Hello", 23)
fmt.Println(fmt.Sprint("Hello ", 23))
```

As mentioned in the [Tour](#), `fmt.Fprint` and friends take as a first argument any object that implements the `io.Writer` interface; the variables `os.Stdout` and `os.Stderr` are familiar instances.

Here things start to diverge from C. First, the numeric formats such as `%d` do not take flags for signedness or size; instead, the printing routines use the type of the argument to decide these properties.

```
var x uint64 = 1<<64 - 1
fmt.Printf("%d %x; %d %x\n", x, x, int64(x), int64(x))
```

prints

```
18446744073709551615 ffffffffffffffffffff; -1 -1
```

If you just want the default conversion, such as decimal for integers, you can use the catchall format `%v` (for “value”); the result is exactly what `Print` and `Println` would produce. Moreover, that format can print *any* value, even arrays, structs, and maps. Here is a print statement for the time zone map defined in the

previous section.

```
fmt.Printf("%v\n", timeZone) // or just fmt.Println(timeZone)
```

which gives output

```
map[CST:-21600 PST:-28800 EST:-18000 UTC:0 MST:-25200]
```

For maps the keys may be output in any order, of course. When printing a struct, the modified format `%+v` annotates the fields of the structure with their names, and for any value the alternate format `%#v` prints the value in full Go syntax.

```
type T struct {
    a int
    b float64
    c string
}
t := &T{ 7, -2.35, "abc\tdef" }
fmt.Printf("%v\n", t)
fmt.Printf("%+v\n", t)
fmt.Printf("%#v\n", t)
fmt.Printf("%#v\n", timeZone)
```

prints

```
&{7 -2.35 abc def}
&{a:7 b:-2.35 c:abc def}
&main.T{a:7, b:-2.35, c:"abc\tdef"}
map[string] int{"CST":-21600, "PST":-28800, "EST":-18000, "UTC":0, "
```

(Note the ampersands.) That quoted string format is also available through `%q` when applied to a value of type `string` or `[]byte`; the alternate format `%#q` will use backquotes instead if possible. Also, `%x` works on strings and arrays of bytes as well as on integers, generating a long hexadecimal string, and with a space in the format (`% x`) it puts spaces between the bytes.

Another handy format is `%T`, which prints the *type* of a value.

```
fmt.Printf("%T\n", timeZone)
```

prints

```
map[string] int
```

If you want to control the default format for a custom type, all that's required is to define a method with the signature `String() string` on the type. For our simple type `T`, that might look like this.

```
func (t *T) String() string {
    return fmt.Sprintf("%d/%g/%q", t.a, t.b, t.c)
}
fmt.Printf("%v\n", t)
```

to print in the format

```
7/-2.35/"abc\tdef"
```

(If you need to print *values* of type `T` as well as pointers to `T`, the receiver for `String` must be of value type; this example used a pointer because that's more efficient and idiomatic for struct types. See the section below on [pointers vs. value receivers](#) for more information.)

Our `String` method is able to call `Sprintf` because the print routines are fully reentrant and can be used recursively. We can even go one step further and pass a print routine's arguments directly to another such routine. The signature of `Printf` uses the type `...interface{}` for its final argument to specify that an arbitrary number of parameters (of arbitrary type) can appear after the format.

```
func Printf(format string, v ...interface{}) (n int, err error) {
```

Within the function `Printf`, `v` acts like a variable of type `[]interface{}` but if it is passed to another variadic function, it acts like a regular list of arguments. Here is the implementation of the function `log.Println` we used above. It passes its arguments directly to `fmt.Println` for the actual formatting.

```
//.Println prints to the standard logger in the manner of fmt.Println
func Println(v ...interface{}) {
    std.Output(2, fmt.Println(v...)) // Output takes parameters (i
}
```

We write `...` after `v` in the nested call to `Sprintln` to tell the compiler to treat `v` as a list of arguments; otherwise it would just pass `v` as a single slice argument.

There's even more to printing than we've covered here. See the [godoc documentation](#) for package `fmt` for the details.

By the way, a ... parameter can be of a specific type, for instance ...int for a min function that chooses the least of a list of integers:

```
func Min(a ...int) int {
    min := int(^uint(0) >> 1) // largest int
    for _, i := range a {
        if i < min {
            min = i
        }
    }
    return min
}
```

Append

Now we have the missing piece we needed to explain the design of the append built-in function. The signature of append is different from our custom Append function above. Schematically, it's like this:

```
func append(slice []T, elements...T) []T
```

where T is a placeholder for any given type. You can't actually write a function in Go where the type T is determined by the caller. That's why append is built in: it needs support from the compiler.

What append does is append the elements to the end of the slice and return the result. The result needs to be returned because, as with our hand-written Append, the underlying array may change. This simple example

```
x := []int{1,2,3}
x = append(x, 4, 5, 6)
fmt.Println(x)
```

prints [1 2 3 4 5 6]. So append works a little like Printf, collecting an arbitrary number of arguments.

But what if we wanted to do what our Append does and append a slice to a slice? Easy: use ... at the call site, just as we did in the call to output above. This snippet produces identical output to the one above.

```
x := []int{1,2,3}
y := []int{4,5,6}
x = append(x, y...)
```

```
fmt.Println(x)
```

Without that . . ., it wouldn't compile because the types would be wrong; y is not of type int.

Initialization

Although it doesn't look superficially very different from initialization in C or C++, initialization in Go is more powerful. Complex structures can be built during initialization and the ordering issues between initialized objects in different packages are handled correctly.

Constants

Constants in Go are just that—constant. They are created at compile time, even when defined as locals in functions, and can only be numbers, strings or booleans. Because of the compile-time restriction, the expressions that define them must be constant expressions, evaluatable by the compiler. For instance, `1<<3` is a constant expression, while `math.Sin(math.Pi/4)` is not because the function call to `math.Sin` needs to happen at run time.

In Go, enumerated constants are created using the `iota` enumerator. Since `iota` can be part of an expression and expressions can be implicitly repeated, it is easy to build intricate sets of values.

```
type ByteSize float64

const (
    _ = iota // ignore first value by assigning to blank i
    KB ByteSize = 1 << (10 * iota)
    MB
    GB
    TB
    PB
    EB
    ZB
    YB
)
```

The ability to attach a method such as `String` to a type makes it possible for such values to format themselves automatically for printing, even as part of a general type.

```
func (b ByteSize) String() string {
    switch {
    case b >= YB:
```

```

        return fmt.Sprintf("%.2fYB", b/YB)
    case b >= ZB:
        return fmt.Sprintf("%.2fZB", b/ZB)
    case b >= EB:
        return fmt.Sprintf("%.2fEB", b/EB)
    case b >= PB:
        return fmt.Sprintf("%.2fPB", b/PB)
    case b >= TB:
        return fmt.Sprintf("%.2fTB", b/TB)
    case b >= GB:
        return fmt.Sprintf("%.2fGB", b/GB)
    case b >= MB:
        return fmt.Sprintf("%.2fMB", b/MB)
    case b >= KB:
        return fmt.Sprintf("%.2fKB", b/KB)
    }
    return fmt.Sprintf("%.2fB", b)
}

```

The expression `YB` prints as `1.00YB`, while `ByteSize(1e13)` prints as `9.09TB`.

Note that it's fine to call `Printf` and friends in the implementation of `String` methods, but beware of recurring into the `String` method through the nested `Printf` call using a string format (`%s`, `%q`, `%v`, `%x` or `%X`). The `ByteSize` implementation of `String` is safe because it calls `Printf` with `%f`.

Variables

Variables can be initialized just like constants but the initializer can be a general expression computed at run time.

```

var (
    HOME = os.Getenv("HOME")
    USER = os.Getenv("USER")
    GOROOT = os.Getenv("GOROOT")
)

```

The `init` function

Finally, each source file can define its own `init` function to set up whatever state is required. (Actually each file can have multiple `init` functions.) And finally means finally: `init` is called after all the variable declarations in the package have evaluated their initializers, and those are evaluated only after all the imported packages have been initialized.

Besides initializations that cannot be expressed as declarations, a common use of init functions is to verify or repair correctness of the program state before real execution begins.

```
func init() {
    if USER == "" {
        log.Fatal("$USER not set")
    }
    if HOME == "" {
        HOME = "/usr/" + USER
    }
    if GOROOT == "" {
        GOROOT = HOME + "/go"
    }
    // GOROOT may be overridden by --goroot flag on command line.
    flag.StringVar(&GOROOT, "goroot", GOROOT, "Go root directory")
}
```

Methods

Pointers vs. Values

Methods can be defined for any named type that is not a pointer or an interface; the receiver does not have to be a struct.

In the discussion of slices above, we wrote an `Append` function. We can define it as a method on slices instead. To do this, we first declare a named type to which we can bind the method, and then make the receiver for the method a value of that type.

```
type ByteSlice []byte

func (slice ByteSlice) Append(data []byte) []byte {
    // Body exactly the same as above
}
```

This still requires the method to return the updated slice. We can eliminate that clumsiness by redefining the method to take a *pointer* to a `ByteSlice` as its receiver, so the method can overwrite the caller's slice.

```
func (p *ByteSlice) Append(data []byte) {
    slice := *p
    // Body as above, without the return.
    *p = slice
}
```

In fact, we can do even better. If we modify our function so it looks like a standard write method, like this,

```
func (p *ByteSlice) Write(data []byte) (n int, err error) {
    slice := *p
    // Again as above.
    *p = slice
    return len(data), nil
}
```

then the type `*ByteSlice` satisfies the standard interface `io.Writer`, which is handy. For instance, we can print into one.

```
var b ByteSlice
```

```
fmt.Fprintf(&b, "This hour has %d days\n", 7)
```

We pass the address of a `ByteSlice` because only `*ByteSlice` satisfies `io.Writer`. The rule about pointers vs. values for receivers is that value methods can be invoked on pointers and values, but pointer methods can only be invoked on pointers. This is because pointer methods can modify the receiver; invoking them on a copy of the value would cause those modifications to be discarded.

By the way, the idea of using `write` on a slice of bytes is implemented by `bytes.Buffer`.

Interfaces and other types

Interfaces

Interfaces in Go provide a way to specify the behavior of an object: if something can do *this*, then it can be used *here*. We've seen a couple of simple examples already; custom printers can be implemented by a `String` method while `Fprintf` can generate output to anything with a `Write` method. Interfaces with only one or two methods are common in Go code, and are usually given a name derived from the method, such as `io.Writer` for something that implements `Write`.

A type can implement multiple interfaces. For instance, a collection can be sorted by the routines in package `sort` if it implements `sort.Interface`, which contains `Len()`, `Less(i, j int) bool`, and `Swap(i, j int)`, and it could also have a custom formatter. In this contrived example `Sequence` satisfies both.

```
type Sequence []int

// Methods required by sort.Interface.
func (s Sequence) Len() int {
    return len(s)
}
func (s Sequence) Less(i, j int) bool {
    return s[i] < s[j]
}
func (s Sequence) Swap(i, j int) {
    s[i], s[j] = s[j], s[i]
}

// Method for printing - sorts the elements before printing.
func (s Sequence) String() string {
    sort.Sort(s)
    str := "["
    for i, elem := range s {
        if i > 0 {
            str += " "
        }
        str += fmt.Sprintf(elem)
    }
    return str + "]"
}
```

Conversions

The `String` method of `Sequence` is recreating the work that `Sprint` already does for slices. We can share the effort if we convert the `Sequence` to a plain `[]int` before calling `Sprint`.

```
func (s Sequence) String() string {
    sort.Sort(s)
    return fmt.Sprint([]int(s))
}
```

The conversion causes `s` to be treated as an ordinary slice and therefore receive the default formatting. Without the conversion, `Sprint` would find the `String` method of `Sequence` and recur indefinitely. Because the two types (`Sequence` and `[]int`) are the same if we ignore the type name, it's legal to convert between them. The conversion doesn't create a new value, it just temporarily acts as though the existing value has a new type. (There are other legal conversions, such as from integer to floating point, that do create a new value.)

It's an idiom in Go programs to convert the type of an expression to access a different set of methods. As an example, we could use the existing type `sort.IntSlice` to reduce the entire example to this:

```
type Sequence []int

// Method for printing - sorts the elements before printing
func (s Sequence) String() string {
    sort.IntSlice(s).Sort()
    return fmt.Sprint([]int(s))
}
```

Now, instead of having `Sequence` implement multiple interfaces (sorting and printing), we're using the ability of a data item to be converted to multiple types (`Sequence`, `sort.IntSlice` and `[]int`), each of which does some part of the job. That's more unusual in practice but can be effective.

Generality

If a type exists only to implement an interface and has no exported methods beyond that interface, there is no need to export the type itself. Exporting just the interface makes it clear that it's the behavior that matters, not the implementation, and that other implementations with different properties can mirror the behavior of the original type. It also avoids the need to repeat the documentation on every instance of a common method.

In such cases, the constructor should return an interface value rather than the implementing type. As an example, in the hash libraries both `crc32.NewIEEE` and `adler32.New` return the interface type `hash.Hash32`. Substituting the CRC-32 algorithm for Adler-32 in a Go program requires only changing the constructor call; the rest of the code is unaffected by the change of algorithm.

A similar approach allows the streaming cipher algorithms in the various `crypto` packages to be separated from the block ciphers they chain together. The `Block` interface in the `crypto/cipher` package specifies the behavior of a block cipher, which provides encryption of a single block of data. Then, by analogy with the `bufio` package, cipher packages that implement this interface can be used to construct streaming ciphers, represented by the `Stream` interface, without knowing the details of the block encryption.

The `crypto/cipher` interfaces look like this:

```
type Block interface {
    BlockSize() int
    Encrypt(src, dst []byte)
    Decrypt(src, dst []byte)
}

type Stream interface {
    XORKeyStream(dst, src []byte)
}
```

Here's the definition of the counter mode (CTR) stream, which turns a block cipher into a streaming cipher; notice that the block cipher's details are abstracted away:

```
// NewCTR returns a Stream that encrypts/decrypts using the given Block
// counter mode. The length of iv must be the same as the Block's block
func NewCTR(block Block, iv []byte) Stream
```

`NewCTR` applies not just to one specific encryption algorithm and data source but to any implementation of the `Block` interface and any `Stream`. Because they return interface values, replacing CTR encryption with other encryption modes is a localized change. The constructor calls must be edited, but because the surrounding code must treat the result only as a `Stream`, it won't notice the difference.

Interfaces and methods

Since almost anything can have methods attached, almost anything can satisfy an interface. One illustrative example is in the `http` package, which defines the `Handler` interface. Any object that implements `Handler` can serve HTTP requests.

```
type Handler interface {
    ServeHTTP(ResponseWriter, *Request)
}
```

`ResponseWriter` is itself an interface that provides access to the methods needed to return the response to the client. Those methods include the standard `write` method, so an `http.ResponseWriter` can be used wherever an `io.Writer` can be used. `Request` is a struct containing a parsed representation of the request from the client.

For brevity, let's ignore POSTs and assume HTTP requests are always GETs; that simplification does not affect the way the handlers are set up. Here's a trivial but complete implementation of a handler to count the number of times the page is visited.

```
// Simple counter server.
type Counter struct {
    n int
}

func (ctr *Counter) ServeHTTP(w http.ResponseWriter, req *http.Reque
    ctr.n++
    fmt.Fprintf(w, "counter = %d\n", ctr.n)
}
```

(Keeping with our theme, note how `Fprintf` can print to an `http.ResponseWriter`.) For reference, here's how to attach such a server to a node on the URL tree.

```
import "net/http"
...
ctr := new(Counter)
http.Handle("/counter", ctr)
```

But why make `Counter` a struct? An integer is all that's needed. (The receiver needs to be a pointer so the increment is visible to the caller.)

```
// Simpler counter server.
type Counter int
```

```
func (ctr *Counter) ServeHTTP(w http.ResponseWriter, req *http.Reque
    *ctr++
    fmt.Fprintf(w, "counter = %d\n", *ctr)
}
```

What if your program has some internal state that needs to be notified that a page has been visited? Tie a channel to the web page.

```
// A channel that sends a notification on each visit.
// (Probably want the channel to be buffered.)
type Chan chan *http.Request

func (ch Chan) ServeHTTP(w http.ResponseWriter, req *http.Request) {
    ch <- req
    fmt.Fprint(w, "notification sent")
}
```

Finally, let's say we wanted to present on `/args` the arguments used when invoking the server binary. It's easy to write a function to print the arguments.

```
func ArgServer() {
    for _, s := range os.Args {
        fmt.Println(s)
    }
}
```

How do we turn that into an HTTP server? We could make `ArgServer` a method of some type whose value we ignore, but there's a cleaner way. Since we can define a method for any type except pointers and interfaces, we can write a method for a function. The `http` package contains this code:

```
// The HandlerFunc type is an adapter to allow the use of
// ordinary functions as HTTP handlers. If f is a function
// with the appropriate signature, HandlerFunc(f) is a
// Handler object that calls f.
type HandlerFunc func(ResponseWriter, *Request)

// ServeHTTP calls f(c, req).
func (f HandlerFunc) ServeHTTP(w ResponseWriter, req *Request) {
    f(w, req)
}
```

`HandlerFunc` is a type with a method, `ServeHTTP`, so values of that type can serve HTTP requests. Look at the implementation of the method: the receiver is a function, `f`, and the method calls `f`. That may seem odd but it's not that

different from, say, the receiver being a channel and the method sending on the channel.

To make `ArgServer` into an HTTP server, we first modify it to have the right signature.

```
// Argument server.  
func ArgServer(w http.ResponseWriter, req *http.Request) {  
    for _, s := range os.Args {  
        fmt.Fprintln(w, s)  
    }  
}
```

`ArgServer` now has same signature as `HandlerFunc`, so it can be converted to that type to access its methods, just as we converted `Sequence` to `IntSlice` to access `IntSlice.Sort`. The code to set it up is concise:

```
http.Handle("/args", http.HandlerFunc(ArgServer))
```

When someone visits the page `/args`, the handler installed at that page has value `ArgServer` and type `HandlerFunc`. The HTTP server will invoke the method `ServeHTTP` of that type, with `ArgServer` as the receiver, which will in turn call `ArgServer` (via the invocation `f(c, req)` inside `HandlerFunc.ServeHTTP`). The arguments will then be displayed.

In this section we have made an HTTP server from a struct, an integer, a channel, and a function, all because interfaces are just sets of methods, which can be defined for (almost) any type.

Embedding

Go does not provide the typical, type-driven notion of subclassing, but it does have the ability to “borrow” pieces of an implementation by *embedding* types within a struct or interface.

Interface embedding is very simple. We've mentioned the `io.Reader` and `io.Writer` interfaces before; here are their definitions.

```
type Reader interface {
    Read(p []byte) (n int, err error)
}

type Writer interface {
    Write(p []byte) (n int, err error)
}
```

The `io` package also exports several other interfaces that specify objects that can implement several such methods. For instance, there is `io.ReadWriter`, an interface containing both `Read` and `write`. We could specify `io.ReadWriter` by listing the two methods explicitly, but it's easier and more evocative to embed the two interfaces to form the new one, like this:

```
// ReadWriter is the interface that combines the Reader and Writer i
type ReadWriter interface {
    Reader
    Writer
}
```

This says just what it looks like: A `ReadWriter` can do what a `Reader` does *and* what a `writer` does; it is a union of the embedded interfaces (which must be disjoint sets of methods). Only interfaces can be embedded within interfaces.

The same basic idea applies to structs, but with more far-reaching implications. The `bufio` package has two struct types, `bufio.Reader` and `bufio.Writer`, each of which of course implements the analogous interfaces from package `io`. And `bufio` also implements a buffered reader/writer, which it does by combining a reader and a writer into one struct using embedding: it lists the types within the struct but does not give them field names.

```
// ReadWriter stores pointers to a Reader and a Writer.
```

```
// It implements io.ReadWriter.
type ReadWriter struct {
    *Reader // *bufio.Reader
    *Writer // *bufio.Writer
}
```

The embedded elements are pointers to structs and of course must be initialized to point to valid structs before they can be used. The `ReadWriter` struct could be written as

```
type ReadWriter struct {
    reader *Reader
    writer *Writer
}
```

but then to promote the methods of the fields and to satisfy the `io` interfaces, we would also need to provide forwarding methods, like this:

```
func (rw *ReadWriter) Read(p []byte) (n int, err error) {
    return rw.reader.Read(p)
}
```

By embedding the structs directly, we avoid this bookkeeping. The methods of embedded types come along for free, which means that `bufio.ReadWriter` not only has the methods of `bufio.Reader` and `bufio.Writer`, it also satisfies all three interfaces: `io.Reader`, `io.Writer`, and `io.ReadWriter`.

There's an important way in which embedding differs from subclassing. When we embed a type, the methods of that type become methods of the outer type, but when they are invoked the receiver of the method is the inner type, not the outer one. In our example, when the `Read` method of a `bufio.ReadWriter` is invoked, it has exactly the same effect as the forwarding method written out above; the receiver is the `reader` field of the `ReadWriter`, not the `ReadWriter` itself.

Embedding can also be a simple convenience. This example shows an embedded field alongside a regular, named field.

```
type Job struct {
    Command string
    *log.Logger
}
```

The Job type now has the Log, Logf and other methods of `*log.Logger`. We could have given the Logger a field name, of course, but it's not necessary to do so. And now, once initialized, we can log to the Job:

```
job.Log("starting now...")
```

The Logger is a regular field of the struct and we can initialize it in the usual way with a constructor,

```
func NewJob(command string, logger *log.Logger) *Job {  
    return &Job{command, logger}  
}
```

or with a composite literal,

```
job := &Job{command, log.New(os.Stderr, "Job: ", log.Ldate)}
```

If we need to refer to an embedded field directly, the type name of the field, ignoring the package qualifier, serves as a field name. If we needed to access the `*log.Logger` of a Job variable `job`, we would write `job.Logger`. This would be useful if we wanted to refine the methods of Logger.

```
func (job *Job) Logf(format string, args ...interface{}) {  
    job.Logger.Logf("%q: %s", job.Command, fmt.Sprintf(format, args...))  
}
```

Embedding types introduces the problem of name conflicts but the rules to resolve them are simple. First, a field or method `x` hides any other item `x` in a more deeply nested part of the type. If `log.Logger` contained a field or method called `Command`, the `Command` field of `Job` would dominate it.

Second, if the same name appears at the same nesting level, it is usually an error; it would be erroneous to embed `log.Logger` if the `Job` struct contained another field or method called `Logger`. However, if the duplicate name is never mentioned in the program outside the type definition, it is OK. This qualification provides some protection against changes made to types embedded from outside; there is no problem if a field is added that conflicts with another field in another subtype if neither field is ever used.

Concurrency

Share by communicating

Concurrent programming is a large topic and there is space only for some Go-specific highlights here.

Concurrent programming in many environments is made difficult by the subtleties required to implement correct access to shared variables. Go encourages a different approach in which shared values are passed around on channels and, in fact, never actively shared by separate threads of execution. Only one goroutine has access to the value at any given time. Data races cannot occur, by design. To encourage this way of thinking we have reduced it to a slogan:

Do not communicate by sharing memory; instead, share memory by communicating.

This approach can be taken too far. Reference counts may be best done by putting a mutex around an integer variable, for instance. But as a high-level approach, using channels to control access makes it easier to write clear, correct programs.

One way to think about this model is to consider a typical single-threaded program running on one CPU. It has no need for synchronization primitives. Now run another such instance; it too needs no synchronization. Now let those two communicate; if the communication is the synchronizer, there's still no need for other synchronization. Unix pipelines, for example, fit this model perfectly. Although Go's approach to concurrency originates in Hoare's Communicating Sequential Processes (CSP), it can also be seen as a type-safe generalization of Unix pipes.

Goroutines

They're called *goroutines* because the existing terms—threads, coroutines, processes, and so on—convey inaccurate connotations. A goroutine has a simple model: it is a function executing concurrently with other goroutines in the same

address space. It is lightweight, costing little more than the allocation of stack space. And the stacks start small, so they are cheap, and grow by allocating (and freeing) heap storage as required.

Goroutines are multiplexed onto multiple OS threads so if one should block, such as while waiting for I/O, others continue to run. Their design hides many of the complexities of thread creation and management.

Prefix a function or method call with the `go` keyword to run the call in a new goroutine. When the call completes, the goroutine exits, silently. (The effect is similar to the Unix shell's `&` notation for running a command in the background.)

```
go list.Sort() // run list.Sort concurrently; don't wait for it.
```

A function literal can be handy in a goroutine invocation.

```
func Announce(message string, delay time.Duration) {
    go func() {
        time.Sleep(delay)
        fmt.Println(message)
    }() // Note the parentheses - must call the function.
}
```

In Go, function literals are closures: the implementation makes sure the variables referred to by the function survive as long as they are active.

These examples aren't too practical because the functions have no way of signaling completion. For that, we need channels.

Channels

Like maps, channels are a reference type and are allocated with `make`. If an optional integer parameter is provided, it sets the buffer size for the channel. The default is zero, for an unbuffered or synchronous channel.

```
ci := make(chan int)           // unbuffered channel of integers
cj := make(chan int, 0)       // unbuffered channel of integers
cs := make(chan *os.File, 100) // buffered channel of pointers to F
```

Channels combine communication—the exchange of a value—with synchronization—guaranteeing that two calculations (goroutines) are in a known state.

There are lots of nice idioms using channels. Here's one to get us started. In the previous section we launched a sort in the background. A channel can allow the launching goroutine to wait for the sort to complete.

```
c := make(chan int) // Allocate a channel.
// Start the sort in a goroutine; when it completes, signal on the c
go func() {
    list.Sort()
    c <- 1 // Send a signal; value does not matter.
}()
doSomethingForAWhile()
<-c // Wait for sort to finish; discard sent value.
```

Receivers always block until there is data to receive. If the channel is unbuffered, the sender blocks until the receiver has received the value. If the channel has a buffer, the sender blocks only until the value has been copied to the buffer; if the buffer is full, this means waiting until some receiver has retrieved a value.

A buffered channel can be used like a semaphore, for instance to limit throughput. In this example, incoming requests are passed to `handle`, which sends a value into the channel, processes the request, and then receives a value from the channel. The capacity of the channel buffer limits the number of simultaneous calls to process.

```
var sem = make(chan int, MaxOutstanding)

func handle(r *Request) {
    sem <- 1 // Wait for active queue to drain.
    process(r) // May take a long time.
    <-sem // Done; enable next request to run.
}

func Serve(queue chan *Request) {
    for {
        req := <-queue
        go handle(req) // Don't wait for handle to finish.
    }
}
```

Here's the same idea implemented by starting a fixed number of `handle` goroutines all reading from the request channel. The number of goroutines limits the number of simultaneous calls to process. This `Serve` function also accepts a channel on which it will be told to exit; after launching the goroutines it blocks

receiving from that channel.

```
func handle(queue chan *Request) {
    for r := range queue {
        process(r)
    }
}

func Serve(clientRequests chan *Request, quit chan bool) {
    // Start handlers
    for i := 0; i < MaxOutstanding; i++ {
        go handle(clientRequests)
    }
    <-quit // Wait to be told to exit.
}
```

Channels of channels

One of the most important properties of Go is that a channel is a first-class value that can be allocated and passed around like any other. A common use of this property is to implement safe, parallel demultiplexing.

In the example in the previous section, `handle` was an idealized handler for a request but we didn't define the type it was handling. If that type includes a channel on which to reply, each client can provide its own path for the answer. Here's a schematic definition of type `Request`.

```
type Request struct {
    args      []int
    f         func([]int) int
    resultChan chan int
}
```

The client provides a function and its arguments, as well as a channel inside the request object on which to receive the answer.

```
func sum(a []int) (s int) {
    for _, v := range a {
        s += v
    }
    return
}

request := &Request{[]int{3, 4, 5}, sum, make(chan int)}
// Send request
```

```
clientRequests <- request
// Wait for response.
fmt.Printf("answer: %d\n", <-request.resultChan)
```

On the server side, the handler function is the only thing that changes.

```
func handle(queue chan *Request) {
    for req := range queue {
        req.resultChan <- req.f(req.args)
    }
}
```

There's clearly a lot more to do to make it realistic, but this code is a framework for a rate-limited, parallel, non-blocking RPC system, and there's not a mutex in sight.

Parallelization

Another application of these ideas is to parallelize a calculation across multiple CPU cores. If the calculation can be broken into separate pieces that can execute independently, it can be parallelized, with a channel to signal when each piece completes.

Let's say we have an expensive operation to perform on a vector of items, and that the value of the operation on each item is independent, as in this idealized example.

```
type Vector []float64

// Apply the operation to v[i], v[i+1] ... up to v[n-1].
func (v Vector) DoSome(i, n int, u Vector, c chan int) {
    for ; i < n; i++ {
        v[i] += u.Op(v[i])
    }
    c <- 1    // signal that this piece is done
}
```

We launch the pieces independently in a loop, one per CPU. They can complete in any order but it doesn't matter; we just count the completion signals by draining the channel after launching all the goroutines.

```
const NCPU = 4 // number of CPU cores

func (v Vector) DoAll(u Vector) {
```

```

    c := make(chan int, NCPU) // Buffering optional but sensible.
    for i := 0; i < NCPU; i++ {
        go v.DoSome(i*len(v)/NCPU, (i+1)*len(v)/NCPU, u, c)
    }
    // Drain the channel.
    for i := 0; i < NCPU; i++ {
        <-c // wait for one task to complete
    }
    // All done.
}

```

The current implementation of the Go runtime will not parallelize this code by default. It dedicates only a single core to user-level processing. An arbitrary number of goroutines can be blocked in system calls, but by default only one can be executing user-level code at any time. It should be smarter and one day it will be smarter, but until it is if you want CPU parallelism you must tell the run-time how many goroutines you want executing code simultaneously. There are two related ways to do this. Either run your job with environment variable `GOMAXPROCS` set to the number of cores to use or import the `runtime` package and call `runtime.GOMAXPROCS(NCPU)`. A helpful value might be `runtime.NumCPU()`, which reports the number of logical CPUs on the local machine. Again, this requirement is expected to be retired as the scheduling and run-time improve.

A leaky buffer

The tools of concurrent programming can even make non-concurrent ideas easier to express. Here's an example abstracted from an RPC package. The client goroutine loops receiving data from some source, perhaps a network. To avoid allocating and freeing buffers, it keeps a free list, and uses a buffered channel to represent it. If the channel is empty, a new buffer gets allocated. Once the message buffer is ready, it's sent to the server on `serverChan`.

```

var freeList = make(chan *Buffer, 100)
var serverChan = make(chan *Buffer)

func client() {
    for {
        var b *Buffer
        // Grab a buffer if available; allocate if not.
        select {
        case b = <-freeList:
            // Got one; nothing more to do.
        default:

```

```

        // None free, so allocate a new one.
        b = new(Buffer)
    }
    load(b)           // Read next message from the net.
    serverChan <- b  // Send to server.
}
}

```

The server loop receives each message from the client, processes it, and returns the buffer to the free list.

```

func server() {
    for {
        b := <-serverChan // Wait for work.
        process(b)
        // Reuse buffer if there's room.
        select {
        case freeList <- b:
            // Buffer on free list; nothing more to do.
        default:
            // Free list full, just carry on.
        }
    }
}

```

The client attempts to retrieve a buffer from `freeList`; if none is available, it allocates a fresh one. The server's send to `freeList` puts `b` back on the free list unless the list is full, in which case the buffer is dropped on the floor to be reclaimed by the garbage collector. (The `default` clauses in the `select` statements execute when no other case is ready, meaning that the selects never block.) This implementation builds a leaky bucket free list in just a few lines, relying on the buffered channel and the garbage collector for bookkeeping.

Errors

Library routines must often return some sort of error indication to the caller. As mentioned earlier, Go's multivalue return makes it easy to return a detailed error description alongside the normal return value. By convention, errors have type `error`, a simple built-in interface.

```
type error interface {
    Error() string
}
```

A library writer is free to implement this interface with a richer model under the covers, making it possible not only to see the error but also to provide some context. For example, `os.Open` returns an `os.PathError`.

```
// PathError records an error and the operation and
// file path that caused it.
type PathError struct {
    Op string    // "open", "unlink", etc.
    Path string  // The associated file.
    Err error      // Returned by the system call.
}

func (e *PathError) Error() string {
    return e.Op + " " + e.Path + ": " + e.Err.Error()
}
```

`PathError`'s `Error` generates a string like this:

```
open /etc/passwx: no such file or directory
```

Such an error, which includes the problematic file name, the operation, and the operating system error it triggered, is useful even if printed far from the call that caused it; it is much more informative than the plain "no such file or directory".

When feasible, error strings should identify their origin, such as by having a prefix naming the package that generated the error. For example, in package `image`, the string representation for a decoding error due to an unknown format is "image: unknown format".

Callers that care about the precise error details can use a type switch or a type

assertion to look for specific errors and extract details. For `PathErrors` this might include examining the internal `Err` field for recoverable failures.

```
for try := 0; try < 2; try++ {
    file, err = os.Create(filename)
    if err == nil {
        return
    }
    if e, ok := err.(*os.PathError); ok && e.Err == syscall.ENOSPC {
        deleteTempFiles() // Recover some space.
        continue
    }
    return
}
```

The second `if` statement here is idiomatic Go. The type assertion `err.(*os.PathError)` is checked with the "comma ok" idiom (mentioned [earlier](#) in the context of examining maps). If the type assertion fails, `ok` will be `false`, and `e` will be `nil`. If it succeeds, `ok` will be `true`, which means the error was of type `*os.PathError`, and then so is `e`, which we can examine for more information about the error.

Panic

The usual way to report an error to a caller is to return an error as an extra return value. The canonical `Read` method is a well-known instance; it returns a byte count and an error. But what if the error is unrecoverable? Sometimes the program simply cannot continue.

For this purpose, there is a built-in function `panic` that in effect creates a run-time error that will stop the program (but see the next section). The function takes a single argument of arbitrary type—often a string—to be printed as the program dies. It's also a way to indicate that something impossible has happened, such as exiting an infinite loop. In fact, the compiler recognizes a panic at the end of a function and suppresses the usual check for a return statement.

```
// A toy implementation of cube root using Newton's method.
func CubeRoot(x float64) float64 {
    z := x/3 // Arbitrary initial value
    for i := 0; i < 1e6; i++ {
        prevz := z
        z -= (z*z*z-x) / (3*z*z)
        if veryClose(z, prevz) {
```

```

        return z
    }
}
// A million iterations has not converged; something is wrong.
panic(fmt.Sprintf("CubeRoot(%g) did not converge", x))
}

```

This is only an example but real library functions should avoid panic. If the problem can be masked or worked around, it's always better to let things continue to run rather than taking down the whole program. One possible counterexample is during initialization: if the library truly cannot set itself up, it might be reasonable to panic, so to speak.

```

var user = os.Getenv("USER")

func init() {
    if user == "" {
        panic("no value for $USER")
    }
}

```

Recover

When panic is called, including implicitly for run-time errors such as indexing an array out of bounds or failing a type assertion, it immediately stops execution of the current function and begins unwinding the stack of the goroutine, running any deferred functions along the way. If that unwinding reaches the top of the goroutine's stack, the program dies. However, it is possible to use the built-in function recover to regain control of the goroutine and resume normal execution.

A call to recover stops the unwinding and returns the argument passed to panic. Because the only code that runs while unwinding is inside deferred functions, recover is only useful inside deferred functions.

One application of recover is to shut down a failing goroutine inside a server without killing the other executing goroutines.

```

func server(workChan <-chan *Work) {
    for work := range workChan {
        go safelyDo(work)
    }
}

```

```

func safelyDo(work *Work) {
    defer func() {
        if err := recover(); err != nil {
            log.Println("work failed:", err)
        }
    }()
    do(work)
}

```

In this example, if `do(work)` panics, the result will be logged and the goroutine will exit cleanly without disturbing the others. There's no need to do anything else in the deferred closure; calling `recover` handles the condition completely.

Because `recover` always returns `nil` unless called directly from a deferred function, deferred code can call library routines that themselves use `panic` and `recover` without failing. As an example, the deferred function in `safelyDo` might call a logging function before calling `recover`, and that logging code would run unaffected by the panicking state.

With our recovery pattern in place, the `do` function (and anything it calls) can get out of any bad situation cleanly by calling `panic`. We can use that idea to simplify error handling in complex software. Let's look at an idealized excerpt from the `regexp` package, which reports parsing errors by calling `panic` with a local error type. Here's the definition of `Error`, an error method, and the `Compile` function.

```

// Error is the type of a parse error; it satisfies the error interf
type Error string
func (e Error) Error() string {
    return string(e)
}

// error is a method of *Regexp that reports parsing errors by
// panicking with an Error.
func (regexp *Regexp) error(err string) {
    panic(Error(err))
}

// Compile returns a parsed representation of the regular expression
func Compile(str string) (regexp *Regexp, err error) {
    regexp = new(Regexp)
    // doParse will panic if there is a parse error.
    defer func() {
        if e := recover(); e != nil {

```

```

        regexp = nil    // Clear return value.
        err = e.(Error) // Will re-panic if not a parse error.
    }
}()
return regexp.doParse(str), nil
}

```

If `doParse` panics, the recovery block will set the return value to `nil`—deferred functions can modify named return values. It then will then check, in the assignment to `err`, that the problem was a parse error by asserting that it has the local type `Error`. If it does not, the type assertion will fail, causing a run-time error that continues the stack unwinding as though nothing had interrupted it. This check means that if something unexpected happens, such as an array index out of bounds, the code will fail even though we are using `panic` and `recover` to handle user-triggered errors.

With error handling in place, the error method makes it easy to report parse errors without worrying about unwinding the parse stack by hand.

Useful though this pattern is, it should be used only within a package. `Parse` turns its internal panic calls into error values; it does not expose panics to its client. That is a good rule to follow.

By the way, this re-panic idiom changes the panic value if an actual error occurs. However, both the original and new failures will be presented in the crash report, so the root cause of the problem will still be visible. Thus this simple re-panic approach is usually sufficient—it's a crash after all—but if you want to display only the original value, you can write a little more code to filter unexpected problems and re-panic with the original error. That's left as an exercise for the reader.

A web server

Let's finish with a complete Go program, a web server. This one is actually a kind of web re-server. Google provides a service at <http://chart.apis.google.com> that does automatic formatting of data into charts and graphs. It's hard to use interactively, though, because you need to put the data into the URL as a query. The program here provides a nicer interface to one form of data: given a short piece of text, it calls on the chart server to produce a QR code, a matrix of boxes that encode the text. That image can be grabbed with your cell phone's camera and interpreted as, for instance, a URL, saving you typing the URL into the phone's tiny keyboard.

Here's the complete program. An explanation follows.

```
package main

import (
    "flag"
    "log"
    "net/http"
    "text/template"
)

var addr = flag.String("addr", ":1718", "http service address") // Q
var templ = template.Must(template.New("qr").Parse(templateStr))

func main() {
    flag.Parse()
    http.Handle("/", http.HandlerFunc(QR))
    err := http.ListenAndServe(*addr, nil)
    if err != nil {
        log.Fatal("ListenAndServe:", err)
    }
}

func QR(w http.ResponseWriter, req *http.Request) {
    templ.Execute(w, req.FormValue("s"))
}

const templateStr = `
<html>
<head>
<title>QR Link Generator</title>
```

```

</head>
<body>
{{if .}}
<input maxLength=1024 size=70
name=s value="" title="Text to QR Encode"><input type=submit
value="Show QR" name=qr>
</form>
</body>
</html>
`

```

The pieces up to main should be easy to follow. The one flag sets a default HTTP port for our server. The template variable `templ` is where the fun happens. It builds an HTML template that will be executed by the server to display the page; more about that in a moment.

The main function parses the flags and, using the mechanism we talked about above, binds the function `QR` to the root path for the server. Then `http.ListenAndServe` is called to start the server; it blocks while the server runs.

`QR` just receives the request, which contains form data, and executes the template on the data in the form value named `s`.

The template package is powerful; this program just touches on its capabilities. In essence, it rewrites a piece of text on the fly by substituting elements derived from data items passed to `templ.Execute`, in this case the form value. Within the template text (`templateStr`), double-brace-delimited pieces denote template actions. The piece from `{{if .}}` to `{{end}}` executes only if the value of the current data item, called `.` (dot), is non-empty. That is, when the string is empty, this piece of the template is suppressed.

The snippet `{{urlquery .}}` says to process the data with the function `urlquery`, which sanitizes the query string for safe display on the web page.

The rest of the template string is just the HTML to show when the page loads. If this is too quick an explanation, see the [documentation](#) for the template package

for a more thorough discussion.

And there you have it: a useful web server in a few lines of code plus some data-driven HTML text. Go is powerful enough to make a lot happen in a few lines.

Build version go1.0.1.

Command go

Go is a tool for managing Go source code.

Usage:

```
go command [arguments]
```

The commands are:

build	compile packages and dependencies
clean	remove object files
doc	run godoc on package sources
env	print Go environment information
fix	run go tool fix on packages
fmt	run gofmt on package sources
get	download and install packages and dependencies
install	compile and install packages and dependencies
list	list packages
run	compile and run Go program
test	test packages
tool	run specified go tool
version	print Go version
vet	run go tool vet on packages

Use "go help [command]" for more information about a command.

Additional help topics:

gopath	GOPATH environment variable
packages	description of package lists
remote	remote import path syntax
testflag	description of testing flags
testfunc	description of testing functions

Use "go help [topic]" for more information about that topic.

Compile packages and dependencies

Usage:

```
go build [-o output] [build flags] [packages]
```

Build compiles the packages named by the import paths, along with their dependencies, but it does not install the results.

If the arguments are a list of .go files, build treats them as a list of source files specifying a single package.

When the command line specifies a single main package, build writes the resulting executable to output. Otherwise build compiles the packages but discards the results, serving only as a check that the packages can be built.

The -o flag specifies the output file name. If not specified, the name is packagename.a (for a non-main package) or the base name of the first source file (for a main package).

The build flags are shared by the build, install, run, and test commands:

```
-a          force rebuilding of packages that are already up-to-date.
-n          print the commands but do not run them.
-p n       the number of builds that can be run in parallel.
           The default is the number of CPUs available.
-v          print the names of packages as they are compiled.
-work      print the name of the temporary work directory and
           do not delete it when exiting.
-x          print the commands.

-compiler name
           name of compiler to use, as in runtime.Compiler (gccgo or gc
-gccgoflags 'arg list'
           arguments to pass on each gccgo compiler/linker invocation
-gcflags 'arg list'
           arguments to pass on each 5g, 6g, or 8g compiler invocation
-ldflags 'flag list'
           arguments to pass on each 5l, 6l, or 8l linker invocation
-tags 'tag list'
           a list of build tags to consider satisfied during the build.
           See the documentation for the go/build package for
           more information about build tags.
```

For more about specifying packages, see 'go help packages'. For more about

where packages and binaries are installed, see 'go help gopath'.

See also: go install, go get, go clean.

Remove object files

Usage:

```
go clean [-i] [-r] [-n] [-x] [packages]
```

Clean removes object files from package source directories. The go command builds most objects in a temporary directory, so go clean is mainly concerned with object files left by other tools or by manual invocations of go build.

Specifically, clean removes the following files from each of the source directories corresponding to the import paths:

<code>_obj/</code>	old object directory, left from Makefiles
<code>_test/</code>	old test directory, left from Makefiles
<code>_testmain.go</code>	old gotest file, left from Makefiles
<code>test.out</code>	old test log, left from Makefiles
<code>build.out</code>	old test log, left from Makefiles
<code>*.[568ao]</code>	object files, left from Makefiles
<code>DIR(.exe)</code>	from go build
<code>DIR.test(.exe)</code>	from go test -c
<code>MAINFILE(.exe)</code>	from go build MAINFILE.go

In the list, DIR represents the final path element of the directory, and MAINFILE is the base name of any Go source file in the directory that is not included when building the package.

The -i flag causes clean to remove the corresponding installed archive or binary (what 'go install' would create).

The -n flag causes clean to print the remove commands it would execute, but not run them.

The -r flag causes clean to be applied recursively to all the dependencies of the packages named by the import paths.

The -x flag causes clean to print remove commands as it executes them.

For more about specifying packages, see 'go help packages'.

Run godoc on package sources

Usage:

```
go doc [packages]
```

Doc runs the godoc command on the packages named by the import paths.

For more about godoc, see 'godoc godoc'. For more about specifying packages, see 'go help packages'.

To run godoc with specific options, run godoc itself.

See also: go fix, go fmt, go vet.

Print Go environment information

Usage:

```
go env [var ...]
```

Env prints Go environment information.

By default env prints information as a shell script (on Windows, a batch file). If one or more variable names is given as arguments, env prints the value of each named variable on its own line.

Run go tool fix on packages

Usage:

```
go fix [packages]
```

Fix runs the Go fix command on the packages named by the import paths.

For more about fix, see 'godoc fix'. For more about specifying packages, see 'go help packages'.

To run fix with specific options, run 'go tool fix'.

See also: go fmt, go vet.

Run gofmt on package sources

Usage:

```
go fmt [packages]
```

Fmt runs the command 'gofmt -l -w' on the packages named by the import paths. It prints the names of the files that are modified.

For more about gofmt, see 'godoc gofmt'. For more about specifying packages, see 'go help packages'.

To run gofmt with specific options, run gofmt itself.

See also: go doc, go fix, go vet.

Download and install packages and dependencies

Usage:

```
go get [-a] [-d] [-fix] [-n] [-p n] [-u] [-v] [-x] [packages]
```

Get downloads and installs the packages named by the import paths, along with their dependencies.

The -a, -n, -v, -x, and -p flags have the same meaning as in 'go build' and 'go install'. See 'go help build'.

The -d flag instructs get to stop after downloading the packages; that is, it instructs get not to install the packages.

The -fix flag instructs get to run the fix tool on the downloaded packages before resolving dependencies or building the code.

The -u flag instructs get to use the network to update the named packages and their dependencies. By default, get uses the network to check out missing

packages but does not use it to look for updates to existing packages.

When checking out or updating a package, `get` looks for a branch or tag that matches the locally installed version of Go. The most important rule is that if the local installation is running version "go1", `get` searches for a branch or tag named "go1". If no such version exists it retrieves the most recent version of the package.

For more about specifying packages, see '`go help packages`'.

For more about how '`go get`' finds source code to download, see '`go help remote`'.

See also: `go build`, `go install`, `go clean`.

Compile and install packages and dependencies

Usage:

```
go install [build flags] [packages]
```

`Install` compiles and installs the packages named by the import paths, along with their dependencies.

For more about the build flags, see '`go help build`'. For more about specifying packages, see '`go help packages`'.

See also: `go build`, `go get`, `go clean`.

List packages

Usage:

```
go list [-e] [-f format] [-json] [packages]
```

`List` lists the packages named by the import paths, one per line.

The default output shows the package import path:

```
code.google.com/p/google-api-go-client/books/v1
code.google.com/p/goauth2/oauth
code.google.com/p/sqlite
```

The `-f` flag specifies an alternate format for the list, using the syntax of package template. The default output is equivalent to `-f '{{.ImportPath}}'`. The struct being passed to the template is:

```
type Package struct {
    Dir          string // directory containing package sources
    ImportPath   string // import path of package in dir
    Name         string // package name
    Doc          string // package documentation string
    Target       string // install path
    Goroot       bool    // is this package in the Go root?
    Standard     bool    // is this package part of the standard Go lib
    Stale        bool    // would 'go install' do anything for this pac
    Root         string // Go root or Go path dir containing this pack

    // Source files
    GoFiles      []string // .go source files (excluding CgoFiles, Test
    CgoFiles     []string // .go sources files that import "C"
    CFiles       []string // .c source files
    HFiles       []string // .h source files
    SFiles       []string // .s source files
    SysoFiles    []string // .syso object files to add to archive

    // Cgo directives
    CgoCFLAGS    []string // cgo: flags for C compiler
    CgoLDFLAGS   []string // cgo: flags for linker
    CgoPkgConfig []string // cgo: pkg-config names

    // Dependency information
    Imports      []string // import paths used by this package
    Deps         []string // all (recursively) imported dependencies

    // Error information
    Incomplete bool           // this package or a dependency has a
    Error       *PackageError // error loading package
    DepsErrors  []*PackageError // errors loading dependencies

    TestGoFiles  []string // _test.go files in package
    TestImports  []string // imports from TestGoFiles
    XTestGoFiles []string // _test.go files outside package
    XTestImports []string // imports from XTestGoFiles
}
```

The `-json` flag causes the package data to be printed in JSON format instead of using the template format.

The `-e` flag changes the handling of erroneous packages, those that cannot be

found or are malformed. By default, the list command prints an error to standard error for each erroneous package and omits the packages from consideration during the usual printing. With the `-e` flag, the list command never prints errors to standard error and instead processes the erroneous packages with the usual printing. Erroneous packages will have a non-empty `ImportPath` and a non-nil `Error` field; other information may or may not be missing (zeroed).

For more about specifying packages, see 'go help packages'.

Compile and run Go program

Usage:

```
go run [build flags] gofiles... [arguments...]
```

Run compiles and runs the main package comprising the named Go source files.

For more about build flags, see 'go help build'.

See also: go build.

Test packages

Usage:

```
go test [-c] [-i] [build flags] [packages] [flags for test binary]
```

'Go test' automates testing the packages named by the import paths. It prints a summary of the test results in the format:

```
ok    archive/tar    0.011s
FAIL  archive/zip    0.022s
ok    compress/gzip  0.033s
...
```

followed by detailed output for each failed package.

'Go test' recompiles each package along with any files with names matching the file pattern `"*_test.go"`. These additional files can contain test functions, benchmark functions, and example functions. See 'go help testfunc' for more.

By default, `go test` needs no arguments. It compiles and tests the package with source in the current directory, including tests, and runs the tests.

The package is built in a temporary directory so it does not interfere with the non-test installation.

In addition to the build flags, the flags handled by `'go test'` itself are:

`-c` Compile the test binary to `pkg.test` but do not run it.

`-i` Install packages that are dependencies of the test.
Do not run the test.

The test binary also accepts flags that control execution of the test; these flags are also accessible by `'go test'`. See `'go help testflag'` for details.

For more about build flags, see `'go help build'`. For more about specifying packages, see `'go help packages'`.

See also: `go build`, `go vet`.

Run specified go tool

Usage:

```
go tool [-n] command [args...]
```

Tool runs the `go tool` command identified by the arguments. With no arguments it prints the list of known tools.

The `-n` flag causes `tool` to print the command that would be executed but not execute it.

For more about each tool command, see `'go tool command -h'`.

Print Go version

Usage:

```
go version
```

Version prints the Go version, as reported by runtime.Version.

Run go tool vet on packages

Usage:

```
go vet [packages]
```

Vet runs the Go vet command on the packages named by the import paths.

For more about vet, see 'godoc vet'. For more about specifying packages, see 'go help packages'.

To run the vet tool with specific options, run 'go tool vet'.

See also: go fmt, go fix.

GOPATH environment variable

The Go path is used to resolve import statements. It is implemented by and documented in the go/build package.

The GOPATH environment variable lists places to look for Go code. On Unix, the value is a colon-separated string. On Windows, the value is a semicolon-separated string. On Plan 9, the value is a list.

GOPATH must be set to build and install packages outside the standard Go tree.

Each directory listed in GOPATH must have a prescribed structure:

The src/ directory holds source code. The path below 'src' determines the import path or executable name.

The pkg/ directory holds installed package objects. As in the Go tree, each target operating system and architecture pair has its own subdirectory of pkg (pkg/GOOS_GOARCH).

If DIR is a directory listed in the GOPATH, a package with source in DIR/src/foo/bar can be imported as "foo/bar" and has its compiled form installed to "DIR/pkg/GOOS_GOARCH/foo/bar.a".

The bin/ directory holds compiled commands. Each command is named for its source directory, but only the final element, not the entire path. That is, the command with source in DIR/src/foo/quux is installed into DIR/bin/quux, not DIR/bin/foo/quux. The foo/ is stripped so that you can add DIR/bin to your PATH to get at the installed commands. If the GOBIN environment variable is set, commands are installed to the directory it names instead of DIR/bin.

Here's an example directory layout:

```
GOPATH=/home/user/gocode
```

```
/home/user/gocode/  
  src/  
    foo/  
      bar/                (go code in package bar)  
        x.go  
      quux/              (go code in package main)  
        y.go  
  bin/  
    quux                 (installed command)  
  pkg/  
    linux_amd64/  
      foo/  
        bar.a            (installed package object)
```

Go searches each directory listed in GOPATH to find source code, but new packages are always downloaded into the first directory in the list.

Description of package lists

Many commands apply to a set of packages:

```
go action [packages]
```

Usually, [packages] is a list of import paths.

An import path that is a rooted path or that begins with a . or .. element is interpreted as a file system path and denotes the package in that directory.

Otherwise, the import path P denotes the package found in the directory DIR/src/P for some DIR listed in the GOPATH environment variable (see 'go help gopath').

If no import paths are given, the action applies to the package in the current directory.

The special import path "all" expands to all package directories found in all the GOPATH trees. For example, 'go list all' lists all the packages on the local system.

The special import path "std" is like all but expands to just the packages in the standard Go library.

An import path is a pattern if it includes one or more "..." wildcards, each of which can match any string, including the empty string and strings containing slashes. Such a pattern expands to all package directories found in the GOPATH trees with names matching the patterns. As a special case, x/... matches x as well as x's subdirectories. For example, net/... expands to net and packages in its subdirectories.

An import path can also name a package to be downloaded from a remote repository. Run 'go help remote' for details.

Every package in a program must have a unique import path. By convention, this is arranged by starting each path with a unique prefix that belongs to you. For example, paths used internally at Google all begin with 'google', and paths denoting remote repositories begin with the path to the code, such as 'code.google.com/p/project'.

As a special case, if the package list is a list of .go files from a single directory, the command is applied to a single synthesized package made up of exactly those files, ignoring any build constraints in those files and ignoring any other files in the directory.

Remote import path syntax

An import path (see 'go help importpath') denotes a package stored in the local file system. Certain import paths also describe how to obtain the source code for the package using a revision control system.

A few common code hosting sites have special syntax:

BitBucket (Mercurial)

```
import "bitbucket.org/user/project"  
import "bitbucket.org/user/project/sub/directory"
```

GitHub (Git)

```
import "github.com/user/project"  
import "github.com/user/project/sub/directory"
```

Google Code Project Hosting (Git, Mercurial, Subversion)

```
import "code.google.com/p/project"  
import "code.google.com/p/project/sub/directory"  
  
import "code.google.com/p/project.subrepository"  
import "code.google.com/p/project.subrepository/sub/director"
```

Launchpad (Bazaar)

```
import "launchpad.net/project"  
import "launchpad.net/project/series"  
import "launchpad.net/project/series/sub/directory"  
  
import "launchpad.net/~user/project/branch"  
import "launchpad.net/~user/project/branch/sub/directory"
```

For code hosted on other servers, import paths may either be qualified with the version control type, or the go tool can dynamically fetch the import path over https/http and discover where the code resides from a <meta> tag in the HTML.

To declare the code location, an import path of the form

```
repository.vcs/path
```

specifies the given repository, with or without the .vcs suffix, using the named version control system, and then the path inside that repository. The supported version control systems are:

Bazaar	.bzd
Git	.git
Mercurial	.hg
Subversion	.svn

For example,

```
import "example.org/user/foo.hg"
```

denotes the root directory of the Mercurial repository at example.org/user/foo or foo.hg, and

```
import "example.org/repo.git/foo/bar"
```

denotes the foo/bar directory of the Git repository at example.com/repo or repo.git.

When a version control system supports multiple protocols, each is tried in turn when downloading. For example, a Git download tries git://, then https://, then http://.

If the import path is not a known code hosting site and also lacks a version control qualifier, the go tool attempts to fetch the import over https/http and looks for a <meta> tag in the document's HTML <head>.

The meta tag has the form:

```
<meta name="go-import" content="import-prefix vcs repo-root">
```

The import-prefix is the import path corresponding to the repository root. It must be a prefix or an exact match of the package being fetched with "go get". If it's not an exact match, another http request is made at the prefix to verify the <meta> tags match.

The vcs is one of "git", "hg", "svn", etc,

The repo-root is the root of the version control system containing a scheme and not containing a .vcs qualifier.

For example,

```
import "example.org/pkg/foo"
```

will result in the following request(s):

<https://example.org/pkg/foo?go-get=1> (preferred)
<http://example.org/pkg/foo?go-get=1> (fallback)

If that page contains the meta tag

```
<meta name="go-import" content="example.org git https://code.org/r/p
```

the go tool will verify that <https://example.org/?go-get=1> contains the same meta tag and then git clone <https://code.org/r/p/exproj> into GOPATH/src/example.org.

New downloaded packages are written to the first directory listed in the GOPATH environment variable (see 'go help gopath').

The go command attempts to download the version of the package appropriate for the Go release being used. Run 'go help install' for more.

Description of testing flags

The 'go test' command takes both flags that apply to 'go test' itself and flags that apply to the resulting test binary.

The test binary, called pkg.test, where pkg is the name of the directory containing the package sources, has its own flags:

- test.v
Verbose output: log all tests as they are run.
- test.run pattern
Run only those tests and examples matching the regular expression.
- test.bench pattern
Run benchmarks matching the regular expression.
By default, no benchmarks run.
- test.cpuprofile cpu.out
Write a CPU profile to the specified file before exiting.
- test.memprofile mem.out
Write a memory profile to the specified file when all tests are complete.
- test.memprofilerate n
Enable more precise (and expensive) memory profiles by setting runtime.MemProfileRate. See 'godoc runtime MemProfileRate'.
To profile all memory allocations, use -test.memprofilerate=1 and set the environment variable GOGC=off to disable the garbage collector, provided the test can run in the available memory without garbage collection.
- test.parallel n
Allow parallel execution of test functions that call t.Parallel.

The value of this flag is the maximum number of tests to run simultaneously; by default, it is set to the value of GOMAXPROCS

`-test.short`

Tell long-running tests to shorten their run time. It is off by default but set during `all.bash` so that installing the Go tree can run a sanity check but not spend time running exhaustive tests.

`-test.timeout t`

If a test runs longer than `t`, panic.

`-test.benchmark n`

Run enough iterations of each benchmark to take `n` seconds. The default is 1 second.

`-test.cpu 1,2,4`

Specify a list of GOMAXPROCS values for which the tests or benchmarks should be executed. The default is the current value of GOMAXPROCS.

For convenience, each of these `-test.X` flags of the test binary is also available as the flag `-X` in 'go test' itself. Flags not listed here are passed through unaltered. For instance, the command

```
go test -x -v -cpuprofile=prof.out -dir=testdata -update
```

will compile the test binary and then run it as

```
pkg.test -test.v -test.cpuprofile=prof.out -dir=testdata -update
```

Description of testing functions

The 'go test' command expects to find test, benchmark, and example functions in the `"*_test.go"` files corresponding to the package under test.

A test function is one named `TestXXX` (where `XXX` is any alphanumeric string not starting with a lower case letter) and should have the signature,

```
func TestXXX(t *testing.T) { ... }
```

A benchmark function is one named `BenchmarkXXX` and should have the signature,

```
func BenchmarkXXX(b *testing.B) { ... }
```

An example function is similar to a test function but, instead of using `*testing.T` to report success or failure, prints output to `os.Stdout` and `os.Stderr`. That output is compared against the function's "Output:" comment, which must be the last comment in the function body (see example below). An example with no such comment, or with no text after "Output:" is compiled but not executed.

Godoc displays the body of `ExampleXXX` to demonstrate the use of the function, constant, or variable `XXX`. An example of a method `M` with receiver type `T` or `*T` is named `ExampleT_M`. There may be multiple examples for a given function, constant, or variable, distinguished by a trailing `_xxx`, where `xxx` is a suffix not beginning with an upper case letter.

Here is an example of an example:

```
func ExamplePrintln() {
    Println("The output of\nthis example.")
    // Output: The output of
    // this example.
}
```

The entire test file is presented as the example when it contains a single example function, at least one other function, type, variable, or constant declaration, and no test or benchmark functions.

See the documentation of the testing package for more information.

FAQ

Origins

What is the purpose of the project?

No major systems language has emerged in over a decade, but over that time the computing landscape has changed tremendously. There are several trends:

- Computers are enormously quicker but software development is not faster.
- Dependency management is a big part of software development today but the “header files” of languages in the C tradition are antithetical to clean dependency analysis—and fast compilation.
- There is a growing rebellion against cumbersome type systems like those of Java and C++, pushing people towards dynamically typed languages such as Python and JavaScript.
- Some fundamental concepts such as garbage collection and parallel computation are not well supported by popular systems languages.
- The emergence of multicore computers has generated worry and confusion.

We believe it's worth trying again with a new language, a concurrent, garbage-collected language with fast compilation. Regarding the points above:

- It is possible to compile a large Go program in a few seconds on a single computer.
- Go provides a model for software construction that makes dependency analysis easy and avoids much of the overhead of C-style include files and libraries.
- Go's type system has no hierarchy, so no time is spent defining the relationships between types. Also, although Go has static types the language attempts to make types feel lighter weight than in typical OO languages.
- Go is fully garbage-collected and provides fundamental support for concurrent execution and communication.
- By its design, Go proposes an approach for the construction of system software on multicore machines.

What is the origin of the name?

“Ogle” would be a good name for a Go debugger.

What's the origin of the mascot?

The mascot and logo were designed by [Renée French](#), who also designed [Glenda](#), the Plan 9 bunny. The gopher is derived from one she used for an [WFMU](#) T-shirt design some years ago. The logo and mascot are covered by the [Creative Commons Attribution 3.0](#) license.

What is the history of the project?

Robert Griesemer, Rob Pike and Ken Thompson started sketching the goals for a new language on the white board on September 21, 2007. Within a few days the goals had settled into a plan to do something and a fair idea of what it would be. Design continued part-time in parallel with unrelated work. By January 2008, Ken had started work on a compiler with which to explore ideas; it generated C code as its output. By mid-year the language had become a full-time project and had settled enough to attempt a production compiler. In May 2008, Ian Taylor independently started on a GCC front end for Go using the draft specification. Russ Cox joined in late 2008 and helped move the language and libraries from prototype to reality.

Go became a public open source project on November 10, 2009. Many people from the community have contributed ideas, discussions, and code.

Why are you creating a new language?

Go was born out of frustration with existing languages and environments for systems programming. Programming had become too difficult and the choice of languages was partly to blame. One had to choose either efficient compilation, efficient execution, or ease of programming; all three were not available in the same mainstream language. Programmers who could were choosing ease over safety and efficiency by moving to dynamically typed languages such as Python and JavaScript rather than C++ or, to a lesser extent, Java.

Go is an attempt to combine the ease of programming of an interpreted, dynamically typed language with the efficiency and safety of a statically typed, compiled language. It also aims to be modern, with support for networked and multicore computing. Finally, it is intended to be *fast*: it should take at most a

few seconds to build a large executable on a single computer. To meet these goals required addressing a number of linguistic issues: an expressive but lightweight type system; concurrency and garbage collection; rigid dependency specification; and so on. These cannot be addressed well by libraries or tools; a new language was called for.

What are Go's ancestors?

Go is mostly in the C family (basic syntax), with significant input from the Pascal/Modula/Oberon family (declarations, packages), plus some ideas from languages inspired by Tony Hoare's CSP, such as Newsqueak and Limbo (concurrency). However, it is a new language across the board. In every respect the language was designed by thinking about what programmers do and how to make programming, at least the kind of programming we do, more effective, which means more fun.

What are the guiding principles in the design?

Programming today involves too much bookkeeping, repetition, and clerical work. As Dick Gabriel says, “Old programs read like quiet conversations between a well-spoken research worker and a well-studied mechanical colleague, not as a debate with a compiler. Who'd have guessed sophistication bought such noise?” The sophistication is worthwhile—no one wants to go back to the old languages—but can it be more quietly achieved?

Go attempts to reduce the amount of typing in both senses of the word. Throughout its design, we have tried to reduce clutter and complexity. There are no forward declarations and no header files; everything is declared exactly once. Initialization is expressive, automatic, and easy to use. Syntax is clean and light on keywords. Stuttering (`foo.Foo* myFoo = new(foo.Foo)`) is reduced by simple type derivation using the `:=` declare-and-initialize construct. And perhaps most radically, there is no type hierarchy: types just *are*, they don't have to announce their relationships. These simplifications allow Go to be expressive yet comprehensible without sacrificing, well, sophistication.

Another important principle is to keep the concepts orthogonal. Methods can be implemented for any type; structures represent data while interfaces represent abstraction; and so on. Orthogonality makes it easier to understand what happens when things combine.

Usage

Is Google using Go internally?

Yes. There are now several Go programs deployed in production inside Google. A public example is the server behind <http://golang.org>. It's just the [godoc](#) document server running in a production configuration on [Google App Engine](#).

Do Go programs link with C/C++ programs?

There are two Go compiler implementations, gc (the 6g program and friends) and gccgo. Gc uses a different calling convention and linker and can therefore only be linked with C programs using the same convention. There is such a C compiler but no C++ compiler. gccgo is a GCC front-end that can, with care, be linked with GCC-compiled C or C++ programs.

The [cgo](#) program provides the mechanism for a “foreign function interface” to allow safe calling of C libraries from Go code. SWIG extends this capability to C++ libraries.

Does Go support Google's protocol buffers?

A separate open source project provides the necessary compiler plugin and library. It is available at <http://code.google.com/p/goprotobuf/>

Can I translate the Go home page into another language?

Absolutely. We encourage developers to make Go Language sites in their own languages. However, if you choose to add the Google logo or branding to your site (it does not appear on golang.org), you will need to abide by the guidelines at <http://www.google.com/permissions/guidelines.html>

Design

What's up with Unicode identifiers?

It was important to us to extend the space of identifiers from the confines of ASCII. Go's rule—identifier characters must be letters or digits as defined by Unicode—is simple to understand and to implement but has restrictions. Combining characters are excluded by design, for instance. Until there is an agreed external definition of what an identifier might be, plus a definition of canonicalization of identifiers that guarantees no ambiguity, it seemed better to keep combining characters out of the mix. Thus we have a simple rule that can be expanded later without breaking programs, one that avoids bugs that would surely arise from a rule that admits ambiguous identifiers.

On a related note, since an exported identifier must begin with an upper-case letter, identifiers created from “letters” in some languages can, by definition, not be exported. For now the only solution is to use something like `x0000Z`, which is clearly unsatisfactory; we are considering other options. The case-for-visibility rule is unlikely to change however; it's one of our favorite features of Go.

Why does Go not have feature X?

Every language contains novel features and omits someone's favorite feature. Go was designed with an eye on felicity of programming, speed of compilation, orthogonality of concepts, and the need to support features such as concurrency and garbage collection. Your favorite feature may be missing because it doesn't fit, because it affects compilation speed or clarity of design, or because it would make the fundamental system model too difficult.

If it bothers you that Go is missing feature *X*, please forgive us and investigate the features that Go does have. You might find that they compensate in interesting ways for the lack of *X*.

Why does Go not have generic types?

Generics may well be added at some point. We don't feel an urgency for them, although we understand some programmers do.

Generics are convenient but they come at a cost in complexity in the type system and run-time. We haven't yet found a design that gives value proportionate to the complexity, although we continue to think about it. Meanwhile, Go's built-in maps and slices, plus the ability to use the empty interface to construct containers (with explicit unboxing) mean in many cases it is possible to write code that does what generics would enable, if less smoothly.

This remains an open issue.

Why does Go not have exceptions?

We believe that coupling exceptions to a control structure, as in the try-catch-finally idiom, results in convoluted code. It also tends to encourage programmers to label too many ordinary errors, such as failing to open a file, as exceptional.

Go takes a different approach. For plain error handling, Go's multi-value returns make it easy to report an error without overloading the return value. [A canonical error type, coupled with Go's other features](#), makes error handling pleasant but quite different from that in other languages.

Go also has a couple of built-in functions to signal and recover from truly exceptional conditions. The recovery mechanism is executed only as part of a function's state being torn down after an error, which is sufficient to handle catastrophe but requires no extra control structures and, when used well, can result in clean error-handling code.

See the [Defer, Panic, and Recover](#) article for details.

Why does Go not have assertions?

Go doesn't provide assertions. They are undeniably convenient, but our experience has been that programmers use them as a crutch to avoid thinking about proper error handling and reporting. Proper error handling means that servers continue operation after non-fatal errors instead of crashing. Proper error reporting means that errors are direct and to the point, saving the programmer from interpreting a large crash trace. Precise errors are particularly important when the programmer seeing the errors is not familiar with the code.

We understand that this is a point of contention. There are many things in the Go language and libraries that differ from modern practices, simply because we feel it's sometimes worth trying a different approach.

Why build concurrency on the ideas of CSP?

Concurrency and multi-threaded programming have a reputation for difficulty. We believe this is due partly to complex designs such as pthreads and partly to overemphasis on low-level details such as mutexes, condition variables, and memory barriers. Higher-level interfaces enable much simpler code, even if there are still mutexes and such under the covers.

One of the most successful models for providing high-level linguistic support for concurrency comes from Hoare's Communicating Sequential Processes, or CSP. Occam and Erlang are two well known languages that stem from CSP. Go's concurrency primitives derive from a different part of the family tree whose main contribution is the powerful notion of channels as first class objects.

Why goroutines instead of threads?

Goroutines are part of making concurrency easy to use. The idea, which has been around for a while, is to multiplex independently executing functions—coroutines—onto a set of threads. When a coroutine blocks, such as by calling a blocking system call, the run-time automatically moves other coroutines on the same operating system thread to a different, runnable thread so they won't be blocked. The programmer sees none of this, which is the point. The result, which we call goroutines, can be very cheap: unless they spend a lot of time in long-running system calls, they cost little more than the memory for the stack, which is just a few kilobytes.

To make the stacks small, Go's run-time uses segmented stacks. A newly minted goroutine is given a few kilobytes, which is almost always enough. When it isn't, the run-time allocates (and frees) extension segments automatically. The overhead averages about three cheap instructions per function call. It is practical to create hundreds of thousands of goroutines in the same address space. If goroutines were just threads, system resources would run out at a much smaller number.

Why are map operations not defined to be atomic?

After long discussion it was decided that the typical use of maps did not require safe access from multiple threads, and in those cases where it did, the map was probably part of some larger data structure or computation that was already synchronized. Therefore requiring that all map operations grab a mutex would slow down most programs and add safety to few. This was not an easy decision, however, since it means uncontrolled map access can crash the program.

The language does not preclude atomic map updates. When required, such as when hosting an untrusted program, the implementation could interlock map access.

Types

Is Go an object-oriented language?

Yes and no. Although Go has types and methods and allows an object-oriented style of programming, there is no type hierarchy. The concept of “interface” in Go provides a different approach that we believe is easy to use and in some ways more general. There are also ways to embed types in other types to provide something analogous—but not identical—to subclassing. Moreover, methods in Go are more general than in C++ or Java: they can be defined for any sort of data, even built-in types such as plain, “unboxed” integers. They are not restricted to structs (classes).

Also, the lack of type hierarchy makes “objects” in Go feel much more lightweight than in languages such as C++ or Java.

How do I get dynamic dispatch of methods?

The only way to have dynamically dispatched methods is through an interface. Methods on a struct or any other concrete type are always resolved statically.

Why is there no type inheritance?

Object-oriented programming, at least in the best-known languages, involves too much discussion of the relationships between types, relationships that often could be derived automatically. Go takes a different approach.

Rather than requiring the programmer to declare ahead of time that two types are related, in Go a type automatically satisfies any interface that specifies a subset of its methods. Besides reducing the bookkeeping, this approach has real advantages. Types can satisfy many interfaces at once, without the complexities of traditional multiple inheritance. Interfaces can be very lightweight—an interface with one or even zero methods can express a useful concept. Interfaces can be added after the fact if a new idea comes along or for testing—without annotating the original types. Because there are no explicit relationships between types and interfaces, there is no type hierarchy to manage or discuss.

It's possible to use these ideas to construct something analogous to type-safe Unix pipes. For instance, see how `fmt.Fprintf` enables formatted printing to any output, not just a file, or how the `bufio` package can be completely separate from file I/O, or how the `image` packages generate compressed image files. All these ideas stem from a single interface (`io.Writer`) representing a single method (`write`). And that's only scratching the surface. Go's interfaces have a profound influence on how programs are structured.

It takes some getting used to but this implicit style of type dependency is one of the most productive things about Go.

Why is `len` a function and not a method?

We debated this issue but decided implementing `len` and friends as functions was fine in practice and didn't complicate questions about the interface (in the Go type sense) of basic types.

Why does Go not support overloading of methods and operators?

Method dispatch is simplified if it doesn't need to do type matching as well. Experience with other languages told us that having a variety of methods with the same name but different signatures was occasionally useful but that it could also be confusing and fragile in practice. Matching only by name and requiring consistency in the types was a major simplifying decision in Go's type system.

Regarding operator overloading, it seems more a convenience than an absolute requirement. Again, things are simpler without it.

Why doesn't Go have "implements" declarations?

A Go type satisfies an interface by implementing the methods of that interface, nothing more. This property allows interfaces to be defined and used without having to modify existing code. It enables a kind of "duck typing" that promotes separation of concerns and improves code re-use, and makes it easier to build on patterns that emerge as the code develops. The semantics of interfaces is one of the main reasons for Go's nimble, lightweight feel.

See the [question on type inheritance](#) for more detail.

How can I guarantee my type satisfies an interface?

You can ask the compiler to check that the type `T` implements the interface `I` by attempting an assignment:

```
type T struct{}
var _ I = T{} // Verify that T implements I.
```

If `T` doesn't implement `I`, the mistake will be caught at compile time.

If you wish the users of an interface to explicitly declare that they implement it, you can add a method with a descriptive name to the interface's method set. For example:

```
type Fooer interface {
    Foo()
    ImplementsFooer()
}
```

A type must then implement the `ImplementsFooer` method to be a `Fooer`, clearly documenting the fact and announcing it in [godoc](#)'s output.

```
type Bar struct{}
func (b Bar) ImplementsFooer() {}
func (b Bar) Foo() {}
```

Most code doesn't make use of such constraints, since they limit the utility of the interface idea. Sometimes, though, they're necessary to resolve ambiguities among similar interfaces.

Why doesn't type `T` satisfy the `Equal` interface?

Consider this simple interface to represent an object that can compare itself with another value:

```
type Equaler interface {
    Equal(Equaler) bool
}
```

and this type, `T`:

```
type T int
func (t T) Equal(u T) bool { return t == u } // does not satisfy Equ
```

Unlike the analogous situation in some polymorphic type systems, τ does not implement `Equaler`. The argument type of `τ .Equal` is τ , not literally the required type `Equaler`.

In Go, the type system does not promote the argument of `Equal`; that is the programmer's responsibility, as illustrated by the type `T2`, which does implement `Equaler`:

```
type T2 int
func (t T2) Equal(u Equaler) bool { return t == u.(T2) } // satisfi
```

Even this isn't like other type systems, though, because in Go *any* type that satisfies `Equaler` could be passed as the argument to `T2.Equal`, and at run time we must check that the argument is of type `T2`. Some languages arrange to make that guarantee at compile time.

A related example goes the other way:

```
type Opener interface {
    Open(name) Reader
}

func (t T3) Open() *os.File
```

In Go, `T3` does not satisfy `Opener`, although it might in another language.

While it is true that Go's type system does less for the programmer in such cases, the lack of subtyping makes the rules about interface satisfaction very easy to state: are the function's names and signatures exactly those of the interface? Go's rule is also easy to implement efficiently. We feel these benefits offset the lack of automatic type promotion. Should Go one day adopt some form of generic typing, we expect there would be a way to express the idea of these examples and also have them be statically checked.

Can I convert a `[]T` to an `[]interface{}`?

Not directly, because they do not have the same representation in memory. It is necessary to copy the elements individually to the destination slice. This example converts a slice of `int` to a slice of `interface{}`:

```
t := []int{1, 2, 3, 4}
s := make([]interface{}, len(t))
```

```
for i, v := range t {
    s[i] = v
}
```

Why is my nil error value not equal to nil?

Under the covers, interfaces are implemented as two elements, a type and a value. The value, called the interface's dynamic value, is an arbitrary concrete value and the type is that of the value. For the `int` value 3, an interface value contains, schematically, `(int, 3)`.

An interface value is `nil` only if the inner value and type are both unset, `(nil, nil)`. In particular, a `nil` interface will always hold a `nil` type. If we store a pointer of type `*int` inside an interface value, the inner type will be `*int` regardless of the value of the pointer: `(*int, nil)`. Such an interface value will therefore be non-`nil` *even when the pointer inside is nil*.

This situation can be confusing, and often arises when a `nil` value is stored inside an interface value such as an error return:

```
func returnsError() error {
    var p *MyError = nil
    if bad() {
        p = ErrBad
    }
    return p // Will always return a non-nil error.
}
```

If all goes well, the function returns a `nil` `p`, so the return value is an error interface value holding `(*MyError, nil)`. This means that if the caller compares the returned error to `nil`, it will always look as if there was an error even if nothing bad happened. To return a proper `nil` error to the caller, the function must return an explicit `nil`:

```
func returnsError() error {
    if bad() {
        return ErrBad
    }
    return nil
}
```

It's a good idea for functions that return errors always to use the error type in their signature (as we did above) rather than a concrete type such as `*MyError`, to

help guarantee the error is created correctly. As an example, [os.Open](#) returns an error even though, if not nil, it's always of concrete type [*os.PathError](#).

Similar situations to those described here can arise whenever interfaces are used. Just keep in mind that if any concrete value has been stored in the interface, the interface will not be nil. For more information, see [The Laws of Reflection](#).

Why are there no untagged unions, as in C?

Untagged unions would violate Go's memory safety guarantees.

Why does Go not have variant types?

Variant types, also known as algebraic types, provide a way to specify that a value might take one of a set of other types, but only those types. A common example in systems programming would specify that an error is, say, a network error, a security error or an application error and allow the caller to discriminate the source of the problem by examining the type of the error. Another example is a syntax tree in which each node can be a different type: declaration, statement, assignment and so on.

We considered adding variant types to Go, but after discussion decided to leave them out because they overlap in confusing ways with interfaces. What would happen if the elements of a variant type were themselves interfaces?

Also, some of what variant types address is already covered by the language. The error example is easy to express using an interface value to hold the error and a type switch to discriminate cases. The syntax tree example is also doable, although not as elegantly.

Values

Why does Go not provide implicit numeric conversions?

The convenience of automatic conversion between numeric types in C is outweighed by the confusion it causes. When is an expression unsigned? How big is the value? Does it overflow? Is the result portable, independent of the machine on which it executes? It also complicates the compiler; “the usual arithmetic conversions” are not easy to implement and inconsistent across architectures. For reasons of portability, we decided to make things clear and straightforward at the cost of some explicit conversions in the code. The definition of constants in Go—arbitrary precision values free of signedness and size annotations—ameliorates matters considerably, though.

A related detail is that, unlike in C, `int` and `int64` are distinct types even if `int` is a 64-bit type. The `int` type is generic; if you care about how many bits an integer holds, Go encourages you to be explicit.

Why are maps built in?

The same reason strings are: they are such a powerful and important data structure that providing one excellent implementation with syntactic support makes programming more pleasant. We believe that Go's implementation of maps is strong enough that it will serve for the vast majority of uses. If a specific application can benefit from a custom implementation, it's possible to write one but it will not be as convenient syntactically; this seems a reasonable tradeoff.

Why don't maps allow slices as keys?

Map lookup requires an equality operator, which slices do not implement. They don't implement equality because equality is not well defined on such types; there are multiple considerations involving shallow vs. deep comparison, pointer vs. value comparison, how to deal with recursive types, and so on. We may revisit this issue—and implementing equality for slices will not invalidate any existing programs—but without a clear idea of what equality of slices should mean, it was simpler to leave it out for now.

In Go 1, unlike prior releases, equality is defined for structs and arrays, so such types can be used as map keys. Slices still do not have a definition of equality, though.

Why are maps, slices, and channels references while arrays are values?

There's a lot of history on that topic. Early on, maps and channels were syntactically pointers and it was impossible to declare or use a non-pointer instance. Also, we struggled with how arrays should work. Eventually we decided that the strict separation of pointers and values made the language harder to use. Introducing reference types, including slices to handle the reference form of arrays, resolved these issues. Reference types add some regrettable complexity to the language but they have a large effect on usability: Go became a more productive, comfortable language when they were introduced.

Writing Code

How are libraries documented?

There is a program, `godoc`, written in Go, that extracts package documentation from the source code. It can be used on the command line or on the web. An instance is running at <http://golang.org/pkg/>. In fact, `godoc` implements the full site at <http://golang.org/>.

Is there a Go programming style guide?

Eventually, there may be a small number of rules to guide things like naming, layout, and file organization. The document [Effective Go](#) contains some style advice. More directly, the program `gofmt` is a pretty-printer whose purpose is to enforce layout rules; it replaces the usual compendium of do's and don'ts that allows interpretation. All the Go code in the repository has been run through `gofmt`.

How do I submit patches to the Go libraries?

The library sources are in `go/src/pkg`. If you want to make a significant change, please discuss on the mailing list before embarking.

See the document [Contributing to the Go project](#) for more information about how to proceed.

Pointers and Allocation

When are function parameters passed by value?

As in all languages in the C family, everything in Go is passed by value. That is, a function always gets a copy of the thing being passed, as if there were an assignment statement assigning the value to the parameter. For instance, passing an `int` value to a function makes a copy of the `int`, and passing a pointer value makes a copy of the pointer, but not the data it points to. (See the next section for a discussion of how this affects method receivers.)

Map and slice values behave like pointers: they are descriptors that contain pointers to the underlying map or slice data. Copying a map or slice value doesn't copy the data it points to. Copying an interface value makes a copy of the thing stored in the interface value. If the interface value holds a struct, copying the interface value makes a copy of the struct. If the interface value holds a pointer, copying the interface value makes a copy of the pointer, but again not the data it points to.

Should I define methods on values or pointers?

```
func (s *MyStruct) pointerMethod() { } // method on pointer
func (s MyStruct) valueMethod()   { } // method on value
```

For programmers unaccustomed to pointers, the distinction between these two examples can be confusing, but the situation is actually very simple. When defining a method on a type, the receiver (`s` in the above examples) behaves exactly as if it were an argument to the method. Whether to define the receiver as a value or as a pointer is the same question, then, as whether a function argument should be a value or a pointer. There are several considerations.

First, and most important, does the method need to modify the receiver? If it does, the receiver *must* be a pointer. (Slices and maps are reference types, so their story is a little more subtle, but for instance to change the length of a slice in a method the receiver must still be a pointer.) In the examples above, if `pointerMethod` modifies the fields of `s`, the caller will see those changes, but `valueMethod` is called with a copy of the caller's argument (that's the definition of passing a value), so changes it makes will be invisible to the caller.

By the way, pointer receivers are identical to the situation in Java, although in Java the pointers are hidden under the covers; it's Go's value receivers that are unusual.

Second is the consideration of efficiency. If the receiver is large, a big struct for instance, it will be much cheaper to use a pointer receiver.

Next is consistency. If some of the methods of the type must have pointer receivers, the rest should too, so the method set is consistent regardless of how the type is used. See the section on [method sets](#) for details.

For types such as basic types, slices, and small structs, a value receiver is very cheap so unless the semantics of the method requires a pointer, a value receiver is efficient and clear.

What's the difference between new and make?

In short: `new` allocates memory, `make` initializes the slice, map, and channel types.

See the [relevant section of Effective Go](#) for more details.

Why is int 32 bits on 64 bit machines?

The sizes of `int` and `uint` are implementation-specific but the same as each other on a given platform. The 64 bit Go compilers (both `gc` and `gccgo`) use a 32 bit representation for `int`. Code that relies on a particular size of value should use an explicitly sized type, like `int64`. On the other hand, floating-point scalars and complex numbers are always sized: `float32`, `complex64`, etc., because programmers should be aware of precision when using floating-point numbers. The default size of a floating-point constant is `float64`.

At the moment, all implementations use 32-bit ints, an essentially arbitrary decision. However, we expect that `int` will be increased to 64 bits on 64-bit architectures in a future release of Go.

How do I know whether a variable is allocated on the heap or the stack?

From a correctness standpoint, you don't need to know. Each variable in Go exists as long as there are references to it. The storage location chosen by the implementation is irrelevant to the semantics of the language.

The storage location does have an effect on writing efficient programs. When possible, the Go compilers will allocate variables that are local to a function in that function's stack frame. However, if the compiler cannot prove that the variable is not referenced after the function returns, then the compiler must allocate the variable on the garbage-collected heap to avoid dangling pointer errors. Also, if a local variable is very large, it might make more sense to store it on the heap rather than the stack.

In the current compilers, if a variable has its address taken, that variable is a candidate for allocation on the heap. However, a basic *escape analysis* recognizes some cases when such variables will not live past the return from the function and can reside on the stack.

Concurrency

What operations are atomic? What about mutexes?

We haven't fully defined it all yet, but some details about atomicity are available in the [Go Memory Model specification](#).

Regarding mutexes, the [sync](#) package implements them, but we hope Go programming style will encourage people to try higher-level techniques. In particular, consider structuring your program so that only one goroutine at a time is ever responsible for a particular piece of data.

Do not communicate by sharing memory. Instead, share memory by communicating.

See the [Share Memory By Communicating](#) code walk and its [associated article](#) for a detailed discussion of this concept.

Why doesn't my multi-goroutine program use multiple CPUs?

You must set the `GOMAXPROCS` shell environment variable or use the similarly-named [function](#) of the runtime package to allow the run-time support to utilize more than one OS thread.

Programs that perform parallel computation should benefit from an increase in `GOMAXPROCS`.

Why does using `GOMAXPROCS > 1` sometimes make my program slower?

It depends on the nature of your program. Problems that are intrinsically sequential cannot be sped up by adding more goroutines. Concurrency only becomes parallelism when the problem is intrinsically parallel.

In practical terms, programs that spend more time communicating on channels than doing computation will experience performance degradation when using multiple OS threads. This is because sending data between threads involves

switching contexts, which has significant cost. For instance, the [prime sieve example](#) from the Go specification has no significant parallelism although it launches many goroutines; increasing GOMAXPROCS is more likely to slow it down than to speed it up.

Go's goroutine scheduler is not as good as it needs to be. In future, it should recognize such cases and optimize its use of OS threads. For now, GOMAXPROCS should be set on a per-application basis.

Functions and Methods

Why do T and *T have different method sets?

From the [Go Spec](#):

The method set of any other named type τ consists of all methods with receiver type τ . The method set of the corresponding pointer type $*\tau$ is the set of all methods with receiver $*\tau$ or τ (that is, it also contains the method set of τ).

If an interface value contains a pointer $*\tau$, a method call can obtain a value by dereferencing the pointer, but if an interface value contains a value τ , there is no useful way for a method call to obtain a pointer.

Even in cases where the compiler could take the address of a value to pass to the method, if the method modifies the value the changes will be lost in the caller. As a common example, this code:

```
var buf bytes.Buffer
io.Copy(buf, os.Stdin)
```

would copy standard input into a *copy* of `buf`, not into `buf` itself. This is almost never the desired behavior.

What happens with closures running as goroutines?

Some confusion may arise when using closures with concurrency. Consider the following program:

```
func main() {
    done := make(chan bool)

    values := []string{"a", "b", "c"}
    for _, v := range values {
        go func() {
            fmt.Println(v)
            done <- true
        }()
    }
}
```

```
    // wait for all goroutines to complete before exiting
    for _ = range values {
        <-done
    }
}
```

One might mistakenly expect to see `a, b, c` as the output. What you'll probably see instead is `c, c, c`. This is because each iteration of the loop uses the same instance of the variable `v`, so each closure shares that single variable. When the closure runs, it prints the value of `v` at the time `fmt.Println` is executed, but `v` may have been modified since the goroutine was launched.

To bind the value of `v` to each closure as they are launched, one could modify the inner loop to read:

```
    for _, v := range values {
        go func(u string) {
            fmt.Println(u)
            done <- true
        }(v)
    }
```

In this example, the value of `v` is passed as an argument to the anonymous function. That value is then accessible inside the function as the variable `u`.

Control flow

Does Go have the `?:` operator?

There is no ternary form in Go. You may use the following to achieve the same result:

```
if expr {  
    n = trueVal  
} else {  
    n = falseVal  
}
```

Packages and Testing

How do I create a multifile package?

Put all the source files for the package in a directory by themselves. Source files can refer to items from different files at will; there is no need for forward declarations or a header file.

Other than being split into multiple files, the package will compile and test just like a single-file package.

How do I write a unit test?

Create a new file ending in `_test.go` in the same directory as your package sources. Inside that file, import `"testing"` and write functions of the form

```
func TestFoo(t *testing.T) {  
    ...  
}
```

Run `go test` in that directory. That script finds the `Test` functions, builds a test binary, and runs it.

See the [How to Write Go Code](#) document, the [testing](#) package and the [go test](#) subcommand for more details.

Where is my favorite helper function for testing?

Go's standard [testing](#) package makes it easy to write unit tests, but it lacks features provided in other language's testing frameworks such as assertion functions. An [earlier section](#) of this document explained why Go doesn't have assertions, and the same arguments apply to the use of `assert` in tests. Proper error handling means letting other tests run after one has failed, so that the person debugging the failure gets a complete picture of what is wrong. It is more useful for a test to report that `isPrime` gives the wrong answer for 2, 3, 5, and 7 (or for 2, 4, 8, and 16) than to report that `isPrime` gives the wrong answer for 2 and therefore no more tests were run. The programmer who triggers the test failure may not be familiar with the code that fails. Time invested writing a good

error message now pays off later when the test breaks.

A related point is that testing frameworks tend to develop into mini-languages of their own, with conditionals and controls and printing mechanisms, but Go already has all those capabilities; why recreate them? We'd rather write tests in Go; it's one fewer language to learn and the approach keeps the tests straightforward and easy to understand.

If the amount of extra code required to write good errors seems repetitive and overwhelming, the test might work better if table-driven, iterating over a list of inputs and outputs defined in a data structure (Go has excellent support for data structure literals). The work to write a good test and good error messages will then be amortized over many test cases. The standard Go library is full of illustrative examples, such as in [the formatting tests for the fmt package](#).

Implementation

What compiler technology is used to build the compilers?

`gccgo` has a C++ front-end with a recursive descent parser coupled to the standard GCC back end. `gc` is written in C using `yacc/bison` for the parser. Although it's a new program, it fits in the Plan 9 C compiler suite (<http://plan9.bell-labs.com/sys/doc/compiler.html>) and uses a variant of the Plan 9 loader to generate ELF/Mach-O/PE binaries.

We considered writing `gc`, the original Go compiler, in Go itself but elected not to do so because of the difficulties of bootstrapping and especially of open source distribution—you'd need a Go compiler to set up a Go environment. `gccgo`, which came later, makes it possible to consider writing a compiler in Go, which might well happen. (Go would be a fine language in which to implement a compiler; a native lexer and parser are already available in the `go` package.)

We also considered using LLVM for `gc` but we felt it was too large and slow to meet our performance goals.

How is the run-time support implemented?

Again due to bootstrapping issues, the run-time code is mostly in C (with a tiny bit of assembler) although Go is capable of implementing most of it now. `gccgo`'s run-time support uses `glibc`. `gc` uses a custom library to keep the footprint under control; it is compiled with a version of the Plan 9 C compiler that supports segmented stacks for goroutines. The `gccgo` compiler implements segmented stacks on Linux only, supported by recent modifications to the gold linker.

Why is my trivial program such a large binary?

The linkers in the `gc` tool chain (51, 61, and 81) do static linking. All Go binaries therefore include the Go run-time, along with the run-time type information necessary to support dynamic type checks, reflection, and even panic-time stack traces.

A simple C "hello, world" program compiled and linked statically using `gcc` on

Linux is around 750 kB, including an implementation of `printf`. An equivalent Go program using `fmt.Printf` is around 1.2 MB, but that includes more powerful run-time support.

Can I stop these complaints about my unused variable/import?

The presence of an unused variable may indicate a bug, while unused imports just slow down compilation. Accumulate enough unused imports in your code tree and things can get very slow. For these reasons, Go allows neither.

When developing code, it's common to create these situations temporarily and it can be annoying to have to edit them out before the program will compile.

Some have asked for a compiler option to turn those checks off or at least reduce them to warnings. Such an option has not been added, though, because compiler options should not affect the semantics of the language and because the Go compiler does not report warnings, only errors that prevent compilation.

There are two reasons for having no warnings. First, if it's worth complaining about, it's worth fixing in the code. (And if it's not worth fixing, it's not worth mentioning.) Second, having the compiler generate warnings encourages the implementation to warn about weak cases that can make compilation noisy, masking real errors that *should* be fixed.

It's easy to address the situation, though. Use the blank identifier to let unused things persist while you're developing.

```
import "unused"

// This declaration marks the import as used by referencing an
// item from the package.
var _ = unused.Item // TODO: Delete before committing!

func main() {
    debugData := debug.Profile()
    _ = debugData // Used only during debugging.
    ....
}
```

Performance

Why does Go perform badly on benchmark X?

One of Go's design goals is to approach the performance of C for comparable programs, yet on some benchmarks it does quite poorly, including several in [test/bench/shootout](#). The slowest depend on libraries for which versions of comparable performance are not available in Go. For instance, [pidigits.go](#) depends on a multi-precision math package, and the C versions, unlike Go's, use [GMP](#) (which is written in optimized assembler). Benchmarks that depend on regular expressions ([regex-dna.go](#), for instance) are essentially comparing Go's native [regexp package](#) to mature, highly optimized regular expression libraries like PCRE.

Benchmark games are won by extensive tuning and the Go versions of most of the benchmarks need attention. If you measure comparable C and Go programs ([reverse-complement.go](#) is one example), you'll see the two languages are much closer in raw performance than this suite would indicate.

Still, there is room for improvement. The compilers are good but could be better, many libraries need major performance work, and the garbage collector isn't fast enough yet. (Even if it were, taking care not to generate unnecessary garbage can have a huge effect.)

In any case, Go can often be very competitive. There has been significant improvement in the performance of many programs as the language and tools have developed. See the blog post about [profiling Go programs](#) for an informative example.

Changes from C

Why is the syntax so different from C?

Other than declaration syntax, the differences are not major and stem from two desires. First, the syntax should feel light, without too many mandatory keywords, repetition, or arcana. Second, the language has been designed to be easy to analyze and can be parsed without a symbol table. This makes it much easier to build tools such as debuggers, dependency analyzers, automated documentation extractors, IDE plug-ins, and so on. C and its descendants are notoriously difficult in this regard.

Why are declarations backwards?

They're only backwards if you're used to C. In C, the notion is that a variable is declared like an expression denoting its type, which is a nice idea, but the type and expression grammars don't mix very well and the results can be confusing; consider function pointers. Go mostly separates expression and type syntax and that simplifies things (using prefix `*` for pointers is an exception that proves the rule). In C, the declaration

```
int* a, b;
```

declares `a` to be a pointer but not `b`; in Go

```
var a, b *int
```

declares both to be pointers. This is clearer and more regular. Also, the `:=` short declaration form argues that a full variable declaration should present the same order as `:=` so

```
var a uint64 = 1
```

has the same effect as

```
a := uint64(1)
```

Parsing is also simplified by having a distinct grammar for types that is not just the expression grammar; keywords such as `func` and `chan` keep things clear.

See the article about [Go's Declaration Syntax](#) for more details.

Why is there no pointer arithmetic?

Safety. Without pointer arithmetic it's possible to create a language that can never derive an illegal address that succeeds incorrectly. Compiler and hardware technology have advanced to the point where a loop using array indices can be as efficient as a loop using pointer arithmetic. Also, the lack of pointer arithmetic can simplify the implementation of the garbage collector.

Why are ++ and -- statements and not expressions? And why postfix, not prefix?

Without pointer arithmetic, the convenience value of pre- and postfix increment operators drops. By removing them from the expression hierarchy altogether, expression syntax is simplified and the messy issues around order of evaluation of ++ and -- (consider $f(i++)$ and $p[i] = q[++i]$) are eliminated as well. The simplification is significant. As for postfix vs. prefix, either would work fine but the postfix version is more traditional; insistence on prefix arose with the STL, a library for a language whose name contains, ironically, a postfix increment.

Why are there braces but no semicolons? And why can't I put the opening brace on the next line?

Go uses brace brackets for statement grouping, a syntax familiar to programmers who have worked with any language in the C family. Semicolons, however, are for parsers, not for people, and we wanted to eliminate them as much as possible. To achieve this goal, Go borrows a trick from BCPL: the semicolons that separate statements are in the formal grammar but are injected automatically, without lookahead, by the lexer at the end of any line that could be the end of a statement. This works very well in practice but has the effect that it forces a brace style. For instance, the opening brace of a function cannot appear on a line by itself.

Some have argued that the lexer should do lookahead to permit the brace to live on the next line. We disagree. Since Go code is meant to be formatted automatically by [gofmt](#), *some* style must be chosen. That style may differ from what you've used in C or Java, but Go is a new language and gofmt's style is as

good as any other. More important—much more important—the advantages of a single, programmatically mandated format for all Go programs greatly outweigh any perceived disadvantages of the particular style. Note too that Go's style means that an interactive implementation of Go can use the standard syntax one line at a time without special rules.

Why do garbage collection? Won't it be too expensive?

One of the biggest sources of bookkeeping in systems programs is memory management. We feel it's critical to eliminate that programmer overhead, and advances in garbage collection technology in the last few years give us confidence that we can implement it with low enough overhead and no significant latency.

Another point is that a large part of the difficulty of concurrent and multi-threaded programming is memory management; as objects get passed among threads it becomes cumbersome to guarantee they become freed safely. Automatic garbage collection makes concurrent code far easier to write. Of course, implementing garbage collection in a concurrent environment is itself a challenge, but meeting it once rather than in every program helps everyone.

Finally, concurrency aside, garbage collection makes interfaces simpler because they don't need to specify how memory is managed across them.

The current implementation is a parallel mark-and-sweep collector but a future version might take a different approach.

On the topic of performance, keep in mind that Go gives the programmer considerable control over memory layout and allocation, much more than is typical in garbage-collected languages. A careful programmer can reduce the garbage collection overhead dramatically by using the language well; see the article about [profiling Go programs](#) for a worked example, including a demonstration of Go's profiling tools.

★ **GOPATH**

The GOPATH environment variable and its uses

Updated Apr 6, 2012 by [kev...@google.com](#)

Introduction

The GOPATH environment variable is used to specify directories outside of \$GOROOT that contain the source for Go projects and their binaries.

GOPATH is used by goinstall and the "go" tool as a destination for the binaries it builds and a location to search for imports.

GOPATH is a path list - multiple directories can be specified by separating them with a ":" (on os x or linux) or a ";" (on windows). When multiple directories are listed, and goinstall or "go" are used from outside any of them, the first directory is used as the installation destination. When using either tool from within one of the listed directories, the containing directory is used as the installation destination.

For most of this document, \$GOPATH will refer to whichever of the listed directories is the currently active one.

Integrating GOPATH

On os x or linux, adding the following expression to PATH will add all \$GOPATH

```
${GOPATH//:/:bin:}/bin
```

Adding the following block to a standard Go makefile will bring in all \$GOPATH

```
GOPATHSEP=:
ifeq ($(GOHOSTOS),windows)
GOPATHSEP=;
endif
GCIMPORTS+=-I $(subst $(GOPATHSEP),/pkg/$(GOOS)_$(GOARCH) -I , $(GO
LDIMPORTS+=-L $(subst $(GOPATHSEP),/pkg/$(GOOS)_$(GOARCH) -L , $(GO
```

goinstall and the "go" tool already know about GOPATH.

Directory layout

The source for a package with the import path "X/Y/Z" is in the directory

`$GOPATH/src/X/Y/Z`

The binary for a package with the import path "X/Y/Z" is in

`$GOPATH/pkg/$GOOS_$GOARCH/X/Y/Z.a`

The binary for a command whose source is in `$GOPATH/src/A/B` is

`$GOPATH/bin/B`

repository integration and creating "goinstallable" projects

goinstall, when fetching a package, looks at the package's import path to discover a URL. For instance, if you attempt to

```
goinstall code.google.com/p/gomatrix/matrix
```

goinstall will get the source from the project hosted at <http://code.google.com/p/gomatrix>, and it will clone the repository to

```
$GOPATH/src/code.google.com/p/gomatrix
```

As a result, if (from your repository project) you import a package that is in the same repository, you need to use its "full" import path - the place goinstall puts it. In this example, if something else wants to import the "matrix" package, it should import "code.google.com/p/gomatrix/matrix" rather than "matrix".

If you prefer to use makefiles to build on your own machine and you still want your project to work well with goinstall, set the TARG variable to the long import path. goinstall will ignore this makefile, but as long as TARG matches the package's location relative to the repository, goinstall will choose the same import path.

Tips and tricks

Third-party Packages

It is useful to have two GOPATH entries. One for a location for 3rd party goinstalled packages, and the second for your own projects. List the 3rd party GOPATH first, so that goinstall will use it as a default destination. Then you can work in the second GOPATH directory and have all your packages be importable by using the "go" command, goinstall, or a GOPATH-aware 3rd party build tool like [gb](#).

FAQ

Why won't `$GOPATH/src/cmd/mycmd/*.go` build?

When the go command is looking for packages, it always looks in `$GOROOT` first. This includes directories, so if it finds (as in the case above) a `cmd/` directory in `$GOROOT` it won't proceed to look in any of the `GOPATH` directories. This prevents you from defining your own `math/matrix` package as well as your own `cmd/mycmd` commands.

★ **SQLDrivers**

SQL database drivers [database](#), [sql](#)

Updated Apr 5, 2012 by bradfitz@golang.org

SQL database drivers

The database/sql and database/sql/driver packages are designed for using databases from Go and implementing database drivers, respectively.

See the design goals doc:

<http://golang.org/src/pkg/database/sql/doc.txt>

Drivers

Drivers for Go's sql package include:

- **MS ADODB:** <https://github.com/mattn/go-adodb>
- **MySQL:** <https://github.com/ziutek/mymysql>
- **ODBC:** <https://bitbucket.org/miquella/mgodbc>
- **Postgres** (uses cgo): <https://github.com/jbarham/gopgsqldriver>
- **Postgres** (pure Go): <https://github.com/bmizerany/pq>
- **SQLite:** <https://github.com/mattn/go-sqlite3>
- **Oracle:** <https://github.com/mattn/go-oci8>
- **DB2:** <https://bitbucket.org/phiggins/go-db2-cli>

★ **WindowsDLLs**

calling Windows DLLs from Go [windows](#), [syscall](#), [dll](#), [sample](#)

Updated May 23, 2011 by [a...@golang.org](#)

Calling a Windows DLL

A sample program that calls Windows DLLs from Go:

```
package main

import (
    "syscall"
    "unsafe"
    "fmt"
)

func abort(funcname string, err int) {
    panic(funcname + " failed: " + syscall.Errstr(err))
}

var (
    kernel32, _ = syscall.LoadLibrary("kernel32.dll")
    getModuleHandle, _ = syscall.GetProcAddress(kernel32, "GetMo

    user32, _ = syscall.LoadLibrary("user32.dll")
    messageBox, _ = syscall.GetProcAddress(user32, "MessageBoxW"
)

const (
    MB_OK                = 0x00000000
    MB_OKCANCEL          = 0x00000001
    MB_ABORTRETRYIGNORE = 0x00000002
    MB_YESNOCANCEL       = 0x00000003
    MB_YESNO             = 0x00000004
    MB_RETRYCANCEL       = 0x00000005
    MB_CANCELTRYCONTINUE = 0x00000006
    MB_ICONHAND          = 0x00000010
    MB_ICONQUESTION      = 0x00000020
    MB_ICONEXCLAMATION   = 0x00000030
    MB_ICONASTERISK      = 0x00000040
    MB_USERICON          = 0x00000080
    MB_ICONWARNING       = MB_ICONEXCLAMATION
    MB_ICONERROR         = MB_ICONHAND
    MB_ICONINFORMATION   = MB_ICONASTERISK
    MB_ICONSTOP          = MB_ICONHAND

    MB_DEFBUTTON1        = 0x00000000
```

```

        MB_DEFBUTTON2           = 0x00000100
        MB_DEFBUTTON3           = 0x00000200
        MB_DEFBUTTON4           = 0x00000300
    )

func MessageBox(caption, text string, style uintptr) (result int) {
    ret, _, callErr := syscall.Syscall9(uintptr(messageBox),
        0,
        uintptr(unsafe.Pointer(syscall.StringToUTF16Ptr(text))),
        uintptr(unsafe.Pointer(syscall.StringToUTF16Ptr(caption))),
        style,
        0,
        0,
        0,
        0,
        0)
    if callErr != 0 {
        abort("Call MessageBox", int(callErr))
    }
    result = int(ret)
    return
}

func GetModuleHandle() (handle uint) {
    if ret, _, callErr := syscall.Syscall(uintptr(getModuleHandle),
        0,
        abort("Call GetModuleHandle", int(callErr))
    } else {
        handle = ret
    }
    return
}

func main() {
    defer syscall.FreeLibrary(kernel32)
    defer syscall.FreeLibrary(user32)

    fmt.Printf("Return: %d\n", MessageBox("Done Title", "This te
}

func init() {
    fmt.Print("Starting Up\n")
}

```

☆ **GoForCPPProgrammers**

Go for C++ Programmers

Updated Mar 6, 2012 by a...@golang.org

Go is a systems programming language intended to be a general-purpose systems language, like C++. These are some notes on Go for experienced C++ programmers. This document discusses the differences between Go and C++, and says little to nothing about the similarities.

For a more general introduction to Go, see the [Go Tour](#), [How to Write Go Code](#) and [Effective Go](#).

For a detailed description of the Go language, see the [Go spec](#).

Conceptual Differences

- Go does not have classes with constructors or destructors. Instead of class methods, a class inheritance hierarchy, and virtual functions, Go provides *interfaces*, which are discussed in more detail below. Interfaces are also used where C++ uses templates.
- Go uses garbage collection. It is not necessary (or possible) to release memory explicitly.
- Go has pointers but not pointer arithmetic. You cannot use a pointer variable to walk through the bytes of a string.
- Arrays in Go are first class values. When an array is used as a function parameter, the function receives a copy of the array, not a pointer to it. However, in practice functions often use slices for parameters; slices hold pointers to underlying arrays. Slices are discussed further below.
- Strings are provided by the language. They may not be changed once they have been created.
- Hash tables are provided by the language. They are called maps.
- Separate threads of execution, and communication channels between them, are provided by the language. This is discussed further below.
- Certain types (maps and channels, described further below) are passed by reference, not by value. That is, passing a map to a function does not copy the map, and if the function changes the map the change will be seen by the caller. In C++ terms, one can think of these as being reference types.
- Go does not use header files. Instead, each source file is part of a defined *package*. When a package defines an object (type, constant, variable, function) with a name starting with an upper case letter, that object is visible to any other file which imports that package.
- Go does not support implicit type conversion. Operations that mix different types require casts (called conversions in Go).

- Go does not support function overloading and does not support user defined operators.
- Go does not support `const` or `volatile` qualifiers.
- Go uses `nil` for invalid pointers, where C++ uses `NULL` or simply `0`.

Syntax

The declaration syntax is reversed compared to C++. You write the name followed by the type. Unlike in C++, the syntax for a type does not match the way in which the variable is used. Type declarations may be read easily from left to right.

```
Go                C++
var v1 int        // int v1;
var v2 string     // const std::string v2; (approximately)
var v3 [10]int    // int v3[10];
var v4 []int      // int* v4; (approximately)
var v5 struct { f int } // struct { int f; } v5;
var v6 *int       // int* v6; (but no pointer arithmetic)
var v7 map[string]int // unordered_map<string, int>* v7; (approx)
var v8 func(a int) int // int (*v8)(int a);
```

Declarations generally take the form of a keyword followed by the name of the variable being declared. The keyword is one of `var`, `func`, `const`, or `type`. Method declarations are an exception in that the receiver appears before the name of the object being declared. See the discussion of interfaces.

You can also use a keyword followed by a series of declarations in parentheses.

```
var (
    i int
    m float64
)
```

When declaring a function, you must either provide a name for each parameter or a name for any parameter; you can't omit some names and provide others. You may use several names with the same type:

```
func f(i, j, k int, s, t string)
```

A variable may be initialized when it is declared. When this is done, specifying the type is permitted but not required. When the type is not specified, the type of the variable is the type of the initialization expression.

```
var v = *p
```

See also the discussion of constants, below. If a variable is not initialized explicitly

must be specified. In that case it will be implicitly initialized to the type's zero value (e.g., 0 for integers, false for booleans, etc.). There are no uninitialized variables in Go.

Within a function, a short declaration syntax is available with `:=`.

```
v1 := v2
```

This is equivalent to

```
var v1 = v2
```

Go permits multiple assignments, which are done in parallel.

```
i, j = j, i // Swap i and j.
```

Functions may have multiple return values, indicated by a list in parentheses. The values can be stored by assignment to a list of variables.

```
func f() (i int, j int) { ... }  
v1, v2 = f()
```

Go code uses very few semicolons in practice. Technically, all Go statements are terminated by a semicolon. However, Go treats the end of a non-blank line as a semicolon unless the line is clearly incomplete (the exact rules are in the language specification). A consequence is that in some cases Go does not permit you to use a line break. For example, you may not write

```
func g()  
{  
    // INVALID  
}
```

A semicolon will be inserted after `g()`, causing it to be a function declaration rather than a function definition. Similarly, you may not write

```
if x {  
}  
else {  
    // INVALID  
}
```

A semicolon will be inserted after the `}` preceding the `else`, causing a syntax error.

Since semicolons do not end statements, you may continue using them as in C++. However, this is not the recommended style. Idiomatic Go code omits unnecessary semicolons,

practice is all of them other than the initial for loop clause and cases where you short statements on a single line.

While we're on the topic, we recommend that rather than worry about semicolon placement, you format your code with the `gofmt` program. That will produce a standard Go style, and let you worry about your code rather than your formatting. While the rules initially seem odd, it is as good as any other style, and familiarity will lead to comfort.

When using a pointer to a struct, you use `.` instead of `->`. Thus syntactically speaking, a struct and a pointer to a structure are used in the same way.

```
type myStruct struct { i int }
var v9 myStruct           // v9 has structure type
var p9 *myStruct         // p9 is a pointer to a structure
f(v9.i, p9.i)
```

Go does not require parentheses around the condition of an `if` statement, or the condition of a `for` statement, or the value of a `switch` statement. On the other hand, it does require braces around the body of an `if` or `for` statement.

```
if a < b { f() }           // Valid
if (a < b) { f() }        // Valid (condition is a parenthesized
if (a < b) f()            // INVALID
for i = 0; i < 10; i++ {} // Valid
for (i = 0; i < 10; i++) {} // INVALID
```

Go does not have a `while` statement nor does it have a `do/while` statement. The `for` statement may be used with a single condition, which makes it equivalent to a `while` statement. Omitting the condition entirely is an endless loop.

Go permits `break` and `continue` to specify a label. The label must refer to a `for`, `select` statement.

In a `switch` statement, case labels do not fall through. You can make them fall through with the `fallthrough` keyword. This applies even to adjacent cases.

```
switch i {
case 0: // empty case body
case 1:
    f() // f is not called when i == 0!
}
```

But a case can have multiple values.

```
switch i {
case 0, 1:
    f() // f is called if i == 0 || i == 1.
}
```

The values in a case need not be constants--or even integers; any type that supports equality comparison operator, such as strings or pointers, can be used--and if the value is omitted it defaults to `true`.

```
switch {
case i < 0:
    f1()
case i == 0:
    f2()
case i > 0:
    f3()
}
```

The `++` and `--` operators may only be used in statements, not in expressions. You can write `c = *p++`. `*p++` is parsed as `(*p)++`.

The `defer` statement may be used to call a function after the function containing the statement returns.

```
fd := open("filename")
defer close(fd) // fd will be closed when this function returns
```

Constants

In Go constants may be *untyped*. This applies even to constants named with a `const` declaration, if no type is given in the declaration and the initializer expression uses only untyped constants. A value derived from an untyped constant becomes typed when it is used within a context that requires a typed value. This permits constants to be used relatively freely without requiring general implicit type conversion.

```
var a uint
f(a + 1) // untyped numeric constant "1" becomes typed as uint
```

The language does not impose any limits on the size of an untyped numeric constant or constant expression. A limit is only applied when a constant is used where a type is required.

```
const huge = 1 << 100
f(huge >> 98)
```

Go does not support enums. Instead, you can use the special name `iota` in a single `const` declaration to get a series of increasing value. When an initialization expression is omitted for a `const`, it reuses the preceding expression.

```
const (
    red = iota // red == 0
    blue      // blue == 1
    green     // green == 2
)
```

Slices

A slice is conceptually a struct with three fields: a pointer to an array, a length, and a capacity. Slices support the `[]` operator to access elements of the underlying array. The builtin `len` function returns the length of the slice. The builtin `cap` function returns the capacity.

Given an array, or another slice, a new slice is created via `a[i:j]`. This creates a new slice which refers to `a`, starts at index `i`, and ends before index `j`. It has length `j - i`. If `i` is omitted, the slice starts at `0`. If `j` is omitted, the slice ends at `len(a)`. The new slice refers to the same array to which `a` refers. That is, changes made using the new slice may be seen using `a`. The capacity of the new slice is simply the capacity of `a` minus `i`. The capacity of an array is the length of the array.

What this means is that Go uses slices for some cases where C++ uses pointers. If you create a value of type `[100]byte` (an array of 100 bytes, perhaps a buffer) and you want to pass it to a function without copying it, you should declare the function parameter to have type `[]byte`, and pass a slice of the array (`a[:]` will pass the entire array). Unlike in C++, it is not necessary to pass the length of the buffer; it is efficiently accessible via `len`.

The slice syntax may also be used with a string. It returns a new string, whose value is a substring of the original string. Because strings are immutable, string slices can be implemented without allocating new storage for the slices's contents.

Making values

Go has a builtin function `new` which takes a type and allocates space on the heap. The allocated space will be zero-initialized for the type. For example, `new(int)` allocates a new `int` on the heap, initializes it with the value `0`, and returns its address, which has type `*int`. Unlike in C++, `new` is a function, not an operator; `new int` is a syntax error.

Perhaps surprisingly, `new` is not commonly used in Go programs. In Go taking the address of a variable is always safe and never yields a dangling pointer. If the program takes the address of a variable, it will be allocated on the heap if necessary. So these functions are equivalent:

```
type S { I int }

func f1() *S {
    return new(S)
}

func f2() *S {
    var s S
    return &s
}

func f3() *S {
    // More idiomatic: use composite literal syntax.
    return &S{0}
}
```

Map and channel values must be allocated using the builtin function `make`. A variable declared with map or channel type without an initializer will be automatically initialized to `nil`. Calling `make(map[int]int)` returns a newly allocated value of type `map[int]int`. Note that `make` returns a value, not a pointer. This is consistent with the fact that map and channel values are passed by reference. Calling `make` with a map type takes an optional argument which is the expected capacity of the map. Calling `make` with a channel type takes an optional argument which sets the buffering capacity of the channel; the default is 0 (unbuffered).

The `make` function may also be used to allocate a slice. In this case it allocates memory for the underlying array and returns a slice referring to it. There is one

required argument, which is the number of elements in the slice. A second, optional, argument is the capacity of the slice. For example, `make([]int, 10, 20)`. This is identical to `new([20]int)[0:10]`. Since Go uses garbage collection, the newly allocated array will be discarded sometime after there are no references to the returned slice.

Interfaces

Where C++ provides classes, subclasses and templates, Go provides interfaces. An interface is similar to a C++ pure abstract class: a class with no data members, with methods which are all pure virtual. However, in Go, any type which provides the methods named in the interface may be treated as an implementation of the interface. No declared inheritance is required. The implementation of the interface is entirely separate from the interface itself.

A method looks like an ordinary function definition, except that it has a *receiver*. The receiver is similar to the `this` pointer in a C++ class method.

```
type myType struct { i int }
func (p *myType) Get() int { return p.i }
```

This declares a method `Get` associated with `myType`. The receiver is named `p` in the function.

Methods are defined on named types. If you convert the value to a different type, the value will have the methods of the new type, not the old type.

You may define methods on a builtin type by declaring a new named type derived from the builtin type. The new type is distinct from the builtin type.

```
type myInteger int
func (p myInteger) Get() int { return int(p) } // Conversion required
func f(i int) { }
var v myInteger
// f(v) is invalid.
// f(int(v)) is valid; int(v) has no defined methods.
```

Given this interface:

```
type myInterface interface {
    Get() int
    Set(i int)
}
```

we can make `myType` satisfy the interface by adding

```
func (p *myType) Set(i int) { p.i = i }
```

Now any function which takes `myInterface` as a parameter will accept a variable `*myType`.

```
func GetAndSet(x myInterface) {}  
func f1() {  
    var p myType  
    GetAndSet(&p)  
}
```

In other words, if we view `myInterface` as a C++ pure abstract base class, defining `Get` and `Set` for `*myType` made `*myType` automatically inherit from `myInterface`. A type can satisfy multiple interfaces.

An anonymous field may be used to implement something much like a C++ child class.

```
type myChildType struct { myType; j int }  
func (p *myChildType) Get() int { p.j++; return p.myType.Get() }
```

This effectively implements `myChildType` as a child of `myType`.

```
func f2() {  
    var p myChildType  
    GetAndSet(&p)  
}
```

The `Set` method is effectively inherited from `myType`, because methods associated with the anonymous field are promoted to become methods of the enclosing type. In this example, because `myChildType` has an anonymous field of type `myType`, the methods of `myType` also become methods of `myChildType`. In this example, the `Get` method was overridden and the `Set` method was inherited.

This is not precisely the same as a child class in C++. When a method of an anonymous field is called, its receiver is the field, not the surrounding struct. In other words, anonymous fields are not virtual functions. When you want the equivalent of a child class, use an interface.

A variable that has an interface type may be converted to have a different interface using a special construct called a type assertion. This is implemented dynamically at runtime, like C++ `dynamic_cast`. Unlike `dynamic_cast`, there does not need to be a declared relationship between the two interfaces.

```
type myPrintInterface interface {  
    Print()  
}
```

```

}
func f3(x myInterface) {
    x.(myPrintInterface).Print() // type assertion to myPrintI
}

```

The conversion to `myPrintInterface` is entirely dynamic. It will work as long as the underlying type of `x` (the *dynamic type*) defines a `Print` method.

Because the conversion is dynamic, it may be used to implement generic programs similar to templates in C++. This is done by manipulating values of the minimal interface.

```

type Any interface { }

```

Containers may be written in terms of `Any`, but the caller must unbox using a type assertion to recover values of the contained type. As the typing is dynamic rather than static, there is no equivalent of the way that a C++ template may inline the relevant operations. The operations are fully type-checked at run time, but all operations involve a function call.

```

type Iterator interface {
    Get() Any
    Set(v Any)
    Increment()
    Equal(arg Iterator) bool
}

```

Note that `Equal` has an argument of type `Iterator`. This does not behave like a C++ template. See the FAQ.

Goroutines

Go permits starting a new thread of execution (a *goroutine*) using the `go` statement. The `go` statement runs a function in a different, newly created, goroutine. All goroutines in a single program share the same address space.

Internally, goroutines act like coroutines that are multiplexed among multiple operating system threads. You do not have to worry about these details.

```
func server(i int) {
    for {
        fmt.Print(i)
        time.Sleep(10 * time.Second)
    }
}
go server(1)
go server(2)
```

(Note that the `for` statement in the `server` function is equivalent to a C++ `while (true)` loop.)

Goroutines are (intended to be) cheap.

Function literals (which Go implements as closures) can be useful with the `go` statement.

```
var g int
go func(i int) {
    s := 0
    for j := 0; j < i; j++ { s += j }
    g = s
}(1000) // Passes argument 1000 to the function literal.
```

Channels

Channels are used to communicate between goroutines. Any value may be sent over a channel. Channels are (intended to be) efficient and cheap. To send a value on a channel, use `<-` as a binary operator. To receive a value on a channel, use `<-` as a unary operator. When calling functions, channels are passed by reference.

The Go library provides mutexes, but you can also use a single goroutine with a shared channel. Here is an example of using a manager function to control access to a single value.

```
type Cmd struct { Get bool; Val int }
func Manager(ch chan Cmd) {
    val := 0
    for {
        c := <-ch
        if c.Get { c.Val = val; ch <- c }
        else { val = c.Val }
    }
}
```

In that example the same channel is used for input and output. This is incorrect if there are multiple goroutines communicating with the manager at once: a goroutine waiting for a response from the manager might receive a request from another goroutine instead. A solution is to pass in a channel.

```
type Cmd2 struct { Get bool; Val int; Ch <- chan int }
func Manager2(ch chan Cmd2) {
    val := 0
    for {
        c := <-ch
        if c.Get { c.Ch <- val }
        else { val = c.Val }
    }
}
```

To use `Manager2`, given a channel to it:

```
func f4(ch <- chan Cmd2) int {
    myCh := make(chan int)
    c := Cmd2{ true, 0, myCh } // Composite literal syntax.
    ch <- c
}
```

```
    return <-myCh  
}
```

★ **cgo**

Tips for interfacing with C code and libraries using cgo.

Updated Mar 30, 2012 by minux...@gmail.com

Introduction

First, <http://golang.org/cmd/cgo> is the primary cgo documentation.

There is also a good introduction article at http://golang.org/doc/articles/c_go_cgo.html.

The basics

If a Go source file imports "C", it is using cgo. The Go file will have access to anything appearing in the comment immediately preceding the line `import "C"`, and will be linked against all other cgo comments in other Go files, and all C files included in the build process.

Note that there must be no blank lines in between the cgo comment and the `import` statement.

To access a symbol originating from the C side, use the package name `c`. That is, if you want to call the C function `printf()` from Go code, you write `C.printf()`.

```
package cgoexample

/*
#include <stdio.h>
#include <stdlib.h>

void myprint(char* s) {
    printf("%s", s);
}
*/
import "C"

import "unsafe"

func Example() {
    cs := C.CString("Hello from stdio\n")
    C.myprint(cs)
    C.free(unsafe.Pointer(cs))
}
```

Calling Go functions from C

It is possible to call both top-level Go functions and function variables from C code.

Global functions

Go makes its functions available to C code through use of a special `//export c` directive.

```
package gocallback

import "fmt"

/*
#include <stdio.h>

extern void AGoFunction();

void ACFunction() {
    printf("ACFunction()\n");
    AGoFunction();
}
*/
import "C"

//export AGoFunction
func AGoFunction() {
    fmt.Println("AGoFunction()")
}

func Example() {
    C.ACFunction()
}
```

Function variables

The following code shows an example of invoking a Go callback from C code. `CallMyFunction()`. `CallMyFunction()` invokes the callback by sending it back to the Go runtime.

```
package gocallback

import (
    "unsafe"
    "fmt"
)
```

```
/*
extern void go_callback_int(void* foo, int p1);

void CallMyFunction(void* pfoo) {
    go_callback_int(pfoo, 5);
}
*/
import "C"

//export go_callback_int
func go_callback_int(pfoo unsafe.Pointer, p1 C.int) {
    foo := *(*func(C.int))(pfoo)
    foo(p1)
}

func MyCallback(x C.int) {
    fmt.Println("callback with", x)
}
//we store it in a global variable so that the garbage collector do
var MyCallbackFunc = MyCallback

func Example() {
    C.CallMyFunction(unsafe.Pointer(&MyCallbackFunc))
}
```

Go strings and C strings

Go strings and C strings are different. Go strings are the combination of a length and a pointer to the first character in the string. C strings are just the pointer to the first character, and are terminated by the first instance of the null character, `'\0'`.

Go provides means to go from one to another in the form of the following three functions:

- `func C.CString(goString string) *C.char`
- `func C.GoString(cString *C.char) string`
- `func C.GoStringN(cString *C.char, length C.int) string`

One important thing to remember is that `C.CString()` will allocate a new string of the appropriate length, and return it. That means the C string is not going to be garbage collected and it is up to **you** to free it. A standard way to do this follows.

```
// #include <stdlib.h>
import "C"
import "unsafe"
...
    var cmsg *C.char = C.CString("hi")
    defer C.free(unsafe.Pointer(cmsg))
    // do something with the C string
```

Of course, you aren't required to use `defer` to call `C.free()`. You can free the C string whenever you like, but it is your responsibility to make sure it happens.

Turning C arrays into Go slices

C arrays are typically either null-terminated or have a length kept elsewhere.

Go provides the following function to make a new Go byte slice from a C array:

- `func C.GoBytes(cArray unsafe.Pointer, length C.int) []byte`

To create a Go slice backed by a C array (without copying the original data), one acquires this length at runtime and uses `reflect.SliceHeader`.

```
import "C"
import "unsafe"
...
var theCArray *TheCType := C.getTheArray()
length := C.getTheArrayLength()
var theGoSlice []TheCType
sliceHeader := (*reflect.SliceHeader)((unsafe.Pointer(&theGoSlice))
sliceHeader.Cap = length
sliceHeader.Len = length
sliceHeader.Data = uintptr(unsafe.Pointer(&theCArray[0]))
// now theGoSlice is a normal Go slice backed by the C array
```

It is important to keep in mind that the Go garbage collector will not interact with C code and that if it is freed from the C side of things, the behavior of any Go code using the slice is nondeterministic.

Common Pitfalls

Struct Alignment Issues

As Go doesn't support packed struct (e.g., structs where maximum alignment is 1 byte), you can't use packed C struct in Go. Even if your program passes compilation, it won't do what you want. To use it, you have to read/write the struct as byte array/slice.

//export and definition in preamble

If your program uses any `//export` directives, then the C code in the comment may only include declarations (`extern int f();`), not definitions (`int f() { return 1; }` or `int n;`).

Writing Web Applications

Introduction

Covered in this tutorial:

- Creating a data structure with load and save methods
- Using the `net/http` package to build web applications
- Using the `html/template` package to process HTML templates
- Using the `regexp` package to validate user input
- Using closures

Assumed knowledge:

- Programming experience
- Understanding of basic web technologies (HTTP, HTML)
- Some UNIX/DOS command-line knowledge

Getting Started

At present, you need to have a FreeBSD, Linux, OS X, or Windows machine to run Go. We will use \$ to represent the command prompt.

Install Go (see the [Installation Instructions](#)).

Make a new directory for this tutorial inside your GOPATH and cd to it:

```
$ mkdir gowiki
$ cd gowiki
```

Create a file named `wiki.go`, open it in your favorite editor, and add the following lines:

```
package main

import (
    "fmt"
    "io/ioutil"
)
```

We import the `fmt` and `ioutil` packages from the Go standard library. Later, as we implement additional functionality, we will add more packages to this `import` declaration.

Data Structures

Let's start by defining the data structures. A wiki consists of a series of interconnected pages, each of which has a title and a body (the page content). Here, we define `Page` as a struct with two fields representing the title and body.

```
type Page struct {
    Title string
    Body  []byte
}
```

The type `[]byte` means "a byte slice". (See [Slices: usage and internals](#) for more on slices.) The `Body` element is a `[]byte` rather than `string` because that is the type expected by the `io` libraries we will use, as you'll see below.

The `Page` struct describes how page data will be stored in memory. But what about persistent storage? We can address that by creating a `save` method on `Page`:

```
func (p *Page) save() error {
    filename := p.Title + ".txt"
    return ioutil.WriteFile(filename, p.Body, 0600)
}
```

This method's signature reads: "This is a method named `save` that takes as its receiver `p`, a pointer to `Page`. It takes no parameters, and returns a value of type `error`."

This method will save the `Page`'s `Body` to a text file. For simplicity, we will use the `Title` as the file name.

The `save` method returns an error value because that is the return type of `writeFile` (a standard library function that writes a byte slice to a file). The `save` method returns the error value, to let the application handle it should anything go wrong while writing the file. If all goes well, `Page.save()` will return `nil` (the zero-value for pointers, interfaces, and some other types).

The octal integer constant `0600`, passed as the third parameter to `writeFile`, indicates that the file should be created with read-write permissions for the current user only. (See the Unix man page `open(2)` for details.)

We will want to load pages, too:

```
func loadPage(title string) *Page {
    filename := title + ".txt"
    body, _ := ioutil.ReadFile(filename)
    return &Page{Title: title, Body: body}
}
```

The function `loadPage` constructs the file name from `title`, reads the file's contents into a new `Page`, and returns a pointer to that new page.

Functions can return multiple values. The standard library function `io.ReadFile` returns `[]byte` and `error`. In `loadPage`, error isn't being handled yet; the "blank identifier" represented by the underscore (`_`) symbol is used to throw away the error return value (in essence, assigning the value to nothing).

But what happens if `ReadFile` encounters an error? For example, the file might not exist. We should not ignore such errors. Let's modify the function to return `*Page` and `error`.

```
func loadPage(title string) (*Page, error) {
    filename := title + ".txt"
    body, err := ioutil.ReadFile(filename)
    if err != nil {
        return nil, err
    }
    return &Page{Title: title, Body: body}, nil
}
```

Callers of this function can now check the second parameter; if it is `nil` then it has successfully loaded a `Page`. If not, it will be an error that can be handled by the caller (see the [language specification](#) for details).

At this point we have a simple data structure and the ability to save to and load from a file. Let's write a main function to test what we've written:

```
func main() {
    p1 := &Page{Title: "TestPage", Body: []byte("This is a sample Pa
p1.save()
    p2, _ := loadPage("TestPage")
    fmt.Println(string(p2.Body))
}
```

After compiling and executing this code, a file named `TestPage.txt` would be

created, containing the contents of p1. The file would then be read into the struct p2, and its Body element printed to the screen.

You can compile and run the program like this:

```
$ go build wiki.go
$ ./wiki
This is a sample page.
```

(If you're using Windows you must type "wiki" without the "./" to run the program.)

[Click here to view the code we've written so far.](#)

Introducing the `net/http` package (an interlude)

Here's a full working example of a simple web server:

```
package main

import (
    "fmt"
    "net/http"
)

func handler(w http.ResponseWriter, r *http.Request) {
    fmt.Fprintf(w, "Hi there, I love %s!", r.URL.Path[1:])
}

func main() {
    http.HandleFunc("/", handler)
    http.ListenAndServe(":8080", nil)
}
```

The `main` function begins with a call to `http.HandleFunc`, which tells the `http` package to handle all requests to the web root (`/`) with `handler`.

It then calls `http.ListenAndServe`, specifying that it should listen on port 8080 on any interface (`:8080`). (Don't worry about its second parameter, `nil`, for now.) This function will block until the program is terminated.

The function `handler` is of the type `http.HandlerFunc`. It takes an `http.ResponseWriter` and an `http.Request` as its arguments.

An `http.ResponseWriter` value assembles the HTTP server's response; by writing to it, we send data to the HTTP client.

An `http.Request` is a data structure that represents the client HTTP request. The string `r.URL.Path` is the path component of the request URL. The trailing `[1:]` means "create a sub-slice of `Path` from the 1st character to the end." This drops the leading `/` from the path name.

If you run this program and access the URL:

```
http://localhost:8080/monkeys
```

the program would present a page containing:

Hi there, I love monkeys!

Using net/http to serve wiki pages

To use the net/http package, it must be imported:

```
import (  
    "fmt"  
    "net/http"  
    "io/ioutil"  
)
```

Let's create a handler to view a wiki page:

```
const lenPath = len("/view/")  
  
func viewHandler(w http.ResponseWriter, r *http.Request) {  
    title := r.URL.Path[lenPath:]  
    p, _ := loadPage(title)  
    fmt.Fprintf(w, "<h1>%s</h1><div>%s</div>", p.Title, p.Body)  
}
```

First, this function extracts the page title from `r.URL.Path`, the path component of the request URL. The global constant `lenPath` is the length of the leading `"/view/"` component of the request path. The `Path` is re-sliced with `[lenPath:]` to drop the first 6 characters of the string. This is because the path will invariably begin with `"/view/"`, which is not part of the page title.

The function then loads the page data, formats the page with a string of simple HTML, and writes it to `w`, the `http.ResponseWriter`.

Again, note the use of `_` to ignore the error return value from `loadPage`. This is done here for simplicity and generally considered bad practice. We will attend to this later.

To use this handler, we create a main function that initializes `http` using the `viewHandler` to handle any requests under the path `/view/`.

```
func main() {  
    http.HandleFunc("/view/", viewHandler)  
    http.ListenAndServe(":8080", nil)  
}
```

[Click here to view the code we've written so far.](#)

Let's create some page data (as `test.txt`), compile our code, and try serving a wiki page.

Open `test.txt` file in your editor, and save the string "Hello world" (without quotes) in it.

```
$ go build wiki.go  
$ ./wiki
```

With this web server running, a visit to <http://localhost:8080/view/test> should show a page titled "test" containing the words "Hello world".

Editing Pages

A wiki is not a wiki without the ability to edit pages. Let's create two new handlers: one named `editHandler` to display an 'edit page' form, and the other named `saveHandler` to save the data entered via the form.

First, we add them to `main()`:

```
func main() {
    http.HandleFunc("/view/", viewHandler)
    http.HandleFunc("/edit/", editHandler)
    http.HandleFunc("/save/", saveHandler)
    http.ListenAndServe(":8080", nil)
}
```

The function `editHandler` loads the page (or, if it doesn't exist, create an empty `Page` struct), and displays an HTML form.

```
func editHandler(w http.ResponseWriter, r *http.Request) {
    title := r.URL.Path[lenPath:]
    p, err := loadPage(title)
    if err != nil {
        p = &Page{Title: title}
    }
    fmt.Fprintf(w, "<h1>Editing %s</h1>"+
        "<form action=\"/save/%s\" method=\"POST\">"+
        "<textarea name=\"body\">%s</textarea><br>"+
        "<input type=\"submit\" value=\"Save\">"+
        "</form>",
        p.Title, p.Title, p.Body)
}
```

This function will work fine, but all that hard-coded HTML is ugly. Of course, there is a better way.

The html/template package

The `html/template` package is part of the Go standard library. We can use `html/template` to keep the HTML in a separate file, allowing us to change the layout of our edit page without modifying the underlying Go code.

First, we must add `html/template` to the list of imports:

```
import (  
    "html/template"  
    "http"  
    "io/ioutil"  
    "os"  
)
```

Let's create a template file containing the HTML form. Open a new file named `edit.html`, and add the following lines:

```
<h1>Editing {{.Title}}</h1>  
  
<form action="/save/{{.Title}}" method="POST">  
<div><textarea name="body" rows="20" cols="80">{{printf "%s" .Body}}  
<div><input type="submit" value="Save"></div>  
</form>
```

Modify `editHandler` to use the template, instead of the hard-coded HTML:

```
func editHandler(w http.ResponseWriter, r *http.Request) {  
    title := r.URL.Path[lenPath:]  
    p, err := loadPage(title)  
    if err != nil {  
        p = &Page{Title: title}  
    }  
    t, _ := template.ParseFiles("edit.html")  
    t.Execute(w, p)  
}
```

The function `template.ParseFiles` will read the contents of `edit.html` and return a `*template.Template`.

The method `t.Execute` executes the template, writing the generated HTML to the `http.ResponseWriter`. The `.Title` and `.Body` dotted identifiers refer to `p.Title` and `p.Body`.

Template directives are enclosed in double curly braces. The `printf "%s" .Body` instruction is a function call that outputs `.Body` as a string instead of a stream of bytes, the same as a call to `fmt.Printf`. The `html/template` package helps guarantee that only safe and correct-looking HTML is generated by template actions. For instance, it automatically escapes any greater than sign (`>`), replacing it with `>`, to make sure user data does not corrupt the form HTML.

Now that we've removed the `fmt.Fprintf` statement, we can remove `"fmt"` from the `import` list.

While we're working with templates, let's create a template for our `viewHandler` called `view.html`:

```
<h1>{{.Title}}</h1>
<p>[<a href="/edit/{{.Title}}">edit</a>]</p>
<div>{{printf "%s" .Body}}</div>
```

Modify `viewHandler` accordingly:

```
func viewHandler(w http.ResponseWriter, r *http.Request) {
    title := r.URL.Path[lenPath:]
    p, _ := loadPage(title)
    t, _ := template.ParseFiles("view.html")
    t.Execute(w, p)
}
```

Notice that we've used almost exactly the same templating code in both handlers. Let's remove this duplication by moving the templating code to its own function:

```
func viewHandler(w http.ResponseWriter, r *http.Request) {
    title := r.URL.Path[lenPath:]
    p, _ := loadPage(title)
    renderTemplate(w, "view", p)
}

func editHandler(w http.ResponseWriter, r *http.Request) {
    title := r.URL.Path[lenPath:]
    p, err := loadPage(title)
    if err != nil {
        p = &Page{Title: title}
    }
    renderTemplate(w, "edit", p)
}
```

```
func renderTemplate(w http.ResponseWriter, tmpl string, p *Page) {  
    t, _ := template.ParseFiles(tmpl + ".html")  
    t.Execute(w, p)  
}
```

The handlers are now shorter and simpler.

Handling non-existent pages

What if you visit [/view/APageThatDoesntExist](#)? The program will crash. This is because it ignores the error return value from `loadPage`. Instead, if the requested Page doesn't exist, it should redirect the client to the edit Page so the content may be created:

```
func viewHandler(w http.ResponseWriter, r *http.Request) {
    title, err := getTitle(w, r)
    if err != nil {
        return
    }
    p, err := loadPage(title)
    if err != nil {
        http.Redirect(w, r, "/edit/"+title, http.StatusFound)
        return
    }
    renderTemplate(w, "view", p)
}
```

The `http.Redirect` function adds an HTTP status code of `http.StatusFound` (302) and a `Location` header to the HTTP response.

Saving Pages

The function `saveHandler` will handle the form submission.

```
func saveHandler(w http.ResponseWriter, r *http.Request) {
    title := r.URL.Path[lenPath:]
    body := r.FormValue("body")
    p := &Page{Title: title, Body: []byte(body)}
    p.save()
    http.Redirect(w, r, "/view/"+title, http.StatusFound)
}
```

The page title (provided in the URL) and the form's only field, `Body`, are stored in a new `Page`. The `save()` method is then called to write the data to a file, and the client is redirected to the `/view/` page.

The value returned by `FormValue` is of type `string`. We must convert that value to `[]byte` before it will fit into the `Page` struct. We use `[]byte(body)` to perform the conversion.

Error handling

There are several places in our program where errors are being ignored. This is bad practice, not least because when an error does occur the program will crash. A better solution is to handle the errors and return an error message to the user. That way if something does go wrong, the server will continue to function and the user will be notified.

First, let's handle the errors in `renderTemplate`:

```
func renderTemplate(w http.ResponseWriter, tmpl string, p *Page) {
    t, err := template.ParseFiles(tmpl + ".html")
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
        return
    }
    err = t.Execute(w, p)
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
    }
}
```

The `http.Error` function sends a specified HTTP response code (in this case "Internal Server Error") and error message. Already the decision to put this in a separate function is paying off.

Now let's fix up `saveHandler`:

```
func saveHandler(w http.ResponseWriter, r *http.Request) {
    title, err := getTitle(w, r)
    if err != nil {
        return
    }
    body := r.FormValue("body")
    p := &Page{Title: title, Body: []byte(body)}
    err = p.save()
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
        return
    }
    http.Redirect(w, r, "/view/"+title, http.StatusFound)
}
```

Any errors that occur during `p.save()` will be reported to the user.

Template caching

There is an inefficiency in this code: `renderTemplate` calls `ParseFiles` every time a page is rendered. A better approach would be to call `ParseFiles` once at program initialization, parsing all templates into a single `*Template`. Then we can use the [ExecuteTemplate](#) method to render a specific template.

First we create a global variable named `templates`, and initialize it with `ParseFiles`.

```
var templates = template.Must(template.ParseFiles("edit.html", "view
```

The function `template.Must` is a convenience wrapper that panics when passed a non-nil error value, and otherwise returns the `*Template` unaltered. A panic is appropriate here; if the templates can't be loaded the only sensible thing to do is exit the program.

A for loop is used with a range statement to iterate over an array constant containing the names of the templates we want parsed. If we were to add more templates to our program, we would add their names to that array.

We then modify the `renderTemplate` function to call the `templates.ExecuteTemplate` method with the name of the appropriate template:

```
func renderTemplate(w http.ResponseWriter, tmpl string, p *Page) {
    err := templates.ExecuteTemplate(w, tmpl+".html", p)
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
    }
}
```

Note that the template name is the template file name, so we must append `".html"` to the `tmpl` argument.

Validation

As you may have observed, this program has a serious security flaw: a user can supply an arbitrary path to be read/written on the server. To mitigate this, we can write a function to validate the title with a regular expression.

First, add "regexp" to the import list. Then we can create a global variable to store our validation regexp:

```
var titleValidator = regexp.MustCompile("^[a-zA-Z0-9]+$")
```

The function `regexp.MustCompile` will parse and compile the regular expression, and return a `regexp.Regexp`. `MustCompile` is distinct from `Compile` in that it will panic if the expression compilation fails, while `Compile` returns an error as a second parameter.

Now, let's write a function that extracts the title string from the request URL, and tests it against our `TitleValidator` expression:

```
func getTitle(w http.ResponseWriter, r *http.Request) (title string,
    title = r.URL.Path[lenPath:]
    if !titleValidator.MatchString(title) {
        http.NotFound(w, r)
        err = errors.New("Invalid Page Title")
    }
    return
}
```

If the title is valid, it will be returned along with a `nil` error value. If the title is invalid, the function will write a "404 Not Found" error to the HTTP connection, and return an error to the handler.

Let's put a call to `getTitle` in each of the handlers:

```
func viewHandler(w http.ResponseWriter, r *http.Request) {
    title, err := getTitle(w, r)
    if err != nil {
        return
    }
    p, err := loadPage(title)
    if err != nil {
        http.Redirect(w, r, "/edit/"+title, http.StatusFound)
    }
}
```

```

        return
    }
    renderTemplate(w, "view", p)
}

func editHandler(w http.ResponseWriter, r *http.Request) {
    title, err := getTitle(w, r)
    if err != nil {
        return
    }
    p, err := loadPage(title)
    if err != nil {
        p = &Page{Title: title}
    }
    renderTemplate(w, "edit", p)
}

func saveHandler(w http.ResponseWriter, r *http.Request) {
    title, err := getTitle(w, r)
    if err != nil {
        return
    }
    body := r.FormValue("body")
    p := &Page{Title: title, Body: []byte(body)}
    err = p.save()
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
        return
    }
    http.Redirect(w, r, "/view/"+title, http.StatusFound)
}

```

Introducing Function Literals and Closures

Catching the error condition in each handler introduces a lot of repeated code. What if we could wrap each of the handlers in a function that does this validation and error checking? Go's [function literals](#) provide a powerful means of abstracting functionality that can help us here.

First, we re-write the function definition of each of the handlers to accept a title string:

```
func viewHandler(w http.ResponseWriter, r *http.Request, title string) {
func editHandler(w http.ResponseWriter, r *http.Request, title string) {
func saveHandler(w http.ResponseWriter, r *http.Request, title string) {
```

Now let's define a wrapper function that *takes a function of the above type*, and returns a function of type `http.HandlerFunc` (suitable to be passed to the function `http.HandleFunc`):

```
func makeHandler(fn func(http.ResponseWriter, *http.Request, string)
    return func(w http.ResponseWriter, r *http.Request) {
        // Here we will extract the page title from the Request
        // and call the provided handler 'fn'
    }
}
```

The returned function is called a closure because it encloses values defined outside of it. In this case, the variable `fn` (the single argument to `makeHandler`) is enclosed by the closure. The variable `fn` will be one of our `save`, `edit`, or `view` handlers.

Now we can take the code from `getTitle` and use it here (with some minor modifications):

```
func makeHandler(fn func(http.ResponseWriter, *http.Request, string)
    return func(w http.ResponseWriter, r *http.Request) {
        title := r.URL.Path[lenPath:]
        if !titleValidator.MatchString(title) {
            http.NotFound(w, r)
            return
        }
        fn(w, r, title)
    }
}
```

```
}
```

The closure returned by `makeHandler` is a function that takes an `http.ResponseWriter` and `http.Request` (in other words, an `http.HandlerFunc`). The closure extracts the `title` from the request path, and validates it with the `titleValidator` regexp. If the `title` is invalid, an error will be written to the `ResponseWriter` using the `http.NotFound` function. If the `title` is valid, the enclosed handler function `fn` will be called with the `ResponseWriter`, `Request`, and `title` as arguments.

Now we can wrap the handler functions with `makeHandler` in `main`, before they are registered with the `http` package:

```
func main() {
    http.HandleFunc("/view/", makeHandler(viewHandler))
    http.HandleFunc("/edit/", makeHandler(editHandler))
    http.HandleFunc("/save/", makeHandler(saveHandler))
    http.ListenAndServe(":8080", nil)
}
```

Finally we remove the calls to `getTitle` from the handler functions, making them much simpler:

```
func viewHandler(w http.ResponseWriter, r *http.Request, title string,
    p, err := loadPage(title)
    if err != nil {
        http.Redirect(w, r, "/edit/"+title, http.StatusFound)
        return
    }
    renderTemplate(w, "view", p)
}
```

```
func editHandler(w http.ResponseWriter, r *http.Request, title string,
    p, err := loadPage(title)
    if err != nil {
        p = &Page{Title: title}
    }
    renderTemplate(w, "edit", p)
}
```

```
func saveHandler(w http.ResponseWriter, r *http.Request, title string,
    body := r.FormValue("body")
    p := &Page{Title: title, Body: []byte(body)}
    err := p.save()
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
    }
}
```

```
        return
    }
    http.Redirect(w, r, "/view/"+title, http.StatusFound)
}
```

Try it out!

[Click here to view the final code listing.](#)

Recompile the code, and run the app:

```
$ go build wiki.go  
$ ./wiki
```

Visiting <http://localhost:8080/view/ANewPage> should present you with the page edit form. You should then be able to enter some text, click 'Save', and be redirected to the newly created page.

Other tasks

Here are some simple tasks you might want to tackle on your own:

- Store templates in `tmpl/` and page data in `data/`.
- Add a handler to make the web root redirect to `/view/FrontPage`.
- Spruce up the page templates by making them valid HTML and adding some CSS rules.
- Implement inter-page linking by converting instances of `[PageName]` to `PageName`. (hint: you could use `regexp.ReplaceAllFunc` to do this)

Build version `go1.0.1`.

JSON-RPC: a tale of interfaces

Here we present an example where Go's [interfaces](#) made it easy to refactor some existing code to make it more flexible and extensible. Originally, the standard library's [RPC package](#) used a custom wire format called [gob](#). For a particular application, we wanted to use [JSON](#) as an alternate wire format.

We first defined a pair of interfaces to describe the functionality of the existing wire format, one for the client, and one for the server (depicted below).

```
type ServerCodec interface {
    ReadRequestHeader(*Request) error
    ReadRequestBody(interface{}) error
    WriteResponse(*Response, interface{}) error
    Close() error
}
```

On the server side, we then changed two internal function signatures to accept the `ServerCodec` interface instead of our existing `gob.Encoder`. Here's one of them:

```
func sendResponse(sending *sync.Mutex, req *Request,
    reply interface{}, enc *gob.Encoder, errmsg string)
```

became

```
func sendResponse(sending *sync.Mutex, req *Request,
    reply interface{}, enc ServerCodec, errmsg string)
```

We then wrote a trivial `gobServerCodec` wrapper to reproduce the original functionality. From there it is simple to build a `jsonServerCodec`.

After some similar changes to the client side, this was the full extent of the work we needed to do on the `RPC` package. This whole exercise took about 20 minutes! After tidying up and testing the new code, the [final changeset](#) was submitted.

In an inheritance-oriented language like Java or C++, the obvious path would be to generalize the `RPC` class, and create `JsonRPC` and `GobRPC` subclasses. However, this approach becomes tricky if you want to make a further

generalization orthogonal to that hierarchy. (For example, if you were to implement an alternate RPC standard). In our Go package, we took a route that is both conceptually simpler and requires less code be written or changed.

A vital quality for any codebase is maintainability. As needs change, it is essential to adapt your code easily and cleanly, lest it become unwieldy to work with. We believe Go's lightweight, composition-oriented type system provides a means of structuring code that scales.

Go's Declaration Syntax

Newcomers to Go wonder why the declaration syntax is different from the tradition established in the C family. In this post we'll compare the two approaches and explain why Go's declarations look as they do.

C syntax

First, let's talk about C syntax. C took an unusual and clever approach to declaration syntax. Instead of describing the types with special syntax, one writes an expression involving the item being declared, and states what type that expression will have. Thus

```
int x;
```

declares `x` to be an `int`: the expression '`x`' will have type `int`. In general, to figure out how to write the type of a new variable, write an expression involving that variable that evaluates to a basic type, then put the basic type on the left and the expression on the right.

Thus, the declarations

```
int *p;  
int a[3];
```

state that `p` is a pointer to `int` because '`*p`' has type `int`, and that `a` is an array of `ints` because `a[3]` (ignoring the particular index value, which is punned to be the size of the array) has type `int`.

What about functions? Originally, C's function declarations wrote the types of the arguments outside the parens, like this:

```
int main(argc, argv)  
    int argc;  
    char *argv[];  
{ /* ... */ }
```

Again, we see that `main` is a function because the expression `main(argc, argv)` returns an `int`. In modern notation we'd write

```
int main(int argc, char *argv[]) { /* ... */ }
```

but the basic structure is the same.

This is a clever syntactic idea that works well for simple types but can get confusing fast. The famous example is declaring a function pointer. Follow the rules and you get this:

```
int (*fp)(int a, int b);
```

Here, fp is a pointer to a function because if you write the expression (*fp)(a, b) you'll call a function that returns int. What if one of fp's arguments is itself a function?

```
int (*fp)(int (*ff)(int x, int y), int b)
```

That's starting to get hard to read.

Of course, we can leave out the name of the parameters when we declare a function, so main can be declared

```
int main(int, char *[])
```

Recall that argv is declared like this,

```
char *argv[]
```

so you drop the name from the *middle* of its declaration to construct its type. It's not obvious, though, that you declare something of type char *[] by putting its name in the middle.

And look what happens to fp's declaration if you don't name the parameters:

```
int (*fp)(int (*)(int, int), int)
```

Not only is it not obvious where to put the name inside

```
int (*)(int, int)
```

it's not exactly clear that it's a function pointer declaration at all. And what if the return type is a function pointer?

```
int ((*fp)(int (*)(int, int), int))(int, int)
```

It's hard even to see that this declaration is about fp.

You can construct more elaborate examples but these should illustrate some of the difficulties that C's declaration syntax can introduce.

There's one more point that needs to be made, though. Because type and declaration syntax are the same, it can be difficult to parse expressions with types in the middle. This is why, for instance, C casts always parenthesize the type, as in

```
(int)M_PI
```

Go syntax

Languages outside the C family usually use a distinct type syntax in declarations. Although it's a separate point, the name usually comes first, often followed by a colon. Thus our examples above become something like (in a fictional but illustrative language)

```
x: int  
p: pointer to int  
a: array[3] of int
```

These declarations are clear, if verbose - you just read them left to right. Go takes its cue from here, but in the interests of brevity it drops the colon and removes some of the keywords:

```
x int  
p *int  
a [3]int
```

There is no direct correspondence between the look of [3]int and how to use a in an expression. (We'll come back to pointers in the next section.) You gain clarity at the cost of a separate syntax.

Now consider functions. Let's transcribe the declaration for main, even though the main function in Go takes no arguments:

```
func main(argc int, argv *[]byte) int
```

Superficially that's not much different from C, but it reads well from left to right:

function main takes an int and a pointer to a slice of bytes and returns an int.

Drop the parameter names and it's just as clear - they're always first so there's no confusion.

```
func main(int, *[]byte) int
```

One value of this left-to-right style is how well it works as the types become more complex. Here's a declaration of a function variable (analogous to a function pointer in C):

```
f func(func(int,int) int, int) int
```

Or if f returns a function:

```
f func(func(int,int) int, int) func(int, int) int
```

It still reads clearly, from left to right, and it's always obvious which name is being declared - the name comes first.

The distinction between type and expression syntax makes it easy to write and invoke closures in Go:

```
sum := func(a, b int) int { return a+b } (3, 4)
```

Pointers

Pointers are the exception that proves the rule. Notice that in arrays and slices, for instance, Go's type syntax puts the brackets on the left of the type but the expression syntax puts them on the right of the expression:

```
var a []int  
x = a[1]
```

For familiarity, Go's pointers use the * notation from C, but we could not bring ourselves to make a similar reversal for pointer types. Thus pointers work like this

```
var p *int  
x = *p
```

We couldn't say

```
var p *int
x = p*
```

because that postfix `*` would conflate with multiplication. We could have used the Pascal `^`, for example:

```
var p ^int
x = p^
```

and perhaps we should have (and chosen another operator for xor), because the prefix asterisk on both types and expressions complicates things in a number of ways. For instance, although one can write

```
[]int("hi")
```

as a conversion, one must parenthesize the type if it starts with a `*`:

```
(*int)(nil)
```

Had we been willing to give up `*` as pointer syntax, those parentheses would be unnecessary.

So Go's pointer syntax is tied to the familiar C form, but those ties mean that we cannot break completely from using parentheses to disambiguate types and expressions in the grammar.

Overall, though, we believe Go's type syntax is easier to understand than C's, especially when things get complicated.

Notes

Go's declarations read left to right. It's been pointed out that C's read in a spiral! See [The "Clockwise/Spiral Rule"](#) by David Anderson.

Defer, Panic, and Recover

Go has the usual mechanisms for control flow: if, for, switch, goto. It also has the go statement to run code in a separate goroutine. Here I'd like to discuss some of the less common ones: defer, panic, and recover.

A **defer statement** pushes a function call onto a list. The list of saved calls is executed after the surrounding function returns. Defer is commonly used to simplify functions that perform various clean-up actions.

For example, let's look at a function that opens two files and copies the contents of one file to the other:

```
func CopyFile(dstName, srcName string) (written int64, err error) {
    src, err := os.Open(srcName)
    if err != nil {
        return
    }

    dst, err := os.Create(dstName)
    if err != nil {
        return
    }

    written, err = io.Copy(dst, src)
    dst.Close()
    src.Close()
    return
}
```

This works, but there is a bug. If the call to `os.Create` fails, the function will return without closing the source file. This can be easily remedied by putting a call to `src.Close` before the second return statement, but if the function were more complex the problem might not be so easily noticed and resolved. By introducing defer statements we can ensure that the files are always closed:

```
func CopyFile(dstName, srcName string) (written int64, err error) {
    src, err := os.Open(srcName)
    if err != nil {
        return
    }
    defer src.Close()

    dst, err := os.Create(dstName)
    if err != nil {
        return
    }

    written, err = io.Copy(dst, src)
    dst.Close()
    return
}
```

```

    dst, err := os.Create(dstName)
    if err != nil {
        return
    }
    defer dst.Close()

    return io.Copy(dst, src)
}

```

Defer statements allow us to think about closing each file right after opening it, guaranteeing that, regardless of the number of return statements in the function, the files *will* be closed.

The behavior of defer statements is straightforward and predictable. There are three simple rules:

1. *A deferred function's arguments are evaluated when the defer statement is evaluated.*

In this example, the expression "i" is evaluated when the Println call is deferred. The deferred call will print "0" after the function returns.

```

func a() {
    i := 0
    defer fmt.Println(i)
    i++
    return
}

```

2. *Deferred function calls are executed in Last In First Out order after the surrounding function returns.*

This function prints "3210":

```

func b() {
    for i := 0; i < 4; i++ {
        defer fmt.Print(i)
    }
}

```

3. *Deferred functions may read and assign to the returning function's named return values.*

In this example, a deferred function increments the return value *i* *after* the surrounding function returns. Thus, this function returns 2:

```
func c() (i int) {
    defer func() { i++ }()
    return 1
}
```

This is convenient for modifying the error return value of a function; we will see an example of this shortly.

Panic is a built-in function that stops the ordinary flow of control and begins *panicking*. When the function *F* calls `panic`, execution of *F* stops, any deferred functions in *F* are executed normally, and then *F* returns to its caller. To the caller, *F* then behaves like a call to `panic`. The process continues up the stack until all functions in the current goroutine have returned, at which point the program crashes. Panics can be initiated by invoking `panic` directly. They can also be caused by runtime errors, such as out-of-bounds array accesses.

Recover is a built-in function that regains control of a panicking goroutine. `Recover` is only useful inside deferred functions. During normal execution, a call to `recover` will return `nil` and have no other effect. If the current goroutine is panicking, a call to `recover` will capture the value given to `panic` and resume normal execution.

Here's an example program that demonstrates the mechanics of `panic` and `defer`:

```
package main

import "fmt"

func main() {
    f()
    fmt.Println("Returned normally from f.")
}

func f() {
    defer func() {
        if r := recover(); r != nil {
            fmt.Println("Recovered in f", r)
        }
    }()
    fmt.Println("Calling g.")
    g(0)
}
```

```

    fmt.Println("Returned normally from g.")
}

func g(i int) {
    if i > 3 {
        fmt.Println("Panicking!")
        panic(fmt.Sprintf("%v", i))
    }
    defer fmt.Println("Defer in g", i)
    fmt.Println("Printing in g", i)
    g(i + 1)
}

```

The function `g` takes the `int` `i`, and panics if `i` is greater than 3, or else it calls itself with the argument `i+1`. The function `f` defers a function that calls `recover` and prints the recovered value (if it is non-nil). Try to picture what the output of this program might be before reading on.

The program will output:

```

Calling g.
Printing in g 0
Printing in g 1
Printing in g 2
Printing in g 3
Panicking!
Defer in g 3
Defer in g 2
Defer in g 1
Defer in g 0
Recovered in f 4
Returned normally from f.

```

If we remove the deferred function from `f` the panic is not recovered and reaches the top of the goroutine's call stack, terminating the program. This modified program will output:

```

Calling g.
Printing in g 0
Printing in g 1
Printing in g 2
Printing in g 3
Panicking!
Defer in g 3
Defer in g 2
Defer in g 1
Defer in g 0

```

```
panic: 4
```

```
panic PC=0x2a9cd8  
[stack trace omitted]
```

For a real-world example of **panic** and **recover**, see the [json package](#) from the Go standard library. It decodes JSON-encoded data with a set of recursive functions. When malformed JSON is encountered, the parser calls panic to unwind the stack to the top-level function call, which recovers from the panic and returns an appropriate error value (see the 'error' and 'unmarshal' methods of the decodeState type in [decode.go](#)).

The convention in the Go libraries is that even when a package uses panic internally, its external API still presents explicit error return values.

Other uses of **defer** (beyond the file.Close example given earlier) include releasing a mutex:

```
mu.Lock()  
defer mu.Unlock()
```

printing a footer:

```
printHeader()  
defer printFooter()
```

and more.

In summary, the defer statement (with or without panic and recover) provides an unusual and powerful mechanism for control flow. It can be used to model a number of features implemented by special-purpose structures in other programming languages. Try it out.

Go Concurrency Patterns: Timing out, moving on

Concurrent programming has its own idioms. A good example is timeouts. Although Go's channels do not support them directly, they are easy to implement. Say we want to receive from the channel `ch`, but want to wait at most one second for the value to arrive. We would start by creating a signalling channel and launching a goroutine that sleeps before sending on the channel:

```
timeout := make(chan bool, 1)
go func() {
    time.Sleep(1 * time.Second)
    timeout <- true
}()
```

We can then use a `select` statement to receive from either `ch` or `timeout`. If nothing arrives on `ch` after one second, the `timeout` case is selected and the attempt to read from `ch` is abandoned.

```
select {
case <-ch:
    // a read from ch has occurred
case <-timeout:
    // the read from ch has timed out
}
```

The `timeout` channel is buffered with space for 1 value, allowing the `timeout` goroutine to send to the channel and then exit. The goroutine doesn't know (or care) whether the value is received. This means the goroutine won't hang around forever if the `ch` receive happens before the timeout is reached. The `timeout` channel will eventually be deallocated by the garbage collector.

(In this example we used `time.Sleep` to demonstrate the mechanics of goroutines and channels. In real programs you should use [time.After](#), a function that returns a channel and sends on that channel after the specified duration.)

Let's look at another variation of this pattern. In this example we have a program

that reads from multiple replicated databases simultaneously. The program needs only one of the answers, and it should accept the answer that arrives first.

The function `Query` takes a slice of database connections and a query string. It queries each of the databases in parallel and returns the first response it receives:

```
func Query(conns []Conn, query string) Result {
    ch := make(chan Result, 1)
    for _, conn := range conns {
        go func(c Conn) {
            select {
                case ch <- c.DoQuery(query):
                default:
            }
        }(conn)
    }
    return <-ch
}
```

In this example, the closure does a non-blocking send, which it achieves by using the `send` operation in `select` statement with a `default` case. If the send cannot go through immediately the default case will be selected. Making the send non-blocking guarantees that none of the goroutines launched in the loop will hang around. However, if the result arrives before the main function has made it to the receive, the send could fail since no one is ready.

This problem is a textbook example of what is known as a [race condition](#), but the fix is trivial. We just make sure to buffer the channel `ch` (by adding the buffer length as the second argument to [make](#)), guaranteeing that the first send has a place to put the value. This ensures the send will always succeed, and the first value to arrive will be retrieved regardless of the order of execution.

These two examples demonstrate the simplicity with which Go can express complex interactions between goroutines.

Slices: usage and internals

Go's slice type provides a convenient and efficient means of working with sequences of typed data. Slices are analogous to arrays in other languages, but have some unusual properties. This article will look at what slices are and how they are used.

Arrays

The slice type is an abstraction built on top of Go's array type, and so to understand slices we must first understand arrays.

An array type definition specifies a length and an element type. For example, the type `[4]int` represents an array of four integers. An array's size is fixed; its length is part of its type (`[4]int` and `[5]int` are distinct, incompatible types). Arrays can be indexed in the usual way, so the expression `s[n]` accesses the *n*th element:

```
var a [4]int
a[0] = 1
i := a[0]
// i == 1
```

Arrays do not need to be initialized explicitly; the zero value of an array is a ready-to-use array whose elements are themselves zeroed:

```
// a[2] == 0, the zero value of the int type
```

The in-memory representation of `[4]int` is just four integer values laid out sequentially:

Go's arrays are values. An array variable denotes the entire array; it is not a pointer to the first array element (as would be the case in C). This means that when you assign or pass around an array value you will make a copy of its contents. (To avoid the copy you could pass a *pointer* to the array, but then that's a pointer to an array, not an array.) One way to think about arrays is as a sort of struct but with indexed rather than named fields: a fixed-size composite value.

An array literal can be specified like so:

```
b := [2]string{"Penn", "Teller"}
```

Or, you can have the compiler count the array elements for you:

```
b := [...]string{"Penn", "Teller"}
```

In both cases, the type of `b` is `[2]string`.

Slices

Arrays have their place, but they're a bit inflexible, so you don't see them too often in Go code. Slices, though, are everywhere. They build on arrays to provide great power and convenience.

The type specification for a slice is `[]T`, where `T` is the type of the elements of the slice. Unlike an array type, a slice type has no specified length.

A slice literal is declared just like an array literal, except you leave out the element count:

```
letters := []string{"a", "b", "c", "d"}
```

A slice can be created with the built-in function called `make`, which has the signature,

```
func make([]T, len, cap) []T
```

where `T` stands for the element type of the slice to be created. The `make` function takes a type, a length, and an optional capacity. When called, `make` allocates an array and returns a slice that refers to that array.

```
var s []byte
s = make([]byte, 5, 5)
// s == []byte{0, 0, 0, 0, 0}
```

When the capacity argument is omitted, it defaults to the specified length. Here's a more succinct version of the same code:

```
s := make([]byte, 5)
```

The length and capacity of a slice can be inspected using the built-in `len` and `cap` functions.

```
len(s) == 5
cap(s) == 5
```

The next two sections discuss the relationship between length and capacity.

The zero value of a slice is `nil`. The `len` and `cap` functions will both return 0 for a `nil` slice.

A slice can also be formed by "slicing" an existing slice or array. Slicing is done by specifying a half-open range with two indices separated by a colon. For example, the expression `b[1:4]` creates a slice including elements 1 through 3 of `b` (the indices of the resulting slice will be 0 through 2).

```
b := []byte{'g', 'o', 'l', 'a', 'n', 'g'}
// b[1:4] == []byte{'o', 'l', 'a'}, sharing the same storage as b
```

The start and end indices of a slice expression are optional; they default to zero and the slice's length respectively:

```
// b[:2] == []byte{'g', 'o'}
// b[2:] == []byte{'l', 'a', 'n', 'g'}
// b[:] == b
```

This is also the syntax to create a slice given an array:

```
x := [3]string{"000A", "000", "00"}
s := x[:] // a slice referencing the storage of x
```

Slice internals

A slice is a descriptor of an array segment. It consists of a pointer to the array, the length of the segment, and its capacity (the maximum length of the segment).

Our variable `s`, created earlier by `make([]byte, 5)`, is structured like this:

The length is the number of elements referred to by the slice. The capacity is the

number of elements in the underlying array (beginning at the element referred to by the slice pointer). The distinction between length and capacity will be made clear as we walk through the next few examples.

As we slice `s`, observe the changes in the slice data structure and their relation to the underlying array:

```
s = s[2:4]
```

Slicing does not copy the slice's data. It creates a new slice value that points to the original array. This makes slice operations as efficient as manipulating array indices. Therefore, modifying the *elements* (not the slice itself) of a re-slice modifies the elements of the original slice:

```
d := []byte{'r', 'o', 'a', 'd'}
e := d[2:]
// e == []byte{'a', 'd'}
e[1] == 'm'
// e == []byte{'a', 'm'}
// d == []byte{'r', 'o', 'a', 'm'}
```

Earlier we sliced `s` to a length shorter than its capacity. We can grow `s` to its capacity by slicing it again:

```
s = s[:cap(s)]
```

A slice cannot be grown beyond its capacity. Attempting to do so will cause a runtime panic, just as when indexing outside the bounds of a slice or array. Similarly, slices cannot be re-sliced below zero to access earlier elements in the array.

Growing slices (the copy and append functions)

To increase the capacity of a slice one must create a new, larger slice and copy the contents of the original slice into it. This technique is how dynamic array implementations from other languages work behind the scenes. The next example doubles the capacity of `s` by making a new slice, `t`, copying the contents of `s` into `t`, and then assigning the slice value `t` to `s`:

```
t := make([]byte, len(s), (cap(s)+1)*2) // +1 in case cap(s) == 0
for i := range s {
    t[i] = s[i]
}
s = t
```

The looping piece of this common operation is made easier by the built-in copy function. As the name suggests, copy copies data from a source slice to a destination slice. It returns the number of elements copied.

```
func copy(dst, src []T) int
```

The copy function supports copying between slices of different lengths (it will copy only up to the smaller number of elements). In addition, copy can handle source and destination slices that share the same underlying array, handling overlapping slices correctly.

Using copy, we can simplify the code snippet above:

```
t := make([]byte, len(s), (cap(s)+1)*2)
copy(t, s)
s = t
```

A common operation is to append data to the end of a slice. This function appends byte elements to a slice of bytes, growing the slice if necessary, and returns the updated slice value:

```
func AppendByte(slice []byte, data ...byte) []byte {
    m := len(slice)
    n := m + len(data)
    if n > cap(slice) { // if necessary, reallocate
        // allocate double what's needed, for future growth.
        newSlice := make([]byte, (n+1)*2)
        copy(newSlice, slice)
        slice = newSlice
    }
    slice = slice[0:n]
    copy(slice[m:n], data)
    return slice
}
```

One could use AppendByte like this:

```
p := []byte{2, 3, 5}
p = AppendByte(p, 7, 11, 13)
```

```
// p == []byte{2, 3, 5, 7, 11, 13}
```

Functions like `AppendByte` are useful because they offer complete control over the way the slice is grown. Depending on the characteristics of the program, it may be desirable to allocate in smaller or larger chunks, or to put a ceiling on the size of a reallocation.

But most programs don't need complete control, so Go provides a built-in `append` function that's good for most purposes; it has the signature

```
func append(s []T, x ...T) []T
```

The `append` function appends the elements `x` to the end of the slice `s`, and grows the slice if a greater capacity is needed.

```
a := make([]int, 1)
// a == []int{0}
a = append(a, 1, 2, 3)
// a == []int{0, 1, 2, 3}
```

To append one slice to another, use `...` to expand the second argument to a list of arguments.

```
a := []string{"John", "Paul"}
b := []string{"George", "Ringo", "Pete"}
a = append(a, b...) // equivalent to "append(a, b[0], b[1], b[2])"
// a == []string{"John", "Paul", "George", "Ringo", "Pete"}
```

Since the zero value of a slice (`nil`) acts like a zero-length slice, you can declare a slice variable and then append to it in a loop:

```
// Filter returns a new slice holding only
// the elements of s that satisfy f()
func Filter(s []int, fn func(int) bool) []int {
    var p []int // == nil
    for _, i := range s {
        if fn(i) {
            p = append(p, i)
        }
    }
    return p
}
```

A possible "gotcha"

As mentioned earlier, re-slicing a slice doesn't make a copy of the underlying array. The full array will be kept in memory until it is no longer referenced. Occasionally this can cause the program to hold all the data in memory when only a small piece of it is needed.

For example, this `FindDigits` function loads a file into memory and searches it for the first group of consecutive numeric digits, returning them as a new slice.

```
var digitRegexp = regexp.MustCompile("[0-9]+")

func FindDigits(filename string) []byte {
    b, _ := ioutil.ReadFile(filename)
    return digitRegexp.Find(b)
}
```

This code behaves as advertised, but the returned `[]byte` points into an array containing the entire file. Since the slice references the original array, as long as the slice is kept around the garbage collector can't release the array; the few useful bytes of the file keep the entire contents in memory.

To fix this problem one can copy the interesting data to a new slice before returning it:

```
func CopyDigits(filename string) []byte {
    b, _ := ioutil.ReadFile(filename)
    b = digitRegexp.Find(b)
    c := make([]byte, len(b))
    copy(c, b)
    return c
}
```

A more concise version of this function could be constructed by using `append`. This is left as an exercise for the reader.

Error Handling and Go

If you have written any Go code you have probably encountered the built-in error type. Go code uses error values to indicate an abnormal state. For example, the `os.Open` function returns a non-nil error value when it fails to open a file.

```
func Open(name string) (file *File, err error)
```

The following code uses `os.Open` to open a file. If an error occurs it calls `log.Fatal` to print the error message and stop.

```
f, err := os.Open("filename.ext")
if err != nil {
    log.Fatal(err)
}
// do something with the open *File f
```

You can get a lot done in Go knowing just this about the error type, but in this article we'll take a closer look at error and discuss some good practices for error handling in Go.

The error type

The error type is an interface type. An error variable represents any value that can describe itself as a string. Here is the interface's declaration:

```
type error interface {
    Error() string
}
```

The error type, as with all built in types, is [predeclared](#) in the [universe block](#).

The most commonly-used error implementation is the [errors](#) package's unexported `errorString` type.

```
// errorString is a trivial implementation of error.
type errorString struct {
    s string
}
```

```
func (e *errorString) Error() string {
    return e.s
}
```

You can construct one of these values with the `errors.New` function. It takes a string that it converts to an `errors.errorString` and returns as an error value.

```
// New returns an error that formats as the given text.
func New(text string) error {
    return &errorString{text}
}
```

Here's how you might use `errors.New`:

```
func Sqrt(f float64) (float64, error) {
    if f < 0 {
        return 0, errors.New("math: square root of negative number")
    }
    // implementation
}
```

A caller passing a negative argument to `Sqrt` receives a non-nil error value (whose concrete representation is an `errors.errorString` value). The caller can access the error string ("math: square root of...") by calling the error's `Error` method, or by just printing it:

```
f, err := Sqrt(-1)
if err != nil {
    fmt.Println(err)
}
```

The [fmt](#) package formats an error value by calling its `Error()` string method.

It is the error implementation's responsibility to summarize the context. The error returned by `os.Open` formats as "open /etc/passwd: permission denied," not just "permission denied." The error returned by our `Sqrt` is missing information about the invalid argument.

To add that information, a useful function is the `fmt` package's `Errorf`. It formats a string according to `Printf`'s rules and returns it as an error created by `errors.New`.

```
if f < 0 {
    return 0, fmt.Errorf("math: square root of negative number %
```

```
}
```

In many cases `fmt.Errorf` is good enough, but since `error` is an interface, you can use arbitrary data structures as error values, to allow callers to inspect the details of the error.

For instance, our hypothetical callers might want to recover the invalid argument passed to `Sqrt`. We can enable that by defining a new error implementation instead of using `errors.Errorf`:

```
type NegativeSqrtError float64

func (f NegativeSqrtError) Error() string {
    return fmt.Sprintf("math: square root of negative number %g", f)
}
```

A sophisticated caller can then use a [type assertion](#) to check for a `NegativeSqrtError` and handle it specially, while callers that just pass the error to `fmt.Println` or `log.Fatal` will see no change in behavior.

As another example, the [json](#) package specifies a `SyntaxError` type that the `json.Decode` function returns when it encounters a syntax error parsing a JSON blob.

```
type SyntaxError struct {
    msg      string // description of error
    Offset int64  // error occurred after reading Offset bytes
}

func (e *SyntaxError) Error() string { return e.msg }
```

The `Offset` field isn't even shown in the default formatting of the error, but callers can use it to add file and line information to their error messages:

```
if err := dec.Decode(&val); err != nil {
    if serr, ok := err.(*json.SyntaxError); ok {
        line, col := findLine(f, serr.Offset)
        return fmt.Errorf("%s:%d:%d: %v", f.Name(), line, col, e)
    }
    return err
}
```

(This is a slightly simplified version of some [actual code](#) from the [Camlistore](#) project.)

The error interface requires only a `Error` method; specific error implementations might have additional methods. For instance, the [net](#) package returns errors of type `error`, following the usual convention, but some of the error implementations have additional methods defined by the `net.Error` interface:

```
package net

type Error interface {
    error
    Timeout() bool // Is the error a timeout?
    Temporary() bool // Is the error temporary?
}
```

Client code can test for a `net.Error` with a type assertion and then distinguish transient network errors from permanent ones. For instance, a web crawler might sleep and retry when it encounters a temporary error and give up otherwise.

```
    if nerr, ok := err.(net.Error); ok && nerr.Temporary() {
        time.Sleep(1e9)
        continue
    }
    if err != nil {
        log.Fatal(err)
    }
```

Simplifying repetitive error handling

In Go, error handling is important. The language's design and conventions encourage you to explicitly check for errors where they occur (as distinct from the convention in other languages of throwing exceptions and sometimes catching them). In some cases this makes Go code verbose, but fortunately there are some techniques you can use to minimize repetitive error handling.

Consider an [App Engine](#) application with an HTTP handler that retrieves a record from the datastore and formats it with a template.

```
func init() {
    http.HandleFunc("/view", viewRecord)
}

func viewRecord(w http.ResponseWriter, r *http.Request) {
    c := appengine.NewContext(r)
    key := datastore.NewKey(c, "Record", r.FormValue("id"), 0, nil)
```

```

    record := new(Record)
    if err := datastore.Get(c, key, record); err != nil {
        http.Error(w, err.Error(), 500)
        return
    }
    if err := viewTemplate.Execute(w, record); err != nil {
        http.Error(w, err.Error(), 500)
    }
}

```

This function handles errors returned by the `datastore.Get` function and `viewTemplate's Execute` method. In both cases, it presents a simple error message to the user with the HTTP status code 500 ("Internal Server Error"). This looks like a manageable amount of code, but add some more HTTP handlers and you quickly end up with many copies of identical error handling code.

To reduce the repetition we can define our own HTTP `appHandler` type that includes an error return value:

```
type appHandler func(http.ResponseWriter, *http.Request) error
```

Then we can change our `viewRecord` function to return errors:

```

func viewRecord(w http.ResponseWriter, r *http.Request) error {
    c := appengine.NewContext(r)
    key := datastore.NewKey(c, "Record", r.FormValue("id"), 0, nil)
    record := new(Record)
    if err := datastore.Get(c, key, record); err != nil {
        return err
    }
    return viewTemplate.Execute(w, record)
}

```

This is simpler than the original version, but the [http](#) package doesn't understand functions that return error. To fix this we can implement the `http.Handler` interface's `ServeHTTP` method on `appHandler`:

```

func (fn appHandler) ServeHTTP(w http.ResponseWriter, r *http.Reques
    if err := fn(w, r); err != nil {
        http.Error(w, err.Error(), 500)
    }
}

```

The `ServeHTTP` method calls the `appHandler` function and displays the returned

error (if any) to the user. Notice that the method's receiver, `fn`, is a function. (Go can do that!) The method invokes the function by calling the receiver in the expression `fn(w, r)`.

Now when registering `viewRecord` with the `http` package we use the `Handle` function (instead of `HandleFunc`) as `appHandler` is an `http.Handler` (not an `http.HandlerFunc`).

```
func init() {
    http.Handle("/view", appHandler(viewRecord))
}
```

With this basic error handling infrastructure in place, we can make it more user friendly. Rather than just displaying the error string, it would be better to give the user a simple error message with an appropriate HTTP status code, while logging the full error to the App Engine developer console for debugging purposes.

To do this we create an `appError` struct containing an error and some other fields:

```
type appError struct {
    Error    error
    Message  string
    Code     int
}
```

Next we modify the `appHandler` type to return `*appError` values:

```
type appHandler func(http.ResponseWriter, *http.Request) *appError
```

(It's usually a mistake to pass back the concrete type of an error rather than `error`, for reasons discussed in [the Go FAQ](#), but it's the right thing to do here because `ServeHTTP` is the only place that sees the value and uses its contents.)

And make `appHandler`'s `ServeHTTP` method display the `appError`'s `Message` to the user with the correct HTTP status code and log the full `Error` to the developer console:

```
func (fn appHandler) ServeHTTP(w http.ResponseWriter, r *http.Request) {
    if e := fn(w, r); e != nil { // e is *appError, not os.Error.
        c := appengine.NewContext(r)
        c.Errorf("%v", e.Error)
    }
}
```

```
        http.Error(w, e.Message, e.Code)
    }
}
```

Finally, we update `viewRecord` to the new function signature and have it return more context when it encounters an error:

```
func viewRecord(w http.ResponseWriter, r *http.Request) *appError {
    c := appengine.NewContext(r)
    key := datastore.NewKey(c, "Record", r.FormValue("id"), 0, nil)
    record := new(Record)
    if err := datastore.Get(c, key, record); err != nil {
        return &appError{err, "Record not found", 404}
    }
    if err := viewTemplate.Execute(w, record); err != nil {
        return &appError{err, "Can't display record", 500}
    }
    return nil
}
```

This version of `viewRecord` is the same length as the original, but now each of those lines has specific meaning and we are providing a friendlier user experience.

It doesn't end there; we can further improve the error handling in our application. Some ideas:

- give the error handler a pretty HTML template,
- make debugging easier by writing the stack trace to the HTTP response when the user is an administrator,
- write a constructor function for `appError` that stores the stack trace for easier debugging,
- recover from panics inside the `appHandler`, logging the error to the console as "Critical," while telling the user "a serious error has occurred." This is a nice touch to avoid exposing the user to inscrutable error messages caused by programming errors. See the [Defer, Panic, and Recover](#) article for more details.

Conclusion

Proper error handling is an essential requirement of good software. By employing the techniques described in this post you should be able to write more reliable and succinct Go code.

Directory /src/pkg

Name	Synopsis
archive	
tar	Package tar implements access to tar archives.
zip	Package zip provides support for reading and writing ZIP archives.
bufio	Package bufio implements buffered I/O. It wraps an io.Reader or io.Writer object, creating another object (Reader or Writer) that also implements the interface but provides buffering and some help for textual I/O.
builtin	Package builtin provides documentation for Go's predeclared identifiers.
bytes	Package bytes implements functions for the manipulation of byte slices.
compress	
bzip2	Package bzip2 implements bzip2 decompression.
flate	Package flate implements the DEFLATE compressed data format, described in RFC 1951.
gzip	Package gzip implements reading and writing of gzip format compressed files, as specified in RFC 1952.
lzw	Package lzw implements the Lempel-Ziv-Welch compressed data format, described in T. A. Welch, "A Technique for High-Performance Data Compression", Computer, 17(6) (June 1984), pp 8-19.
zlib	Package zlib implements reading and writing of zlib format compressed data, as specified in RFC 1950.
container	
heap	Package heap provides heap operations for any type that implements heap.Interface.
list	Package list implements a doubly linked list.
ring	Package ring implements operations on circular lists.
crypto	Package crypto collects common cryptographic constants.

<u>aes</u>	Package aes implements AES encryption (formerly Rijndael), as defined in U.S. Federal Information Processing Standards Publication 197.
<u>cipher</u>	Package cipher implements standard block cipher modes that can be wrapped around low-level block cipher implementations.
<u>des</u>	Package des implements the Data Encryption Standard (DES) and the Triple Data Encryption Algorithm (TDEA) as defined in U.S. Federal Information Processing Standards Publication 46-3.
<u>dsa</u>	Package dsa implements the Digital Signature Algorithm, as defined in FIPS 186-3.
<u>ecdsa</u>	Package ecdsa implements the Elliptic Curve Digital Signature Algorithm, as defined in FIPS 186-3.
<u>elliptic</u>	Package elliptic implements several standard elliptic curves over prime fields.
<u>hmac</u>	Package hmac implements the Keyed-Hash Message Authentication Code (HMAC) as defined in U.S. Federal Information Processing Standards Publication 198.
<u>md5</u>	Package md5 implements the MD5 hash algorithm as defined in RFC 1321.
<u>rand</u>	Package rand implements a cryptographically secure pseudorandom number generator.
<u>rc4</u>	Package rc4 implements RC4 encryption, as defined in Bruce Schneier's Applied Cryptography.
<u>rsa</u>	Package rsa implements RSA encryption as specified in PKCS#1.
<u>sha1</u>	Package sha1 implements the SHA1 hash algorithm as defined in RFC 3174.
<u>sha256</u>	Package sha256 implements the SHA224 and SHA256 hash algorithms as defined in FIPS 180-2.
<u>sha512</u>	Package sha512 implements the SHA384 and SHA512 hash algorithms as defined in FIPS 180-2.
<u>subtle</u>	Package subtle implements functions that are often useful in cryptographic code but require careful thought to use correctly.

tls	Package <code>tls</code> partially implements TLS 1.0, as specified in RFC 2246.
x509	Package <code>x509</code> parses X.509-encoded keys and certificates.
pkix	Package <code>pkix</code> contains shared, low level structures used for ASN.1 parsing and serialization of X.509 certificates, CRL and OCSP.
database	
sql	Package <code>sql</code> provides a generic interface around SQL (or SQL-like) databases.
driver	Package <code>driver</code> defines interfaces to be implemented by database drivers as used by package <code>sql</code> .
debug	
dwarf	Package <code>dwarf</code> provides access to DWARF debugging information loaded from executable files, as defined in the DWARF 2.0 Standard at http://dwarfstd.org/doc/dwarf-2.0.0.pdf
elf	Package <code>elf</code> implements access to ELF object files.
gosym	Package <code>gosym</code> implements access to the Go symbol and line number tables embedded in Go binaries generated by the <code>gc</code> compilers.
macho	Package <code>macho</code> implements access to Mach-O object files.
pe	Package <code>pe</code> implements access to PE (Microsoft Windows Portable Executable) files.
encoding	
ascii85	Package <code>ascii85</code> implements the <code>ascii85</code> data encoding as used in the <code>btoa</code> tool and Adobe's PostScript and PDF document formats.
asn1	Package <code>asn1</code> implements parsing of DER-encoded ASN.1 data structures, as defined in ITU-T Rec X.690.
base32	Package <code>base32</code> implements <code>base32</code> encoding as specified by RFC 4648.
base64	Package <code>base64</code> implements <code>base64</code> encoding as specified by RFC 4648.
binary	Package <code>binary</code> implements translation between numbers and byte sequences and encoding and decoding of varints.

<u>csv</u>	Package csv reads and writes comma-separated values (CSV) files.
<u>gob</u>	Package gob manages streams of gobs - binary values exchanged between an Encoder (transmitter) and a Decoder (receiver).
<u>hex</u>	Package hex implements hexadecimal encoding and decoding.
<u>json</u>	Package json implements encoding and decoding of JSON objects as defined in RFC 4627.
<u>pem</u>	Package pem implements the PEM data encoding, which originated in Privacy Enhanced Mail.
<u>xml</u>	Package xml implements a simple XML 1.0 parser that understands XML name spaces.
<u>errors</u>	Package errors implements functions to manipulate errors.
<u>expvar</u>	Package expvar provides a standardized interface to public variables, such as operation counters in servers.
<u>flag</u>	Package flag implements command-line flag parsing.
<u>fmt</u>	Package fmt implements formatted I/O with functions analogous to C's printf and scanf.
<u>go</u>	
<u>ast</u>	Package ast declares the types used to represent syntax trees for Go packages.
<u>build</u>	Package build gathers information about Go packages.
<u>doc</u>	Package doc extracts source code documentation from a Go AST.
<u>parser</u>	Package parser implements a parser for Go source files.
<u>printer</u>	Package printer implements printing of AST nodes.
<u>scanner</u>	Package scanner implements a scanner for Go source text.
<u>token</u>	Package token defines constants representing the lexical tokens of the Go programming language and basic operations on tokens (printing, predicates).
<u>hash</u>	Package hash provides interfaces for hash functions.
<u>adler32</u>	Package adler32 implements the Adler-32 checksum.
<u>crc32</u>	Package crc32 implements the 32-bit cyclic redundancy check, or CRC-32, checksum.
	Package crc64 implements the 64-bit cyclic redundancy

crc64	check, or CRC-64, checksum.
fnv	Package fnv implements FNV-1 and FNV-1a, non-cryptographic hash functions created by Glenn Fowler, Landon Curt Noll, and Phong Vo.
html	Package html provides functions for escaping and unescaping HTML text.
template	Package template (html/template) implements data-driven templates for generating HTML output safe against code injection.
image	Package image implements a basic 2-D image library.
color	Package color implements a basic color library.
draw	Package draw provides image composition functions.
gif	Package gif implements a GIF image decoder.
jpeg	Package jpeg implements a JPEG image decoder and encoder.
png	Package png implements a PNG image decoder and encoder.
index	
suffixarray	Package suffixarray implements substring search in logarithmic time using an in-memory suffix array.
io	Package io provides basic interfaces to I/O primitives.
ioutil	Package ioutil implements some I/O utility functions.
log	Package log implements a simple logging package.
syslog	Package syslog provides a simple interface to the system log service.
math	Package math provides basic constants and mathematical functions.
big	Package big implements multi-precision arithmetic (big numbers).
cmplx	Package cmplx provides basic constants and mathematical functions for complex numbers.
rand	Package rand implements pseudo-random number generators.
mime	Package mime implements parts of the MIME spec.
multipart	Package multipart implements MIME multipart parsing, as defined in RFC 2046.
	Package net provides a portable interface for network I/O,

[net](#) including TCP/IP, UDP, domain name resolution, and Unix domain sockets.

[http](#) Package http provides HTTP client and server implementations.

[cgi](#) Package cgi implements CGI (Common Gateway Interface) as specified in RFC 3875.

[fcgi](#) Package fcgi implements the FastCGI protocol.

[httpstest](#) Package httpstest provides utilities for HTTP testing.

[httputil](#) Package httputil provides HTTP utility functions, complementing the more common ones in the net/http package.

[pprof](#) Package pprof serves via its HTTP server runtime profiling data in the format expected by the pprof visualization tool.

[mail](#) Package mail implements parsing of mail messages.

[rpc](#) Package rpc provides access to the exported methods of an object across a network or other I/O connection.

[jsonrpc](#) Package jsonrpc implements a JSON-RPC ClientCodec and ServerCodec for the rpc package.

[smtp](#) Package smtp implements the Simple Mail Transfer Protocol as defined in RFC 5321.

[textproto](#) Package textproto implements generic support for text-based request/response protocols in the style of HTTP, NNTP, and SMTP.

[url](#) Package url parses URLs and implements query escaping.

[os](#) Package os provides a platform-independent interface to operating system functionality.

[exec](#) Package exec runs external commands.

[signal](#) Package signal implements access to incoming signals.

[user](#) Package user allows user account lookups by name or id.

[path](#) Package path implements utility routines for manipulating slash-separated paths.

[filepath](#) Package filepath implements utility routines for manipulating filename paths in a way compatible with the target operating system-defined file paths.

[reflect](#) Package reflect implements run-time reflection, allowing a

program to manipulate objects with arbitrary types.

[regexp](#)

Package regexp implements regular expression search.

[syntax](#)

Package syntax parses regular expressions into parse trees and compiles parse trees into programs.

[runtime](#)

Package runtime contains operations that interact with Go's runtime system, such as functions to control goroutines.

[cgo](#)

Package cgo contains runtime support for code generated by the cgo tool.

[debug](#)

Package debug contains facilities for programs to debug themselves while they are running.

[pprof](#)

Package pprof writes runtime profiling data in the format expected by the pprof visualization tool.

[sort](#)

Package sort provides primitives for sorting slices and user-defined collections.

[strconv](#)

Package strconv implements conversions to and from string representations of basic data types.

[strings](#)

Package strings implements simple functions to manipulate strings.

[sync](#)

Package sync provides basic synchronization primitives such as mutual exclusion locks.

[atomic](#)

Package atomic provides low-level atomic memory primitives useful for implementing synchronization algorithms.

[syscall](#)

Package syscall contains an interface to the low-level operating system primitives.

[testing](#)

Package testing provides support for automated testing of Go packages.

[iotest](#)

Package iotest implements Readers and Writers useful mainly for testing.

[quick](#)

Package quick implements utility functions to help with black box testing.

[text](#)

[scanner](#)

Package scanner provides a scanner and tokenizer for UTF-8-encoded text.

[tabwriter](#)

Package tabwriter implements a write filter (tabwriter.Writer) that translates tabbed columns in input into properly aligned

	text.
template	Package template implements data-driven templates for generating textual output.
parse	Package parse builds parse trees for templates as defined by text/template and html/template.
time	Package time provides functionality for measuring and displaying time.
unicode	Package unicode provides data and functions to test some properties of Unicode code points.
utf16	Package utf16 implements encoding and decoding of UTF-16 sequences.
utf8	Package utf8 implements functions and constants to support text encoded in UTF-8.
unsafe	Package unsafe contains operations that step around the type safety of Go programs.

Package tar

```
import "archive/tar"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package tar implements access to tar archives. It aims to cover most of the variations, including those produced by GNU and BSD tars.

    TypeDir         = '5'    // directory  
    TypeFifo        = '6'    // fifo node  
    TypeCont        = '7'    // reserved  
    TypeXHeader     = 'x'    // extended header  
    TypeXGlobalHeader = 'g'  // global extended header  
)
```

Variables

```
var (  
    ErrWriteTooLong      = errors.New("archive/tar: write too long")  
    ErrFieldTooLong      = errors.New("archive/tar: header field too l  
    ErrWriteAfterClose = errors.New("archive/tar: write after close"  
)
```

```
var (  
    ErrHeader = errors.New("archive/tar: invalid tar header")  
)
```

type [Header](#)

```
type Header struct {
    Name      string // name of header file entry
    Mode      int64  // permission and mode bits
    Uid       int    // user id of owner
    Gid       int    // group id of owner
    Size      int64  // length in bytes
    ModTime   time.Time // modified time
    Typeflag  byte   // type of header entry
    Linkname  string // target name of link
    Uname     string // user name of owner
    Gname     string // group name of owner
    Devmajor  int64  // major number of character or block device
    Devminor  int64  // minor number of character or block device
    AccessTime time.Time // access time
    ChangeTime time.Time // status change time
}
```

A Header represents a single header in a tar archive. Some fields may not be populated.

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

A Reader provides sequential access to the contents of a tar archive. A tar archive consists of a sequence of files. The Next method advances to the next file in the archive (including the first), and then it can be treated as an io.Reader to access the file's data.

Example:

```
tr := tar.NewReader(r)  
for {  
    hdr, err := tr.Next()  
    if err == io.EOF {  
        // end of tar archive  
        break  
    }  
    if err != nil {  
        // handle error  
    }  
    io.Copy(data, tr)  
}
```

func [NewReader](#)

```
func NewReader(r io.Reader) *Reader
```

NewReader creates a new Reader reading from r.

func (*Reader) [Next](#)

```
func (tr *Reader) Next() (*Header, error)
```

Next advances to the next entry in the tar archive.

func (*Reader) [Read](#)

```
func (tr *Reader) Read(b []byte) (n int, err error)
```

Read reads from the current entry in the tar archive. It returns 0, io.EOF when it reaches the end of that entry, until Next is called to advance to the next entry.

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A `Writer` provides sequential writing of a tar archive in POSIX.1 format. A tar archive consists of a sequence of files. Call `WriteHeader` to begin a new file, and then call `Write` to supply that file's data, writing at most `hdr.Size` bytes in total.

Example:

```
tw := tar.NewWriter(w)  
hdr := new(Header)  
hdr.Size = length of data in bytes  
// populate other hdr fields as desired  
if err := tw.WriteHeader(hdr); err != nil {  
    // handle error  
}  
io.Copy(tw, data)  
tw.Close()
```

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

`NewWriter` creates a new `Writer` writing to `w`.

func ([*Writer](#)) [Close](#)

```
func (tw *Writer) Close() error
```

`Close` closes the tar archive, flushing any unwritten data to the underlying writer.

func ([*Writer](#)) [Flush](#)

```
func (tw *Writer) Flush() error
```

`Flush` finishes writing the current file (optional).

func ([*Writer](#)) [Write](#)

```
func (tw *Writer) Write(b []byte) (n int, err error)
```

Write writes to the current entry in the tar archive. Write returns the error ErrWriteTooLong if more than hdr.Size bytes are written after WriteHeader.

func (*Writer) [WriteHeader](#)

```
func (tw *Writer) WriteHeader(hdr *Header) error
```

WriteHeader writes hdr and prepares to accept the file's contents. WriteHeader calls Flush if it is not the first header. Calling after a Close will return ErrWriteAfterClose.

Build version go1.0.1.

Examples

[Reader](#)

[Writer](#)

Package files

[reader.go](#) [struct.go](#) [writer.go](#)

Constants

```
const (  
    Store    uint16 = 0  
    Deflate  uint16 = 8  
)
```

Compression methods.

Variables

```
var (  
    ErrFormat      = errors.New("zip: not a valid zip file")  
    ErrAlgorithm   = errors.New("zip: unsupported compression algorithm")  
    ErrChecksum    = errors.New("zip: checksum error")  
)
```

type [File](#)

```
type File struct {  
    FileHeader  
    // contains filtered or unexported fields  
}
```

func (*File) [Open](#)

```
func (f *File) Open() (rc io.ReadCloser, err error)
```

Open returns a ReadCloser that provides access to the File's contents. Multiple files may be read concurrently.

type [FileHeader](#)

```
type FileHeader struct {
    Name            string
    CreatorVersion  uint16
    ReaderVersion   uint16
    Flags           uint16
    Method          uint16
    ModifiedTime    uint16 // MS-DOS time
    ModifiedDate    uint16 // MS-DOS date
    CRC32           uint32
    CompressedSize  uint32
    UncompressedSize uint32
    Extra           []byte
    ExternalAttrs   uint32 // Meaning depends on CreatorVersion
    Comment         string
}
```

func [FileInfoHeader](#)

```
func FileInfoHeader(fi os.FileInfo) (*FileHeader, error)
```

FileInfoHeader creates a partially-populated FileHeader from an os.FileInfo.

func (*FileHeader) [FileInfo](#)

```
func (h *FileHeader) FileInfo() os.FileInfo
```

FileInfo returns an os.FileInfo for the FileHeader.

func (*FileHeader) [ModTime](#)

```
func (h *FileHeader) ModTime() time.Time
```

ModTime returns the modification time. The resolution is 2s.

func (*FileHeader) [Mode](#)

```
func (h *FileHeader) Mode() (mode os.FileMode)
```

Mode returns the permission and mode bits for the FileHeader.

func (*FileHeader) [SetModTime](#)

```
func (h *FileHeader) SetModTime(t time.Time)
```

SetModTime sets the ModifiedTime and ModifiedDate fields to the given time. The resolution is 2s.

func (*FileHeader) [SetMode](#)

```
func (h *FileHeader) SetMode(mode os.FileMode)
```

SetMode changes the permission and mode bits for the FileHeader.

type [ReadCloser](#)

```
type ReadCloser struct {  
    Reader  
    // contains filtered or unexported fields  
}
```

func [OpenReader](#)

```
func OpenReader(name string) (*ReadCloser, error)
```

OpenReader will open the Zip file specified by name and return a ReadCloser.

func (*ReadCloser) [Close](#)

```
func (rc *ReadCloser) Close() error
```

Close closes the Zip file, rendering it unusable for I/O.

type [Reader](#)

```
type Reader struct {
    File    []*File
    Comment string
    // contains filtered or unexported fields
}
```

? Example

? Example

Code:

```
// Open a zip archive for reading.
r, err := zip.OpenReader("testdata/readme.zip")
if err != nil {
    log.Fatal(err)
}
defer r.Close()

// Iterate through the files in the archive,
// printing some of their contents.
for _, f := range r.File {
    fmt.Printf("Contents of %s:\n", f.Name)
    rc, err := f.Open()
    if err != nil {
        log.Fatal(err)
    }
    _, err = io.CopyN(os.Stdout, rc, 68)
    if err != nil {
        log.Fatal(err)
    }
    rc.Close()
    fmt.Println()
}
```

Output:

```
Contents of README:
This is the source code repository for the Go programming language.
```

func [NewReader](#)

```
func NewReader(r io.ReaderAt, size int64) (*Reader, error)
```

NewReader returns a new Reader reading from r, which is assumed to have the given size in bytes.

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

Writer implements a zip file writer.

? Example

? Example

Code:

```
// Create a buffer to write our archive to.  
buf := new(bytes.Buffer)  
  
// Create a new zip archive.  
w := zip.NewWriter(buf)  
  
// Add some files to the archive.  
var files = []struct {  
    Name, Body string  
}{  
    {"readme.txt", "This archive contains some text files."},  
    {"gopher.txt", "Gopher names:\nGeorge\nGeoffrey\nGonzo"},  
    {"todo.txt", "Get animal handling licence.\nWrite more examples."  
}  
for _, file := range files {  
    f, err := w.Create(file.Name)  
    if err != nil {  
        log.Fatal(err)  
    }  
    _, err = f.Write([]byte(file.Body))  
    if err != nil {  
        log.Fatal(err)  
    }  
}  
  
// Make sure to check the error on Close.  
err := w.Close()  
if err != nil {  
    log.Fatal(err)  
}
```

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

NewWriter returns a new Writer writing a zip file to w.

func (*Writer) [Close](#)

```
func (w *Writer) Close() error
```

Close finishes writing the zip file by writing the central directory. It does not (and can not) close the underlying writer.

func (*Writer) [Create](#)

```
func (w *Writer) Create(name string) (io.Writer, error)
```

Create adds a file to the zip file using the provided name. It returns a Writer to which the file contents should be written. The file's contents must be written to the io.Writer before the next call to Create, CreateHeader, or Close.

func (*Writer) [CreateHeader](#)

```
func (w *Writer) CreateHeader(fh *FileHeader) (io.Writer, error)
```

CreateHeader adds a file to the zip file using the provided FileHeader for the file metadata. It returns a Writer to which the file contents should be written. The file's contents must be written to the io.Writer before the next call to Create, CreateHeader, or Close.

Build version go1.0.1.

Package bufio

```
import "bufio"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `bufio` implements buffered I/O. It wraps an `io.Reader` or `io.Writer` object, creating another object (Reader or Writer) that also implements the interface but provides buffering and some help for textual I/O.

Package files

bufio.go

Variables

```
var (  
    ErrInvalidUnreadByte = errors.New("bufio: invalid use of UnreadB  
    ErrInvalidUnreadRune = errors.New("bufio: invalid use of UnreadR  
    ErrBufferFull        = errors.New("bufio: buffer full")  
    ErrNegativeCount     = errors.New("bufio: negative count")  
)
```

type [ReadWrite](#)

```
type ReadWriter struct {  
    *Reader  
    *Writer  
}
```

ReadWrite stores pointers to a Reader and a Writer. It implements `io.ReadWriter`.

func [NewReadWrite](#)

```
func NewReadWrite(r *Reader, w *Writer) *ReadWrite
```

NewReadWrite allocates a new ReadWriter that dispatches to r and w.

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

Reader implements buffering for an `io.Reader` object.

func [NewReader](#)

```
func NewReader(rd io.Reader) *Reader
```

`NewReader` returns a new `Reader` whose buffer has the default size.

func [NewReaderSize](#)

```
func NewReaderSize(rd io.Reader, size int) *Reader
```

`NewReaderSize` returns a new `Reader` whose buffer has at least the specified size. If the argument `io.Reader` is already a `Reader` with large enough size, it returns the underlying `Reader`.

func (***Reader**) [Buffered](#)

```
func (b *Reader) Buffered() int
```

`Buffered` returns the number of bytes that can be read from the current buffer.

func (***Reader**) [Peek](#)

```
func (b *Reader) Peek(n int) ([]byte, error)
```

`Peek` returns the next `n` bytes without advancing the reader. The bytes stop being valid at the next read call. If `Peek` returns fewer than `n` bytes, it also returns an error explaining why the read is short. The error is `ErrBufferFull` if `n` is larger than `b`'s buffer size.

func (***Reader**) [Read](#)

```
func (b *Reader) Read(p []byte) (n int, err error)
```

Read reads data into p. It returns the number of bytes read into p. It calls Read at most once on the underlying Reader, hence n may be less than len(p). At EOF, the count will be zero and err will be io.EOF.

func (*Reader) [ReadByte](#)

```
func (b *Reader) ReadByte() (c byte, err error)
```

ReadByte reads and returns a single byte. If no byte is available, returns an error.

func (*Reader) [ReadBytes](#)

```
func (b *Reader) ReadBytes(delim byte) (line []byte, err error)
```

ReadBytes reads until the first occurrence of delim in the input, returning a slice containing the data up to and including the delimiter. If ReadBytes encounters an error before finding a delimiter, it returns the data read before the error and the error itself (often io.EOF). ReadBytes returns err != nil if and only if the returned data does not end in delim.

func (*Reader) [ReadLine](#)

```
func (b *Reader) ReadLine() (line []byte, isPrefix bool, err error)
```

ReadLine tries to return a single line, not including the end-of-line bytes. If the line was too long for the buffer then isPrefix is set and the beginning of the line is returned. The rest of the line will be returned from future calls. isPrefix will be false when returning the last fragment of the line. The returned buffer is only valid until the next call to ReadLine. ReadLine either returns a non-nil line or it returns an error, never both.

func (*Reader) [ReadRune](#)

```
func (b *Reader) ReadRune() (r rune, size int, err error)
```

ReadRune reads a single UTF-8 encoded Unicode character and returns the rune and its size in bytes. If the encoded rune is invalid, it consumes one byte and returns unicode.ReplacementChar (U+FFFD) with a size of 1.

func (*Reader) [ReadSlice](#)

```
func (b *Reader) ReadSlice(delim byte) (line []byte, err error)
```

ReadSlice reads until the first occurrence of delim in the input, returning a slice pointing at the bytes in the buffer. The bytes stop being valid at the next read call. If ReadSlice encounters an error before finding a delimiter, it returns all the data in the buffer and the error itself (often io.EOF). ReadSlice fails with error ErrBufferFull if the buffer fills without a delim. Because the data returned from ReadSlice will be overwritten by the next I/O operation, most clients should use ReadBytes or ReadString instead. ReadSlice returns err != nil if and only if line does not end in delim.

func (*Reader) [ReadString](#)

```
func (b *Reader) ReadString(delim byte) (line string, err error)
```

ReadString reads until the first occurrence of delim in the input, returning a string containing the data up to and including the delimiter. If ReadString encounters an error before finding a delimiter, it returns the data read before the error and the error itself (often io.EOF). ReadString returns err != nil if and only if the returned data does not end in delim.

func (*Reader) [UnreadByte](#)

```
func (b *Reader) UnreadByte() error
```

UnreadByte unreads the last byte. Only the most recently read byte can be unread.

func (*Reader) [UnreadRune](#)

```
func (b *Reader) UnreadRune() error
```

UnreadRune unreads the last rune. If the most recent read operation on the buffer was not a ReadRune, UnreadRune returns an error. (In this regard it is stricter than UnreadByte, which will unread the last byte from any read operation.)

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

Writer implements buffering for an `io.Writer` object. If an error occurs writing to a Writer, no more data will be accepted and all subsequent writes will return the error.

func [NewWriter](#)

```
func NewWriter(wr io.Writer) *Writer
```

NewWriter returns a new Writer whose buffer has the default size.

func [NewWriterSize](#)

```
func NewWriterSize(wr io.Writer, size int) *Writer
```

NewWriterSize returns a new Writer whose buffer has at least the specified size. If the argument `io.Writer` is already a Writer with large enough size, it returns the underlying Writer.

func (***Writer**) [Available](#)

```
func (w *Writer) Available() int
```

Available returns how many bytes are unused in the buffer.

func (***Writer**) [Buffered](#)

```
func (w *Writer) Buffered() int
```

Buffered returns the number of bytes that have been written into the current buffer.

func (***Writer**) [Flush](#)

```
func (b *Writer) Flush() error
```

Flush writes any buffered data to the underlying io.Writer.

func (*Writer) [Write](#)

```
func (b *Writer) Write(p []byte) (nn int, err error)
```

Write writes the contents of p into the buffer. It returns the number of bytes written. If nn < len(p), it also returns an error explaining why the write is short.

func (*Writer) [WriteByte](#)

```
func (b *Writer) WriteByte(c byte) error
```

WriteByte writes a single byte.

func (*Writer) [WriteRune](#)

```
func (b *Writer) WriteRune(r rune) (size int, err error)
```

WriteRune writes a single Unicode code point, returning the number of bytes written and any error.

func (*Writer) [WriteString](#)

```
func (b *Writer) WriteString(s string) (int, error)
```

WriteString writes a string. It returns the number of bytes written. If the count is less than len(s), it also returns an error explaining why the write is short.

Package files

builtin.go

func [append](#)

```
func append(slice []Type, elems ...Type) []Type
```

The `append` built-in function appends elements to the end of a slice. If it has sufficient capacity, the destination is resliced to accommodate the new elements. If it does not, a new underlying array will be allocated. `Append` returns the updated slice. It is therefore necessary to store the result of `append`, often in the variable holding the slice itself:

```
slice = append(slice, elem1, elem2)  
slice = append(slice, anotherSlice...)
```

func [close](#)

```
func close(c chan<- Type)
```

The `close` built-in function closes a channel, which must be either bidirectional or send-only. It should be executed only by the sender, never the receiver, and has the effect of shutting down the channel after the last sent value is received. After the last value has been received from a closed channel `c`, any receive from `c` will succeed without blocking, returning the zero value for the channel element. The form

```
x, ok := <-c
```

will also set `ok` to `false` for a closed channel.

func [delete](#)

```
func delete(m map[Type]Type1, key Type)
```

The delete built-in function deletes the element with the specified key (m[key]) from the map. If there is no such element, delete is a no-op. If m is nil, delete panics.

func [panic](#)

```
func panic(v interface{})
```

The panic built-in function stops normal execution of the current goroutine. When a function F calls panic, normal execution of F stops immediately. Any functions whose execution was deferred by F are run in the usual way, and then F returns to its caller. To the caller G, the invocation of F then behaves like a call to panic, terminating G's execution and running any deferred functions. This continues until all functions in the executing goroutine have stopped, in reverse order. At that point, the program is terminated and the error condition is reported, including the value of the argument to panic. This termination sequence is called panicking and can be controlled by the built-in function recover.

func [recover](#)

```
func recover() interface{}
```

The `recover` built-in function allows a program to manage behavior of a panicking goroutine. Executing a call to `recover` inside a deferred function (but not any function called by it) stops the panicking sequence by restoring normal execution and retrieves the error value passed to the call of `panic`. If `recover` is called outside the deferred function it will not stop a panicking sequence. In this case, or when the goroutine is not panicking, or if the argument supplied to `panic` was `nil`, `recover` returns `nil`. Thus the return value from `recover` reports whether the goroutine is panicking.

type [ComplexType](#)

```
type ComplexType complex64
```

ComplexType is here for the purposes of documentation only. It is a stand-in for either complex type: complex64 or complex128.

func [complex](#)

```
func complex(r, i FloatType) ComplexType
```

The complex built-in function constructs a complex value from two floating-point values. The real and imaginary parts must be of the same size, either float32 or float64 (or assignable to them), and the return value will be the corresponding complex type (complex64 for float32, complex128 for float64).

type [FloatType](#)

```
type FloatType float32
```

FloatType is here for the purposes of documentation only. It is a stand-in for either float type: float32 or float64.

func [imag](#)

```
func imag(c ComplexType) FloatType
```

The imag built-in function returns the imaginary part of the complex number c. The return value will be floating point type corresponding to the type of c.

func [real](#)

```
func real(c ComplexType) FloatType
```

The real built-in function returns the real part of the complex number c. The return value will be floating point type corresponding to the type of c.

type [IntegerType](#)

```
type IntegerType int
```

IntegerType is here for the purposes of documentation only. It is a stand-in for any integer type: int, uint, int8 etc.

type [Type](#)

```
type Type int
```

Type is here for the purposes of documentation only. It is a stand-in for any Go type, but represents the same type for any given function invocation.

func [make](#)

```
func make(Type, size IntegerType) Type
```

The make built-in function allocates and initializes an object of type slice, map, or chan (only). Like new, the first argument is a type, not a value. Unlike new, make's return type is the same as the type of its argument, not a pointer to it. The specification of the result depends on the type:

Slice: The size specifies the length. The capacity of the slice is equal to its length. A second integer argument may be provided to specify a different capacity; it must be no smaller than the length, so `make([]int, 0, 10)` allocates a slice of length 0 and capacity 10.

Map: An initial allocation is made according to the size but the resulting map has length 0. The size may be omitted, in which case a small starting size is allocated.

Channel: The channel's buffer is initialized with the specified buffer capacity. If zero, or the size is omitted, the channel is unbuffered.

func [new](#)

```
func new(Type) *Type
```

The new built-in function allocates memory. The first argument is a type, not a value, and the value returned is a pointer to a newly allocated zero value of that type.

type [Type1](#)

```
type Type1 int
```

Type1 is here for the purposes of documentation only. It is a stand-in for any Go type, but represents the same type for any given function invocation.

type [bool](#)

```
type bool bool
```

bool is the set of boolean values, true and false.

type [byte](#)

type byte byte

byte is an alias for uint8 and is equivalent to uint8 in all ways. It is used, by convention, to distinguish byte values from 8-bit unsigned integer values.

type [complex128](#)

type complex128 complex128

complex128 is the set of all complex numbers with float64 real and imaginary parts.

type [complex64](#)

```
type complex64 complex64
```

complex64 is the set of all complex numbers with float32 real and imaginary parts.

type [error](#)

```
type error interface {  
    Error() string  
}
```

The error built-in interface type is the conventional interface for representing an error condition, with the nil value representing no error.

type [float32](#)

type float32 float32

float32 is the set of all IEEE-754 32-bit floating-point numbers.

type [float64](#)

type float64 float64

float64 is the set of all IEEE-754 64-bit floating-point numbers.

type [int](#)

```
type int int
```

int is a signed integer type that is at least 32 bits in size. It is a distinct type, however, and not an alias for, say, int32.

func [cap](#)

```
func cap(v Type) int
```

The cap built-in function returns the capacity of v, according to its type:

Array: the number of elements in v (same as len(v)).
Pointer to array: the number of elements in *v (same as len(v)).
Slice: the maximum length the slice can reach when resliced;
if v is nil, cap(v) is zero.
Channel: the channel buffer capacity, in units of elements;
if v is nil, cap(v) is zero.

func [copy](#)

```
func copy(dst, src []Type) int
```

The copy built-in function copies elements from a source slice into a destination slice. (As a special case, it also will copy bytes from a string to a slice of bytes.) The source and destination may overlap. Copy returns the number of elements copied, which will be the minimum of len(src) and len(dst).

func [len](#)

```
func len(v Type) int
```

The len built-in function returns the length of v, according to its type:

Array: the number of elements in v.
Pointer to array: the number of elements in *v (even if v is nil).
Slice, or map: the number of elements in v; if v is nil, len(v) is zero.
String: the number of bytes in v.
Channel: the number of elements queued (unread) in the channel buffer;
if v is nil, len(v) is zero.

type [int16](#)

```
type int16 int16
```

int16 is the set of all signed 16-bit integers. Range: -32768 through 32767.

type [int32](#)

```
type int32 int32
```

int32 is the set of all signed 32-bit integers. Range: -2147483648 through 2147483647.

type [int64](#)

```
type int64 int64
```

int64 is the set of all signed 64-bit integers. Range: -9223372036854775808 through 9223372036854775807.

type [int8](#)

```
type int8 int8
```

int8 is the set of all signed 8-bit integers. Range: -128 through 127.

type [rune](#)

```
type rune rune
```

rune is an alias for int and is equivalent to int in all ways. It is used, by convention, to distinguish character values from integer values. In a future version of Go, it will change to an alias of int32.

type [string](#)

```
type string string
```

string is the set of all strings of 8-bit bytes, conventionally but not necessarily representing UTF-8-encoded text. A string may be empty, but not nil. Values of string type are immutable.

type [uint](#)

```
type uint uint
```

uint is an unsigned integer type that is at least 32 bits in size. It is a distinct type, however, and not an alias for, say, uint32.

type [uint16](#)

type uint16 uint16

uint16 is the set of all unsigned 16-bit integers. Range: 0 through 65535.

type [uint32](#)

type uint32 uint32

uint32 is the set of all unsigned 32-bit integers. Range: 0 through 4294967295.

type [uint64](#)

type uint64 uint64

uint64 is the set of all unsigned 64-bit integers. Range: 0 through 18446744073709551615.

type [uint8](#)

```
type uint8 uint8
```

uint8 is the set of all unsigned 8-bit integers. Range: 0 through 255.

type [uintptr](#)

```
type uintptr uintptr
```

uintptr is an integer type that is large enough to hold the bit pattern of any pointer.

Build version go1.0.1.

Package bytes

```
import "bytes"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package bytes implements functions for the manipulation of byte slices. It is analogous to the facilities of the strings package.

[Bugs](#)

Examples

[Buffer](#)

[Buffer \(Reader\)](#)

Package files

[buffer.go](#) [bytes.go](#) [bytes_decl.go](#) [reader.go](#)

Constants

```
const MinRead = 512
```

MinRead is the minimum slice size passed to a Read call by Buffer.ReadFrom. As long as the Buffer has at least MinRead bytes beyond what is required to hold the contents of r, ReadFrom will not grow the underlying buffer.

Variables

```
var ErrTooLarge = errors.New("bytes.Buffer: too large")
```

ErrTooLarge is passed to panic if memory cannot be allocated to store data in a buffer.

func Compare

```
func Compare(a, b []byte) int
```

Compare returns an integer comparing the two byte arrays lexicographically. The result will be 0 if $a==b$, -1 if $a < b$, and +1 if $a > b$. A nil argument is equivalent to an empty slice.

func Contains

```
func Contains(b, subslice []byte) bool
```

Contains returns whether subslice is within b.

func Count

```
func Count(s, sep []byte) int
```

Count counts the number of non-overlapping instances of sep in s.

func Equal

```
func Equal(a, b []byte) bool
```

Equal returns a boolean reporting whether `a == b`. A nil argument is equivalent to an empty slice.

func [EqualFold](#)

```
func EqualFold(s, t []byte) bool
```

EqualFold reports whether s and t, interpreted as UTF-8 strings, are equal under Unicode case-folding.

func [Fields](#)

```
func Fields(s []byte) [][]byte
```

Fields splits the array `s` around each instance of one or more consecutive white space characters, returning a slice of subarrays of `s` or an empty list if `s` contains only white space.

func [FieldsFunc](#)

```
func FieldsFunc(s []byte, f func(rune) bool) [][]byte
```

FieldsFunc interprets `s` as a sequence of UTF-8-encoded Unicode code points. It splits the array `s` at each run of code points `c` satisfying `f(c)` and returns a slice of subarrays of `s`. If no code points in `s` satisfy `f(c)`, an empty slice is returned.

func [HasPrefix](#)

```
func HasPrefix(s, prefix []byte) bool
```

HasPrefix tests whether the byte array `s` begins with `prefix`.

func [HasSuffix](#)

```
func HasSuffix(s, suffix []byte) bool
```

HasSuffix tests whether the byte array s ends with suffix.

func [Index](#)

```
func Index(s, sep []byte) int
```

Index returns the index of the first instance of sep in s, or -1 if sep is not present in s.

func [IndexAny](#)

```
func IndexAny(s []byte, chars string) int
```

IndexAny interprets s as a sequence of UTF-8-encoded Unicode code points. It returns the byte index of the first occurrence in s of any of the Unicode code points in chars. It returns -1 if chars is empty or if there is no code point in common.

func IndexByte

```
func IndexByte(s []byte, c byte) int
```

IndexByte returns the index of the first instance of c in s, or -1 if c is not present in s.

func [IndexFunc](#)

```
func IndexFunc(s []byte, f func(r rune) bool) int
```

IndexFunc interprets s as a sequence of UTF-8-encoded Unicode code points. It returns the byte index in s of the first Unicode code point satisfying f(c), or -1 if none do.

func [IndexRune](#)

```
func IndexRune(s []byte, r rune) int
```

IndexRune interprets s as a sequence of UTF-8-encoded Unicode code points. It returns the byte index of the first occurrence in s of the given rune. It returns -1 if rune is not present in s.

func [Join](#)

```
func Join(a [][]byte, sep []byte) []byte
```

Join concatenates the elements of a to create a single byte array. The separator sep is placed between elements in the resulting array.

func LastIndex

```
func LastIndex(s, sep []byte) int
```

LastIndex returns the index of the last instance of sep in s, or -1 if sep is not present in s.

func [LastIndexAny](#)

```
func LastIndexAny(s []byte, chars string) int
```

LastIndexAny interprets s as a sequence of UTF-8-encoded Unicode code points. It returns the byte index of the last occurrence in s of any of the Unicode code points in chars. It returns -1 if chars is empty or if there is no code point in common.

func [LastIndexFunc](#)

```
func LastIndexFunc(s []byte, f func(r rune) bool) int
```

LastIndexFunc interprets s as a sequence of UTF-8-encoded Unicode code points. It returns the byte index in s of the last Unicode code point satisfying f(c), or -1 if none do.

func [Map](#)

```
func Map(mapping func(r rune) rune, s []byte) []byte
```

Map returns a copy of the byte array `s` with all its characters modified according to the mapping function. If mapping returns a negative value, the character is dropped from the string with no replacement. The characters in `s` and the output are interpreted as UTF-8-encoded Unicode code points.

func Repeat

```
func Repeat(b []byte, count int) []byte
```

Repeat returns a new byte slice consisting of count copies of b.

func [Replace](#)

```
func Replace(s, old, new []byte, n int) []byte
```

Replace returns a copy of the slice `s` with the first `n` non-overlapping instances of `old` replaced by `new`. If `n < 0`, there is no limit on the number of replacements.

func [Runes](#)

```
func Runes(s []byte) []rune
```

Runes returns a slice of runes (Unicode code points) equivalent to s.

func [Split](#)

```
func Split(s, sep []byte) [][]byte
```

Split slices `s` into all subslices separated by `sep` and returns a slice of the subslices between those separators. If `sep` is empty, Split splits after each UTF-8 sequence. It is equivalent to `SplitN` with a count of `-1`.

func [SplitAfter](#)

```
func SplitAfter(s, sep []byte) [][]byte
```

SplitAfter slices `s` into all subslices after each instance of `sep` and returns a slice of those subslices. If `sep` is empty, SplitAfter splits after each UTF-8 sequence. It is equivalent to SplitAfterN with a count of -1.

func [SplitAfterN](#)

```
func SplitAfterN(s, sep []byte, n int) [][]byte
```

SplitAfterN slices s into subslices after each instance of sep and returns a slice of those subslices. If sep is empty, SplitAfterN splits after each UTF-8 sequence.

The count determines the number of subslices to return:

n > 0: at most n subslices; the last subslice will be the unsplit re

n == 0: the result is nil (zero subslices)

n < 0: all subslices

func [SplitN](#)

```
func SplitN(s, sep []byte, n int) [][]byte
```

SplitN slices `s` into subslices separated by `sep` and returns a slice of the subslices between those separators. If `sep` is empty, SplitN splits after each UTF-8 sequence. The count determines the number of subslices to return:

```
n > 0: at most n subslices; the last subslice will be the unsplit re  
n == 0: the result is nil (zero subslices)  
n < 0: all subslices
```

func [Title](#)

```
func Title(s []byte) []byte
```

Title returns a copy of s with all Unicode letters that begin words mapped to their title case.

func ToLower

```
func ToLower(s []byte) []byte
```

ToUpper returns a copy of the byte array s with all Unicode letters mapped to their lower case.

func [ToLowerSpecial](#)

```
func ToLowerSpecial(_case unicode.SpecialCase, s []byte) []byte
```

ToLowerSpecial returns a copy of the byte array `s` with all Unicode letters mapped to their lower case, giving priority to the special casing rules.

func [ToTitle](#)

```
func ToTitle(s []byte) []byte
```

ToTitle returns a copy of the byte array s with all Unicode letters mapped to their title case.

func [ToTitleSpecial](#)

```
func ToTitleSpecial(_case unicode.SpecialCase, s []byte) []byte
```

ToTitleSpecial returns a copy of the byte array `s` with all Unicode letters mapped to their title case, giving priority to the special casing rules.

func ToUpper

```
func ToUpper(s []byte) []byte
```

ToUpper returns a copy of the byte array s with all Unicode letters mapped to their upper case.

func [ToUpperSpecial](#)

```
func ToUpperSpecial(_case unicode.SpecialCase, s []byte) []byte
```

ToUpperSpecial returns a copy of the byte array `s` with all Unicode letters mapped to their upper case, giving priority to the special casing rules.

func [Trim](#)

```
func Trim(s []byte, cutset string) []byte
```

Trim returns a subslice of s by slicing off all leading and trailing UTF-8-encoded Unicode code points contained in cutset.

func [TrimFunc](#)

```
func TrimFunc(s []byte, f func(r rune) bool) []byte
```

TrimFunc returns a subslice of s by slicing off all leading and trailing UTF-8-encoded Unicode code points c that satisfy f(c).

func [TrimLeft](#)

```
func TrimLeft(s []byte, cutset string) []byte
```

TrimLeft returns a subslice of s by slicing off all leading UTF-8-encoded Unicode code points contained in cutset.

func [TrimLeftFunc](#)

```
func TrimLeftFunc(s []byte, f func(r rune) bool) []byte
```

TrimLeftFunc returns a subslice of s by slicing off all leading UTF-8-encoded Unicode code points c that satisfy f(c).

func [TrimRight](#)

```
func TrimRight(s []byte, cutset string) []byte
```

TrimRight returns a subslice of s by slicing off all trailing UTF-8-encoded Unicode code points that are contained in cutset.

func [TrimRightFunc](#)

```
func TrimRightFunc(s []byte, f func(r rune) bool) []byte
```

TrimRightFunc returns a subslice of s by slicing off all trailing UTF-8 encoded Unicode code points c that satisfy f(c).

func [TrimSpace](#)

```
func TrimSpace(s []byte) []byte
```

TrimSpace returns a subslice of s by slicing off all leading and trailing white space, as defined by Unicode.

type [Buffer](#)

```
type Buffer struct {  
    // contains filtered or unexported fields  
}
```

A Buffer is a variable-sized buffer of bytes with Read and Write methods. The zero value for Buffer is an empty buffer ready to use.

? Example

? Example

Code:

```
var b Buffer // A Buffer needs no initialization.  
b.Write([]byte("Hello "))  
b.Write([]byte("world!"))  
b.WriteTo(os.Stdout)
```

Output:

Hello world!

? Example (Reader)

? Example (Reader)

Code:

```
// A Buffer can turn a string or a []byte into an io.Reader.  
buf := NewBufferString("R29waGVycyBydWxlIQ==")  
dec := base64.NewDecoder(base64.StdEncoding, buf)  
io.Copy(os.Stdout, dec)
```

Output:

Gophers rule!

func [NewBuffer](#)

```
func NewBuffer(buf []byte) *Buffer
```

NewBuffer creates and initializes a new Buffer using buf as its initial contents. It is intended to prepare a Buffer to read existing data. It can also be used to size the internal buffer for writing. To do that, buf should have the desired capacity but a length of zero.

In most cases, new(Buffer) (or just declaring a Buffer variable) is sufficient to initialize a Buffer.

func [NewBufferString](#)

```
func NewBufferString(s string) *Buffer
```

NewBufferString creates and initializes a new Buffer using string s as its initial contents. It is intended to prepare a buffer to read an existing string.

In most cases, new(Buffer) (or just declaring a Buffer variable) is sufficient to initialize a Buffer.

func (***Buffer**) [Bytes](#)

```
func (b *Buffer) Bytes() []byte
```

Bytes returns a slice of the contents of the unread portion of the buffer; len(b.Bytes()) == b.Len(). If the caller changes the contents of the returned slice, the contents of the buffer will change provided there are no intervening method calls on the Buffer.

func (***Buffer**) [Len](#)

```
func (b *Buffer) Len() int
```

Len returns the number of bytes of the unread portion of the buffer; b.Len() == len(b.Bytes()).

func (***Buffer**) [Next](#)

```
func (b *Buffer) Next(n int) []byte
```

Next returns a slice containing the next n bytes from the buffer, advancing the buffer as if the bytes had been returned by Read. If there are fewer than n bytes

in the buffer, Next returns the entire buffer. The slice is only valid until the next call to a read or write method.

func (*Buffer) [Read](#)

```
func (b *Buffer) Read(p []byte) (n int, err error)
```

Read reads the next len(p) bytes from the buffer or until the buffer is drained. The return value n is the number of bytes read. If the buffer has no data to return, err is io.EOF (unless len(p) is zero); otherwise it is nil.

func (*Buffer) [ReadByte](#)

```
func (b *Buffer) ReadByte() (c byte, err error)
```

ReadByte reads and returns the next byte from the buffer. If no byte is available, it returns error io.EOF.

func (*Buffer) [ReadBytes](#)

```
func (b *Buffer) ReadBytes(delim byte) (line []byte, err error)
```

ReadBytes reads until the first occurrence of delim in the input, returning a slice containing the data up to and including the delimiter. If ReadBytes encounters an error before finding a delimiter, it returns the data read before the error and the error itself (often io.EOF). ReadBytes returns err != nil if and only if the returned data does not end in delim.

func (*Buffer) [ReadFrom](#)

```
func (b *Buffer) ReadFrom(r io.Reader) (n int64, err error)
```

ReadFrom reads data from r until EOF and appends it to the buffer. The return value n is the number of bytes read. Any error except io.EOF encountered during the read is also returned. If the buffer becomes too large, ReadFrom will panic with ErrTooLarge.

func (*Buffer) [ReadRune](#)

```
func (b *Buffer) ReadRune() (r rune, size int, err error)
```

ReadRune reads and returns the next UTF-8-encoded Unicode code point from the buffer. If no bytes are available, the error returned is io.EOF. If the bytes are an erroneous UTF-8 encoding, it consumes one byte and returns U+FFFD, 1.

func (*Buffer) [ReadString](#)

```
func (b *Buffer) ReadString(delim byte) (line string, err error)
```

ReadString reads until the first occurrence of delim in the input, returning a string containing the data up to and including the delimiter. If ReadString encounters an error before finding a delimiter, it returns the data read before the error and the error itself (often io.EOF). ReadString returns err != nil if and only if the returned data does not end in delim.

func (*Buffer) [Reset](#)

```
func (b *Buffer) Reset()
```

Reset resets the buffer so it has no content. b.Reset() is the same as b.Truncate(0).

func (*Buffer) [String](#)

```
func (b *Buffer) String() string
```

String returns the contents of the unread portion of the buffer as a string. If the Buffer is a nil pointer, it returns "<nil>".

func (*Buffer) [Truncate](#)

```
func (b *Buffer) Truncate(n int)
```

Truncate discards all but the first n unread bytes from the buffer. It panics if n is negative or greater than the length of the buffer.

func (*Buffer) [UnreadByte](#)

```
func (b *Buffer) UnreadByte() error
```

UnreadByte unreads the last byte returned by the most recent read operation. If

write has happened since the last read, `UnreadByte` returns an error.

func (*Buffer) [UnreadRune](#)

```
func (b *Buffer) UnreadRune() error
```

`UnreadRune` unread the last rune returned by `ReadRune`. If the most recent read or write operation on the buffer was not a `ReadRune`, `UnreadRune` returns an error. (In this regard it is stricter than `UnreadByte`, which will unread the last byte from any read operation.)

func (*Buffer) [Write](#)

```
func (b *Buffer) Write(p []byte) (n int, err error)
```

`Write` appends the contents of `p` to the buffer. The return value `n` is the length of `p`; `err` is always `nil`. If the buffer becomes too large, `Write` will panic with `ErrTooLarge`.

func (*Buffer) [WriteByte](#)

```
func (b *Buffer) WriteByte(c byte) error
```

`WriteByte` appends the byte `c` to the buffer. The returned error is always `nil`, but is included to match `bufio.Writer's WriteByte`. If the buffer becomes too large, `WriteByte` will panic with `ErrTooLarge`.

func (*Buffer) [WriteRune](#)

```
func (b *Buffer) WriteRune(r rune) (n int, err error)
```

`WriteRune` appends the UTF-8 encoding of Unicode code point `r` to the buffer, returning its length and an error, which is always `nil` but is included to match `bufio.Writer's WriteRune`. If the buffer becomes too large, `WriteRune` will panic with `ErrTooLarge`.

func (*Buffer) [WriteString](#)

```
func (b *Buffer) WriteString(s string) (n int, err error)
```

WriteString appends the contents of s to the buffer. The return value n is the length of s; err is always nil. If the buffer becomes too large, WriteString will panic with ErrTooLarge.

func (*Buffer) [WriteTo](#)

```
func (b *Buffer) WriteTo(w io.Writer) (n int64, err error)
```

WriteTo writes data to w until the buffer is drained or an error occurs. The return value n is the number of bytes written; it always fits into an int, but it is int64 to match the io.WriterTo interface. Any error encountered during the write is also returned.

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

A Reader implements the `io.Reader`, `io.ReaderAt`, `io.Seeker`, `io.ByteScanner`, and `io.RuneScanner` interfaces by reading from a byte slice. Unlike a Buffer, a Reader is read-only and supports seeking.

func [NewReader](#)

```
func NewReader(b []byte) *Reader
```

NewReader returns a new Reader reading from b.

func (***Reader**) [Len](#)

```
func (r *Reader) Len() int
```

Len returns the number of bytes of the unread portion of the slice.

func (***Reader**) [Read](#)

```
func (r *Reader) Read(b []byte) (n int, err error)
```

func (***Reader**) [ReadAt](#)

```
func (r *Reader) ReadAt(b []byte, off int64) (n int, err error)
```

func (***Reader**) [ReadByte](#)

```
func (r *Reader) ReadByte() (b byte, err error)
```

func (***Reader**) [ReadRune](#)

```
func (r *Reader) ReadRune() (ch rune, size int, err error)
```

func (***Reader**) [Seek](#)

```
func (r *Reader) Seek(offset int64, whence int) (int64, error)
```

Seek implements the io.Seeker interface.

func (*Reader) [UnreadByte](#)

```
func (r *Reader) UnreadByte() error
```

func (*Reader) [UnreadRune](#)

```
func (r *Reader) UnreadRune() error
```

Bugs

The rule Title uses for word boundaries does not handle Unicode punctuation properly.

Constants

```
const (  
    NoCompression = 0  
    BestSpeed     = 1  
  
    BestCompression = 9  
    DefaultCompression = -1  
)
```

func [NewReader](#)

```
func NewReader(r io.Reader) io.ReadCloser
```

NewReader returns a new ReadCloser that can be used to read the uncompressed version of r. It is the caller's responsibility to call Close on the ReadCloser when finished reading.

func [NewReaderDict](#)

```
func NewReaderDict(r io.Reader, dict []byte) io.ReadCloser
```

NewReaderDict is like NewReader but initializes the reader with a preset dictionary. The returned Reader behaves as if the uncompressed data stream started with the given dictionary, which has already been read. NewReaderDict is typically used to read data compressed by NewWriterDict.

type [CorruptInputError](#)

```
type CorruptInputError int64
```

A `CorruptInputError` reports the presence of corrupt input at a given offset.

func (CorruptInputError) [Error](#)

```
func (e CorruptInputError) Error() string
```

type [InternalError](#)

```
type InternalError string
```

An InternalError reports an error in the flate code itself.

func (InternalError) [Error](#)

```
func (e InternalError) Error() string
```

type [ReadError](#)

```
type ReadError struct {  
    Offset int64 // byte offset where error occurred  
    Err     error // error returned by underlying Read  
}
```

A ReadError reports an error encountered while reading input.

func (*ReadError) [Error](#)

```
func (e *ReadError) Error() string
```

type Reader

```
type Reader interface {  
    io.Reader  
    ReadByte() (c byte, err error)  
}
```

The actual read interface needed by NewReader. If the passed in io.Reader does not also have ReadByte, the NewReader will introduce its own buffering.

type [WriteError](#)

```
type WriteError struct {  
    Offset int64 // byte offset where error occurred  
    Err     error // error returned by underlying Write  
}
```

A WriteError reports an error encountered while writing output.

func (*WriteError) [Error](#)

```
func (e *WriteError) Error() string
```

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A `Writer` takes data written to it and writes the compressed form of that data to an underlying writer (see `NewWriter`).

func [NewWriter](#)

```
func NewWriter(w io.Writer, level int) (*Writer, error)
```

`NewWriter` returns a new `Writer` compressing data at the given level. Following `zlib`, levels range from 1 (`BestSpeed`) to 9 (`BestCompression`); higher levels typically run slower but compress more. Level 0 (`NoCompression`) does not attempt any compression; it only adds the necessary DEFLATE framing. Level -1 (`DefaultCompression`) uses the default compression level.

If `level` is in the range `[-1, 9]` then the error returned will be `nil`. Otherwise the error returned will be non-`nil`.

func [NewWriterDict](#)

```
func NewWriterDict(w io.Writer, level int, dict []byte) (*Writer, error)
```

`NewWriterDict` is like `NewWriter` but initializes the new `Writer` with a preset dictionary. The returned `Writer` behaves as if the dictionary had been written to it without producing any compressed output. The compressed data written to `w` can only be decompressed by a `Reader` initialized with the same dictionary.

func (*Writer) [Close](#)

```
func (w *Writer) Close() error
```

`Close` flushes and closes the writer.

func (*Writer) [Flush](#)

```
func (w *Writer) Flush() error
```

Flush flushes any pending compressed data to the underlying writer. It is useful mainly in compressed network protocols, to ensure that a remote reader has enough data to reconstruct a packet. Flush does not return until the data has been written. If the underlying writer returns an error, Flush returns that error.

In the terminology of the zlib library, Flush is equivalent to Z_SYNC_FLUSH.

func (*Writer) [Write](#)

```
func (w *Writer) Write(data []byte) (n int, err error)
```

Write writes data to w, which will eventually write the compressed form of data to its underlying writer.

Build version go1.0.1.

Package gzip

```
import "compress/gzip"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package gzip implements reading and writing of gzip format compressed files, as specified in RFC 1952.

Index

[Constants](#)

[Variables](#)

[type Header](#)

[type Reader](#)

[func NewReader\(r io.Reader\) \(*Reader, error\)](#)

[func \(z *Reader\) Close\(\) error](#)

[func \(z *Reader\) Read\(p \[\]byte\) \(n int, err error\)](#)

[type Writer](#)

[func NewWriter\(w io.Writer\) *Writer](#)

[func NewWriterLevel\(w io.Writer, level int\) \(*Writer, error\)](#)

[func \(z *Writer\) Close\(\) error](#)

[func \(z *Writer\) Write\(p \[\]byte\) \(int, error\)](#)

Package files

[gunzip.go](#) [gzip.go](#)

Constants

```
const (  
    NoCompression      = flate.NoCompression  
    BestSpeed          = flate.BestSpeed  
    BestCompression    = flate.BestCompression  
    DefaultCompression = flate.DefaultCompression  
)
```

These constants are copied from the flate package, so that code that imports "compress/gzip" does not also have to import "compress/flate".

Variables

```
var (  
    // ErrChecksum is returned when reading GZIP data that has an in  
    ErrChecksum = errors.New("gzip: invalid checksum")  
    // ErrHeader is returned when reading GZIP data that has an inva  
    ErrHeader = errors.New("gzip: invalid header")  
)
```

type [Header](#)

```
type Header struct {  
    Comment string    // comment  
    Extra   []byte     // "extra data"  
    ModTime time.Time // modification time  
    Name    string     // file name  
    OS      byte       // operating system type  
}
```

The gzip file stores a header giving metadata about the compressed file. That header is exposed as the fields of the Writer and Reader structs.

type [Reader](#)

```
type Reader struct {
    Header
    // contains filtered or unexported fields
}
```

A Reader is an `io.Reader` that can be read to retrieve uncompressed data from a gzip-format compressed file.

In general, a gzip file can be a concatenation of gzip files, each with its own header. Reads from the Reader return the concatenation of the uncompressed data of each. Only the first header is recorded in the Reader fields.

Gzip files store a length and checksum of the uncompressed data. The Reader will return a `ErrChecksum` when `Read` reaches the end of the uncompressed data if it does not have the expected length or checksum. Clients should treat data returned by `Read` as tentative until they receive the `io.EOF` marking the end of the data.

func [NewReader](#)

```
func NewReader(r io.Reader) (*Reader, error)
```

`NewReader` creates a new Reader reading the given reader. The implementation buffers input and may read more data than necessary from `r`. It is the caller's responsibility to call `Close` on the Reader when done.

func (***Reader**) [Close](#)

```
func (z *Reader) Close() error
```

`Close` closes the Reader. It does not close the underlying `io.Reader`.

func (***Reader**) [Read](#)

```
func (z *Reader) Read(p []byte) (n int, err error)
```

type [Writer](#)

```
type Writer struct {
    Header
    // contains filtered or unexported fields
}
```

A `Writer` is an `io.WriteCloser` that satisfies writes by compressing data written to its wrapped `io.Writer`.

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

`NewWriter` creates a new `Writer` that satisfies writes by compressing data written to `w`.

It is the caller's responsibility to call `Close` on the `WriteCloser` when done. Writes may be buffered and not flushed until `Close`.

Callers that wish to set the fields in `Writer.Header` must do so before the first call to `Write` or `Close`. The `Comment` and `Name` header fields are UTF-8 strings in Go, but the underlying format requires NUL-terminated ISO 8859-1 (Latin-1). NUL or non-Latin-1 runes in those strings will lead to an error on `Write`.

func [NewWriterLevel](#)

```
func NewWriterLevel(w io.Writer, level int) (*Writer, error)
```

`NewWriterLevel` is like `NewWriter` but specifies the compression level instead of assuming `DefaultCompression`.

The compression level can be `DefaultCompression`, `NoCompression`, or any integer value between `BestSpeed` and `BestCompression` inclusive. The error returned will be `nil` if the level is valid.

func (*Writer) [Close](#)

```
func (z *Writer) Close() error
```

Close closes the Writer. It does not close the underlying io.Writer.

func (*Writer) [Write](#)

```
func (z *Writer) Write(p []byte) (int, error)
```

Write writes a compressed form of p to the underlying io.Writer. The compressed bytes are not necessarily flushed until the Writer is closed.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package lzw

```
import "compress/lzw"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package lzw implements the Lempel-Ziv-Welch compressed data format, described in T. A. Welch, "A Technique for High-Performance Data Compression", *Computer*, 17(6) (June 1984), pp 8-19.

In particular, it implements LZW as used by the GIF, TIFF and PDF file formats, which means variable-width codes up to 12 bits and the first two non-literal codes are a clear code and an EOF code.

Index

[func NewReader\(r io.Reader, order Order, litWidth int\) io.ReadCloser](#)
[func NewWriter\(w io.Writer, order Order, litWidth int\) io.WriteCloser](#)
[type Order](#)

Package files

[reader.go](#) [writer.go](#)

func [NewReader](#)

```
func NewReader(r io.Reader, order Order, litWidth int) io.ReadCloser
```

NewReader creates a new `io.ReadCloser` that satisfies reads by decompressing the data read from `r`. It is the caller's responsibility to call `Close` on the `ReadCloser` when finished reading. The number of bits to use for literal codes, `litWidth`, must be in the range `[2,8]` and is typically `8`.

func [NewWriter](#)

```
func NewWriter(w io.Writer, order Order, litWidth int) io.WriteClose
```

NewWriter creates a new io.WriteCloser that satisfies writes by compressing the data and writing it to w. It is the caller's responsibility to call Close on the WriteCloser when finished writing. The number of bits to use for literal codes, litWidth, must be in the range [2,8] and is typically 8.

type [Order](#)

type Order int

Order specifies the bit ordering in an LZW data stream.

```
const (  
    // LSB means Least Significant Bits first, as used in the GIF fi  
    LSB Order = iota  
    // MSB means Most Significant Bits first, as used in the TIFF an  
    // file formats.  
    MSB  
)
```

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package zlib

```
import "compress/zlib"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `zlib` implements reading and writing of `zlib` format compressed data, as specified in RFC 1950.

The implementation provides filters that uncompress during reading and compress during writing. For example, to write compressed data to a buffer:

```
var b bytes.Buffer
w, err := zlib.NewWriter(&b)
w.Write([]byte("hello, world\n"))
w.Close()
```

and to read that data back:

```
r, err := zlib.NewReader(&b)
io.Copy(os.Stdout, r)
r.Close()
```

Package files

[reader.go](#) [writer.go](#)

Constants

```
const (  
    NoCompression      = flate.NoCompression  
    BestSpeed          = flate.BestSpeed  
    BestCompression    = flate.BestCompression  
    DefaultCompression = flate.DefaultCompression  
)
```

These constants are copied from the flate package, so that code that imports "compress/zlib" does not also have to import "compress/flate".

Variables

```
var (  
    // ErrChecksum is returned when reading ZLIB data that has an in  
    ErrChecksum = errors.New("zlib: invalid checksum")  
    // ErrDictionary is returned when reading ZLIB data that has an  
    ErrDictionary = errors.New("zlib: invalid dictionary")  
    // ErrHeader is returned when reading ZLIB data that has an inva  
    ErrHeader = errors.New("zlib: invalid header")  
)
```

func [NewReader](#)

```
func NewReader(r io.Reader) (io.ReadCloser, error)
```

NewReader creates a new `io.ReadCloser` that satisfies reads by decompressing data read from `r`. The implementation buffers input and may read more data than necessary from `r`. It is the caller's responsibility to call `Close` on the `ReadCloser` when done.

func [NewReaderDict](#)

```
func NewReaderDict(r io.Reader, dict []byte) (io.ReadCloser, error)
```

NewReaderDict is like NewReader but uses a preset dictionary. NewReaderDict ignores the dictionary if the compressed data does not refer to it.

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A `Writer` takes data written to it and writes the compressed form of that data to an underlying writer (see `NewWriter`).

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

`NewWriter` creates a new `Writer` that satisfies writes by compressing data written to `w`.

It is the caller's responsibility to call `Close` on the `Writer` when done. Writes may be buffered and not flushed until `Close`.

func [NewWriterLevel](#)

```
func NewWriterLevel(w io.Writer, level int) (*Writer, error)
```

`NewWriterLevel` is like `NewWriter` but specifies the compression level instead of assuming `DefaultCompression`.

The compression level can be `DefaultCompression`, `NoCompression`, or any integer value between `BestSpeed` and `BestCompression` inclusive. The error returned will be `nil` if the level is valid.

func [NewWriterLevelDict](#)

```
func NewWriterLevelDict(w io.Writer, level int, dict []byte) (*Writer, error)
```

`NewWriterLevelDict` is like `NewWriterLevel` but specifies a dictionary to compress with.

The dictionary may be `nil`. If not, its contents should not be modified until the `Writer` is closed.

func (*Writer) [Close](#)

```
func (z *Writer) Close() error
```

Calling Close does not close the wrapped io.Writer originally passed to NewWriter.

func (*Writer) [Flush](#)

```
func (z *Writer) Flush() error
```

Flush flushes the Writer to its underlying io.Writer.

func (*Writer) [Write](#)

```
func (z *Writer) Write(p []byte) (n int, err error)
```

Write writes a compressed form of p to the underlying io.Writer. The compressed bytes are not necessarily flushed until the Writer is closed or explicitly flushed.

Package heap

```
import "container/heap"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package heap provides heap operations for any type that implements heap.Interface. A heap is a tree with the property that each node is the highest-valued node in its subtree.

A heap is a common way to implement a priority queue. To build a priority queue, implement the Heap interface with the (negative) priority as the ordering for the Less method, so Push adds items while Pop removes the highest-priority item from the queue. The Examples include such an implementation; the file example_test.go has the complete source.

? Example

? Example

This example pushes 10 items into a PriorityQueue and takes them out in order of priority.

Code:

```
// This example demonstrates a priority queue built using the heap i
package heap_test

import (
    "container/heap"
    "fmt"
)

// An Item is something we manage in a priority queue.
type Item struct {
    value    string // The value of the item; arbitrary.
    priority int    // The priority of the item in the queue.
    // The index is needed by changePriority and is maintained by th
    index int // The index of the item in the heap.
}

// A PriorityQueue implements heap.Interface and holds Items.
type PriorityQueue []*Item

func (pq PriorityQueue) Len() int { return len(pq) }

func (pq PriorityQueue) Less(i, j int) bool {
```

```

    // We want Pop to give us the highest, not lowest, priority so w
    return pq[i].priority > pq[j].priority
}

func (pq PriorityQueue) Swap(i, j int) {
    pq[i], pq[j] = pq[j], pq[i]
    pq[i].index = i
    pq[j].index = j
}

func (pq *PriorityQueue) Push(x interface{}) {
    // Push and Pop use pointer receivers because they modify the sl
    // not just its contents.
    // To simplify indexing expressions in these methods, we save a
    // slice object. We could instead write (*pq)[i].
    a := *pq
    n := len(a)
    a = a[0 : n+1]
    item := x.(*Item)
    item.index = n
    a[n] = item
    *pq = a
}

func (pq *PriorityQueue) Pop() interface{} {
    a := *pq
    n := len(a)
    item := a[n-1]
    item.index = -1 // for safety
    *pq = a[0 : n-1]
    return item
}

// update is not used by the example but shows how to take the top i
// the queue, update its priority and value, and put it back.
func (pq *PriorityQueue) update(value string, priority int) {
    item := heap.Pop(pq).(*Item)
    item.value = value
    item.priority = priority
    heap.Push(pq, item)
}

// changePriority is not used by the example but shows how to change
// priority of an arbitrary item.
func (pq *PriorityQueue) changePriority(item *Item, priority int) {
    heap.Remove(pq, item.index)
    item.priority = priority
    heap.Push(pq, item)
}

```

```

// This example pushes 10 items into a PriorityQueue and takes them
// order of priority.
func Example() {
    const nItem = 10
    // Random priorities for the items (a permutation of 0..9, times
    priorities := [nItem]int{
        77, 22, 44, 55, 11, 88, 33, 99, 00, 66,
    }
    values := [nItem]string{
        "zero", "one", "two", "three", "four", "five", "six", "seven
    }
    // Create a priority queue and put some items in it.
    pq := make(PriorityQueue, 0, nItem)
    for i := 0; i < cap(pq); i++ {
        item := &Item{
            value:    values[i],
            priority: priorities[i],
        }
        heap.Push(&pq, item)
    }
    // Take the items out; should arrive in decreasing priority orde
    // For example, the highest priority (99) is the seventh item, s
    for i := 0; i < nItem; i++ {
        item := heap.Pop(&pq).(*Item)
        fmt.Printf("%.2d:%s ", item.priority, item.value)
    }
    // Output:
    // 99:seven 88:five 77:zero 66:nine 55:three 44:two 33:six 22:on
}

```

[func Init\(h Interface\)](#)
[func Pop\(h Interface\) interface{}](#)
[func Push\(h Interface, x interface{}\)](#)
[func Remove\(h Interface, i int\) interface{}](#)
[type Interface](#)

Examples

[Package](#)

Package files

[heap.go](#)

func Init

```
func Init(h Interface)
```

A heap must be initialized before any of the heap operations can be used. Init is idempotent with respect to the heap invariants and may be called whenever the heap invariants may have been invalidated. Its complexity is $O(n)$ where $n = h.Len()$.

func Pop

```
func Pop(h Interface) interface{}
```

Pop removes the minimum element (according to Less) from the heap and returns it. The complexity is $O(\log(n))$ where $n = h.Len()$. Same as `Remove(h, 0)`.

func Push

```
func Push(h Interface, x interface{})
```

Push pushes the element x onto the heap. The complexity is $O(\log(n))$ where $n = h.Len()$.

func Remove

```
func Remove(h Interface, i int) interface{}
```

Remove removes the element at index i from the heap. The complexity is $O(\log(n))$ where $n = h.Len()$.

type [Interface](#)

```
type Interface interface {
    sort.Interface
    Push(x interface{}) // add x as element Len()
    Pop() interface{}   // remove and return element Len() - 1.
}
```

Any type that implements `heap.Interface` may be used as a min-heap with the following invariants (established after `Init` has been called or if the data is empty or sorted):

`!h.Less(j, i)` for $0 \leq i < h.Len()$ and $j = 2*i+1$ or $2*i+2$ and $j < h.Len()$.

Note that `Push` and `Pop` in this interface are for package `heap`'s implementation to call. To add and remove things from the heap, use `heap.Push` and `heap.Pop`.

Build version `go1.0.1`.

Overview ?

Overview ?

Package list implements a doubly linked list.

To iterate over a list (where l is a *List):

```
for e := l.Front(); e != nil; e = e.Next() {  
    // do something with e.Value  
}
```

Index

type Element

func (e *Element) Next() *Element

func (e *Element) Prev() *Element

func (l *List) MoveToFront(e *Element)

func (l *List) PushBack(value interface{}) *Element

func (l *List) PushBackList(ol *List)

func (l *List) PushFront(value interface{}) *Element

func (l *List) PushFrontList(ol *List)

func (l *List) Remove(e *Element) interface{}

Package files

[list.go](#)

type [Element](#)

```
type Element struct {  
    // The contents of this list element.  
    Value interface{}  
    // contains filtered or unexported fields  
}
```

Element is an element in the linked list.

func (*Element) [Next](#)

```
func (e *Element) Next() *Element
```

Next returns the next list element or nil.

func (*Element) [Prev](#)

```
func (e *Element) Prev() *Element
```

Prev returns the previous list element or nil.

type [List](#)

```
type List struct {  
    // contains filtered or unexported fields  
}
```

List represents a doubly linked list. The zero value for List is an empty list ready to use.

func [New](#)

```
func New() *List
```

New returns an initialized list.

func ([*List](#)) [Back](#)

```
func (l *List) Back() *Element
```

Back returns the last element in the list.

func ([*List](#)) [Front](#)

```
func (l *List) Front() *Element
```

Front returns the first element in the list.

func ([*List](#)) [Init](#)

```
func (l *List) Init() *List
```

Init initializes or clears a List.

func ([*List](#)) [InsertAfter](#)

```
func (l *List) InsertAfter(value interface{}, mark *Element) *Element
```

InsertAfter inserts the value immediately after mark and returns a new Element containing the value.

func (*List) [InsertBefore](#)

```
func (l *List) InsertBefore(value interface{}, mark *Element) *Element
```

InsertBefore inserts the value immediately before mark and returns a new Element containing the value.

func (*List) [Len](#)

```
func (l *List) Len() int
```

Len returns the number of elements in the list.

func (*List) [MoveToBack](#)

```
func (l *List) MoveToBack(e *Element)
```

MoveToBack moves the element to the back of the list.

func (*List) [MoveToFront](#)

```
func (l *List) MoveToFront(e *Element)
```

MoveToFront moves the element to the front of the list.

func (*List) [PushBack](#)

```
func (l *List) PushBack(value interface{}) *Element
```

PushBack inserts the value at the back of the list and returns a new Element containing the value.

func (*List) [PushBackList](#)

```
func (l *List) PushBackList(ol *List)
```

PushBackList inserts each element of ol at the back of the list.

func (*List) [PushFront](#)

```
func (l *List) PushFront(value interface{}) *Element
```

PushFront inserts the value at the front of the list and returns a new Element containing the value.

func (*List) [PushFrontList](#)

```
func (l *List) PushFrontList(ol *List)
```

PushFrontList inserts each element of ol at the front of the list. The ordering of the passed list is preserved.

func (*List) [Remove](#)

```
func (l *List) Remove(e *Element) interface{}
```

Remove removes the element from the list and returns its Value.

Build version go1.0.1.

Package ring

```
import "container/ring"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package ring implements operations on circular lists.

Index

[type Ring](#)

[func New\(n int\) *Ring](#)

[func \(r *Ring\) Do\(f func\(interface{}\)\)](#)

[func \(r *Ring\) Len\(\) int](#)

[func \(r *Ring\) Link\(s *Ring\) *Ring](#)

[func \(r *Ring\) Move\(n int\) *Ring](#)

[func \(r *Ring\) Next\(\) *Ring](#)

[func \(r *Ring\) Prev\(\) *Ring](#)

[func \(r *Ring\) Unlink\(n int\) *Ring](#)

Package files

[ring.go](#)

type [Ring](#)

```
type Ring struct {
    Value interface{} // for use by client; untouched by this library
    // contains filtered or unexported fields
}
```

A Ring is an element of a circular list, or ring. Rings do not have a beginning or end; a pointer to any ring element serves as reference to the entire ring. Empty rings are represented as nil Ring pointers. The zero value for a Ring is a one-element ring with a nil Value.

func [New](#)

```
func New(n int) *Ring
```

New creates a ring of n elements.

func (*Ring) [Do](#)

```
func (r *Ring) Do(f func(interface{}))
```

Do calls function f on each element of the ring, in forward order. The behavior of Do is undefined if f changes *r.

func (*Ring) [Len](#)

```
func (r *Ring) Len() int
```

Len computes the number of elements in ring r. It executes in time proportional to the number of elements.

func (*Ring) [Link](#)

```
func (r *Ring) Link(s *Ring) *Ring
```

Link connects ring r with ring s such that r.Next() becomes s and returns the original value for r.Next(). r must not be empty.

If r and s point to the same ring, linking them removes the elements between r and s from the ring. The removed elements form a subring and the result is a reference to that subring (if no elements were removed, the result is still the original value for r.Next(), and not nil).

If r and s point to different rings, linking them creates a single ring with the elements of s inserted after r. The result points to the element following the last element of s after insertion.

func (*Ring) [Move](#)

```
func (r *Ring) Move(n int) *Ring
```

Move moves $n \% r.Len()$ elements backward ($n < 0$) or forward ($n \geq 0$) in the ring and returns that ring element. r must not be empty.

func (*Ring) [Next](#)

```
func (r *Ring) Next() *Ring
```

Next returns the next ring element. r must not be empty.

func (*Ring) [Prev](#)

```
func (r *Ring) Prev() *Ring
```

Prev returns the previous ring element. r must not be empty.

func (*Ring) [Unlink](#)

```
func (r *Ring) Unlink(n int) *Ring
```

Unlink removes $n \% r.Len()$ elements from the ring r, starting at r.Next(). If $n \% r.Len() == 0$, r remains unchanged. The result is the removed subring. r must not be empty.

Build version go1.0.1.

Package crypto

```
import "crypto"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `crypto` collects common cryptographic constants.

Index

[func RegisterHash\(h Hash, f func\(\) hash.Hash\)](#)

[type Hash](#)

[func \(h Hash\) Available\(\) bool](#)

[func \(h Hash\) New\(\) hash.Hash](#)

[func \(h Hash\) Size\(\) int](#)

[type PrivateKey](#)

Package files

[crypto.go](#)

func [RegisterHash](#)

```
func RegisterHash(h Hash, f func() hash.Hash)
```

RegisterHash registers a function that returns a new instance of the given hash function. This is intended to be called from the init function in packages that implement hash functions.

type [Hash](#)

```
type Hash uint
```

Hash identifies a cryptographic hash function that is implemented in another package.

```
const (
    MD4          Hash = 1 + iota // import code.google.com/p/go.crypto/
    MD5          // import crypto/md5
    SHA1         // import crypto/sha1
    SHA224       // import crypto/sha256
    SHA256       // import crypto/sha256
    SHA384       // import crypto/sha512
    SHA512       // import crypto/sha512
    MD5SHA1      // no implementation; MD5+SHA1 used fo
    RIPEMD160    // import code.google.com/p/go.crypto/
)
)
```

func (Hash) [Available](#)

```
func (h Hash) Available() bool
```

Available reports whether the given hash function is linked into the binary.

func (Hash) [New](#)

```
func (h Hash) New() hash.Hash
```

New returns a new hash.Hash calculating the given hash function. New panics if the hash function is not linked into the binary.

func (Hash) [Size](#)

```
func (h Hash) Size() int
```

Size returns the length, in bytes, of a digest resulting from the given hash function. It doesn't require that the hash function in question be linked into the program.

type PrivateKey

```
type PrivateKey interface{}
```

PrivateKey represents a private key using an unspecified algorithm.

[func \(w StreamWriter\) Write\(src \[\]byte\) \(n int, err error\)](#)

Package files

[cbc.go](#) [cfb.go](#) [cipher.go](#) [ctr.go](#) [io.go](#) [ofb.go](#)

type [Block](#)

```
type Block interface {
    // BlockSize returns the cipher's block size.
    BlockSize() int

    // Encrypt encrypts the first block in src into dst.
    // Dst and src may point at the same memory.
    Encrypt(dst, src []byte)

    // Decrypt decrypts the first block in src into dst.
    // Dst and src may point at the same memory.
    Decrypt(dst, src []byte)
}
```

A Block represents an implementation of block cipher using a given key. It provides the capability to encrypt or decrypt individual blocks. The mode implementations extend that capability to streams of blocks.

type [BlockMode](#)

```
type BlockMode interface {
    // BlockSize returns the mode's block size.
    BlockSize() int

    // CryptBlocks encrypts or decrypts a number of blocks. The leng
    // src must be a multiple of the block size. Dst and src may poi
    // the same memory.
    CryptBlocks(dst, src []byte)
}
```

A BlockMode represents a block cipher running in a block-based mode (CBC, ECB etc).

func [NewCBCDecrypter](#)

```
func NewCBCDecrypter(b Block, iv []byte) BlockMode
```

NewCBCDecrypter returns a BlockMode which decrypts in cipher block chaining mode, using the given Block. The length of iv must be the same as the Block's block size and must match the iv used to encrypt the data.

func [NewCBCEncrypter](#)

```
func NewCBCEncrypter(b Block, iv []byte) BlockMode
```

NewCBCEncrypter returns a BlockMode which encrypts in cipher block chaining mode, using the given Block. The length of iv must be the same as the Block's block size.

type [Stream](#)

```
type Stream interface {  
    // XORKeyStream XORs each byte in the given slice with a byte fr  
    // cipher's key stream. Dst and src may point to the same memory  
    XORKeyStream(dst, src []byte)  
}
```

A Stream represents a stream cipher.

func [NewCFBDecrypter](#)

```
func NewCFBDecrypter(block Block, iv []byte) Stream
```

NewCFBDecrypter returns a Stream which decrypts with cipher feedback mode, using the given Block. The iv must be the same length as the Block's block size.

func [NewCFBEncrypter](#)

```
func NewCFBEncrypter(block Block, iv []byte) Stream
```

NewCFBEncrypter returns a Stream which encrypts with cipher feedback mode, using the given Block. The iv must be the same length as the Block's block size.

func [NewCTR](#)

```
func NewCTR(block Block, iv []byte) Stream
```

NewCTR returns a Stream which encrypts/decrypts using the given Block in counter mode. The length of iv must be the same as the Block's block size.

func [NewOFB](#)

```
func NewOFB(b Block, iv []byte) Stream
```

NewOFB returns a Stream that encrypts or decrypts using the block cipher b in output feedback mode. The initialization vector iv's length must be equal to b's block size.

type [StreamReader](#)

```
type StreamReader struct {  
    S Stream  
    R io.Reader  
}
```

StreamReader wraps a Stream into an io.Reader. It calls XORKeyStream to process each slice of data which passes through.

func (StreamReader) [Read](#)

```
func (r StreamReader) Read(dst []byte) (n int, err error)
```

type [StreamWriter](#)

```
type StreamWriter struct {  
    S    Stream  
    W    io.Writer  
    Err  error  
}
```

StreamWriter wraps a Stream into an io.Writer. It calls XORKeyStream to process each slice of data which passes through. If any Write call returns short then the StreamWriter is out of sync and must be discarded.

func (StreamWriter) [Close](#)

```
func (w StreamWriter) Close() error
```

func (StreamWriter) [Write](#)

```
func (w StreamWriter) Write(src []byte) (n int, err error)
```

dsa.go

Variables

```
var ErrInvalidPublicKey = errors.New("crypto/dsa: invalid public key")
```

`ErrInvalidPublicKey` results when a public key is not usable by this code. FIPS is quite strict about the format of DSA keys, but other code may be less so. Thus, when using keys which may have been generated by other code, this error must be handled.

func [GenerateKey](#)

```
func GenerateKey(priv *PrivateKey, rand io.Reader) error
```

GenerateKey generates a public&private key pair. The Parameters of the PrivateKey must already be valid (see GenerateParameters).

func GenerateParameters

```
func GenerateParameters(params *Parameters, rand io.Reader, sizes Pa
```

GenerateParameters puts a random, valid set of DSA parameters into params.
This function takes many seconds, even on fast machines.

func [Sign](#)

```
func Sign(rand io.Reader, priv *PrivateKey, hash []byte) (r, s *big.
```

Sign signs an arbitrary length hash (which should be the result of hashing a larger message) using the private key, priv. It returns the signature as a pair of integers. The security of the private key depends on the entropy of rand.

Note that FIPS 186-3 section 4.6 specifies that the hash should be truncated to the byte-length of the subgroup. This function does not perform that truncation itself.

func [Verify](#)

```
func Verify(pub *PublicKey, hash []byte, r, s *big.Int) bool
```

Verify verifies the signature in r, s of hash using the public key, pub. It reports whether the signature is valid.

Note that FIPS 186-3 section 4.6 specifies that the hash should be truncated to the byte-length of the subgroup. This function does not perform that truncation itself.

type [ParameterSizes](#)

```
type ParameterSizes int
```

ParameterSizes is an enumeration of the acceptable bit lengths of the primes in a set of DSA parameters. See FIPS 186-3, section 4.2.

```
const (  
    L1024N160 ParameterSizes = iota  
    L2048N224  
    L2048N256  
    L3072N256  
)
```

type Parameters

```
type Parameters struct {  
    P, Q, G *big.Int  
}
```

Parameters represents the domain parameters for a key. These parameters can be shared across many keys. The bit length of Q must be a multiple of 8.

type [PrivateKey](#)

```
type PrivateKey struct {  
    PublicKey  
    X *big.Int  
}
```

PrivateKey represents a DSA private key.

type [PublicKey](#)

```
type PublicKey struct {  
    Parameters  
    Y *big.Int  
}
```

PublicKey represents a DSA public key.

Build version go1.0.1.

func Sign

```
func Sign(rand io.Reader, priv *PrivateKey, hash []byte) (r, s *big.
```

Sign signs an arbitrary length hash (which should be the result of hashing a larger message) using the private key, priv. It returns the signature as a pair of integers. The security of the private key depends on the entropy of rand.

func [Verify](#)

```
func Verify(pub *PublicKey, hash []byte, r, s *big.Int) bool
```

Verify verifies the signature in r, s of hash using the public key, pub. It returns true iff the signature is valid.

type [PrivateKey](#)

```
type PrivateKey struct {  
    PublicKey  
    D *big.Int  
}
```

PrivateKey represents a ECDSA private key.

func [GenerateKey](#)

```
func GenerateKey(c elliptic.Curve, rand io.Reader) (priv *PrivateKey
```

GenerateKey generates a public&private key pair.

type [PublicKey](#)

```
type PublicKey struct {  
    elliptic.Curve  
    X, Y *big.Int  
}
```

PublicKey represents an ECDSA public key.

Package files

[elliptic.go](#) [p224.go](#)

func [GenerateKey](#)

```
func GenerateKey(curve Curve, rand io.Reader) (priv []byte, x, y *bi
```

GenerateKey returns a public/private key pair. The private key is generated using the given reader, which must return random data.

func [Marshal](#)

```
func Marshal(curve Curve, x, y *big.Int) []byte
```

Marshal converts a point into the form specified in section 4.3.6 of ANSI X9.62.

func [Unmarshal](#)

```
func Unmarshal(curve Curve, data []byte) (x, y *big.Int)
```

Unmarshal converts a point, serialized by Marshal, into an x, y pair. On error, x = nil.

type [Curve](#)

```
type Curve interface {
    // Params returns the parameters for the curve.
    Params() *CurveParams
    // IsOnCurve returns true if the given (x,y) lies on the curve.
    IsOnCurve(x, y *big.Int) bool
    // Add returns the sum of (x1,y1) and (x2,y2)
    Add(x1, y1, x2, y2 *big.Int) (x, y *big.Int)
    // Double returns 2*(x,y)
    Double(x1, y1 *big.Int) (x, y *big.Int)
    // ScalarMult returns k*(Bx,By) where k is a number in big-endian
    ScalarMult(x1, y1 *big.Int, scalar []byte) (x, y *big.Int)
    // ScalarBaseMult returns k*G, where G is the base point of the
    // is an integer in big-endian form.
    ScalarBaseMult(scalar []byte) (x, y *big.Int)
}
```

A Curve represents a short-form Weierstrass curve with $a=-3$. See <http://www.hyperelliptic.org/EFD/g1p/auto-shortw.html>

func [P224](#)

```
func P224() Curve
```

P224 returns a Curve which implements P-224 (see FIPS 186-3, section D.2.2)

func [P256](#)

```
func P256() Curve
```

P256 returns a Curve which implements P-256 (see FIPS 186-3, section D.2.3)

func [P384](#)

```
func P384() Curve
```

P384 returns a Curve which implements P-384 (see FIPS 186-3, section D.2.4)

func [P521](#)

func P521() Curve

P256 returns a Curve which implements P-521 (see FIPS 186-3, section D.2.5)

type [CurveParams](#)

```
type CurveParams struct {
    P      *big.Int // the order of the underlying field
    N      *big.Int // the order of the base point
    B      *big.Int // the constant of the curve equation
    Gx, Gy *big.Int // (x,y) of the base point
    BitSize int    // the size of the underlying field
}
```

CurveParams contains the parameters of an elliptic curve and also provides a generic, non-constant time implementation of Curve.

func (*CurveParams) [Add](#)

```
func (curve *CurveParams) Add(x1, y1, x2, y2 *big.Int) (*big.Int, *big.Int)
```

func (*CurveParams) [Double](#)

```
func (curve *CurveParams) Double(x1, y1 *big.Int) (*big.Int, *big.Int)
```

func (*CurveParams) [IsOnCurve](#)

```
func (curve *CurveParams) IsOnCurve(x, y *big.Int) bool
```

func (*CurveParams) [Params](#)

```
func (curve *CurveParams) Params() *CurveParams
```

func (*CurveParams) [ScalarBaseMult](#)

```
func (curve *CurveParams) ScalarBaseMult(k []byte) (*big.Int, *big.Int)
```

func (*CurveParams) [ScalarMult](#)

```
func (curve *CurveParams) ScalarMult(Bx, By *big.Int, k []byte) (*big.Int, *big.Int)
```

Build version go1.0.1.

Package hmac

```
import "crypto/hmac"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `hmac` implements the Keyed-Hash Message Authentication Code (HMAC) as defined in U.S. Federal Information Processing Standards Publication 198. An HMAC is a cryptographic hash that uses a key to sign a message. The receiver verifies the hash by recomputing it using the same key.

Index

[func New\(h func\(\) hash.Hash, key \[\]byte\) hash.Hash](#)

Package files

[hmac.go](#)

func [New](#)

```
func New(h func() hash.Hash, key []byte) hash.Hash
```

New returns a new HMAC hash using the given hash.Hash type and key.

Build version go1.0.1.

Package md5

```
import "crypto/md5"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package md5 implements the MD5 hash algorithm as defined in RFC 1321.

Index

[Constants](#)

[func New\(\) hash.Hash](#)

Examples

[New](#)

Package files

[md5.go](#) [md5block.go](#)

Constants

```
const BlockSize = 64
```

The blocksize of MD5 in bytes.

```
const Size = 16
```

The size of an MD5 checksum in bytes.

func [New](#)

```
func New() hash.Hash
```

New returns a new hash.Hash computing the MD5 checksum.

? Example

? Example

Code:

```
h := md5.New()  
io.WriteString(h, "The fog is getting thicker!")  
io.WriteString(h, "And Leon's getting laaarger!")  
fmt.Printf("%x", h.Sum(nil))
```

Output:

```
e2c569be17396eca2a2e3c11578123ed
```

Build version go1.0.1.

[Terms of Service](#) | [Privacy Policy](#)

Package rand

```
import "crypto/rand"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package rand implements a cryptographically secure pseudorandom number generator.

Index

Variables

[func Int\(rand io.Reader, max *big.Int\) \(n *big.Int, err error\)](#)

[func Prime\(rand io.Reader, bits int\) \(p *big.Int, err error\)](#)

[func Read\(b \[\]byte\) \(n int, err error\)](#)

Package files

[rand.go](#) [rand_unix.go](#) [util.go](#)

Variables

```
var Reader io.Reader
```

Reader is a global, shared instance of a cryptographically strong pseudo-random generator. On Unix-like systems, Reader reads from `/dev/urandom`. On Windows systems, Reader uses the CryptGenRandom API.

func [Int](#)

```
func Int(rand io.Reader, max *big.Int) (*big.Int, error)
```

Int returns a uniform random value in [0, max).

func Prime

```
func Prime(rand io.Reader, bits int) (p *big.Int, err error)
```

Prime returns a number, p, of the given size, such that p is prime with high probability.

func [Read](#)

```
func Read(b []byte) (n int, err error)
```

Read is a helper function that calls Reader.Read.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package rc4

```
import "crypto/rc4"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package rc4 implements RC4 encryption, as defined in Bruce Schneier's Applied Cryptography.

Index

[type Cipher](#)

[func NewCipher\(key \[\]byte\) \(*Cipher, error\)](#)

[func \(c *Cipher\) Reset\(\)](#)

[func \(c *Cipher\) XORKeyStream\(dst, src \[\]byte\)](#)

[type KeySizeError](#)

[func \(k KeySizeError\) Error\(\) string](#)

[Bugs](#)

Package files

[rc4.go](#)

type [Cipher](#)

```
type Cipher struct {  
    // contains filtered or unexported fields  
}
```

A Cipher is an instance of RC4 using a particular key.

func [NewCipher](#)

```
func NewCipher(key []byte) (*Cipher, error)
```

NewCipher creates and returns a new Cipher. The key argument should be the RC4 key, at least 1 byte and at most 256 bytes.

func (***Cipher**) [Reset](#)

```
func (c *Cipher) Reset()
```

Reset zeros the key data so that it will no longer appear in the process's memory.

func (***Cipher**) [XORKeyStream](#)

```
func (c *Cipher) XORKeyStream(dst, src []byte)
```

XORKeyStream sets dst to the result of XORing src with the key stream. Dst and src may be the same slice but otherwise should not overlap.

type [KeySizeError](#)

```
type KeySizeError int
```

func (KeySizeError) [Error](#)

```
func (k KeySizeError) Error() string
```

Bugs

RC4 is in common use but has design weaknesses that make it a poor choice for new protocols.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).

[func \(priv *PrivateKey\) Precompute\(\)](#)

[func \(priv *PrivateKey\) Validate\(\) error](#)

[type PublicKey](#)

Package files

[pkcs1v15.go](#) [rsa.go](#)

Variables

```
var ErrDecryption = errors.New("crypto/rsa: decryption error")
```

ErrDecryption represents a failure to decrypt a message. It is deliberately vague to avoid adaptive attacks.

```
var ErrMessageTooLong = errors.New("crypto/rsa: message too long for
```

ErrMessageTooLong is returned when attempting to encrypt a message which is too large for the size of the public key.

```
var ErrVerification = errors.New("crypto/rsa: verification error")
```

ErrVerification represents a failure to verify a signature. It is deliberately vague to avoid adaptive attacks.

func DecryptOAEP

```
func DecryptOAEP(hash hash.Hash, random io.Reader, priv *PrivateKey,
```

DecryptOAEP decrypts ciphertext using RSA-OAEP. If random != nil, DecryptOAEP uses RSA blinding to avoid timing side-channel attacks.

func [DecryptPKCS1v15](#)

```
func DecryptPKCS1v15(rand io.Reader, priv *PrivateKey, ciphertext []
```

DecryptPKCS1v15 decrypts a plaintext using RSA and the padding scheme from PKCS#1 v1.5. If rand != nil, it uses RSA blinding to avoid timing side-channel attacks.

func [DecryptPKCS1v15SessionKey](#)

```
func DecryptPKCS1v15SessionKey(rand io.Reader, priv *PrivateKey, cip
```

DecryptPKCS1v15SessionKey decrypts a session key using RSA and the padding scheme from PKCS#1 v1.5. If rand != nil, it uses RSA blinding to avoid timing side-channel attacks. It returns an error if the ciphertext is the wrong length or if the ciphertext is greater than the public modulus. Otherwise, no error is returned. If the padding is valid, the resulting plaintext message is copied into key. Otherwise, key is unchanged. These alternatives occur in constant time. It is intended that the user of this function generate a random session key beforehand and continue the protocol with the resulting value. This will remove any possibility that an attacker can learn any information about the plaintext. See “Chosen Ciphertext Attacks Against Protocols Based on the RSA Encryption Standard PKCS #1”, Daniel Bleichenbacher, Advances in Cryptology (Crypto '98).

func [EncryptOAEP](#)

```
func EncryptOAEP(hash hash.Hash, random io.Reader, pub *PublicKey, m
```

EncryptOAEP encrypts the given message with RSA-OAEP. The message must be no longer than the length of the public modulus less twice the hash length plus 2.

func [EncryptPKCS1v15](#)

```
func EncryptPKCS1v15(rand io.Reader, pub *PublicKey, msg []byte) (ou
```

EncryptPKCS1v15 encrypts the given message with RSA and the padding scheme from PKCS#1 v1.5. The message must be no longer than the length of the public modulus minus 11 bytes. **WARNING:** use of this function to encrypt plaintexts other than session keys is dangerous. Use RSA OAEP in new protocols.

func [SignPKCS1v15](#)

```
func SignPKCS1v15(rand io.Reader, priv *PrivateKey, hash crypto.Hash
```

SignPKCS1v15 calculates the signature of hashed using RSASSA-PKCS1-V1_5-SIGN from RSA PKCS#1 v1.5. Note that hashed must be the result of hashing the input message using the given hash function.

func [VerifyPKCS1v15](#)

```
func VerifyPKCS1v15(pub *PublicKey, hash crypto.Hash, hashed []byte,
```

VerifyPKCS1v15 verifies an RSA PKCS#1 v1.5 signature. hashed is the result of hashing the input message using the given hash function and sig is the signature. A valid signature is indicated by returning a nil error.

type [CRTValue](#)

```
type CRTValue struct {  
    Exp    *big.Int // D mod (prime-1).  
    Coeff  *big.Int // RCoeff 1 mod Prime.  
    R      *big.Int // product of primes prior to this (inc p and q).  
}
```

CRTValue contains the precomputed chinese remainder theorem values.

type PrecomputedValues

```
type PrecomputedValues struct {
    Dp, Dq *big.Int // D mod (P-1) (or mod Q-1)
    Qinv  *big.Int

    // CRTValues is used for the 3rd and subsequent primes. Due to a
    // historical accident, the CRT for the first two primes is hand
    // differently in PKCS#1 and interoperability is sufficiently
    // important that we mirror this.
    CRTValues []CRTValue
}
```

type [PrivateKey](#)

```
type PrivateKey struct {
    PublicKey          // public part.
    D                 *big.Int // private exponent
    Primes            []*big.Int

    // Precomputed contains precomputed values that speed up private
    // operations, if available.
    Precomputed PrecomputedValues
}
```

A PrivateKey represents an RSA key

func [GenerateKey](#)

```
func GenerateKey(random io.Reader, bits int) (priv *PrivateKey, err
```

GenerateKey generates an RSA keypair of the given bit size.

func [GenerateMultiPrimeKey](#)

```
func GenerateMultiPrimeKey(random io.Reader, nprimes int, bits int)
```

GenerateMultiPrimeKey generates a multi-prime RSA keypair of the given bit size, as suggested in [1]. Although the public keys are compatible (actually, indistinguishable) from the 2-prime case, the private keys are not. Thus it may not be possible to export multi-prime private keys in certain formats or to subsequently import them into other code.

Table 1 in [2] suggests maximum numbers of primes for a given size.

[1] US patent 4405829 (1972, expired) [2]

<http://www.cacr.math.uwaterloo.ca/techreports/2006/cacr2006-16.pdf>

func (*PrivateKey) [Precompute](#)

```
func (priv *PrivateKey) Precompute()
```

Precompute performs some calculations that speed up private key operations in

the future.

func (*PrivateKey) [Validate](#)

```
func (priv *PrivateKey) Validate() error
```

Validate performs basic sanity checks on the key. It returns nil if the key is valid, or else an error describing a problem.

type [PublicKey](#)

```
type PublicKey struct {  
    N *big.Int // modulus  
    E int      // public exponent  
}
```

A `PublicKey` represents the public part of an RSA key.

Build version go1.0.1.

[constant_time.go](#)

func ConstantTimeByteEq

```
func ConstantTimeByteEq(x, y uint8) int
```

ConstantTimeByteEq returns 1 if $x == y$ and 0 otherwise.

func ConstantTimeCompare

```
func ConstantTimeCompare(x, y []byte) int
```

ConstantTimeCompare returns 1 iff the two equal length slices, x and y, have equal contents. The time taken is a function of the length of the slices and is independent of the contents.

func ConstantTimeCopy

```
func ConstantTimeCopy(v int, x, y []byte)
```

ConstantTimeCopy copies the contents of y into x iff v == 1. If v == 0, x is left unchanged. Its behavior is undefined if v takes any other value.

func ConstantTimeEq

```
func ConstantTimeEq(x, y int32) int
```

ConstantTimeEq returns 1 if $x == y$ and 0 otherwise.

func [ConstantTimeSelect](#)

```
func ConstantTimeSelect(v, x, y int) int
```

ConstantTimeSelect returns x if v is 1 and y if v is 0. Its behavior is undefined if v takes any other value.

Build version go1.0.1.

Constants

```
const (  
    TLS_RSA_WITH_RC4_128_SHA          uint16 = 0x0005  
    TLS_RSA_WITH_3DES_EDE_CBC_SHA     uint16 = 0x000a  
    TLS_RSA_WITH_AES_128_CBC_SHA      uint16 = 0x002f  
    TLS_ECDHE_RSA_WITH_RC4_128_SHA    uint16 = 0xc011  
    TLS_ECDHE_RSA_WITH_3DES_EDE_CBC_SHA uint16 = 0xc012  
    TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA uint16 = 0xc013  
)
```

A list of the possible cipher suite ids. Taken from

<http://www.iana.org/assignments/tls-parameters/tls-parameters.xml>

func [Listen](#)

```
func Listen(network, laddr string, config *Config) (net.Listener, error)
```

Listen creates a TLS listener accepting connections on the given network address using `net.Listen`. The configuration `config` must be non-nil and must have at least one certificate.

func [NewListener](#)

```
func NewListener(inner net.Listener, config *Config) net.Listener
```

NewListener creates a Listener which accepts connections from an inner Listener and wraps each connection with Server. The configuration config must be non-nil and must have at least one certificate.

type [Certificate](#)

```
type Certificate struct {
    Certificate [][]byte
    PrivateKey crypto.PrivateKey // supported types: *rsa.PrivateKe
    // OCSPStaple contains an optional OCSP response which will be s
    // to clients that request it.
    OCSPStaple []byte
    // Leaf is the parsed form of the leaf certificate, which may be
    // initialized using x509.ParseCertificate to reduce per-handsha
    // processing for TLS clients doing client authentication. If ni
    // leaf certificate will be parsed as needed.
    Leaf *x509.Certificate
}
```

A Certificate is a chain of one or more certificates, leaf first.

func [LoadX509KeyPair](#)

```
func LoadX509KeyPair(certFile, keyFile string) (cert Certificate, er
```

LoadX509KeyPair reads and parses a public/private key pair from a pair of files. The files must contain PEM encoded data.

func [X509KeyPair](#)

```
func X509KeyPair(certPEMBlock, keyPEMBlock []byte) (cert Certificate
```

X509KeyPair parses a public/private key pair from a pair of PEM encoded data.

type [ClientAuthType](#)

```
type ClientAuthType int
```

ClientAuthType declares the policy the server will follow for TLS Client Authentication.

```
const (  
    NoClientCert ClientAuthType = iota  
    RequestClientCert  
    RequireAnyClientCert  
    VerifyClientCertIfGiven  
    RequireAndVerifyClientCert  
)
```

type [Config](#)

```
type Config struct {
    // Rand provides the source of entropy for nonces and RSA blinding
    // If Rand is nil, TLS uses the cryptographic random reader in package
    // crypto/rand.
    Rand io.Reader

    // Time returns the current time as the number of seconds since epoch
    // If Time is nil, TLS uses time.Now.
    Time func() time.Time

    // Certificates contains one or more certificate chains
    // to present to the other side of the connection.
    // Server configurations must include at least one certificate.
    Certificates []Certificate

    // NameToCertificate maps from a certificate name to an element
    // of Certificates. Note that a certificate name can be of the form
    // '*.example.com' and so doesn't have to be a domain name as such.
    // See Config.BuildNameToCertificate
    // The nil value causes the first element of Certificates to be
    // used for all connections.
    NameToCertificate map[string]*Certificate

    // RootCAs defines the set of root certificate authorities
    // that clients use when verifying server certificates.
    // If RootCAs is nil, TLS uses the host's root CA set.
    RootCAs *x509.CertPool

    // NextProtos is a list of supported, application level protocols
    NextProtos []string

    // ServerName is included in the client's handshake to support virtual
    // hosting.
    ServerName string

    // ClientAuth determines the server's policy for
    // TLS Client Authentication. The default is NoClientCert.
    ClientAuth ClientAuthType

    // ClientCAs defines the set of root certificate authorities
    // that servers use if required to verify a client certificate
    // by the policy in ClientAuth.
    ClientCAs *x509.CertPool

    // InsecureSkipVerify controls whether a client verifies the

```

```

// server's certificate chain and host name.
// If InsecureSkipVerify is true, TLS accepts any certificate
// presented by the server and any host name in that certificate
// In this mode, TLS is susceptible to man-in-the-middle attacks
// This should be used only for testing.
InsecureSkipVerify bool

// CipherSuites is a list of supported cipher suites. If CipherS
// is nil, TLS uses a list of suites supported by the implementa
CipherSuites []uint16
}

```

A Config structure is used to configure a TLS client or server. After one has been passed to a TLS function it must not be modified.

func (*Config) [BuildNameToCertificate](#)

```
func (c *Config) BuildNameToCertificate()
```

BuildNameToCertificate parses c.Certificates and builds c.NameToCertificate from the CommonName and SubjectAlternateName fields of each of the leaf certificates.

type [Conn](#)

```
type Conn struct {  
    // contains filtered or unexported fields  
}
```

A Conn represents a secured connection. It implements the net.Conn interface.

func [Client](#)

```
func Client(conn net.Conn, config *Config) *Conn
```

Client returns a new TLS client side connection using conn as the underlying transport. Client interprets a nil configuration as equivalent to the zero configuration; see the documentation of Config for the defaults.

func [Dial](#)

```
func Dial(network, addr string, config *Config) (*Conn, error)
```

Dial connects to the given network address using net.Dial and then initiates a TLS handshake, returning the resulting TLS connection. Dial interprets a nil configuration as equivalent to the zero configuration; see the documentation of Config for the defaults.

func [Server](#)

```
func Server(conn net.Conn, config *Config) *Conn
```

Server returns a new TLS server side connection using conn as the underlying transport. The configuration config must be non-nil and must have at least one certificate.

func (***Conn**) [Close](#)

```
func (c *Conn) Close() error
```

Close closes the connection.

func (*Conn) [ConnectionState](#)

```
func (c *Conn) ConnectionState() ConnectionState
```

ConnectionState returns basic TLS details about the connection.

func (*Conn) [Handshake](#)

```
func (c *Conn) Handshake() error
```

Handshake runs the client or server handshake protocol if it has not yet been run. Most uses of this package need not call Handshake explicitly: the first Read or Write will call it automatically.

func (*Conn) [LocalAddr](#)

```
func (c *Conn) LocalAddr() net.Addr
```

LocalAddr returns the local network address.

func (*Conn) [OCSPResponse](#)

```
func (c *Conn) OCSPResponse() []byte
```

OCSPResponse returns the stapled OCSP response from the TLS server, if any. (Only valid for client connections.)

func (*Conn) [Read](#)

```
func (c *Conn) Read(b []byte) (n int, err error)
```

Read can be made to time out and return a net.Error with Timeout() == true after a fixed time limit; see SetDeadline and SetReadDeadline.

func (*Conn) [RemoteAddr](#)

```
func (c *Conn) RemoteAddr() net.Addr
```

RemoteAddr returns the remote network address.

func (*Conn) [SetDeadline](#)

```
func (c *Conn) SetDeadline(t time.Time) error
```

SetDeadline sets the read and write deadlines associated with the connection. A zero value for t means Read and Write will not time out. After a Write has timed out, the TLS state is corrupt and all future writes will return the same error.

func (*Conn) [SetReadDeadline](#)

```
func (c *Conn) SetReadDeadline(t time.Time) error
```

SetReadDeadline sets the read deadline on the underlying connection. A zero value for t means Read will not time out.

func (*Conn) [SetWriteDeadline](#)

```
func (c *Conn) SetWriteDeadline(t time.Time) error
```

SetWriteDeadline sets the write deadline on the underlying connection. A zero value for t means Write will not time out. After a Write has timed out, the TLS state is corrupt and all future writes will return the same error.

func (*Conn) [VerifyHostname](#)

```
func (c *Conn) VerifyHostname(host string) error
```

VerifyHostname checks that the peer certificate chain is valid for connecting to host. If so, it returns nil; if not, it returns an error describing the problem.

func (*Conn) [Write](#)

```
func (c *Conn) Write(b []byte) (int, error)
```

Write writes data to the connection.

type [ConnectionState](#)

```
type ConnectionState struct {
    HandshakeComplete      bool
    CipherSuite            uint16
    NegotiatedProtocol     string
    NegotiatedProtocolIsMutual bool

    // ServerName contains the server name indicated by the client,
    // (Only valid for server connections.)
    ServerName string

    // the certificate chain that was presented by the other side
    PeerCertificates []*x509.Certificate
    // the verified certificate chains built from PeerCertificates.
    VerifiedChains [][]*x509.Certificate
}
```

ConnectionState records basic TLS details about the connection.

Build version go1.0.1.

Package files

[cert_pool.go](#) [pkcs1.go](#) [pkcs8.go](#) [root.go](#) [root_unix.go](#) [verify.go](#) [x509.go](#)

Variables

```
var ErrUnsupportedAlgorithm = errors.New("crypto/x509: cannot verify
```

ErrUnsupportedAlgorithm results from attempting to perform an operation that involves algorithms that are not currently implemented.

func [CreateCertificate](#)

```
func CreateCertificate(rand io.Reader, template, parent *Certificate
```

CreateCertificate creates a new certificate based on a template. The following members of template are used: SerialNumber, Subject, NotBefore, NotAfter, KeyUsage, BasicConstraintsValid, IsCA, MaxPathLen, SubjectKeyId, DNSNames, PermittedDNSDomainsCritical, PermittedDNSDomains.

The certificate is signed by parent. If parent is equal to template then the certificate is self-signed. The parameter pub is the public key of the signee and priv is the private key of the signer.

The returned slice is the certificate in DER encoding.

The only supported key type is RSA (*rsa.PublicKey for pub, *rsa.PrivateKey for priv).

func [MarshalPKCS1PrivateKey](#)

```
func MarshalPKCS1PrivateKey(key *rsa.PrivateKey) []byte
```

MarshalPKCS1PrivateKey converts a private key to ASN.1 DER encoded form.

func [MarshalPKIXPublicKey](#)

```
func MarshalPKIXPublicKey(pub interface{}) ([]byte, error)
```

MarshalPKIXPublicKey serialises a public key to DER-encoded PKIX format.

func [ParseCRL](#)

```
func ParseCRL(crlBytes []byte) (certList *pkix.CertificateList, err
```

ParseCRL parses a CRL from the given bytes. It's often the case that PEM encoded CRLs will appear where they should be DER encoded, so this function will transparently handle PEM encoding as long as there isn't any leading garbage.

func [ParseCertificates](#)

```
func ParseCertificates(asn1Data []byte) ([]*Certificate, error)
```

ParseCertificates parses one or more certificates from the given ASN.1 DER data. The certificates must be concatenated with no intermediate padding.

func ParseDERCRL

```
func ParseDERCRL(derBytes []byte) (certList *pkix.CertificateList, e
```

ParseDERCRL parses a DER encoded CRL from the given bytes.

func [ParsePKCS1PrivateKey](#)

```
func ParsePKCS1PrivateKey(der []byte) (key *rsa.PrivateKey, err error)
```

ParsePKCS1PrivateKey returns an RSA private key from its ASN.1 PKCS#1 DER encoded form.

func [ParsePKCS8PrivateKey](#)

func ParsePKCS8PrivateKey(der []byte) (key interface{}, err error)

ParsePKCS8PrivateKey parses an unencrypted, PKCS#8 private key. See <http://www.rsa.com/rsalabs/node.asp?id=2130>

func [ParsePKIXPublicKey](#)

```
func ParsePKIXPublicKey(derBytes []byte) (pub interface{}, err error
```

ParsePKIXPublicKey parses a DER encoded public key. These values are typically found in PEM blocks with "BEGIN PUBLIC KEY".

type [CertPool](#)

```
type CertPool struct {  
    // contains filtered or unexported fields  
}
```

CertPool is a set of certificates.

func [NewCertPool](#)

```
func NewCertPool() *CertPool
```

NewCertPool returns a new, empty CertPool.

func (***CertPool**) [AddCert](#)

```
func (s *CertPool) AddCert(cert *Certificate)
```

AddCert adds a certificate to a pool.

func (***CertPool**) [AppendCertsFromPEM](#)

```
func (s *CertPool) AppendCertsFromPEM(pemCerts []byte) (ok bool)
```

AppendCertsFromPEM attempts to parse a series of PEM encoded certificates. It appends any certificates found to s and returns true if any certificates were successfully parsed.

On many Linux systems, /etc/ssl/cert.pem will contain the system wide set of root CAs in a format suitable for this function.

func (***CertPool**) [Subjects](#)

```
func (s *CertPool) Subjects() (res [][]byte)
```

Subjects returns a list of the DER-encoded subjects of all of the certificates in the pool.

type [Certificate](#)

```
type Certificate struct {
    Raw []byte // Complete ASN.1 DER content (certificate)
    RawTBSCertificate []byte // Certificate part of raw ASN.1
    RawSubjectPublicKeyInfo []byte // DER encoded SubjectPublicKeyInfo
    RawSubject []byte // DER encoded Subject
    RawIssuer []byte // DER encoded Issuer

    Signature []byte
    SignatureAlgorithm SignatureAlgorithm

    PublicKeyAlgorithm PublicKeyAlgorithm
    PublicKey interface{}

    Version int
    SerialNumber *big.Int
    Issuer pkix.Name
    Subject pkix.Name
    NotBefore, NotAfter time.Time // Validity bounds.
    KeyUsage KeyUsage

    ExtKeyUsage []ExtKeyUsage // Sequence of extended key usages
    UnknownExtKeyUsage []asn1.ObjectIdentifier // Encountered extended key usages

    BasicConstraintsValid bool // if true then the next two fields are present
    IsCA bool
    MaxPathLen int

    SubjectKeyId []byte
    AuthorityKeyId []byte

    // Subject Alternate Name values
    DNSNames []string
    EmailAddresses []string

    // Name constraints
    PermittedDNSDomainsCritical bool // if true then the name constraints are critical
    PermittedDNSDomains []string

    PolicyIdentifiers []asn1.ObjectIdentifier
}
```

A Certificate represents an X.509 certificate.

func [ParseCertificate](#)

```
func ParseCertificate(asn1Data []byte) (*Certificate, error)
```

ParseCertificate parses a single certificate from the given ASN.1 DER data.

func (*Certificate) [CheckCRLSignature](#)

```
func (c *Certificate) CheckCRLSignature(crl *pkix.CertificateList) (
```

CheckCRLSignature checks that the signature in crl is from c.

func (*Certificate) [CheckSignature](#)

```
func (c *Certificate) CheckSignature(algo SignatureAlgorithm, signed
```

CheckSignature verifies that signature is a valid signature over signed from c's public key.

func (*Certificate) [CheckSignatureFrom](#)

```
func (c *Certificate) CheckSignatureFrom(parent *Certificate) (err e
```

CheckSignatureFrom verifies that the signature on c is a valid signature from parent.

func (*Certificate) [CreateCRL](#)

```
func (c *Certificate) CreateCRL(rand io.Reader, priv interface{}, re
```

CreateCRL returns a DER encoded CRL, signed by this Certificate, that contains the given list of revoked certificates.

The only supported key type is RSA (*rsa.PrivateKey for priv).

func (*Certificate) [Equal](#)

```
func (c *Certificate) Equal(other *Certificate) bool
```

func (*Certificate) [Verify](#)

```
func (c *Certificate) Verify(opts VerifyOptions) (chains [][]*Certif
```

Verify attempts to verify `c` by building one or more chains from `c` to a certificate in `opts.Roots`, using certificates in `opts.Intermediates` if needed. If successful, it returns one or more chains where the first element of the chain is `c` and the last element is from `opts.Roots`.

WARNING: this doesn't do any revocation checking.

func (*Certificate) [VerifyHostname](#)

```
func (c *Certificate) VerifyHostname(h string) error
```

`VerifyHostname` returns `nil` if `c` is a valid certificate for the named host. Otherwise it returns an error describing the mismatch.

type [CertificateInvalidError](#)

```
type CertificateInvalidError struct {  
    Cert    *Certificate  
    Reason  InvalidReason  
}
```

CertificateInvalidError results when an odd error occurs. Users of this library probably want to handle all these errors uniformly.

func (CertificateInvalidError) [Error](#)

```
func (e CertificateInvalidError) Error() string
```

type [ConstraintViolationError](#)

```
type ConstraintViolationError struct{}
```

ConstraintViolationError results when a requested usage is not permitted by a certificate. For example: checking a signature when the public key isn't a certificate signing key.

func (ConstraintViolationError) [Error](#)

```
func (ConstraintViolationError) Error() string
```

type [ExtKeyUsage](#)

```
type ExtKeyUsage int
```

ExtKeyUsage represents an extended set of actions that are valid for a given key. Each of the ExtKeyUsage* constants define a unique action.

```
const (  
    ExtKeyUsageAny ExtKeyUsage = iota  
    ExtKeyUsageServerAuth  
    ExtKeyUsageClientAuth  
    ExtKeyUsageCodeSigning  
    ExtKeyUsageEmailProtection  
    ExtKeyUsageTimeStamping  
    ExtKeyUsageOCSPSigning  
)
```

type [HostnameError](#)

```
type HostnameError struct {  
    Certificate *Certificate  
    Host       string  
}
```

HostnameError results when the set of authorized names doesn't match the requested name.

func ([HostnameError](#)) [Error](#)

```
func (h HostnameError) Error() string
```

type InvalidReason

```
type InvalidReason int
```

```
const (  
    // NotAuthorizedToSign results when a certificate is signed by a  
    // which isn't marked as a CA certificate.  
    NotAuthorizedToSign InvalidReason = iota  
    // Expired results when a certificate has expired, based on the  
    // given in the VerifyOptions.  
    Expired  
    // CANotAuthorizedForThisName results when an intermediate or ro  
    // certificate has a name constraint which doesn't include the n  
    // being checked.  
    CANotAuthorizedForThisName  
    // TooManyIntermediates results when a path length constraint is  
    // violated.  
    TooManyIntermediates  
)
```

type [KeyUsage](#)

```
type KeyUsage int
```

KeyUsage represents the set of actions that are valid for a given key. It's a bitmap of the KeyUsage* constants.

```
const (  
    KeyUsageDigitalSignature KeyUsage = 1 << iota  
    KeyUsageContentCommitment  
    KeyUsageKeyEncipherment  
    KeyUsageDataEncipherment  
    KeyUsageKeyAgreement  
    KeyUsageCertSign  
    KeyUsageCRLSign  
    KeyUsageEncipherOnly  
    KeyUsageDecipherOnly  
)
```

type PublicKeyAlgorithm

```
type PublicKeyAlgorithm int
```

```
const (  
    UnknownPublicKeyAlgorithm PublicKeyAlgorithm = iota  
    RSA  
    DSA  
)
```

type [SignatureAlgorithm](#)

```
type SignatureAlgorithm int
```

```
const (  
    UnknownSignatureAlgorithm SignatureAlgorithm = iota  
    MD2WithRSA  
    MD5WithRSA  
    SHA1WithRSA  
    SHA256WithRSA  
    SHA384WithRSA  
    SHA512WithRSA  
    DSAWithSHA1  
    DSAWithSHA256  
)
```

type [UnhandledCriticalExtension](#)

```
type UnhandledCriticalExtension struct{}
```

func (UnhandledCriticalExtension) [Error](#)

```
func (h UnhandledCriticalExtension) Error() string
```

type [UnknownAuthorityError](#)

```
type UnknownAuthorityError struct {  
    // contains filtered or unexported fields  
}
```

UnknownAuthorityError results when the certificate issuer is unknown

func (UnknownAuthorityError) [Error](#)

```
func (e UnknownAuthorityError) Error() string
```

type [VerifyOptions](#)

```
type VerifyOptions struct {
    DNSName      string
    Intermediates *CertPool
    Roots        *CertPool // if nil, the system roots are used
    CurrentTime  time.Time // if zero, the current time is used
}
```

VerifyOptions contains parameters for Certificate.Verify. It's a structure because other PKIX verification APIs have ended up needing many options.

[type TBSCertificateList](#)

Package files

[pkix.go](#)

type [AlgorithmIdentifier](#)

```
type AlgorithmIdentifier struct {  
    Algorithm asn1.ObjectIdentifier  
    Parameters asn1.RawValue `asn1:"optional"`  
}
```

AlgorithmIdentifier represents the ASN.1 structure of the same name. See RFC 5280, section 4.1.1.2.

type AttributeTypeAndValue

```
type AttributeTypeAndValue struct {  
    Type  asn1.ObjectIdentifier  
    Value interface{}}
```

AttributeTypeAndValue mirrors the ASN.1 structure of the same name in <http://tools.ietf.org/html/rfc5280#section-4.1.2.4>

type [CertificateList](#)

```
type CertificateList struct {  
    TBSCertList      TBSCertificateList  
    SignatureAlgorithm AlgorithmIdentifier  
    SignatureValue   asn1.BitString  
}
```

CertificateList represents the ASN.1 structure of the same name. See RFC 5280, section 5.1. Use Certificate.CheckCRLSignature to verify the signature.

func (*CertificateList) [HasExpired](#)

```
func (certList *CertificateList) HasExpired(now time.Time) bool
```

HasExpired returns true iff now is past the expiry time of certList.

type [Extension](#)

```
type Extension struct {
    Id          asn1.ObjectIdentifier
    Critical    bool `asn1:"optional"`
    Value      []byte
}
```

Extension represents the ASN.1 structure of the same name. See RFC 5280, section 4.2.

type [Name](#)

```
type Name struct {
    Country, Organization, OrganizationalUnit []string
    Locality, Province                       []string
    StreetAddress, PostalCode                []string
    SerialNumber, CommonName                 string
    Names []AttributeTypeAndValue
}
```

Name represents an X.509 distinguished name. This only includes the common elements of a DN. Additional elements in the name are ignored.

func (*Name) [FillFromRDNSequence](#)

```
func (n *Name) FillFromRDNSequence(rdns *RDNSequence)
```

func (Name) [ToRDNSequence](#)

```
func (n Name) ToRDNSequence() (ret RDNSequence)
```

type [RDNSequence](#)

type RDNSequence []RelativeDistinguishedNameSET

type RelativeDistinguishedNameSET

type RelativeDistinguishedNameSET []AttributeTypeAndValue

type [RevokedCertificate](#)

```
type RevokedCertificate struct {  
    SerialNumber    *big.Int  
    RevocationTime  time.Time  
    Extensions      []Extension `asn1:"optional"`  
}
```

RevokedCertificate represents the ASN.1 structure of the same name. See RFC 5280, section 5.1.

type [TBSCertificateList](#)

```
type TBSCertificateList struct {
    Raw          asn1.RawContent
    Version      int `asn1:"optional,default:2"`
    Signature    AlgorithmIdentifier
    Issuer       RDNSequence
    ThisUpdate   time.Time
    NextUpdate   time.Time
    RevokedCertificates []RevokedCertificate `asn1:"optional"`
    Extensions   []Extension           `asn1:"tag:0,optional,e`
}
```

TBSCertificateList represents the ASN.1 structure of the same name. See RFC 5280, section 5.1.

Package files

[convert.go](#) [sql.go](#)

Variables

```
var ErrNoRows = errors.New("sql: no rows in result set")
```

ErrNoRows is returned by Scan when QueryRow doesn't return a row. In such a case, QueryRow returns a placeholder *Row value that defers this error until a Scan.

```
var ErrTxDone = errors.New("sql: Transaction has already been commit
```

func [Register](#)

```
func Register(name string, driver driver.Driver)
```

Register makes a database driver available by the provided name. If Register is called twice with the same name or if driver is nil, it panics.

type [DB](#)

```
type DB struct {  
    // contains filtered or unexported fields  
}
```

DB is a database handle. It's safe for concurrent use by multiple goroutines.

If the underlying database driver has the concept of a connection and per-connection session state, the sql package manages creating and freeing connections automatically, including maintaining a free pool of idle connections. If observing session state is required, either do not share a *DB between multiple concurrent goroutines or create and observe all state only within a transaction. Once DB.Open is called, the returned Tx is bound to a single isolated connection. Once Tx.Commit or Tx.Rollback is called, that connection is returned to DB's idle connection pool.

func [Open](#)

```
func Open(driverName, dataSourceName string) (*DB, error)
```

Open opens a database specified by its database driver name and a driver-specific data source name, usually consisting of at least a database name and connection information.

Most users will open a database via a driver-specific connection helper function that returns a *DB.

func (*DB) [Begin](#)

```
func (db *DB) Begin() (*Tx, error)
```

Begin starts a transaction. The isolation level is dependent on the driver.

func (*DB) [Close](#)

```
func (db *DB) Close() error
```

Close closes the database, releasing any open resources.

func (*DB) [Driver](#)

```
func (db *DB) Driver() driver.Driver
```

Driver returns the database's underlying driver.

func (*DB) [Exec](#)

```
func (db *DB) Exec(query string, args ...interface{}) (Result, error)
```

Exec executes a query without returning any rows.

func (*DB) [Prepare](#)

```
func (db *DB) Prepare(query string) (*Stmt, error)
```

Prepare creates a prepared statement for later execution.

func (*DB) [Query](#)

```
func (db *DB) Query(query string, args ...interface{}) (*Rows, error)
```

Query executes a query that returns rows, typically a SELECT.

func (*DB) [QueryRow](#)

```
func (db *DB) QueryRow(query string, args ...interface{}) *Row
```

QueryRow executes a query that is expected to return at most one row. QueryRow always return a non-nil value. Errors are deferred until Row's Scan method is called.

type [NullBool](#)

```
type NullBool struct {  
    Bool bool  
    Valid bool // Valid is true if Bool is not NULL  
}
```

NullBool represents a bool that may be null. NullBool implements the Scanner interface so it can be used as a scan destination, similar to NullString.

func (***NullBool**) [Scan](#)

```
func (n *NullBool) Scan(value interface{}) error
```

Scan implements the Scanner interface.

func (**NullBool**) [Value](#)

```
func (n NullBool) Value() (driver.Value, error)
```

Value implements the driver Valuer interface.

type [NullFloat64](#)

```
type NullFloat64 struct {  
    Float64 float64  
    Valid    bool // Valid is true if Float64 is not NULL  
}
```

NullFloat64 represents a float64 that may be null. NullFloat64 implements the Scanner interface so it can be used as a scan destination, similar to NullString.

func (*NullFloat64) [Scan](#)

```
func (n *NullFloat64) Scan(value interface{}) error
```

Scan implements the Scanner interface.

func (NullFloat64) [Value](#)

```
func (n NullFloat64) Value() (driver.Value, error)
```

Value implements the driver Valuer interface.

type [NullInt64](#)

```
type NullInt64 struct {  
    Int64 int64  
    Valid bool // Valid is true if Int64 is not NULL  
}
```

NullInt64 represents an int64 that may be null. NullInt64 implements the Scanner interface so it can be used as a scan destination, similar to NullString.

func (***NullInt64**) [Scan](#)

```
func (n *NullInt64) Scan(value interface{}) error
```

Scan implements the Scanner interface.

func (**NullInt64**) [Value](#)

```
func (n NullInt64) Value() (driver.Value, error)
```

Value implements the driver Valuer interface.

type [NullString](#)

```
type NullString struct {
    String string
    Valid bool // Valid is true if String is not NULL
}
```

NullString represents a string that may be null. NullString implements the Scanner interface so it can be used as a scan destination:

```
var s NullString
err := db.QueryRow("SELECT name FROM foo WHERE id=?", id).Scan(&s)
...
if s.Valid {
    // use s.String
} else {
    // NULL value
}
```

func (***NullString**) [Scan](#)

```
func (ns *NullString) Scan(value interface{}) error
```

Scan implements the Scanner interface.

func (**NullString**) [Value](#)

```
func (ns NullString) Value() (driver.Value, error)
```

Value implements the driver Valuer interface.

type [RawBytes](#)

```
type RawBytes []byte
```

RawBytes is a byte slice that holds a reference to memory owned by the database itself. After a Scan into a RawBytes, the slice is only valid until the next call to Next, Scan, or Close.

type [Result](#)

```
type Result interface {  
    LastInsertId() (int64, error)  
    RowsAffected() (int64, error)  
}
```

A Result summarizes an executed SQL command.

type [Row](#)

```
type Row struct {  
    // contains filtered or unexported fields  
}
```

Row is the result of calling QueryRow to select a single row.

func (*Row) [Scan](#)

```
func (r *Row) Scan(dest ...interface{}) error
```

Scan copies the columns from the matched row into the values pointed at by dest. If more than one row matches the query, Scan uses the first row and discards the rest. If no row matches the query, Scan returns ErrNoRows.

type [Rows](#)

```
type Rows struct {  
    // contains filtered or unexported fields  
}
```

Rows is the result of a query. Its cursor starts before the first row of the result set. Use Next to advance through the rows:

```
rows, err := db.Query("SELECT ...")  
...  
for rows.Next() {  
    var id int  
    var name string  
    err = rows.Scan(&id, &name)  
    ...  
}  
err = rows.Err() // get any error encountered during iteration  
...
```

func (***Rows**) [Close](#)

```
func (rs *Rows) Close() error
```

Close closes the Rows, preventing further enumeration. If the end is encountered, the Rows are closed automatically. Close is idempotent.

func (***Rows**) [Columns](#)

```
func (rs *Rows) Columns() ([]string, error)
```

Columns returns the column names. Columns returns an error if the rows are closed, or if the rows are from QueryRow and there was a deferred error.

func (***Rows**) [Err](#)

```
func (rs *Rows) Err() error
```

Err returns the error, if any, that was encountered during iteration.

func (***Rows**) [Next](#)

```
func (rs *Rows) Next() bool
```

Next prepares the next result row for reading with the Scan method. It returns true on success, false if there is no next result row. Every call to Scan, even the first one, must be preceded by a call to Next.

func (*Rows) [Scan](#)

```
func (rs *Rows) Scan(dest ...interface{}) error
```

Scan copies the columns in the current row into the values pointed at by dest.

If an argument has type `[]byte`, Scan saves in that argument a copy of the corresponding data. The copy is owned by the caller and can be modified and held indefinitely. The copy can be avoided by using an argument of type `*RawBytes` instead; see the documentation for `RawBytes` for restrictions on its use.

If an argument has type `*interface{}`, Scan copies the value provided by the underlying driver without conversion. If the value is of type `[]byte`, a copy is made and the caller owns the result.

type [Scanner](#)

```
type Scanner interface {
    // Scan assigns a value from a database driver.
    //
    // The src value will be of one of the following restricted
    // set of types:
    //
    //     int64
    //     float64
    //     bool
    //     []byte
    //     string
    //     time.Time
    //     nil - for NULL values
    //
    // An error should be returned if the value can not be stored
    // without loss of information.
    Scan(src interface{}) error
}
```

Scanner is an interface used by Scan.

type [Stmt](#)

```
type Stmt struct {  
    // contains filtered or unexported fields  
}
```

Stmt is a prepared statement. Stmt is safe for concurrent use by multiple goroutines.

func (*Stmt) [Close](#)

```
func (s *Stmt) Close() error
```

Close closes the statement.

func (*Stmt) [Exec](#)

```
func (s *Stmt) Exec(args ...interface{}) (Result, error)
```

Exec executes a prepared statement with the given arguments and returns a Result summarizing the effect of the statement.

func (*Stmt) [Query](#)

```
func (s *Stmt) Query(args ...interface{}) (*Rows, error)
```

Query executes a prepared query statement with the given arguments and returns the query results as a *Rows.

func (*Stmt) [QueryRow](#)

```
func (s *Stmt) QueryRow(args ...interface{}) *Row
```

QueryRow executes a prepared query statement with the given arguments. If an error occurs during the execution of the statement, that error will be returned by a call to Scan on the returned *Row, which is always non-nil. If the query selects no rows, the *Row's Scan will return ErrNoRows. Otherwise, the *Row's Scan scans the first selected row and discards the rest.

Example usage:

```
var name string
err := nameByUserIdStmt.QueryRow(id).Scan(&name)
```

type Tx

```
type Tx struct {  
    // contains filtered or unexported fields  
}
```

Tx is an in-progress database transaction.

A transaction must end with a call to Commit or Rollback.

After a call to Commit or Rollback, all operations on the transaction fail with ErrTxDone.

func (*Tx) Commit

```
func (tx *Tx) Commit() error
```

Commit commits the transaction.

func (*Tx) Exec

```
func (tx *Tx) Exec(query string, args ...interface{}) (Result, error)
```

Exec executes a query that doesn't return rows. For example: an INSERT and UPDATE.

func (*Tx) Prepare

```
func (tx *Tx) Prepare(query string) (*Stmt, error)
```

Prepare creates a prepared statement for use within a transaction.

The returned statement operates within the transaction and can no longer be used once the transaction has been committed or rolled back.

To use an existing prepared statement on this transaction, see Tx.Stmt.

func (*Tx) Query

```
func (tx *Tx) Query(query string, args ...interface{}) (*Rows, error
```

Query executes a query that returns rows, typically a SELECT.

func (*Tx) [QueryRow](#)

```
func (tx *Tx) QueryRow(query string, args ...interface{}) *Row
```

QueryRow executes a query that is expected to return at most one row. QueryRow always return a non-nil value. Errors are deferred until Row's Scan method is called.

func (*Tx) [Rollback](#)

```
func (tx *Tx) Rollback() error
```

Rollback aborts the transaction.

func (*Tx) [Stmt](#)

```
func (tx *Tx) Stmt(stmt *Stmt) *Stmt
```

Stmt returns a transaction-specific prepared statement from an existing statement.

Example:

```
updateMoney, err := db.Prepare("UPDATE balance SET money=money+? WHE  
...  
tx, err := db.Begin()  
...  
res, err := tx.Stmt(updateMoney).Exec(123.45, 98293203)
```

[type Value](#)

[type ValueConverter](#)

[type Valuer](#)

Package files

[driver.go](#) [types.go](#)

Variables

```
var Bool boolType
```

Bool is a ValueConverter that converts input values to bools.

The conversion rules are:

- booleans are returned unchanged
- for integer types,
 - 1 is true
 - 0 is false,
 - other integers are an error
- for strings and []byte, same rules as strconv.ParseBool
- all other types are an error

```
var DefaultParameterConverter defaultConverter
```

DefaultParameterConverter is the default implementation of ValueConverter that's used when a Stmt doesn't implement ColumnConverter.

DefaultParameterConverter returns the given value directly if IsValue(value). Otherwise integer type are converted to int64, floats to float64, and strings to []byte. Other types are an error.

```
var ErrBadConn = errors.New("driver: bad connection")
```

ErrBadConn should be returned by a driver to signal to the sql package that a driver.Conn is in a bad state (such as the server having earlier closed the connection) and the sql package should retry on a new connection.

To prevent duplicate operations, ErrBadConn should NOT be returned if there's a possibility that the database server might have performed the operation. Even if the server sends back an error, you shouldn't return ErrBadConn.

```
var ErrSkip = errors.New("driver: skip fast-path; continue as if uni
```

ErrSkip may be returned by some optional interfaces' methods to indicate at runtime that the fast path is unavailable and the sql package should continue as if the optional interface was not implemented. ErrSkip is only supported where explicitly documented.

```
var Int32 int32Type
```

Int32 is a ValueConverter that converts input values to int64, respecting the limits of an int32 value.

```
var ResultNoRows noRows
```

ResultNoRows is a pre-defined Result for drivers to return when a DDL command (such as a CREATE TABLE) succeeds. It returns an error for both LastInsertId and RowsAffected.

```
var String stringType
```

String is a ValueConverter that converts its input to a string. If the value is already a string or []byte, it's unchanged. If the value is of another type, conversion to string is done with `fmt.Sprintf("%v", v)`.

func [IsScanValue](#)

```
func IsScanValue(v interface{}) bool
```

IsScanValue reports whether v is a valid Value scan type. Unlike IsValue, IsScanValue does not permit the string type.

func [IsValue](#)

```
func IsValue(v interface{}) bool
```

IsValue reports whether v is a valid Value parameter type. Unlike IsScanValue, IsValue permits the string type.

type ColumnConverter

```
type ColumnConverter interface {  
    // ColumnConverter returns a ValueConverter for the provided  
    // column index. If the type of a specific column isn't known  
    // or shouldn't be handled specially, DefaultValueConverter  
    // can be returned.  
    ColumnConverter(idx int) ValueConverter  
}
```

ColumnConverter may be optionally implemented by Stmt if the the statement is aware of its own columns' types and can convert from any type to a driver Value.

type Conn

```
type Conn interface {
    // Prepare returns a prepared statement, bound to this connectio
    Prepare(query string) (Stmt, error)

    // Close invalidates and potentially stops any current
    // prepared statements and transactions, marking this
    // connection as no longer in use.
    //
    // Because the sql package maintains a free pool of
    // connections and only calls Close when there's a surplus of
    // idle connections, it shouldn't be necessary for drivers to
    // do their own connection caching.
    Close() error

    // Begin starts and returns a new transaction.
    Begin() (Tx, error)
}
```

Conn is a connection to a database. It is not used concurrently by multiple goroutines.

Conn is assumed to be stateful.

type [Driver](#)

```
type Driver interface {
    // Open returns a new connection to the database.
    // The name is a string in a driver-specific format.
    //
    // Open may return a cached connection (one previously
    // closed), but doing so is unnecessary; the sql package
    // maintains a pool of idle connections for efficient re-use.
    //
    // The returned connection is only used by one goroutine at a
    // time.
    Open(name string) (Conn, error)
}
```

Driver is the interface that must be implemented by a database driver.

type [Execer](#)

```
type Execer interface {  
    Exec(query string, args []Value) (Result, error)  
}
```

Execer is an optional interface that may be implemented by a Conn.

If a Conn does not implement Execer, the db package's DB.Exec will first prepare a query, execute the statement, and then close the statement.

Exec may return ErrSkip.

type [NotNull](#)

```
type NotNull struct {  
    Converter ValueConverter  
}
```

NotNull is a type that implements ValueConverter by disallowing nil values but otherwise delegating to another ValueConverter.

func (NotNull) [ConvertValue](#)

```
func (n NotNull) ConvertValue(v interface{}) (Value, error)
```

type [Null](#)

```
type Null struct {  
    Converter ValueConverter  
}
```

Null is a type that implements ValueConverter by allowing nil values but otherwise delegating to another ValueConverter.

func (Null) [ConvertValue](#)

```
func (n Null) ConvertValue(v interface{}) (Value, error)
```

type [Result](#)

```
type Result interface {  
    // LastInsertId returns the database's auto-generated ID  
    // after, for example, an INSERT into a table with primary  
    // key.  
    LastInsertId() (int64, error)  
  
    // RowsAffected returns the number of rows affected by the  
    // query.  
    RowsAffected() (int64, error)  
}
```

Result is the result of a query execution.

type Rows

```
type Rows interface {
    // Columns returns the names of the columns. The number of
    // columns of the result is inferred from the length of the
    // slice. If a particular column name isn't known, an empty
    // string should be returned for that entry.
    Columns() []string

    // Close closes the rows iterator.
    Close() error

    // Next is called to populate the next row of data into
    // the provided slice. The provided slice will be the same
    // size as the Columns() are wide.
    //
    // The dest slice may be populated only with
    // a driver Value type, but excluding string.
    // All string values must be converted to []byte.
    //
    // Next should return io.EOF when there are no more rows.
    Next(dest []Value) error
}
```

Rows is an iterator over an executed query's results.

type [RowsAffected](#)

type RowsAffected int64

RowsAffected implements Result for an INSERT or UPDATE operation which mutates a number of rows.

func (RowsAffected) [LastInsertId](#)

func (RowsAffected) LastInsertId() (int64, error)

func (RowsAffected) [RowsAffected](#)

func (v RowsAffected) RowsAffected() (int64, error)

type Stmt

```
type Stmt interface {
    // Close closes the statement.
    //
    // Closing a statement should not interrupt any outstanding
    // query created from that statement. That is, the following
    // order of operations is valid:
    //
    // * create a driver statement
    // * call Query on statement, returning Rows
    // * close the statement
    // * read from Rows
    //
    // If closing a statement invalidates currently-running
    // queries, the final step above will incorrectly fail.
    //
    // TODO(bradfitz): possibly remove the restriction above, if
    // enough driver authors object and find it complicates their
    // code too much. The sql package could be smarter about
    // recounting the statement and closing it at the appropriate
    // time.
    Close() error

    // NumInput returns the number of placeholder parameters.
    //
    // If NumInput returns >= 0, the sql package will sanity check
    // argument counts from callers and return errors to the caller
    // before the statement's Exec or Query methods are called.
    //
    // NumInput may also return -1, if the driver doesn't know
    // its number of placeholders. In that case, the sql package
    // will not sanity check Exec or Query argument counts.
    NumInput() int

    // Exec executes a query that doesn't return rows, such
    // as an INSERT or UPDATE.
    Exec(args []Value) (Result, error)

    // Exec executes a query that may return rows, such as a
    // SELECT.
    Query(args []Value) (Rows, error)
}
```

Stmt is a prepared statement. It is bound to a Conn and not used by multiple goroutines concurrently.

type Tx

```
type Tx interface {  
    Commit() error  
    Rollback() error  
}
```

Tx is a transaction.

type [Value](#)

```
type Value interface{}
```

A driver Value is a value that drivers must be able to handle. A Value is either nil or an instance of one of these types:

```
int64  
float64  
bool  
[]byte  
string  [*] everywhere except from Rows.Next.  
time.Time
```

type [ValueConverter](#)

```
type ValueConverter interface {  
    // ConvertValue converts a value to a driver Value.  
    ConvertValue(v interface{}) (Value, error)  
}
```

ValueConverter is the interface providing the ConvertValue method.

Various implementations of ValueConverter are provided by the driver package to provide consistent implementations of conversions between drivers. The ValueConverters have several uses:

- * converting from the Value types as provided by the sql package into a database table's specific column type and making sure it fits, such as making sure a particular int64 fits in a table's uint16 column.
- * converting a value as given from the database into one of the driver Value types.
- * by the sql package, for converting from a driver's Value type to a user's type in a scan.

type [Valuer](#)

```
type Valuer interface {  
    // Value returns a driver Value.  
    Value() (Value, error)  
}
```

Valuer is the interface providing the Value method.

Types implementing Valuer interface are able to convert themselves to a driver Value.

Name	Synopsis
dwarf	Package dwarf provides access to DWARF debugging information loaded from executable files, as defined in the DWARF 2.0 Standard at http://dwarfstd.org/doc/dwarf-2.0.0.pdf
elf	Package elf implements access to ELF object files.
gosym	Package gosym implements access to the Go symbol and line number tables embedded in Go binaries generated by the gc compilers.
macho	Package macho implements access to Mach-O object files.
pe	Package pe implements access to PE (Microsoft Windows Portable Executable) files.

Need more packages? Take a look at the [Go Project Dashboard](#).

Package files

[buf.go](#) [const.go](#) [entry.go](#) [open.go](#) [type.go](#) [unit.go](#)

type [AddrType](#)

```
type AddrType struct {  
    BasicType  
}
```

An AddrType represents a machine address type.

type [ArrayType](#)

```
type ArrayType struct {
    CommonType
    Type          Type
    StrideBitSize int64 // if > 0, number of bits to hold each eleme
    Count         int64 // if == -1, an incomplete array, like char
}
```

An ArrayType represents a fixed size array type.

func (***ArrayType**) [Size](#)

```
func (t *ArrayType) Size() int64
```

func (***ArrayType**) [String](#)

```
func (t *ArrayType) String() string
```

type [Attr](#)

type Attr uint32

An Attr identifies the attribute type in a DWARF Entry's Field.

```
const (
    AttrSibling           Attr = 0x01
    AttrLocation         Attr = 0x02
    AttrName             Attr = 0x03
    AttrOrdering        Attr = 0x09
    AttrByteSize        Attr = 0x0B
    AttrBitOffset       Attr = 0x0C
    AttrBitSize         Attr = 0x0D

AttrCallFile	Attr = 0x58
AttrCallLine	Attr = 0x59
AttrDescription	Attr = 0x5A

)

func (Attr) [GoString](#)

```
func (a Attr) GoString() string
```

func (Attr) [String](#)

```
func (a Attr) String() string
```

type [BasicType](#)

```
type BasicType struct {  
    CommonType  
    BitSize    int64  
    BitOffset  int64  
}
```

A BasicType holds fields common to all basic types.

func (***BasicType**) [Basic](#)

```
func (b *BasicType) Basic() *BasicType
```

func (***BasicType**) [String](#)

```
func (t *BasicType) String() string
```

type BoolType

```
type BoolType struct {  
    BasicType  
}
```

A BoolType represents a boolean type.

type [CharType](#)

```
type CharType struct {  
    BasicType  
}
```

A CharType represents a signed character type.

type [CommonType](#)

```
type CommonType struct {  
    ByteSize int64 // size of value of this type, in bytes  
    Name      string // name that can be used to refer to type  
}
```

A CommonType holds fields common to multiple types. If a field is not known or not applicable for a given type, the zero value is used.

func (***CommonType**) [Common](#)

```
func (c *CommonType) Common() *CommonType
```

func (***CommonType**) [Size](#)

```
func (c *CommonType) Size() int64
```

type ComplexType

```
type ComplexType struct {  
    BasicType  
}
```

A ComplexType represents a complex floating point type.

type [Data](#)

```
type Data struct {  
    // contains filtered or unexported fields  
}
```

Data represents the DWARF debugging information loaded from an executable file (for example, an ELF or Mach-O executable).

func [New](#)

```
func New(abbrev, aranges, frame, info, line, pubnames, ranges, str []
```

New returns a new Data object initialized from the given parameters. Rather than calling this function directly, clients should typically use the DWARF method of the File type of the appropriate package debug/elf, debug/macho, or debug/pe.

The []byte arguments are the data from the corresponding debug section in the object file; for example, for an ELF object, abbrev is the contents of the ".debug_abbrev" section.

func (*Data) [Reader](#)

```
func (d *Data) Reader() *Reader
```

Reader returns a new Reader for Data. The reader is positioned at byte offset 0 in the DWARF “info” section.

func (*Data) [Type](#)

```
func (d *Data) Type(off Offset) (Type, error)
```

type [DecodeError](#)

```
type DecodeError struct {  
    Name    string  
    Offset  Offset  
    Err     string  
}
```

func (DecodeError) [Error](#)

```
func (e DecodeError) Error() string
```

type [DotDotDotType](#)

```
type DotDotDotType struct {  
    CommonType  
}
```

A DotDotDotType represents the variadic ... function parameter.

func (*DotDotDotType) [String](#)

```
func (t *DotDotDotType) String() string
```

type [Entry](#)

```
type Entry struct {
    Offset    Offset // offset of Entry in DWARF info
    Tag       Tag      // tag (kind of Entry)
    Children  bool    // whether Entry is followed by children
    Field     []Field
}
```

An entry is a sequence of attribute/value pairs.

func (*Entry) [Val](#)

```
func (e *Entry) Val(a Attr) interface{}
```

Val returns the value associated with attribute Attr in Entry, or nil if there is no such attribute.

A common idiom is to merge the check for nil return with the check that the value has the expected dynamic type, as in:

```
v, ok := e.Val(AttrSibling).(int64);
```

type [EnumType](#)

```
type EnumType struct {  
    CommonType  
    EnumName string  
    Val      []*EnumValue  
}
```

An EnumType represents an enumerated type. The only indication of its native integer type is its ByteSize (inside CommonType).

func (*EnumType) [String](#)

```
func (t *EnumType) String() string
```

type EnumValue

```
type EnumValue struct {  
    Name string  
    Val  int64  
}
```

An EnumValue represents a single enumeration value.

type Field

```
type Field struct {  
    Attr Attr  
    Val  interface{  
}
```

A Field is a single attribute/value pair in an Entry.

type [FloatType](#)

```
type FloatType struct {  
    BasicType  
}
```

A FloatType represents a floating point type.

type [FuncType](#)

```
type FuncType struct {  
    CommonType  
    Returntype Type  
    ParamType []Type  
}
```

A FuncType represents a function type.

func (*FuncType) [String](#)

```
func (t *FuncType) String() string
```

type [IntType](#)

```
type IntType struct {  
    BasicType  
}
```

An IntType represents a signed integer type.

type [Offset](#)

```
type Offset uint32
```

An Offset represents the location of an Entry within the DWARF info. (See Reader.Seek.)

type [PtrType](#)

```
type PtrType struct {  
    CommonType  
    Type Type  
}
```

A PtrType represents a pointer type.

func (*PtrType) [String](#)

```
func (t *PtrType) String() string
```

type [QualType](#)

```
type QualType struct {  
    CommonType  
    Qual string  
    Type Type  
}
```

A QualType represents a type that has the C/C++ "const", "restrict", or "volatile" qualifier.

func (***QualType**) [Size](#)

```
func (t *QualType) Size() int64
```

func (***QualType**) [String](#)

```
func (t *QualType) String() string
```

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

A Reader allows reading Entry structures from a DWARF “info” section. The Entry structures are arranged in a tree. The Reader's Next function return successive entries from a pre-order traversal of the tree. If an entry has children, its Children field will be true, and the children follow, terminated by an Entry with Tag 0.

func (*Reader) [Next](#)

```
func (r *Reader) Next() (*Entry, error)
```

Next reads the next entry from the encoded entry stream. It returns nil, nil when it reaches the end of the section. It returns an error if the current offset is invalid or the data at the offset cannot be decoded as a valid Entry.

func (*Reader) [Seek](#)

```
func (r *Reader) Seek(off Offset)
```

Seek positions the Reader at offset off in the encoded entry stream. Offset 0 can be used to denote the first entry.

func (*Reader) [SkipChildren](#)

```
func (r *Reader) SkipChildren()
```

SkipChildren skips over the child entries associated with the last Entry returned by Next. If that Entry did not have children or Next has not been called, SkipChildren is a no-op.

type [StructField](#)

```
type StructField struct {
    Name      string
    Type      Type
    ByteOffset int64
    ByteSize  int64
    BitOffset  int64 // within the ByteSize bytes at ByteOffset
    BitSize   int64 // zero if not a bit field
}
```

A StructField represents a field in a struct, union, or C++ class type.

type [StructType](#)

```
type StructType struct {
    CommonType
    StructName string
    Kind        string // "struct", "union", or "class".
    Field       []*StructField
    Incomplete bool // if true, struct, union, class is declared but
}
```

A StructType represents a struct, union, or C++ class type.

func (*StructType) [Defn](#)

```
func (t *StructType) Defn() string
```

func (*StructType) [String](#)

```
func (t *StructType) String() string
```

type [Tag](#)

```
type Tag uint32
```

A Tag is the classification (the type) of an Entry.

```
const (  
    TagArrayType           Tag = 0x01  
    TagClassType          Tag = 0x02  
    TagEntryPoint         Tag = 0x03  
    TagEnumerationType    Tag = 0x04

TagUnspecifiedType	Tag = 0x3B
TagPartialUnit	Tag = 0x3C
TagImportedUnit	Tag = 0x3D
TagMutableType	Tag = 0x3E

)

func (Tag) [GoString](#)

```
func (t Tag) GoString() string
```

func (Tag) [String](#)

```
func (t Tag) String() string
```

type Type

```
type Type interface {  
    Common() *CommonType  
    String() string  
    Size() int64  
}
```

A Type conventionally represents a pointer to any of the specific Type structures (CharType, StructType, etc.).

type [TypedefType](#)

```
type TypedefType struct {  
    CommonType  
    Type Type  
}
```

A TypedefType represents a named type.

func (*TypedefType) [Size](#)

```
func (t *TypedefType) Size() int64
```

func (*TypedefType) [String](#)

```
func (t *TypedefType) String() string
```

type [UcharType](#)

```
type UcharType struct {  
    BasicType  
}
```

A UcharType represents an unsigned character type.

type [UIntType](#)

```
type UIntType struct {  
    BasicType  
}
```

A UIntType represents an unsigned integer type.

type [VoidType](#)

```
type VoidType struct {  
    CommonType  
}
```

A VoidType represents the C void type.

func (*VoidType) [String](#)

```
func (t *VoidType) String() string
```

Constants

```
const (  
    EI_CLASS      = 4 /* Class of machine. */  
    EI_DATA       = 5 /* Data format. */  
    EI_VERSION    = 6 /* ELF format version. */  
    EI_OSABI      = 7 /* Operating system / ABI identification */  
    EI_ABIVERSION = 8 /* ABI version */  
    EI_PAD        = 9 /* Start of padding (per SVR4 ABI). */  
    EI_NIDENT     = 16 /* Size of e_ident array. */  
)
```

Indexes into the Header.Ident array.

```
const ARM_MAGIC_TRAMP_NUMBER = 0x5c000003
```

Magic number for the elf trampoline, chosen wisely to be an immediate value.

```
const ELFMAG = "\177ELF"
```

Initial magic number for ELF files.

```
const Sym32Size = 16
```

```
const Sym64Size = 24
```

func [R_INFO](#)

```
func R_INFO(sym, typ uint32) uint64
```

func [R_INFO32](#)

func R_INFO32(sym, typ uint32) uint32

func [R_SYM32](#)

```
func R_SYM32(info uint32) uint32
```

func [R_SYM64](#)

func R_SYM64(info uint64) uint32

func R_TYPE32

```
func R_TYPE32(info uint32) uint32
```

func R_TYPE64

```
func R_TYPE64(info uint64) uint32
```

func [ST_INFO](#)

```
func ST_INFO(bind SymBind, typ SymType) uint8
```

type [Class](#)

type Class byte

Class is found in Header.Ident[EI_CLASS] and Header.Class.

```
const (  
    ELFCLASSNONE Class = 0 /* Unknown class. */  
    ELFCLASS32   Class = 1 /* 32-bit architecture. */  
    ELFCLASS64   Class = 2 /* 64-bit architecture. */  
)
```

func (Class) [GoString](#)

func (i Class) GoString() string

func (Class) [String](#)

func (i Class) String() string

type [Data](#)

type Data byte

Data is found in Header.Ident[EI_DATA] and Header.Data.

```
const (  
    ELFDATANONE Data = 0 /* Unknown data format. */  
    ELFDATA2LSB Data = 1 /* 2's complement little-endian. */  
    ELFDATA2MSB Data = 2 /* 2's complement big-endian. */  
)
```

func (Data) [GoString](#)

func (i Data) GoString() string

func (Data) [String](#)

func (i Data) String() string

type [Dyn32](#)

```
type Dyn32 struct {
    Tag int32 /* Entry type. */
    Val uint32 /* Integer/Address value. */
}
```

ELF32 Dynamic structure. The ".dynamic" section contains an array of them.

type [Dyn64](#)

```
type Dyn64 struct {  
    Tag int64 /* Entry type. */  
    Val uint64 /* Integer/address value */  
}
```

ELF64 Dynamic structure. The ".dynamic" section contains an array of them.

type [DynFlag](#)

```
type DynFlag int
```

DT_FLAGS values.

```
const (  
    DF_ORIGIN DynFlag = 0x0001 /* Indicates that the object being lo  
        make reference to the  
        $ORIGIN substitution string */

DT_HIPROC          DynTag = 0x7fffffff /* Last processor-specific
)
```

func (DynTag) [GoString](#)

```
func (i DynTag) GoString() string
```

func (DynTag) [String](#)

```
func (i DynTag) String() string
```

type [File](#)

```
type File struct {
    FileHeader
    Sections []*Section
    Progs     []*Prog
    // contains filtered or unexported fields
}
```

A File represents an open ELF file.

func [NewFile](#)

```
func NewFile(r io.ReaderAt) (*File, error)
```

NewFile creates a new File for accessing an ELF binary in an underlying reader. The ELF binary is expected to start at position 0 in the ReaderAt.

func [Open](#)

```
func Open(name string) (*File, error)
```

Open opens the named file using os.Open and prepares it for use as an ELF binary.

func (*File) [Close](#)

```
func (f *File) Close() error
```

Close closes the File. If the File was created using NewFile directly instead of Open, Close has no effect.

func (*File) [DWARF](#)

```
func (f *File) DWARF() (*dwarf.Data, error)
```

func (*File) [ImportedLibraries](#)

```
func (f *File) ImportedLibraries() ([]string, error)
```

ImportedLibraries returns the names of all libraries referred to by the binary f that are expected to be linked with the binary at dynamic link time.

func (*File) [ImportedSymbols](#)

```
func (f *File) ImportedSymbols() ([]ImportedSymbol, error)
```

ImportedSymbols returns the names of all symbols referred to by the binary f that are expected to be satisfied by other libraries at dynamic load time. It does not return weak symbols.

func (*File) [Section](#)

```
func (f *File) Section(name string) *Section
```

Section returns a section with the given name, or nil if no such section exists.

func (*File) [SectionByType](#)

```
func (f *File) SectionByType(typ SectionType) *Section
```

SectionByType returns the first section in f with the given type, or nil if there is no such section.

func (*File) [Symbols](#)

```
func (f *File) Symbols() ([]Symbol, error)
```

Symbols returns the symbol table for f.

type [FileHeader](#)

```
type FileHeader struct {  
    Class      Class  
    Data       Data  
    Version    Version  
    OSABI      OSABI  
    ABIVersion uint8  
    ByteOrder  binary.ByteOrder  
    Type       Type  
    Machine    Machine  
}
```

A FileHeader represents an ELF file header.

type [FormatError](#)

```
type FormatError struct {  
    // contains filtered or unexported fields  
}
```

func ([*FormatError](#)) [Error](#)

```
func (e *FormatError) Error() string
```

type Header32

```
type Header32 struct {
    Ident    [EI_NIDENT]byte /* File identification. */
    Type     uint16      /* File type. */
    Machine  uint16      /* Machine architecture. */
    Version  uint32      /* ELF format version. */
    Entry    uint32      /* Entry point. */
    Phoff    uint32      /* Program header file offset. */
    Shoff    uint32      /* Section header file offset. */
    Flags    uint32      /* Architecture-specific flags. */
    Ehsize   uint16      /* Size of ELF header in bytes. */
    Phentsize uint16     /* Size of program header entry. */
    Phnum    uint16     /* Number of program header entries. */
    Shentsize uint16     /* Size of section header entry. */
    Shnum    uint16     /* Number of section header entries. */
    Shstrndx uint16     /* Section name strings section. */
}
```

ELF32 File header.

type Header64

```
type Header64 struct {
    Ident    [EI_NIDENT]byte /* File identification. */
    Type     uint16        /* File type. */
    Machine  uint16        /* Machine architecture. */
    Version  uint32        /* ELF format version. */
    Entry    uint64        /* Entry point. */
    Phoff    uint64        /* Program header file offset. */
    Shoff    uint64        /* Section header file offset. */
    Flags    uint32        /* Architecture-specific flags. */
    Ehsize   uint16        /* Size of ELF header in bytes. */
    Phentsize uint16       /* Size of program header entry. */
    Phnum    uint16        /* Number of program header entries. *
    Shentsize uint16       /* Size of section header entry. */
    Shnum    uint16        /* Number of section header entries. *
    Shstrndx uint16        /* Section name strings section. */
}
```

ELF64 file header.

type ImportedSymbol

```
type ImportedSymbol struct {  
    Name    string  
    Version string  
    Library string  
}
```

type [Machine](#)

type Machine uint16

Machine is found in Header.Machine.

```
const (

)
```

func (OSABI) [GoString](#)

func (i OSABI) GoString() string

func (OSABI) [String](#)

func (i OSABI) String() string

type [Prog](#)

```
type Prog struct {
    ProgHeader

    // Embed ReaderAt for ReadAt method.
    // Do not embed SectionReader directly
    // to avoid having Read and Seek.
    // If a client wants Read and Seek it must use
    // Open() to avoid fighting over the seek offset
    // with other clients.
    io.ReaderAt
    // contains filtered or unexported fields
}
```

A Prog represents a single ELF program header in an ELF binary.

func ([*Prog](#)) [Open](#)

```
func (p *Prog) Open() io.ReadSeeker
```

Open returns a new ReadSeeker reading the ELF program body.

type [Prog32](#)

```
type Prog32 struct {
    Type    uint32 /* Entry type. */
    Off     uint32 /* File offset of contents. */
    Vaddr   uint32 /* Virtual address in memory image. */
    Paddr   uint32 /* Physical address (not used). */
    Filesz  uint32 /* Size of contents in file. */
    Memsz   uint32 /* Size of contents in memory. */
    Flags   uint32 /* Access permission flags. */
    Align   uint32 /* Alignment in memory and file. */
}
```

ELF32 Program header.

type [Prog64](#)

)
```

func (R_X86_64) [GoString](#)

```
func (i R_X86_64) GoString() string
```

func (R_X86_64) [String](#)

```
func (i R_X86_64) String() string
```

type [Rel32](#)

```
type Rel32 struct {  
    Off  uint32 /* Location to be relocated. */  
    Info uint32 /* Relocation type and symbol index. */  
}
```

ELF32 Relocations that don't need an addend field.

type [Rel64](#)

```
type Rel64 struct {  
    Off  uint64 /* Location to be relocated. */  
    Info uint64 /* Relocation type and symbol index. */  
}
```

ELF64 relocations that don't need an addend field.

type [Rela32](#)

```
type Rela32 struct {
    Off    uint32 /* Location to be relocated. */
    Info   uint32 /* Relocation type and symbol index. */
    Addend int32 /* Addend. */
}
```

ELF32 Relocations that need an addend field.

type [Rela64](#)

```
type Rela64 struct {
    Off    uint64 /* Location to be relocated. */
    Info   uint64 /* Relocation type and symbol index. */
    Addend int64 /* Addend. */
}
```

ELF64 relocations that need an addend field.

type [Section](#)

```
type Section struct {
    SectionHeader

    // Embed ReaderAt for ReadAt method.
    // Do not embed SectionReader directly
    // to avoid having Read and Seek.
    // If a client wants Read and Seek it must use
    // Open() to avoid fighting over the seek offset
    // with other clients.
    io.ReaderAt
    // contains filtered or unexported fields
}
```

A Section represents a single section in an ELF file.

func (***Section**) [Data](#)

```
func (s *Section) Data() ([]byte, error)
```

Data reads and returns the contents of the ELF section.

func (***Section**) [Open](#)

```
func (s *Section) Open() io.ReadSeeker
```

Open returns a new ReadSeeker reading the ELF section.

type [Section32](#)

```
type Section32 struct {
    Name      uint32 /* Section name (index into the section header) */
    Type      uint32 /* Section type. */
    Flags     uint32 /* Section flags. */
    Addr      uint32 /* Address in memory image. */
    Off       uint32 /* Offset in file. */
    Size      uint32 /* Size in bytes. */
    Link      uint32 /* Index of a related section. */
    Info      uint32 /* Depends on section type. */
    Addralign uint32 /* Alignment in bytes. */
    Entsize   uint32 /* Size of each entry in section. */
}
```

ELF32 Section header.

type [Section64](#)

```
type Section64 struct {
    Name      uint32 /* Section name (index into the section header
    Type      uint32 /* Section type. */
    Flags     uint64 /* Section flags. */
    Addr      uint64 /* Address in memory image. */
    Off       uint64 /* Offset in file. */
    Size      uint64 /* Size in bytes. */
    Link      uint32 /* Index of a related section. */
    Info      uint32 /* Depends on section type. */
    Addralign uint64 /* Alignment in bytes. */
    Entsize   uint64 /* Size of each entry in section. */
}
```

ELF64 Section header.

type [SectionFlag](#)

```
type SectionFlag uint32
```

Section flags.

```
const (
    SHF_WRITE           SectionFlag = 0x1        /* Section contain
    SHF_ALLOC           SectionFlag = 0x2        /* Section occupie

    SHF_MASKPROC        SectionFlag = 0xf0000000 /* Processor-speci
)
```

func (SectionFlag) [GoString](#)

```
func (i SectionFlag) GoString() string
```

func (SectionFlag) [String](#)

```
func (i SectionFlag) String() string
```

type SectionHeader

```
type SectionHeader struct {  
    Name      string  
    Type      SectionType  
    Flags     SectionFlag  
    Addr      uint64  
    Offset    uint64  
    Size      uint64  
    Link      uint32  
    Info      uint32  
    Addralign uint64  
    Entsize   uint64  
}
```

A SectionHeader represents a single ELF section header.

type [SectionIndex](#)

```
type SectionIndex int
```

Special section indices.

```
const (  
    SHN_UNDEF      SectionIndex = 0      /* Undefined, missing, irrel  
    SHN_LORESERVE  SectionIndex = 0xff00 /* First of reserved range.

Package files

[pclntab.go](#) [symtab.go](#)

type [DecodingError](#)

```
type DecodingError struct {  
    // contains filtered or unexported fields  
}
```

DecodingError represents an error during the decoding of the symbol table.

func ([*DecodingError](#)) [Error](#)

```
func (e *DecodingError) Error() string
```

type [Func](#)

```
type Func struct {
    Entry uint64
    *Sym
    End      uint64
    Params   []*Sym
    Locals   []*Sym
    FrameSize int
    LineTable *LineTable
    Obj      *Obj
}
```

A Func collects information about a single function.

type [LineTable](#)

```
type LineTable struct {  
    Data []byte  
    PC   uint64  
    Line int  
}
```

func [NewLineTable](#)

```
func NewLineTable(data []byte, text uint64) *LineTable
```

NewLineTable returns a new PC/line table corresponding to the encoded data. Text must be the start address of the corresponding text segment.

func (*LineTable) [LineToPC](#)

```
func (t *LineTable) LineToPC(line int, maxpc uint64) uint64
```

func (*LineTable) [PCToLine](#)

```
func (t *LineTable) PCToLine(pc uint64) int
```

type Obj

```
type Obj struct {  
    Funcs []Func  
    Paths []Sym  
}
```

An Obj represents a single object file.

type [Sym](#)

```
type Sym struct {
    Value  uint64
    Type   byte
    Name   string
    GoType uint64
    // If this symbol is a function symbol, the corresponding Func
    Func  *Func
}
```

A Sym represents a single symbol table entry.

func (*Sym) [BaseName](#)

```
func (s *Sym) BaseName() string
```

BaseName returns the symbol name without the package or receiver name.

func (*Sym) [PackageName](#)

```
func (s *Sym) PackageName() string
```

PackageName returns the package part of the symbol name, or the empty string if there is none.

func (*Sym) [ReceiverName](#)

```
func (s *Sym) ReceiverName() string
```

ReceiverName returns the receiver type name of this symbol, or the empty string if there is none.

func (*Sym) [Static](#)

```
func (s *Sym) Static() bool
```

Static returns whether this symbol is static (not visible outside its file).

type [Table](#)

```
type Table struct {
    Syms    []Sym
    Funcs   []Func
    Files   map[string]*Obj
    Objs    []Obj
}
```

Table represents a Go symbol table. It stores all of the symbols decoded from the program and provides methods to translate between symbols, names, and addresses.

func [NewTable](#)

```
func NewTable(symtab []byte, pcIn *LineTable) (*Table, error)
```

NewTable decodes the Go symbol table in data, returning an in-memory representation.

func (*Table) [LineToPC](#)

```
func (t *Table) LineToPC(file string, line int) (pc uint64, fn *Func)
```

LineToPC looks up the first program counter on the given line in the named file. Returns `UnknownPathError` or `UnknownLineError` if there is an error looking up this line.

func (*Table) [LookupFunc](#)

```
func (t *Table) LookupFunc(name string) *Func
```

LookupFunc returns the text, data, or bss symbol with the given name, or nil if no such symbol is found.

func (*Table) [LookupSym](#)

```
func (t *Table) LookupSym(name string) *Sym
```

LookupSym returns the text, data, or bss symbol with the given name, or nil if no such symbol is found.

func (*Table) [PCToFunc](#)

```
func (t *Table) PCToFunc(pc uint64) *Func
```

PCToFunc returns the function containing the program counter pc, or nil if there is no such function.

func (*Table) [PCToLine](#)

```
func (t *Table) PCToLine(pc uint64) (file string, line int, fn *Func)
```

PCToLine looks up line number information for a program counter. If there is no information, it returns fn == nil.

func (*Table) [SymByAddr](#)

```
func (t *Table) SymByAddr(addr uint64) *Sym
```

SymByAddr returns the text, data, or bss symbol starting at the given address.
TODO(rsc): Allow lookup by any address within the symbol.

type [UnknownFileError](#)

```
type UnknownFileError string
```

UnknownFileError represents a failure to find the specific file in the symbol table.

func (UnknownFileError) [Error](#)

```
func (e UnknownFileError) Error() string
```

type [UnknownLineError](#)

```
type UnknownLineError struct {  
    File string  
    Line int  
}
```

UnknownLineError represents a failure to map a line to a program counter, either because the line is beyond the bounds of the file or because there is no code on the given line.

func (*UnknownLineError) [Error](#)

```
func (e *UnknownLineError) Error() string
```

Build version go1.0.1.

func NewFile(r io.ReaderAt) (*File, error)

func Open(name string) (*File, error)

func (f *File) Close() error

func (f *File) DWARF() (*dwarf.Data, error)

func (f *File) ImportedLibraries() ([]string, error)

func (f *File) ImportedSymbols() ([]string, error)

func (f *File) Section(name string) *Section

func (f *File) Segment(name string) *Segment

type FileHeader

type FormatError

func (e *FormatError) Error() string

type Load

type LoadBytes

func (b LoadBytes) Raw() []byte

type LoadCmd

func (i LoadCmd) GoString() string

func (i LoadCmd) String() string

type Nlist32

type Nlist64

type Regs386

type RegsAMD64

type Section

func (s *Section) Data() ([]byte, error)

func (s *Section) Open() io.ReadSeeker

type Section32

type Section64

[type SectionHeader](#)
[type Segment](#)
 [func \(s *Segment\) Data\(\) \(\[\]byte, error\)](#)
 [func \(s *Segment\) Open\(\) io.ReadSeeker](#)
[type Segment32](#)
[type Segment64](#)

[type Symbol](#)
[type Symtab](#)
[type SymtabCmd](#)
[type Thread](#)
[type Type](#)

Package files

[file.go](#) [macho.go](#)

Constants

```
const (  
    Magic32 uint32 = 0xfeedface  
    Magic64 uint32 = 0xfeedfacf  
)
```

type [Cpu](#)

```
type Cpu uint32
```

A Cpu is a Mach-O cpu type.

```
const (  
    Cpu386    Cpu = 7  
    CpuAmd64 Cpu = Cpu386 + 1<<24  
)
```

func (Cpu) [GoString](#)

```
func (i Cpu) GoString() string
```

func (Cpu) [String](#)

```
func (i Cpu) String() string
```

type [Dylib](#)

```
type Dylib struct {  
    LoadBytes  
    Name          string  
    Time          uint32  
    CurrentVersion uint32  
    CompatVersion uint32  
}
```

A Dylib represents a Mach-O load dynamic library command.

type [DylibCmd](#)

```
type DylibCmd struct {  
    Cmd          LoadCmd  
    Len          uint32  
    Name        uint32  
    Time        uint32  
    CurrentVersion uint32  
    CompatVersion uint32  
}
```

A DylibCmd is a Mach-O load dynamic library command.

type [Dysymtab](#)

```
type Dysymtab struct {  
    LoadBytes  
    DysymtabCmd  
    IndirectSyms []uint32 // indices into Symtab.Syms  
}
```

A Dysymtab represents a Mach-O dynamic symbol table command.

type [DysymtabCmd](#)

```
type DysymtabCmd struct {
    Cmd          LoadCmd
    Len          uint32
    Ilocalsym    uint32
    Nlocalsym    uint32
    Iextdefsym   uint32
    Nextdefsym   uint32
    Iundefsym    uint32
    Nundefsym    uint32
    Tocoffset    uint32
    Ntoc         uint32
    Modtaboff    uint32
    Nmodtab      uint32
    Extrefsymoff uint32
    Nextrefsyms  uint32
    Indirectsymoff uint32
    Nindirectsyms uint32
    Extreloff    uint32
    Nextrel      uint32
    Locreloff    uint32
    Nlocrel      uint32
}
```

A DysymtabCmd is a Mach-O dynamic symbol table command.

type [File](#)

```
type File struct {
    FileHeader
    ByteOrder binary.ByteOrder
    Loads      []Load
    Sections   []*Section

    Symtab     *Symtab
    Dysymtab   *Dysymtab
    // contains filtered or unexported fields
}
```

A File represents an open Mach-O file.

func [NewFile](#)

```
func NewFile(r io.ReaderAt) (*File, error)
```

NewFile creates a new File for accessing a Mach-O binary in an underlying reader. The Mach-O binary is expected to start at position 0 in the ReaderAt.

func [Open](#)

```
func Open(name string) (*File, error)
```

Open opens the named file using os.Open and prepares it for use as a Mach-O binary.

func (*File) [Close](#)

```
func (f *File) Close() error
```

Close closes the File. If the File was created using NewFile directly instead of Open, Close has no effect.

func (*File) [DWARF](#)

```
func (f *File) DWARF() (*dwarf.Data, error)
```

DWARF returns the DWARF debug information for the Mach-O file.

func (*File) [ImportedLibraries](#)

```
func (f *File) ImportedLibraries() ([]string, error)
```

ImportedLibraries returns the paths of all libraries referred to by the binary f that are expected to be linked with the binary at dynamic link time.

func (*File) [ImportedSymbols](#)

```
func (f *File) ImportedSymbols() ([]string, error)
```

ImportedSymbols returns the names of all symbols referred to by the binary f that are expected to be satisfied by other libraries at dynamic load time.

func (*File) [Section](#)

```
func (f *File) Section(name string) *Section
```

Section returns the first section with the given name, or nil if no such section exists.

func (*File) [Segment](#)

```
func (f *File) Segment(name string) *Segment
```

Segment returns the first Segment with the given name, or nil if no such segment exists.

type [FileHeader](#)

```
type FileHeader struct {  
    Magic    uint32  
    Cpu      Cpu  
    SubCpu   uint32  
    Type     Type  
    Ncmd     uint32  
    Cmdsz    uint32  
    Flags    uint32  
}
```

A FileHeader represents a Mach-O file header.

type [FormatError](#)

```
type FormatError struct {  
    // contains filtered or unexported fields  
}
```

func ([*FormatError](#)) [Error](#)

```
func (e *FormatError) Error() string
```

type [Load](#)

```
type Load interface {  
    Raw() []byte  
}
```

A Load represents any Mach-O load command.

type [LoadBytes](#)

```
type LoadBytes []byte
```

A LoadBytes is the uninterpreted bytes of a Mach-O load command.

func (LoadBytes) Raw

```
func (b LoadBytes) Raw() []byte
```

type [LoadCmd](#)

```
type LoadCmd uint32
```

A LoadCmd is a Mach-O load command.

```
const (  
    LoadCmdSegment      LoadCmd = 1  
    LoadCmdSymtab       LoadCmd = 2  
    LoadCmdThread       LoadCmd = 4  
    LoadCmdUnixThread   LoadCmd = 5 // thread+stack  
    LoadCmdDysymtab     LoadCmd = 11  
    LoadCmdDylib        LoadCmd = 12  
    LoadCmdDylinker     LoadCmd = 15  
    LoadCmdSegment64    LoadCmd = 25  
)
```

func (LoadCmd) [GoString](#)

```
func (i LoadCmd) GoString() string
```

func (LoadCmd) [String](#)

```
func (i LoadCmd) String() string
```

type [Nlist32](#)

```
type Nlist32 struct {  
    Name  uint32  
    Type  uint8  
    Sect  uint8  
    Desc  uint16  
    Value uint32  
}
```

An Nlist32 is a Mach-O 32-bit symbol table entry.

type [Nlist64](#)

```
type Nlist64 struct {  
    Name  uint32  
    Type  uint8  
    Sect  uint8  
    Desc  uint16  
    Value uint64  
}
```

An Nlist64 is a Mach-O 64-bit symbol table entry.

type [Regs386](#)

```
type Regs386 struct {
    AX    uint32
    BX    uint32
    CX    uint32
    DX    uint32
    DI    uint32
    SI    uint32
    BP    uint32
    SP    uint32
    SS    uint32
    FLAGS uint32
    IP    uint32
    CS    uint32
    DS    uint32
    ES    uint32
    FS    uint32
    GS    uint32
}
```

Regs386 is the Mach-O 386 register structure.

type [RegsAMD64](#)

```
type RegsAMD64 struct {  
    AX    uint64  
    BX    uint64  
    CX    uint64  
    DX    uint64  
    DI    uint64  
    SI    uint64  
    BP    uint64  
    SP    uint64  
    R8    uint64  
    R9    uint64  
    R10   uint64  
    R11   uint64  
    R12   uint64  
    R13   uint64  
    R14   uint64  
    R15   uint64  
    IP    uint64  
    FLAGS uint64  
    CS    uint64  
    FS    uint64  
    GS    uint64  
}
```

RegsAMD64 is the Mach-O AMD64 register structure.

type [Section](#)

```
type Section struct {
    SectionHeader

    // Embed ReaderAt for ReadAt method.
    // Do not embed SectionReader directly
    // to avoid having Read and Seek.
    // If a client wants Read and Seek it must use
    // Open() to avoid fighting over the seek offset
    // with other clients.
    io.ReaderAt
    // contains filtered or unexported fields
}
```

func (*Section) [Data](#)

```
func (s *Section) Data() ([]byte, error)
```

Data reads and returns the contents of the Mach-O section.

func (*Section) [Open](#)

```
func (s *Section) Open() io.ReadSeeker
```

Open returns a new ReadSeeker reading the Mach-O section.

type [Section32](#)

```
type Section32 struct {
    Name      [16]byte
    Seg       [16]byte
    Addr      uint32
    Size      uint32
    Offset    uint32
    Align     uint32
    Reloff    uint32
    Nreloc    uint32
    Flags     uint32
    Reserve1  uint32
    Reserve2  uint32
}
```

A Section32 is a 32-bit Mach-O section header.

type [Section64](#)

```
type Section64 struct {
    Name      [16]byte
    Seg       [16]byte
    Addr      uint64
    Size      uint64
    Offset    uint32
    Align     uint32
    Reloff    uint32
    Nreloc    uint32
    Flags     uint32
    Reserve1  uint32
    Reserve2  uint32
    Reserve3  uint32
}
```

A Section32 is a 64-bit Mach-O section header.

type SectionHeader

```
type SectionHeader struct {  
    Name    string  
    Seg     string  
    Addr    uint64  
    Size    uint64  
    Offset  uint32  
    Align   uint32  
    Reloff  uint32  
    Nreloc  uint32  
    Flags   uint32  
}
```

type [Segment](#)

```
type Segment struct {
    LoadBytes
    SegmentHeader

    // Embed ReaderAt for ReadAt method.
    // Do not embed SectionReader directly
    // to avoid having Read and Seek.
    // If a client wants Read and Seek it must use
    // Open() to avoid fighting over the seek offset
    // with other clients.
    io.ReaderAt
    // contains filtered or unexported fields
}
```

A Segment represents a Mach-O 32-bit or 64-bit load segment command.

func (*Segment) [Data](#)

```
func (s *Segment) Data() ([]byte, error)
```

Data reads and returns the contents of the segment.

func (*Segment) [Open](#)

```
func (s *Segment) Open() io.ReadSeeker
```

Open returns a new ReadSeeker reading the segment.

type Segment32

```
type Segment32 struct {  
    Cmd      LoadCmd  
    Len      uint32  
    Name     [16]byte  
    Addr     uint32  
    Memsz    uint32  
    Offset   uint32  
    Filesz   uint32  
    Maxprot  uint32  
    Prot     uint32  
    Nsect    uint32  
    Flag     uint32  
}
```

A Segment32 is a 32-bit Mach-O segment load command.

type Segment64

```
type Segment64 struct {  
    Cmd      LoadCmd  
    Len      uint32  
    Name     [16]byte  
    Addr     uint64  
    Memsz    uint64  
    Offset   uint64  
    Filesz   uint64  
    Maxprot  uint32  
    Prot     uint32  
    Nsect    uint32  
    Flag     uint32  
}
```

A Segment64 is a 64-bit Mach-O segment load command.

type SegmentHeader

```
type SegmentHeader struct {  
    Cmd      LoadCmd  
    Len      uint32  
    Name     string  
    Addr     uint64  
    Memsz    uint64  
    Offset   uint64  
    Filesz   uint64  
    Maxprot  uint32  
    Prot     uint32  
    Nsect    uint32  
    Flag     uint32  
}
```

A SegmentHeader is the header for a Mach-O 32-bit or 64-bit load segment command.

type [Symbol](#)

```
type Symbol struct {  
    Name  string  
    Type  uint8  
    Sect  uint8  
    Desc  uint16  
    Value uint64  
}
```

A Symbol is a Mach-O 32-bit or 64-bit symbol table entry.

type [Symtab](#)

```
type Symtab struct {  
    LoadBytes  
    SymtabCmd  
    Syms []Symbol  
}
```

A Symtab represents a Mach-O symbol table command.

type [SymtabCmd](#)

```
type SymtabCmd struct {  
    Cmd      LoadCmd  
    Len      uint32  
    Symoff   uint32  
    Nsyms    uint32  
    Stroff   uint32  
    Strsize  uint32  
}
```

A SymtabCmd is a Mach-O symbol table command.

type [Thread](#)

```
type Thread struct {  
    Cmd  LoadCmd  
    Len  uint32  
    Type uint32  
    Data []uint32  
}
```

A Thread is a Mach-O thread state command.

type [Type](#)

```
type Type uint32
```

A Type is a Mach-O file type, either an object or an executable.

```
const (  
    TypeObj   Type = 1  
    TypeExec  Type = 2  
)
```

Build version go1.0.1.

)
```

type [File](#)

```
type File struct {
    FileHeader
    Sections []*Section
    // contains filtered or unexported fields
}
```

A File represents an open PE file.

func [NewFile](#)

```
func NewFile(r io.ReaderAt) (*File, error)
```

NewFile creates a new File for accessing a PE binary in an underlying reader.

func [Open](#)

```
func Open(name string) (*File, error)
```

Open opens the named file using os.Open and prepares it for use as a PE binary.

func (***File**) [Close](#)

```
func (f *File) Close() error
```

Close closes the File. If the File was created using NewFile directly instead of Open, Close has no effect.

func (***File**) [DWARF](#)

```
func (f *File) DWARF() (*dwarf.Data, error)
```

func (***File**) [ImportedLibraries](#)

```
func (f *File) ImportedLibraries() ([]string, error)
```

ImportedLibraries returns the names of all libraries referred to by the binary f that are expected to be linked with the binary at dynamic link time.

func (*File) [ImportedSymbols](#)

```
func (f *File) ImportedSymbols() ([]string, error)
```

ImportedSymbols returns the names of all symbols referred to by the binary f that are expected to be satisfied by other libraries at dynamic load time. It does not return weak symbols.

func (*File) [Section](#)

```
func (f *File) Section(name string) *Section
```

Section returns the first section with the given name, or nil if no such section exists.

type [FileHeader](#)

```
type FileHeader struct {  
    Machine          uint16  
    NumberOfSections uint16  
    TimeDateStamp    uint32  
    PointerToSymbolTable uint32  
    NumberOfSymbols  uint32  
    SizeOfOptionalHeader uint16  
    Characteristics  uint16  
}
```

type [FormatError](#)

```
type FormatError struct {  
    // contains filtered or unexported fields  
}
```

func ([*FormatError](#)) [Error](#)

```
func (e *FormatError) Error() string
```

type ImportDirectory

```
type ImportDirectory struct {
    OriginalFirstThunk uint32
    TimeDateStamp      uint32
    ForwarderChain     uint32
    Name               uint32
    FirstThunk         uint32
    // contains filtered or unexported fields
}
```

type [Section](#)

```
type Section struct {
    SectionHeader

    // Embed ReaderAt for ReadAt method.
    // Do not embed SectionReader directly
    // to avoid having Read and Seek.
    // If a client wants Read and Seek it must use
    // Open() to avoid fighting over the seek offset
    // with other clients.
    io.ReaderAt
    // contains filtered or unexported fields
}
```

func (*Section) [Data](#)

```
func (s *Section) Data() ([]byte, error)
```

Data reads and returns the contents of the PE section.

func (*Section) [Open](#)

```
func (s *Section) Open() io.ReadSeeker
```

Open returns a new ReadSeeker reading the PE section.

type SectionHeader

```
type SectionHeader struct {  
    Name                string  
    VirtualSize         uint32  
    VirtualAddress      uint32  
    Size                uint32  
    Offset              uint32  
    PointerToRelocations uint32  
    PointerToLineNumbers uint32  
    NumberOfRelocations uint16  
    NumberOfLineNumbers  uint16  
    Characteristics     uint32  
}
```

type [SectionHeader32](#)

```
type SectionHeader32 struct {  
    Name           [8]uint8  
    VirtualSize    uint32  
    VirtualAddress uint32  
    SizeOfRawData  uint32  
    PointerToRawData uint32  
    PointerToRelocations uint32  
    PointerToLineNumbers uint32  
    NumberOfRelocations uint16  
    NumberOfLineNumbers uint16  
    Characteristics   uint32  
}
```

Directory /src/pkg/encoding

Name	Synopsis
ascii85	Package ascii85 implements the ascii85 data encoding as used in the btoa tool and Adobe's PostScript and PDF document formats.
asn1	Package asn1 implements parsing of DER-encoded ASN.1 data structures, as defined in ITU-T Rec X.690.
base32	Package base32 implements base32 encoding as specified by RFC 4648.
base64	Package base64 implements base64 encoding as specified by RFC 4648.
binary	Package binary implements translation between numbers and byte sequences and encoding and decoding of varints.
csv	Package csv reads and writes comma-separated values (CSV) files.
gob	Package gob manages streams of gobs - binary values exchanged between an Encoder (transmitter) and a Decoder (receiver).
hex	Package hex implements hexadecimal encoding and decoding.
json	Package json implements encoding and decoding of JSON objects as defined in RFC 4627.
pem	Package pem implements the PEM data encoding, which originated in Privacy Enhanced Mail.
xml	Package xml implements a simple XML 1.0 parser that understands XML name spaces.

[func NewDecoder\(r io.Reader\) io.Reader](#)

[func NewEncoder\(w io.Writer\) io.WriteCloser](#)

[type CorruptInputError](#)

[func \(e CorruptInputError\) Error\(\) string](#)

Package files

[ascii85.go](#)

func [Decode](#)

```
func Decode(dst, src []byte, flush bool) (ndst, nsrc int, err error)
```

Decode decodes src into dst, returning both the number of bytes written to dst and the number consumed from src. If src contains invalid ascii85 data, Decode will return the number of bytes successfully written and a `CorruptInputError`. Decode ignores space and control characters in src. Often, ascii85-encoded data is wrapped in `<~` and `~>` symbols. Decode expects these to have been stripped by the caller.

If flush is true, Decode assumes that src represents the end of the input stream and processes it completely rather than wait for the completion of another 32-bit block.

`NewDecoder` wraps an `io.Reader` interface around `Decode`.

func Encode

```
func Encode(dst, src []byte) int
```

Encode encodes src into at most MaxEncodedLen(len(src)) bytes of dst, returning the actual number of bytes written.

The encoding handles 4-byte chunks, using a special encoding for the last fragment, so Encode is not appropriate for use on individual blocks of a large data stream. Use NewEncoder() instead.

Often, ascii85-encoded data is wrapped in <~ and ~> symbols. Encode does not add these.

func MaxEncodedLen

```
func MaxEncodedLen(n int) int
```

MaxEncodedLen returns the maximum length of an encoding of n source bytes.

func [NewDecoder](#)

```
func NewDecoder(r io.Reader) io.Reader
```

NewDecoder constructs a new ascii85 stream decoder.

func [NewEncoder](#)

```
func NewEncoder(w io.Writer) io.WriteCloser
```

NewEncoder returns a new ascii85 stream encoder. Data written to the returned writer will be encoded and then written to w. Ascii85 encodings operate in 32-bit blocks; when finished writing, the caller must Close the returned encoder to flush any trailing partial block.

type [CorruptInputError](#)

```
type CorruptInputError int64
```

func (CorruptInputError) [Error](#)

```
func (e CorruptInputError) Error() string
```

Package asn1

```
import "encoding/asn1"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `asn1` implements parsing of DER-encoded ASN.1 data structures, as defined in ITU-T Rec X.690.

See also “A Layman's Guide to a Subset of ASN.1, BER, and DER,”
<http://luca.ntop.org/Teaching/Appunti/asn1.html>.

[type SyntaxError](#)
 [func \(e SyntaxError\) Error\(\) string](#)

Package files

[asn1.go](#) [common.go](#) [marshal.go](#)

func [Marshal](#)

```
func Marshal(val interface{}) ([]byte, error)
```

Marshal returns the ASN.1 encoding of val.

func [Unmarshal](#)

```
func Unmarshal(b []byte, val interface{}) (rest []byte, err error)
```

Unmarshal parses the DER-encoded ASN.1 data structure `b` and uses the `reflect` package to fill in an arbitrary value pointed at by `val`. Because Unmarshal uses the `reflect` package, the structs being written to must use upper case field names.

An ASN.1 INTEGER can be written to an `int`, `int32`, `int64`, or `*big.Int` (from the `math/big` package). If the encoded value does not fit in the Go type, Unmarshal returns a parse error.

An ASN.1 BIT STRING can be written to a `BitString`.

An ASN.1 OCTET STRING can be written to a `[]byte`.

An ASN.1 OBJECT IDENTIFIER can be written to an `ObjectIdentifier`.

An ASN.1 ENUMERATED can be written to an `Enumerated`.

An ASN.1 UTCTIME or GENERALIZEDTIME can be written to a `time.Time`.

An ASN.1 PrintableString or IA5String can be written to a `string`.

Any of the above ASN.1 values can be written to an `interface{}`. The value stored in the interface has the corresponding Go type. For integers, that type is `int64`.

An ASN.1 SEQUENCE OF `x` or SET OF `x` can be written to a slice if an `x` can be written to the slice's element type.

An ASN.1 SEQUENCE or SET can be written to a struct if each of the elements in the sequence can be written to the corresponding element in the struct.

The following tags on struct fields have special meaning to Unmarshal:

<code>optional</code>	marks the field as ASN.1 OPTIONAL
<code>[explicit] tag:x</code>	specifies the ASN.1 tag number; implies ASN.
<code>default:x</code>	sets the default value for optional integer

If the type of the first field of a structure is RawContent then the raw ASN1 contents of the struct will be stored in it.

Other ASN.1 types are not supported; if it encounters them, Unmarshal returns a parse error.

func UnmarshalWithParams

```
func UnmarshalWithParams(b []byte, val interface{}, params string) (
```

UnmarshalWithParams allows field parameters to be specified for the top-level element. The form of the params is the same as the field tags.

type [BitString](#)

```
type BitString struct {  
    Bytes      []byte // bits packed into bytes.  
    BitLength int    // length in bits.  
}
```

BitString is the structure to use when you want an ASN.1 BIT STRING type. A bit string is padded up to the nearest byte in memory and the number of valid bits is recorded. Padding bits will be zero.

func (BitString) [At](#)

```
func (b BitString) At(i int) int
```

At returns the bit at the given index. If the index is out of range it returns false.

func (BitString) [RightAlign](#)

```
func (b BitString) RightAlign() []byte
```

RightAlign returns a slice where the padding bits are at the beginning. The slice may share memory with the BitString.

type Enumerated

type Enumerated int

An Enumerated is represented as a plain int.

type **Flag**

```
type Flag bool
```

A Flag accepts any data and is set to true if present.

type [ObjectIdentifier](#)

```
type ObjectIdentifier []int
```

An ObjectIdentifier represents an ASN.1 OBJECT IDENTIFIER.

func (ObjectIdentifier) [Equal](#)

```
func (oi ObjectIdentifier) Equal(other ObjectIdentifier) bool
```

Equal returns true iff oi and other represent the same identifier.

type [RawContent](#)

```
type RawContent []byte
```

RawContent is used to signal that the undecoded, DER data needs to be preserved for a struct. To use it, the first field of the struct must have this type. It's an error for any of the other fields to have this type.

type [RawValue](#)

```
type RawValue struct {  
    Class, Tag int  
    IsCompound bool  
    Bytes      []byte  
    FullBytes  []byte // includes the tag and length  
}
```

A RawValue represents an undecoded ASN.1 object.

type [StructuralError](#)

```
type StructuralError struct {  
    Msg string  
}
```

A StructuralError suggests that the ASN.1 data is valid, but the Go type which is receiving it doesn't match.

func (StructuralError) [Error](#)

```
func (e StructuralError) Error() string
```

type [SyntaxError](#)

```
type SyntaxError struct {  
    Msg string  
}
```

A SyntaxError suggests that the ASN.1 data is invalid.

func (SyntaxError) [Error](#)

```
func (e SyntaxError) Error() string
```

Build version go1.0.1.

[func \(enc *Encoding\) Encode\(dst, src \[\]byte\)](#)

[func \(enc *Encoding\) EncodeToString\(src \[\]byte\) string](#)

[func \(enc *Encoding\) EncodedLen\(n int\) int](#)

Package files

[base32.go](#)

Variables

```
var HexEncoding = NewEncoding(encodeHex)
```

HexEncoding is the “Extended Hex Alphabet” defined in RFC 4648. It is typically used in DNS.

```
var StdEncoding = NewEncoding(encodeStd)
```

StdEncoding is the standard base32 encoding, as defined in RFC 4648.

func [NewDecoder](#)

```
func NewDecoder(enc *Encoding, r io.Reader) io.Reader
```

NewDecoder constructs a new base32 stream decoder.

func [NewEncoder](#)

```
func NewEncoder(enc *Encoding, w io.Writer) io.WriteCloser
```

NewEncoder returns a new base32 stream encoder. Data written to the returned writer will be encoded using enc and then written to w. Base32 encodings operate in 5-byte blocks; when finished writing, the caller must Close the returned encoder to flush any partially written blocks.

type CorruptInputError

type CorruptInputError int64

func (CorruptInputError) Error

func (e CorruptInputError) Error() string

type [Encoding](#)

```
type Encoding struct {  
    // contains filtered or unexported fields  
}
```

An Encoding is a radix 32 encoding/decoding scheme, defined by a 32-character alphabet. The most common is the "base32" encoding introduced for SASL GSSAPI and standardized in RFC 4648. The alternate "base32hex" encoding is used in DNSSEC.

func [NewEncoding](#)

```
func NewEncoding(encoder string) *Encoding
```

NewEncoding returns a new Encoding defined by the given alphabet, which must be a 32-byte string.

func (*Encoding) [Decode](#)

```
func (enc *Encoding) Decode(dst, src []byte) (n int, err error)
```

Decode decodes src using the encoding enc. It writes at most DecodedLen(len(src)) bytes to dst and returns the number of bytes written. If src contains invalid base32 data, it will return the number of bytes successfully written and CorruptInputError. New line characters (\r and \n) are ignored.

func (*Encoding) [DecodeString](#)

```
func (enc *Encoding) DecodeString(s string) ([]byte, error)
```

DecodeString returns the bytes represented by the base32 string s.

func (*Encoding) [DecodedLen](#)

```
func (enc *Encoding) DecodedLen(n int) int
```

DecodedLen returns the maximum length in bytes of the decoded data corresponding to n bytes of base32-encoded data.

func (*Encoding) [Encode](#)

```
func (enc *Encoding) Encode(dst, src []byte)
```

Encode encodes src using the encoding enc, writing EncodedLen(len(src)) bytes to dst.

The encoding pads the output to a multiple of 8 bytes, so Encode is not appropriate for use on individual blocks of a large data stream. Use NewEncoder() instead.

func (*Encoding) [EncodeToString](#)

```
func (enc *Encoding) EncodeToString(src []byte) string
```

EncodeToString returns the base32 encoding of src.

func (*Encoding) [EncodedLen](#)

```
func (enc *Encoding) EncodedLen(n int) int
```

EncodedLen returns the length in bytes of the base32 encoding of an input buffer of length n.

Build version go1.0.1.

[func \(enc *Encoding\) EncodeToString\(src \[\]byte\) string](#)

[func \(enc *Encoding\) EncodedLen\(n int\) int](#)

Package files

[base64.go](#)

Variables

```
var StdEncoding = NewEncoding(encodeStd)
```

StdEncoding is the standard base64 encoding, as defined in RFC 4648.

```
var URLEncoding = NewEncoding(encodeURL)
```

URLEncoding is the alternate base64 encoding defined in RFC 4648. It is typically used in URLs and file names.

func [NewDecoder](#)

```
func NewDecoder(enc *Encoding, r io.Reader) io.Reader
```

NewDecoder constructs a new base64 stream decoder.

func [NewEncoder](#)

```
func NewEncoder(enc *Encoding, w io.Writer) io.WriteCloser
```

NewEncoder returns a new base64 stream encoder. Data written to the returned writer will be encoded using enc and then written to w. Base64 encodings operate in 4-byte blocks; when finished writing, the caller must Close the returned encoder to flush any partially written blocks.

type CorruptInputError

type CorruptInputError int64

func (CorruptInputError) Error

func (e CorruptInputError) Error() string

type [Encoding](#)

```
type Encoding struct {  
    // contains filtered or unexported fields  
}
```

An Encoding is a radix 64 encoding/decoding scheme, defined by a 64-character alphabet. The most common encoding is the "base64" encoding defined in RFC 4648 and used in MIME (RFC 2045) and PEM (RFC 1421). RFC 4648 also defines an alternate encoding, which is the standard encoding with - and _ substituted for + and /.

func [NewEncoding](#)

```
func NewEncoding(encoder string) *Encoding
```

NewEncoding returns a new Encoding defined by the given alphabet, which must be a 64-byte string.

func (*Encoding) [Decode](#)

```
func (enc *Encoding) Decode(dst, src []byte) (n int, err error)
```

Decode decodes src using the encoding enc. It writes at most DecodedLen(len(src)) bytes to dst and returns the number of bytes written. If src contains invalid base64 data, it will return the number of bytes successfully written and CorruptInputError. New line characters (\r and \n) are ignored.

func (*Encoding) [DecodeString](#)

```
func (enc *Encoding) DecodeString(s string) ([]byte, error)
```

DecodeString returns the bytes represented by the base64 string s.

func (*Encoding) [DecodedLen](#)

```
func (enc *Encoding) DecodedLen(n int) int
```

DecodedLen returns the maximum length in bytes of the decoded data

corresponding to n bytes of base64-encoded data.

func (*Encoding) [Encode](#)

```
func (enc *Encoding) Encode(dst, src []byte)
```

Encode encodes src using the encoding enc, writing EncodedLen(len(src)) bytes to dst.

The encoding pads the output to a multiple of 4 bytes, so Encode is not appropriate for use on individual blocks of a large data stream. Use NewEncoder() instead.

func (*Encoding) [EncodeToString](#)

```
func (enc *Encoding) EncodeToString(src []byte) string
```

EncodeToString returns the base64 encoding of src.

func (*Encoding) [EncodedLen](#)

```
func (enc *Encoding) EncodedLen(n int) int
```

EncodedLen returns the length in bytes of the base64 encoding of an input buffer of length n.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package binary

```
import "encoding/binary"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package `binary` implements translation between numbers and byte sequences and encoding and decoding of varints.

Numbers are translated by reading and writing fixed-size values. A fixed-size value is either a fixed-size arithmetic type (`int8`, `uint8`, `int16`, `float32`, `complex64`, ...) or an array or struct containing only fixed-size values.

Varints are a method of encoding integers using one or more bytes; numbers with smaller absolute value take a smaller number of bytes. For a specification, see <http://code.google.com/apis/protocolbuffers/docs/encoding.html>.

Index

[Constants](#)

[Variables](#)

[func PutUvarint\(buf \[\]byte, x uint64\) int](#)

[func PutVarint\(buf \[\]byte, x int64\) int](#)

[func Uvarint\(buf \[\]byte\) \(uint64, int\)](#)

[func Varint\(buf \[\]byte\) \(int64, int\)](#)

[func Write\(w io.Writer, order ByteOrder, data interface{ }\) error](#)

[type ByteOrder](#)

Examples

[Read](#)

[Write](#)

[Write \(Multi\)](#)

Package files

[binary.go](#) [varint.go](#)

Constants

```
const (  
    MaxVarintLen16 = 3  
    MaxVarintLen32 = 5  
    MaxVarintLen64 = 10  
)
```

MaxVarintLenN is the maximum length of a varint-encoded N-bit integer.

Variables

```
var BigEndian bigEndian
```

BigEndian is the big-endian implementation of ByteOrder.

```
var LittleEndian littleEndian
```

LittleEndian is the little-endian implementation of ByteOrder.

func [PutUvarint](#)

```
func PutUvarint(buf []byte, x uint64) int
```

PutUvarint encodes a uint64 into buf and returns the number of bytes written. If the buffer is too small, PutUvarint will panic.

func [PutVarint](#)

```
func PutVarint(buf []byte, x int64) int
```

PutVarint encodes an int64 into buf and returns the number of bytes written. If the buffer is too small, PutVarint will panic.

func [Read](#)

```
func Read(r io.Reader, order ByteOrder, data interface{}) error
```

Read reads structured binary data from r into data. Data must be a pointer to a fixed-size value or a slice of fixed-size values. Bytes read from r are decoded using the specified byte order and written to successive fields of the data.

? Example

? Example

Code:

```
var pi float64
b := []byte{0x18, 0x2d, 0x44, 0x54, 0xfb, 0x21, 0x09, 0x40}
buf := bytes.NewBuffer(b)
err := binary.Read(buf, binary.LittleEndian, &pi)
if err != nil {
    fmt.Println("binary.Read failed:", err)
}
fmt.Print(pi)
```

Output:

```
3.141592653589793
```

func [ReadUvarint](#)

```
func ReadUvarint(r io.ByteReader) (uint64, error)
```

ReadUvarint reads an encoded unsigned integer from r and returns it as a uint64.

func [ReadVarint](#)

```
func ReadVarint(r io.ByteReader) (int64, error)
```

ReadVarint reads an encoded unsigned integer from r and returns it as a uint64.

func [Size](#)

```
func Size(v interface{}) int
```

Size returns how many bytes Write would generate to encode the value v, which must be a fixed-size value or a slice of fixed-size values, or a pointer to such data.

func [Uvarint](#)

```
func Uvarint(buf []byte) (uint64, int)
```

Uvarint decodes a uint64 from buf and returns that value and the number of bytes read (> 0). If an error occurred, the value is 0 and the number of bytes n is <= 0 meaning:

```
n == 0: buf too small  
n < 0: value larger than 64 bits (overflow)  
       and -n is the number of bytes read
```

func [Varint](#)

```
func Varint(buf []byte) (int64, int)
```

Varint decodes an int64 from buf and returns that value and the number of bytes read (> 0). If an error occurred, the value is 0 and the number of bytes n is <= 0 with the following meaning:

```
n == 0: buf too small  
n < 0: value larger than 64 bits (overflow)  
       and -n is the number of bytes read
```

func [Write](#)

```
func Write(w io.Writer, order ByteOrder, data interface{}) error
```

Write writes the binary representation of data into w. Data must be a fixed-size value or a slice of fixed-size values, or a pointer to such data. Bytes written to w are encoded using the specified byte order and read from successive fields of the data.

? Example

? Example

Code:

```
buf := new(bytes.Buffer)
var pi float64 = math.Pi
err := binary.Write(buf, binary.LittleEndian, pi)
if err != nil {
    fmt.Println("binary.Write failed:", err)
}
fmt.Printf("% x", buf.Bytes())
```

Output:

```
18 2d 44 54 fb 21 09 40
```

? Example (Multi)

? Example (Multi)

Code:

```
buf := new(bytes.Buffer)
var data = []interface{}{
    uint16(61374),
    int8(-54),
    uint8(254),
}
for _, v := range data {
    err := binary.Write(buf, binary.LittleEndian, v)
    if err != nil {
        fmt.Println("binary.Write failed:", err)
    }
}
```

```
    }  
}  
fmt.Printf("%x", buf.Bytes())
```

Output:

beefcafe

type [ByteOrder](#)

```
type ByteOrder interface {
    Uint16([]byte) uint16
    Uint32([]byte) uint32
    Uint64([]byte) uint64
    PutUint16([]byte, uint16)
    PutUint32([]byte, uint32)
    PutUint64([]byte, uint64)
    String() string
}
```

A `ByteOrder` specifies how to convert byte sequences into 16-, 32-, or 64-bit unsigned integers.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package csv

```
import "encoding/csv"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package csv reads and writes comma-separated values (CSV) files.

A csv file contains zero or more records of one or more fields per record. Each record is separated by the newline character. The final record may optionally be followed by a newline character.

```
field1,field2,field3
```

White space is considered part of a field.

Carriage returns before newline characters are silently removed.

Blank lines are ignored. A line with only whitespace characters (excluding the ending newline character) is not considered a blank line.

Fields which start and stop with the quote character " are called quoted-fields. The beginning and ending quote are not part of the field.

The source:

```
normal string,"quoted-field"
```

results in the fields

```
{`normal string`, `quoted-field`}
```

Within a quoted-field a quote character followed by a second quote character is considered a single quote.

```
"the ""word"" is true","a ""quoted-field"""
```

results in

```
{`the "word" is true`, `a "quoted-field"`}
```

Newlines and commas may be included in a quoted-field

```
"Multi-line  
field","comma is ,"
```

results in

```
{`Multi-line  
field`, `comma is ,`}
```

Index

Variables

type ParseError

func (e *ParseError) Error() string

type Reader

func NewReader(r io.Reader) *Reader

func (r *Reader) Read() (record []string, err error)

func (r *Reader) ReadAll() (records [][]string, err error)

type Writer

func NewWriter(w io.Writer) *Writer

func (w *Writer) Flush()

func (w *Writer) Write(record []string) (err error)

func (w *Writer) WriteAll(records [][]string) (err error)

Package files

[reader.go](#) [writer.go](#)

Variables

```
var (  
    ErrTrailingComma = errors.New("extra delimiter at end of line")  
    ErrBareQuote     = errors.New("bare \" in non-quoted-field")  
    ErrQuote         = errors.New("extraneous \" in field")  
    ErrFieldCount    = errors.New("wrong number of fields in line")  
)
```

These are the errors that can be returned in `ParseError.Error`

type [ParseError](#)

```
type ParseError struct {  
    Line    int    // Line where the error occurred  
    Column  int    // Column (rune index) where the error occurred  
    Err     error  // The actual error  
}
```

A ParseError is returned for parsing errors. The first line is 1. The first column is 0.

func (*ParseError) [Error](#)

```
func (e *ParseError) Error() string
```

type [Reader](#)

```
type Reader struct {
    Comma          rune // Field delimiter (set to ',' by NewReader)
    Comment        rune // Comment character for start of line
    FieldsPerRecord int  // Number of expected fields per record
    LazyQuotes     bool // Allow lazy quotes
    TrailingComma  bool // Allow trailing comma
    TrimLeadingSpace bool // Trim leading space
    // contains filtered or unexported fields
}
```

A Reader reads records from a CSV-encoded file.

As returned by `NewReader`, a Reader expects input conforming to RFC 4180. The exported fields can be changed to customize the details before the first call to `Read` or `ReadAll`.

`Comma` is the field delimiter. It defaults to `'`.

`Comment`, if not 0, is the comment character. Lines beginning with the `Comment` character are ignored.

If `FieldsPerRecord` is positive, `Read` requires each record to have the given number of fields. If `FieldsPerRecord` is 0, `Read` sets it to the number of fields in the first record, so that future records must have the same field count. If `FieldsPerRecord` is negative, no check is made and records may have a variable number of fields.

If `LazyQuotes` is true, a quote may appear in an unquoted field and a non-doubled quote may appear in a quoted field.

If `TrailingComma` is true, the last field may be an unquoted empty field.

If `TrimLeadingSpace` is true, leading white space in a field is ignored.

func [NewReader](#)

```
func NewReader(r io.Reader) *Reader
```

NewReader returns a new Reader that reads from r.

func (*Reader) [Read](#)

```
func (r *Reader) Read() (record []string, err error)
```

Read reads one record from r. The record is a slice of strings with each string representing one field.

func (*Reader) [ReadAll](#)

```
func (r *Reader) ReadAll() (records [][]string, err error)
```

ReadAll reads all the remaining records from r. Each record is a slice of fields. A successful call returns `err == nil`, not `err == EOF`. Because ReadAll is defined to read until EOF, it does not treat end of file as an error to be reported.

type [Writer](#)

```
type Writer struct {  
    Comma    rune // Field delimiter (set to to ',' by NewWriter)  
    UseCRLF  bool // True to use \r\n as the line terminator  
    // contains filtered or unexported fields  
}
```

A Writer writes records to a CSV encoded file.

As returned by `NewWriter`, a Writer writes records terminated by a newline and uses ',' as the field delimiter. The exported fields can be changed to customize the details before the first call to `Write` or `WriteAll`.

Comma is the field delimiter.

If `UseCRLF` is true, the Writer ends each record with `\r\n` instead of `\n`.

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

`NewWriter` returns a new `Writer` that writes to `w`.

func (*Writer) [Flush](#)

```
func (w *Writer) Flush()
```

`Flush` writes any buffered data to the underlying `io.Writer`.

func (*Writer) [Write](#)

```
func (w *Writer) Write(record []string) (err error)
```

`Writer` writes a single CSV record to `w` along with any necessary quoting. A record is a slice of strings with each string being one field.

func (*Writer) [WriteAll](#)

```
func (w *Writer) WriteAll(records [][]string) (err error)
```

WriteAll writes multiple CSV records to w using Write and then calls Flush.

Build version go1.0.1.

Package gob

```
import "encoding/gob"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `gob` manages streams of gobs - binary values exchanged between an Encoder (transmitter) and a Decoder (receiver). A typical use is transporting arguments and results of remote procedure calls (RPCs) such as those provided by package `"rpc"`.

A stream of gobs is self-describing. Each data item in the stream is preceded by a specification of its type, expressed in terms of a small set of predefined types. Pointers are not transmitted, but the things they point to are transmitted; that is, the values are flattened. Recursive types work fine, but recursive values (data with cycles) are problematic. This may change.

To use gobs, create an Encoder and present it with a series of data items as values or addresses that can be dereferenced to values. The Encoder makes sure all type information is sent before it is needed. At the receive side, a Decoder retrieves values from the encoded stream and unpacks them into local variables.

The source and destination values/types need not correspond exactly. For structs, fields (identified by name) that are in the source but absent from the receiving variable will be ignored. Fields that are in the receiving variable but missing from the transmitted type or value will be ignored in the destination. If a field with the same name is present in both, their types must be compatible. Both the receiver and transmitter will do all necessary indirection and dereferencing to convert between gobs and actual Go values. For instance, a gob type that is schematically,

```
struct { A, B int }
```

can be sent from or received into any of these Go types:

```
struct { A, B int }      // the same
*struct { A, B int }    // extra indirection of the struct
struct { *A, **B int }  // extra indirection of the fields
struct { A, B int64 }   // different concrete value type; see below
```

It may also be received into any of these:

```
struct { A, B int }      // the same
struct { B, A int }      // ordering doesn't matter; matching is by n
```

```
struct { A, B, C int } // extra field (C) ignored
struct { B int } // missing field (A) ignored; data will be d
struct { B, C int } // missing field (A) ignored; extra field (C
```

Attempting to receive into these types will draw a decode error:

```
struct { A int; B uint } // change of signedness for B
struct { A int; B float } // change of type for B
struct { } // no field names in common
struct { C, D int } // no field names in common
```

Integers are transmitted two ways: arbitrary precision signed integers or arbitrary precision unsigned integers. There is no int8, int16 etc. discrimination in the gob format; there are only signed and unsigned integers. As described below, the transmitter sends the value in a variable-length encoding; the receiver accepts the value and stores it in the destination variable. Floating-point numbers are always sent using IEEE-754 64-bit precision (see below).

Signed integers may be received into any signed integer variable: int, int16, etc.; unsigned integers may be received into any unsigned integer variable; and floating point values may be received into any floating point variable. However, the destination variable must be able to represent the value or the decode operation will fail.

Structs, arrays and slices are also supported. Strings and arrays of bytes are supported with a special, efficient representation (see below). When a slice is decoded, if the existing slice has capacity the slice will be extended in place; if not, a new array is allocated. Regardless, the length of the resulting slice reports the number of elements decoded.

Functions and channels cannot be sent in a gob. Attempting to encode a value that contains one will fail.

The rest of this comment documents the encoding, details that are not important for most users. Details are presented bottom-up.

An unsigned integer is sent one of two ways. If it is less than 128, it is sent as a byte with that value. Otherwise it is sent as a minimal-length big-endian (high byte first) byte stream holding the value, preceded by one byte holding the byte count, negated. Thus 0 is transmitted as (00), 7 is transmitted as (07) and 256 is transmitted as (FE 01 00).

A boolean is encoded within an unsigned integer: 0 for false, 1 for true.

A signed integer, i , is encoded within an unsigned integer, u . Within u , bits 1 upward contain the value; bit 0 says whether they should be complemented upon receipt. The encode algorithm looks like this:

```
uint u;
if i < 0 {
    u = (^i << 1) | 1    // complement i, bit 0 is 1
} else {
    u = (i << 1)    // do not complement i, bit 0 is 0
}
encodeUnsigned(u)
```

The low bit is therefore analogous to a sign bit, but making it the complement bit instead guarantees that the largest negative integer is not a special case. For example, $-129 = ^{128} = (^{256} >> 1)$ encodes as (FE 01 01).

Floating-point numbers are always sent as a representation of a float64 value. That value is converted to a uint64 using `math.Float64bits`. The uint64 is then byte-reversed and sent as a regular unsigned integer. The byte-reversal means the exponent and high-precision part of the mantissa go first. Since the low bits are often zero, this can save encoding bytes. For instance, 17.0 is encoded in only three bytes (FE 31 40).

Strings and slices of bytes are sent as an unsigned count followed by that many uninterpreted bytes of the value.

All other slices and arrays are sent as an unsigned count followed by that many elements using the standard gob encoding for their type, recursively.

Maps are sent as an unsigned count followed by that many key, element pairs. Empty but non-nil maps are sent, so if the sender has allocated a map, the receiver will allocate a map even no elements are transmitted.

Structs are sent as a sequence of (field number, field value) pairs. The field value is sent using the standard gob encoding for its type, recursively. If a field has the zero value for its type, it is omitted from the transmission. The field number is defined by the type of the encoded struct: the first field of the encoded type is field 0, the second is field 1, etc. When encoding a value, the field numbers are delta encoded for efficiency and the fields are always sent in order of increasing

field number; the deltas are therefore unsigned. The initialization for the delta encoding sets the field number to -1, so an unsigned integer field 0 with value 7 is transmitted as unsigned delta = 1, unsigned value = 7 or (01 07). Finally, after all the fields have been sent a terminating mark denotes the end of the struct. That mark is a delta=0 value, which has representation (00).

Interface types are not checked for compatibility; all interface types are treated, for transmission, as members of a single "interface" type, analogous to int or []byte - in effect they're all treated as interface{}. Interface values are transmitted as a string identifying the concrete type being sent (a name that must be pre-defined by calling Register), followed by a byte count of the length of the following data (so the value can be skipped if it cannot be stored), followed by the usual encoding of concrete (dynamic) value stored in the interface value. (A nil interface value is identified by the empty string and transmits no value.) Upon receipt, the decoder verifies that the unpacked concrete item satisfies the interface of the receiving variable.

The representation of types is described below. When a type is defined on a given connection between an Encoder and Decoder, it is assigned a signed integer type id. When Encoder.Encode(v) is called, it makes sure there is an id assigned for the type of v and all its elements and then it sends the pair (typeid, encoded-v) where typeid is the type id of the encoded type of v and encoded-v is the gob encoding of the value v.

To define a type, the encoder chooses an unused, positive type id and sends the pair (-type id, encoded-type) where encoded-type is the gob encoding of a wireType description, constructed from these types:

```
type wireType struct {
    ArrayT  *ArrayType
    SliceT  *SliceType
    StructT *StructType
    MapT    *MapType
}
type arrayType struct {
    CommonType
    Elem typeId
    Len  int
}
type CommonType struct {
    Name string // the name of the struct type
    Id   int     // the id of the type, repeated so it's inside th
```

```

}
type sliceType struct {
    CommonType
    Elem typeId
}
type structType struct {
    CommonType
    Field []*fieldType // the fields of the struct.
}
type fieldType struct {
    Name string // the name of the field.
    Id    int    // the type id of the field, which must be alrea
}
type mapType struct {
    CommonType
    Key  typeId
    Elem typeId
}
}

```

If there are nested type ids, the types for all inner type ids must be defined before the top-level type id is used to describe an encoded-v.

For simplicity in setup, the connection is defined to understand these types a priori, as well as the basic gob types int, uint, etc. Their ids are:

```

bool        1
int         2
uint        3
float       4
[]byte      5
string      6
complex     7
interface   8
// gap for reserved ids.
WireType    16
ArrayType    17
CommonType  18
SliceType   19
StructType  20
FieldType   21
// 22 is slice of fieldType.
MapType     23

```

Finally, each message created by a call to Encode is preceded by an encoded unsigned integer count of the number of bytes remaining in the message. After the initial type name, interface values are wrapped the same way; in effect, the interface value acts like a recursive invocation of Encode.

In summary, a gob stream looks like

`(byteCount (-type id, encoding of a wireType))* (type id, encoding of`

where * signifies zero or more repetitions and the type id of a value must be predefined or be defined before the value in the stream.

See "Gobs of data" for a design discussion of the gob wire format:

http://golang.org/doc/articles/gobs_of_data.html

Package files

[decode.go](#) [decoder.go](#) [doc.go](#) [encode.go](#) [encoder.go](#) [error.go](#) [type.go](#)

func Register

```
func Register(value interface{})
```

Register records a type, identified by a value for that type, under its internal type name. That name will identify the concrete type of a value sent or received as an interface variable. Only types that will be transferred as implementations of interface values need to be registered. Expecting to be used only during initialization, it panics if the mapping between types and names is not a bijection.

func [RegisterName](#)

```
func RegisterName(name string, value interface{})
```

RegisterName is like Register but uses the provided name rather than the type's default.

type [CommonType](#)

```
type CommonType struct {  
    Name string  
    Id    typeId  
}
```

CommonType holds elements of all types. It is a historical artifact, kept for binary compatibility and exported only for the benefit of the package's encoding of type descriptors. It is not intended for direct use by clients.

type [Decoder](#)

```
type Decoder struct {  
    // contains filtered or unexported fields  
}
```

A Decoder manages the receipt of type and data information read from the remote side of a connection.

func [NewDecoder](#)

```
func NewDecoder(r io.Reader) *Decoder
```

NewDecoder returns a new decoder that reads from the io.Reader. If r does not also implement io.ByteReader, it will be wrapped in a bufio.Reader.

func (***Decoder**) [Decode](#)

```
func (dec *Decoder) Decode(e interface{}) error
```

Decode reads the next value from the connection and stores it in the data represented by the empty interface value. If e is nil, the value will be discarded. Otherwise, the value underlying e must be a pointer to the correct type for the next data item received.

func (***Decoder**) [DecodeValue](#)

```
func (dec *Decoder) DecodeValue(v reflect.Value) error
```

DecodeValue reads the next value from the connection. If v is the zero reflect.Value (v.Kind() == Invalid), DecodeValue discards the value. Otherwise, it stores the value into v. In that case, v must represent a non-nil pointer to data or be an assignable reflect.Value (v.CanSet())

type [Encoder](#)

```
type Encoder struct {  
    // contains filtered or unexported fields  
}
```

An Encoder manages the transmission of type and data information to the other side of a connection.

func [NewEncoder](#)

```
func NewEncoder(w io.Writer) *Encoder
```

NewEncoder returns a new encoder that will transmit on the io.Writer.

func (***Encoder**) [Encode](#)

```
func (enc *Encoder) Encode(e interface{}) error
```

Encode transmits the data item represented by the empty interface value, guaranteeing that all necessary type information has been transmitted first.

func (***Encoder**) [EncodeValue](#)

```
func (enc *Encoder) EncodeValue(value reflect.Value) error
```

EncodeValue transmits the data item represented by the reflection value, guaranteeing that all necessary type information has been transmitted first.

type [GobDecoder](#)

```
type GobDecoder interface {  
    // GobDecode overwrites the receiver, which must be a pointer,  
    // with the value represented by the byte slice, which was writt  
    // by GobEncode, usually for the same concrete type.  
    GobDecode([]byte) error  
}
```

GobDecoder is the interface describing data that provides its own routine for decoding transmitted values sent by a GobEncoder.

type [GobEncoder](#)

```
type GobEncoder interface {  
    // GobEncode returns a byte slice representing the encoding of t  
    // receiver for transmission to a GobDecoder, usually of the same  
    // concrete type.  
    GobEncode() ([]byte, error)  
}
```

GobEncoder is the interface describing data that provides its own representation for encoding values for transmission to a GobDecoder. A type that implements GobEncoder and GobDecoder has complete control over the representation of its data and may therefore contain things such as private fields, channels, and functions, which are not usually transmissible in gob streams.

Note: Since gobs can be stored permanently, It is good design to guarantee the encoding used by a GobEncoder is stable as the software evolves. For instance, it might make sense for GobEncode to include a version number in the encoding.

Build version go1.0.1.

Package hex

```
import "encoding/hex"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package hex implements hexadecimal encoding and decoding.

Index

Variables

func Decode(dst, src []byte) (int, error)
func DecodeString(s string) ([]byte, error)
func DecodedLen(x int) int
func Dump(data []byte) string
func Dumper(w io.Writer) io.WriteCloser
func Encode(dst, src []byte) int
func EncodeToString(src []byte) string
func EncodedLen(n int) int
type InvalidByteError
func (e InvalidByteError) Error() string

Package files

hex.go

Variables

```
var ErrLength = errors.New("encoding/hex: odd length hex string")
```

ErrLength results from decoding an odd length slice.

func [Decode](#)

```
func Decode(dst, src []byte) (int, error)
```

Decode decodes src into DecodedLen(len(src)) bytes, returning the actual number of bytes written to dst.

If Decode encounters invalid input, it returns an error describing the failure.

func DecodeString

```
func DecodeString(s string) ([]byte, error)
```

DecodeString returns the bytes represented by the hexadecimal string s.

func DecodedLen

```
func DecodedLen(x int) int
```

func [Dump](#)

```
func Dump(data []byte) string
```

Dump returns a string that contains a hex dump of the given data. The format of the hex dump matches the output of `hexdump -C` on the command line.

func [Dumper](#)

```
func Dumper(w io.Writer) io.WriteCloser
```

Dumper returns a WriteCloser that writes a hex dump of all written data to w. The format of the dump matches the output of `hexdump -C` on the command line.

func [Encode](#)

```
func Encode(dst, src []byte) int
```

Encode encodes src into EncodedLen(len(src)) bytes of dst. As a convenience, it returns the number of bytes written to dst, but this value is always EncodedLen(len(src)). Encode implements hexadecimal encoding.

func [EncodeToString](#)

```
func EncodeToString(src []byte) string
```

EncodeToString returns the hexadecimal encoding of src.

func EncodedLen

```
func EncodedLen(n int) int
```

EncodedLen returns the length of an encoding of n source bytes.

type [InvalidByteError](#)

```
type InvalidByteError byte
```

InvalidByteError values describe errors resulting from an invalid byte in a hex string.

func (InvalidByteError) [Error](#)

```
func (e InvalidByteError) Error() string
```

Build version go1.0.1.

Examples

[Decoder](#)

[Marshal](#)

[Unmarshal](#)

Package files

[decode.go](#) [encode.go](#) [indent.go](#) [scanner.go](#) [stream.go](#) [tags.go](#)

func Compact

```
func Compact(dst *bytes.Buffer, src []byte) error
```

Compact appends to dst the JSON-encoded src with insignificant space characters elided.

func [HTMLEscape](#)

```
func HTMLEscape(dst *bytes.Buffer, src []byte)
```

HTMLEscape appends to dst the JSON-encoded src with <, >, and & characters inside string literals changed to \u003c, \u003e, \u0026 so that the JSON will be safe to embed inside HTML <script> tags. For historical reasons, web browsers don't honor standard HTML escaping within <script> tags, so an alternative JSON encoding must be used.

func Indent

```
func Indent(dst *bytes.Buffer, src []byte, prefix, indent string) error
```

Indent appends to dst an indented form of the JSON-encoded src. Each element in a JSON object or array begins on a new, indented line beginning with prefix followed by one or more copies of indent according to the indentation nesting. The data appended to dst has no trailing newline, to make it easier to embed inside other formatted JSON data.

func [Marshal](#)

```
func Marshal(v interface{}) ([]byte, error)
```

Marshal returns the JSON encoding of v.

Marshal traverses the value v recursively. If an encountered value implements the Marshaler interface and is not a nil pointer, Marshal calls its MarshalJSON method to produce JSON. The nil pointer exception is not strictly necessary but mimics a similar, necessary exception in the behavior of UnmarshalJSON.

Otherwise, Marshal uses the following type-dependent default encodings:

Boolean values encode as JSON booleans.

Floating point and integer values encode as JSON numbers.

String values encode as JSON strings, with each invalid UTF-8 sequence replaced by the encoding of the Unicode replacement character U+FFFD. The angle brackets "<" and ">" are escaped to "\u003c" and "\u003e" to keep some browsers from misinterpreting JSON output as HTML.

Array and slice values encode as JSON arrays, except that []byte encodes as a base64-encoded string, and a nil slice encodes as the null JSON object.

Struct values encode as JSON objects. Each exported struct field becomes a member of the object unless

- the field's tag is "-", or
- the field is empty and its tag specifies the "omitempty" option.

The empty values are false, 0, any nil pointer or interface value, and any array, slice, map, or string of length zero. The object's default key string is the struct field name but can be specified in the struct field's tag value. The "json" key in struct field's tag value is the key name, followed by an optional comma and options. Examples:

```
// Field is ignored by this package.  
Field int `json:"- "`
```

```
// Field appears in JSON as key "myName".
Field int `json:"myName"`

// Field appears in JSON as key "myName" and
// the field is omitted from the object if its value is empty,
// as defined above.
Field int `json:"myName,omitempty"`

// Field appears in JSON as key "Field" (the default), but
// the field is skipped if empty.
// Note the leading comma.
Field int `json:",omitempty"`
```

The "string" option signals that a field is stored as JSON inside a JSON-encoded string. This extra level of encoding is sometimes used when communicating with JavaScript programs:

```
Int64String int64 `json:",string"`
```

The key name will be used if it's a non-empty string consisting of only Unicode letters, digits, dollar signs, percent signs, hyphens, underscores and slashes.

Map values encode as JSON objects. The map's key type must be string; the object keys are used directly as map keys.

Pointer values encode as the value pointed to. A nil pointer encodes as the null JSON object.

Interface values encode as the value contained in the interface. A nil interface value encodes as the null JSON object.

Channel, complex, and function values cannot be encoded in JSON. Attempting to encode such a value causes Marshal to return an `InvalidTypeError`.

JSON cannot represent cyclic data structures and Marshal does not handle them. Passing cyclic structures to Marshal will result in an infinite recursion.

? Example

? Example

Code:

```
type ColorGroup struct {
    ID      int
    Name    string
    Colors []string
}
group := ColorGroup{
    ID:      1,
    Name:    "Reds",
    Colors: []string{"Crimson", "Red", "Ruby", "Maroon"},
}
b, err := json.Marshal(group)
if err != nil {
    fmt.Println("error:", err)
}
os.Stdout.Write(b)
```

Output:

```
{"ID":1,"Name":"Reds","Colors":["Crimson","Red","Ruby","Maroon"]}
```

func [MarshalIndent](#)

```
func MarshalIndent(v interface{}, prefix, indent string) ([]byte, error)
```

MarshalIndent is like Marshal but applies Indent to format the output.

func [Unmarshal](#)

```
func Unmarshal(data []byte, v interface{}) error
```

Unmarshal parses the JSON-encoded data and stores the result in the value pointed to by v.

Unmarshal uses the inverse of the encodings that Marshal uses, allocating maps, slices, and pointers as necessary, with the following additional rules:

To unmarshal JSON into a pointer, Unmarshal first handles the case of the JSON being the JSON literal null. In that case, Unmarshal sets the pointer to nil. Otherwise, Unmarshal unmarshals the JSON into the value pointed at by the pointer. If the pointer is nil, Unmarshal allocates a new value for it to point to.

To unmarshal JSON into an interface value, Unmarshal unmarshals the JSON into the concrete value contained in the interface value. If the interface value is nil, that is, has no concrete value stored in it, Unmarshal stores one of these in the interface value:

```
bool, for JSON booleans
float64, for JSON numbers
string, for JSON strings
[]interface{}, for JSON arrays
map[string]interface{}, for JSON objects
nil for JSON null
```

If a JSON value is not appropriate for a given target type, or if a JSON number overflows the target type, Unmarshal skips that field and completes the unmarshalling as best it can. If no more serious errors are encountered, Unmarshal returns an `UnmarshalTypeError` describing the earliest such error.

? Example

? Example

Code:

```
var jsonBlob = []byte(`[
  {"Name": "Platypus", "Order": "Monotremata"},
  {"Name": "Quoll", "Order": "Dasyuromorphia"}
]`)
```

```
]`)  
type Animal struct {  
    Name string  
    Order string  
}  
var animals []Animal  
err := json.Unmarshal(jsonBlob, &animals)  
if err != nil {  
    fmt.Println("error:", err)  
}  
fmt.Printf("%+v", animals)
```

Output:

```
[{Name:Platypus Order:Monotremata} {Name:Quoll Order:Dasyuromorphia}]
```

type [Decoder](#)

```
type Decoder struct {  
    // contains filtered or unexported fields  
}
```

A Decoder reads and decodes JSON objects from an input stream.

? Example

? Example

This example uses a Decoder to decode a stream of distinct JSON values.

Code:

```
const jsonStream = `  
    {"Name": "Ed", "Text": "Knock knock."}  
    {"Name": "Sam", "Text": "Who's there?"}  
    {"Name": "Ed", "Text": "Go fmt."}  
    {"Name": "Sam", "Text": "Go fmt who?"}  
    {"Name": "Ed", "Text": "Go fmt yourself!"}  
`  
  
type Message struct {  
    Name, Text string  
}  
dec := json.NewDecoder(strings.NewReader(jsonStream))  
for {  
    var m Message  
    if err := dec.Decode(&m); err == io.EOF {  
        break  
    } else if err != nil {  
        log.Fatal(err)  
    }  
    fmt.Printf("%s: %s\n", m.Name, m.Text)  
}
```

Output:

```
Ed: Knock knock.  
Sam: Who's there?  
Ed: Go fmt.  
Sam: Go fmt who?  
Ed: Go fmt yourself!
```

func [NewDecoder](#)

```
func NewDecoder(r io.Reader) *Decoder
```

NewDecoder returns a new decoder that reads from r.

The decoder introduces its own buffering and may read data from r beyond the JSON values requested.

func (*Decoder) [Decode](#)

```
func (dec *Decoder) Decode(v interface{}) error
```

Decode reads the next JSON-encoded value from its input and stores it in the value pointed to by v.

See the documentation for Unmarshal for details about the conversion of JSON into a Go value.

type [Encoder](#)

```
type Encoder struct {  
    // contains filtered or unexported fields  
}
```

An Encoder writes JSON objects to an output stream.

func [NewEncoder](#)

```
func NewEncoder(w io.Writer) *Encoder
```

NewEncoder returns a new encoder that writes to w.

func (***Encoder**) [Encode](#)

```
func (enc *Encoder) Encode(v interface{}) error
```

Encode writes the JSON encoding of v to the connection.

See the documentation for Marshal for details about the conversion of Go values to JSON.

type [InvalidUTF8Error](#)

```
type InvalidUTF8Error struct {  
    S string  
}
```

func ([*InvalidUTF8Error](#)) [Error](#)

```
func (e \*InvalidUTF8Error) Error() string
```

type [InvalidUnmarshalError](#)

```
type InvalidUnmarshalError struct {  
    Type reflect.Type  
}
```

An `InvalidUnmarshalError` describes an invalid argument passed to `Unmarshal`. (The argument to `Unmarshal` must be a non-nil pointer.)

func ([*InvalidUnmarshalError](#)) [Error](#)

```
func (e \*InvalidUnmarshalError) Error() string
```

type [Marshaler](#)

```
type Marshaler interface {  
    MarshalJSON() ([]byte, error)  
}
```

Marshaler is the interface implemented by objects that can marshal themselves into valid JSON.

type [MarshalerError](#)

```
type MarshalerError struct {  
    Type reflect.Type  
    Err  error  
}
```

func (*MarshalerError) [Error](#)

```
func (e *MarshalerError) Error() string
```

type [RawMessage](#)

```
type RawMessage []byte
```

RawMessage is a raw encoded JSON object. It implements Marshaler and Unmarshaler and can be used to delay JSON decoding or precompute a JSON encoding.

func (*RawMessage) [MarshalJSON](#)

```
func (m *RawMessage) MarshalJSON() ([]byte, error)
```

MarshalJSON returns *m as the JSON encoding of m.

func (*RawMessage) [UnmarshalJSON](#)

```
func (m *RawMessage) UnmarshalJSON(data []byte) error
```

UnmarshalJSON sets *m to a copy of data.

type [SyntaxError](#)

```
type SyntaxError struct {  
    Offset int64 // error occurred after reading Offset bytes  
    // contains filtered or unexported fields  
}
```

A `SyntaxError` is a description of a JSON syntax error.

func ([*SyntaxError](#)) [Error](#)

```
func (e *SyntaxError) Error() string
```

type [UnmarshalFieldError](#)

```
type UnmarshalFieldError struct {  
    Key    string  
    Type   reflect.Type  
    Field  reflect.StructField  
}
```

An `UnmarshalFieldError` describes a JSON object key that led to an unexported (and therefore unwritable) struct field.

func ([*UnmarshalFieldError](#)) [Error](#)

```
func (e *UnmarshalFieldError) Error() string
```

type [UnmarshalTypeError](#)

```
type UnmarshalTypeError struct {  
    Value string // description of JSON value - "bool", "array"  
    Type  reflect.Type // type of Go value it could not be assigned  
}
```

An `UnmarshalTypeError` describes a JSON value that was not appropriate for a value of a specific Go type.

func ([*UnmarshalTypeError](#)) [Error](#)

```
func (e *UnmarshalTypeError) Error() string
```

type Unmarshaler

```
type Unmarshaler interface {  
    UnmarshalJSON([]byte) error  
}
```

Unmarshaler is the interface implemented by objects that can unmarshal a JSON description of themselves. The input can be assumed to be a valid JSON object encoding. UnmarshalJSON must copy the JSON data if it wishes to retain the data after returning.

type [UnsupportedTypeError](#)

```
type UnsupportedTypeError struct {  
    Type reflect.Type  
}
```

func (*UnsupportedTypeError) [Error](#)

```
func (e *UnsupportedTypeError) Error() string
```

type UnsupportedValueError

```
type UnsupportedValueError struct {  
    Value reflect.Value  
    Str    string  
}
```

func (*UnsupportedValueError) Error

```
func (e *UnsupportedValueError) Error() string
```

Bugs

This package ignores anonymous (embedded) struct fields during encoding and decoding. A future version may assign meaning to them. To force an anonymous field to be ignored in all future versions of this package, use an explicit ``json:"-"` tag in the struct definition.

Build version go1.0.1.

Package pem

```
import "encoding/pem"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package pem implements the PEM data encoding, which originated in Privacy Enhanced Mail. The most common use of PEM encoding today is in TLS keys and certificates. See RFC 1421.

Index

[func Encode\(out io.Writer, b *Block\) \(err error\)](#)
[func EncodeToMemory\(b *Block\) \[\]byte](#)
[type Block](#)
[func Decode\(data \[\]byte\) \(p *Block, rest \[\]byte\)](#)

Package files

pem.go

func Encode

```
func Encode(out io.Writer, b *Block) (err error)
```

func EncodeToMemory

```
func EncodeToMemory(b *Block) []byte
```

type [Block](#)

```
type Block struct {
    Type      string           // The type, taken from the preamble (
    Headers   map[string]string // Optional headers.
    Bytes     []byte           // The decoded bytes of the contents.
}
```

A Block represents a PEM encoded structure.

The encoded form is:

```
-----BEGIN Type-----
Headers
base64-encoded Bytes
-----END Type-----
```

where Headers is a possibly empty sequence of Key: Value lines.

func [Decode](#)

```
func Decode(data []byte) (p *Block, rest []byte)
```

Decode will find the next PEM formatted block (certificate, private key etc) in the input. It returns that block and the remainder of the input. If no PEM data is found, p is nil and the whole of the input is returned in rest.

Build version go1.0.1.

Examples

[MarshalIndent](#)
[Unmarshal](#)

Package files

[marshal.go](#) [read.go](#) [typeinfo.go](#) [xml.go](#)

Constants

```
const (  
    // A generic XML header suitable for use with the output of Mars  
    // This is not automatically added to any output of this package  
    // it is provided as a convenience.  
    Header = `<?xml version="1.0" encoding="UTF-8"?>` + "\n"  
)
```

Variables

```
var HTMLAutoClose = htmlAutoClose
```

HTMLAutoClose is the set of HTML elements that should be considered to close automatically.

```
var HTMLEntity = htmlEntity
```

HTMLEntity is an entity map containing translations for the standard HTML entity characters.

func Escape

```
func Escape(w io.Writer, s []byte)
```

Escape writes to w the properly escaped XML equivalent of the plain text data s.

func [Marshal](#)

```
func Marshal(v interface{}) ([]byte, error)
```

Marshal returns the XML encoding of v.

Marshal handles an array or slice by marshalling each of the elements. Marshal handles a pointer by marshalling the value it points at or, if the pointer is nil, by writing nothing. Marshal handles an interface value by marshalling the value it contains or, if the interface value is nil, by writing nothing. Marshal handles all other data by writing one or more XML elements containing the data.

The name for the XML elements is taken from, in order of preference:

- the tag on the XMLName field, if the data is a struct
- the value of the XMLName field of type xml.Name
- the tag of the struct field used to obtain the data
- the name of the struct field used to obtain the data
- the name of the marshalled type

The XML element for a struct contains marshalled elements for each of the exported fields of the struct, with these exceptions:

- the XMLName field, described above, is omitted.
- a field with tag "-" is omitted.
- a field with tag "name,attr" becomes an attribute with the given name in the XML element.
- a field with tag ",attr" becomes an attribute with the field name in the in the XML element.
- a field with tag ",chardata" is written as character data, not as an XML element.
- a field with tag ",innerxml" is written verbatim, not subject to the usual marshalling procedure.
- a field with tag ",comment" is written as an XML comment, not subject to the usual marshalling procedure. It must not contain the "--" string within it.
- a field with a tag including the "omitempty" option is omitted if the field value is empty. The empty values are false, 0, any nil pointer or interface value, and any array, slice, map, or string of length zero.
- a non-pointer anonymous struct field is handled as if the fields of its value were part of the outer struct.

If a field uses a tag "a>b>c", then the element c will be nested inside parent elements a and b. Fields that appear next to each other that name the same parent will be enclosed in one XML element.

See MarshalIndent for an example.

Marshal will return an error if asked to marshal a channel, function, or map.

func [MarshalIndent](#)

```
func MarshalIndent(v interface{}, prefix, indent string) ([]byte, error)
```

MarshalIndent works like Marshal, but each XML element begins on a new indented line that starts with prefix and is followed by one or more copies of indent according to the nesting depth.

? Example

? Example

Code:

```
type Address struct {
    City, State string
}
type Person struct {
    XMLName    xml.Name `xml:"person"`
    Id         int      `xml:"id,attr"`
    FirstName  string   `xml:"name>first"`
    LastName   string   `xml:"name>last"`
    Age        int      `xml:"age"`
    Height     float32  `xml:"height,omitempty"`
    Married    bool
    Address
    Comment string `xml:",comment"`
}

v := &Person{Id: 13, FirstName: "John", LastName: "Doe", Age: 42}
v.Comment = " Need more details. "
v.Address = Address{"Hanga Roa", "Easter Island"}

output, err := xml.MarshalIndent(v, "  ", "    ")
if err != nil {
    fmt.Printf("error: %v\n", err)
}

os.Stdout.Write(output)
```

Output:

```
<person id="13">
    <name>
```

```
    <first>John</first>
    <last>Doe</last>
  </name>
  <age>42</age>
  <Married>>false</Married>
  <City>Hanga Roa</City>
  <State>Easter Island</State>
  <!-- Need more details. -->
</person>
```

func [Unmarshal](#)

```
func Unmarshal(data []byte, v interface{}) error
```

Unmarshal parses the XML-encoded data and stores the result in the value pointed to by `v`, which must be an arbitrary struct, slice, or string. Well-formed data that does not fit into `v` is discarded.

Because Unmarshal uses the reflect package, it can only assign to exported (upper case) fields. Unmarshal uses a case-sensitive comparison to match XML element names to tag values and struct field names.

Unmarshal maps an XML element to a struct using the following rules. In the rules, the tag of a field refers to the value associated with the key 'xml' in the struct field's tag (see the example above).

- * If the struct has a field of type `[]byte` or `string` with tag `",innerxml"`, Unmarshal accumulates the raw XML nested inside the element in that field. The rest of the rules still apply.
- * If the struct has a field named `XMLName` of type `xml.Name`, Unmarshal records the element name in that field.
- * If the `XMLName` field has an associated tag of the form `"name"` or `"namespace-URL name"`, the XML element must have the given name (and, optionally, name space) or else Unmarshal returns an error.
- * If the XML element has an attribute whose name matches a struct field name with an associated tag containing `",attr"` or the explicit name in a struct field tag of the form `"name,attr"`, Unmarshal records the attribute value in that field.
- * If the XML element contains character data, that data is accumulated in the first struct field that has tag `"chardata"`. The struct field may have type `[]byte` or `string`. If there is no such field, the character data is discarded.
- * If the XML element contains comments, they are accumulated in the first struct field that has tag `",comments"`. The struct field may have type `[]byte` or `string`. If there is no such field, the comments are discarded.
- * If the XML element contains a sub-element whose name matches

the prefix of a tag formatted as "a" or "a>b>c", unmarshal will descend into the XML structure looking for elements with the given names, and will map the innermost elements to that struct field. A tag starting with ">" is equivalent to one starting with the field name followed by ">".

- * If the XML element contains a sub-element whose name matches a struct field's XMLName tag and the struct field has no explicit name tag as per the previous rule, unmarshal maps the sub-element to that struct field.
- * If the XML element contains a sub-element whose name matches a field without any mode flags ("attr", "chardata", etc), Unmarsh maps the sub-element to that struct field.
- * If the XML element contains a sub-element that hasn't matched any of the above rules and the struct has a field with tag ",any", unmarshal maps the sub-element to that struct field.
- * A non-pointer anonymous struct field is handled as if the fields of its value were part of the outer struct.
- * A struct field with tag "-" is never unmarshalled into.

Unmarshal maps an XML element to a string or []byte by saving the concatenation of that element's character data in the string or []byte. The saved []byte is never nil.

Unmarshal maps an attribute value to a string or []byte by saving the value in the string or slice.

Unmarshal maps an XML element to a slice by extending the length of the slice and mapping the element to the newly created value.

Unmarshal maps an XML element or attribute value to a bool by setting it to the boolean value represented by the string.

Unmarshal maps an XML element or attribute value to an integer or floating-point field by setting the field to the result of interpreting the string value in decimal. There is no check for overflow.

Unmarshal maps an XML element to an xml.Name by recording the element name.

Unmarshal maps an XML element to a pointer by setting the pointer to a freshly

allocated value and then mapping the element to that value.

? Example

? Example

This example demonstrates unmarshaling an XML excerpt into a value with some preset fields. Note that the Phone field isn't modified and that the XML <Company> element is ignored. Also, the Groups field is assigned considering the element path provided in its tag.

Code:

```
type Email struct {
    Where string `xml:"where,attr"`
    Addr  string
}
type Address struct {
    City, State string
}
type Result struct {
    XMLName xml.Name `xml:"Person"`
    Name    string  `xml:"FullName"`
    Phone   string
    Email   []Email
    Groups  []string `xml:"Group>Value"`
    Address
}
v := Result{Name: "none", Phone: "none"}

data := `
<Person>
  <FullName>Grace R. Emlin</FullName>
  <Company>Example Inc.</Company>
  <Email where="home">
    <Addr>gre@example.com</Addr>
  </Email>
  <Email where='work'>
    <Addr>gre@work.com</Addr>
  </Email>
  <Group>
    <Value>Friends</Value>
    <Value>Squash</Value>
  </Group>
  <City>Hanga Roa</City>
  <State>Easter Island</State>
</Person>
```

```
err := xml.Unmarshal([]byte(data), &v)
if err != nil {
    fmt.Printf("error: %v", err)
    return
}
fmt.Printf("XMLName: %#v\n", v.XMLName)
fmt.Printf("Name: %q\n", v.Name)
fmt.Printf("Phone: %q\n", v.Phone)
fmt.Printf("Email: %v\n", v.Email)
fmt.Printf("Groups: %v\n", v.Groups)
fmt.Printf("Address: %v\n", v.Address)
```

Output:

```
XMLName: xml.Name{Space:"", Local:"Person"}
Name: "Grace R. Emlin"
Phone: "none"
Email: [{home gre@example.com} {work gre@work.com}]
Groups: [Friends Squash]
Address: {Hanga Roa Easter Island}
```

type [Attr](#)

```
type Attr struct {  
    Name Name  
    Value string  
}
```

An Attr represents an attribute in an XML element (Name=Value).

type [CharData](#)

type CharData []byte

A CharData represents XML character data (raw text), in which XML escape sequences have been replaced by the characters they represent.

func (CharData) [Copy](#)

func (c CharData) Copy() CharData

type [Comment](#)

type Comment []byte

A Comment represents an XML comment of the form <!--comment-->. The bytes do not include the <!-- and --> comment markers.

func (Comment) [Copy](#)

func (c Comment) Copy() Comment

type [Decoder](#)

```
type Decoder struct {
    // Strict defaults to true, enforcing the requirements
    // of the XML specification.
    // If set to false, the parser allows input containing common
    // mistakes:
    // * If an element is missing an end tag, the parser invents
    //   end tags as necessary to keep the return values from Token
    //   properly balanced.
    // * In attribute values and character data, unknown or malformed
    //   character entities (sequences beginning with &) are left a
    //
    // Setting:
    //
    // d.Strict = false;
    // d.AutoClose = HTMLAutoClose;
    // d.Entity = HTMLEntity
    //
    // creates a parser that can handle typical HTML.
    Strict bool

    // When Strict == false, AutoClose indicates a set of elements t
    // consider closed immediately after they are opened, regardless
    // of whether an end element is present.
    AutoClose []string

    // Entity can be used to map non-standard entity names to string
    // The parser behaves as if these standard mappings are present
    // regardless of the actual map content:
    //
    // "lt": "<",
    // "gt": ">",
    // "amp": "&",
    // "apos": "'",
    // "quot": `"`
    Entity map[string]string

    // CharsetReader, if non-nil, defines a function to generate
    // charset-conversion readers, converting from the provided
    // non-UTF-8 charset into UTF-8. If CharsetReader is nil or
    // returns an error, parsing stops with an error. One of the
    // the CharsetReader's result values must be non-nil.
    CharsetReader func(charset string, input io.Reader) (io.Reader,
    // contains filtered or unexported fields
}
}
```

A Decoder represents an XML parser reading a particular input stream. The parser assumes that its input is encoded in UTF-8.

func [NewDecoder](#)

```
func NewDecoder(r io.Reader) *Decoder
```

NewDecoder creates a new XML parser reading from r.

func (*Decoder) [Decode](#)

```
func (d *Decoder) Decode(v interface{}) error
```

Decode works like `xml.Unmarshal`, except it reads the decoder stream to find the start element.

func (*Decoder) [DecodeElement](#)

```
func (d *Decoder) DecodeElement(v interface{}, start *StartElement)
```

DecodeElement works like `xml.Unmarshal` except that it takes a pointer to the start XML element to decode into v. It is useful when a client reads some raw XML tokens itself but also wants to defer to `Unmarshal` for some elements.

func (*Decoder) [RawToken](#)

```
func (d *Decoder) RawToken() (Token, error)
```

RawToken is like `Token` but does not verify that start and end elements match and does not translate name space prefixes to their corresponding URLs.

func (*Decoder) [Skip](#)

```
func (d *Decoder) Skip() error
```

Skip reads tokens until it has consumed the end element matching the most recent start element already consumed. It recurs if it encounters a start element, so it can be used to skip nested structures. It returns nil if it finds an end element matching the start element; otherwise it returns an error describing the problem.

func (*Decoder) [Token](#)

```
func (d *Decoder) Token() (t Token, err error)
```

Token returns the next XML token in the input stream. At the end of the input stream, Token returns nil, io.EOF.

Slices of bytes in the returned token data refer to the parser's internal buffer and remain valid only until the next call to Token. To acquire a copy of the bytes, call CopyToken or the token's Copy method.

Token expands self-closing elements such as
 into separate start and end elements returned by successive calls.

Token guarantees that the StartElement and EndElement tokens it returns are properly nested and matched: if Token encounters an unexpected end element, it will return an error.

Token implements XML name spaces as described by <http://www.w3.org/TR/REC-xml-names/>. Each of the Name structures contained in the Token has the Space set to the URL identifying its name space when known. If Token encounters an unrecognized name space prefix, it uses the prefix as the Space rather than report an error.

type [Directive](#)

```
type Directive []byte
```

A Directive represents an XML directive of the form `<!text>`. The bytes do not include the `<!` and `>` markers.

func (Directive) [Copy](#)

```
func (d Directive) Copy() Directive
```

type [Encoder](#)

```
type Encoder struct {  
    // contains filtered or unexported fields  
}
```

An Encoder writes XML data to an output stream.

func [NewEncoder](#)

```
func NewEncoder(w io.Writer) *Encoder
```

NewEncoder returns a new encoder that writes to w.

func (***Encoder**) [Encode](#)

```
func (enc *Encoder) Encode(v interface{}) error
```

Encode writes the XML encoding of v to the stream.

See the documentation for Marshal for details about the conversion of Go values to XML.

type EndElement

```
type EndElement struct {  
    Name Name  
}
```

An EndElement represents an XML end element.

type [Name](#)

```
type Name struct {  
    Space, Local string  
}
```

A Name represents an XML name (Local) annotated with a name space identifier (Space). In tokens returned by `Decoder.Token`, the Space identifier is given as a canonical URL, not the short prefix used in the document being parsed.

type [ProcInst](#)

```
type ProcInst struct {  
    Target string  
    Inst    []byte  
}
```

A ProcInst represents an XML processing instruction of the form <?target inst?>

func (ProcInst) [Copy](#)

```
func (p ProcInst) Copy() ProcInst
```

type [StartElement](#)

```
type StartElement struct {  
    Name Name  
    Attr []Attr  
}
```

A StartElement represents an XML start element.

func (StartElement) [Copy](#)

```
func (e StartElement) Copy() StartElement
```

type [SyntaxError](#)

```
type SyntaxError struct {  
    Msg string  
    Line int  
}
```

A `SyntaxError` represents a syntax error in the XML input stream.

func (*SyntaxError) [Error](#)

```
func (e *SyntaxError) Error() string
```

type [TagPathError](#)

```
type TagPathError struct {  
    Struct      reflect.Type  
    Field1, Tag1 string  
    Field2, Tag2 string  
}
```

A `TagPathError` represents an error in the unmarshalling process caused by the use of field tags with conflicting paths.

func (*TagPathError) [Error](#)

```
func (e *TagPathError) Error() string
```

type [Token](#)

```
type Token interface{}
```

A Token is an interface holding one of the token types: StartElement, EndElement, CharData, Comment, ProcInst, or Directive.

func [CopyToken](#)

```
func CopyToken(t Token) Token
```

CopyToken returns a copy of a Token.

type [UnmarshalError](#)

```
type UnmarshalError string
```

An UnmarshalError represents an error in the unmarshalling process.

func (UnmarshalError) [Error](#)

```
func (e UnmarshalError) Error() string
```

type [UnsupportedTypeError](#)

```
type UnsupportedTypeError struct {  
    Type reflect.Type  
}
```

A MarshalXMLError is returned when Marshal encounters a type that cannot be converted into XML.

func (*UnsupportedTypeError) [Error](#)

```
func (e *UnsupportedTypeError) Error() string
```

Bugs

Mapping between XML elements and data structures is inherently flawed: an XML element is an order-dependent collection of anonymous values, while a data structure is an order-independent collection of named values. See package `json` for a textual representation more suitable to data structures.

Build version `go1.0.1`.

Overview ?

Overview ?

Package errors implements functions to manipulate errors.

? Example

? Example

Code:

```
package errors_test

import (
    "fmt"
    "time"
)

// MyError is an error implementation that includes a time and messa
type MyError struct {
    When time.Time
    What string
}

func (e MyError) Error() string {
    return fmt.Sprintf("%v: %v", e.When, e.What)
}

func oops() error {
    return MyError{
        time.Date(1989, 3, 15, 22, 30, 0, 0, time.UTC),
        "the file system has gone away",
    }
}

func Example() {
    if err := oops(); err != nil {
        fmt.Println(err)
    }
    // Output: 1989-03-15 22:30:00 +0000 UTC: the file system has go
}
```

[func New\(text string\) error](#)

Examples

[Package](#)

[New](#)

[New \(Errorf\)](#)

Package files

errors.golang.org

func [New](#)

```
func New(text string) error
```

New returns an error that formats as the given text.

? Example

? Example

Code:

```
err := errors.New("emit macho dwarf: elf header corrupted")
if err != nil {
    fmt.Print(err)
}
```

Output:

```
emit macho dwarf: elf header corrupted
```

? Example (Errorf)

? Example (Errorf)

The `fmt` package's `Errorf` function lets us use the package's formatting features to create descriptive error messages.

Code:

```
const name, id = "bimmler", 17
err := fmt.Errorf("user %q (id %d) not found", name, id)
if err != nil {
    fmt.Print(err)
}
```

Output:

```
user "bimmler" (id 17) not found
```

Build version go1.0.1.

Package expvar

```
import "expvar"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `expvar` provides a standardized interface to public variables, such as operation counters in servers. It exposes these variables via HTTP at `/debug/vars` in JSON format.

Operations to set or modify these public variables are atomic.

In addition to adding the HTTP handler, this package registers the following variables:

```
cmdline    os.Args
memstats   runtime.Memstats
```

The package is sometimes only imported for the side effect of registering its HTTP handler and the above variables. To use it this way, link this package into your program:

```
import _ "expvar"
```

Package files

expvar.go

func [Do](#)

```
func Do(f func(KeyValue))
```

Do calls f for each exported variable. The global variable map is locked during the iteration, but existing entries may be concurrently updated.

func [Publish](#)

```
func Publish(name string, v Var)
```

Publish declares a named exported variable. This should be called from a package's init function when it creates its Vars. If the name is already registered then this will log.Panic.

type [Float](#)

```
type Float struct {  
    // contains filtered or unexported fields  
}
```

Float is a 64-bit float variable that satisfies the Var interface.

func [NewFloat](#)

```
func NewFloat(name string) *Float
```

func (*Float) [Add](#)

```
func (v *Float) Add(delta float64)
```

Add adds delta to v.

func (*Float) [Set](#)

```
func (v *Float) Set(value float64)
```

Set sets v to value.

func (*Float) [String](#)

```
func (v *Float) String() string
```

type [Func](#)

```
type Func func() interface{}
```

Func implements Var by calling the function and formatting the returned value using JSON.

func (Func) [String](#)

```
func (f Func) String() string
```

type [Int](#)

```
type Int struct {  
    // contains filtered or unexported fields  
}
```

Int is a 64-bit integer variable that satisfies the Var interface.

func [NewInt](#)

```
func NewInt(name string) *Int
```

func ([*Int](#)) [Add](#)

```
func (v *Int) Add(delta int64)
```

func ([*Int](#)) [Set](#)

```
func (v *Int) Set(value int64)
```

func ([*Int](#)) [String](#)

```
func (v *Int) String() string
```

type [KeyValue](#)

```
type KeyValue struct {  
    Key    string  
    Value  Var  
}
```

KeyValue represents a single entry in a Map.

type [Map](#)

```
type Map struct {  
    // contains filtered or unexported fields  
}
```

Map is a string-to-Var map variable that satisfies the Var interface.

func [NewMap](#)

```
func NewMap(name string) *Map
```

func (***Map**) [Add](#)

```
func (v *Map) Add(key string, delta int64)
```

func (***Map**) [AddFloat](#)

```
func (v *Map) AddFloat(key string, delta float64)
```

AddFloat adds delta to the *Float value stored under the given map key.

func (***Map**) [Do](#)

```
func (v *Map) Do(f func(KeyValue))
```

Do calls f for each entry in the map. The map is locked during the iteration, but existing entries may be concurrently updated.

func (***Map**) [Get](#)

```
func (v *Map) Get(key string) Var
```

func (***Map**) [Init](#)

```
func (v *Map) Init() *Map
```

func (***Map**) [Set](#)

```
func (v *Map) Set(key string, av Var)
```

```
func (*Map) String
```

```
func (v *Map) String() string
```

type [String](#)

```
type String struct {  
    // contains filtered or unexported fields  
}
```

String is a string variable, and satisfies the Var interface.

func [NewString](#)

```
func NewString(name string) *String
```

func (*String) [Set](#)

```
func (v *String) Set(value string)
```

func (*String) [String](#)

```
func (v *String) String() string
```

type [Var](#)

```
type Var interface {  
    String() string  
}
```

Var is an abstract type for all exported variables.

func [Get](#)

```
func Get(name string) Var
```

Get retrieves a named exported variable.

Build version go1.0.1.

Package flag

```
import "flag"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package flag implements command-line flag parsing.

Usage:

Define flags using flag.String(), Bool(), Int(), etc.

This declares an integer flag, -flagname, stored in the pointer ip, with type *int.

```
import "flag"
var ip = flag.Int("flagname", 1234, "help message for flagname")
```

If you like, you can bind the flag to a variable using the Var() functions.

```
var flagvar int
func init() {
    flag.IntVar(&flagvar, "flagname", 1234, "help message for fl
}
```

Or you can create custom flags that satisfy the Value interface (with pointer receivers) and couple them to flag parsing by

```
flag.Var(&flagVal, "name", "help message for flagname")
```

For such flags, the default value is just the initial value of the variable.

After all flags are defined, call

```
flag.Parse()
```

to parse the command line into the defined flags.

Flags may then be used directly. If you're using the flags themselves, they are all pointers; if you bind to variables, they're values.

```
fmt.Println("ip has value ", *ip)
fmt.Println("flagvar has value ", flagvar)
```

After parsing, the arguments after the flag are available as the slice flag.Args() or individually as flag.Arg(i). The arguments are indexed from 0 up to flag.NArg().

Command line flag syntax:

```
-flag  
-flag=x  
-flag x // non-boolean flags only
```

One or two minus signs may be used; they are equivalent. The last form is not permitted for boolean flags because the meaning of the command

```
cmd -x *
```

will change if there is a file called 0, false, etc. You must use the `-flag=false` form to turn off a boolean flag.

Flag parsing stops just before the first non-flag argument ("`-`" is a non-flag argument) or after the terminator "`--`".

Integer flags accept 1234, 0664, 0x1234 and may be negative. Boolean flags may be 1, 0, t, f, true, false, TRUE, FALSE, True, False. Duration flags accept any input valid for `time.ParseDuration`.

The default set of command-line flags is controlled by top-level functions. The `FlagSet` type allows one to define independent sets of flags, such as to implement subcommands in a command-line interface. The methods of `FlagSet` are analogous to the top-level functions for the command-line flag set.

? Example

? Example

Code:

```
// These examples demonstrate more intricate uses of the flag package  
package flag_test
```

```
import (  
    "errors"  
    "flag"  
    "fmt"  
    "strings"  
    "time"  
)
```

```
// Example 1: A single string flag called "species" with default val
```

```

var species = flag.String("species", "gopher", "the species we are s

// Example 2: Two flags sharing a variable, so we can have a shortha
// The order of initialization is undefined, so make sure both use t
// same default value. They must be set up with an init function.
var gopherType string

func init() {
    const (
        defaultGopher = "pocket"
        usage          = "the variety of gopher"
    )
    flag.StringVar(&gopherType, "gopher_type", defaultGopher, usage)
    flag.StringVar(&gopherType, "g", defaultGopher, usage+" (shortha
}

// Example 3: A user-defined flag type, a slice of durations.
type interval []time.Duration

// String is the method to format the flag's value, part of the flag
// The String method's output will be used in diagnostics.
func (i *interval) String() string {
    return fmt.Sprint(*i)
}

// Set is the method to set the flag value, part of the flag.Value i
// Set's argument is a string to be parsed to set the flag.
// It's a comma-separated list, so we split it.
func (i *interval) Set(value string) error {
    // If we wanted to allow the flag to be set multiple times,
    // accumulating values, we would delete this if statement.
    // That would permit usages such as
    // -deltaT 10s -deltaT 15s
    // and other combinations.
    if len(*i) > 0 {
        return errors.New("interval flag already set")
    }
    for _, dt := range strings.Split(value, ",") {
        duration, err := time.ParseDuration(dt)
        if err != nil {
            return err
        }
        *i = append(*i, duration)
    }
    return nil
}

// Define a flag to accumulate durations. Because it has a special t
// we need to use the Var function and therefore create the flag dur
// init.

```

```
var intervalFlag interval

func init() {
    // Tie the command-line flag to the intervalFlag variable and
    // set a usage message.
    flag.Var(&intervalFlag, "deltaT", "comma-separated list of inter
}

func Example() {
    // All the interesting pieces are with the variables declared ab
    // to enable the flag package to see the flags defined there, on
    // execute, typically at the start of main (not init!):
    // flag.Parse()
    // We don't run it here because this is not a main function and
    // the testing suite has already parsed the flags.
}
```

Examples

[Package](#)

Package files

[flag.go](#)

Variables

```
var ErrHelp = errors.New("flag: help requested")
```

ErrHelp is the error returned if the flag -help is invoked but no such flag is defined.

```
var Usage = func() {  
    fmt.Fprintf(os.Stderr, "Usage of %s:\n", os.Args[0])  
    PrintDefaults()  
}
```

Usage prints to standard error a usage message documenting all defined command-line flags. The function is a variable that may be changed to point to a custom function.

func [Arg](#)

```
func Arg(i int) string
```

Arg returns the i'th command-line argument. Arg(0) is the first remaining argument after flags have been processed.

func [Args](#)

```
func Args() []string
```

Args returns the non-flag command-line arguments.

func Bool

```
func Bool(name string, value bool, usage string) *bool
```

Bool defines a bool flag with specified name, default value, and usage string.
The return value is the address of a bool variable that stores the value of the flag.

func BoolVar

```
func BoolVar(p *bool, name string, value bool, usage string)
```

BoolVar defines a bool flag with specified name, default value, and usage string. The argument p points to a bool variable in which to store the value of the flag.

func Duration

```
func Duration(name string, value time.Duration, usage string) *time.
```

Duration defines a time.Duration flag with specified name, default value, and usage string. The return value is the address of a time.Duration variable that stores the value of the flag.

func DurationVar

```
func DurationVar(p *time.Duration, name string, value time.Duration,
```

DurationVar defines a time.Duration flag with specified name, default value, and usage string. The argument p points to a time.Duration variable in which to store the value of the flag.

func [Float64](#)

```
func Float64(name string, value float64, usage string) *float64
```

Float64 defines a float64 flag with specified name, default value, and usage string. The return value is the address of a float64 variable that stores the value of the flag.

func Float64Var

```
func Float64Var(p *float64, name string, value float64, usage string
```

Float64Var defines a float64 flag with specified name, default value, and usage string. The argument p points to a float64 variable in which to store the value of the flag.

func [Int](#)

```
func Int(name string, value int, usage string) *int
```

Int defines an int flag with specified name, default value, and usage string. The return value is the address of an int variable that stores the value of the flag.

func [Int64](#)

```
func Int64(name string, value int64, usage string) *int64
```

Int64 defines an int64 flag with specified name, default value, and usage string. The return value is the address of an int64 variable that stores the value of the flag.

func [Int64Var](#)

```
func Int64Var(p *int64, name string, value int64, usage string)
```

Int64Var defines an int64 flag with specified name, default value, and usage string. The argument p points to an int64 variable in which to store the value of the flag.

func [IntVar](#)

```
func IntVar(p *int, name string, value int, usage string)
```

IntVar defines an int flag with specified name, default value, and usage string. The argument p points to an int variable in which to store the value of the flag.

func NArg

```
func NArg() int
```

NArg is the number of arguments remaining after flags have been processed.

func [NFlag](#)

```
func NFlag() int
```

NFlag returns the number of command-line flags that have been set.

func [Parse](#)

`func Parse()`

Parse parses the command-line flags from `os.Args[1:]`. Must be called after all flags are defined and before flags are accessed by the program.

func Parsed

```
func Parsed() bool
```

Parsed returns true if the command-line flags have been parsed.

func PrintDefaults

```
func PrintDefaults()
```

PrintDefaults prints to standard error the default values of all defined command-line flags.

func [Set](#)

```
func Set(name, value string) error
```

Set sets the value of the named command-line flag.

func [String](#)

```
func String(name string, value string, usage string) *string
```

String defines a string flag with specified name, default value, and usage string. The return value is the address of a string variable that stores the value of the flag.

func StringVar

```
func StringVar(p *string, name string, value string, usage string)
```

StringVar defines a string flag with specified name, default value, and usage string. The argument p points to a string variable in which to store the value of the flag.

func [Uint](#)

```
func Uint(name string, value uint, usage string) *uint
```

Uin defines a uint flag with specified name, default value, and usage string. The return value is the address of a uint variable that stores the value of the flag.

func [Uint64](#)

```
func Uint64(name string, value uint64, usage string) *uint64
```

Uin64 defines a uint64 flag with specified name, default value, and usage string. The return value is the address of a uint64 variable that stores the value of the flag.

func [Uin64Var](#)

```
func Uin64Var(p *uint64, name string, value uint64, usage string)
```

Uin64Var defines a uint64 flag with specified name, default value, and usage string. The argument p points to a uint64 variable in which to store the value of the flag.

func UinVar

```
func UinVar(p *uint, name string, value uint, usage string)
```

UinVar defines a uint flag with specified name, default value, and usage string. The argument p points to a uint variable in which to store the value of the flag.

func [Var](#)

```
func Var(value Value, name string, usage string)
```

Var defines a flag with the specified name and usage string. The type and value of the flag are represented by the first argument, of type Value, which typically holds a user-defined implementation of Value. For instance, the caller could create a flag that turns a comma-separated string into a slice of strings by giving the slice the methods of Value; in particular, Set would decompose the comma-separated string into the slice.

func [Visit](#)

```
func Visit(fn func(*Flag))
```

Visit visits the command-line flags in lexicographical order, calling fn for each. It visits only those flags that have been set.

func [VisitAll](#)

```
func VisitAll(fn func(*Flag))
```

VisitAll visits the command-line flags in lexicographical order, calling fn for each. It visits all flags, even those not set.

type [ErrorHandling](#)

```
type ErrorHandling int
```

ErrorHandling defines how to handle flag parsing errors.

```
const (  
    ContinueOnError ErrorHandling = iota  
    ExitOnError  
    PanicOnError  
)
```

type [Flag](#)

```
type Flag struct {
    Name      string // name as it appears on command line
    Usage     string // help message
    Value     Value  // value as set
    DefValue  string // default value (as text); for usage message
}
```

A Flag represents the state of a flag.

func [Lookup](#)

```
func Lookup(name string) *Flag
```

Lookup returns the Flag structure of the named command-line flag, returning nil if none exists.

type [FlagSet](#)

```
type FlagSet struct {  
    // Usage is the function called when an error occurs while parsing  
    // The field is a function (not a method) that may be changed to  
    // a custom error handler.  
    Usage func()  
    // contains filtered or unexported fields  
}
```

A FlagSet represents a set of defined flags.

func [NewFlagSet](#)

```
func NewFlagSet(name string, errorHandler ErrorHandling) *FlagSet
```

NewFlagSet returns a new, empty flag set with the specified name and error handling property.

func (*FlagSet) [Arg](#)

```
func (f *FlagSet) Arg(i int) string
```

Arg returns the i'th argument. Arg(0) is the first remaining argument after flags have been processed.

func (*FlagSet) [Args](#)

```
func (f *FlagSet) Args() []string
```

Args returns the non-flag arguments.

func (*FlagSet) [Bool](#)

```
func (f *FlagSet) Bool(name string, value bool, usage string) *bool
```

Bool defines a bool flag with specified name, default value, and usage string. The return value is the address of a bool variable that stores the value of the flag.

func (*FlagSet) [BoolVar](#)

```
func (f *FlagSet) BoolVar(p *bool, name string, value bool, usage st
```

BoolVar defines a bool flag with specified name, default value, and usage string. The argument p points to a bool variable in which to store the value of the flag.

func (*FlagSet) [Duration](#)

```
func (f *FlagSet) Duration(name string, value time.Duration, usage s
```

Duration defines a time.Duration flag with specified name, default value, and usage string. The return value is the address of a time.Duration variable that stores the value of the flag.

func (*FlagSet) [DurationVar](#)

```
func (f *FlagSet) DurationVar(p *time.Duration, name string, value t
```

DurationVar defines a time.Duration flag with specified name, default value, and usage string. The argument p points to a time.Duration variable in which to store the value of the flag.

func (*FlagSet) [Float64](#)

```
func (f *FlagSet) Float64(name string, value float64, usage string)
```

Float64 defines a float64 flag with specified name, default value, and usage string. The return value is the address of a float64 variable that stores the value of the flag.

func (*FlagSet) [Float64Var](#)

```
func (f *FlagSet) Float64Var(p *float64, name string, value float64,
```

Float64Var defines a float64 flag with specified name, default value, and usage string. The argument p points to a float64 variable in which to store the value of the flag.

func (*FlagSet) [Init](#)

```
func (f *FlagSet) Init(name string, errorHandler ErrorHandling)
```

Init sets the name and error handling property for a flag set. By default, the zero FlagSet uses an empty name and the ContinueOnError error handling policy.

func (*FlagSet) [Int](#)

```
func (f *FlagSet) Int(name string, value int, usage string) *int
```

Int defines an int flag with specified name, default value, and usage string. The return value is the address of an int variable that stores the value of the flag.

func (*FlagSet) [Int64](#)

```
func (f *FlagSet) Int64(name string, value int64, usage string) *int
```

Int64 defines an int64 flag with specified name, default value, and usage string. The return value is the address of an int64 variable that stores the value of the flag.

func (*FlagSet) [Int64Var](#)

```
func (f *FlagSet) Int64Var(p *int64, name string, value int64, usage
```

Int64Var defines an int64 flag with specified name, default value, and usage string. The argument p points to an int64 variable in which to store the value of the flag.

func (*FlagSet) [IntVar](#)

```
func (f *FlagSet) IntVar(p *int, name string, value int, usage strin
```

IntVar defines an int flag with specified name, default value, and usage string. The argument p points to an int variable in which to store the value of the flag.

func (*FlagSet) [Lookup](#)

```
func (f *FlagSet) Lookup(name string) *Flag
```

Lookup returns the Flag structure of the named flag, returning nil if none exists.

func (*FlagSet) [NArg](#)

```
func (f *FlagSet) NArg() int
```

NArg is the number of arguments remaining after flags have been processed.

func (*FlagSet) [NFlag](#)

```
func (f *FlagSet) NFlag() int
```

NFlag returns the number of flags that have been set.

func (*FlagSet) [Parse](#)

```
func (f *FlagSet) Parse(arguments []string) error
```

Parse parses flag definitions from the argument list, which should not include the command name. Must be called after all flags in the FlagSet are defined and before flags are accessed by the program. The return value will be ErrHelp if -help was set but not defined.

func (*FlagSet) [Parsed](#)

```
func (f *FlagSet) Parsed() bool
```

Parsed reports whether f.Parse has been called.

func (*FlagSet) [PrintDefaults](#)

```
func (f *FlagSet) PrintDefaults()
```

PrintDefaults prints, to standard error unless configured otherwise, the default values of all defined flags in the set.

func (*FlagSet) [Set](#)

```
func (f *FlagSet) Set(name, value string) error
```

Set sets the value of the named flag.

func (*FlagSet) [SetOutput](#)

```
func (f *FlagSet) SetOutput(output io.Writer)
```

SetOutput sets the destination for usage and error messages. If output is nil, os.Stderr is used.

func (*FlagSet) [String](#)

```
func (f *FlagSet) String(name string, value string, usage string) *s
```

String defines a string flag with specified name, default value, and usage string. The return value is the address of a string variable that stores the value of the flag.

func (*FlagSet) [StringVar](#)

```
func (f *FlagSet) StringVar(p *string, name string, value string, us
```

StringVar defines a string flag with specified name, default value, and usage string. The argument p points to a string variable in which to store the value of the flag.

func (*FlagSet) [Uint](#)

```
func (f *FlagSet) Uint(name string, value uint, usage string) *uint
```

Uint defines a uint flag with specified name, default value, and usage string. The return value is the address of a uint variable that stores the value of the flag.

func (*FlagSet) [Uint64](#)

```
func (f *FlagSet) Uint64(name string, value uint64, usage string) *u
```

Uint64 defines a uint64 flag with specified name, default value, and usage string. The return value is the address of a uint64 variable that stores the value of the flag.

func (*FlagSet) [Uint64Var](#)

```
func (f *FlagSet) Uint64Var(p *uint64, name string, value uint64, us
```

Uint64Var defines a uint64 flag with specified name, default value, and usage string. The argument p points to a uint64 variable in which to store the value of the flag.

func (*FlagSet) [UintVar](#)

```
func (f *FlagSet) UintVar(p *uint, name string, value uint, usage st
```

UintVar defines a uint flag with specified name, default value, and usage string. The argument p points to a uint variable in which to store the value of the flag.

func (*FlagSet) [Var](#)

```
func (f *FlagSet) Var(value Value, name string, usage string)
```

Var defines a flag with the specified name and usage string. The type and value of the flag are represented by the first argument, of type Value, which typically holds a user-defined implementation of Value. For instance, the caller could create a flag that turns a comma-separated string into a slice of strings by giving the slice the methods of Value; in particular, Set would decompose the comma-separated string into the slice.

func (*FlagSet) [Visit](#)

```
func (f *FlagSet) Visit(fn func(*Flag))
```

Visit visits the flags in lexicographical order, calling fn for each. It visits only those flags that have been set.

func (*FlagSet) [VisitAll](#)

```
func (f *FlagSet) VisitAll(fn func(*Flag))
```

VisitAll visits the flags in lexicographical order, calling fn for each. It visits all flags, even those not set.

type [Value](#)

```
type Value interface {  
    String() string  
    Set(string) error  
}
```

Value is the interface to the dynamic value stored in a flag. (The default value is represented as a string.)

Package fmt

```
import "fmt"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `fmt` implements formatted I/O with functions analogous to C's `printf` and `scanf`. The format 'verbs' are derived from C's but are simpler.

Printing

The verbs:

General:

```
%v      the value in a default format.
         when printing structs, the plus flag (%+v) adds field names
%#v     a Go-syntax representation of the value
%T      a Go-syntax representation of the type of the value
%%      a literal percent sign; consumes no value
```

Boolean:

```
%t      the word true or false
```

Integer:

```
%b      base 2
%c      the character represented by the corresponding Unicode code
%d      base 10
%o      base 8
%q      a single-quoted character literal safely escaped with Go syn
%x      base 16, with lower-case letters for a-f
%X      base 16, with upper-case letters for A-F
%U      Unicode format: U+1234; same as "U+%04X"
```

Floating-point and complex constituents:

```
%b      decimalless scientific notation with exponent a power of two
         in the manner of strconv.FormatFloat with the 'b' format,
         e.g. -123456p-78
%e      scientific notation, e.g. -1234.456e+78
%E      scientific notation, e.g. -1234.456E+78
%f      decimal point but no exponent, e.g. 123.456
%g      whichever of %e or %f produces more compact output
%G      whichever of %E or %f produces more compact output
```

String and slice of bytes:

<code>%s</code>	the uninterpreted bytes of the string or slice
<code>%q</code>	a double-quoted string safely escaped with Go syntax
<code>%x</code>	base 16, lower-case, two characters per byte
<code>%X</code>	base 16, upper-case, two characters per byte

Pointer:

<code>%p</code>	base 16 notation, with leading <code>0x</code>
-----------------	--

There is no 'u' flag. Integers are printed unsigned if they have unsigned type. Similarly, there is no need to specify the size of the operand (`int8`, `int64`).

The width and precision control formatting and are in units of Unicode code points. (This differs from C's `printf` where the units are numbers of bytes.) Either or both of the flags may be replaced with the character '*', causing their values to be obtained from the next operand, which must be of type `int`.

For numeric values, width sets the width of the field and precision sets the number of places after the decimal, if appropriate. For example, the format `%6.2f` prints 123.45.

For strings, width is the minimum number of characters to output, padding with spaces if necessary, and precision is the maximum number of characters to output, truncating if necessary.

Other flags:

<code>+</code>	always print a sign for numeric values; guarantee ASCII-only output for <code>%q</code> (<code> %+q</code>)
<code>-</code>	pad with spaces on the right rather than the left (left-just)
<code>#</code>	alternate format: add leading <code>0</code> for octal (<code> %#o</code>), <code>0x</code> for hex <code>0X</code> for hex (<code> %#X</code>); suppress <code>0x</code> for <code>%p</code> (<code> %#p</code>); print a raw (backquoted) string if possible for <code>%q</code> (<code> %#q</code>); write e.g. <code>U+0078 'x'</code> if the character is printable for <code>%U</code> (
<code>' '</code>	(space) leave a space for elided sign in numbers (<code> % d</code>); put spaces between bytes printing strings or slices in hex (
<code>0</code>	pad with leading zeros rather than spaces

For each `Printf`-like function, there is also a `Print` function that takes no format and is equivalent to saying `%v` for every operand. Another variant `Println` inserts blanks between operands and appends a newline.

Regardless of the verb, if an operand is an interface value, the internal concrete value is used, not the interface itself. Thus:

```
var i interface{} = 23
fmt.Printf("%v\n", i)
```

will print 23.

If an operand implements interface `Formatter`, that interface can be used for fine control of formatting.

If the format (which is implicitly `%v` for `Println` etc.) is valid for a string (`%s %q %v %x %X`), the following two rules also apply:

1. If an operand implements the error interface, the `Error` method will be used to convert the object to a string, which will then be formatted as required by the verb (if any).
2. If an operand implements method `String()` string, that method will be used to convert the object to a string, which will then be formatted as required by the verb (if any).

To avoid recursion in cases such as

```
type X string
func (x X) String() string { return Sprintf("<%s>", x) }
```

convert the value before recurring:

```
func (x X) String() string { return Sprintf("<%s>", string(x)) }
```

Format errors:

If an invalid argument is given for a verb, such as providing a string to `%d`, the generated string will contain a description of the problem, as in these examples:

```
Wrong type or unknown verb: %!verb(type=value)
    Printf("%d", hi):           %!d(string=hi)
Too many arguments: %!(EXTRA type=value)
    Printf("hi", "guys"):      hi%!(EXTRA string=guys)
Too few arguments: %!verb(MISSING)
    Printf("hi%d"):           hi %!d(MISSING)
Non-int for width or precision: %!(BADWIDTH) or %!(BADPREC)
```

```
Printf("%*s", 4.5, "hi"): %(BADWIDTH)hi  
Printf("%. *s", 4.5, "hi"): %(BADPREC)hi
```

All errors begin with the string "%!" followed sometimes by a single character (the verb) and end with a parenthesized description.

Scanning

An analogous set of functions scans formatted text to yield values. Scan, Scanf and Scanln read from os.Stdin; Fscan, Fscanf and Fscanln read from a specified io.Reader; Sscan, Sscanf and Sscanln read from an argument string. Scanln, Fscanln and Sscanln stop scanning at a newline and require that the items be followed by one; Sscanf, Fscanf and Sscanf require newlines in the input to match newlines in the format; the other routines treat newlines as spaces.

Scanf, Fscanf, and Sscanf parse the arguments according to a format string, analogous to that of Printf. For example, %x will scan an integer as a hexadecimal number, and %v will scan the default representation format for the value.

The formats behave analogously to those of Printf with the following exceptions:

```
%p is not implemented  
%T is not implemented  
%e %E %f %F %g %G are all equivalent and scan any floating point or  
%s and %v on strings scan a space-delimited token
```

The familiar base-setting prefixes 0 (octal) and 0x (hexadecimal) are accepted when scanning integers without a format or with the %v verb.

Width is interpreted in the input text (%5s means at most five runes of input will be read to scan a string) but there is no syntax for scanning with a precision (no %5.2f, just %5f).

When scanning with a format, all non-empty runs of space characters (except newline) are equivalent to a single space in both the format and the input. With that proviso, text in the format string must match the input text; scanning stops if it does not, with the return value of the function indicating the number of arguments scanned.

In all the scanning functions, if an operand implements method Scan (that is, it

implements the Scanner interface) that method will be used to scan the text for that operand. Also, if the number of arguments scanned is less than the number of arguments provided, an error is returned.

All arguments to be scanned must be either pointers to basic types or implementations of the Scanner interface.

Note: Fscan etc. can read one character (rune) past the input they return, which means that a loop calling a scan routine may skip some of the input. This is usually a problem only when there is no space between input values. If the reader provided to Fscan implements ReadRune, that method will be used to read characters. If the reader also implements UnreadRune, that method will be used to save the character and successive calls will not lose data. To attach ReadRune and UnreadRune methods to a reader without that capability, use bufio.NewReader.

[type Stringer](#)

Package files

[doc.go](#) [format.go](#) [print.go](#) [scan.go](#)

func [Errorf](#)

```
func Errorf(format string, a ...interface{}) error
```

Errorf formats according to a format specifier and returns the string as a value that satisfies error.

func [Fprint](#)

```
func Fprint(w io.Writer, a ...interface{}) (n int, err error)
```

Fprint formats using the default formats for its operands and writes to w. Spaces are added between operands when neither is a string. It returns the number of bytes written and any write error encountered.

func [Fprintf](#)

```
func Fprintf(w io.Writer, format string, a ...interface{}) (n int, e
```

Fprintf formats according to a format specifier and writes to w. It returns the number of bytes written and any write error encountered.

func [Fprintln](#)

```
func Fprintln(w io.Writer, a ...interface{}) (n int, err error)
```

Fprintln formats using the default formats for its operands and writes to w. Spaces are always added between operands and a newline is appended. It returns the number of bytes written and any write error encountered.

func [Fscan](#)

```
func Fscan(r io.Reader, a ...interface{}) (n int, err error)
```

Fscan scans text read from `r`, storing successive space-separated values into successive arguments. Newlines count as space. It returns the number of items successfully scanned. If that is less than the number of arguments, `err` will report why.

func [Fscanf](#)

```
func Fscanf(r io.Reader, format string, a ...interface{}) (n int, err error)
```

Fscanf scans text read from r, storing successive space-separated values into successive arguments as determined by the format. It returns the number of items successfully parsed.

func [Fscanln](#)

```
func Fscanln(r io.Reader, a ...interface{}) (n int, err error)
```

Fscanln is similar to Fscan, but stops scanning at a newline and after the final item there must be a newline or EOF.

func [Print](#)

```
func Print(a ...interface{}) (n int, err error)
```

Print formats using the default formats for its operands and writes to standard output. Spaces are added between operands when neither is a string. It returns the number of bytes written and any write error encountered.

func [Printf](#)

```
func Printf(format string, a ...interface{}) (n int, err error)
```

Printf formats according to a format specifier and writes to standard output. It returns the number of bytes written and any write error encountered.

func [Println](#)

```
func Println(a ...interface{}) (n int, err error)
```

Println formats using the default formats for its operands and writes to standard output. Spaces are always added between operands and a newline is appended. It returns the number of bytes written and any write error encountered.

func Scan

```
func Scan(a ...interface{}) (n int, err error)
```

Scan scans text read from standard input, storing successive space-separated values into successive arguments. Newlines count as space. It returns the number of items successfully scanned. If that is less than the number of arguments, err will report why.

func [Scanf](#)

```
func Scanf(format string, a ...interface{}) (n int, err error)
```

Scanf scans text read from standard input, storing successive space-separated values into successive arguments as determined by the format. It returns the number of items successfully scanned.

func [Scanln](#)

```
func Scanln(a ...interface{}) (n int, err error)
```

Scanln is similar to Scan, but stops scanning at a newline and after the final item there must be a newline or EOF.

func [Sprintf](#)

```
func Sprintf(a ...interface{}) string
```

Sprintf formats using the default formats for its operands and returns the resulting string. Spaces are added between operands when neither is a string.

func [Sprintf](#)

```
func Sprintf(format string, a ...interface{}) string
```

Sprintf formats according to a format specifier and returns the resulting string.

func Sprintln

```
func Sprintln(a ...interface{}) string
```

Sprintln formats using the default formats for its operands and returns the resulting string. Spaces are always added between operands and a newline is appended.

func [Sscan](#)

```
func Sscan(str string, a ...interface{}) (n int, err error)
```

Sscan scans the argument string, storing successive space-separated values into successive arguments. Newlines count as space. It returns the number of items successfully scanned. If that is less than the number of arguments, err will report why.

func [Sscanf](#)

```
func Sscanf(str string, format string, a ...interface{}) (n int, err
```

Sscanf scans the argument string, storing successive space-separated values into successive arguments as determined by the format. It returns the number of items successfully parsed.

func [Sscanln](#)

```
func Sscanln(str string, a ...interface{}) (n int, err error)
```

Sscanln is similar to Sscan, but stops scanning at a newline and after the final item there must be a newline or EOF.

type [Formatter](#)

```
type Formatter interface {  
    Format(f State, c rune)  
}
```

Formatter is the interface implemented by values with a custom formatter. The implementation of Format may call Sprintf or Fprintf(f) etc. to generate its output.

type [GoStringer](#)

```
type GoStringer interface {  
    GoString() string  
}
```

GoStringer is implemented by any value that has a GoString method, which defines the Go syntax for that value. The GoString method is used to print values passed as an operand to a %#v format.

type [ScanState](#)

```
type ScanState interface {
    // ReadRune reads the next rune (Unicode code point) from the in
    // If invoked during Scanln, Fscanln, or Sscanln, ReadRune() wil
    // return EOF after returning the first '\n' or when reading bey
    // the specified width.
    ReadRune() (r rune, size int, err error)
    // UnreadRune causes the next call to ReadRune to return the sam
    UnreadRune() error
    // SkipSpace skips space in the input. Newlines are treated as s
    // unless the scan operation is Scanln, Fscanln or Sscanln, in w
    // a newline is treated as EOF.
    SkipSpace()
    // Token skips space in the input if skipSpace is true, then ret
    // run of Unicode code points c satisfying f(c). If f is nil,
    // !unicode.IsSpace(c) is used; that is, the token will hold non
    // characters. Newlines are treated as space unless the scan op
    // is Scanln, Fscanln or Sscanln, in which case a newline is tre
    // EOF. The returned slice points to shared data that may be ov
    // by the next call to Token, a call to a Scan function using th
    // as input, or when the calling Scan method returns.
    Token(skipSpace bool, f func(rune) bool) (token []byte, err erro
    // Width returns the value of the width option and whether it ha
    // The unit is Unicode code points.
    Width() (wid int, ok bool)
    // Because ReadRune is implemented by the interface, Read should
    // called by the scanning routines and a valid implementation of
    // ScanState may choose always to return an error from Read.
    Read(buf []byte) (n int, err error)
}
```

ScanState represents the scanner state passed to custom scanners. Scanners may do rune-at-a-time scanning or ask the ScanState to discover the next space-delimited token.

type [Scanner](#)

```
type Scanner interface {  
    Scan(state ScanState, verb rune) error  
}
```

Scanner is implemented by any value that has a Scan method, which scans the input for the representation of a value and stores the result in the receiver, which must be a pointer to be useful. The Scan method is called for any argument to Scan, Scanf, or Scanln that implements it.

type [State](#)

```
type State interface {
    // Write is the function to call to emit formatted output to be
    Write(b []byte) (ret int, err error)
    // Width returns the value of the width option and whether it has
    Width() (wid int, ok bool)
    // Precision returns the value of the precision option and whether
    Precision() (prec int, ok bool)

    // Flag returns whether the flag c, a character, has been set.
    Flag(c int) bool
}
```

State represents the printer state passed to custom formatters. It provides access to the `io.Writer` interface plus information about the flags and options for the operand's format specifier.

type [Stringer](#)

```
type Stringer interface {  
    String() string  
}
```

Stringer is implemented by any value that has a String method, which defines the “native” format for that value. The String method is used to print values passed as an operand to a %s or %v format or to an unformatted printer such as Print.

Examples

[Inspect](#)
[Print](#)

Package files

[ast.go](#) [filter.go](#) [import.go](#) [print.go](#) [resolve.go](#) [scope.go](#) [walk.go](#)

func [FileExports](#)

```
func FileExports(src *File) bool
```

FileExports trims the AST for a Go source file in place such that only exported nodes remain: all top-level identifiers which are not exported and their associated information (such as type, initial value, or function body) are removed. Non-exported fields and methods of exported types are stripped. The File.Comments list is not changed.

FileExports returns true if there are exported declarations; it returns false otherwise.

func [FilterDecl](#)

```
func FilterDecl(decl Decl, f Filter) bool
```

FilterDecl trims the AST for a Go declaration in place by removing all names (including struct field and interface method names, but not from parameter lists) that don't pass through the filter f.

FilterDecl returns true if there are any declared names left after filtering; it returns false otherwise.

func [FilterFile](#)

```
func FilterFile(src *File, f Filter) bool
```

FilterFile trims the AST for a Go file in place by removing all names from top-level declarations (including struct field and interface method names, but not from parameter lists) that don't pass through the filter `f`. If the declaration is empty afterwards, the declaration is removed from the AST. The `File.Comments` list is not changed.

FilterFile returns true if there are any top-level declarations left after filtering; it returns false otherwise.

func [FilterPackage](#)

```
func FilterPackage(pkg *Package, f Filter) bool
```

FilterPackage trims the AST for a Go package in place by removing all names from top-level declarations (including struct field and interface method names, but not from parameter lists) that don't pass through the filter `f`. If the declaration is empty afterwards, the declaration is removed from the AST. The `pkg.Files` list is not changed, so that file names and top-level package comments don't get lost.

FilterPackage returns true if there are any top-level declarations left after filtering; it returns false otherwise.

func [Fprint](#)

```
func Fprint(w io.Writer, fset *token.FileSet, x interface{}, f Field
```

Fprint prints the (sub-)tree starting at AST node x to w. If fset != nil, position information is interpreted relative to that file set. Otherwise positions are printed as integer values (file set specific offsets).

A non-nil FieldFilter f may be provided to control the output: struct fields for which f(fieldname, fieldvalue) is true are printed; all others are filtered from the output.

func [Inspect](#)

```
func Inspect(node Node, f func(Node) bool)
```

Inspect traverses an AST in depth-first order: It starts by calling `f(node)`; `node` must not be `nil`. If `f` returns `true`, `Inspect` invokes `f` for all the non-`nil` children of `node`, recursively.

? Example

? Example

This example demonstrates how to inspect the AST of a Go program.

Code:

```
// src is the input for which we want to inspect the AST.
src := `
package p
const c = 1.0
var X = f(3.14)*2 + c
`

// Create the AST by parsing src.
fset := token.NewFileSet() // positions are relative to fset
f, err := parser.ParseFile(fset, "src.go", src, 0)
if err != nil {
    panic(err)
}

// Inspect the AST and print all identifiers and literals.
ast.Inspect(f, func(n ast.Node) bool {
    var s string
    switch x := n.(type) {
    case *ast.BasicLit:
        s = x.Value
    case *ast.Ident:
        s = x.Name
    }
    if s != "" {
        fmt.Printf("%s:\t%s\n", fset.Position(n.Pos()), s)
    }
    return true
})
```

Output:

```
src.go:2:9:      p
src.go:3:7:      c
src.go:3:11:     1.0
src.go:4:5:      X
src.go:4:9:      f
src.go:4:11:     3.14
src.go:4:17:     2
src.go:4:21:     c
```

func IsExported

```
func IsExported(name string) bool
```

IsExported returns whether name is an exported Go symbol (i.e., whether it begins with an uppercase letter).

func [NotNilFilter](#)

```
func NotNilFilter(_ string, v reflect.Value) bool
```

NotNilFilter returns true for field values that are not nil; it returns false otherwise.

func PackageExports

```
func PackageExports(pkg *Package) bool
```

PackageExports trims the AST for a Go package in place such that only exported nodes remain. The pkg.Files list is not changed, so that file names and top-level package comments don't get lost.

PackageExports returns true if there are exported declarations; it returns false otherwise.

func [Print](#)

```
func Print(fset *token.FileSet, x interface{}) error
```

Print prints x to standard output, skipping nil fields. Print(fset, x) is the same as Fprint(os.Stdout, fset, x, NotNilFilter).

? Example

? Example

This example shows what an AST looks like when printed for debugging.

Code:

```
// src is the input for which we want to print the AST.
src := `
package main
func main() {
println("Hello, World!")
}
`

// Create the AST by parsing src.
fset := token.NewFileSet() // positions are relative to fset
f, err := parser.ParseFile(fset, "", src, 0)
if err != nil {
    panic(err)
}

// Print the AST.
ast.Print(fset, f)
```

Output:

```
0 *ast.File {
  1 . Package: 2:1
  2 . Name: *ast.Ident {
  3 . . NamePos: 2:9
  4 . . Name: "main"
  5 . }
  6 . Decls: []ast.Decl (len = 1) {
  7 . . 0: *ast.FuncDecl {
```

```

 8 . . . Name: *ast.Ident {

53 . . }
54 . }
55 . Unresolved: []*ast.Ident (len = 1) {
56 . . 0: *(obj @ 29)

```

57 . }
58 }

func [SortImports](#)

```
func SortImports(fset *token.FileSet, f *File)
```

SortImports sorts runs of consecutive import lines in import blocks in f.

func [Walk](#)

```
func Walk(v Visitor, node Node)
```

Walk traverses an AST in depth-first order: It starts by calling `v.Visit(node)`; `node` must not be `nil`. If the visitor `w` returned by `v.Visit(node)` is not `nil`, Walk is invoked recursively with visitor `w` for each of the non-`nil` children of `node`, followed by a call of `w.Visit(nil)`.

type [ArrayType](#)

```
type ArrayType struct {
    Lbrack token.Pos // position of "["
    Len    Expr          // Ellipsis node for [...]T array types, nil fo
    Elt    Expr          // element type
}
```

An ArrayType node represents an array or slice type.

func (***ArrayType**) [End](#)

```
func (x *ArrayType) End() token.Pos
```

func (***ArrayType**) [Pos](#)

```
func (x *ArrayType) Pos() token.Pos
```

type [AssignStmt](#)

```
type AssignStmt struct {
    Lhs    []Expr
    TokPos token.Pos // position of Tok
    Tok    token.Token // assignment token, DEFINE
    Rhs    []Expr
}
```

An AssignStmt node represents an assignment or a short variable declaration.

func (*AssignStmt) [End](#)

```
func (s *AssignStmt) End() token.Pos
```

func (*AssignStmt) [Pos](#)

```
func (s *AssignStmt) Pos() token.Pos
```

type [BadDecl](#)

```
type BadDecl struct {  
    From, To token.Pos // position range of bad declaration  
}
```

A `BadDecl` node is a placeholder for declarations containing syntax errors for which no correct declaration nodes can be created.

func (*BadDecl) [End](#)

```
func (d *BadDecl) End() token.Pos
```

func (*BadDecl) [Pos](#)

```
func (d *BadDecl) Pos() token.Pos
```

Pos and End implementations for declaration nodes.

type BadExpr

```
type BadExpr struct {  
    From, To token.Pos // position range of bad expression  
}
```

A `BadExpr` node is a placeholder for expressions containing syntax errors for which no correct expression nodes can be created.

func (*BadExpr) End

```
func (x *BadExpr) End() token.Pos
```

func (*BadExpr) Pos

```
func (x *BadExpr) Pos() token.Pos
```

Pos and End implementations for expression/type nodes.

type [BadStmt](#)

```
type BadStmt struct {  
    From, To token.Pos // position range of bad statement  
}
```

A `BadStmt` node is a placeholder for statements containing syntax errors for which no correct statement nodes can be created.

func (*BadStmt) [End](#)

```
func (s *BadStmt) End() token.Pos
```

func (*BadStmt) [Pos](#)

```
func (s *BadStmt) Pos() token.Pos
```

`Pos` and `End` implementations for statement nodes.

type **BasicLit**

```
type BasicLit struct {
    ValuePos token.Pos // literal position
    Kind     token.Token // token.INT, token.FLOAT, token.IMAG, toke
    Value    string    // literal string; e.g. 42, 0x7f, 3.14, 1e-
}
```

A BasicLit node represents a literal of basic type.

func (*BasicLit) **End**

```
func (x *BasicLit) End() token.Pos
```

func (*BasicLit) **Pos**

```
func (x *BasicLit) Pos() token.Pos
```

type **BinaryExpr**

```
type BinaryExpr struct {
    X      Expr      // left operand
    OpPos  token.Pos  // position of Op
    Op     token.Token // operator
    Y      Expr      // right operand
}
```

A BinaryExpr node represents a binary expression.

func (*BinaryExpr) **End**

```
func (x *BinaryExpr) End() token.Pos
```

func (*BinaryExpr) **Pos**

```
func (x *BinaryExpr) Pos() token.Pos
```

type BlockStmt

```
type BlockStmt struct {
    Lbrace token.Pos // position of "{"
    List   []Stmt
    Rbrace token.Pos // position of "}"
}
```

A BlockStmt node represents a braced statement list.

func (*BlockStmt) End

```
func (s *BlockStmt) End() token.Pos
```

func (*BlockStmt) Pos

```
func (s *BlockStmt) Pos() token.Pos
```

type [BranchStmt](#)

```
type BranchStmt struct {  
    TokPos token.Pos // position of Tok  
    Tok    token.Token // keyword token (BREAK, CONTINUE, GOTO, FALL  
    Label  *Ident      // label name; or nil  
}
```

A BranchStmt node represents a break, continue, goto, or fallthrough statement.

func (*BranchStmt) [End](#)

```
func (s *BranchStmt) End() token.Pos
```

func (*BranchStmt) [Pos](#)

```
func (s *BranchStmt) Pos() token.Pos
```

type [CallExpr](#)

```
type CallExpr struct {
    Fun      Expr      // function expression
    Lparen   token.Pos // position of "("
    Args     []Expr   // function arguments; or nil
    Ellipsis token.Pos // position of "...", if any
    Rparen   token.Pos // position of ")"
}
```

A CallExpr node represents an expression followed by an argument list.

func (*CallExpr) [End](#)

```
func (x *CallExpr) End() token.Pos
```

func (*CallExpr) [Pos](#)

```
func (x *CallExpr) Pos() token.Pos
```

type [CaseClause](#)

```
type CaseClause struct {
    Case token.Pos // position of "case" or "default" keyword
    List []Expr    // list of expressions or types; nil means default
    Colon token.Pos // position of ":"
    Body []Stmt     // statement list; or nil
}
```

A CaseClause represents a case of an expression or type switch statement.

func (***CaseClause**) [End](#)

```
func (s *CaseClause) End() token.Pos
```

func (***CaseClause**) [Pos](#)

```
func (s *CaseClause) Pos() token.Pos
```

type [ChanDir](#)

```
type ChanDir int
```

The direction of a channel type is indicated by one of the following constants.

```
const (  
    SEND ChanDir = 1 << iota  
    RECV  
)
```

type [ChanType](#)

```
type ChanType struct {  
    Begin token.Pos // position of "chan" keyword or "<-" (whichever  
    Dir    ChanDir   // channel direction  
    Value Expr       // value type  
}
```

A ChanType node represents a channel type.

func (***ChanType**) [End](#)

```
func (x *ChanType) End() token.Pos
```

func (***ChanType**) [Pos](#)

```
func (x *ChanType) Pos() token.Pos
```

type CommClause

```
type CommClause struct {
    Case token.Pos // position of "case" or "default" keyword
    Comm Stmt      // send or receive statement; nil means default
    Colon token.Pos // position of ":"
    Body []Stmt     // statement list; or nil
}
```

A CommClause node represents a case of a select statement.

func (*CommClause) End

```
func (s *CommClause) End() token.Pos
```

func (*CommClause) Pos

```
func (s *CommClause) Pos() token.Pos
```

type Comment

```
type Comment struct {
    Slash token.Pos // position of "/" starting the comment
    Text  string    // comment text (excluding '\n' for //-style com
}
```

A Comment node represents a single //-style or /*-style comment.

func (*Comment) End

```
func (c *Comment) End() token.Pos
```

func (*Comment) Pos

```
func (c *Comment) Pos() token.Pos
```

type [CommentGroup](#)

```
type CommentGroup struct {  
    List []*Comment // len(List) > 0  
}
```

A CommentGroup represents a sequence of comments with no other tokens and no empty lines between.

func (*CommentGroup) [End](#)

```
func (g *CommentGroup) End() token.Pos
```

func (*CommentGroup) [Pos](#)

```
func (g *CommentGroup) Pos() token.Pos
```

func (*CommentGroup) [Text](#)

```
func (g *CommentGroup) Text() string
```

Text returns the text of the comment, with the comment markers - //, /*, and */ - removed.

type CompositeLit

```
type CompositeLit struct {
    Type   Expr      // literal type; or nil
    Lbrace token.Pos // position of "{"
    Elts   []Expr     // list of composite elements; or nil
    Rbrace token.Pos // position of "}"
}
```

A CompositeLit node represents a composite literal.

func (*CompositeLit) End

```
func (x *CompositeLit) End() token.Pos
```

func (*CompositeLit) Pos

```
func (x *CompositeLit) Pos() token.Pos
```

type Decl

```
type Decl interface {  
    Node  
    // contains filtered or unexported methods  
}
```

All declaration nodes implement the Decl interface.

type DeclStmt

```
type DeclStmt struct {  
    Decl Decl  
}
```

A DeclStmt node represents a declaration in a statement list.

func (*DeclStmt) End

```
func (s *DeclStmt) End() token.Pos
```

func (*DeclStmt) Pos

```
func (s *DeclStmt) Pos() token.Pos
```

type **DeferStmt**

```
type DeferStmt struct {  
    Defer token.Pos // position of "defer" keyword  
    Call *CallExpr  
}
```

A DeferStmt node represents a defer statement.

func (*DeferStmt) **End**

```
func (s *DeferStmt) End() token.Pos
```

func (*DeferStmt) **Pos**

```
func (s *DeferStmt) Pos() token.Pos
```

type [Ellipsis](#)

```
type Ellipsis struct {  
    Ellipsis token.Pos // position of "..."  
    Elt      Expr      // ellipsis element type (parameter lists onl  
}
```

An Ellipsis node stands for the "..." type in a parameter list or the "..." length in an array type.

func (*Ellipsis) [End](#)

```
func (x *Ellipsis) End() token.Pos
```

func (*Ellipsis) [Pos](#)

```
func (x *Ellipsis) Pos() token.Pos
```

type EmptyStmt

```
type EmptyStmt struct {  
    Semicolon token.Pos // position of preceding ";"  
}
```

An EmptyStmt node represents an empty statement. The "position" of the empty statement is the position of the immediately preceding semicolon.

func (*EmptyStmt) End

```
func (s *EmptyStmt) End() token.Pos
```

func (*EmptyStmt) Pos

```
func (s *EmptyStmt) Pos() token.Pos
```

type [Expr](#)

```
type Expr interface {  
    Node  
    // contains filtered or unexported methods  
}
```

All expression nodes implement the Expr interface.

type ExprStmt

```
type ExprStmt struct {  
    X Expr // expression  
}
```

An ExprStmt node represents a (stand-alone) expression in a statement list.

func (*ExprStmt) End

```
func (s *ExprStmt) End() token.Pos
```

func (*ExprStmt) Pos

```
func (s *ExprStmt) Pos() token.Pos
```

type [Field](#)

```
type Field struct {
    Doc      *CommentGroup // associated documentation; or nil
    Names    []*Ident       // field/method/parameter names; or nil if
    Type     Expr        // field/method/parameter type
    Tag      *BasicLit     // field tag; or nil
    Comment  *CommentGroup // line comments; or nil
}
```

A Field represents a Field declaration list in a struct type, a method list in an interface type, or a parameter/result declaration in a signature.

func (*Field) [End](#)

```
func (f *Field) End() token.Pos
```

func (*Field) [Pos](#)

```
func (f *Field) Pos() token.Pos
```

type [FieldFilter](#)

```
type FieldFilter func(name string, value reflect.Value) bool
```

A FieldFilter may be provided to Fprint to control the output.

type [FieldList](#)

```
type FieldList struct {  
    Opening token.Pos // position of opening parenthesis/brace, if a  
    List    []*Field // field list; or nil  
    Closing token.Pos // position of closing parenthesis/brace, if a  
}
```

A FieldList represents a list of Fields, enclosed by parentheses or braces.

func (*FieldList) [End](#)

```
func (f *FieldList) End() token.Pos
```

func (*FieldList) [NumFields](#)

```
func (f *FieldList) NumFields() int
```

NumFields returns the number of (named and anonymous fields) in a FieldList.

func (*FieldList) [Pos](#)

```
func (f *FieldList) Pos() token.Pos
```

type [File](#)

```
type File struct {
    Doc          *CommentGroup // associated documentation; or nil
    Package      token.Pos      // position of "package" keyword
    Name         *Ident         // package name
    Decls        []Decl        // top-level declarations; or nil
    Scope        *Scope        // package scope (this file only)
    Imports      []*ImportSpec // imports in this file
    Unresolved   []*Ident       // unresolved identifiers in this file
    Comments     []*CommentGroup // list of all comments in the source
}
```

A File node represents a Go source file.

The Comments list contains all comments in the source file in order of appearance, including the comments that are pointed to from other nodes via Doc and Comment fields.

func [MergePackageFiles](#)

```
func MergePackageFiles(pkg *Package, mode MergeMode) *File
```

MergePackageFiles creates a file AST by merging the ASTs of the files belonging to a package. The mode flags control merging behavior.

func (*File) [End](#)

```
func (f *File) End() token.Pos
```

func (*File) [Pos](#)

```
func (f *File) Pos() token.Pos
```

type **Filter**

```
type Filter func(string) bool
```

type **ForStmt**

```
type ForStmt struct {
    For token.Pos // position of "for" keyword
    Init Stmt     // initialization statement; or nil
    Cond Expr     // condition; or nil
    Post Stmt     // post iteration statement; or nil
    Body *BlockStmt
}
```

A ForStmt represents a for statement.

func (*ForStmt) **End**

```
func (s *ForStmt) End() token.Pos
```

func (*ForStmt) **Pos**

```
func (s *ForStmt) Pos() token.Pos
```

type [FuncDecl](#)

```
type FuncDecl struct {  
    Doc    *CommentGroup // associated documentation; or nil  
    Recv   *FieldList    // receiver (methods); or nil (functions)  
    Name   *Ident         // function/method name  
    Type   *FuncType     // position of Func keyword, parameters and r  
    Body   *BlockStmt    // function body; or nil (forward declaration  
}
```

A FuncDecl node represents a function declaration.

func (*FuncDecl) [End](#)

```
func (d *FuncDecl) End() token.Pos
```

func (*FuncDecl) [Pos](#)

```
func (d *FuncDecl) Pos() token.Pos
```

type FuncLit

```
type FuncLit struct {  
    Type *FuncType // function type  
    Body *BlockStmt // function body  
}
```

A FuncLit node represents a function literal.

func (*FuncLit) End

```
func (x *FuncLit) End() token.Pos
```

func (*FuncLit) Pos

```
func (x *FuncLit) Pos() token.Pos
```

type **FuncType**

```
type FuncType struct {  
    Func    token.Pos // position of "func" keyword  
    Params  *FieldList // (incoming) parameters; or nil  
    Results *FieldList // (outgoing) results; or nil  
}
```

A FuncType node represents a function type.

func (*FuncType) End

```
func (x *FuncType) End() token.Pos
```

func (*FuncType) Pos

```
func (x *FuncType) Pos() token.Pos
```

type [GenDecl](#)

```
type GenDecl struct {
    Doc      *CommentGroup // associated documentation; or nil
    TokPos   token.Pos    // position of Tok
    Tok      token.Token   // IMPORT, CONST, TYPE, VAR
    Lparen   token.Pos    // position of '(', if any
    Specs    []Spec
    Rparen   token.Pos    // position of ')', if any
}
```

A GenDecl node (generic declaration node) represents an import, constant, type or variable declaration. A valid Lparen position (Lparen.Line > 0) indicates a parenthesized declaration.

Relationship between Tok value and Specs element type:

```
token.IMPORT  *ImportSpec
token.CONST   *ValueSpec
token.TYPE    *TypeSpec
token.VAR     *ValueSpec
```

func (*GenDecl) [End](#)

```
func (d *GenDecl) End() token.Pos
```

func (*GenDecl) [Pos](#)

```
func (d *GenDecl) Pos() token.Pos
```

type GoStmt

```
type GoStmt struct {  
    Go    token.Pos // position of "go" keyword  
    Call *CallExpr  
}
```

A GoStmt node represents a go statement.

func (*GoStmt) End

```
func (s *GoStmt) End() token.Pos
```

func (*GoStmt) Pos

```
func (s *GoStmt) Pos() token.Pos
```

type [Ident](#)

```
type Ident struct {
    NamePos token.Pos // identifier position
    Name    string    // identifier name
    Obj     *Object   // denoted object; or nil
}
```

An Ident node represents an identifier.

func [NewIdent](#)

```
func NewIdent(name string) *Ident
```

NewIdent creates a new Ident without position. Useful for ASTs generated by code other than the Go parser.

func (***Ident**) [End](#)

```
func (x *Ident) End() token.Pos
```

func (***Ident**) [IsExported](#)

```
func (id *Ident) IsExported() bool
```

IsExported returns whether id is an exported Go symbol (i.e., whether it begins with an uppercase letter).

func (***Ident**) [Pos](#)

```
func (x *Ident) Pos() token.Pos
```

func (***Ident**) [String](#)

```
func (id *Ident) String() string
```

type [IfStmt](#)

```
type IfStmt struct {
    If    token.Pos // position of "if" keyword
    Init Stmt       // initialization statement; or nil
    Cond Expr       // condition
    Body *BlockStmt
    Else Stmt // else branch; or nil
}
```

An IfStmt node represents an if statement.

func (*IfStmt) [End](#)

```
func (s *IfStmt) End() token.Pos
```

func (*IfStmt) [Pos](#)

```
func (s *IfStmt) Pos() token.Pos
```

type [ImportSpec](#)

```
type ImportSpec struct {
    Doc      *CommentGroup // associated documentation; or nil
    Name     *Ident         // local package name (including "."); or
    Path     *BasicLit     // import path
    Comment  *CommentGroup // line comments; or nil
    EndPos   token.Pos    // end of spec (overrides Path.Pos if nonz
}
```

An ImportSpec node represents a single package import.

func (*ImportSpec) [End](#)

```
func (s *ImportSpec) End() token.Pos
```

func (*ImportSpec) [Pos](#)

```
func (s *ImportSpec) Pos() token.Pos
```

Pos and End implementations for spec nodes.

type Importer

```
type Importer func(imports map[string]*Object, path string) (pkg *Ob
```

An Importer resolves import paths to package Objects. The imports map records the packages already imported, indexed by package id (canonical import path).

An Importer must determine the canonical import path and check the map to see if it is already present in the imports map. If so, the Importer can return the map entry. Otherwise, the Importer should load the package data for the given path into a new *Object (pkg), record pkg in the imports map, and then return pkg.

type IncDecStmt

```
type IncDecStmt struct {  
    X      Expr  
    TokPos token.Pos // position of Tok  
    Tok    token.Token // INC or DEC  
}
```

An IncDecStmt node represents an increment or decrement statement.

func (*IncDecStmt) End

```
func (s *IncDecStmt) End() token.Pos
```

func (*IncDecStmt) Pos

```
func (s *IncDecStmt) Pos() token.Pos
```

type [IndexExpr](#)

```
type IndexExpr struct {
    X      Expr      // expression
    Lbrack token.Pos // position of "["
    Index  Expr      // index expression
    Rbrack token.Pos // position of "]"
}
```

An IndexExpr node represents an expression followed by an index.

func (*IndexExpr) [End](#)

```
func (x *IndexExpr) End() token.Pos
```

func (*IndexExpr) [Pos](#)

```
func (x *IndexExpr) Pos() token.Pos
```

type [InterfaceType](#)

```
type InterfaceType struct {  
    Interface token.Pos // position of "interface" keyword  
    Methods   *FieldList // list of methods  
    Incomplete bool      // true if (source) methods are missing in  
}
```

An InterfaceType node represents an interface type.

func (*InterfaceType) [End](#)

```
func (x *InterfaceType) End() token.Pos
```

func (*InterfaceType) [Pos](#)

```
func (x *InterfaceType) Pos() token.Pos
```

type KeyValueExpr

```
type KeyValueExpr struct {
    Key    Expr
    Colon token.Pos // position of ":"
    Value Expr
}
```

A KeyValueExpr node represents (key : value) pairs in composite literals.

func (*KeyValueExpr) End

```
func (x *KeyValueExpr) End() token.Pos
```

func (*KeyValueExpr) Pos

```
func (x *KeyValueExpr) Pos() token.Pos
```

type LabeledStmt

```
type LabeledStmt struct {  
    Label *Ident  
    Colon token.Pos // position of ":"  
    Stmt  Stmt  
}
```

A LabeledStmt node represents a labeled statement.

func (*LabeledStmt) End

```
func (s *LabeledStmt) End() token.Pos
```

func (*LabeledStmt) Pos

```
func (s *LabeledStmt) Pos() token.Pos
```

type [MapType](#)

```
type MapType struct {  
    Map    token.Pos // position of "map" keyword  
    Key    Expr  
    Value  Expr  
}
```

A MapType node represents a map type.

func (***MapType**) [End](#)

```
func (x *MapType) End() token.Pos
```

func (***MapType**) [Pos](#)

```
func (x *MapType) Pos() token.Pos
```

type [MergeMode](#)

```
type MergeMode uint
```

The MergeMode flags control the behavior of MergePackageFiles.

```
const (  
    // If set, duplicate function declarations are excluded.  
    FilterFuncDuplicates MergeMode = 1 << iota  
    // If set, comments that are not associated with a specific  
    // AST node (as Doc or Comment) are excluded.  
    FilterUnassociatedComments  
    // If set, duplicate import declarations are excluded.  
    FilterImportDuplicates  
)
```

type [Node](#)

```
type Node interface {  
    Pos() token.Pos // position of first character belonging to the  
    End() token.Pos // position of first character immediately after  
}
```

All node types implement the Node interface.

type [ObjKind](#)

```
type ObjKind int
```

ObjKind describes what an object represents.

```
const (  
    Bad ObjKind = iota // for error handling  
    Pkg           // package  
    Con           // constant  
    Typ           // type  
    Var           // variable  
    Fun           // function or method  
    Lbl           // label  
)
```

The list of possible Object kinds.

func (ObjKind) [String](#)

```
func (kind ObjKind) String() string
```

type [Object](#)

```
type Object struct {
    Kind ObjKind
    Name string      // declared name
    Decl interface{} // corresponding Field, XxxSpec, FuncDecl, Label
    Data interface{} // object-specific data; or nil
    Type interface{} // place holder for type information; may be nil
}
```

An Object describes a named language entity such as a package, constant, type, variable, function (incl. methods), or label.

The Data field contains object-specific data:

Kind	Data type	Data value
Pkg	*Scope	package scope
Con	int	iota for the respective declaration
Con	!= nil	constant value

func [NewObj](#)

```
func NewObj(kind ObjKind, name string) *Object
```

NewObj creates a new object of a given kind and name.

func (*Object) [Pos](#)

```
func (obj *Object) Pos() token.Pos
```

Pos computes the source position of the declaration of an object name. The result may be an invalid position if it cannot be computed (obj.Decl may be nil or not correct).

type [Package](#)

```
type Package struct {
    Name      string           // package name
    Scope     *Scope          // package scope across all files
    Imports   map[string]*Object // map of package id -> package object
    Files     map[string]*File  // Go source files by filename
}
```

A Package node represents a set of source files collectively building a Go package.

func [NewPackage](#)

```
func NewPackage(fset *token.FileSet, files map[string]*File, importer
```

`NewPackage` creates a new Package node from a set of File nodes. It resolves unresolved identifiers across files and updates each file's Unresolved list accordingly. If a non-nil importer and universe scope are provided, they are used to resolve identifiers not declared in any of the package files. Any remaining unresolved identifiers are reported as undeclared. If the files belong to different packages, one package name is selected and files with different package names are reported and then ignored. The result is a package node and a `scanner.ErrorList` if there were errors.

func (*Package) [End](#)

```
func (p *Package) End() token.Pos
```

func (*Package) [Pos](#)

```
func (p *Package) Pos() token.Pos
```

type ParenExpr

```
type ParenExpr struct {
    Lparen token.Pos // position of "("
    X      Expr      // parenthesized expression
    Rparen token.Pos // position of ")"
}
```

A ParenExpr node represents a parenthesized expression.

func (*ParenExpr) End

```
func (x *ParenExpr) End() token.Pos
```

func (*ParenExpr) Pos

```
func (x *ParenExpr) Pos() token.Pos
```

type [RangeStmt](#)

```
type RangeStmt struct {
    For      token.Pos // position of "for" keyword
    Key, Value Expr    // Value may be nil
    TokPos   token.Pos // position of Tok
    Tok      token.Token // ASSIGN, DEFINE
    X        Expr    // value to range over
    Body     *BlockStmt
}
```

A RangeStmt represents a for statement with a range clause.

func (*RangeStmt) [End](#)

```
func (s *RangeStmt) End() token.Pos
```

func (*RangeStmt) [Pos](#)

```
func (s *RangeStmt) Pos() token.Pos
```

type ReturnStmt

```
type ReturnStmt struct {  
    Return token.Pos // position of "return" keyword  
    Results []Expr    // result expressions; or nil  
}
```

A ReturnStmt node represents a return statement.

func (*ReturnStmt) End

```
func (s *ReturnStmt) End() token.Pos
```

func (*ReturnStmt) Pos

```
func (s *ReturnStmt) Pos() token.Pos
```

type [Scope](#)

```
type Scope struct {
    Outer    *Scope
    Objects map[string]*Object
}
```

A Scope maintains the set of named language entities declared in the scope and a link to the immediately surrounding (outer) scope.

func [NewScope](#)

```
func NewScope(outer *Scope) *Scope
```

NewScope creates a new scope nested in the outer scope.

func (***Scope**) [Insert](#)

```
func (s *Scope) Insert(obj *Object) (alt *Object)
```

Insert attempts to insert a named object obj into the scope s. If the scope already contains an object alt with the same name, Insert leaves the scope unchanged and returns alt. Otherwise it inserts obj and returns nil."

func (***Scope**) [Lookup](#)

```
func (s *Scope) Lookup(name string) *Object
```

Lookup returns the object with the given name if it is found in scope s, otherwise it returns nil. Outer scopes are ignored.

func (***Scope**) [String](#)

```
func (s *Scope) String() string
```

Debugging support

type [SelectStmt](#)

```
type SelectStmt struct {  
    Select token.Pos // position of "select" keyword  
    Body   *BlockStmt // CommClauses only  
}
```

An SelectStmt node represents a select statement.

func (*SelectStmt) [End](#)

```
func (s *SelectStmt) End() token.Pos
```

func (*SelectStmt) [Pos](#)

```
func (s *SelectStmt) Pos() token.Pos
```

type SelectorExpr

```
type SelectorExpr struct {  
    X Expr // expression  
    Sel *Ident // field selector  
}
```

A SelectorExpr node represents an expression followed by a selector.

func (*SelectorExpr) End

```
func (x *SelectorExpr) End() token.Pos
```

func (*SelectorExpr) Pos

```
func (x *SelectorExpr) Pos() token.Pos
```

type [SendStmt](#)

```
type SendStmt struct {  
    Chan Expr  
    Arrow token.Pos // position of "<-"  
    Value Expr  
}
```

A SendStmt node represents a send statement.

func (*SendStmt) [End](#)

```
func (s *SendStmt) End() token.Pos
```

func (*SendStmt) [Pos](#)

```
func (s *SendStmt) Pos() token.Pos
```

type [SliceExpr](#)

```
type SliceExpr struct {
    X      Expr    // expression
    Lbrack token.Pos // position of "["
    Low    Expr    // begin of slice range; or nil
    High   Expr    // end of slice range; or nil
    Rbrack token.Pos // position of "]"
}
```

An SliceExpr node represents an expression followed by slice indices.

func (*SliceExpr) [End](#)

```
func (x *SliceExpr) End() token.Pos
```

func (*SliceExpr) [Pos](#)

```
func (x *SliceExpr) Pos() token.Pos
```

type [Spec](#)

```
type Spec interface {  
    Node  
    // contains filtered or unexported methods  
}
```

The Spec type stands for any of *ImportSpec, *ValueSpec, and *TypeSpec.

type StarExpr

```
type StarExpr struct {  
    Star token.Pos // position of "*"   
    X    Expr      // operand   
}
```

A StarExpr node represents an expression of the form "*" Expression. Semantically it could be a unary "*" expression, or a pointer type.

func (*StarExpr) End

```
func (x *StarExpr) End() token.Pos
```

func (*StarExpr) Pos

```
func (x *StarExpr) Pos() token.Pos
```

type [Stmt](#)

```
type Stmt interface {  
    Node  
    // contains filtered or unexported methods  
}
```

All statement nodes implement the Stmt interface.

type [StructType](#)

```
type StructType struct {  
    Struct      token.Pos // position of "struct" keyword  
    Fields      *FieldList // list of field declarations  
    Incomplete bool      // true if (source) fields are missing in  
}
```

A StructType node represents a struct type.

func (***StructType**) [End](#)

```
func (x *StructType) End() token.Pos
```

func (***StructType**) [Pos](#)

```
func (x *StructType) Pos() token.Pos
```

type [SwitchStmt](#)

```
type SwitchStmt struct {
    Switch token.Pos // position of "switch" keyword
    Init   Stmt       // initialization statement; or nil
    Tag    Expr       // tag expression; or nil
    Body   *BlockStmt // CaseClauses only
}
```

A SwitchStmt node represents an expression switch statement.

func (*SwitchStmt) [End](#)

```
func (s *SwitchStmt) End() token.Pos
```

func (*SwitchStmt) [Pos](#)

```
func (s *SwitchStmt) Pos() token.Pos
```

type TypeAssertExpr

```
type TypeAssertExpr struct {  
    X      Expr // expression  
    Type Expr // asserted type; nil means type switch X.(type)  
}
```

A TypeAssertExpr node represents an expression followed by a type assertion.

func (*TypeAssertExpr) End

```
func (x *TypeAssertExpr) End() token.Pos
```

func (*TypeAssertExpr) Pos

```
func (x *TypeAssertExpr) Pos() token.Pos
```

type [TypeSpec](#)

```
type TypeSpec struct {
    Doc      *CommentGroup // associated documentation; or nil
    Name     *Ident         // type name
    Type     Expr          // *Ident, *ParenExpr, *SelectorExpr, *Sta
    Comment  *CommentGroup // line comments; or nil
}
```

A TypeSpec node represents a type declaration (TypeSpec production).

func (*TypeSpec) [End](#)

```
func (s *TypeSpec) End() token.Pos
```

func (*TypeSpec) [Pos](#)

```
func (s *TypeSpec) Pos() token.Pos
```

type [TypeSwitchStmt](#)

```
type TypeSwitchStmt struct {  
    Switch token.Pos // position of "switch" keyword  
    Init  Stmt        // initialization statement; or nil  
    Assign Stmt       // x := y.(type) or y.(type)  
    Body  *BlockStmt // CaseClauses only  
}
```

An TypeSwitchStmt node represents a type switch statement.

func (*TypeSwitchStmt) [End](#)

```
func (s *TypeSwitchStmt) End() token.Pos
```

func (*TypeSwitchStmt) [Pos](#)

```
func (s *TypeSwitchStmt) Pos() token.Pos
```

type UnaryExpr

```
type UnaryExpr struct {
    OpPos token.Pos // position of Op
    Op    token.Token // operator
    X     Expr      // operand
}
```

A UnaryExpr node represents a unary expression. Unary "*" expressions are represented via StarExpr nodes.

func (*UnaryExpr) End

```
func (x *UnaryExpr) End() token.Pos
```

func (*UnaryExpr) Pos

```
func (x *UnaryExpr) Pos() token.Pos
```

type [ValueSpec](#)

```
type ValueSpec struct {
    Doc      *CommentGroup // associated documentation; or nil
    Names    []*Ident      // value names (len(Names) > 0)
    Type     Expr       // value type; or nil
    Values   []Expr       // initial values; or nil
    Comment  *CommentGroup // line comments; or nil
}
```

A ValueSpec node represents a constant or variable declaration (ConstSpec or VarSpec production).

func (*ValueSpec) [End](#)

```
func (s *ValueSpec) End() token.Pos
```

func (*ValueSpec) [Pos](#)

```
func (s *ValueSpec) Pos() token.Pos
```

type [Visitor](#)

```
type Visitor interface {  
    Visit(node Node) (w Visitor)  
}
```

A Visitor's Visit method is invoked for each node encountered by Walk. If the result visitor w is not nil, Walk visits each of the children of node with the visitor w, followed by a call of w.Visit(nil).

Package build

```
import "go/build"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package build gathers information about Go packages.

Go Path

The Go path is a list of directory trees containing Go source code. It is consulted to resolve imports that cannot be found in the standard Go tree. The default path is the value of the GOPATH environment variable, interpreted as a path list appropriate to the operating system (on Unix, the variable is a colon-separated string; on Windows, a semicolon-separated string; on Plan 9, a list).

Each directory listed in the Go path must have a prescribed structure:

The src/ directory holds source code. The path below 'src' determines the import path or executable name.

The pkg/ directory holds installed package objects. As in the Go tree, each target operating system and architecture pair has its own subdirectory of pkg (pkg/GOOS_GOARCH).

If DIR is a directory listed in the Go path, a package with source in DIR/src/foo/bar can be imported as "foo/bar" and has its compiled form installed to "DIR/pkg/GOOS_GOARCH/foo/bar.a" (or, for gccgo, "DIR/pkg/gccgo/foo/libbar.a").

The bin/ directory holds compiled commands. Each command is named for its source directory, but only using the final element, not the entire path. That is, the command with source in DIR/src/foo/quux is installed into DIR/bin/quux, not DIR/bin/foo/quux. The foo/ is stripped so that you can add DIR/bin to your PATH to get at the installed commands.

Here's an example directory layout:

```
GOPATH=/home/user/gocode  
  
/home/user/gocode/  
  src/  
    foo/
```

```

        bar/                (go code in package bar)
            x.go
        quux/              (go code in package main)
            y.go
bin/
  quux                    (installed command)
pkg/
  linux_amd64/
    foo/
      bar.a                (installed package object)

```

Build Constraints

A build constraint is a line comment beginning with the directive `+build` that lists the conditions under which a file should be included in the package. Constraints may appear in any kind of source file (not just Go), but they must appear near the top of the file, preceded only by blank lines and other line comments.

A build constraint is evaluated as the OR of space-separated options; each option evaluates as the AND of its comma-separated terms; and each term is an alphanumeric word or, preceded by `!`, its negation. That is, the build constraint:

```
// +build linux,386 darwin,!cgo
```

corresponds to the boolean formula:

```
(linux AND 386) OR (darwin AND (NOT cgo))
```

During a particular build, the following words are satisfied:

- the target operating system, as spelled by `runtime.GOOS`
- the target architecture, as spelled by `runtime.GOARCH`
- "cgo", if `ctxt.CgoEnabled` is true
- any additional words listed in `ctxt.BuildTags`

If a file's name, after stripping the extension and a possible `_test` suffix, matches `*_GOOS`, `*_GOARCH`, or `*_GOOS_GOARCH` for any known operating system and architecture values, then the file is considered to have an implicit build constraint requiring those terms.

To keep a file from being considered for the build:

```
// +build ignore
```

(any other unsatisfied word will work as well, but “ignore” is conventional.)

To build a file only when using cgo, and only on Linux and OS X:

```
// +build linux,cgo darwin,cgo
```

Such a file is usually paired with another file implementing the default functionality for other systems, which in this case would carry the constraint:

```
// +build !linux !darwin !cgo
```

Naming a file `dns_windows.go` will cause it to be included only when building the package for Windows; similarly, `math_386.s` will be included only when building the package for 32-bit x86.

Package files

[build.go](#) [doc.go](#) [syslist.go](#)

Variables

```
var ToolDir = filepath.Join(runtime.GOROOT(), "pkg/tool/"+runtime.GO
```

ToolDir is the directory containing build tools.

func [ArchChar](#)

```
func ArchChar(goarch string) (string, error)
```

ArchChar returns the architecture character for the given goarch. For example, ArchChar("amd64") returns "6".

func [IsLocalImport](#)

```
func IsLocalImport(path string) bool
```

IsLocalImport reports whether the import path is a local import path, like ".", "..", "./foo", or "../foo".

type [Context](#)

```
type Context struct {
    GOARCH      string // target architecture
    GOOS        string // target operating system
    GOROOT      string // Go root
    GOPATH      string // Go path
    CgoEnabled  bool   // whether cgo can be used
    BuildTags   []string // additional tags to recognize in +build l
    UseAllFiles bool   // use files regardless of +build lines, fi
    Compiler    string

    // JoinPath joins the sequence of path fragments into a single p
    // If JoinPath is nil, Import uses filepath.Join.
    JoinPath func(elem ...string) string

    // SplitPathList splits the path list into a slice of individual
    // If SplitPathList is nil, Import uses filepath.SplitList.
    SplitPathList func(list string) []string

    // IsAbsPath reports whether path is an absolute path.
    // If IsAbsPath is nil, Import uses filepath.IsAbs.
    IsAbsPath func(path string) bool

    // IsDir reports whether the path names a directory.
    // If IsDir is nil, Import calls os.Stat and uses the result's I
    IsDir func(path string) bool

    // HasSubdir reports whether dir is a subdirectory of
    // (perhaps multiple levels below) root.
    // If so, HasSubdir sets rel to a slash-separated path that
    // can be joined to root to produce a path equivalent to dir.
    // If HasSubdir is nil, Import uses an implementation built on
    // filepath.EvalSymlinks.
    HasSubdir func(root, dir string) (rel string, ok bool)

    // ReadDir returns a slice of os.FileInfo, sorted by Name,
    // describing the content of the named directory.
    // If ReadDir is nil, Import uses io.ReadDir.
    ReadDir func(dir string) (fi []os.FileInfo, err error)

    // OpenFile opens a file (not a directory) for reading.
    // If OpenFile is nil, Import uses os.Open.
    OpenFile func(path string) (r io.ReadCloser, err error)
}
```

A Context specifies the supporting context for a build.

```
var Default Context = defaultContext()
```

Default is the default Context for builds. It uses the GOARCH, GOOS, GOROOT, and GOPATH environment variables if set, or else the compiled code's GOARCH, GOOS, and GOROOT.

func (*Context) [Import](#)

```
func (ctxt *Context) Import(path string, srcDir string, mode ImportM
```

Import returns details about the Go package named by the import path, interpreting local import paths relative to the srcDir directory. If the path is a local import path naming a package that can be imported using a standard import path, the returned package will set p.ImportPath to that path.

In the directory containing the package, .go, .c, .h, and .s files are considered part of the package except for:

- .go files in package documentation
- files starting with _ or . (likely editor temporary files)
- files with build constraints not satisfied by the context

If an error occurs, Import returns a non-nil error also returns a non-nil *Package containing partial information.

func (*Context) [ImportDir](#)

```
func (ctxt *Context) ImportDir(dir string, mode ImportMode) (*Packag
```

ImportDir is like Import but processes the Go package found in the named directory.

func (*Context) [SrcDirs](#)

```
func (ctxt *Context) SrcDirs() []string
```

SrcDirs returns a list of package source root directories. It draws from the current Go root and Go path but omits directories that do not exist.

type [ImportMode](#)

```
type ImportMode uint
```

An ImportMode controls the behavior of the Import method.

```
const (  
    // If FindOnly is set, Import stops after locating the directory  
    // that should contain the sources for a package. It does not  
    // read any files in the directory.  
    FindOnly ImportMode = 1 << iota  
  
    // If AllowBinary is set, Import can be satisfied by a compiled  
    // package object without corresponding sources.  
    AllowBinary  
)
```

type [NoGoError](#)

```
type NoGoError struct {  
    Dir string  
}
```

NoGoError is the error used by Import to describe a directory containing no Go source files.

func (*NoGoError) [Error](#)

```
func (e *NoGoError) Error() string
```

type [Package](#)

```
type Package struct {
    Dir      string // directory containing package sources
    Name     string // package name
    Doc      string // documentation synopsis
    ImportPath string // import path of package (" " if unknown)
    Root     string // root of Go tree where this package lives
    SrcRoot  string // package source root directory (" " if unknown)
    PkgRoot  string // package install root directory (" " if unknown)
    BinDir   string // command install directory (" " if unknown)
    Goroot   bool   // package found in Go root
    PkgObj   string

    // Source files
    GoFiles  []string // .go source files (excluding CgoFiles, Test
    CgoFiles []string // .go source files that import "C"
    CFiles   []string // .c source files
    HFiles   []string // .h source files
    SFiles   []string // .s source files
    SysoFiles []string

    // Cgo directives
    CgoPkgConfig []string // Cgo pkg-config directives
    CgoCFLAGS    []string // Cgo CFLAGS directives
    CgoLDFLAGS   []string

    // Dependency information
    Imports  []string // imports from GoFiles, CgoFiles
    ImportPos map[string][]token.Position

    // Test information
    TestGoFiles  []string // _test.go files in
    TestImports  []string // imports from TestG
    TestImportPos map[string][]token.Position // line information f
    XTestGoFiles []string // _test.go files out
    XTestImports []string // imports from XTest
    XTestImportPos map[string][]token.Position // line information f
}
```

A Package describes the Go package found in a directory.

func [Import](#)

```
func Import(path, srcDir string, mode ImportMode) (*Package, error)
```

Import is shorthand for Default.Import.

func [ImportDir](#)

```
func ImportDir(dir string, mode ImportMode) (*Package, error)
```

ImportDir is shorthand for Default.ImportDir.

func (*Package) [IsCommand](#)

```
func (p *Package) IsCommand() bool
```

IsCommand reports whether the package is considered a command to be installed (not just a library). Packages named "main" are treated as commands.

Build version go1.0.1.

[type Type](#)

[type Value](#)

Package files

[comment.go](#) [doc.go](#) [example.go](#) [exports.go](#) [filter.go](#) [reader.go](#) [synopsis.go](#)

func [Examples](#)

```
func Examples(files ...*ast.File) []*Example
```

func Synopsis

```
func Synopsis(s string) string
```

Synopsis returns a cleaned version of the first sentence in s. That sentence ends after the first period followed by space and not preceded by exactly one uppercase letter. The result string has no \n, \r, or \t characters and uses only single spaces between words.

func [ToHTML](#)

```
func ToHTML(w io.Writer, text string, words map[string]string)
```

ToHTML converts comment text to formatted HTML. The comment was prepared by DocReader, so it is known not to have leading, trailing blank lines nor to have trailing spaces at the end of lines. The comment markers have already been removed.

Turn each run of multiple `\n` into `</p><p>`. Turn each run of indented lines into a `<pre>` block without indent. Enclose headings with header tags.

URLs in the comment text are converted into links; if the URL also appears in the words map, the link is taken from the map (if the corresponding map value is the empty string, the URL is not converted into a link).

Go identifiers that appear in the words map are italicized; if the corresponding map value is not the empty string, it is considered a URL and the word is converted into a link.

func [ToText](#)

```
func ToText(w io.Writer, text string, indent, preIndent string, width int)
```

ToText prepares comment text for presentation in textual output. It wraps paragraphs of text to width or fewer Unicode code points and then prefixes each line with the indent. In preformatted sections (such as program text), it prefixes each non-blank line with preIndent.

type [Example](#)

```
type Example struct {  
    Name      string // name of the item being exemplified  
    Doc       string // example function doc string  
    Code      ast.Node  
    Comments  []*ast.CommentGroup  
    Output    string // expected output  
}
```

type **Filter**

```
type Filter func(string) bool
```

type [Func](#)

```
type Func struct {
    Doc string
    Name string
    Decl *ast.FuncDecl

    // methods
    // (for functions, these fields have the respective zero value)
    Recv string // actual receiver "T" or "*T"
    Orig string // original receiver "T" or "*T"
    Level int    // embedding level; 0 means not embedded
}
```

Func is the documentation for a func declaration.

type [Mode](#)

```
type Mode int
```

Mode values control the operation of New.

```
const (  
    // extract documentation for all package-level declarations,  
    // not just exported ones  
    AllDecls Mode = 1 << iota  
  
    // show all embedded methods, not just the ones of  
    // invisible (unexported) anonymous fields  
    AllMethods  
)
```

type [Package](#)

```
type Package struct {
    Doc      string
    Name     string
    ImportPath string
    Imports  []string
    Filenames []string
    Bugs     []string

    // declarations
    Consts []*Value
    Types []*Type
    Vars  []*Value
    Funcs []*Func
}
```

Package is the documentation for an entire package.

func [New](#)

```
func New(pkg *ast.Package, importPath string, mode Mode) *Package
```

New computes the package documentation for the given package AST. New takes ownership of the AST pkg and may edit or overwrite it.

func (*Package) [Filter](#)

```
func (p *Package) Filter(f Filter)
```

Filter eliminates documentation for names that don't pass through the filter f. TODO: Recognize "Type.Method" as a name.

type [Type](#)

```
type Type struct {
    Doc string
    Name string
    Decl *ast.GenDecl

    // associated declarations
    Consts []*Value // sorted list of constants of (mostly) this ty
    Vars    []*Value // sorted list of variables of (mostly) this ty
    Funcs  []*Func  // sorted list of functions returning this type
    Methods []*Func  // sorted list of methods (including embedded c
}
```

Type is the documentation for a type declaration.

type [Value](#)

```
type Value struct {
    Doc    string
    Names []string // var or const names in declaration order
    Decl  *ast.GenDecl
        // contains filtered or unexported fields
}
```

Value is the documentation for a (possibly grouped) var or const declaration.

Build version go1.0.1.

Package parser

```
import "go/parser"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package parser implements a parser for Go source files. Input may be provided in a variety of forms (see the various Parse* functions); the output is an abstract syntax tree (AST) representing the Go source. The parser is invoked through one of the Parse* functions.

Index

[func ParseDir\(fset *token.FileSet, path string, filter func\(os.FileInfo\) bool, mode Mode\) \(pkgs map\[string\]*ast.Package, first error\)](#)

[func ParseExpr\(x string\) \(ast.Expr, error\)](#)

[func ParseFile\(fset *token.FileSet, filename string, src interface{}, mode Mode\) \(*ast.File, error\)](#)

[type Mode](#)

Examples

[ParseFile](#)

Package files

[interface.go](#) [parser.go](#)

func ParseDir

```
func ParseDir(fset *token.FileSet, path string, filter func(os.FileI
```

ParseDir calls ParseFile for the files in the directory specified by path and returns a map of package name -> package AST with all the packages found. If filter != nil, only the files with os.FileInfo entries passing through the filter are considered. The mode bits are passed to ParseFile unchanged. Position information is recorded in the file set fset.

If the directory couldn't be read, a nil map and the respective error are returned. If a parse error occurred, a non-nil but incomplete map and the first error encountered are returned.

func ParseExpr

```
func ParseExpr(x string) (ast.Expr, error)
```

ParseExpr is a convenience function for obtaining the AST of an expression x. The position information recorded in the AST is undefined.

func [ParseFile](#)

```
func ParseFile(fset *token.FileSet, filename string, src interface{})
```

ParseFile parses the source code of a single Go source file and returns the corresponding ast.File node. The source code may be provided via the filename of the source file, or via the src parameter.

If src != nil, ParseFile parses the source from src and the filename is only used when recording position information. The type of the argument for the src parameter must be string, []byte, or io.Reader. If src == nil, ParseFile parses the file specified by filename.

The mode parameter controls the amount of source text parsed and other optional parser functionality. Position information is recorded in the file set fset.

If the source couldn't be read, the returned AST is nil and the error indicates the specific failure. If the source was read but syntax errors were found, the result is a partial AST (with ast.Bad* nodes representing the fragments of erroneous source code). Multiple errors are returned via a scanner.ErrorList which is sorted by file position.

? Example

? Example

Code:

```
fset := token.NewFileSet() // positions are relative to fset

// Parse the file containing this very example
// but stop after processing the imports.
f, err := parser.ParseFile(fset, "example_test.go", nil, parser.Impo
if err != nil {
    fmt.Println(err)
    return
}

// Print the imports from the file's AST.
for _, s := range f.Imports {
    fmt.Println(s.Path.Value)
```

```
}
```

Output:

```
"fmt"  
"go/parser"  
"go/token"
```

type [Mode](#)

```
type Mode uint
```

A Mode value is a set of flags (or 0). They control the amount of source code parsed and other optional parser functionality.

```
const (  
    PackageClauseOnly Mode = 1 << iota // parsing stops after packag  
    ImportsOnly           // parsing stops after import  
    ParseComments        // parse comments and add the  
    Trace                 // print a trace of parsed pr  
    DeclarationErrors    // report declaration errors  
    SpuriousErrors       // report all (not just the f  
)
```

Build version go1.0.1.

Package printer

```
import "go/printer"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package printer implements printing of AST nodes.

Index

[func Fprint\(output io.Writer, fset *token.FileSet, node interface{ }\) error](#)

[type CommentedNode](#)

[type Config](#)

[func \(cfg *Config\) Fprint\(output io.Writer, fset *token.FileSet, node](#)

[interface{ }\) error](#)

[type Mode](#)

Examples

[Fprint](#)

Package files

[nodes.go printer.go](#)

func [Fprint](#)

```
func Fprint(output io.Writer, fset *token.FileSet, node interface{})
```

Fprint "pretty-prints" an AST node to output. It calls Config.Fprint with default settings.

? Example

? Example

Code:

```
// Parse source file and extract the AST without comments for
// this function, with position information referring to the
// file set fset.
funcAST, fset := parseFunc("example_test.go", "ExampleFprint")

// Print the function body into buffer buf.
// The file set is provided to the printer so that it knows
// about the original source formatting and can add additional
// line breaks where they were present in the source.
var buf bytes.Buffer
printer.Fprint(&buf, fset, funcAST.Body)

// Remove braces {} enclosing the function body, unindent,
// and trim leading and trailing white space.
s := buf.String()
s = s[1 : len(s)-1]
s = strings.TrimSpace(strings.Replace(s, "\n\t", "\n", -1))

// Print the cleaned-up body text to stdout.
fmt.Println(s)
```

Output:

```
funcAST, fset := parseFunc("example_test.go", "ExampleFprint")

var buf bytes.Buffer
printer.Fprint(&buf, fset, funcAST.Body)

s := buf.String()
s = s[1 : len(s)-1]
s = strings.TrimSpace(strings.Replace(s, "\n\t", "\n", -1))
```

```
fmt.Println(s)
```

type [CommentedNode](#)

```
type CommentedNode struct {  
    Node      interface{} // *ast.File, or ast.Expr, ast.Decl, ast.Sp  
    Comments []*ast.CommentGroup  
}
```

A `CommentedNode` bundles an AST node and corresponding comments. It may be provided as argument to any of the `Fprint` functions.

type [Config](#)

```
type Config struct {  
    Mode      Mode // default: 0  
    Tabwidth  int  // default: 8  
}
```

A Config node controls the output of Fprint.

func (***Config**) [Fprint](#)

```
func (cfg *Config) Fprint(output io.Writer, fset *token.FileSet, nod
```

Fprint "pretty-prints" an AST node to output for a given configuration cfg. Position information is interpreted relative to the file set fset. The node type must be *ast.File, *CommentedNode, or assignment-compatible to ast.Expr, ast.Decl, ast.Spec, or ast.Stmt.

type [Mode](#)

```
type Mode uint
```

A Mode value is a set of flags (or 0). They control printing.

```
const (  
    RawFormat Mode = 1 << iota // do not use a tabwriter; if set, Us  
    TabIndent           // use tabs for indentation independe  
    UseSpaces          // use spaces instead of tabs for ali  
    SourcePos          // emit //line comments to preserve c  
)
```

Build version go1.0.1.

[func \(s *Scanner\) Init\(file *token.File, src \[\]byte, err ErrorHandler, mode Mode\)](#)

[func \(s *Scanner\) Scan\(\) \(pos token.Pos, tok token.Token, lit string\)](#)

Examples

[Scanner.Scan](#)

Package files

[errors.go scanner.go](#)

func [PrintError](#)

```
func PrintError(w io.Writer, err error)
```

PrintError is a utility function that prints a list of errors to w, one error per line, if the err parameter is an ErrorList. Otherwise it prints the err string.

type [Error](#)

```
type Error struct {  
    Pos token.Position  
    Msg string  
}
```

In an `ErrorList`, an error is represented by an `*Error`. The position `Pos`, if valid, points to the beginning of the offending token, and the error condition is described by `Msg`.

func (Error) [Error](#)

```
func (e Error) Error() string
```

`Error` implements the error interface.

type ErrorHandler

```
type ErrorHandler func(pos token.Position, msg string)
```

An ErrorHandler may be provided to Scanner.Init. If a syntax error is encountered and a handler was installed, the handler is called with a position and an error message. The position points to the beginning of the offending token.

type [ErrorList](#)

```
type ErrorList []*Error
```

ErrorList is a list of *Errors. The zero value for an ErrorList is an empty ErrorList ready to use.

func (*ErrorList) [Add](#)

```
func (p *ErrorList) Add(pos token.Position, msg string)
```

Add adds an Error with given position and error message to an ErrorList.

func (ErrorList) [Err](#)

```
func (p ErrorList) Err() error
```

Err returns an error equivalent to this error list. If the list is empty, Err returns nil.

func (ErrorList) [Error](#)

```
func (p ErrorList) Error() string
```

An ErrorList implements the error interface.

func (ErrorList) [Len](#)

```
func (p ErrorList) Len() int
```

ErrorList implements the sort Interface.

func (ErrorList) [Less](#)

```
func (p ErrorList) Less(i, j int) bool
```

func (*ErrorList) [RemoveMultiples](#)

```
func (p *ErrorList) RemoveMultiples()
```

RemoveMultiples sorts an ErrorList and removes all but the first error per line.

func (*ErrorList) [Reset](#)

```
func (p *ErrorList) Reset()
```

Reset resets an ErrorList to no errors.

func (ErrorList) [Sort](#)

```
func (p ErrorList) Sort()
```

Sort sorts an ErrorList. *Error entries are sorted by position, other errors are sorted by error message, and before any *Error entry.

func (ErrorList) [Swap](#)

```
func (p ErrorList) Swap(i, j int)
```

type [Mode](#)

```
type Mode uint
```

A mode value is set of flags (or 0). They control scanner behavior.

```
const (  
    ScanComments Mode = 1 << iota // return comments as COMMENT token  
)
```

type [Scanner](#)

```
type Scanner struct {  
    // public state - ok to modify  
    ErrorCount int // number of errors encountered  
    // contains filtered or unexported fields  
}
```

A Scanner holds the scanner's internal state while processing a given text. It can be allocated as part of another data structure but must be initialized via `Init` before use.

func (*Scanner) [Init](#)

```
func (s *Scanner) Init(file *token.File, src []byte, err ErrorHandler)
```

`Init` prepares the scanner `s` to tokenize the text `src` by setting the scanner at the beginning of `src`. The scanner uses the file set `file` for position information and it adds line information for each line. It is ok to re-use the same file when re-scanning the same file as line information which is already present is ignored. `Init` causes a panic if the file size does not match the `src` size.

Calls to `Scan` will invoke the error handler `err` if they encounter a syntax error and `err` is not nil. Also, for each error encountered, the Scanner field `ErrorCount` is incremented by one. The `mode` parameter determines how comments are handled.

Note that `Init` may call `err` if there is an error in the first character of the file.

func (*Scanner) [Scan](#)

```
func (s *Scanner) Scan() (pos token.Pos, tok token.Token, lit string)
```

`Scan` scans the next token and returns the token position, the token, and its literal string if applicable. The source end is indicated by `token.EOF`.

If the returned token is a literal (`token.IDENT`, `token.INT`, `token.FLOAT`, `token.IMAG`, `token.CHAR`, `token.STRING`) or `token.COMMENT`, the literal

string has the corresponding value.

If the returned token is `token.SEMICOLON`, the corresponding literal string is ";" if the semicolon was present in the source, and "\n" if the semicolon was inserted because of a newline or at EOF.

If the returned token is `token.ILLEGAL`, the literal string is the offending character.

In all other cases, `Scan` returns an empty literal string.

For more tolerant parsing, `Scan` will return a valid token if possible even if a syntax error was encountered. Thus, even if the resulting token sequence contains no illegal tokens, a client may not assume that no error occurred. Instead it must check the scanner's `ErrorCount` or the number of calls of the error handler, if there was one installed.

`Scan` adds line information to the file added to the file set with `Init`. Token positions are relative to that file and thus relative to the file set.

? Example

? Example

Code:

```
// src is the input that we want to tokenize.
src := []byte("cos(x) + 1i*sin(x) // Euler")

// Initialize the scanner.
var s scanner.Scanner
fset := token.NewFileSet() // positions are relative
file := fset.AddFile("", fset.Base(), len(src)) // register input "file"
s.Init(file, src, nil /* no error handler */, scanner.ScanComments)

// Repeated calls to Scan yield the token sequence found in the input
for {
    pos, tok, lit := s.Scan()
    if tok == token.EOF {
        break
    }
    fmt.Printf("%s\t%s\t%q\n", fset.Position(pos), tok, lit)
}
```

Output:

```
1:1      IDENT  "cos"  
1:4      (      ""  
1:5      IDENT  "x"  
1:6      )      ""  
1:8      +      ""  
1:10     IMAG  "1i"  
1:12     *      ""  
1:13     IDENT  "sin"  
1:16     (      ""  
1:17     IDENT  "x"  
1:18     )      ""  
1:20     ;      "\n"  
1:20     COMMENT "// Euler"
```

Constants

```
const (  
    LowestPrec  = 0 // non-operators  
    UnaryPrec   = 6  
    HighestPrec = 7  
)
```

A set of constants for precedence-based expression parsing. Non-operators have lowest precedence, followed by operators starting with precedence 1 up to unary operators. The highest precedence corresponds serves as "catch-all" precedence for selector, indexing, and other operator and delimiter tokens.

type [File](#)

```
type File struct {  
    // contains filtered or unexported fields  
}
```

A File is a handle for a file belonging to a FileSet. A File has a name, size, and line offset table.

func (*File) [AddLine](#)

```
func (f *File) AddLine(offset int)
```

AddLine adds the line offset for a new line. The line offset must be larger than the offset for the previous line and smaller than the file size; otherwise the line offset is ignored.

func (*File) [AddLineInfo](#)

```
func (f *File) AddLineInfo(offset int, filename string, line int)
```

AddLineInfo adds alternative file and line number information for a given file offset. The offset must be larger than the offset for the previously added alternative line info and smaller than the file size; otherwise the information is ignored.

AddLineInfo is typically used to register alternative position information for //line filename:line comments in source files.

func (*File) [Base](#)

```
func (f *File) Base() int
```

Base returns the base offset of file f as registered with AddFile.

func (*File) [Line](#)

```
func (f *File) Line(p Pos) int
```

Line returns the line number for the given file position p; p must be a Pos value in that file or NoPos.

func (*File) [LineCount](#)

```
func (f *File) LineCount() int
```

LineCount returns the number of lines in file f.

func (*File) [Name](#)

```
func (f *File) Name() string
```

Name returns the file name of file f as registered with AddFile.

func (*File) [Offset](#)

```
func (f *File) Offset(p Pos) int
```

Offset returns the offset for the given file position p; p must be a valid Pos value in that file. `f.Offset(f.Pos(offset)) == offset`.

func (*File) [Pos](#)

```
func (f *File) Pos(offset int) Pos
```

Pos returns the Pos value for the given file offset; the offset must be `<= f.Size()`. `f.Pos(f.Offset(p)) == p`.

func (*File) [Position](#)

```
func (f *File) Position(p Pos) (pos Position)
```

Position returns the Position value for the given file position p; p must be a Pos value in that file or NoPos.

func (*File) [SetLines](#)

```
func (f *File) SetLines(lines []int) bool
```

SetLines sets the line offsets for a file and returns true if successful. The line offsets are the offsets of the first character of each line; for instance for the content "ab\nc\n" the line offsets are {0, 3}. An empty file has an empty line offset table. Each line offset must be larger than the offset for the previous line and smaller than the file size; otherwise SetLines fails and returns false.

func (*File) [SetLinesForContent](#)

```
func (f *File) SetLinesForContent(content []byte)
```

SetLinesForContent sets the line offsets for the given file content.

func (*File) [Size](#)

```
func (f *File) Size() int
```

Size returns the size of file f as registered with AddFile.

type [FileSet](#)

```
type FileSet struct {  
    // contains filtered or unexported fields  
}
```

A FileSet represents a set of source files. Methods of file sets are synchronized; multiple goroutines may invoke them concurrently.

func [NewFileSet](#)

```
func NewFileSet() *FileSet
```

NewFileSet creates a new file set.

func (*FileSet) [AddFile](#)

```
func (s *FileSet) AddFile(filename string, base, size int) *File
```

AddFile adds a new file with a given filename, base offset, and file size to the file set s and returns the file. Multiple files may have the same name. The base offset must not be smaller than the FileSet's Base(), and size must not be negative.

Adding the file will set the file set's Base() value to base + size + 1 as the minimum base value for the next file. The following relationship exists between a Pos value p for a given file offset offs:

$$\text{int}(p) = \text{base} + \text{offs}$$

with offs in the range [0, size] and thus p in the range [base, base+size]. For convenience, File.Pos may be used to create file-specific position values from a file offset.

func (*FileSet) [Base](#)

```
func (s *FileSet) Base() int
```

Base returns the minimum base offset that must be provided to AddFile when

adding the next file.

func (*FileSet) [File](#)

```
func (s *FileSet) File(p Pos) (f *File)
```

File returns the file that contains the position p. If no such file is found (for instance for p == NoPos), the result is nil.

func (*FileSet) [Iterate](#)

```
func (s *FileSet) Iterate(f func(*File) bool)
```

Iterate calls f for the files in the file set in the order they were added until f returns false.

func (*FileSet) [Position](#)

```
func (s *FileSet) Position(p Pos) (pos Position)
```

Position converts a Pos in the fileset into a general Position.

func (*FileSet) [Read](#)

```
func (s *FileSet) Read(decode func(interface{}) error) error
```

Read calls decode to deserialize a file set into s; s must not be nil.

func (*FileSet) [Write](#)

```
func (s *FileSet) Write(encode func(interface{}) error) error
```

Write calls encode to serialize the file set s.

type [Pos](#)

```
type Pos int
```

Pos is a compact encoding of a source position within a file set. It can be converted into a Position for a more convenient, but much larger, representation.

The Pos value for a given file is a number in the range [base, base+size], where base and size are specified when adding the file to the file set via AddFile.

To create the Pos value for a specific source offset, first add the respective file to the current file set (via FileSet.AddFile) and then call File.Pos(offset) for that file. Given a Pos value p for a specific file set fset, the corresponding Position value is obtained by calling fset.Position(p).

Pos values can be compared directly with the usual comparison operators: If two Pos values p and q are in the same file, comparing p and q is equivalent to comparing the respective source file offsets. If p and q are in different files, $p < q$ is true if the file implied by p was added to the respective file set before the file implied by q.

```
const NoPos Pos = 0
```

The zero value for Pos is NoPos; there is no file and line information associated with it, and NoPos().IsValid() is false. NoPos is always smaller than any other Pos value. The corresponding Position value for NoPos is the zero value for Position.

func (Pos) [IsValid](#)

```
func (p Pos) IsValid() bool
```

IsValid returns true if the position is valid.

type [Position](#)

```
type Position struct {  
    Filename string // filename, if any  
    Offset    int     // offset, starting at 0  
    Line      int     // line number, starting at 1  
    Column    int     // column number, starting at 1 (character count  
}
```

Position describes an arbitrary source position including the file, line, and column location. A Position is valid if the line number is > 0 .

func (*Position) [IsValid](#)

```
func (pos *Position) IsValid() bool
```

IsValid returns true if the position is valid.

func (Position) [String](#)

```
func (pos Position) String() string
```

String returns a string in one of several forms:

file:line:column	valid position with file name
line:column	valid position without file name
file	invalid position with file name
-	invalid position without file name

type [Token](#)

type Token int

Token is the set of lexical tokens of the Go programming language.

```
const (  
    // Special tokens  
    ILLEGAL Token = iota  
    EOF  
    COMMENT  
  
    // Identifiers and basic type literals  
    // (these tokens stand for classes of literals)  
    IDENT // main  
    INT   // 12345  
    FLOAT // 123.45  
    IMAG  // 123.45i  
    CHAR  // 'a'  
    STRING  
  
    // Operators and delimiters  
    ADD // +  
    SUB // -  
    MUL // *  
    QUO // /

    AND      // &  
    OR       // |  
    XOR      // ^  
    SHL      // <<  
    SHR      // >>  
    AND_NOT  // &^  
  
    ADD_ASSIGN // +=  
    SUB_ASSIGN // -=  
    MUL_ASSIGN // *=  
    QUO_ASSIGN // /=  
    REM_ASSIGN // %=  
  
    AND_ASSIGN      // &=  
    OR_ASSIGN       // |=  
    XOR_ASSIGN      // ^=  
    SHL_ASSIGN      // <<=  
    SHR_ASSIGN      // >>=  
    AND_NOT_ASSIGN  // &^=
```

PACKAGE
RANGE
RETURN

SELECT
STRUCT
SWITCH
TYPE
VAR
)
```

The list of tokens.

func [Lookup](#)

```
func Lookup(ident string) Token
```

Lookup maps an identifier to its keyword token or IDENT (if not a keyword).

func (Token) [IsKeyword](#)

```
func (tok Token) IsKeyword() bool
```

IsKeyword returns true for tokens corresponding to keywords; it returns false otherwise.

func (Token) [IsLiteral](#)

```
func (tok Token) IsLiteral() bool
```

IsLiteral returns true for tokens corresponding to identifiers and basic type literals; it returns false otherwise.

func (Token) [IsOperator](#)

```
func (tok Token) IsOperator() bool
```

IsOperator returns true for tokens corresponding to operators and delimiters; it returns false otherwise.

func (Token) [Precedence](#)

```
func (op Token) Precedence() int
```

Precedence returns the operator precedence of the binary operator op. If op is not a binary operator, the result is LowestPrecedence.

func (Token) [String](#)

```
func (tok Token) String() string
```

String returns the string corresponding to the token tok. For operators, delimiters, and keywords the string is the actual token character sequence (e.g., for the token ADD, the string is "+"). For all other tokens the string corresponds to the token constant name (e.g. for the token IDENT, the string is "IDENT").

Package `adler32`

```
import "hash/adler32"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `adler32` implements the Adler-32 checksum. Defined in RFC 1950:

Adler-32 is composed of two sums accumulated per byte: `s1` is the sum of all bytes, `s2` is the sum of all `s1` values. Both sums are done modulo 65521. `s1` is initialized to 1, `s2` to zero. The Adler-32 checksum is stored as $s2 * 65536 + s1$ in most-significant-byte first (network) order.

)
```

Predefined polynomials.

```
const Size = 4
```

The size of a CRC-32 checksum in bytes.

Variables

```
var IEEETable = makeTable(IEEE)
```

IEEETable is the table for the IEEE polynomial.

func [Checksum](#)

```
func Checksum(data []byte, tab *Table) uint32
```

Checksum returns the CRC-32 checksum of data using the polynomial represented by the Table.

func [ChecksumIEEE](#)

```
func ChecksumIEEE(data []byte) uint32
```

ChecksumIEEE returns the CRC-32 checksum of data using the IEEE polynomial.

func [New](#)

```
func New(tab *Table) hash.Hash32
```

New creates a new hash.Hash32 computing the CRC-32 checksum using the polynomial represented by the Table.

func [NewIEEE](#)

```
func NewIEEE() hash.Hash32
```

NewIEEE creates a new hash.Hash32 computing the CRC-32 checksum using the IEEE polynomial.

func [Update](#)

```
func Update(crc uint32, tab *Table, p []byte) uint32
```

Update returns the result of adding the bytes in p to the crc.

type [Table](#)

```
type Table [256]uint32
```

Table is a 256-word table representing the polynomial for efficient processing.

func [MakeTable](#)

```
func MakeTable(poly uint32) *Table
```

MakeTable returns the Table constructed from the specified polynomial.

Build version go1.0.1.

Overview ?

Overview ?

Package `html` provides functions for escaping and unescaping HTML text.

Index

[func EscapeString\(s string\) string](#)

[func UnescapeString\(s string\) string](#)

Package files

[entity.go](#) [escape.go](#)

func EscapeString

```
func EscapeString(s string) string
```

EscapeString escapes special characters like "<" to become "<". It escapes only five such characters: <, >, &, ' and ". UnescapeString(EscapeString(s)) == s always holds, but the converse isn't always true.

func UnescapeString

```
func UnescapeString(s string) string
```

UnescapeString unescapes entities like "<" to become "<". It unescapes a larger range of entities than EscapeString escapes. For example, "á" unescapes to "", as does "á" and "&xE1;".

UnescapeString(EscapeString(s)) == s always holds, but the converse isn't always true.

```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `html/template` implements data-driven templates for generating HTML output safe against code injection. It provides the same interface as package `text/template` and should be used instead of `text/template` whenever the output is HTML.

The documentation here focuses on the security features of the package. For information about how to program the templates themselves, see the documentation for `text/template`.

Introduction

This package wraps package `text/template` so you can share its template API to parse and execute HTML templates safely.

```
tmpl, err := template.New("name").Parse(...)
// Error checking elided
err = tmpl.Execute(out, data)
```

If successful, `tmpl` will now be injection-safe. Otherwise, `err` is an error defined in the docs for `ErrorCode`.

HTML templates treat data values as plain text which should be encoded so they can be safely embedded in an HTML document. The escaping is contextual, so actions can appear within JavaScript, CSS, and URI contexts.

The security model used by this package assumes that template authors are trusted, while `Execute`'s data parameter is not. More details are provided below.

Example

```
import "text/template"
...
t, err := template.New("foo").Parse(`{{define "T"}}Hello, {{.}}!{{end}}`)
err = t.ExecuteTemplate(out, "T", "<script>alert('you have been pwne
```

produces

```
Hello, <script>alert('you have been pwned')</script>!
```

but the contextual autoescaping in html/template

```
import "html/template"
...
t, err := template.New("foo").Parse(`{{define "T"}}Hello, {{.}}!{{end}}
err = t.ExecuteTemplate(out, "T", "<script>alert('you have been pwne
```

produces safe, escaped HTML output

```
Hello, &lt;script&gt;alert(&#39;you have been pwned&#39;)&lt;/script
```

Contexts

This package understands HTML, CSS, JavaScript, and URIs. It adds sanitizing functions to each simple action pipeline, so given the excerpt

```
<a href="/search?q={{.}}">{{.}}</a>
```

At parse time each `{{.}}` is overwritten to add escaping functions as necessary. In this case it becomes

```
<a href="/search?q={{. | urlquery}}">{{. | html}}</a>
```

Errors

See the documentation of `ErrorCode` for details.

A fuller picture

The rest of this package comment may be skipped on first reading; it includes details necessary to understand escaping contexts and error messages. Most users will not need to understand these details.

Contexts

Assuming `{{.}}` is ``O'Reilly: How are <i>you</i>?``, the table below shows how `{{.}}` appears when used in the context to the left.

Context	<code>{{.}}</code> After
<code>{{.}}</code>	<code>O'Reilly: How are &lt;i&gt;you&lt;/i>?</code>
<code></code>	<code>O&#39;Reilly: How are you?</code>

<code></code>	<code>O&#39;Reilly: How are %3ci%3eyou%3c</code>
<code></code>	<code>O&#39;Reilly%3a%20How%20are%3ci%3e.</code>
<code></code>	<code>0\x27Reilly: How are \x3ci\x3eyou..</code>
<code></code>	<code>"0\x27Reilly: How are \x3ci\x3eyou.</code>
<code></code>	<code>0\x27Reilly: How are \x3ci\x3eyou..</code>

If used in an unsafe context, then the value might be filtered out:

Context	{{.}} After
<code></code>	<code>#ZgotmplZ</code>

since "O'Reilly:" is not an allowed protocol like "http:".

If {{.}} is the innocuous word, `left`, then it can appear more widely,

Context	{{.}} After
<code>{{.}}</code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code></code>	<code>left</code>
<code><style>p.{{.}} {color:red}</style></code>	<code>left</code>

Non-string values can be used in JavaScript contexts. If {{.}} is

```
[]struct{A,B string}{ "foo", "bar" }
```

in the escaped template

```
<script>var pair = {{.}};</script>
```

then the template output is

```
<script>var pair = {"A": "foo", "B": "bar"};</script>
```

See package json to understand how non-string content is marshalled for embedding in JavaScript contexts.

Typed Strings

By default, this package assumes that all pipelines produce a plain text string. It

adds escaping pipeline stages necessary to correctly and safely embed that plain text string in the appropriate context.

When a data value is not plain text, you can make sure it is not over-escaped by marking it with its type.

Types HTML, JS, URL, and others from content.go can carry safe content that is exempted from escaping.

The template

```
Hello, {{.}}!
```

can be invoked with

```
tmpl.Execute(out, HTML(`World`))
```

to produce

```
Hello, World!
```

instead of the

```
Hello, &lt;b&gt;World&lt;b&gt;!
```

that would have been produced if `{{.}}` was a regular string.

Security Model

http://js-quasis-libraries-and-repl.googlecode.com/svn/trunk/safetemplate.html#problem_definition defines "safe" as used by this package.

This package assumes that template authors are trusted, that `Execute`'s data parameter is not, and seeks to preserve the properties below in the face of untrusted data:

Structure Preservation Property: "... when a template author writes an HTML tag in a safe templating language, the browser will interpret the corresponding portion of the output as a tag regardless of the values of untrusted data, and similarly for other structures such as attribute boundaries and JS and CSS string

boundaries."

Code Effect Property: "... only code specified by the template author should run as a result of injecting the template output into a page and all code specified by the template author should run as a result of the same."

Least Surprise Property: "A developer (or code reviewer) familiar with HTML, CSS, and JavaScript, who knows that contextual autoescaping happens should be able to look at a `{{.}}` and correctly infer what sanitization happens."

func [HTMLEscape](#)

```
func HTMLEscape(w io.Writer, b []byte)
```

HTMLEscape writes to w the escaped HTML equivalent of the plain text data b.

func [HTMLEscapeString](#)

```
func HTMLEscapeString(s string) string
```

HTMLEscapeString returns the escaped HTML equivalent of the plain text data s.

func [HTMLEscaper](#)

```
func HTMLEscaper(args ...interface{}) string
```

HTMLEscaper returns the escaped HTML equivalent of the textual representation of its arguments.

func [JSEscape](#)

```
func JSEscape(w io.Writer, b []byte)
```

JSEscape writes to w the escaped JavaScript equivalent of the plain text data b.

func JSEscapeString

```
func JSEscapeString(s string) string
```

JSEscapeString returns the escaped JavaScript equivalent of the plain text data s.

func [JSEscaper](#)

```
func JSEscaper(args ...interface{}) string
```

JSEscaper returns the escaped JavaScript equivalent of the textual representation of its arguments.

func [URLQueryEscaper](#)

```
func URLQueryEscaper(args ...interface{}) string
```

URLQueryEscaper returns the escaped value of the textual representation of its arguments in a form suitable for embedding in a URL query.

type [CSS](#)

type CSS string

CSS encapsulates known safe content that matches any of:

1. The CSS3 stylesheet production, such as ``p { color: purple }``.
2. The CSS3 rule production, such as ``a[href=~"https:"].foo#bar``.
3. CSS3 declaration productions, such as ``color: red; margin: 2px``.
4. The CSS3 value production, such as ``rgba(0, 0, 255, 127)``.

See <http://www.w3.org/TR/css3-syntax/#style>

type [Error](#)

```
type Error struct {  
    // ErrorCode describes the kind of error.  
    ErrorCode ErrorCode  
    // Name is the name of the template in which the error was encou  
    Name string  
    // Line is the line number of the error in the template source o  
    Line int  
    // Description is a human-readable description of the problem.  
    Description string  
}
```

Error describes a problem encountered during template Escaping.

func (***Error**) [Error](#)

```
func (e *Error) Error() string
```

type [ErrorCode](#)

```
type ErrorCode int
```

ErrorCode is a code for a kind of error.

```
const (
    // OK indicates the lack of an error.
    OK ErrorCode = iota

    // ErrAmbigContext: "... appears in an ambiguous URL context"
    // Example:
    //   <a href="
    //       {{if .C}}
    //         /path/
    //       {{else}}
    //         /search?q=
    //       {{end}}
    //       {{.X}}
    //   ">
    // Discussion:
    //   {{.X}} is in an ambiguous URL context since, depending on {
    //   it may be either a URL suffix or a query parameter.
    //   Moving {{.X}} into the condition removes the ambiguity:
    //   <a href="{{if .C}}/path/{{.X}}{{else}}/search?q={{.X}}">
    ErrAmbigContext

    // ErrBadHTML: "expected space, attr name, or end of tag, but go
    //   "... in unquoted attr", "... in attribute name"
    // Example:
    //   <a href = /search?q=foo>
    //   <href=foo>
    //   <form na<e=...>
    //   <option selected<
    // Discussion:
    //   This is often due to a typo in an HTML element, but some ru
    //   are banned in tag names, attribute names, and unquoted attr
    //   values because they can tickle parser ambiguities.
    //   Quoting all attributes is the best policy.
    ErrBadHTML

    // ErrBranchEnd: "{{if}} branches end in different contexts"
    // Example:
    //   {{if .C}}<a href="{{end}}{{.X}}
    // Discussion:
    //   Package html/template statically examines each path through
    //   {{if}}, {{range}}, or {{with}} to escape any following pipe
```

```

// The example is ambiguous since {{.X}} might be an HTML text
// or a URL prefix in an HTML attribute. The context of {{.X}}
// used to figure out how to escape it, but that context depen
// the run-time value of {{.C}} which is not statically known.
//
// The problem is usually something like missing quotes or ang
// brackets, or can be avoided by refactoring to put the two c
// into different branches of an if, range or with. If the pro
// is in a {{range}} over a collection that should never be er
// adding a dummy {{else}} can help.
ErrBranchEnd

// ErrEndContext: "... ends in a non-text context: ..."
// Examples:
// <div
// <div title="no close quote>
// <script>f()
// Discussion:
// Executed templates should produce a DocumentFragment of HTML
// Templates that end without closing tags will trigger this e
// Templates that should not be used in an HTML context or tha
// produce incomplete Fragments should not be executed directl
//
// {{define "main"}} <script>{{template "helper"}}</script> {{
// {{define "helper"}} document.write(' <div title=" ') {{end}}
//
// "helper" does not produce a valid document fragment, so sho
// not be Executed directly.
ErrEndContext

// ErrNoSuchTemplate: "no such template ..."
// Examples:
// {{define "main"}}<div {{template "attrs"}}>{{end}}
// {{define "attrs"}}href="{{.URL}}"{{end}}
// Discussion:
// Package html/template looks through template calls to compu
// context.
// Here the {{.URL}} in "attrs" must be treated as a URL when
// from "main", but you will get this error if "attrs" is not
// when "main" is parsed.
ErrNoSuchTemplate

// ErrOutputContext: "cannot compute output context for template
// Examples:
// {{define "t"}}{{if .T}}{{template "t" .T}}{{end}}{{.H}}",{{
// Discussion:
// A recursive template does not end in the same context in wh
// starts, and a reliable output context cannot be computed.
// Look for typos in the named template.

```

```

// If the template should not be called in the named start con
// look for calls to that template in unexpected contexts.
// Maybe refactor recursive templates to not be recursive.
ErrOutputContext

// ErrPartialCharset: "unfinished JS regexp charset in ..."
// Example:
//   <script>var pattern = /foo[{{.Chars}}]/</script>
// Discussion:
//   Package html/template does not support interpolation into r
//   expression literal character sets.
ErrPartialCharset

// ErrPartialEscape: "unfinished escape sequence in ..."
// Example:
//   <script>alert("\{{.X}}")</script>
// Discussion:
//   Package html/template does not support actions following a
//   backslash.
//   This is usually an error and there are better solutions; fo
//   example
//   <script>alert("{{.X}}")</script>
//   should work, and if {{.X}} is a partial escape sequence suc
//   "xA0", mark the whole sequence as safe content: JSStr(`xA0
ErrPartialEscape

// ErrRangeLoopReentry: "on range loop re-entry: ..."
// Example:
//   <script>var x = [{{range .}}'{{.}},{{end}}]</script>
// Discussion:
//   If an iteration through a range would cause it to end in a
//   different context than an earlier pass, there is no single
//   In the example, there is missing a quote, so it is not clea
//   whether {{.}} is meant to be inside a JS string or in a JS
//   context. The second iteration would produce something like
//
//   <script>var x = ['firstValue,'secondValue]</script>
ErrRangeLoopReentry

// ErrSlashAmbig: '/' could start a division or regexp.
// Example:
//   <script>
//     {{if .C}}var x = 1{{end}}
//     /-{{.N}}/i.test(x) ? doThis : doThat();
//   </script>
// Discussion:
//   The example above could produce `var x = 1/-2/i.test(s)...`
//   in which the first '/' is a mathematical division operator
//   could produce `/-2/i.test(s)` in which the first '/' starts

```

```
//  regexp literal.
//  Look for missing semicolons inside branches, and maybe add
//  parentheses to make it clear which interpretation you intend
ErrSlashAmbig
)
```

We define codes for each error that manifests while escaping templates, but escaped templates may also fail at runtime.

Output: "ZgotmplZ" Example:

```

where {{.X}} evaluates to `javascript:...`
```

Discussion:

"ZgotmplZ" is a special value that indicates that unsafe content reached CSS or URL context at runtime. The output of the example will be

```

If the data comes from a trusted source, use content types to exempt
from filtering: URL(`javascript:...`).
```

type [FuncMap](#)

```
type FuncMap map[string]interface{}
```

FuncMap is the type of the map defining the mapping from names to functions. Each function must have either a single return value, or two return values of which the second has type error. In that case, if the second (error) argument evaluates to non-nil during execution, execution terminates and Execute returns that error. FuncMap has the same base type as `template.FuncMap`, copied here so clients need not import "text/template".

type [HTML](#)

type HTML string

HTML encapsulates a known safe HTML document fragment. It should not be used for HTML from a third-party, or HTML with unclosed tags or comments. The outputs of a sound HTML sanitizer and a template escaped by this package are fine for use with HTML.

type [HTMLAttr](#)

```
type HTMLAttr string
```

HTMLAttr encapsulates an HTML attribute from a trusted source, for example, `dir="ltr"`.

type [JS](#)

type JS string

JS encapsulates a known safe EcmaScript5 Expression, for example, `(x + y * z())`. Template authors are responsible for ensuring that typed expressions do not break the intended precedence and that there is no statement/expression ambiguity as when passing an expression like `{ foo: bar() }\n['foo']()`, which is both a valid Expression and a valid Program with a very different meaning.

type [JSStr](#)

```
type JSStr string
```

JSStr encapsulates a sequence of characters meant to be embedded between quotes in a JavaScript expression. The string must match a series of `StringCharacter`s:

```
StringCharacter :: SourceCharacter but not `` or LineTerminator  
                | EscapeSequence
```

Note that `LineContinuations` are not allowed. `JSStr("foo\nbar")` is fine, but `JSStr("foo\\nbar")` is not.

type [Template](#)

```
type Template struct {  
    // contains filtered or unexported fields  
}
```

Template is a specialized template.Template that produces a safe HTML document fragment.

func [Must](#)

```
func Must(t *Template, err error) *Template
```

Must panics if err is non-nil in the same way as template.Must.

func [New](#)

```
func New(name string) *Template
```

New allocates a new HTML template with the given name.

func [ParseFiles](#)

```
func ParseFiles(filenamees ...string) (*Template, error)
```

ParseFiles creates a new Template and parses the template definitions from the named files. The returned template's name will have the (base) name and (parsed) contents of the first file. There must be at least one file. If an error occurs, parsing stops and the returned *Template is nil.

func [ParseGlob](#)

```
func ParseGlob(pattern string) (*Template, error)
```

ParseGlob creates a new Template and parses the template definitions from the files identified by the pattern, which must match at least one file. The returned template will have the (base) name and (parsed) contents of the first file matched by the pattern. ParseGlob is equivalent to calling ParseFiles with the list of files matched by the pattern.

func (*Template) [AddParseTree](#)

```
func (t *Template) AddParseTree(name string, tree *parse.Tree) (*Tem
```

AddParseTree creates a new template with the name and parse tree and associates it with t.

It returns an error if t has already been executed.

func (*Template) [Clone](#)

```
func (t *Template) Clone() (*Template, error)
```

Clone returns a duplicate of the template, including all associated templates. The actual representation is not copied, but the name space of associated templates is, so further calls to Parse in the copy will add templates to the copy but not to the original. Clone can be used to prepare common templates and use them with variant definitions for other templates by adding the variants after the clone is made.

It returns an error if t has already been executed.

func (*Template) [Delims](#)

```
func (t *Template) Delims(left, right string) *Template
```

Delims sets the action delimiters to the specified strings, to be used in subsequent calls to Parse, ParseFiles, or ParseGlob. Nested template definitions will inherit the settings. An empty delimiter stands for the corresponding default: {{ or }}. The return value is the template, so calls can be chained.

func (*Template) [Execute](#)

```
func (t *Template) Execute(wr io.Writer, data interface{}) (err error)
```

Execute applies a parsed template to the specified data object, writing the output to wr.

func (*Template) [ExecuteTemplate](#)

```
func (t *Template) ExecuteTemplate(wr io.Writer, name string, data i
```

ExecuteTemplate applies the template associated with t that has the given name to the specified data object and writes the output to wr.

func (*Template) [Funcs](#)

```
func (t *Template) Funcs(funcMap FuncMap) *Template
```

Funcs adds the elements of the argument map to the template's function map. It panics if a value in the map is not a function with appropriate return type. However, it is legal to overwrite elements of the map. The return value is the template, so calls can be chained.

func (*Template) [Lookup](#)

```
func (t *Template) Lookup(name string) *Template
```

Lookup returns the template with the given name that is associated with t, or nil if there is no such template.

func (*Template) [Name](#)

```
func (t *Template) Name() string
```

Name returns the name of the template.

func (*Template) [New](#)

```
func (t *Template) New(name string) *Template
```

New allocates a new HTML template associated with the given one and with the same delimiters. The association, which is transitive, allows one template to invoke another with a {{template}} action.

func (*Template) [Parse](#)

```
func (t *Template) Parse(src string) (*Template, error)
```

Parse parses a string into a template. Nested template definitions will be

associated with the top-level template `t`. `Parse` may be called multiple times to parse definitions of templates to associate with `t`. It is an error if a resulting template is non-empty (contains content other than template definitions) and would replace a non-empty template with the same name. (In multiple calls to `Parse` with the same receiver template, only one call can contain text other than space, comments, and template definitions.)

func (*Template) [ParseFiles](#)

```
func (t *Template) ParseFiles(filenamees ...string) (*Template, error)
```

`ParseFiles` parses the named files and associates the resulting templates with `t`. If an error occurs, parsing stops and the returned template is `nil`; otherwise it is `t`. There must be at least one file.

func (*Template) [ParseGlob](#)

```
func (t *Template) ParseGlob(pattern string) (*Template, error)
```

`ParseGlob` parses the template definitions in the files identified by the pattern and associates the resulting templates with `t`. The pattern is processed by `filepath.Glob` and must match at least one file. `ParseGlob` is equivalent to calling `t.ParseFiles` with the list of files matched by the pattern.

func (*Template) [Templates](#)

```
func (t *Template) Templates() []*Template
```

`Templates` returns a slice of the templates associated with `t`, including `t` itself.

type [URL](#)

type URL string

URL encapsulates a known safe URL as defined in RFC 3896. A URL like ``javascript:checkThatFormNotEditedBeforeLeavingPage()`` from a trusted source should go in the page, but by default dynamic ``javascript:`` URLs are filtered out since they are a frequently exploited injection vector.

Build version go1.0.1.

Package image

```
import "image"
```

[Overview](#)

[Index](#)

[Examples](#)

[Subdirectories](#)

Overview ?

Overview ?

Package image implements a basic 2-D image library.

The fundamental interface is called Image. An Image contains colors, which are described in the image/color package.

Values of the Image interface are created either by calling functions such as NewRGBA and NewPaletted, or by calling Decode on an io.Reader containing image data in a format such as GIF, JPEG or PNG. Decoding any particular image format requires the prior registration of a decoder function. Registration is typically automatic as a side effect of initializing that format's package so that, to decode a PNG image, it suffices to have

```
import _ "image/png"
```

in a program's main package. The _ means to import a package purely for its initialization side effects.

See "The Go image package" for more details:

http://golang.org/doc/articles/image_package.html

? Example

? Example

Code:

```
// Open the file.
file, err := os.Open("testdata/video-001.jpeg")
if err != nil {
    log.Fatal(err)
}
defer file.Close()

// Decode the image.
m, _, err := image.Decode(file)
if err != nil {
    log.Fatal(err)
}
bounds := m.Bounds()
```

```

// Calculate a 16-bin histogram for m's red, green, blue and alpha c
//
// An image's bounds do not necessarily start at (0, 0), so the two
// at bounds.Min.Y and bounds.Min.X. Looping over Y first and X seco
// likely to result in better memory access patterns than X first an
var histogram [16][4]int
for y := bounds.Min.Y; y < bounds.Max.Y; y++ {
    for x := bounds.Min.X; x < bounds.Max.X; x++ {
        r, g, b, a := m.At(x, y).RGBA()
        // A color's RGBA method returns values in the range [0, 655
        // Shifting by 12 reduces this to the range [0, 15].
        histogram[r>>12][0]++
        histogram[g>>12][1]++
        histogram[b>>12][2]++
        histogram[a>>12][3]++
    }
}

// Print the results.
fmt.Printf("%-14s %6s %6s %6s %6s\n", "bin", "red", "green", "blue",
for i, x := range histogram {
    fmt.Printf("0x%04x-0x%04x: %6d %6d %6d %6d\n", i<<12, (i+1)<<12-
}

```

Output:

Examples

[Package](#)

Package files

[format.go](#) [geom.go](#) [image.go](#) [names.go](#) [ycbcr.go](#)

Variables

```
var (  
    // Black is an opaque black uniform image.  
    Black = NewUniform(color.Black)  
    // White is an opaque white uniform image.  
    White = NewUniform(color.White)  
    // Transparent is a fully transparent uniform image.  
    Transparent = NewUniform(color.Transparent)  
    // Opaque is a fully opaque uniform image.  
    Opaque = NewUniform(color.Opaque)  
)  
  
var ErrFormat = errors.New("image: unknown format")
```

ErrFormat indicates that decoding encountered an unknown format.

func RegisterFormat

```
func RegisterFormat(name, magic string, decode func(io.Reader) (Imag
```

RegisterFormat registers an image format for use by Decode. Name is the name of the format, like "jpeg" or "png". Magic is the magic prefix that identifies the format's encoding. The magic string can contain "?" wildcards that each match any one byte. Decode is the function that decodes the encoded image. DecodeConfig is the function that decodes just its configuration.

type [Alpha](#)

```
type Alpha struct {
    // Pix holds the image's pixels, as alpha values. The pixel at
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*1
    Pix []uint8
    // Stride is the Pix stride (in bytes) between vertically adjae
    Stride int
    // Rect is the image's bounds.
    Rect Rectangle
}
```

Alpha is an in-memory image whose `At` method returns `color.Alpha` values.

func [NewAlpha](#)

```
func NewAlpha(r Rectangle) *Alpha
```

`NewAlpha` returns a new `Alpha` with the given bounds.

func (*Alpha) [At](#)

```
func (p *Alpha) At(x, y int) color.Color
```

func (*Alpha) [Bounds](#)

```
func (p *Alpha) Bounds() Rectangle
```

func (*Alpha) [ColorModel](#)

```
func (p *Alpha) ColorModel() color.Model
```

func (*Alpha) [Opaque](#)

```
func (p *Alpha) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*Alpha) [PixOffset](#)

```
func (p *Alpha) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*Alpha) [Set](#)

```
func (p *Alpha) Set(x, y int, c color.Color)
```

func (*Alpha) [SetAlpha](#)

```
func (p *Alpha) SetAlpha(x, y int, c color.Alpha)
```

func (*Alpha) [SubImage](#)

```
func (p *Alpha) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Alpha16](#)

```
type Alpha16 struct {  
    // Pix holds the image's pixels, as alpha values in big-endian f  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*2  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adja  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

Alpha16 is an in-memory image whose `At` method returns `color.Alpha64` values.

func [NewAlpha16](#)

```
func NewAlpha16(r Rectangle) *Alpha16
```

`NewAlpha16` returns a new `Alpha16` with the given bounds.

func (*Alpha16) [At](#)

```
func (p *Alpha16) At(x, y int) color.Color
```

func (*Alpha16) [Bounds](#)

```
func (p *Alpha16) Bounds() Rectangle
```

func (*Alpha16) [ColorModel](#)

```
func (p *Alpha16) ColorModel() color.Model
```

func (*Alpha16) [Opaque](#)

```
func (p *Alpha16) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*Alpha16) [PixOffset](#)

```
func (p *Alpha16) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*Alpha16) [Set](#)

```
func (p *Alpha16) Set(x, y int, c color.Color)
```

func (*Alpha16) [SetAlpha16](#)

```
func (p *Alpha16) SetAlpha16(x, y int, c color.Alpha16)
```

func (*Alpha16) [SubImage](#)

```
func (p *Alpha16) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Config](#)

```
type Config struct {  
    ColorModel    color.Model  
    Width, Height int  
}
```

Config holds an image's color model and dimensions.

func [DecodeConfig](#)

```
func DecodeConfig(r io.Reader) (Config, string, error)
```

DecodeConfig decodes the color model and dimensions of an image that has been encoded in a registered format. The string returned is the format name used during format registration. Format registration is typically done by the init method of the codec-specific package.

type [Gray](#)

```
type Gray struct {
    // Pix holds the image's pixels, as gray values. The pixel at
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*1
    Pix []uint8
    // Stride is the Pix stride (in bytes) between vertically adjae
    Stride int
    // Rect is the image's bounds.
    Rect Rectangle
}
```

Gray is an in-memory image whose `At` method returns `color.Gray` values.

func [NewGray](#)

```
func NewGray(r Rectangle) *Gray
```

`NewGray` returns a new `Gray` with the given bounds.

func (***Gray**) [At](#)

```
func (p *Gray) At(x, y int) color.Color
```

func (***Gray**) [Bounds](#)

```
func (p *Gray) Bounds() Rectangle
```

func (***Gray**) [ColorModel](#)

```
func (p *Gray) ColorModel() color.Model
```

func (***Gray**) [Opaque](#)

```
func (p *Gray) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (***Gray**) [PixOffset](#)

```
func (p *Gray) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*Gray) [Set](#)

```
func (p *Gray) Set(x, y int, c color.Color)
```

func (*Gray) [SetGray](#)

```
func (p *Gray) SetGray(x, y int, c color.Gray)
```

func (*Gray) [SubImage](#)

```
func (p *Gray) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Gray16](#)

```
type Gray16 struct {  
    // Pix holds the image's pixels, as gray values in big-endian fo  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*2  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adja  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

Gray16 is an in-memory image whose `At` method returns `color.Gray16` values.

func [NewGray16](#)

```
func NewGray16(r Rectangle) *Gray16
```

`NewGray16` returns a new `Gray16` with the given bounds.

func (*Gray16) [At](#)

```
func (p *Gray16) At(x, y int) color.Color
```

func (*Gray16) [Bounds](#)

```
func (p *Gray16) Bounds() Rectangle
```

func (*Gray16) [ColorModel](#)

```
func (p *Gray16) ColorModel() color.Model
```

func (*Gray16) [Opaque](#)

```
func (p *Gray16) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*Gray16) [PixOffset](#)

```
func (p *Gray16) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*Gray16) [Set](#)

```
func (p *Gray16) Set(x, y int, c color.Color)
```

func (*Gray16) [SetGray16](#)

```
func (p *Gray16) SetGray16(x, y int, c color.Gray16)
```

func (*Gray16) [SubImage](#)

```
func (p *Gray16) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Image](#)

```
type Image interface {
    // ColorModel returns the Image's color model.
    ColorModel() color.Model
    // Bounds returns the domain for which At can return non-zero co
    // The bounds do not necessarily contain the point (0, 0).
    Bounds() Rectangle
    // At returns the color of the pixel at (x, y).
    // At(Bounds().Min.X, Bounds().Min.Y) returns the upper-left pix
    // At(Bounds().Max.X-1, Bounds().Max.Y-1) returns the lower-right
    At(x, y int) color.Color
}
```

Image is a finite rectangular grid of color.Color values taken from a color model.

func [Decode](#)

```
func Decode(r io.Reader) (Image, string, error)
```

Decode decodes an image that has been encoded in a registered format. The string returned is the format name used during format registration. Format registration is typically done by the init method of the codec- specific package.

type [NRGBA](#)

```
type NRGBA struct {  
    // Pix holds the image's pixels, in R, G, B, A order. The pixel  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*4  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adjae  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

NRGBA is an in-memory image whose `At` method returns `color.NRGBA` values.

func [NewNRGBA](#)

```
func NewNRGBA(r Rectangle) *NRGBA
```

`NewNRGBA` returns a new `NRGBA` with the given bounds.

func (*NRGBA) [At](#)

```
func (p *NRGBA) At(x, y int) color.Color
```

func (*NRGBA) [Bounds](#)

```
func (p *NRGBA) Bounds() Rectangle
```

func (*NRGBA) [ColorModel](#)

```
func (p *NRGBA) ColorModel() color.Model
```

func (*NRGBA) [Opaque](#)

```
func (p *NRGBA) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*NRGBA) [PixOffset](#)

```
func (p *NRGBA) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*NRGBA) [Set](#)

```
func (p *NRGBA) Set(x, y int, c color.Color)
```

func (*NRGBA) [SetNRGBA](#)

```
func (p *NRGBA) SetNRGBA(x, y int, c color.NRGBA)
```

func (*NRGBA) [SubImage](#)

```
func (p *NRGBA) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [NRGBA64](#)

```
type NRGBA64 struct {  
    // Pix holds the image's pixels, in R, G, B, A order and big-end  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*8  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adjace  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

NRGBA64 is an in-memory image whose `At` method returns `color.NRGBA64` values.

func [NewNRGBA64](#)

```
func NewNRGBA64(r Rectangle) *NRGBA64
```

`NewNRGBA64` returns a new `NRGBA64` with the given bounds.

func (***NRGBA64**) [At](#)

```
func (p *NRGBA64) At(x, y int) color.Color
```

func (***NRGBA64**) [Bounds](#)

```
func (p *NRGBA64) Bounds() Rectangle
```

func (***NRGBA64**) [ColorModel](#)

```
func (p *NRGBA64) ColorModel() color.Model
```

func (***NRGBA64**) [Opaque](#)

```
func (p *NRGBA64) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (***NRGBA64**) [PixOffset](#)

```
func (p *NRGBA64) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*NRGBA64) [Set](#)

```
func (p *NRGBA64) Set(x, y int, c color.Color)
```

func (*NRGBA64) [SetNRGBA64](#)

```
func (p *NRGBA64) SetNRGBA64(x, y int, c color.NRGBA64)
```

func (*NRGBA64) [SubImage](#)

```
func (p *NRGBA64) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Paletted](#)

```
type Paletted struct {  
    // Pix holds the image's pixels, as palette indices. The pixel a  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*1  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adja  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
    // Palette is the image's palette.  
    Palette color.Palette  
}
```

Paletted is an in-memory image of uint8 indices into a given palette.

func [NewPaletted](#)

```
func NewPaletted(r Rectangle, p color.Palette) *Paletted
```

NewPaletted returns a new Paletted with the given width, height and palette.

func (*Paletted) [At](#)

```
func (p *Paletted) At(x, y int) color.Color
```

func (*Paletted) [Bounds](#)

```
func (p *Paletted) Bounds() Rectangle
```

func (*Paletted) [ColorIndexAt](#)

```
func (p *Paletted) ColorIndexAt(x, y int) uint8
```

func (*Paletted) [ColorModel](#)

```
func (p *Paletted) ColorModel() color.Model
```

func (*Paletted) [Opaque](#)

```
func (p *Paletted) Opaque() bool
```

Opaque scans the entire image and returns whether or not it is fully opaque.

func (*Paletted) [PixOffset](#)

```
func (p *Paletted) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*Paletted) [Set](#)

```
func (p *Paletted) Set(x, y int, c color.Color)
```

func (*Paletted) [SetColorIndex](#)

```
func (p *Paletted) SetColorIndex(x, y int, index uint8)
```

func (*Paletted) [SubImage](#)

```
func (p *Paletted) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [PalettedImage](#)

```
type PalettedImage interface {  
    // ColorIndexAt returns the palette index of the pixel at (x, y)  
    ColorIndexAt(x, y int) uint8  
    Image  
}
```

PalettedImage is an image whose colors may come from a limited palette. If *m* is a PalettedImage and *m*.ColorModel() returns a PalettedColorModel *p*, then *m*.At(*x*, *y*) should be equivalent to *p*[*m*.ColorIndexAt(*x*, *y*)]. If *m*'s color model is not a PalettedColorModel, then ColorIndexAt's behavior is undefined.

type [Point](#)

```
type Point struct {  
    X, Y int  
}
```

A Point is an X, Y coordinate pair. The axes increase right and down.

```
var ZP Point
```

ZP is the zero Point.

func [Pt](#)

```
func Pt(X, Y int) Point
```

Pt is shorthand for Point{X, Y}.

func (Point) [Add](#)

```
func (p Point) Add(q Point) Point
```

Add returns the vector $p+q$.

func (Point) [Div](#)

```
func (p Point) Div(k int) Point
```

Div returns the vector p/k .

func (Point) [Eq](#)

```
func (p Point) Eq(q Point) bool
```

Eq returns whether p and q are equal.

func (Point) [In](#)

```
func (p Point) In(r Rectangle) bool
```

In returns whether p is in r.

func (Point) [Mod](#)

```
func (p Point) Mod(r Rectangle) Point
```

Mod returns the point q in r such that $p.X - q.X$ is a multiple of r's width and $p.Y - q.Y$ is a multiple of r's height.

func (Point) [Mul](#)

```
func (p Point) Mul(k int) Point
```

Mul returns the vector $p * k$.

func (Point) [String](#)

```
func (p Point) String() string
```

String returns a string representation of p like "(3,4)".

func (Point) [Sub](#)

```
func (p Point) Sub(q Point) Point
```

Sub returns the vector $p - q$.

type [RGBA](#)

```
type RGBA struct {  
    // Pix holds the image's pixels, in R, G, B, A order. The pixel  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*4  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adjae  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

RGBA is an in-memory image whose `At` method returns `color.RGBA` values.

func [NewRGBA](#)

```
func NewRGBA(r Rectangle) *RGBA
```

`NewRGBA` returns a new `RGBA` with the given bounds.

func (***RGBA**) [At](#)

```
func (p *RGBA) At(x, y int) color.Color
```

func (***RGBA**) [Bounds](#)

```
func (p *RGBA) Bounds() Rectangle
```

func (***RGBA**) [ColorModel](#)

```
func (p *RGBA) ColorModel() color.Model
```

func (***RGBA**) [Opaque](#)

```
func (p *RGBA) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (***RGBA**) [PixOffset](#)

```
func (p *RGBA) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*RGBA) [Set](#)

```
func (p *RGBA) Set(x, y int, c color.Color)
```

func (*RGBA) [SetRGBA](#)

```
func (p *RGBA) SetRGBA(x, y int, c color.RGBA)
```

func (*RGBA) [SubImage](#)

```
func (p *RGBA) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [RGBA64](#)

```
type RGBA64 struct {  
    // Pix holds the image's pixels, in R, G, B, A order and big-end  
    // (x, y) starts at Pix[(y-Rect.Min.Y)*Stride + (x-Rect.Min.X)*8  
    Pix []uint8  
    // Stride is the Pix stride (in bytes) between vertically adja  
    Stride int  
    // Rect is the image's bounds.  
    Rect Rectangle  
}
```

RGBA64 is an in-memory image whose `At` method returns `color.RGBA64` values.

func [NewRGBA64](#)

```
func NewRGBA64(r Rectangle) *RGBA64
```

`NewRGBA64` returns a new `RGBA64` with the given bounds.

func (*[RGBA64](#)) [At](#)

```
func (p *RGBA64) At(x, y int) color.Color
```

func (*[RGBA64](#)) [Bounds](#)

```
func (p *RGBA64) Bounds() Rectangle
```

func (*[RGBA64](#)) [ColorModel](#)

```
func (p *RGBA64) ColorModel() color.Model
```

func (*[RGBA64](#)) [Opaque](#)

```
func (p *RGBA64) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*[RGBA64](#)) [PixOffset](#)

```
func (p *RGBA64) PixOffset(x, y int) int
```

PixOffset returns the index of the first element of Pix that corresponds to the pixel at (x, y).

func (*RGBA64) [Set](#)

```
func (p *RGBA64) Set(x, y int, c color.Color)
```

func (*RGBA64) [SetRGBA64](#)

```
func (p *RGBA64) SetRGBA64(x, y int, c color.RGBA64)
```

func (*RGBA64) [SubImage](#)

```
func (p *RGBA64) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

type [Rectangle](#)

```
type Rectangle struct {  
    Min, Max Point  
}
```

A Rectangle contains the points with $\text{Min.X} \leq X < \text{Max.X}$, $\text{Min.Y} \leq Y < \text{Max.Y}$. It is well-formed if $\text{Min.X} \leq \text{Max.X}$ and likewise for Y. Points are always well-formed. A rectangle's methods always return well-formed outputs for well-formed inputs.

```
var ZR Rectangle
```

ZR is the zero Rectangle.

func [Rect](#)

```
func Rect(x0, y0, x1, y1 int) Rectangle
```

Rect is shorthand for `Rectangle{Pt(x0, y0), Pt(x1, y1)}`.

func (Rectangle) [Add](#)

```
func (r Rectangle) Add(p Point) Rectangle
```

Add returns the rectangle r translated by p.

func (Rectangle) [Canon](#)

```
func (r Rectangle) Canon() Rectangle
```

Canon returns the canonical version of r. The returned rectangle has minimum and maximum coordinates swapped if necessary so that it is well-formed.

func (Rectangle) [Dx](#)

```
func (r Rectangle) Dx() int
```

Dx returns r's width.

func (Rectangle) [Dy](#)

```
func (r Rectangle) Dy() int
```

Dy returns r's height.

func (Rectangle) [Empty](#)

```
func (r Rectangle) Empty() bool
```

Empty returns whether the rectangle contains no points.

func (Rectangle) [Eq](#)

```
func (r Rectangle) Eq(s Rectangle) bool
```

Eq returns whether r and s are equal.

func (Rectangle) [In](#)

```
func (r Rectangle) In(s Rectangle) bool
```

In returns whether every point in r is in s.

func (Rectangle) [Inset](#)

```
func (r Rectangle) Inset(n int) Rectangle
```

Inset returns the rectangle r inset by n, which may be negative. If either of r's dimensions is less than $2*n$ then an empty rectangle near the center of r will be returned.

func (Rectangle) [Intersect](#)

```
func (r Rectangle) Intersect(s Rectangle) Rectangle
```

Intersect returns the largest rectangle contained by both r and s. If the two rectangles do not overlap then the zero rectangle will be returned.

func (Rectangle) [Overlaps](#)

```
func (r Rectangle) Overlaps(s Rectangle) bool
```

Overlaps returns whether r and s have a non-empty intersection.

func (Rectangle) [Size](#)

```
func (r Rectangle) Size() Point
```

Size returns r's width and height.

func (Rectangle) [String](#)

```
func (r Rectangle) String() string
```

String returns a string representation of r like "(3,4)-(6,5)".

func (Rectangle) [Sub](#)

```
func (r Rectangle) Sub(p Point) Rectangle
```

Sub returns the rectangle r translated by -p.

func (Rectangle) [Union](#)

```
func (r Rectangle) Union(s Rectangle) Rectangle
```

Union returns the smallest rectangle that contains both r and s.

type [Uniform](#)

```
type Uniform struct {  
    C color.Color  
}
```

Uniform is an infinite-sized Image of uniform color. It implements the `color.Color`, `color.ColorModel`, and `Image` interfaces.

func [NewUniform](#)

```
func NewUniform(c color.Color) *Uniform
```

func (*Uniform) [At](#)

```
func (c *Uniform) At(x, y int) color.Color
```

func (*Uniform) [Bounds](#)

```
func (c *Uniform) Bounds() Rectangle
```

func (*Uniform) [ColorModel](#)

```
func (c *Uniform) ColorModel() color.Model
```

func (*Uniform) [Convert](#)

```
func (c *Uniform) Convert(color.Color) color.Color
```

func (*Uniform) [Opaque](#)

```
func (c *Uniform) Opaque() bool
```

`Opaque` scans the entire image and returns whether or not it is fully opaque.

func (*Uniform) [RGBA](#)

```
func (c *Uniform) RGBA() (r, g, b, a uint32)
```

type [YCbCr](#)

```
type YCbCr struct {
    Y, Cb, Cr    []uint8
    YStride      int
    CStride      int
    SubsampleRatio YCbCrSubsampleRatio
    Rect         Rectangle
}
```

YCbCr is an in-memory image of Y'CbCr colors. There is one Y sample per pixel, but each Cb and Cr sample can span one or more pixels. YStride is the Y slice index delta between vertically adjacent pixels. CStride is the Cb and Cr slice index delta between vertically adjacent pixels that map to separate chroma samples. It is not an absolute requirement, but YStride and len(Y) are typically multiples of 8, and:

```
For 4:4:4, CStride == YStride/1 && len(Cb) == len(Cr) == len(Y)/1.
For 4:2:2, CStride == YStride/2 && len(Cb) == len(Cr) == len(Y)/2.
For 4:2:0, CStride == YStride/2 && len(Cb) == len(Cr) == len(Y)/4.
```

func [NewYCbCr](#)

```
func NewYCbCr(r Rectangle, subsampleRatio YCbCrSubsampleRatio) *YCbCr
```

NewYCbCr returns a new YCbCr with the given bounds and subsample ratio.

func (*YCbCr) [At](#)

```
func (p *YCbCr) At(x, y int) color.Color
```

func (*YCbCr) [Bounds](#)

```
func (p *YCbCr) Bounds() Rectangle
```

func (*YCbCr) [COffset](#)

```
func (p *YCbCr) COffset(x, y int) int
```

COffset returns the index of the first element of Cb or Cr that corresponds to the

pixel at (x, y).

func (*YCbCr) [ColorModel](#)

```
func (p *YCbCr) ColorModel() color.Model
```

func (*YCbCr) [Opaque](#)

```
func (p *YCbCr) Opaque() bool
```

func (*YCbCr) [SubImage](#)

```
func (p *YCbCr) SubImage(r Rectangle) Image
```

SubImage returns an image representing the portion of the image p visible through r. The returned value shares pixels with the original image.

func (*YCbCr) [YOffset](#)

```
func (p *YCbCr) YOffset(x, y int) int
```

YOffset returns the index of the first element of Y that corresponds to the pixel at (x, y).

type [YCbCrSubsampleRatio](#)

```
type YCbCrSubsampleRatio int
```

YCbCrSubsampleRatio is the chroma subsample ratio used in a YCbCr image.

```
const (  
    YCbCrSubsampleRatio444 YCbCrSubsampleRatio = iota  
    YCbCrSubsampleRatio422  
    YCbCrSubsampleRatio420  
)
```

func (YCbCrSubsampleRatio) [String](#)

```
func (s YCbCrSubsampleRatio) String() string
```

[color.go](#) [ycbcr.go](#)

Variables

```
var (  
    Black      = Gray16{0}  
    White      = Gray16{0xffff}  
    Transparent = Alpha16{0}  
    Opaque     = Alpha16{0xffff}  
)
```

Standard colors.

func [RGBToYCbCr](#)

```
func RGBToYCbCr(r, g, b uint8) (uint8, uint8, uint8)
```

RGBToYCbCr converts an RGB triple to a Y'CbCr triple.

func YCbCrToRGB

```
func YCbCrToRGB(y, cb, cr uint8) (uint8, uint8, uint8)
```

YCbCrToRGB converts a Y'CbCr triple to an RGB triple.

type [Alpha](#)

```
type Alpha struct {  
    A uint8  
}
```

Alpha represents an 8-bit alpha color.

func (Alpha) [RGBA](#)

```
func (c Alpha) RGBA() (r, g, b, a uint32)
```

type [Alpha16](#)

```
type Alpha16 struct {  
    A uint16  
}
```

Alpha16 represents a 16-bit alpha color.

func (Alpha16) [RGBA](#)

```
func (c Alpha16) RGBA() (r, g, b, a uint32)
```

type [Color](#)

```
type Color interface {
    // RGBA returns the alpha-premultiplied red, green, blue and alp
    // for the color. Each value ranges within [0, 0xFFFF], but is r
    // by a uint32 so that multiplying by a blend factor up to 0xFFF
    // overflow.
    RGBA() (r, g, b, a uint32)
}
```

Color can convert itself to alpha-premultiplied 16-bits per channel RGBA. The conversion may be lossy.

type [Gray](#)

```
type Gray struct {  
    Y uint8  
}
```

Gray represents an 8-bit grayscale color.

func (Gray) [RGBA](#)

```
func (c Gray) RGBA() (r, g, b, a uint32)
```

type [Gray16](#)

```
type Gray16 struct {  
    Y uint16  
}
```

Gray16 represents a 16-bit grayscale color.

func (Gray16) [RGBA](#)

```
func (c Gray16) RGBA() (r, g, b, a uint32)
```

type [Model](#)

```
type Model interface {  
    Convert(c Color) Color  
}
```

Model can convert any Color to one from its own color model. The conversion may be lossy.

```
var (  
    RGBAModel    Model = ModelFunc(rgbaModel)  
    RGBA64Model  Model = ModelFunc(rgba64Model)  
    NRGBAModel   Model = ModelFunc(nrgbaModel)  
    NRGBA64Model Model = ModelFunc(nrgba64Model)  
    AlphaModel    Model = ModelFunc(alphaModel)  
    Alpha16Model  Model = ModelFunc(alpha16Model)  
    GrayModel     Model = ModelFunc(grayModel)  
    Gray16Model   Model = ModelFunc(gray16Model)  
)
```

Models for the standard color types.

```
var YCbCrModel Model = ModelFunc(yCbCrModel)
```

YCbCrModel is the Model for Y'CbCr colors.

func [ModelFunc](#)

```
func ModelFunc(f func(Color) Color) Model
```

ModelFunc returns a Model that invokes f to implement the conversion.

type [NRGBA](#)

```
type NRGBA struct {  
    R, G, B, A uint8  
}
```

NRGBA represents a non-alpha-premultiplied 32-bit color.

func (NRGBA) [RGBA](#)

```
func (c NRGBA) RGBA() (r, g, b, a uint32)
```

type [NRGBA64](#)

```
type NRGBA64 struct {  
    R, G, B, A uint16  
}
```

NRGBA64 represents a non-alpha-premultiplied 64-bit color, having 16 bits for each of red, green, blue and alpha.

func (NRGBA64) [RGBA](#)

```
func (c NRGBA64) RGBA() (r, g, b, a uint32)
```

type [Palette](#)

```
type Palette []Color
```

Palette is a palette of colors.

func (Palette) [Convert](#)

```
func (p Palette) Convert(c Color) Color
```

Convert returns the palette color closest to c in Euclidean R,G,B space.

func (Palette) [Index](#)

```
func (p Palette) Index(c Color) int
```

Index returns the index of the palette color closest to c in Euclidean R,G,B space.

type [RGBA](#)

```
type RGBA struct {  
    R, G, B, A uint8  
}
```

RGBA represents a traditional 32-bit alpha-premultiplied color, having 8 bits for each of red, green, blue and alpha.

func (RGBA) [RGBA](#)

```
func (c RGBA) RGBA() (r, g, b, a uint32)
```

type [RGBA64](#)

```
type RGBA64 struct {  
    R, G, B, A uint16  
}
```

RGBA64 represents a 64-bit alpha-premultiplied color, having 16 bits for each of red, green, blue and alpha.

func (RGBA64) [RGBA](#)

```
func (c RGBA64) RGBA() (r, g, b, a uint32)
```

type [YCbCr](#)

```
type YCbCr struct {  
    Y, Cb, Cr uint8  
}
```

YCbCr represents a fully opaque 24-bit Y'CbCr color, having 8 bits each for one luma and two chroma components.

JPEG, VP8, the MPEG family and other codecs use this color model. Such codecs often use the terms YUV and Y'CbCr interchangeably, but strictly speaking, the term YUV applies only to analog video signals, and Y' (luma) is Y (luminance) after applying gamma correction.

Conversion between RGB and Y'CbCr is lossy and there are multiple, slightly different formulae for converting between the two. This package follows the JFIF specification at <http://www.w3.org/Graphics/JPEG/jfif3.pdf>.

func (YCbCr) [RGBA](#)

```
func (c YCbCr) RGBA() (uint32, uint32, uint32, uint32)
```

Build version go1.0.1.

Package draw

```
import "image/draw"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package draw provides image composition functions.

See "The Go image/draw package" for an introduction to this package:
http://golang.org/doc/articles/image_draw.html

Index

[func Draw\(dst Image, r image.Rectangle, src image.Image, sp image.Point, op Op\)](#)

[func DrawMask\(dst Image, r image.Rectangle, src image.Image, sp image.Point, mask image.Image, mp image.Point, op Op\)](#)

[type Image](#)

[type Op](#)

Package files

[draw.go](#)

func [Draw](#)

```
func Draw(dst Image, r image.Rectangle, src image.Image, sp image.Po
```

Draw calls DrawMask with a nil mask.

func DrawMask

```
func DrawMask(dst Image, r image.Rectangle, src image.Image, sp imag
```

DrawMask aligns r.Min in dst with sp in src and mp in mask and then replaces the rectangle r in dst with the result of a Porter-Duff composition. A nil mask is treated as opaque.

type Image

```
type Image interface {  
    image.Image  
    Set(x, y int, c color.Color)  
}
```

A `draw.Image` is an `image.Image` with a `Set` method to change a single pixel.

type [Op](#)

```
type Op int
```

Op is a Porter-Duff compositing operator.

```
const (  
    // Over specifies ``(src in mask) over dst''.  
    Over Op = iota  
    // Src specifies ``src in mask''.  
    Src  
)
```

Build version go1.0.1.

Package gif

```
import "image/gif"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package gif implements a GIF image decoder.

The GIF specification is at <http://www.w3.org/Graphics/GIF/spec-gif89a.txt>.

Index

[func Decode\(r io.Reader\) \(image.Image, error\)](#)
[func DecodeConfig\(r io.Reader\) \(image.Config, error\)](#)
[type GIF](#)
[func DecodeAll\(r io.Reader\) \(*GIF, error\)](#)

Package files

[reader.go](#)

func Decode

```
func Decode(r io.Reader) (image.Image, error)
```

Decode reads a GIF image from r and returns the first embedded image as an image.Image.

func [DecodeConfig](#)

```
func DecodeConfig(r io.Reader) (image.Config, error)
```

DecodeConfig returns the global color model and dimensions of a GIF image without decoding the entire image.

type [GIF](#)

```
type GIF struct {
    Image      []*image.Paletted // The successive images.
    Delay      []int           // The successive delay times, one p
    LoopCount  int             // The loop count.
}
```

GIF represents the possibly multiple images stored in a GIF file.

func [DecodeAll](#)

```
func DecodeAll(r io.Reader) (*GIF, error)
```

DecodeAll reads a GIF image from r and returns the sequential frames and timing information.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package jpeg

```
import "image/jpeg"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package jpeg implements a JPEG image decoder and encoder.

JPEG is defined in ITU-T T.81: <http://www.w3.org/Graphics/JPEG/itu-t81.pdf>.

Index

Constants

[func Decode\(r io.Reader\) \(image.Image, error\)](#)

[func DecodeConfig\(r io.Reader\) \(image.Config, error\)](#)

[func Encode\(w io.Writer, m image.Image, o *Options\) error](#)

[type FormatError](#)

[func \(e FormatError\) Error\(\) string](#)

[type Options](#)

[type UnsupportedError](#)

[func \(e UnsupportedError\) Error\(\) string](#)

Package files

[fdct.go](#) [huffman.go](#) [idct.go](#) [reader.go](#) [writer.go](#)

Constants

```
const DefaultQuality = 75
```

DefaultQuality is the default quality encoding parameter.

func [Decode](#)

```
func Decode(r io.Reader) (image.Image, error)
```

Decode reads a JPEG image from r and returns it as an image.Image.

func [DecodeConfig](#)

```
func DecodeConfig(r io.Reader) (image.Config, error)
```

DecodeConfig returns the color model and dimensions of a JPEG image without decoding the entire image.

func [Encode](#)

```
func Encode(w io.Writer, m image.Image, o *Options) error
```

Encode writes the Image m to w in JPEG 4:2:0 baseline format with the given options. Default parameters are used if a nil *Options is passed.

type [FormatError](#)

```
type FormatError string
```

A FormatError reports that the input is not a valid JPEG.

func (FormatError) [Error](#)

```
func (e FormatError) Error() string
```

type Options

```
type Options struct {  
    Quality int  
}
```

Options are the encoding parameters. Quality ranges from 1 to 100 inclusive, higher is better.

type Reader

```
type Reader interface {  
    io.Reader  
    ReadByte() (c byte, err error)  
}
```

If the passed in `io.Reader` does not also have `ReadByte`, then `Decode` will introduce its own buffering.

type [UnsupportedError](#)

```
type UnsupportedError string
```

An UnsupportedError reports that the input uses a valid but unimplemented JPEG feature.

func (UnsupportedError) [Error](#)

```
func (e UnsupportedError) Error() string
```

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).

 [func \(e FormatError\) Error\(\) string](#)
[type UnsupportedError](#)
 [func \(e UnsupportedError\) Error\(\) string](#)

Package files

[reader.go](#) [writer.go](#)

func [Decode](#)

```
func Decode(r io.Reader) (image.Image, error)
```

Decode reads a PNG image from `r` and returns it as an `image.Image`. The type of `Image` returned depends on the PNG contents.

func [DecodeConfig](#)

```
func DecodeConfig(r io.Reader) (image.Config, error)
```

DecodeConfig returns the color model and dimensions of a PNG image without decoding the entire image.

func [Encode](#)

```
func Encode(w io.Writer, m image.Image) error
```

Encode writes the Image m to w in PNG format. Any Image may be encoded, but images that are not image.NRGBA might be encoded lossily.

type [FormatError](#)

```
type FormatError string
```

A FormatError reports that the input is not a valid PNG.

func (FormatError) [Error](#)

```
func (e FormatError) Error() string
```

type [UnsupportedError](#)

```
type UnsupportedError string
```

An `UnsupportedError` reports that the input uses a valid but unimplemented PNG feature.

func (UnsupportedError) [Error](#)

```
func (e UnsupportedError) Error() string
```

Package suffixarray

```
import "index/suffixarray"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `suffixarray` implements substring search in logarithmic time using an in-memory suffix array.

Example use:

```
// create index for some data
index := suffixarray.New(data)

// lookup byte slice s
offsets1 := index.Lookup(s, -1) // the list of all indices where s occurs
offsets2 := index.Lookup(s, 3)  // the list of at most 3 indices where s occurs
```

Index

[type Index](#)

[func New\(data \[\]byte\) *Index](#)

[func \(x *Index\) Bytes\(\) \[\]byte](#)

[func \(x *Index\) FindAllIndex\(r *regexp.Regexp, n int\) \(result \[\]\[\]int\)](#)

[func \(x *Index\) Lookup\(s \[\]byte, n int\) \(result \[\]int\)](#)

[func \(x *Index\) Read\(r io.Reader\) error](#)

[func \(x *Index\) Write\(w io.Writer\) error](#)

Package files

[qsufsort.go](#) [suffixarray.go](#)

type [Index](#)

```
type Index struct {  
    // contains filtered or unexported fields  
}
```

Index implements a suffix array for fast substring search.

func [New](#)

```
func New(data []byte) *Index
```

New creates a new Index for data. Index creation time is $O(N \cdot \log(N))$ for $N = \text{len}(\text{data})$.

func (*Index) [Bytes](#)

```
func (x *Index) Bytes() []byte
```

Bytes returns the data over which the index was created. It must not be modified.

func (*Index) [FindAllIndex](#)

```
func (x *Index) FindAllIndex(r *regexp.Regexp, n int) (result [][]int)
```

FindAllIndex returns a sorted list of non-overlapping matches of the regular expression r , where a match is a pair of indices specifying the matched slice of $x.\text{Bytes}()$. If $n < 0$, all matches are returned in successive order. Otherwise, at most n matches are returned and they may not be successive. The result is nil if there are no matches, or if $n == 0$.

func (*Index) [Lookup](#)

```
func (x *Index) Lookup(s []byte, n int) (result []int)
```

Lookup returns an unsorted list of at most n indices where the byte string s occurs in the indexed data. If $n < 0$, all occurrences are returned. The result is nil if s is empty, s is not found, or $n == 0$. Lookup time is $O(\log(N) \cdot \text{len}(s) + \text{len}(\text{result}))$ where N is the size of the indexed data.

func (*Index) [Read](#)

```
func (x *Index) Read(r io.Reader) error
```

Read reads the index from r into x; x must not be nil.

func (*Index) [Write](#)

```
func (x *Index) Write(w io.Writer) error
```

Write writes the index x to w.

Build version go1.0.1.

Package io

```
import "io"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `io` provides basic interfaces to I/O primitives. Its primary job is to wrap existing implementations of such primitives, such as those in package `os`, into shared public interfaces that abstract the functionality, plus some other related primitives.

Because these interfaces and primitives wrap lower-level operations with various implementations, unless otherwise informed clients should not assume they are safe for parallel execution.

[type WriterTo](#)

Package files

[io.go](#) [multi.go](#) [pipe.go](#)

Variables

```
var EOF = errors.New("EOF")
```

EOF is the error returned by Read when no more input is available. Functions should return EOF only to signal a graceful end of input. If the EOF occurs unexpectedly in a structured data stream, the appropriate error is either ErrUnexpectedEOF or some other error giving more detail.

```
var ErrClosedPipe = errors.New("io: read/write on closed pipe")
```

ErrClosedPipe is the error used for read or write operations on a closed pipe.

```
var ErrShortBuffer = errors.New("short buffer")
```

ErrShortBuffer means that a read required a longer buffer than was provided.

```
var ErrShortWrite = errors.New("short write")
```

ErrShortWrite means that a write accepted fewer bytes than requested but failed to return an explicit error.

```
var ErrUnexpectedEOF = errors.New("unexpected EOF")
```

ErrUnexpectedEOF means that EOF was encountered in the middle of reading a fixed-size block or data structure.

func Copy

```
func Copy(dst Writer, src Reader) (written int64, err error)
```

Copy copies from src to dst until either EOF is reached on src or an error occurs. It returns the number of bytes copied and the first error encountered while copying, if any.

A successful Copy returns `err == nil`, not `err == EOF`. Because Copy is defined to read from src until EOF, it does not treat an EOF from Read as an error to be reported.

If dst implements the ReaderFrom interface, the copy is implemented by calling `dst.ReadFrom(src)`. Otherwise, if src implements the WriterTo interface, the copy is implemented by calling `src.WriteTo(dst)`.

func CopyN

`func CopyN(dst Writer, src Reader, n int64) (written int64, err error)`

CopyN copies n bytes (or until an error) from src to dst. It returns the number of bytes copied and the earliest error encountered while copying. Because Read can return the full amount requested as well as an error (including EOF), so can CopyN.

If dst implements the ReaderFrom interface, the copy is implemented using it.

func ReadAtLeast

```
func ReadAtLeast(r Reader, buf []byte, min int) (n int, err error)
```

ReadAtLeast reads from r into buf until it has read at least min bytes. It returns the number of bytes copied and an error if fewer bytes were read. The error is EOF only if no bytes were read. If an EOF happens after reading fewer than min bytes, ReadAtLeast returns ErrUnexpectedEOF. If min is greater than the length of buf, ReadAtLeast returns ErrShortBuffer.

func ReadFull

```
func ReadFull(r Reader, buf []byte) (n int, err error)
```

ReadFull reads exactly len(buf) bytes from r into buf. It returns the number of bytes copied and an error if fewer bytes were read. The error is EOF only if no bytes were read. If an EOF happens after reading some but not all the bytes, ReadFull returns ErrUnexpectedEOF.

func [WriteString](#)

```
func WriteString(w Writer, s string) (n int, err error)
```

WriteString writes the contents of the string `s` to `w`, which accepts an array of bytes. If `w` already implements a `WriteString` method, it is invoked directly.

type ByteReader

```
type ByteReader interface {  
    ReadByte() (c byte, err error)  
}
```

ByteReader is the interface that wraps the ReadByte method.

ReadByte reads and returns the next byte from the input. If no byte is available, err will be set.

type ByteScanner

```
type ByteScanner interface {  
    ByteReader  
    UnreadByte() error  
}
```

ByteScanner is the interface that adds the UnreadByte method to the basic ReadByte method.

UnreadByte causes the next call to ReadByte to return the same byte as the previous call to ReadByte. It may be an error to call UnreadByte twice without an intervening call to ReadByte.

type [Closer](#)

```
type Closer interface {  
    Close() error  
}
```

Closer is the interface that wraps the basic Close method.

type [LimitedReader](#)

```
type LimitedReader struct {  
    R Reader // underlying reader  
    N int64  // max bytes remaining  
}
```

A `LimitedReader` reads from `R` but limits the amount of data returned to just `N` bytes. Each call to `Read` updates `N` to reflect the new amount remaining.

func (***LimitedReader**) [Read](#)

```
func (l *LimitedReader) Read(p []byte) (n int, err error)
```

type [PipeReader](#)

```
type PipeReader struct {  
    // contains filtered or unexported fields  
}
```

A PipeReader is the read half of a pipe.

func [Pipe](#)

```
func Pipe() (*PipeReader, *PipeWriter)
```

Pipe creates a synchronous in-memory pipe. It can be used to connect code expecting an io.Reader with code expecting an io.Writer. Reads on one end are matched with writes on the other, copying data directly between the two; there is no internal buffering. It is safe to call Read and Write in parallel with each other or with Close. Close will complete once pending I/O is done. Parallel calls to Read, and parallel calls to Write, are also safe: the individual calls will be gated sequentially.

func (*PipeReader) [Close](#)

```
func (r *PipeReader) Close() error
```

Close closes the reader; subsequent writes to the write half of the pipe will return the error ErrClosedPipe.

func (*PipeReader) [CloseWithError](#)

```
func (r *PipeReader) CloseWithError(err error) error
```

CloseWithError closes the reader; subsequent writes to the write half of the pipe will return the error err.

func (*PipeReader) [Read](#)

```
func (r *PipeReader) Read(data []byte) (n int, err error)
```

Read implements the standard Read interface: it reads data from the pipe,

blocking until a writer arrives or the write end is closed. If the write end is closed with an error, that error is returned as err; otherwise err is EOF.

type [PipeWriter](#)

```
type PipeWriter struct {  
    // contains filtered or unexported fields  
}
```

A PipeWriter is the write half of a pipe.

func (*PipeWriter) [Close](#)

```
func (w *PipeWriter) Close() error
```

Close closes the writer; subsequent reads from the read half of the pipe will return no bytes and EOF.

func (*PipeWriter) [CloseWithError](#)

```
func (w *PipeWriter) CloseWithError(err error) error
```

CloseWithError closes the writer; subsequent reads from the read half of the pipe will return no bytes and the error err.

func (*PipeWriter) [Write](#)

```
func (w *PipeWriter) Write(data []byte) (n int, err error)
```

Write implements the standard Write interface: it writes data to the pipe, blocking until readers have consumed all the data or the read end is closed. If the read end is closed with an error, that err is returned as err; otherwise err is ErrClosedPipe.

type [ReadCloser](#)

```
type ReadCloser interface {  
    Reader  
    Closer  
}
```

ReadCloser is the interface that groups the basic Read and Close methods.

type [ReadSeeker](#)

```
type ReadSeeker interface {  
    Reader  
    Seeker  
}
```

ReadSeeker is the interface that groups the basic Read and Seek methods.

type [ReadWriteCloser](#)

```
type ReadWriteCloser interface {  
    Reader  
    Writer  
    Closer  
}
```

ReadWriteCloser is the interface that groups the basic Read, Write and Close methods.

type [ReadWriteSeeker](#)

```
type ReadWriteSeeker interface {  
    Reader  
    Writer  
    Seeker  
}
```

ReadWriteSeeker is the interface that groups the basic Read, Write and Seek methods.

type ReadWrite

```
type ReadWriter interface {  
    Reader  
    Writer  
}
```

ReadWrite is the interface that groups the basic Read and Write methods.

type [Reader](#)

```
type Reader interface {  
    Read(p []byte) (n int, err error)  
}
```

Reader is the interface that wraps the basic Read method.

Read reads up to len(p) bytes into p. It returns the number of bytes read (0 ≤ n ≤ len(p)) and any error encountered. Even if Read returns n < len(p), it may use all of p as scratch space during the call. If some data is available but not len(p) bytes, Read conventionally returns what is available instead of waiting for more.

When Read encounters an error or end-of-file condition after successfully reading n > 0 bytes, it returns the number of bytes read. It may return the (non-nil) error from the same call or return the error (and n == 0) from a subsequent call. An instance of this general case is that a Reader returning a non-zero number of bytes at the end of the input stream may return either err == EOF or err == nil. The next Read should return 0, EOF regardless.

Callers should always process the n > 0 bytes returned before considering the error err. Doing so correctly handles I/O errors that happen after reading some bytes and also both of the allowed EOF behaviors.

func [LimitReader](#)

```
func LimitReader(r Reader, n int64) Reader
```

LimitReader returns a Reader that reads from r but stops with EOF after n bytes. The underlying implementation is a *LimitedReader.

func [MultiReader](#)

```
func MultiReader(readers ...Reader) Reader
```

MultiReader returns a Reader that's the logical concatenation of the provided input readers. They're read sequentially. Once all inputs are drained, Read will return EOF.

func [TeeReader](#)

```
func TeeReader(r Reader, w Writer) Reader
```

TeeReader returns a Reader that writes to w what it reads from r. All reads from r performed through it are matched with corresponding writes to w. There is no internal buffering - the write must complete before the read completes. Any error encountered while writing is reported as a read error.

type [ReaderAt](#)

```
type ReaderAt interface {  
    ReadAt(p []byte, off int64) (n int, err error)  
}
```

ReaderAt is the interface that wraps the basic ReadAt method.

ReadAt reads len(p) bytes into p starting at offset off in the underlying input source. It returns the number of bytes read ($0 \leq n \leq \text{len}(p)$) and any error encountered.

When ReadAt returns $n < \text{len}(p)$, it returns a non-nil error explaining why more bytes were not returned. In this respect, ReadAt is stricter than Read.

Even if ReadAt returns $n < \text{len}(p)$, it may use all of p as scratch space during the call. If some data is available but not len(p) bytes, ReadAt blocks until either all the data is available or an error occurs. In this respect ReadAt is different from Read.

If the $n = \text{len}(p)$ bytes returned by ReadAt are at the end of the input source, ReadAt may return either `err == EOF` or `err == nil`.

If ReadAt is reading from an input source with a seek offset, ReadAt should not affect nor be affected by the underlying seek offset.

Clients of ReadAt can execute parallel ReadAt calls on the same input source.

type [ReaderFrom](#)

```
type ReaderFrom interface {  
    ReadFrom(r Reader) (n int64, err error)  
}
```

ReaderFrom is the interface that wraps the ReadFrom method.

type [RuneReader](#)

```
type RuneReader interface {  
    ReadRune() (r rune, size int, err error)  
}
```

RuneReader is the interface that wraps the ReadRune method.

ReadRune reads a single UTF-8 encoded Unicode character and returns the rune and its size in bytes. If no character is available, err will be set.

type [RuneScanner](#)

```
type RuneScanner interface {  
    RuneReader  
    UnreadRune() error  
}
```

RuneScanner is the interface that adds the UnreadRune method to the basic RuneReader method.

UnreadRune causes the next call to RuneReader to return the same rune as the previous call to RuneReader. It may be an error to call UnreadRune twice without an intervening call to RuneReader.

type [SectionReader](#)

```
type SectionReader struct {  
    // contains filtered or unexported fields  
}
```

SectionReader implements Read, Seek, and ReadAt on a section of an underlying ReaderAt.

func [NewSectionReader](#)

```
func NewSectionReader(r ReaderAt, off int64, n int64) *SectionReader
```

NewSectionReader returns a SectionReader that reads from r starting at offset off and stops with EOF after n bytes.

func (***SectionReader**) [Read](#)

```
func (s *SectionReader) Read(p []byte) (n int, err error)
```

func (***SectionReader**) [ReadAt](#)

```
func (s *SectionReader) ReadAt(p []byte, off int64) (n int, err error)
```

func (***SectionReader**) [Seek](#)

```
func (s *SectionReader) Seek(offset int64, whence int) (ret int64, err error)
```

func (***SectionReader**) [Size](#)

```
func (s *SectionReader) Size() int64
```

Size returns the size of the section in bytes.

type [Seeker](#)

```
type Seeker interface {  
    Seek(offset int64, whence int) (ret int64, err error)  
}
```

Seeker is the interface that wraps the basic Seek method.

Seek sets the offset for the next Read or Write to offset, interpreted according to whence: 0 means relative to the origin of the file, 1 means relative to the current offset, and 2 means relative to the end. Seek returns the new offset and an Error, if any.

type [WriteCloser](#)

```
type WriteCloser interface {  
    Writer  
    Closer  
}
```

WriteCloser is the interface that groups the basic Write and Close methods.

type [WriteSeeker](#)

```
type WriteSeeker interface {  
    Writer  
    Seeker  
}
```

WriteSeeker is the interface that groups the basic Write and Seek methods.

type [Writer](#)

```
type Writer interface {  
    Write(p []byte) (n int, err error)  
}
```

Writer is the interface that wraps the basic Write method.

Write writes len(p) bytes from p to the underlying data stream. It returns the number of bytes written from p (0 ≤ n ≤ len(p)) and any error encountered that caused the write to stop early. Write must return a non-nil error if it returns n < len(p).

func [MultiWriter](#)

```
func MultiWriter(writers ...Writer) Writer
```

MultiWriter creates a writer that duplicates its writes to all the provided writers, similar to the Unix tee(1) command.

type [WriterAt](#)

```
type WriterAt interface {  
    WriteAt(p []byte, off int64) (n int, err error)  
}
```

WriterAt is the interface that wraps the basic WriteAt method.

WriteAt writes len(p) bytes from p to the underlying data stream at offset off. It returns the number of bytes written from p (0 ≤ n ≤ len(p)) and any error encountered that caused the write to stop early. WriteAt must return a non-nil error if it returns n < len(p).

If WriteAt is writing to a destination with a seek offset, WriteAt should not affect nor be affected by the underlying seek offset.

Clients of WriteAt can execute parallel WriteAt calls on the same destination if the ranges do not overlap.

type [WriterTo](#)

```
type WriterTo interface {  
    WriteTo(w Writer) (n int64, err error)  
}
```

WriterTo is the interface that wraps the WriteTo method.

[func TempFile\(dir, prefix string\) \(f *os.File, err error\)](#)

[func WriteFile\(filename string, data \[\]byte, perm os.FileMode\) error](#)

Package files

[ioutil.go](#) [tempfile.go](#)

Variables

```
var Discard io.Writer = devNull(0)
```

Discard is an `io.Writer` on which all `Write` calls succeed without doing anything.

func [NopCloser](#)

```
func NopCloser(r io.Reader) io.ReadCloser
```

NopCloser returns a ReadCloser with a no-op Close method wrapping the provided Reader r.

func [ReadAll](#)

```
func ReadAll(r io.Reader) ([]byte, error)
```

ReadAll reads from r until an error or EOF and returns the data it read. A successful call returns err == nil, not err == EOF. Because ReadAll is defined to read from src until EOF, it does not treat an EOF from Read as an error to be reported.

func [ReadDir](#)

```
func ReadDir(dirname string) ([]os.FileInfo, error)
```

ReadDir reads the directory named by dirname and returns a list of sorted directory entries.

func ReadFile

```
func ReadFile(filename string) ([]byte, error)
```

ReadFile reads the file named by filename and returns the contents. A successful call returns `err == nil`, not `err == EOF`. Because ReadFile reads the whole file, it does not treat an EOF from Read as an error to be reported.

func [TempDir](#)

```
func TempDir(dir, prefix string) (name string, err error)
```

TempDir creates a new temporary directory in the directory `dir` with a name beginning with `prefix` and returns the path of the new directory. If `dir` is the empty string, TempDir uses the default directory for temporary files (see `os.TempDir`). Multiple programs calling TempDir simultaneously will not choose the same directory. It is the caller's responsibility to remove the directory when no longer needed.

func [TempFile](#)

```
func TempFile(dir, prefix string) (f *os.File, err error)
```

TempFile creates a new temporary file in the directory dir with a name beginning with prefix, opens the file for reading and writing, and returns the resulting *os.File. If dir is the empty string, TempFile uses the default directory for temporary files (see os.TempDir). Multiple programs calling TempFile simultaneously will not choose the same file. The caller can use f.Name() to find the name of the file. It is the caller's responsibility to remove the file when no longer needed.

func [WriteFile](#)

```
func WriteFile(filename string, data []byte, perm os.FileMode) error
```

WriteFile writes data to a file named by filename. If the file does not exist, WriteFile creates it with permissions perm; otherwise WriteFile truncates it before writing.

Build version go1.0.1.

Package log

```
import "log"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `log` implements a simple logging package. It defines a type, `Logger`, with methods for formatting output. It also has a predefined 'standard' `Logger` accessible through helper functions `Print[f|ln]`, `Fatal[f|ln]`, and `Panic[f|ln]`, which are easier to use than creating a `Logger` manually. That logger writes to standard error and prints the date and time of each logged message. The `Fatal` functions call `os.Exit(1)` after writing the log message. The `Panic` functions call `panic` after writing the log message.

Constants

```
const (  
    // Bits or'ed together to control what's printed. There is no co  
    // order they appear (the order listed here) or the format they  
    // described in the comments). A colon appears after these item  
    // 2009/0123 01:23:23.123123 /a/b/c/d.go:23: message  
    Ldate          = 1 << iota    // the date: 2009/01/23  
    Ltime          // the time: 01:23:23  
    Lmicroseconds  // microsecond resolution: 01:23:2  
    Llongfile      // full file name and line number:  
    Lshortfile     // final file name element and lin  
    LstdFlags      = Ldate | Ltime // initial values for the standard  
)
```

These flags define which text to prefix to each log entry generated by the
Logger.

func Fatal

```
func Fatal(v ...interface{})
```

Fatal is equivalent to Print() followed by a call to os.Exit(1).

func [Fatalf](#)

```
func Fatalf(format string, v ...interface{})
```

Fataf is equivalent to Printf() followed by a call to os.Exit(1).

func [Fataln](#)

```
func Fataln(v ...interface{})
```

Fataln is equivalent to `Println()` followed by a call to `os.Exit(1)`.

func [Flags](#)

```
func Flags() int
```

Flags returns the output flags for the standard logger.

func [Panic](#)

```
func Panic(v ...interface{})
```

Panic is equivalent to Print() followed by a call to panic().

func [Panicf](#)

```
func Panicf(format string, v ...interface{})
```

Panicf is equivalent to Printf() followed by a call to panic().

func [Panicln](#)

```
func Panicln(v ...interface{})
```

Panicln is equivalent to Println() followed by a call to panic().

func Prefix

```
func Prefix() string
```

Prefix returns the output prefix for the standard logger.

func [Print](#)

```
func Print(v ...interface{})
```

Print calls Output to print to the standard logger. Arguments are handled in the manner of `fmt.Print`.

func [Printf](#)

```
func Printf(format string, v ...interface{})
```

Printf calls Output to print to the standard logger. Arguments are handled in the manner of `fmt.Printf`.

func [Println](#)

```
func Println(v ...interface{})
```

Println calls Output to print to the standard logger. Arguments are handled in the manner of `fmt.Println`.

func [SetFlags](#)

```
func SetFlags(flag int)
```

SetFlags sets the output flags for the standard logger.

func [SetOutput](#)

```
func SetOutput(w io.Writer)
```

SetOutput sets the output destination for the standard logger.

func [SetPrefix](#)

```
func SetPrefix(prefix string)
```

SetPrefix sets the output prefix for the standard logger.

type [Logger](#)

```
type Logger struct {  
    // contains filtered or unexported fields  
}
```

A `Logger` represents an active logging object that generates lines of output to an `io.Writer`. Each logging operation makes a single call to the `Writer`'s `Write` method. A `Logger` can be used simultaneously from multiple goroutines; it guarantees to serialize access to the `Writer`.

func [New](#)

```
func New(out io.Writer, prefix string, flag int) *Logger
```

`New` creates a new `Logger`. The `out` variable sets the destination to which log data will be written. The `prefix` appears at the beginning of each generated log line. The `flag` argument defines the logging properties.

func (*Logger) [Fatal](#)

```
func (l *Logger) Fatal(v ...interface{})
```

`Fatal` is equivalent to `l.Print()` followed by a call to `os.Exit(1)`.

func (*Logger) [Fatalf](#)

```
func (l *Logger) Fatalf(format string, v ...interface{})
```

`Fatalf` is equivalent to `l.Printf()` followed by a call to `os.Exit(1)`.

func (*Logger) [Fatalln](#)

```
func (l *Logger) Fatalln(v ...interface{})
```

`Fatalln` is equivalent to `l.Println()` followed by a call to `os.Exit(1)`.

func (*Logger) [Flags](#)

```
func (l *Logger) Flags() int
```

Flags returns the output flags for the logger.

func (*Logger) [Output](#)

```
func (l *Logger) Output(calldepth int, s string) error
```

Output writes the output for a logging event. The string *s* contains the text to print after the prefix specified by the flags of the Logger. A newline is appended if the last character of *s* is not already a newline. Calldepth is used to recover the PC and is provided for generality, although at the moment on all pre-defined paths it will be 2.

func (*Logger) [Panic](#)

```
func (l *Logger) Panic(v ...interface{})
```

Panic is equivalent to `l.Print()` followed by a call to `panic()`.

func (*Logger) [Panicf](#)

```
func (l *Logger) Panicf(format string, v ...interface{})
```

Panicf is equivalent to `l.Printf()` followed by a call to `panic()`.

func (*Logger) [Panicln](#)

```
func (l *Logger) Panicln(v ...interface{})
```

Panicln is equivalent to `l.Println()` followed by a call to `panic()`.

func (*Logger) [Prefix](#)

```
func (l *Logger) Prefix() string
```

Prefix returns the output prefix for the logger.

func (*Logger) [Print](#)

```
func (l *Logger) Print(v ...interface{})
```

Print calls l.Output to print to the logger. Arguments are handled in the manner of fmt.Print.

func (*Logger) [Printf](#)

```
func (l *Logger) Printf(format string, v ...interface{})
```

Printf calls l.Output to print to the logger. Arguments are handled in the manner of fmt.Printf.

func (*Logger) [Println](#)

```
func (l *Logger) Println(v ...interface{})
```

Println calls l.Output to print to the logger. Arguments are handled in the manner of fmt.Println.

func (*Logger) [SetFlags](#)

```
func (l *Logger) SetFlags(flag int)
```

SetFlags sets the output flags for the logger.

func (*Logger) [SetPrefix](#)

```
func (l *Logger) SetPrefix(prefix string)
```

SetPrefix sets the output prefix for the logger.

Package syslog

```
import "log/syslog"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package syslog provides a simple interface to the system log service. It can send messages to the syslog daemon using UNIX domain sockets, UDP, or TCP connections.

Package files

[syslog.go](#) [syslog_unix.go](#)

func [NewLogger](#)

```
func NewLogger(p Priority, logFlag int) (*log.Logger, error)
```

NewLogger creates a log.Logger whose output is written to the system log service with the specified priority. The logFlag argument is the flag set passed through to log.New to create the Logger.

type [Priority](#)

```
type Priority int
```

```
const (  
    // From /usr/include/sys/syslog.h.  
    // These are the same on Linux, BSD, and OS X.  
    LOG_EMERG Priority = iota  
    LOG_ALERT  
    LOG_CRIT  
    LOG_ERR  
    LOG_WARNING  
    LOG_NOTICE  
    LOG_INFO  
    LOG_DEBUG  
)
```

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A Writer is a connection to a syslog server.

func [Dial](#)

```
func Dial(network, raddr string, priority Priority, prefix string) (
```

Dial establishes a connection to a log daemon by connecting to address raddr on the network net. Each write to the returned writer sends a log message with the given priority and prefix.

func [New](#)

```
func New(priority Priority, prefix string) (w *Writer, err error)
```

New establishes a new connection to the system log daemon. Each write to the returned writer sends a log message with the given priority and prefix.

func (*Writer) [Alert](#)

```
func (w *Writer) Alert(m string) (err error)
```

Alert logs a message using the LOG_ALERT priority.

func (*Writer) [Close](#)

```
func (w *Writer) Close() error
```

func (*Writer) [Crit](#)

```
func (w *Writer) Crit(m string) (err error)
```

Crit logs a message using the LOG_CRIT priority.

func (*Writer) [Debug](#)

```
func (w *Writer) Debug(m string) (err error)
```

Debug logs a message using the LOG_DEBUG priority.

func (*Writer) [Emerg](#)

```
func (w *Writer) Emerg(m string) (err error)
```

Emerg logs a message using the LOG_EMERG priority.

func (*Writer) [Err](#)

```
func (w *Writer) Err(m string) (err error)
```

Err logs a message using the LOG_ERR priority.

func (*Writer) [Info](#)

```
func (w *Writer) Info(m string) (err error)
```

Info logs a message using the LOG_INFO priority.

func (*Writer) [Notice](#)

```
func (w *Writer) Notice(m string) (err error)
```

Notice logs a message using the LOG_NOTICE priority.

func (*Writer) [Warning](#)

```
func (w *Writer) Warning(m string) (err error)
```

Warning logs a message using the LOG_WARNING priority.

func (*Writer) [Write](#)

```
func (w *Writer) Write(b []byte) (int, error)
```

Write sends a log message to the syslog daemon.

Build version go1.0.1.

    MaxUInt16 = 1<<16 - 1  
    MaxUInt32 = 1<<32 - 1  
    MaxUInt64 = 1<<64 - 1
```

)

Integer limit values.

func [Abs](#)

```
func Abs(x float64) float64
```

Abs returns the absolute value of x.

Special cases are:

Abs(Inf) = +Inf

Abs(NaN) = NaN

func Acos

func Acos(x float64) float64

Acos returns the arccosine of x.

Special case is:

$\text{Acos}(x) = \text{NaN}$ if $x < -1$ or $x > 1$

func [Acosh](#)

func Acosh(x float64) float64

Acosh(x) calculates the inverse hyperbolic cosine of x.

Special cases are:

Acosh(+Inf) = +Inf

Acosh(x) = NaN if $x < 1$

Acosh(NaN) = NaN

func [Asin](#)

```
func Asin(x float64) float64
```

Asin returns the arcsine of x.

Special cases are:

$\text{Asin}(0) = 0$

$\text{Asin}(x) = \text{NaN}$ if $x < -1$ or $x > 1$

func [Asinh](#)

func Asinh(x float64) float64

Asinh(x) calculates the inverse hyperbolic sine of x.

Special cases are:

Asinh(0) = 0

Asinh(Inf) = Inf

Asinh(NaN) = NaN

func [Atan](#)

```
func Atan(x float64) float64
```

Atan returns the arctangent of x.

Special cases are:

$\text{Atan}(0) = 0$

$\text{Atan}(\text{Inf}) = \text{Pi}/2$

func [Atan2](#)

func Atan2(y, x float64) float64

Atan2 returns the arc tangent of y/x , using the signs of the two to determine the quadrant of the return value.

Special cases are (in order):

```
Atan2(y, NaN) = NaN
Atan2(NaN, x) = NaN
Atan2(+0, x>=0) = +0
Atan2(-0, x>=0) = -0
Atan2(+0, x<=-0) = +Pi
Atan2(-0, x<=-0) = -Pi
Atan2(y>0, 0) = +Pi/2
Atan2(y<0, 0) = -Pi/2
Atan2(+Inf, +Inf) = +Pi/4
Atan2(-Inf, +Inf) = -Pi/4
Atan2(+Inf, -Inf) = 3Pi/4
Atan2(-Inf, -Inf) = -3Pi/4
Atan2(y, +Inf) = 0
Atan2(y>0, -Inf) = +Pi
Atan2(y<0, -Inf) = -Pi
Atan2(+Inf, x) = +Pi/2
Atan2(-Inf, x) = -Pi/2
```

func [Atanh](#)

func Atanh(x float64) float64

Atanh(x) calculates the inverse hyperbolic tangent of x.

Special cases are:

Atanh(1) = +Inf

Atanh(0) = 0

Atanh(-1) = -Inf

Atanh(x) = NaN if $x < -1$ or $x > 1$

Atanh(NaN) = NaN

func [Cbrt](#)

```
func Cbrt(x float64) float64
```

Cbrt returns the cube root of its argument.

Special cases are:

$\text{Cbrt}(0) = 0$

$\text{Cbrt}(\text{Inf}) = \text{Inf}$

$\text{Cbrt}(\text{NaN}) = \text{NaN}$

func Ceil

```
func Ceil(x float64) float64
```

Ceil returns the least integer value greater than or equal to x.

Special cases are:

$\text{Ceil}(0) = 0$

$\text{Ceil}(\text{Inf}) = \text{Inf}$

$\text{Ceil}(\text{NaN}) = \text{NaN}$

func Copysign

```
func Copysign(x, y float64) float64
```

Copysign(x, y) returns a value with the magnitude of x and the sign of y.

func Cos

```
func Cos(x float64) float64
```

Cos returns the cosine of x.

Special cases are:

$\text{Cos}(\text{Inf}) = \text{NaN}$

$\text{Cos}(\text{NaN}) = \text{NaN}$

func Cosh

```
func Cosh(x float64) float64
```

Cosh returns the hyperbolic cosine of x.

Special cases are:

$\text{Cosh}(0) = 1$

$\text{Cosh}(\text{Inf}) = +\text{Inf}$

$\text{Cosh}(\text{NaN}) = \text{NaN}$

func Dim

```
func Dim(x, y float64) float64
```

Dim returns the maximum of x-y or 0.

Special cases are:

Dim(+Inf, +Inf) = NaN

Dim(-Inf, -Inf) = NaN

Dim(x, NaN) = Dim(NaN, x) = NaN

func [Erf](#)

```
func Erf(x float64) float64
```

Erf(x) returns the error function of x.

Special cases are:

Erf(+Inf) = 1

Erf(-Inf) = -1

Erf(NaN) = NaN

func [Erfc](#)

```
func Erfc(x float64) float64
```

Erfc(x) returns the complementary error function of x.

Special cases are:

$\text{Erfc}(+\text{Inf}) = 0$

$\text{Erfc}(-\text{Inf}) = 2$

$\text{Erfc}(\text{NaN}) = \text{NaN}$

func Exp

```
func Exp(x float64) float64
```

Exp returns $e^{**}x$, the base-e exponential of x.

Special cases are:

Exp(+Inf) = +Inf

Exp(NaN) = NaN

Very large values overflow to 0 or +Inf. Very small values underflow to 1.

func [Exp2](#)

```
func Exp2(x float64) float64
```

Exp2 returns $2^{**}x$, the base-2 exponential of x.

Special cases are the same as Exp.

func [Exp1](#)

```
func Exp1(x float64) float64
```

Exp1 returns $e^{**x} - 1$, the base-e exponential of x minus 1. It is more accurate than $\text{Exp}(x) - 1$ when x is near zero.

Special cases are:

```
Exp1(+Inf) = +Inf
```

```
Exp1(-Inf) = -1
```

```
Exp1(NaN) = NaN
```

Very large values overflow to -1 or +Inf.

func Float32bits

```
func Float32bits(f float32) uint32
```

Float32bits returns the IEEE 754 binary representation of f.

func [Float32frombits](#)

```
func Float32frombits(b uint32) float32
```

Float32frombits returns the floating point number corresponding to the IEEE 754 binary representation b.

func [Float64bits](#)

```
func Float64bits(f float64) uint64
```

Float64bits returns the IEEE 754 binary representation of f.

func [Float64frombits](#)

```
func Float64frombits(b uint64) float64
```

Float64frombits returns the floating point number corresponding the IEEE 754 binary representation b.

func Floor

```
func Floor(x float64) float64
```

Floor returns the greatest integer value less than or equal to x.

Special cases are:

Floor(0) = 0

Floor(Inf) = Inf

Floor(NaN) = NaN

func Frexp

func Frexp(f float64) (frac float64, exp int)

Frexp breaks f into a normalized fraction and an integral power of two. It returns $frac$ and exp satisfying $f == frac \cdot 2^{**}exp$, with the absolute value of $frac$ in the interval $[?, 1)$.

Special cases are:

Frexp(0) = 0, 0

Frexp(Inf) = Inf, 0

Frexp(NaN) = NaN, 0

func Gamma

```
func Gamma(x float64) float64
```

Gamma(x) returns the Gamma function of x.

Special cases are:

Gamma(Inf) = Inf

Gamma(NaN) = NaN

Large values overflow to +Inf. Zero and negative integer arguments return Inf.

func Hypot

```
func Hypot(p, q float64) float64
```

Hypot computes $\text{Sqrt}(p^2 + q^2)$, taking care to avoid unnecessary overflow and underflow.

Special cases are:

Hypot(p, q) = +Inf if p or q is infinite

Hypot(p, q) = NaN if p or q is NaN

func [Ilogb](#)

```
func Ilogb(x float64) int
```

Ilogb(x) returns the binary exponent of x as an integer.

Special cases are:

```
Ilogb(Inf) = MaxInt32
```

```
Ilogb(0) = MinInt32
```

```
Ilogb(NaN) = MaxInt32
```

func Inf

```
func Inf(sign int) float64
```

Inf returns positive infinity if $\text{sign} \geq 0$, negative infinity if $\text{sign} < 0$.

func [IsInf](#)

```
func IsInf(f float64, sign int) bool
```

IsInf returns whether f is an infinity, according to sign. If sign > 0, IsInf returns whether f is positive infinity. If sign < 0, IsInf returns whether f is negative infinity. If sign == 0, IsInf returns whether f is either infinity.

func [IsNaN](#)

```
func IsNaN(f float64) (is bool)
```

IsNaN returns whether f is an IEEE 754 “not-a-number” value.

func [J0](#)

func J0(x float64) float64

J0 returns the order-zero Bessel function of the first kind.

Special cases are:

$J_0(\text{Inf}) = 0$

$J_0(0) = 1$

$J_0(\text{NaN}) = \text{NaN}$

func [J1](#)

func J1(x float64) float64

J1 returns the order-one Bessel function of the first kind.

Special cases are:

$J1(\text{Inf}) = 0$

$J1(\text{NaN}) = \text{NaN}$

func [Jn](#)

```
func Jn(n int, x float64) float64
```

Jn returns the order-n Bessel function of the first kind.

Special cases are:

$$J_n(n, \text{Inf}) = 0$$
$$J_n(n, \text{NaN}) = \text{NaN}$$

func Ldexp

func Ldexp(frac float64, exp int) float64

Ldexp is the inverse of Frexp. It returns $\text{frac} \cdot 2^{**}\text{exp}$.

Special cases are:

Ldexp(0, exp) = 0

Ldexp(Inf, exp) = Inf

Ldexp(NaN, exp) = NaN

func Lgamma

```
func Lgamma(x float64) (lgamma float64, sign int)
```

Lgamma returns the natural logarithm and sign (-1 or +1) of Gamma(x).

Special cases are:

```
Lgamma(+Inf) = +Inf  
Lgamma(0) = +Inf  
Lgamma(-integer) = +Inf  
Lgamma(-Inf) = -Inf  
Lgamma(NaN) = NaN
```

func **Log**

```
func Log(x float64) float64
```

Log returns the natural logarithm of x.

Special cases are:

$\text{Log}(+\text{Inf}) = +\text{Inf}$

$\text{Log}(0) = -\text{Inf}$

$\text{Log}(x < 0) = \text{NaN}$

$\text{Log}(\text{NaN}) = \text{NaN}$

func Log10

```
func Log10(x float64) float64
```

Log10 returns the decimal logarithm of x. The special cases are the same as for Log.

func [Log1p](#)

```
func Log1p(x float64) float64
```

Log1p returns the natural logarithm of 1 plus its argument x. It is more accurate than $\text{Log}(1 + x)$ when x is near zero.

Special cases are:

```
Log1p(+Inf) = +Inf  
Log1p(0) = 0  
Log1p(-1) = -Inf  
Log1p(x < -1) = NaN  
Log1p(NaN) = NaN
```

func Log2

```
func Log2(x float64) float64
```

Log2 returns the binary logarithm of x. The special cases are the same as for Log.

func Logb

```
func Logb(x float64) float64
```

Logb(x) returns the binary exponent of x.

Special cases are:

Logb(Inf) = +Inf

Logb(0) = -Inf

Logb(NaN) = NaN

func Max

```
func Max(x, y float64) float64
```

Max returns the larger of x or y.

Special cases are:

$\text{Max}(x, +\text{Inf}) = \text{Max}(+\text{Inf}, x) = +\text{Inf}$

$\text{Max}(x, \text{NaN}) = \text{Max}(\text{NaN}, x) = \text{NaN}$

$\text{Max}(+0, 0) = \text{Max}(0, +0) = +0$

$\text{Max}(-0, -0) = -0$

func Min

```
func Min(x, y float64) float64
```

Min returns the smaller of x or y.

Special cases are:

$\text{Min}(x, -\text{Inf}) = \text{Min}(-\text{Inf}, x) = -\text{Inf}$

$\text{Min}(x, \text{NaN}) = \text{Min}(\text{NaN}, x) = \text{NaN}$

$\text{Min}(-0, 0) = \text{Min}(0, -0) = -0$

func Mod

```
func Mod(x, y float64) float64
```

Mod returns the floating-point remainder of x/y . The magnitude of the result is less than y and its sign agrees with that of x .

Special cases are:

$\text{Mod}(\text{Inf}, y) = \text{NaN}$

$\text{Mod}(\text{NaN}, y) = \text{NaN}$

$\text{Mod}(x, 0) = \text{NaN}$

$\text{Mod}(x, \text{Inf}) = x$

$\text{Mod}(x, \text{NaN}) = \text{NaN}$

func Modf

```
func Modf(f float64) (int float64, frac float64)
```

Modf returns integer and fractional floating-point numbers that sum to f. Both values have the same sign as f.

Special cases are:

$\text{Modf}(\text{Inf}) = \text{Inf}, \text{NaN}$

$\text{Modf}(\text{NaN}) = \text{NaN}, \text{NaN}$

func [NaN](#)

```
func NaN() float64
```

NaN returns an IEEE 754 “not-a-number” value.

func [Nextafter](#)

```
func Nextafter(x, y float64) (r float64)
```

Nextafter returns the next representable value after x towards y. If x == y, then x is returned.

Special cases are:

```
Nextafter(NaN, y) = NaN
```

```
Nextafter(x, NaN) = NaN
```

func Pow

```
func Pow(x, y float64) float64
```

Pow returns $x^{**}y$, the base-x exponential of y.

Special cases are (in order):

$\text{Pow}(x, 0) = 1$ for any x

$\text{Pow}(1, y) = 1$ for any y

$\text{Pow}(x, 1) = x$ for any x

$\text{Pow}(\text{NaN}, y) = \text{NaN}$

$\text{Pow}(x, \text{NaN}) = \text{NaN}$

$\text{Pow}(0, y) = \text{Inf}$ for y an odd integer < 0

$\text{Pow}(0, -\text{Inf}) = +\text{Inf}$

$\text{Pow}(0, +\text{Inf}) = +0$

$\text{Pow}(0, y) = +\text{Inf}$ for finite $y < 0$ and not an odd integer

$\text{Pow}(0, y) = 0$ for y an odd integer > 0

$\text{Pow}(0, y) = +0$ for finite $y > 0$ and not an odd integer

$\text{Pow}(-1, \text{Inf}) = 1$

$\text{Pow}(x, +\text{Inf}) = +\text{Inf}$ for $|x| > 1$

$\text{Pow}(x, -\text{Inf}) = +0$ for $|x| > 1$

$\text{Pow}(x, +\text{Inf}) = +0$ for $|x| < 1$

$\text{Pow}(x, -\text{Inf}) = +\text{Inf}$ for $|x| < 1$

$\text{Pow}(+\text{Inf}, y) = +\text{Inf}$ for $y > 0$

$\text{Pow}(+\text{Inf}, y) = +0$ for $y < 0$

$\text{Pow}(-\text{Inf}, y) = \text{Pow}(-0, -y)$

$\text{Pow}(x, y) = \text{NaN}$ for finite $x < 0$ and finite non-integer y

func Pow10

```
func Pow10(e int) float64
```

Pow10 returns $10^{**}e$, the base-10 exponential of e.

Special cases are:

$\text{Pow10}(e) = +\text{Inf}$ for $e > 309$

$\text{Pow10}(e) = 0$ for $e < -324$

func Remainder

```
func Remainder(x, y float64) float64
```

Remainder returns the IEEE 754 floating-point remainder of x/y.

Special cases are:

Remainder(Inf, y) = NaN

Remainder(NaN, y) = NaN

Remainder(x, 0) = NaN

Remainder(x, Inf) = x

Remainder(x, NaN) = NaN

func [Signbit](#)

```
func Signbit(x float64) bool
```

Signbit returns true if x is negative or negative zero.

func [Sin](#)

```
func Sin(x float64) float64
```

Sin returns the sine of x.

Special cases are:

$\text{Sin}(0) = 0$

$\text{Sin}(\text{Inf}) = \text{NaN}$

$\text{Sin}(\text{NaN}) = \text{NaN}$

func Sincos

func Sincos(x float64) (sin, cos float64)

Sincos(x) returns Sin(x), Cos(x).

Special cases are:

Sincos(0) = 0, 1

Sincos(Inf) = NaN, NaN

Sincos(NaN) = NaN, NaN

func [Sinh](#)

```
func Sinh(x float64) float64
```

Sinh returns the hyperbolic sine of x.

Special cases are:

$\text{Sinh}(0) = 0$

$\text{Sinh}(\text{Inf}) = \text{Inf}$

$\text{Sinh}(\text{NaN}) = \text{NaN}$

func [Sqrt](#)

```
func Sqrt(x float64) float64
```

Sqrt returns the square root of x.

Special cases are:

$\text{Sqrt}(+\text{Inf}) = +\text{Inf}$

$\text{Sqrt}(0) = 0$

$\text{Sqrt}(x < 0) = \text{NaN}$

$\text{Sqrt}(\text{NaN}) = \text{NaN}$

func Tan

```
func Tan(x float64) float64
```

Tan returns the tangent of x.

Special cases are:

$\text{Tan}(0) = 0$

$\text{Tan}(\text{Inf}) = \text{NaN}$

$\text{Tan}(\text{NaN}) = \text{NaN}$

func [Tanh](#)

```
func Tanh(x float64) float64
```

Tanh computes the hyperbolic tangent of x.

Special cases are:

$$\text{Tanh}(0) = 0$$

$$\text{Tanh}(\text{Inf}) = 1$$

$$\text{Tanh}(\text{NaN}) = \text{NaN}$$

func Trunc

```
func Trunc(x float64) float64
```

Trunc returns the integer value of x.

Special cases are:

Trunc(0) = 0

Trunc(Inf) = Inf

Trunc(NaN) = NaN

func [Y0](#)

```
func Y0(x float64) float64
```

Y0 returns the order-zero Bessel function of the second kind.

Special cases are:

$$Y_0(+\text{Inf}) = 0$$

$$Y_0(0) = -\text{Inf}$$

$$Y_0(x < 0) = \text{NaN}$$

$$Y_0(\text{NaN}) = \text{NaN}$$

func [Y1](#)

```
func Y1(x float64) float64
```

Y1 returns the order-one Bessel function of the second kind.

Special cases are:

$$Y1(+Inf) = 0$$

$$Y1(0) = -Inf$$

$$Y1(x < 0) = NaN$$

$$Y1(NaN) = NaN$$

func [Yn](#)

```
func Yn(n int, x float64) float64
```

Yn returns the order-n Bessel function of the second kind.

Special cases are:

$Y_n(n, +\text{Inf}) = 0$

$Y_n(n > 0, 0) = -\text{Inf}$

$Y_n(n < 0, 0) = +\text{Inf}$ if n is odd, $-\text{Inf}$ if n is even

$Y_1(n, x < 0) = \text{NaN}$

$Y_1(n, \text{NaN}) = \text{NaN}$

Package big

```
import "math/big"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package `big` implements multi-precision arithmetic (big numbers). The following numeric types are supported:

- `Int` signed integers
- `Rat` rational numbers

Methods are typically of the form:

```
func (z *Int) Op(x, y *Int) *Int          (similar for *Rat)
```

and implement operations $z = x \text{ Op } y$ with the result as receiver; if it is one of the operands it may be overwritten (and its memory reused). To enable chaining of operations, the result is also returned. Methods returning a result other than `*Int` or `*Rat` take one of the operands as the receiver.

Constants

type Int

func NewInt(x int64) *Int
func (z *Int) Abs(x *Int) *Int
func (z *Int) Add(x, y *Int) *Int
func (z *Int) And(x, y *Int) *Int
func (z *Int) AndNot(x, y *Int) *Int
func (z *Int) Binomial(n, k int64) *Int
func (x *Int) Bit(i int) uint
func (x *Int) BitLen() int
func (x *Int) Bits() []Word
func (x *Int) Bytes() []byte
func (x *Int) Cmp(y *Int) (r int)
func (z *Int) Div(x, y *Int) *Int
func (z *Int) DivMod(x, y, m *Int) (*Int, *Int)
func (z *Int) Exp(x, y, m *Int) *Int
func (x *Int) Format(s fmt.State, ch rune)
func (z *Int) GCD(x, y, a, b *Int) *Int
func (z *Int) GobDecode(buf []byte) error
func (x *Int) GobEncode() ([]byte, error)
func (x *Int) Int64() int64
func (z *Int) Lsh(x *Int, n uint) *Int
func (z *Int) Mod(x, y *Int) *Int
func (z *Int) ModInverse(g, p *Int) *Int
func (z *Int) Mul(x, y *Int) *Int
func (z *Int) MulRange(a, b int64) *Int
func (z *Int) Neg(x *Int) *Int
func (z *Int) Not(x *Int) *Int
func (z *Int) Or(x, y *Int) *Int
func (x *Int) ProbablyPrime(n int) bool
func (z *Int) Quo(x, y *Int) *Int
func (z *Int) QuoRem(x, y, r *Int) (*Int, *Int)
func (z *Int) Rand(rnd *rand.Rand, n *Int) *Int
func (z *Int) Rem(x, y *Int) *Int
func (z *Int) Rsh(x *Int, n uint) *Int

func (z *Int) Scan(s fmt.ScanState, ch rune) error
func (z *Int) Set(x *Int) *Int
func (z *Int) SetBit(x *Int, i int, b uint) *Int
func (z *Int) SetBits(abs []Word) *Int
func (z *Int) SetBytes(buf []byte) *Int
func (z *Int) SetInt64(x int64) *Int
func (z *Int) SetString(s string, base int) (*Int, bool)
func (x *Int) Sign() int
func (x *Int) String() string
func (z *Int) Sub(x, y *Int) *Int
func (z *Int) Xor(x, y *Int) *Int

type Rat

func NewRat(a, b int64) *Rat
func (z *Rat) Abs(x *Rat) *Rat
func (z *Rat) Add(x, y *Rat) *Rat
func (x *Rat) Cmp(y *Rat) int
func (x *Rat) Denom() *Int
func (x *Rat) FloatString(prec int) string
func (z *Rat) GobDecode(buf []byte) error
func (x *Rat) GobEncode() ([]byte, error)
func (z *Rat) Inv(x *Rat) *Rat
func (x *Rat) IsInt() bool
func (z *Rat) Mul(x, y *Rat) *Rat
func (z *Rat) Neg(x *Rat) *Rat
func (x *Rat) Num() *Int
func (z *Rat) Quo(x, y *Rat) *Rat
func (x *Rat) RatString() string
func (z *Rat) Scan(s fmt.ScanState, ch rune) error
func (z *Rat) Set(x *Rat) *Rat
func (z *Rat) SetFrac(a, b *Int) *Rat
func (z *Rat) SetFrac64(a, b int64) *Rat
func (z *Rat) SetInt(x *Int) *Rat
func (z *Rat) SetInt64(x int64) *Rat
func (z *Rat) SetString(s string) (*Rat, bool)
func (x *Rat) Sign() int
func (x *Rat) String() string
func (z *Rat) Sub(x, y *Rat) *Rat

type Word

Examples

[Int.Scan](#)

[Int.SetString](#)

[Rat.Scan](#)

[Rat.SetString](#)

Package files

[arith.go](#) [arith_decl.go](#) [int.go](#) [nat.go](#) [rat.go](#)

Constants

```
const MaxBase = 'z' - 'a' + 10 + 1 // = hexValue('z') + 1
```

MaxBase is the largest number base accepted for string conversions.

type [Int](#)

```
type Int struct {  
    // contains filtered or unexported fields  
}
```

An Int represents a signed multi-precision integer. The zero value for an Int represents the value 0.

func [NewInt](#)

```
func NewInt(x int64) *Int
```

NewInt allocates and returns a new Int set to x.

func ([*Int](#)) [Abs](#)

```
func (z *Int) Abs(x *Int) *Int
```

Abs sets z to $|x|$ (the absolute value of x) and returns z.

func ([*Int](#)) [Add](#)

```
func (z *Int) Add(x, y *Int) *Int
```

Add sets z to the sum $x+y$ and returns z.

func ([*Int](#)) [And](#)

```
func (z *Int) And(x, y *Int) *Int
```

And sets $z = x \& y$ and returns z.

func ([*Int](#)) [AndNot](#)

```
func (z *Int) AndNot(x, y *Int) *Int
```

AndNot sets $z = x \&^{\wedge} y$ and returns z.

func (*Int) [Binomial](#)

```
func (z *Int) Binomial(n, k int64) *Int
```

Binomial sets z to the binomial coefficient of (n, k) and returns z.

func (*Int) [Bit](#)

```
func (x *Int) Bit(i int) uint
```

Bit returns the value of the i'th bit of x. That is, it returns $(x \gg i) \& 1$. The bit index i must be ≥ 0 .

func (*Int) [BitLen](#)

```
func (x *Int) BitLen() int
```

BitLen returns the length of the absolute value of z in bits. The bit length of 0 is 0.

func (*Int) [Bits](#)

```
func (x *Int) Bits() []Word
```

Bits provides raw (unchecked but fast) access to x by returning its absolute value as a little-endian Word slice. The result and x share the same underlying array. Bits is intended to support implementation of missing low-level Int functionality outside this package; it should be avoided otherwise.

func (*Int) [Bytes](#)

```
func (x *Int) Bytes() []byte
```

Bytes returns the absolute value of z as a big-endian byte slice.

func (*Int) [Cmp](#)

```
func (x *Int) Cmp(y *Int) (r int)
```

Cmp compares x and y and returns:

```
-1 if x < y
 0 if x == y
+1 if x > y
```

func (*Int) [Div](#)

```
func (z *Int) Div(x, y *Int) *Int
```

Div sets z to the quotient x/y for y != 0 and returns z. If y == 0, a division-by-zero run-time panic occurs. Div implements Euclidean division (unlike Go); see DivMod for more details.

func (*Int) [DivMod](#)

```
func (z *Int) DivMod(x, y, m *Int) (*Int, *Int)
```

DivMod sets z to the quotient x div y and m to the modulus x mod y and returns the pair (z, m) for y != 0. If y == 0, a division-by-zero run-time panic occurs.

DivMod implements Euclidean division and modulus (unlike Go):

$$q = x \operatorname{div} y \quad \text{such that}$$
$$m = x - y * q \quad \text{with } 0 \leq m < |q|$$

(See Raymond T. Boute, “The Euclidean definition of the functions div and mod”. ACM Transactions on Programming Languages and Systems (TOPLAS), 14(2):127-144, New York, NY, USA, 4/1992. ACM press.) See QuoRem for T-division and modulus (like Go).

func (*Int) [Exp](#)

```
func (z *Int) Exp(x, y, m *Int) *Int
```

Exp sets z = x**y mod m and returns z. If m is nil, z = x**y. See Knuth, volume 2, section 4.6.3.

func (*Int) [Format](#)

```
func (x *Int) Format(s fmt.State, ch rune)
```

Format is a support routine for fmt.Formatter. It accepts the formats 'b' (binary),

'o' (octal), 'd' (decimal), 'x' (lowercase hexadecimal), and 'X' (uppercase hexadecimal). Also supported are the full suite of package `fmt`'s format verbs for integral types, including '+', '-', and ' ' for sign control, '#' for leading zero in octal and for hexadecimal, a leading "0x" or "0X" for "%#x" and "%#X" respectively, specification of minimum digits precision, output field width, space or zero padding, and left or right justification.

func (*Int) [GCD](#)

```
func (z *Int) GCD(x, y, a, b *Int) *Int
```

`GCD` sets `z` to the greatest common divisor of `a` and `b`, which must be positive numbers, and returns `z`. If `x` and `y` are not nil, `GCD` sets `x` and `y` such that $z = a*x + b*y$. If either `a` or `b` is not positive, `GCD` sets $z = x = y = 0$.

func (*Int) [GobDecode](#)

```
func (z *Int) GobDecode(buf []byte) error
```

`GobDecode` implements the `gob.GobDecoder` interface.

func (*Int) [GobEncode](#)

```
func (x *Int) GobEncode() ([]byte, error)
```

`GobEncode` implements the `gob.GobEncoder` interface.

func (*Int) [Int64](#)

```
func (x *Int) Int64() int64
```

`Int64` returns the `int64` representation of `x`. If `x` cannot be represented in an `int64`, the result is undefined.

func (*Int) [Lsh](#)

```
func (z *Int) Lsh(x *Int, n uint) *Int
```

`Lsh` sets $z = x \ll n$ and returns `z`.

func (*Int) [Mod](#)

```
func (z *Int) Mod(x, y *Int) *Int
```

Mod sets z to the modulus $x\%y$ for $y \neq 0$ and returns z. If $y == 0$, a division-by-zero run-time panic occurs. Mod implements Euclidean modulus (unlike Go); see DivMod for more details.

func (*Int) [ModInverse](#)

```
func (z *Int) ModInverse(g, p *Int) *Int
```

ModInverse sets z to the multiplicative inverse of g in the group $\mathbb{Z}/p\mathbb{Z}$ (where p is a prime) and returns z.

func (*Int) [Mul](#)

```
func (z *Int) Mul(x, y *Int) *Int
```

Mul sets z to the product $x*y$ and returns z.

func (*Int) [MulRange](#)

```
func (z *Int) MulRange(a, b int64) *Int
```

MulRange sets z to the product of all integers in the range $[a, b]$ inclusively and returns z. If $a > b$ (empty range), the result is 1.

func (*Int) [Neg](#)

```
func (z *Int) Neg(x *Int) *Int
```

Neg sets z to $-x$ and returns z.

func (*Int) [Not](#)

```
func (z *Int) Not(x *Int) *Int
```

Not sets $z = \neg x$ and returns z.

func (*Int) [Or](#)

```
func (z *Int) Or(x, y *Int) *Int
```

Or sets $z = x | y$ and returns z .

func (*Int) [ProbablyPrime](#)

```
func (x *Int) ProbablyPrime(n int) bool
```

ProbablyPrime performs n Miller-Rabin tests to check whether x is prime. If it returns true, x is prime with probability $1 - 1/4^n$. If it returns false, x is not prime.

func (*Int) [Quo](#)

```
func (z *Int) Quo(x, y *Int) *Int
```

Quo sets z to the quotient x/y for $y \neq 0$ and returns z . If $y == 0$, a division-by-zero run-time panic occurs. Quo implements truncated division (like Go); see QuoRem for more details.

func (*Int) [QuoRem](#)

```
func (z *Int) QuoRem(x, y, r *Int) (*Int, *Int)
```

QuoRem sets z to the quotient x/y and r to the remainder $x\%y$ and returns the pair (z, r) for $y \neq 0$. If $y == 0$, a division-by-zero run-time panic occurs.

QuoRem implements T-division and modulus (like Go):

$$\begin{aligned} q &= x/y && \text{with the result truncated to zero} \\ r &= x - y*q \end{aligned}$$

(See Daan Leijen, “Division and Modulus for Computer Scientists”.) See DivMod for Euclidean division and modulus (unlike Go).

func (*Int) [Rand](#)

```
func (z *Int) Rand(rnd *rand.Rand, n *Int) *Int
```

Rand sets z to a pseudo-random number in [0, n) and returns z.

func (*Int) [Rem](#)

```
func (z *Int) Rem(x, y *Int) *Int
```

Rem sets z to the remainder $x\%y$ for $y \neq 0$ and returns z. If $y == 0$, a division-by-zero run-time panic occurs. Rem implements truncated modulus (like Go); see QuoRem for more details.

func (*Int) [Rsh](#)

```
func (z *Int) Rsh(x *Int, n uint) *Int
```

Rsh sets $z = x \gg n$ and returns z.

func (*Int) [Scan](#)

```
func (z *Int) Scan(s fmt.ScanState, ch rune) error
```

Scan is a support routine for `fmt.Scanner`; it sets z to the value of the scanned number. It accepts the formats 'b' (binary), 'o' (octal), 'd' (decimal), 'x' (lowercase hexadecimal), and 'X' (uppercase hexadecimal).

? Example

? Example

Code:

```
// The Scan function is rarely used directly;
// the fmt package recognizes it as an implementation of fmt.Scanner
i := new(big.Int)
_, err := fmt.Sscan("18446744073709551617", i)
if err != nil {
    log.Println("error scanning value:", err)
} else {
    fmt.Println(i)
}
```

Output:

18446744073709551617

func (*Int) [Set](#)

```
func (z *Int) Set(x *Int) *Int
```

Set sets z to x and returns z.

func (*Int) [SetBit](#)

```
func (z *Int) SetBit(x *Int, i int, b uint) *Int
```

SetBit sets z to x, with x's i'th bit set to b (0 or 1). That is, if bit is 1 SetBit sets $z = x | (1 \ll i)$; if bit is 0 it sets $z = x \& \sim (1 \ll i)$. If bit is not 0 or 1, SetBit will panic.

func (*Int) [SetBits](#)

```
func (z *Int) SetBits(abs []Word) *Int
```

SetBits provides raw (unchecked but fast) access to z by setting its value to abs, interpreted as a little-endian Word slice, and returning z. The result and abs share the same underlying array. SetBits is intended to support implementation of missing low-level Int functionality outside this package; it should be avoided otherwise.

func (*Int) [SetBytes](#)

```
func (z *Int) SetBytes(buf []byte) *Int
```

SetBytes interprets buf as the bytes of a big-endian unsigned integer, sets z to that value, and returns z.

func (*Int) [SetInt64](#)

```
func (z *Int) SetInt64(x int64) *Int
```

SetInt64 sets z to x and returns z.

func (*Int) [SetString](#)

```
func (z *Int) SetString(s string, base int) (*Int, bool)
```

SetString sets z to the value of s, interpreted in the given base, and returns z and a boolean indicating success. If SetString fails, the value of z is undefined but the returned value is nil.

The base argument must be 0 or a value from 2 through MaxBase. If the base is 0, the string prefix determines the actual conversion base. A prefix of “0x” or “0X” selects base 16; the “0” prefix selects base 8, and a “0b” or “0B” prefix selects base 2. Otherwise the selected base is 10.

? Example

? Example

Code:

```
i := new(big.Int)
i.SetString("644", 8) // octal
fmt.Println(i)
```

Output:

420

func (*Int) [Sign](#)

```
func (x *Int) Sign() int
```

Sign returns:

```
-1 if x < 0
 0 if x == 0
+1 if x > 0
```

func (*Int) [String](#)

```
func (x *Int) String() string
```

func (*Int) [Sub](#)

```
func (z *Int) Sub(x, y *Int) *Int
```

Sub sets z to the difference x-y and returns z.

func (*Int) [Xor](#)

```
func (z *Int) Xor(x, y *Int) *Int
```

Xor sets $z = x \wedge y$ and returns z.

type [Rat](#)

```
type Rat struct {  
    // contains filtered or unexported fields  
}
```

A Rat represents a quotient a/b of arbitrary precision. The zero value for a Rat represents the value 0.

func [NewRat](#)

```
func NewRat(a, b int64) *Rat
```

NewRat creates a new Rat with numerator a and denominator b.

func (*Rat) [Abs](#)

```
func (z *Rat) Abs(x *Rat) *Rat
```

Abs sets z to $|x|$ (the absolute value of x) and returns z.

func (*Rat) [Add](#)

```
func (z *Rat) Add(x, y *Rat) *Rat
```

Add sets z to the sum $x+y$ and returns z.

func (*Rat) [Cmp](#)

```
func (x *Rat) Cmp(y *Rat) int
```

Cmp compares x and y and returns:

```
-1 if x < y  
 0 if x == y  
+1 if x > y
```

func (*Rat) [Denom](#)

```
func (x *Rat) Denom() *Int
```

Denom returns the denominator of x; it is always > 0 . The result is a reference to x's denominator; it may change if a new value is assigned to x.

func (*Rat) [FloatString](#)

```
func (x *Rat) FloatString(prec int) string
```

FloatString returns a string representation of z in decimal form with prec digits of precision after the decimal point and the last digit rounded.

func (*Rat) [GobDecode](#)

```
func (z *Rat) GobDecode(buf []byte) error
```

GobDecode implements the gob.GobDecoder interface.

func (*Rat) [GobEncode](#)

```
func (x *Rat) GobEncode() ([]byte, error)
```

GobEncode implements the gob.GobEncoder interface.

func (*Rat) [Inv](#)

```
func (z *Rat) Inv(x *Rat) *Rat
```

Inv sets z to $1/x$ and returns z.

func (*Rat) [IsInt](#)

```
func (x *Rat) IsInt() bool
```

IsInt returns true if the denominator of x is 1.

func (*Rat) [Mul](#)

```
func (z *Rat) Mul(x, y *Rat) *Rat
```

Mul sets z to the product $x*y$ and returns z.

func (*Rat) [Neg](#)

```
func (z *Rat) Neg(x *Rat) *Rat
```

Neg sets z to -x and returns z.

func (*Rat) [Num](#)

```
func (x *Rat) Num() *Int
```

Num returns the numerator of x; it may be ≤ 0 . The result is a reference to x's numerator; it may change if a new value is assigned to x.

func (*Rat) [Quo](#)

```
func (z *Rat) Quo(x, y *Rat) *Rat
```

Quo sets z to the quotient x/y and returns z. If $y == 0$, a division-by-zero runtime panic occurs.

func (*Rat) [RatString](#)

```
func (x *Rat) RatString() string
```

RatString returns a string representation of z in the form "a/b" if $b \neq 1$, and in the form "a" if $b == 1$.

func (*Rat) [Scan](#)

```
func (z *Rat) Scan(s fmt.ScanState, ch rune) error
```

Scan is a support routine for `fmt.Scanner`. It accepts the formats 'e', 'E', 'f', 'F', 'g', 'G', and 'v'. All formats are equivalent.

? Example

? Example

Code:

```
// The Scan function is rarely used directly;
// the fmt package recognizes it as an implementation of fmt.Scanner
r := new(big.Rat)
_, err := fmt.Sscan("1.5000", r)
if err != nil {
    log.Println("error scanning value:", err)
} else {
    fmt.Println(r)
}
```

Output:

3/2

func (*Rat) [Set](#)

```
func (z *Rat) Set(x *Rat) *Rat
```

Set sets z to x (by making a copy of x) and returns z.

func (*Rat) [SetFrac](#)

```
func (z *Rat) SetFrac(a, b *Int) *Rat
```

SetFrac sets z to a/b and returns z.

func (*Rat) [SetFrac64](#)

```
func (z *Rat) SetFrac64(a, b int64) *Rat
```

SetFrac64 sets z to a/b and returns z.

func (*Rat) [SetInt](#)

```
func (z *Rat) SetInt(x *Int) *Rat
```

SetInt sets z to x (by making a copy of x) and returns z.

func (*Rat) [SetInt64](#)

```
func (z *Rat) SetInt64(x int64) *Rat
```

SetInt64 sets z to x and returns z.

func (*Rat) [SetString](#)

```
func (z *Rat) SetString(s string) (*Rat, bool)
```

SetString sets z to the value of s and returns z and a boolean indicating success. s can be given as a fraction "a/b" or as a floating-point number optionally followed by an exponent. If the operation failed, the value of z is undefined but the returned value is nil.

? Example

? Example

Code:

```
r := new(big.Rat)
r.SetString("355/113")
fmt.Println(r.FloatString(3))
```

Output:

3.142

func (*Rat) [Sign](#)

```
func (x *Rat) Sign() int
```

Sign returns:

```
-1 if x < 0
 0 if x == 0
+1 if x > 0
```

func (*Rat) [String](#)

```
func (x *Rat) String() string
```

String returns a string representation of z in the form "a/b" (even if b == 1).

func (*Rat) [Sub](#)

```
func (z *Rat) Sub(x, y *Rat) *Rat
```

Sub sets z to the difference x-y and returns z.

type [Word](#)

```
type word uintptr
```

A Word represents a single digit of a multi-precision unsigned integer.

Build version go1.0.1.

func [Abs](#)

```
func Abs(x complex128) float64
```

Abs returns the absolute value (also called the modulus) of x.

func [Acos](#)

```
func Acos(x complex128) complex128
```

Acos returns the inverse cosine of x.

func [Acosh](#)

`func Acosh(x complex128) complex128`

Acosh returns the inverse hyperbolic cosine of x.

func [Asin](#)

```
func Asin(x complex128) complex128
```

Asin returns the inverse sine of x.

func [Asinh](#)

```
func Asinh(x complex128) complex128
```

Asinh returns the inverse hyperbolic sine of x.

func [Atan](#)

```
func Atan(x complex128) complex128
```

Atan returns the inverse tangent of x.

func [Atanh](#)

`func Atanh(x complex128) complex128`

Atanh returns the inverse hyperbolic tangent of x.

func [Conj](#)

```
func Conj(x complex128) complex128
```

Conj returns the complex conjugate of x.

func Cos

```
func Cos(x complex128) complex128
```

Cos returns the cosine of x.

func Cosh

```
func Cosh(x complex128) complex128
```

Cosh returns the hyperbolic cosine of x .

func [Cot](#)

```
func Cot(x complex128) complex128
```

Cot returns the cotangent of x.

func [Exp](#)

```
func Exp(x complex128) complex128
```

Exp returns e^{**x} , the base-e exponential of x.

func [Inf](#)

```
func Inf() complex128
```

Inf returns a complex infinity, `complex(+Inf, +Inf)`.

func [IsInf](#)

```
func IsInf(x complex128) bool
```

IsInf returns true if either `real(x)` or `imag(x)` is an infinity.

func [IsNaN](#)

```
func IsNaN(x complex128) bool
```

IsNaN returns true if either `real(x)` or `imag(x)` is NaN and neither is an infinity.

func Log

```
func Log(x complex128) complex128
```

Log returns the natural logarithm of x.

func Log10

`func Log10(x complex128) complex128`

Log10 returns the decimal logarithm of x.

func [NaN](#)

```
func NaN() complex128
```

NaN returns a complex “not-a-number” value.

func [Phase](#)

```
func Phase(x complex128) float64
```

Phase returns the phase (also called the argument) of x . The returned value is in the range $[-\pi, \pi]$.

func [Polar](#)

```
func Polar(x complex128) (r, float64)
```

Polar returns the absolute value r and phase of x , such that $x = r * e^{**i}$. The phase is in the range $[-\text{Pi}, \text{Pi}]$.

func Pow

`func Pow(x, y complex128) complex128`

Pow returns $x^{**}y$, the base-x exponential of y.

func [Rect](#)

```
func Rect(r, float64) complex128
```

Rect returns the complex number x with polar coordinates r, θ .

func [Sin](#)

```
func Sin(x complex128) complex128
```

Sin returns the sine of x.

func [Sinh](#)

```
func Sinh(x complex128) complex128
```

Sinh returns the hyperbolic sine of x.

func [Sqrt](#)

```
func Sqrt(x complex128) complex128
```

Sqrt returns the square root of x.

func [Tan](#)

```
func Tan(x complex128) complex128
```

Tan returns the tangent of x.

func [Tanh](#)

```
func Tanh(x complex128) complex128
```

Tanh returns the hyperbolic tangent of x.

Package files

[exp.go](#) [normal.go](#) [rand.go](#) [rng.go](#) [zipf.go](#)

func [ExpFloat64](#)

```
func ExpFloat64() float64
```

ExpFloat64 returns an exponentially distributed float64 in the range (0, +math.MaxFloat64] with an exponential distribution whose rate parameter (lambda) is 1 and whose mean is 1/lambda (1). To produce a distribution with a different rate parameter, callers can adjust the output using:

```
sample = ExpFloat64() / desiredRateParameter
```

func Float32

```
func Float32() float32
```

Float32 returns, as a float32, a pseudo-random number in [0.0,1.0).

func Float64

```
func Float64() float64
```

Float64 returns, as a float64, a pseudo-random number in [0.0,1.0).

func Int

```
func Int() int
```

Int returns a non-negative pseudo-random int.

func [Int31](#)

```
func Int31() int32
```

Int31 returns a non-negative pseudo-random 31-bit integer as an int32.

func [Int31n](#)

```
func Int31n(n int32) int32
```

Int31n returns, as an int32, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func [Int63](#)

```
func Int63() int64
```

Int63 returns a non-negative pseudo-random 63-bit integer as an int64.

func Int63n

```
func Int63n(n int64) int64
```

Int63n returns, as an int64, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func [Intn](#)

```
func Intn(n int) int
```

Intn returns, as an int, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func [NormFloat64](#)

```
func NormFloat64() float64
```

NormFloat64 returns a normally distributed float64 in the range [-math.MaxFloat64, +math.MaxFloat64] with standard normal distribution (mean = 0, stddev = 1). To produce a different normal distribution, callers can adjust the output using:

```
sample = NormFloat64() * desiredStdDev + desiredMean
```

func Perm

```
func Perm(n int) []int
```

Perm returns, as a slice of n ints, a pseudo-random permutation of the integers [0,n).

func [Seed](#)

```
func Seed(seed int64)
```

Seed uses the provided seed value to initialize the generator to a deterministic state. If Seed is not called, the generator behaves as if seeded by Seed(1).

func [Uint32](#)

```
func Uint32() uint32
```

Uin32 returns a pseudo-random 32-bit value as a uint32.

type [Rand](#)

```
type Rand struct {  
    // contains filtered or unexported fields  
}
```

A Rand is a source of random numbers.

func [New](#)

```
func New(src Source) *Rand
```

New returns a new Rand that uses random values from src to generate other random values.

func (*Rand) [ExpFloat64](#)

```
func (r *Rand) ExpFloat64() float64
```

ExpFloat64 returns an exponentially distributed float64 in the range (0, +math.MaxFloat64] with an exponential distribution whose rate parameter (lambda) is 1 and whose mean is 1/lambda (1). To produce a distribution with a different rate parameter, callers can adjust the output using:

```
sample = ExpFloat64() / desiredRateParameter
```

func (*Rand) [Float32](#)

```
func (r *Rand) Float32() float32
```

Float32 returns, as a float32, a pseudo-random number in [0.0,1.0).

func (*Rand) [Float64](#)

```
func (r *Rand) Float64() float64
```

Float64 returns, as a float64, a pseudo-random number in [0.0,1.0).

func (*Rand) [Int](#)

```
func (r *Rand) Int() int
```

Int returns a non-negative pseudo-random int.

func (*Rand) [Int31](#)

```
func (r *Rand) Int31() int32
```

Int31 returns a non-negative pseudo-random 31-bit integer as an int32.

func (*Rand) [Int31n](#)

```
func (r *Rand) Int31n(n int32) int32
```

Int31n returns, as an int32, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func (*Rand) [Int63](#)

```
func (r *Rand) Int63() int64
```

Int63 returns a non-negative pseudo-random 63-bit integer as an int64.

func (*Rand) [Int63n](#)

```
func (r *Rand) Int63n(n int64) int64
```

Int63n returns, as an int64, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func (*Rand) [Intn](#)

```
func (r *Rand) Intn(n int) int
```

Intn returns, as an int, a non-negative pseudo-random number in [0,n). It panics if $n \leq 0$.

func (*Rand) [NormFloat64](#)

```
func (r *Rand) NormFloat64() float64
```

NormFloat64 returns a normally distributed float64 in the range [-math.MaxFloat64, +math.MaxFloat64] with standard normal distribution (mean = 0, stddev = 1). To produce a different normal distribution, callers can adjust the output using:

```
sample = NormFloat64() * desiredStdDev + desiredMean
```

func (*Rand) [Perm](#)

```
func (r *Rand) Perm(n int) []int
```

Perm returns, as a slice of n ints, a pseudo-random permutation of the integers [0,n).

func (*Rand) [Seed](#)

```
func (r *Rand) Seed(seed int64)
```

Seed uses the provided seed value to initialize the generator to a deterministic state.

func (*Rand) [Uint32](#)

```
func (r *Rand) Uint32() uint32
```

Uint32 returns a pseudo-random 32-bit value as a uint32.

type [Source](#)

```
type Source interface {  
    Int63() int64  
    Seed(seed int64)  
}
```

A Source represents a source of uniformly-distributed pseudo-random int64 values in the range $[0, 1 \ll 63)$.

func [NewSource](#)

```
func NewSource(seed int64) Source
```

NewSource returns a new pseudo-random Source seeded with the given value.

type [Zipf](#)

```
type Zipf struct {  
    // contains filtered or unexported fields  
}
```

A Zipf generates Zipf distributed variates.

func [NewZipf](#)

```
func NewZipf(r *Rand, s float64, v float64, imax uint64) *Zipf
```

NewZipf returns a Zipf generating variates $p(k)$ on $[0, imax]$ proportional to $(v+k)^{-s}$ where $s > 1$ and $k \geq 0$, and $v \geq 1$.

func (*Zipf) [Uint64](#)

```
func (z *Zipf) Uint64() uint64
```

Uint64 returns a value drawn from the Zipf distributed described by the Zipf object.

Build version go1.0.1.

Package mime

```
import "mime"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package mime implements parts of the MIME spec.

Index

[func AddExtensionType\(ext, typ string\) error](#)
[func FormatMediaType\(t string, param map\[string\]string\) string](#)
[func ParseMediaType\(v string\) \(mediatype string, params map\[string\]string, err error\)](#)
[func TypeByExtension\(ext string\) string](#)

Package files

[grammar.go](#) [mediatype.go](#) [type.go](#) [type_unix.go](#)

func [AddExtensionType](#)

```
func AddExtensionType(ext, typ string) error
```

AddExtensionType sets the MIME type associated with the extension ext to typ. The extension should begin with a leading dot, as in ".html".

func [FormatMediaType](#)

```
func FormatMediaType(t string, param map[string]string) string
```

FormatMediaType serializes mediatype t and the parameters param as a media type conforming to RFC 2045 and RFC 2616. The type and parameter names are written in lower-case. When any of the arguments result in a standard violation then FormatMediaType returns the empty string.

func [ParseMediaType](#)

```
func ParseMediaType(v string) (mediatype string, params map[string]s
```

ParseMediaType parses a media type value and any optional parameters, per RFC 1521. Media types are the values in Content-Type and Content-Disposition headers (RFC 2183). On success, ParseMediaType returns the media type converted to lowercase and trimmed of white space and a non-nil map. The returned map, params, maps from the lowercase attribute to the attribute value with its case preserved.

func [TypeByExtension](#)

```
func TypeByExtension(ext string) string
```

TypeByExtension returns the MIME type associated with the file extension ext. The extension ext should begin with a leading dot, as in ".html". When ext has no associated type, TypeByExtension returns "".

The built-in table is small but on unix it is augmented by the local system's mime.types file(s) if available under one or more of these names:

```
/etc/mime.types  
/etc/apache2/mime.types  
/etc/apache/mime.types
```

Windows system mime types are extracted from registry.

Text types have the charset parameter set to "utf-8" by default.

Subdirectories

Name	Synopsis
multipart	Package multipart implements MIME multipart parsing, as defined in RFC 2046.

Build version go1.0.1.

Package multipart

```
import "mime/multipart"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package multipart implements MIME multipart parsing, as defined in RFC 2046.

The implementation is sufficient for HTTP (RFC 2388) and the multipart bodies generated by popular browsers.

Package files

[formdata.go](#) [multipart.go](#) [writer.go](#)

type [File](#)

```
type File interface {  
    io.Reader  
    io.ReaderAt  
    io.Seeker  
    io.Closer  
}
```

File is an interface to access the file part of a multipart message. Its contents may be either stored in memory or on disk. If stored on disk, the File's underlying concrete type will be an `*os.File`.

type [FileHeader](#)

```
type FileHeader struct {  
    Filename string  
    Header    textproto.MIMEHeader  
    // contains filtered or unexported fields  
}
```

A FileHeader describes a file part of a multipart request.

func (*FileHeader) [Open](#)

```
func (fh *FileHeader) Open() (File, error)
```

Open opens and returns the FileHeader's associated File.

type [Form](#)

```
type Form struct {  
    Value map[string][]string  
    File  map[string][]*FileHeader  
}
```

Form is a parsed multipart form. Its File parts are stored either in memory or on disk, and are accessible via the *FileHeader's Open method. Its Value parts are stored as strings. Both are keyed by field name.

func (*Form) [RemoveAll](#)

```
func (f *Form) RemoveAll() error
```

RemoveAll removes any temporary files associated with a Form.

type [Part](#)

```
type Part struct {  
    // The headers of the body, if any, with the keys canonicalized  
    // in the same fashion that the Go http.Request headers are.  
    // i.e. "foo-bar" changes case to "Foo-Bar"  
    Header textproto.MIMEHeader  
    // contains filtered or unexported fields  
}
```

A Part represents a single part in a multipart body.

func (***Part**) [Close](#)

```
func (p *Part) Close() error
```

func (***Part**) [FileName](#)

```
func (p *Part) FileName() string
```

FileName returns the filename parameter of the Part's Content-Disposition header.

func (***Part**) [FormName](#)

```
func (p *Part) FormName() string
```

FormName returns the name parameter if p has a Content-Disposition of type "form-data". Otherwise it returns the empty string.

func (***Part**) [Read](#)

```
func (p *Part) Read(d []byte) (n int, err error)
```

Read reads the body of a part, after its headers and before the next part (if any) begins.

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

Reader is an iterator over parts in a MIME multipart body. Reader's underlying parser consumes its input as needed. Seeking isn't supported.

func [NewReader](#)

```
func NewReader(reader io.Reader, boundary string) *Reader
```

NewReader creates a new multipart Reader reading from r using the given MIME boundary.

func (***Reader**) [NextPart](#)

```
func (r *Reader) NextPart() (*Part, error)
```

NextPart returns the next part in the multipart or an error. When there are no more parts, the error io.EOF is returned.

func (***Reader**) [ReadForm](#)

```
func (r *Reader) ReadForm(maxMemory int64) (f *Form, err error)
```

ReadForm parses an entire multipart message whose parts have a Content-Disposition of "form-data". It stores up to maxMemory bytes of the file parts in memory and the remainder on disk in temporary files.

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A Writer generates multipart messages.

func [NewWriter](#)

```
func NewWriter(w io.Writer) *Writer
```

NewWriter returns a new multipart Writer with a random boundary, writing to w.

func (***Writer**) [Boundary](#)

```
func (w *Writer) Boundary() string
```

Boundary returns the Writer's randomly selected boundary string.

func (***Writer**) [Close](#)

```
func (w *Writer) Close() error
```

Close finishes the multipart message and writes the trailing boundary end line to the output.

func (***Writer**) [CreateFormField](#)

```
func (w *Writer) CreateFormField(fieldname string) (io.Writer, error)
```

CreateFormField calls CreatePart with a header using the given field name.

func (***Writer**) [CreateFormFile](#)

```
func (w *Writer) CreateFormFile(fieldname, filename string) (io.Writ
```

CreateFormFile is a convenience wrapper around CreatePart. It creates a new form-data header with the provided field name and file name.

func (*Writer) [CreatePart](#)

```
func (w *Writer) CreatePart(header textproto.MIMEHeader) (io.Writer,
```

CreatePart creates a new multipart section with the provided header. The body of the part should be written to the returned Writer. After calling CreatePart, any previous part may no longer be written to.

func (*Writer) [FormDataContentType](#)

```
func (w *Writer) FormDataContentType() string
```

FormDataContentType returns the Content-Type for an HTTP multipart/form-data with this Writer's Boundary.

func (*Writer) [WriteField](#)

```
func (w *Writer) WriteField(fieldname, value string) error
```

WriteField calls CreateFormField and then writes the given value.

Build version go1.0.1.

Package net

```
import "net"
```

[Overview](#)

[Index](#)

[Examples](#)

[Subdirectories](#)

Overview ?

Overview ?

Package net provides a portable interface for network I/O, including TCP/IP, UDP, domain name resolution, and Unix domain sockets.

Although the package provides access to low-level networking primitives, most clients will need only the basic interface provided by the Dial, Listen, and Accept functions and the associated Conn and Listener interfaces. The crypto/tls package uses the same interfaces and similar Dial and Listen functions.

The Dial function connects to a server:

```
conn, err := net.Dial("tcp", "google.com:80")
if err != nil {
    // handle error
}
fmt.Fprintf(conn, "GET / HTTP/1.0\r\n\r\n")
status, err := bufio.NewReader(conn).ReadString('\n')
// ...
```

The Listen function creates servers:

```
ln, err := net.Listen("tcp", ":8080")
if err != nil {
    // handle error
}
for {
    conn, err := ln.Accept()
    if err != nil {
        // handle error
        continue
    }
    go handleConnection(conn)
}
```

Constants

```
const (  
    IPv4len = 4  
    IPv6len = 16  
)
```

IP address lengths (bytes).

Variables

```
var (  
    IPv4bcast      = IPv4(255, 255, 255, 255) // broadcast  
    IPv4allsys    = IPv4(224, 0, 0, 1)       // all systems  
    IPv4allrouter = IPv4(224, 0, 0, 2)       // all routers  
    IPv4zero      = IPv4(0, 0, 0, 0)        // all zeros  
)
```

Well-known IPv4 addresses

```
var (  
    IPv6zero          = IP{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
    IPv6unspecified  = IP{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
    IPv6loopback     = IP{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
    IPv6interfacelocalallnodes = IP{0xff, 0x01, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
    IPv6linklocalallnodes    = IP{0xff, 0x02, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
    IPv6linklocalallrouters  = IP{0xff, 0x02, 0, 0, 0, 0, 0, 0, 0, 0, 0,  
)
```

Well-known IPv6 addresses

```
var ErrWriteToConnected = errors.New("use of WriteTo with pre-connec
```

func [InterfaceAddr](#)

```
func InterfaceAddr() ([]Addr, error)
```

InterfaceAddr returns a list of the system's network interface addresses.

func [Interfaces](#)

```
func Interfaces() ([]Interface, error)
```

Interfaces returns a list of the system's network interfaces.

func [JoinHostPort](#)

```
func JoinHostPort(host, port string) string
```

JoinHostPort combines host and port into a network address of the form "host:port" or, if host contains a colon, "[host]:port".

func LookupAddr

```
func LookupAddr(addr string) (name []string, err error)
```

LookupAddr performs a reverse lookup for the given address, returning a list of names mapping to that address.

func LookupCNAME

```
func LookupCNAME(name string) (cname string, err error)
```

LookupCNAME returns the canonical DNS host for the given name. Callers that do not care about the canonical name can call LookupHost or LookupIP directly; both take care of resolving the canonical name as part of the lookup.

func LookupHost

```
func LookupHost(host string) (addrs []string, err error)
```

LookupHost looks up the given host using the local resolver. It returns an array of that host's addresses.

func [LookupIP](#)

```
func LookupIP(host string) (addrs []IP, err error)
```

LookupIP looks up host using the local resolver. It returns an array of that host's IPv4 and IPv6 addresses.

func LookupMX

```
func LookupMX(name string) (mx []*MX, err error)
```

LookupMX returns the DNS MX records for the given domain name sorted by preference.

func LookupPort

```
func LookupPort(network, service string) (port int, err error)
```

LookupPort looks up the port for the given network and service.

func [LookupSRV](#)

```
func LookupSRV(service, proto, name string) (cname string, addrs []*)
```

LookupSRV tries to resolve an SRV query of the given service, protocol, and domain name. The proto is "tcp" or "udp". The returned records are sorted by priority and randomized by weight within a priority.

LookupSRV constructs the DNS name to look up following RFC 2782. That is, it looks up `_service._proto.name`. To accommodate services publishing SRV records under non-standard names, if both service and proto are empty strings, LookupSRV looks up name directly.

func LookupTXT

```
func LookupTXT(name string) (txt []string, err error)
```

LookupTXT returns the DNS TXT records for the given domain name.

func [SplitHostPort](#)

```
func SplitHostPort(hostport string) (host, port string, err error)
```

SplitHostPort splits a network address of the form "host:port" or "[host]:port" into host and port. The latter form must be used when host contains a colon.

type [Addr](#)

```
type Addr interface {  
    Network() string // name of the network  
    String() string  // string form of address  
}
```

Addr represents a network end point address.

type [AddrError](#)

```
type AddrError struct {  
    Err string  
    Addr string  
}
```

func (*AddrError) [Error](#)

```
func (e *AddrError) Error() string
```

func (*AddrError) [Temporary](#)

```
func (e *AddrError) Temporary() bool
```

func (*AddrError) [Timeout](#)

```
func (e *AddrError) Timeout() bool
```

type [Conn](#)

```
type Conn interface {
    // Read reads data from the connection.
    // Read can be made to time out and return a Error with Timeout(
    // after a fixed time limit; see SetDeadline and SetReadDeadline
    Read(b []byte) (n int, err error)

    // Write writes data to the connection.
    // Write can be made to time out and return a Error with Timeout
    // after a fixed time limit; see SetDeadline and SetWriteDeadlin
    Write(b []byte) (n int, err error)

    // Close closes the connection.
    // Any blocked Read or Write operations will be unblocked and re
    Close() error

    // LocalAddr returns the local network address.
    LocalAddr() Addr

    // RemoteAddr returns the remote network address.
    RemoteAddr() Addr

    // SetDeadline sets the read and write deadlines associated
    // with the connection. It is equivalent to calling both
    // SetReadDeadline and SetWriteDeadline.
    //
    // A deadline is an absolute time after which I/O operations
    // fail with a timeout (see type Error) instead of
    // blocking. The deadline applies to all future I/O, not just
    // the immediately following call to Read or Write.
    //
    // An idle timeout can be implemented by repeatedly extending
    // the deadline after successful Read or Write calls.
    //
    // A zero value for t means I/O operations will not time out.
    SetDeadline(t time.Time) error

    // SetReadDeadline sets the deadline for future Read calls.
    // A zero value for t means Read will not time out.
    SetReadDeadline(t time.Time) error

    // SetWriteDeadline sets the deadline for future Write calls.
    // Even if write times out, it may return n > 0, indicating that
    // some of the data was successfully written.
    // A zero value for t means Write will not time out.
    SetWriteDeadline(t time.Time) error
}
```

```
}
```

Conn is a generic stream-oriented network connection.

Multiple goroutines may invoke methods on a Conn simultaneously.

func [Dial](#)

```
func Dial(net, addr string) (Conn, error)
```

Dial connects to the address addr on the network net.

Known networks are "tcp", "tcp4" (IPv4-only), "tcp6" (IPv6-only), "udp", "udp4" (IPv4-only), "udp6" (IPv6-only), "ip", "ip4" (IPv4-only), "ip6" (IPv6-only), "unix" and "unixpacket".

For TCP and UDP networks, addresses have the form host:port. If host is a literal IPv6 address, it must be enclosed in square brackets. The functions JoinHostPort and SplitHostPort manipulate addresses in this form.

Examples:

```
Dial("tcp", "12.34.56.78:80")
Dial("tcp", "google.com:80")
Dial("tcp", "[de:ad:be:ef::ca:fe]:80")
```

For IP networks, addr must be "ip", "ip4" or "ip6" followed by a colon and a protocol number or name.

Examples:

```
Dial("ip4:1", "127.0.0.1")
Dial("ip6:ospf", ":::1")
```

func [DialTimeout](#)

```
func DialTimeout(net, addr string, timeout time.Duration) (Conn, err
```

DialTimeout acts like Dial but takes a timeout. The timeout includes name resolution, if required.

func [FileConn](#)

```
func FileConn(f *os.File) (c Conn, err error)
```

FileConn returns a copy of the network connection corresponding to the open file `f`. It is the caller's responsibility to close `f` when finished. Closing `c` does not affect `f`, and closing `f` does not affect `c`.

func [Pipe](#)

```
func Pipe() (Conn, Conn)
```

Pipe creates a synchronous, in-memory, full duplex network connection; both ends implement the Conn interface. Reads on one end are matched with writes on the other, copying data directly between the two; there is no internal buffering.

type [DNSConfigError](#)

```
type DNSConfigError struct {  
    Err error  
}
```

DNSConfigError represents an error reading the machine's DNS configuration.

func (*DNSConfigError) [Error](#)

```
func (e *DNSConfigError) Error() string
```

func (*DNSConfigError) [Temporary](#)

```
func (e *DNSConfigError) Temporary() bool
```

func (*DNSConfigError) [Timeout](#)

```
func (e *DNSConfigError) Timeout() bool
```

type [DNSError](#)

```
type DNSError struct {  
    Err      string // description of the error  
    Name     string // name looked for  
    Server   string // server used  
    IsTimeout bool  
}
```

DNSError represents a DNS lookup error.

func (***DNSError**) [Error](#)

```
func (e *DNSError) Error() string
```

func (***DNSError**) [Temporary](#)

```
func (e *DNSError) Temporary() bool
```

func (***DNSError**) [Timeout](#)

```
func (e *DNSError) Timeout() bool
```

type [Error](#)

```
type Error interface {  
    error  
    Timeout() bool // Is the error a timeout?  
    Temporary() bool // Is the error temporary?  
}
```

An Error represents a network error.

type [Flags](#)

```
type Flags uint
```

```
const (  
    FlagUp           Flags = 1 << iota // interface is up  
    FlagBroadcast    // interface supports broadca  
    FlagLoopback     // interface is a loopback in  
    FlagPointToPoint // interface belongs to a poi  
    FlagMulticast    // interface supports multica  
)
```

func (Flags) [String](#)

```
func (f Flags) String() string
```

type [HardwareAddr](#)

```
type HardwareAddr []byte
```

A HardwareAddr represents a physical hardware address.

func [ParseMAC](#)

```
func ParseMAC(s string) (hw HardwareAddr, err error)
```

ParseMAC parses s as an IEEE 802 MAC-48, EUI-48, or EUI-64 using one of the following formats:

```
01:23:45:67:89:ab  
01:23:45:67:89:ab:cd:ef  
01-23-45-67-89-ab  
01-23-45-67-89-ab-cd-ef  
0123.4567.89ab  
0123.4567.89ab.cdef
```

func (HardwareAddr) [String](#)

```
func (a HardwareAddr) String() string
```

type [IP](#)

type IP []byte

An IP is a single IP address, an array of bytes. Functions in this package accept either 4-byte (IPv4) or 16-byte (IPv6) arrays as input.

Note that in this documentation, referring to an IP address as an IPv4 address or an IPv6 address is a semantic property of the address, not just the length of the byte array: a 16-byte array can still be an IPv4 address.

func [IPv4](#)

func IPv4(a, b, c, d byte) IP

IPv4 returns the IP address (in 16-byte form) of the IPv4 address a.b.c.d.

func [ParseCIDR](#)

func ParseCIDR(s string) (IP, *IPNet, error)

ParseCIDR parses s as a CIDR notation IP address and mask, like "192.168.100.1/24" or "2001:DB8::/48", as defined in RFC 4632 and RFC 4291.

It returns the IP address and the network implied by the IP and mask. For example, ParseCIDR("192.168.100.1/16") returns the IP address 192.168.100.1 and the network 192.168.0.0/16.

func [ParseIP](#)

func ParseIP(s string) IP

ParseIP parses s as an IP address, returning the result. The string s can be in dotted decimal ("74.125.19.99") or IPv6 ("2001:4860:0:2001::68") form. If s is not a valid textual representation of an IP address, ParseIP returns nil.

func (IP) [DefaultMask](#)

```
func (ip IP) DefaultMask() IPMask
```

DefaultMask returns the default IP mask for the IP address ip. Only IPv4 addresses have default masks; DefaultMask returns nil if ip is not a valid IPv4 address.

func (IP) [Equal](#)

```
func (ip IP) Equal(x IP) bool
```

Equal returns true if ip and x are the same IP address. An IPv4 address and that same address in IPv6 form are considered to be equal.

func (IP) [IsGlobalUnicast](#)

```
func (ip IP) IsGlobalUnicast() bool
```

IsGlobalUnicast returns true if ip is a global unicast address.

func (IP) [IsInterfaceLocalMulticast](#)

```
func (ip IP) IsInterfaceLocalMulticast() bool
```

IsInterfaceLinkLocalMulticast returns true if ip is an interface-local multicast address.

func (IP) [IsLinkLocalMulticast](#)

```
func (ip IP) IsLinkLocalMulticast() bool
```

IsLinkLocalMulticast returns true if ip is a link-local multicast address.

func (IP) [IsLinkLocalUnicast](#)

```
func (ip IP) IsLinkLocalUnicast() bool
```

IsLinkLocalUnicast returns true if ip is a link-local unicast address.

func (IP) [IsLoopback](#)

```
func (ip IP) IsLoopback() bool
```

IsLoopback returns true if ip is a loopback address.

func (IP) [IsMulticast](#)

```
func (ip IP) IsMulticast() bool
```

IsMulticast returns true if ip is a multicast address.

func (IP) [IsUnspecified](#)

```
func (ip IP) IsUnspecified() bool
```

IsUnspecified returns true if ip is an unspecified address.

func (IP) [Mask](#)

```
func (ip IP) Mask(mask IPMask) IP
```

Mask returns the result of masking the IP address ip with mask.

func (IP) [String](#)

```
func (ip IP) String() string
```

String returns the string form of the IP address ip. If the address is an IPv4 address, the string representation is dotted decimal ("74.125.19.99"). Otherwise the representation is IPv6 ("2001:4860:0:2001::68").

func (IP) [To16](#)

```
func (ip IP) To16() IP
```

To16 converts the IP address ip to a 16-byte representation. If ip is not an IP address (it is the wrong length), To16 returns nil.

func (IP) [To4](#)

```
func (ip IP) To4() IP
```

To4 converts the IPv4 address ip to a 4-byte representation. If ip is not an IPv4 address, To4 returns nil.

type [IPAddr](#)

```
type IPAddr struct {  
    IP IP  
}
```

IPAddr represents the address of a IP end point.

func [ResolveIPAddr](#)

```
func ResolveIPAddr(net, addr string) (*IPAddr, error)
```

ResolveIPAddr parses addr as a IP address and resolves domain names to numeric addresses on the network net, which must be "ip", "ip4" or "ip6". A literal IPv6 host address must be enclosed in square brackets, as in "[::]".

func (***IPAddr**) [Network](#)

```
func (a *IPAddr) Network() string
```

Network returns the address's network name, "ip".

func (***IPAddr**) [String](#)

```
func (a *IPAddr) String() string
```

type [IPConn](#)

```
type IPConn struct {  
    // contains filtered or unexported fields  
}
```

IPConn is the implementation of the Conn and PacketConn interfaces for IP network connections.

func [DialIP](#)

```
func DialIP(netProto string, laddr, raddr *IPAddr) (*IPConn, error)
```

DialIP connects to the remote address raddr on the network protocol netProto, which must be "ip", "ip4", or "ip6" followed by a colon and a protocol number or name.

func [ListenIP](#)

```
func ListenIP(netProto string, laddr *IPAddr) (*IPConn, error)
```

ListenIP listens for incoming IP packets addressed to the local address laddr. The returned connection c's ReadFrom and WriteTo methods can be used to receive and send IP packets with per-packet addressing.

func (***IPConn**) [Close](#)

```
func (c *IPConn) Close() error
```

Close closes the IP connection.

func (***IPConn**) [File](#)

```
func (c *IPConn) File() (f *os.File, err error)
```

File returns a copy of the underlying os.File, set to blocking mode. It is the caller's responsibility to close f when finished. Closing c does not affect f, and closing f does not affect c.

func (*IPConn) [LocalAddr](#)

```
func (c *IPConn) LocalAddr() Addr
```

LocalAddr returns the local network address.

func (*IPConn) [Read](#)

```
func (c *IPConn) Read(b []byte) (int, error)
```

Read implements the Conn Read method.

func (*IPConn) [ReadFrom](#)

```
func (c *IPConn) ReadFrom(b []byte) (int, Addr, error)
```

ReadFrom implements the PacketConn ReadFrom method.

func (*IPConn) [ReadFromIP](#)

```
func (c *IPConn) ReadFromIP(b []byte) (int, *IPAddr, error)
```

ReadFromIP reads a IP packet from c, copying the payload into b. It returns the number of bytes copied into b and the return address that was on the packet.

ReadFromIP can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetReadDeadline.

func (*IPConn) [RemoteAddr](#)

```
func (c *IPConn) RemoteAddr() Addr
```

RemoteAddr returns the remote network address, a *IPAddr.

func (*IPConn) [SetDeadline](#)

```
func (c *IPConn) SetDeadline(t time.Time) error
```

SetDeadline implements the Conn SetDeadline method.

func (*IPConn) [SetReadBuffer](#)

```
func (c *IPConn) SetReadBuffer(bytes int) error
```

SetReadBuffer sets the size of the operating system's receive buffer associated with the connection.

func (*IPConn) [SetReadDeadline](#)

```
func (c *IPConn) SetReadDeadline(t time.Time) error
```

SetReadDeadline implements the Conn SetReadDeadline method.

func (*IPConn) [SetWriteBuffer](#)

```
func (c *IPConn) SetWriteBuffer(bytes int) error
```

SetWriteBuffer sets the size of the operating system's transmit buffer associated with the connection.

func (*IPConn) [SetWriteDeadline](#)

```
func (c *IPConn) SetWriteDeadline(t time.Time) error
```

SetWriteDeadline implements the Conn SetWriteDeadline method.

func (*IPConn) [Write](#)

```
func (c *IPConn) Write(b []byte) (int, error)
```

Write implements the Conn Write method.

func (*IPConn) [WriteTo](#)

```
func (c *IPConn) WriteTo(b []byte, addr Addr) (int, error)
```

WriteTo implements the PacketConn WriteTo method.

func (*IPConn) [WriteToIP](#)

```
func (c *IPConn) writeToIP(b []byte, addr *IPAddr) (int, error)
```

WriteToIP writes a IP packet to addr via c, copying the payload from b.

WriteToIP can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetWriteDeadline. On packet-oriented connections, write timeouts are rare.

type [IPMask](#)

type IPMask []byte

An IP mask is an IP address.

func [CIDRMask](#)

func CIDRMask(ones, bits int) IPMask

CIDRMask returns an IPMask consisting of `ones` 1 bits followed by 0s up to a total length of `bits` bits. For a mask of this form, CIDRMask is the inverse of IPMask.Size.

func [IPv4Mask](#)

func IPv4Mask(a, b, c, d byte) IPMask

IPv4Mask returns the IP mask (in 4-byte form) of the IPv4 mask a.b.c.d.

func (IPMask) [Size](#)

func (m IPMask) Size() (ones, bits int)

Size returns the number of leading ones and total bits in the mask. If the mask is not in the canonical form--ones followed by zeros--then Size returns 0, 0.

func (IPMask) [String](#)

func (m IPMask) String() string

String returns the hexadecimal form of m, with no punctuation.

type [IPNet](#)

```
type IPNet struct {
    IP    IP    // network number
    Mask IPMask // network mask
}
```

An IPNet represents an IP network.

func (*IPNet) [Contains](#)

```
func (n *IPNet) Contains(ip IP) bool
```

Contains reports whether the network includes ip.

func (*IPNet) [Network](#)

```
func (n *IPNet) Network() string
```

Network returns the address's network name, "ip+net".

func (*IPNet) [String](#)

```
func (n *IPNet) String() string
```

String returns the CIDR notation of n like "192.168.100.1/24" or "2001:DB8::/48" as defined in RFC 4632 and RFC 4291. If the mask is not in the canonical form, it returns the string which consists of an IP address, followed by a slash character and a mask expressed as hexadecimal form with no punctuation like "192.168.100.1/c000ff00".

type [Interface](#)

```
type Interface struct {
    Index      int           // positive integer that starts at one
    MTU        int           // maximum transmission unit
    Name       string        // e.g., "en0", "lo0", "eth0.100"
    HardwareAddr HardwareAddr // IEEE MAC-48, EUI-48 and EUI-64 form
    Flags      Flags         // e.g., FlagUp, FlagLoopback, FlagMul
}
```

Interface represents a mapping between network interface name and index. It also represents network interface facility information.

func [InterfaceByIndex](#)

```
func InterfaceByIndex(index int) (*Interface, error)
```

InterfaceByIndex returns the interface specified by index.

func [InterfaceByName](#)

```
func InterfaceByName(name string) (*Interface, error)
```

InterfaceByName returns the interface specified by name.

func (*Interface) [Addrs](#)

```
func (ifi *Interface) Addrs() ([]Addr, error)
```

Addrs returns interface addresses for a specific interface.

func (*Interface) [MulticastAddrs](#)

```
func (ifi *Interface) MulticastAddrs() ([]Addr, error)
```

MulticastAddrs returns multicast, joined group addresses for a specific interface.

type [InvalidAddrError](#)

```
type InvalidAddrError string
```

func (InvalidAddrError) [Error](#)

```
func (e InvalidAddrError) Error() string
```

func (InvalidAddrError) [Temporary](#)

```
func (e InvalidAddrError) Temporary() bool
```

func (InvalidAddrError) [Timeout](#)

```
func (e InvalidAddrError) Timeout() bool
```

type [Listener](#)

```
type Listener interface {
    // Accept waits for and returns the next connection to the listener.
    Accept() (c Conn, err error)

    // Close closes the listener.
    // Any blocked Accept operations will be unblocked and return errors.
    Close() error

    // Addr returns the listener's network address.
    Addr() Addr
}
```

A Listener is a generic network listener for stream-oriented protocols.

Multiple goroutines may invoke methods on a Listener simultaneously.

? Example

? Example

Code:

```
// Listen on TCP port 2000 on all interfaces.
l, err := net.Listen("tcp", ":2000")
if err != nil {
    log.Fatal(err)
}
for {
    // Wait for a connection.
    conn, err := l.Accept()
    if err != nil {
        log.Fatal(err)
    }
    // Handle the connection in a new goroutine.
    // The loop then returns to accepting, so that
    // multiple connections may be served concurrently.
    go func(c net.Conn) {
        // Echo all incoming data.
        io.Copy(c, c)
        // Shut down the connection.
        c.Close()
    }(conn)
}
```

func [FileListener](#)

```
func FileListener(f *os.File) (l Listener, err error)
```

FileListener returns a copy of the network listener corresponding to the open file `f`. It is the caller's responsibility to close `l` when finished. Closing `c` does not affect `l`, and closing `l` does not affect `c`.

func [Listen](#)

```
func Listen(net, laddr string) (Listener, error)
```

Listen announces on the local network address `laddr`. The network string `net` must be a stream-oriented network: "tcp", "tcp4", "tcp6", or "unix", or "unixpacket".

type [MX](#)

```
type MX struct {  
    Host string  
    Pref uint16  
}
```

An MX represents a single DNS MX record.

type [OpError](#)

```
type OpError struct {  
    Op    string  
    Net   string  
    Addr  Addr  
    Err   error  
}
```

func (*OpError) [Error](#)

```
func (e *OpError) Error() string
```

func (*OpError) [Temporary](#)

```
func (e *OpError) Temporary() bool
```

func (*OpError) [Timeout](#)

```
func (e *OpError) Timeout() bool
```

type [PacketConn](#)

```
type PacketConn interface {
    // ReadFrom reads a packet from the connection,
    // copying the payload into b. It returns the number of
    // bytes copied into b and the return address that
    // was on the packet.
    // ReadFrom can be made to time out and return
    // an error with Timeout() == true after a fixed time limit;
    // see SetDeadline and SetReadDeadline.
    ReadFrom(b []byte) (n int, addr Addr, err error)

    // WriteTo writes a packet with payload b to addr.
    // WriteTo can be made to time out and return
    // an error with Timeout() == true after a fixed time limit;
    // see SetDeadline and SetWriteDeadline.
    // On packet-oriented connections, write timeouts are rare.
    WriteTo(b []byte, addr Addr) (n int, err error)

    // Close closes the connection.
    // Any blocked ReadFrom or WriteTo operations will be unblocked
    Close() error

    // LocalAddr returns the local network address.
    LocalAddr() Addr

    // SetDeadline sets the read and write deadlines associated
    // with the connection.
    SetDeadline(t time.Time) error

    // SetReadDeadline sets the deadline for future Read calls.
    // If the deadline is reached, Read will fail with a timeout
    // (see type Error) instead of blocking.
    // A zero value for t means Read will not time out.
    SetReadDeadline(t time.Time) error

    // SetWriteDeadline sets the deadline for future Write calls.
    // If the deadline is reached, Write will fail with a timeout
    // (see type Error) instead of blocking.
    // A zero value for t means Write will not time out.
    // Even if write times out, it may return n > 0, indicating that
    // some of the data was successfully written.
    SetWriteDeadline(t time.Time) error
}
```

PacketConn is a generic packet-oriented network connection.

Multiple goroutines may invoke methods on a `PacketConn` simultaneously.

func [FilePacketConn](#)

```
func FilePacketConn(f *os.File) (c PacketConn, err error)
```

`FilePacketConn` returns a copy of the packet network connection corresponding to the open file `f`. It is the caller's responsibility to close `f` when finished. Closing `c` does not affect `f`, and closing `f` does not affect `c`.

func [ListenPacket](#)

```
func ListenPacket(net, addr string) (PacketConn, error)
```

`ListenPacket` announces on the local network address `laddr`. The network string `net` must be a packet-oriented network: "udp", "udp4", "udp6", "ip", "ip4", "ip6" or "unixgram".

type [ParseError](#)

```
type ParseError struct {  
    Type string  
    Text string  
}
```

A ParseError represents a malformed text string and the type of string that was expected.

func (*ParseError) [Error](#)

```
func (e *ParseError) Error() string
```

type [SRV](#)

```
type SRV struct {  
    Target    string  
    Port      uint16  
    Priority  uint16  
    Weight    uint16  
}
```

An SRV represents a single DNS SRV record.

type [TCPAddr](#)

```
type TCPAddr struct {  
    IP    IP  
    Port int  
}
```

TCPAddr represents the address of a TCP end point.

func [ResolveTCPAddr](#)

```
func ResolveTCPAddr(net, addr string) (*TCPAddr, error)
```

ResolveTCPAddr parses addr as a TCP address of the form host:port and resolves domain names or port names to numeric addresses on the network net, which must be "tcp", "tcp4" or "tcp6". A literal IPv6 host address must be enclosed in square brackets, as in "[::]:80".

func (***TCPAddr**) [Network](#)

```
func (a *TCPAddr) Network() string
```

Network returns the address's network name, "tcp".

func (***TCPAddr**) [String](#)

```
func (a *TCPAddr) String() string
```

type [TCPConn](#)

```
type TCPConn struct {  
    // contains filtered or unexported fields  
}
```

TCPConn is an implementation of the Conn interface for TCP network connections.

func [DialTCP](#)

```
func DialTCP(net string, laddr, raddr *TCPAddr) (*TCPConn, error)
```

DialTCP connects to the remote address raddr on the network net, which must be "tcp", "tcp4", or "tcp6". If laddr is not nil, it is used as the local address for the connection.

func (***TCPConn**) [Close](#)

```
func (c *TCPConn) Close() error
```

Close closes the TCP connection.

func (***TCPConn**) [CloseRead](#)

```
func (c *TCPConn) CloseRead() error
```

CloseRead shuts down the reading side of the TCP connection. Most callers should just use Close.

func (***TCPConn**) [CloseWrite](#)

```
func (c *TCPConn) CloseWrite() error
```

CloseWrite shuts down the writing side of the TCP connection. Most callers should just use Close.

func (***TCPConn**) [File](#)

```
func (c *TCPConn) File() (f *os.File, err error)
```

File returns a copy of the underlying `os.File`, set to blocking mode. It is the caller's responsibility to close `f` when finished. Closing `c` does not affect `f`, and closing `f` does not affect `c`.

func (*TCPConn) [LocalAddr](#)

```
func (c *TCPConn) LocalAddr() Addr
```

LocalAddr returns the local network address, a `*TCPAddr`.

func (*TCPConn) [Read](#)

```
func (c *TCPConn) Read(b []byte) (n int, err error)
```

Read implements the `Conn Read` method.

func (*TCPConn) [ReadFrom](#)

```
func (c *TCPConn) ReadFrom(r io.Reader) (int64, error)
```

ReadFrom implements the `io.ReaderFrom ReadFrom` method.

func (*TCPConn) [RemoteAddr](#)

```
func (c *TCPConn) RemoteAddr() Addr
```

RemoteAddr returns the remote network address, a `*TCPAddr`.

func (*TCPConn) [SetDeadline](#)

```
func (c *TCPConn) SetDeadline(t time.Time) error
```

SetDeadline implements the `Conn SetDeadline` method.

func (*TCPConn) [SetKeepAlive](#)

```
func (c *TCPConn) SetKeepAlive(keepalive bool) error
```

SetKeepAlive sets whether the operating system should send keepalive messages on the connection.

func (*TCPConn) [SetLinger](#)

```
func (c *TCPConn) SetLinger(sec int) error
```

SetLinger sets the behavior of Close() on a connection which still has data waiting to be sent or to be acknowledged.

If `sec < 0` (the default), Close returns immediately and the operating system finishes sending the data in the background.

If `sec == 0`, Close returns immediately and the operating system discards any unsent or unacknowledged data.

If `sec > 0`, Close blocks for at most `sec` seconds waiting for data to be sent and acknowledged.

func (*TCPConn) [SetNoDelay](#)

```
func (c *TCPConn) SetNoDelay(noDelay bool) error
```

SetNoDelay controls whether the operating system should delay packet transmission in hopes of sending fewer packets (Nagle's algorithm). The default is true (no delay), meaning that data is sent as soon as possible after a Write.

func (*TCPConn) [SetReadBuffer](#)

```
func (c *TCPConn) SetReadBuffer(bytes int) error
```

SetReadBuffer sets the size of the operating system's receive buffer associated with the connection.

func (*TCPConn) [SetReadDeadline](#)

```
func (c *TCPConn) SetReadDeadline(t time.Time) error
```

SetReadDeadline implements the Conn SetReadDeadline method.

func (*TCPConn) [SetWriteBuffer](#)

```
func (c *TCPConn) SetWriteBuffer(bytes int) error
```

SetWriteBuffer sets the size of the operating system's transmit buffer associated with the connection.

func (*TCPConn) [SetWriteDeadline](#)

```
func (c *TCPConn) SetWriteDeadline(t time.Time) error
```

SetWriteDeadline implements the Conn SetWriteDeadline method.

func (*TCPConn) [Write](#)

```
func (c *TCPConn) Write(b []byte) (n int, err error)
```

Write implements the Conn Write method.

type [TCPListener](#)

```
type TCPListener struct {  
    // contains filtered or unexported fields  
}
```

TCPListener is a TCP network listener. Clients should typically use variables of type `Listener` instead of assuming `TCP`.

func [ListenTCP](#)

```
func ListenTCP(net string, laddr *TCPAddr) (*TCPListener, error)
```

`ListenTCP` announces on the TCP address `laddr` and returns a TCP listener. `Net` must be `"tcp"`, `"tcp4"`, or `"tcp6"`. If `laddr` has a port of 0, it means to listen on some available port. The caller can use `l.Addr()` to retrieve the chosen address.

func (***TCPListener**) [Accept](#)

```
func (l *TCPListener) Accept() (c Conn, err error)
```

`Accept` implements the `Accept` method in the `Listener` interface; it waits for the next call and returns a generic `Conn`.

func (***TCPListener**) [AcceptTCP](#)

```
func (l *TCPListener) AcceptTCP() (c *TCPConn, err error)
```

`AcceptTCP` accepts the next incoming call and returns the new connection and the remote address.

func (***TCPListener**) [Addr](#)

```
func (l *TCPListener) Addr() Addr
```

`Addr` returns the listener's network address, a `*TCPAddr`.

func (***TCPListener**) [Close](#)

```
func (l *TCPListener) Close() error
```

Close stops listening on the TCP address. Already Accepted connections are not closed.

func (*TCPListener) [File](#)

```
func (l *TCPListener) File() (f *os.File, err error)
```

File returns a copy of the underlying os.File, set to blocking mode. It is the caller's responsibility to close f when finished. Closing l does not affect f, and closing f does not affect l.

func (*TCPListener) [SetDeadline](#)

```
func (l *TCPListener) SetDeadline(t time.Time) error
```

SetDeadline sets the deadline associated with the listener. A zero time value disables the deadline.

type [UDPAddr](#)

```
type UDPAddr struct {  
    IP    IP  
    Port int  
}
```

UDPAddr represents the address of a UDP end point.

func [ResolveUDPAddr](#)

```
func ResolveUDPAddr(net, addr string) (*UDPAddr, error)
```

ResolveUDPAddr parses addr as a UDP address of the form host:port and resolves domain names or port names to numeric addresses on the network net, which must be "udp", "udp4" or "udp6". A literal IPv6 host address must be enclosed in square brackets, as in "[::]:80".

func (***UDPAddr**) [Network](#)

```
func (a *UDPAddr) Network() string
```

Network returns the address's network name, "udp".

func (***UDPAddr**) [String](#)

```
func (a *UDPAddr) String() string
```

type [UDPConn](#)

```
type UDPConn struct {  
    // contains filtered or unexported fields  
}
```

UDPConn is the implementation of the Conn and PacketConn interfaces for UDP network connections.

func [DialUDP](#)

```
func DialUDP(net string, laddr, raddr *UDPAddr) (*UDPConn, error)
```

DialUDP connects to the remote address raddr on the network net, which must be "udp", "udp4", or "udp6". If laddr is not nil, it is used as the local address for the connection.

func [ListenMulticastUDP](#)

```
func ListenMulticastUDP(net string, ifi *Interface, gaddr *UDPAddr)
```

ListenMulticastUDP listens for incoming multicast UDP packets addressed to the group address gaddr on ifi, which specifies the interface to join. ListenMulticastUDP uses default multicast interface if ifi is nil.

func [ListenUDP](#)

```
func ListenUDP(net string, laddr *UDPAddr) (*UDPConn, error)
```

ListenUDP listens for incoming UDP packets addressed to the local address laddr. The returned connection c's ReadFrom and WriteTo methods can be used to receive and send UDP packets with per-packet addressing.

func [ListenUnixgram](#)

```
func ListenUnixgram(net string, laddr *UnixAddr) (*UDPConn, error)
```

ListenUnixgram listens for incoming Unix datagram packets addressed to the local address laddr. The returned connection c's ReadFrom and WriteTo methods

can be used to receive and send UDP packets with per-packet addressing. The network net must be "unixgram".

func (*UDPConn) [Close](#)

```
func (c *UDPConn) Close() error
```

Close closes the UDP connection.

func (*UDPConn) [File](#)

```
func (c *UDPConn) File() (f *os.File, err error)
```

File returns a copy of the underlying os.File, set to blocking mode. It is the caller's responsibility to close f when finished. Closing c does not affect f, and closing f does not affect c.

func (*UDPConn) [LocalAddr](#)

```
func (c *UDPConn) LocalAddr() Addr
```

LocalAddr returns the local network address.

func (*UDPConn) [Read](#)

```
func (c *UDPConn) Read(b []byte) (int, error)
```

Read implements the Conn Read method.

func (*UDPConn) [ReadFrom](#)

```
func (c *UDPConn) ReadFrom(b []byte) (int, Addr, error)
```

ReadFrom implements the PacketConn ReadFrom method.

func (*UDPConn) [ReadFromUDP](#)

```
func (c *UDPConn) ReadFromUDP(b []byte) (n int, addr *UDPAddr, err e
```

ReadFromUDP reads a UDP packet from c, copying the payload into b. It returns

the number of bytes copied into b and the return address that was on the packet.

ReadFromUDP can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetReadDeadline.

func (*UDPConn) [RemoteAddr](#)

```
func (c *UDPConn) RemoteAddr() Addr
```

RemoteAddr returns the remote network address, a *UDPAddr.

func (*UDPConn) [SetDeadline](#)

```
func (c *UDPConn) SetDeadline(t time.Time) error
```

SetDeadline implements the Conn SetDeadline method.

func (*UDPConn) [SetReadBuffer](#)

```
func (c *UDPConn) SetReadBuffer(bytes int) error
```

SetReadBuffer sets the size of the operating system's receive buffer associated with the connection.

func (*UDPConn) [SetReadDeadline](#)

```
func (c *UDPConn) SetReadDeadline(t time.Time) error
```

SetReadDeadline implements the Conn SetReadDeadline method.

func (*UDPConn) [SetWriteBuffer](#)

```
func (c *UDPConn) SetWriteBuffer(bytes int) error
```

SetWriteBuffer sets the size of the operating system's transmit buffer associated with the connection.

func (*UDPConn) [SetWriteDeadline](#)

```
func (c *UDPConn) SetWriteDeadline(t time.Time) error
```

SetWriteDeadline implements the Conn SetWriteDeadline method.

func (*UDPConn) [Write](#)

```
func (c *UDPConn) Write(b []byte) (int, error)
```

Write implements the Conn Write method.

func (*UDPConn) [WriteTo](#)

```
func (c *UDPConn) WriteTo(b []byte, addr Addr) (int, error)
```

WriteTo implements the PacketConn WriteTo method.

func (*UDPConn) [WriteToUDP](#)

```
func (c *UDPConn) WriteToUDP(b []byte, addr *UDPAddr) (int, error)
```

WriteToUDP writes a UDP packet to addr via c, copying the payload from b.

WriteToUDP can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetWriteDeadline. On packet-oriented connections, write timeouts are rare.

type [UnixAddr](#)

```
type UnixAddr struct {  
    Name string  
    Net  string  
}
```

UnixAddr represents the address of a Unix domain socket end point.

func [ResolveUnixAddr](#)

```
func ResolveUnixAddr(net, addr string) (*UnixAddr, error)
```

ResolveUnixAddr parses addr as a Unix domain socket address. The string net gives the network name, "unix", "unixgram" or "unixpacket".

func (*UnixAddr) [Network](#)

```
func (a *UnixAddr) Network() string
```

Network returns the address's network name, "unix" or "unixgram".

func (*UnixAddr) [String](#)

```
func (a *UnixAddr) String() string
```

type [UnixConn](#)

```
type UnixConn struct {  
    // contains filtered or unexported fields  
}
```

UnixConn is an implementation of the Conn interface for connections to Unix domain sockets.

func [DialUnix](#)

```
func DialUnix(net string, laddr, raddr *UnixAddr) (*UnixConn, error)
```

DialUnix connects to the remote address raddr on the network net, which must be "unix" or "unixgram". If laddr is not nil, it is used as the local address for the connection.

func (*UnixConn) [Close](#)

```
func (c *UnixConn) Close() error
```

Close closes the Unix domain connection.

func (*UnixConn) [File](#)

```
func (c *UnixConn) File() (f *os.File, err error)
```

File returns a copy of the underlying os.File, set to blocking mode. It is the caller's responsibility to close f when finished. Closing c does not affect f, and closing f does not affect c.

func (*UnixConn) [LocalAddr](#)

```
func (c *UnixConn) LocalAddr() Addr
```

LocalAddr returns the local network address, a *UnixAddr. Unlike in other protocols, LocalAddr is usually nil for dialed connections.

func (*UnixConn) [Read](#)

```
func (c *UnixConn) Read(b []byte) (n int, err error)
```

Read implements the Conn Read method.

func (*UnixConn) [ReadFrom](#)

```
func (c *UnixConn) ReadFrom(b []byte) (n int, addr Addr, err error)
```

ReadFrom implements the PacketConn ReadFrom method.

func (*UnixConn) [ReadFromUnix](#)

```
func (c *UnixConn) ReadFromUnix(b []byte) (n int, addr *UnixAddr, er
```

ReadFromUnix reads a packet from c, copying the payload into b. It returns the number of bytes copied into b and the source address of the packet.

ReadFromUnix can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetReadDeadline.

func (*UnixConn) [ReadMsgUnix](#)

```
func (c *UnixConn) ReadMsgUnix(b, oob []byte) (n, oobn, flags int, a
```

ReadMsgUnix reads a packet from c, copying the payload into b and the associated out-of-band data into oob. It returns the number of bytes copied into b, the number of bytes copied into oob, the flags that were set on the packet, and the source address of the packet.

func (*UnixConn) [RemoteAddr](#)

```
func (c *UnixConn) RemoteAddr() Addr
```

RemoteAddr returns the remote network address, a *UnixAddr. Unlike in other protocols, RemoteAddr is usually nil for connections accepted by a listener.

func (*UnixConn) [SetDeadline](#)

```
func (c *UnixConn) SetDeadline(t time.Time) error
```

SetDeadline implements the Conn SetDeadline method.

func (*UnixConn) [SetReadBuffer](#)

```
func (c *UnixConn) SetReadBuffer(bytes int) error
```

SetReadBuffer sets the size of the operating system's receive buffer associated with the connection.

func (*UnixConn) [SetReadDeadline](#)

```
func (c *UnixConn) SetReadDeadline(t time.Time) error
```

SetReadDeadline implements the Conn SetReadDeadline method.

func (*UnixConn) [SetWriteBuffer](#)

```
func (c *UnixConn) SetWriteBuffer(bytes int) error
```

SetWriteBuffer sets the size of the operating system's transmit buffer associated with the connection.

func (*UnixConn) [SetWriteDeadline](#)

```
func (c *UnixConn) SetWriteDeadline(t time.Time) error
```

SetWriteDeadline implements the Conn SetWriteDeadline method.

func (*UnixConn) [Write](#)

```
func (c *UnixConn) Write(b []byte) (n int, err error)
```

Write implements the Conn Write method.

func (*UnixConn) [WriteMsgUnix](#)

```
func (c *UnixConn) WriteMsgUnix(b, oob []byte, addr *UnixAddr) (n, o
```

WriteMsgUnix writes a packet to addr via c, copying the payload from b and the associated out-of-band data from oob. It returns the number of payload and out-

of-band bytes written.

func (*UnixConn) [WriteTo](#)

```
func (c *UnixConn) WriteTo(b []byte, addr Addr) (n int, err error)
```

WriteTo implements the PacketConn WriteTo method.

func (*UnixConn) [WriteToUnix](#)

```
func (c *UnixConn) WriteToUnix(b []byte, addr *UnixAddr) (n int, err
```

WriteToUnix writes a packet to addr via c, copying the payload from b.

WriteToUnix can be made to time out and return an error with Timeout() == true after a fixed time limit; see SetDeadline and SetWriteDeadline. On packet-oriented connections, write timeouts are rare.

type [UnixListener](#)

```
type UnixListener struct {  
    // contains filtered or unexported fields  
}
```

UnixListener is a Unix domain socket listener. Clients should typically use variables of type Listener instead of assuming Unix domain sockets.

func [ListenUnix](#)

```
func ListenUnix(net string, laddr *UnixAddr) (*UnixListener, error)
```

ListenUnix announces on the Unix domain socket laddr and returns a Unix listener. Net must be "unix" (stream sockets).

func (*UnixListener) [Accept](#)

```
func (l *UnixListener) Accept() (c Conn, err error)
```

Accept implements the Accept method in the Listener interface; it waits for the next call and returns a generic Conn.

func (*UnixListener) [AcceptUnix](#)

```
func (l *UnixListener) AcceptUnix() (*UnixConn, error)
```

AcceptUnix accepts the next incoming call and returns the new connection and the remote address.

func (*UnixListener) [Addr](#)

```
func (l *UnixListener) Addr() Addr
```

Addr returns the listener's network address.

func (*UnixListener) [Close](#)

```
func (l *UnixListener) Close() error
```

Close stops listening on the Unix address. Already accepted connections are not closed.

func (*UnixListener) [File](#)

```
func (l *UnixListener) File() (f *os.File, err error)
```

File returns a copy of the underlying `os.File`, set to blocking mode. It is the caller's responsibility to close `f` when finished. Closing `l` does not affect `f`, and closing `f` does not affect `l`.

func (*UnixListener) [SetDeadline](#)

```
func (l *UnixListener) SetDeadline(t time.Time) (err error)
```

SetDeadline sets the deadline associated with the listener. A zero time value disables the deadline.

type UnknownNetworkError

type UnknownNetworkError string

func (UnknownNetworkError) Error

func (e UnknownNetworkError) Error() string

func (UnknownNetworkError) Temporary

func (e UnknownNetworkError) Temporary() bool

func (UnknownNetworkError) Timeout

func (e UnknownNetworkError) Timeout() bool

Bugs

On OpenBSD, listening on the "tcp" network does not listen for both IPv4 and IPv6 connections. This is due to the fact that IPv4 traffic will not be routed to an IPv6 socket - two separate sockets are required if both AFs are to be supported. See `inet6(4)` on OpenBSD for details.

Subdirectories

Name	Synopsis
http	Package http provides HTTP client and server implementations.
cgi	Package cgi implements CGI (Common Gateway Interface) as specified in RFC 3875.
fcgi	Package fcgi implements the FastCGI protocol.
httpptest	Package httpptest provides utilities for HTTP testing.
httputil	Package httputil provides HTTP utility functions, complementing the more common ones in the net/http package.
pprof	Package pprof serves via its HTTP server runtime profiling data in the format expected by the pprof visualization tool.
mail	Package mail implements parsing of mail messages.
rpc	Package rpc provides access to the exported methods of an object across a network or other I/O connection.
jsonrpc	Package jsonrpc implements a JSON-RPC ClientCodec and ServerCodec for the rpc package.
smtp	Package smtp implements the Simple Mail Transfer Protocol as defined in RFC 5321.
textproto	Package textproto implements generic support for text-based request/response protocols in the style of HTTP, NNTP, and SMTP.
url	Package url parses URLs and implements query escaping.

Overview ?

Overview ?

Package `http` provides HTTP client and server implementations.

`Get`, `Head`, `Post`, and `PostForm` make HTTP requests:

```
resp, err := http.Get("http://example.com/")
...
resp, err := http.Post("http://example.com/upload", "image/jpeg", &b
...
resp, err := http.PostForm("http://example.com/form",
    url.Values{"key": {"Value"}, "id": {"123"}})
```

The client must close the response body when finished with it:

```
resp, err := http.Get("http://example.com/")
if err != nil {
    // handle error
}
defer resp.Body.Close()
body, err := ioutil.ReadAll(resp.Body)
// ...
```

For control over HTTP client headers, redirect policy, and other settings, create a `Client`:

```
client := &http.Client{
    CheckRedirect: redirectPolicyFunc,
}

resp, err := client.Get("http://example.com")
// ...

req, err := http.NewRequest("GET", "http://example.com", nil)
// ...
req.Header.Add("If-None-Match", `W/"wyzzy"`)
resp, err := client.Do(req)
// ...
```

For control over proxies, TLS configuration, keep-alives, compression, and other settings, create a `Transport`:

```
tr := &http.Transport{
    TLSClientConfig: &tls.Config{RootCAs: pool},
```

```
        DisableCompression: true,
    }
    client := &http.Client{Transport: tr}
    resp, err := client.Get("https://example.com")
```

Clients and Transports are safe for concurrent use by multiple goroutines and for efficiency should only be created once and re-used.

ListenAndServe starts an HTTP server with a given address and handler. The handler is usually nil, which means to use DefaultServeMux. Handle and HandleFunc add handlers to DefaultServeMux:

```
http.Handle("/foo", fooHandler)

http.HandleFunc("/bar", func(w http.ResponseWriter, r *http.Request)
    fmt.Fprintf(w, "Hello, %q", html.EscapeString(r.URL.Path))
})

log.Fatal(http.ListenAndServe(":8080", nil))
```

More control over the server's behavior is available by creating a custom Server:

```
s := &http.Server{
    Addr:           ":8080",
    Handler:        myHandler,
    ReadTimeout:   10 * time.Second,
    WriteTimeout:  10 * time.Second,
    MaxHeaderBytes: 1 << 20,
}
log.Fatal(s.ListenAndServe())
```

    StatusUnsupportedMediaType = 415  
    StatusRequestedRangeNotSatisfiable = 416  
    StatusExpectationFailed = 417  
    StatusTeapot            = 418  
  
    StatusInternalServerError = 500  
    StatusNotImplemented      = 501  
    StatusBadGateway          = 502  
    StatusServiceUnavailable  = 503  
    StatusGatewayTimeout      = 504
```

```
    StatusHTTPVersionNotSupported = 505
)
```

HTTP status codes, defined in RFC 2616.

```
const DefaultMaxHeaderBytes = 1 << 20 // 1 MB
```

DefaultMaxHeaderBytes is the maximum permitted size of the headers in an HTTP request. This can be overridden by setting `Server.MaxHeaderBytes`.

```
const DefaultMaxIdleConnsPerHost = 2
```

DefaultMaxIdleConnsPerHost is the default value of Transport's `MaxIdleConnsPerHost`.

```
const TimeFormat = "Mon, 02 Jan 2006 15:04:05 GMT"
```

TimeFormat is the time format to use with `time.Parse` and `time.Time.Format` when parsing or generating times in HTTP headers. It is like `time.RFC1123` but hard codes GMT as the time zone.

Variables

```
var (
    ErrHeaderTooLong      = &ProtocolError{"header too long"}
    ErrShortBody          = &ProtocolError{"entity body too short"}
    ErrNotSupported       = &ProtocolError{"feature not supported"}
    ErrUnexpectedTrailer  = &ProtocolError{"trailer header without"}
    ErrMissingContentLength = &ProtocolError{"missing ContentLength"}
    ErrNotMultipart       = &ProtocolError{"request Content-Type i"}
    ErrMissingBoundary    = &ProtocolError{"no multipart boundary"}
)

var (
    ErrWriteAfterFlush = errors.New("Conn.Write called after Flush")
    ErrBodyNotAllowed  = errors.New("http: response status code does")
    ErrHijacked        = errors.New("Conn has been hijacked")
    ErrContentLength   = errors.New("Conn.Write wrote more than the")
)
```

Errors introduced by the HTTP server.

```
var DefaultClient = &Client{}
```

DefaultClient is the default Client and is used by Get, Head, and Post.

```
var DefaultServeMux = NewServeMux()
```

DefaultServeMux is the default ServeMux used by Serve.

```
var ErrBodyReadAfterClose = errors.New("http: invalid Read on closed")
```

ErrBodyReadAfterClose is returned when reading a Request Body after the body has been closed. This typically happens when the body is read after an HTTP Handler calls WriteHeader or Write on its ResponseWriter.

```
var ErrHandlerTimeout = errors.New("http: Handler timeout")
```

ErrHandlerTimeout is returned on ResponseWriter Write calls in handlers which have timed out.

```
var ErrLineTooLong = errors.New("header line too long")
```

```
var ErrMissingFile = errors.New("http: no such file")
```

ErrMissingFile is returned by FormFile when the provided file field name is either not present in the request or not a file field.

```
var ErrNoCookie = errors.New("http: named cookie not present")
```

```
var ErrNoLocation = errors.New("http: no Location header in response")
```

func [CanonicalHeaderKey](#)

```
func CanonicalHeaderKey(s string) string
```

CanonicalHeaderKey returns the canonical format of the header key s. The canonicalization converts the first letter and any letter following a hyphen to upper case; the rest are converted to lowercase. For example, the canonical key for "accept-encoding" is "Accept-Encoding".

func DetectContentType

```
func DetectContentType(data []byte) string
```

DetectContentType implements the algorithm described at <http://mimesniff.spec.whatwg.org/> to determine the Content-Type of the given data. It considers at most the first 512 bytes of data. DetectContentType always returns a valid MIME type: if it cannot determine a more specific one, it returns "application/octet-stream".

func Error

```
func Error(w ResponseWriter, error string, code int)
```

Error replies to the request with the specified error message and HTTP code.

func [Handle](#)

```
func Handle(pattern string, handler Handler)
```

Handle registers the handler for the given pattern in the DefaultServeMux. The documentation for ServeMux explains how patterns are matched.

func [HandleFunc](#)

```
func HandleFunc(pattern string, handler func(ResponseWriter, *Request))
```

HandleFunc registers the handler function for the given pattern in the DefaultServeMux. The documentation for ServeMux explains how patterns are matched.

func [ListenAndServe](#)

```
func ListenAndServe(addr string, handler Handler) error
```

`ListenAndServe` listens on the TCP network address `addr` and then calls `Serve` with `handler` to handle requests on incoming connections. `Handler` is typically `nil`, in which case the `DefaultServeMux` is used.

A trivial example server is:

```
package main

import (
    "io"
    "net/http"
    "log"
)

// hello world, the web server
func HelloServer(w http.ResponseWriter, req *http.Request) {
    io.WriteString(w, "hello, world!\n")
}

func main() {
    http.HandleFunc("/hello", HelloServer)
    err := http.ListenAndServe(":12345", nil)
    if err != nil {
        log.Fatal("ListenAndServe: ", err)
    }
}
```

func ListenAndServeTLS

```
func ListenAndServeTLS(addr string, certFile string, keyFile string,
```

ListenAndServeTLS acts identically to ListenAndServe, except that it expects HTTPS connections. Additionally, files containing a certificate and matching private key for the server must be provided. If the certificate is signed by a certificate authority, the certFile should be the concatenation of the server's certificate followed by the CA's certificate.

A trivial example server is:

```
import (
    "log"
    "net/http"
)

func handler(w http.ResponseWriter, req *http.Request) {
    w.Header().Set("Content-Type", "text/plain")
    w.Write([]byte("This is an example server.\n"))
}

func main() {
    http.HandleFunc("/", handler)
    log.Printf("About to listen on 10443. Go to https://127.0.0.1:10443.")
    err := http.ListenAndServeTLS(":10443", "cert.pem", "key.pem")
    if err != nil {
        log.Fatal(err)
    }
}
```

One can use generate_cert.go in crypto/tls to generate cert.pem and key.pem.

func MaxBytesReader

```
func MaxBytesReader(w ResponseWriter, r io.ReadCloser, n int64) io.R
```

MaxBytesReader is similar to io.LimitReader but is intended for limiting the size of incoming request bodies. In contrast to io.LimitReader, MaxBytesReader's result is a ReadCloser, returns a non-EOF error for a Read beyond the limit, and Closes the underlying reader when its Close method is called.

MaxBytesReader prevents clients from accidentally or maliciously sending a large request and wasting server resources.

func NotFound

```
func NotFound(w ResponseWriter, r *Request)
```

NotFound replies to the request with an HTTP 404 not found error.

func ParseHTTPVersion

```
func ParseHTTPVersion(vers string) (major, minor int, ok bool)
```

ParseHTTPVersion parses a HTTP version string. "HTTP/1.0" returns (1, 0, true).

func ProxyFromEnvironment

```
func ProxyFromEnvironment(req *Request) (*url.URL, error)
```

ProxyFromEnvironment returns the URL of the proxy to use for a given request, as indicated by the environment variables \$HTTP_PROXY and \$NO_PROXY (or \$http_proxy and \$no_proxy). An error is returned if the proxy environment is invalid. A nil URL and nil error are returned if no proxy is defined in the environment, or a proxy should not be used for the given request.

func [ProxyURL](#)

```
func ProxyURL(fixedURL *url.URL) func(*Request) (*url.URL, error)
```

ProxyURL returns a proxy function (for use in a Transport) that always returns the same URL.

func [Redirect](#)

```
func Redirect(w ResponseWriter, r *Request, urlStr string, code int)
```

Redirect replies to the request with a redirect to url, which may be a path relative to the request path.

func [Serve](#)

```
func Serve(l net.Listener, handler Handler) error
```

Serve accepts incoming HTTP connections on the listener `l`, creating a new service thread for each. The service threads read requests and then call `handler` to reply to them. `Handler` is typically `nil`, in which case the `DefaultServeMux` is used.

func [ServeContent](#)

```
func ServeContent(w ResponseWriter, req *Request, name string, modti
```

ServeContent replies to the request using the content in the provided `ReadSeeker`. The main benefit of `ServeContent` over `io.Copy` is that it handles Range requests properly, sets the MIME type, and handles If-Modified-Since requests.

If the response's Content-Type header is not set, `ServeContent` first tries to deduce the type from name's file extension and, if that fails, falls back to reading the first block of the content and passing it to `DetectContentType`. The name is otherwise unused; in particular it can be empty and is never sent in the response.

If `modtime` is not the zero time, `ServeContent` includes it in a Last-Modified header in the response. If the request includes an If-Modified-Since header, `ServeContent` uses `modtime` to decide whether the content needs to be sent at all.

The content's `Seek` method must work: `ServeContent` uses a seek to the end of the content to determine its size.

Note that `*os.File` implements the `io.ReadSeeker` interface.

func [ServeFile](#)

```
func ServeFile(w ResponseWriter, r *Request, name string)
```

ServeFile replies to the request with the contents of the named file or directory.

func [SetCookie](#)

```
func SetCookie(w ResponseWriter, cookie *Cookie)
```

SetCookie adds a Set-Cookie header to the provided ResponseWriter's headers.

func [StatusText](#)

```
func StatusText(code int) string
```

StatusText returns a text for the HTTP status code. It returns the empty string if the code is unknown.

type [Client](#)

```
type Client struct {
    // Transport specifies the mechanism by which individual
    // HTTP requests are made.
    // If nil, DefaultTransport is used.
    Transport RoundTripper

    // CheckRedirect specifies the policy for handling redirects.
    // If CheckRedirect is not nil, the client calls it before
    // following an HTTP redirect. The arguments req and via
    // are the upcoming request and the requests made already,
    // oldest first. If CheckRedirect returns an error, the client
    // returns that error instead of issue the Request req.
    //
    // If CheckRedirect is nil, the Client uses its default policy,
    // which is to stop after 10 consecutive requests.
    CheckRedirect func(req *Request, via []*Request) error

    // Jar specifies the cookie jar.
    // If Jar is nil, cookies are not sent in requests and ignored
    // in responses.
    Jar CookieJar
}
```

A Client is an HTTP client. Its zero value (DefaultClient) is a usable client that uses DefaultTransport.

The Client's Transport typically has internal state (cached TCP connections), so Clients should be reused instead of created as needed. Clients are safe for concurrent use by multiple goroutines.

func (*Client) [Do](#)

```
func (c *Client) Do(req *Request) (resp *Response, err error)
```

Do sends an HTTP request and returns an HTTP response, following policy (e.g. redirects, cookies, auth) as configured on the client.

A non-nil response always contains a non-nil resp.Body.

Callers should close resp.Body when done reading from it. If resp.Body is not closed, the Client's underlying RoundTripper (typically Transport) may not be

able to re-use a persistent TCP connection to the server for a subsequent "keep-alive" request.

Generally Get, Post, or PostForm will be used instead of Do.

func (*Client) [Get](#)

```
func (c *Client) Get(url string) (r *Response, err error)
```

Get issues a GET to the specified URL. If the response is one of the following redirect codes, Get follows the redirect after calling the Client's CheckRedirect function.

```
301 (Moved Permanently)
302 (Found)
303 (See Other)
307 (Temporary Redirect)
```

Caller should close r.Body when done reading from it.

func (*Client) [Head](#)

```
func (c *Client) Head(url string) (r *Response, err error)
```

Head issues a HEAD to the specified URL. If the response is one of the following redirect codes, Head follows the redirect after calling the Client's CheckRedirect function.

```
301 (Moved Permanently)
302 (Found)
303 (See Other)
307 (Temporary Redirect)
```

func (*Client) [Post](#)

```
func (c *Client) Post(url string, bodyType string, body io.Reader) (
```

Post issues a POST to the specified URL.

Caller should close r.Body when done reading from it.

func (*Client) [PostForm](#)

```
func (c *Client) PostForm(url string, data url.Values) (r *Response,
```

PostForm issues a POST to the specified URL, with data's keys and values urlencoded as the request body.

Caller should close r.Body when done reading from it.

type [Cookie](#)

```
type Cookie struct {
    Name      string
    Value     string
    Path      string
    Domain    string
    Expires   time.Time
    RawExpires string

    // MaxAge=0 means no 'Max-Age' attribute specified.
    // MaxAge<0 means delete cookie now, equivalently 'Max-Age: 0'
    // MaxAge>0 means Max-Age attribute present and given in seconds
    MaxAge    int
    Secure    bool
    HttpOnly  bool
    Raw       string
    Unparsed []string // Raw text of unparsed attribute-value pairs
}
```

A Cookie represents an HTTP cookie as sent in the Set-Cookie header of an HTTP response or the Cookie header of an HTTP request.

func (*Cookie) [String](#)

```
func (c *Cookie) String() string
```

String returns the serialization of the cookie for use in a Cookie header (if only Name and Value are set) or a Set-Cookie response header (if other fields are set).

type [CookieJar](#)

```
type CookieJar interface {  
    // SetCookies handles the receipt of the cookies in a reply for  
    // given URL. It may or may not choose to save the cookies, dep  
    // on the jar's policy and implementation.  
    SetCookies(u *url.URL, cookies []*Cookie)  
  
    // Cookies returns the cookies to send in a request for the give  
    // It is up to the implementation to honor the standard cookie u  
    // restrictions such as in RFC 6265.  
    Cookies(u *url.URL) []*Cookie  
}
```

A CookieJar manages storage and use of cookies in HTTP requests.

Implementations of CookieJar must be safe for concurrent use by multiple goroutines.

type [Dir](#)

```
type Dir string
```

A `Dir` implements `http.FileSystem` using the native file system restricted to a specific directory tree.

An empty `Dir` is treated as `"."`.

func ([Dir](#)) [Open](#)

```
func (d Dir) Open(name string) (File, error)
```

type [File](#)

```
type File interface {
    Close() error
    Stat() (os.FileInfo, error)
    Readdir(count int) ([]os.FileInfo, error)
    Read([]byte) (int, error)
    Seek(offset int64, whence int) (int64, error)
}
```

A File is returned by a FileSystem's Open method and can be served by the FileServer implementation.

type [FileSystem](#)

```
type FileSystem interface {  
    Open(name string) (File, error)  
}
```

A `FileSystem` implements access to a collection of named files. The elements in a file path are separated by slash ('/', U+002F) characters, regardless of host operating system convention.

type [Flusher](#)

```
type Flusher interface {  
    // Flush sends any buffered data to the client.  
    Flush()  
}
```

The Flusher interface is implemented by ResponseWriters that allow an HTTP handler to flush buffered data to the client.

Note that even for ResponseWriters that support Flush, if the client is connected through an HTTP proxy, the buffered data may not reach the client until the response completes.

type [Handler](#)

```
type Handler interface {  
    ServeHTTP(ResponseWriter, *Request)  
}
```

Objects implementing the Handler interface can be registered to serve a particular path or subtree in the HTTP server.

ServeHTTP should write reply headers and data to the ResponseWriter and then return. Returning signals that the request is finished and that the HTTP server can move on to the next request on the connection.

func [FileServer](#)

```
func FileServer(root FileSystem) Handler
```

FileServer returns a handler that serves HTTP requests with the contents of the file system rooted at root.

To use the operating system's file system implementation, use http.Dir:

```
http.Handle("/", http.FileServer(http.Dir("/tmp")))
```

? Example

? Example

Code:

```
// we use StripPrefix so that /tmpfiles/somefile will access /tmp/sc  
http.Handle("/tmpfiles/", http.StripPrefix("/tmpfiles/", http.FileSe
```

func [NotFoundHandler](#)

```
func NotFoundHandler() Handler
```

NotFoundHandler returns a simple request handler that replies to each request with a “404 page not found” reply.

func [RedirectHandler](#)

```
func RedirectHandler(url string, code int) Handler
```

RedirectHandler returns a request handler that redirects each request it receives to the given url using the given status code.

func [StripPrefix](#)

```
func StripPrefix(prefix string, h Handler) Handler
```

StripPrefix returns a handler that serves HTTP requests by removing the given prefix from the request URL's Path and invoking the handler h. StripPrefix handles a request for a path that doesn't begin with prefix by replying with an HTTP 404 not found error.

func [TimeoutHandler](#)

```
func TimeoutHandler(h Handler, dt time.Duration, msg string) Handler
```

TimeoutHandler returns a Handler that runs h with the given time limit.

The new Handler calls h.ServeHTTP to handle each request, but if a call runs for more than ns nanoseconds, the handler responds with a 503 Service Unavailable error and the given message in its body. (If msg is empty, a suitable default message will be sent.) After such a timeout, writes by h to its ResponseWriter will return ErrHandlerTimeout.

type [HandlerFunc](#)

```
type HandlerFunc func(ResponseWriter, *Request)
```

The HandlerFunc type is an adapter to allow the use of ordinary functions as HTTP handlers. If `f` is a function with the appropriate signature, `HandlerFunc(f)` is a Handler object that calls `f`.

func (HandlerFunc) [ServeHTTP](#)

```
func (f HandlerFunc) ServeHTTP(w ResponseWriter, r *Request)
```

ServeHTTP calls `f(w, r)`.

type [Header](#)

```
type Header map[string][]string
```

A Header represents the key-value pairs in an HTTP header.

func (Header) [Add](#)

```
func (h Header) Add(key, value string)
```

Add adds the key, value pair to the header. It appends to any existing values associated with key.

func (Header) [Del](#)

```
func (h Header) Del(key string)
```

Del deletes the values associated with key.

func (Header) [Get](#)

```
func (h Header) Get(key string) string
```

Get gets the first value associated with the given key. If there are no values associated with the key, Get returns "". To access multiple values of a key, access the map directly with CanonicalHeaderKey.

func (Header) [Set](#)

```
func (h Header) Set(key, value string)
```

Set sets the header entries associated with key to the single element value. It replaces any existing values associated with key.

func (Header) [Write](#)

```
func (h Header) Write(w io.Writer) error
```

Write writes a header in wire format.

func (Header) [WriteSubset](#)

```
func (h Header) WriteSubset(w io.Writer, exclude map[string]bool) error
```

WriteSubset writes a header in wire format. If exclude is not nil, keys where exclude[key] == true are not written.

type Hijacker

```
type Hijacker interface {
    // Hijack lets the caller take over the connection.
    // After a call to Hijack(), the HTTP server library
    // will not do anything else with the connection.
    // It becomes the caller's responsibility to manage
    // and close the connection.
    Hijack() (net.Conn, *bufio.ReadWriter, error)
}
```

The Hijacker interface is implemented by ResponseWriters that allow an HTTP handler to take over the connection.

? Example

? Example

Code:

```
http.HandleFunc("/hijack", func(w http.ResponseWriter, r *http.Reque
    hj, ok := w.(http.Hijacker)
    if !ok {
        http.Error(w, "webserver doesn't support hijacking", http.St
        return
    }
    conn, bufrw, err := hj.Hijack()
    if err != nil {
        http.Error(w, err.Error(), http.StatusInternalServerError)
        return
    }
    // Don't forget to close the connection:
    defer conn.Close()
    bufrw.WriteString("Now we're speaking raw TCP. Say hi: ")
    bufrw.Flush()
    s, err := bufrw.ReadString('\n')
    if err != nil {
        log.Printf("error reading string: %v", err)
        return
    }
    fmt.Fprintf(bufrw, "You said: %q\nBye.\n", s)
    bufrw.Flush()
})
```

type [ProtocolError](#)

```
type ProtocolError struct {  
    ErrorString string  
}
```

HTTP request parsing errors.

func (*ProtocolError) [Error](#)

```
func (err *ProtocolError) Error() string
```

type [Request](#)

```
type Request struct {
    Method string // GET, POST, PUT, etc.
    URL     *url.URL

    // The protocol version for incoming requests.
    // Outgoing requests always use HTTP/1.1.
    Proto      string // "HTTP/1.0"
    ProtoMajor int    // 1
    ProtoMinor int

    // A header maps request lines to their values.
    // If the header says
    //
    // accept-encoding: gzip, deflate
    // Accept-Language: en-us
    // Connection: keep-alive
    //
    // then
    //
    // Header = map[string][]string{
    //     "Accept-Encoding": {"gzip, deflate"},
    //     "Accept-Language": {"en-us"},
    //     "Connection": {"keep-alive"},
    // }
    //
    // HTTP defines that header names are case-insensitive.
    // The request parser implements this by canonicalizing the
    // name, making the first character and any characters
    // following a hyphen uppercase and the rest lowercase.
    Header Header

    // The message body.
    Body io.ReadCloser

    // ContentLength records the length of the associated content.
    // The value -1 indicates that the length is unknown.
    // Values >= 0 indicate that the given number of bytes may
    // be read from Body.
    // For outgoing requests, a value of 0 means unknown if Body is
    ContentLength int64

    // TransferEncoding lists the transfer encodings from outermost
    // innermost. An empty list denotes the "identity" encoding.
    // TransferEncoding can usually be ignored; chunked encoding is
    // automatically added and removed as necessary when sending and
```

```
// receiving requests.
TransferEncoding []string

// Close indicates whether to close the connection after
// replying to this request.
Close bool

// The host on which the URL is sought.
// Per RFC 2616, this is either the value of the Host: header
// or the host name given in the URL itself.
Host string

// Form contains the parsed form data, including both the URL
// field's query parameters and the POST or PUT form data.
// This field is only available after ParseForm is called.
// The HTTP client ignores Form and uses Body instead.
Form url.Values

// MultipartForm is the parsed multipart form, including file up
// This field is only available after ParseMultipartForm is call
// The HTTP client ignores MultipartForm and uses Body instead.
MultipartForm *multipart.Form

// Trailer maps trailer keys to values. Like for Header, if the
// response has multiple trailer lines with the same key, they w
// concatenated, delimited by commas.
// For server requests, Trailer is only populated after Body has
// closed or fully consumed.
// Trailer support is only partially complete.
Trailer Header

// RemoteAddr allows HTTP servers and other software to record
// the network address that sent the request, usually for
// logging. This field is not filled in by ReadRequest and
// has no defined format. The HTTP server in this package
// sets RemoteAddr to an "IP:port" address before invoking a
// handler.
// This field is ignored by the HTTP client.
RemoteAddr string

// RequestURI is the unmodified Request-URI of the
// Request-Line (RFC 2616, Section 5.1) as sent by the client
// to a server. Usually the URL field should be used instead.
// It is an error to set this field in an HTTP client request.
RequestURI string

// TLS allows HTTP servers and other software to record
// information about the TLS connection on which the request
// was received. This field is not filled in by ReadRequest.
```

```
    // The HTTP server in this package sets the field for
    // TLS-enabled connections before invoking a handler;
    // otherwise it leaves the field nil.
    // This field is ignored by the HTTP client.
    TLS *tls.ConnectionState
}
```

A Request represents an HTTP request received by a server or to be sent by a client.

func [NewRequest](#)

```
func NewRequest(method, urlStr string, body io.Reader) (*Request, error)
```

NewRequest returns a new Request given a method, URL, and optional body.

func [ReadRequest](#)

```
func ReadRequest(b *bufio.Reader) (req *Request, err error)
```

ReadRequest reads and parses a request from b.

func (*Request) [AddCookie](#)

```
func (r *Request) AddCookie(c *Cookie)
```

AddCookie adds a cookie to the request. Per RFC 6265 section 5.4, AddCookie does not attach more than one Cookie header field. That means all cookies, if any, are written into the same line, separated by semicolon.

func (*Request) [Cookie](#)

```
func (r *Request) Cookie(name string) (*Cookie, error)
```

Cookie returns the named cookie provided in the request or ErrNoCookie if not found.

func (*Request) [Cookies](#)

```
func (r *Request) Cookies() []*Cookie
```

Cookies parses and returns the HTTP cookies sent with the request.

func (*Request) [FormFile](#)

```
func (r *Request) FormFile(key string) (multipart.File, *multipart.F
```

FormFile returns the first file for the provided form key. FormFile calls ParseMultipartForm and ParseForm if necessary.

func (*Request) [FormValue](#)

```
func (r *Request) FormValue(key string) string
```

FormValue returns the first value for the named component of the query. FormValue calls ParseMultipartForm and ParseForm if necessary.

func (*Request) [MultipartReader](#)

```
func (r *Request) MultipartReader() (*multipart.Reader, error)
```

MultipartReader returns a MIME multipart reader if this is a multipart/form-data POST request, else returns nil and an error. Use this function instead of ParseMultipartForm to process the request body as a stream.

func (*Request) [ParseForm](#)

```
func (r *Request) ParseForm() (err error)
```

ParseForm parses the raw query from the URL.

For POST or PUT requests, it also parses the request body as a form. If the request Body's size has not already been limited by MaxBytesReader, the size is capped at 10MB.

ParseMultipartForm calls ParseForm automatically. It is idempotent.

func (*Request) [ParseMultipartForm](#)

```
func (r *Request) ParseMultipartForm(maxMemory int64) error
```

ParseMultipartForm parses a request body as multipart/form-data. The whole request body is parsed and up to a total of maxMemory bytes of its file parts are stored in memory, with the remainder stored on disk in temporary files.

ParseMultipartForm calls ParseForm if necessary. After one call to ParseMultipartForm, subsequent calls have no effect.

func (*Request) [ProtoAtLeast](#)

```
func (r *Request) ProtoAtLeast(major, minor int) bool
```

ProtoAtLeast returns whether the HTTP protocol used in the request is at least major.minor.

func (*Request) [Referer](#)

```
func (r *Request) Referer() string
```

Referer returns the referring URL, if sent in the request.

Referer is misspelled as in the request itself, a mistake from the earliest days of HTTP. This value can also be fetched from the Header map as Header["Referer"]; the benefit of making it available as a method is that the compiler can diagnose programs that use the alternate (correct English) spelling req.Referer() but cannot diagnose programs that use Header["Referrer"].

func (*Request) [SetBasicAuth](#)

```
func (r *Request) SetBasicAuth(username, password string)
```

SetBasicAuth sets the request's Authorization header to use HTTP Basic Authentication with the provided username and password.

With HTTP Basic Authentication the provided username and password are not encrypted.

func (*Request) [UserAgent](#)

```
func (r *Request) UserAgent() string
```

UserAgent returns the client's User-Agent, if sent in the request.

func (*Request) [Write](#)

```
func (r *Request) Write(w io.Writer) error
```

Write writes an HTTP/1.1 request -- header and body -- in wire format. This method consults the following fields of the request:

```
Host  
URL  
Method (defaults to "GET")  
Header  
ContentLength  
TransferEncoding  
Body
```

If Body is present, Content-Length is ≤ 0 and TransferEncoding hasn't been set to "identity", Write adds "Transfer-Encoding: chunked" to the header. Body is closed after it is sent.

func (*Request) [WriteProxy](#)

```
func (r *Request) WriteProxy(w io.Writer) error
```

WriteProxy is like Write but writes the request in the form expected by an HTTP proxy. In particular, WriteProxy writes the initial Request-URI line of the request with an absolute URI, per section 5.1.2 of RFC 2616, including the scheme and host. In either case, WriteProxy also writes a Host header, using either r.Host or r.URL.Host.

type [Response](#)

```
type Response struct {
    Status      string // e.g. "200 OK"
    StatusCode  int    // e.g. 200
    Proto       string // e.g. "HTTP/1.0"
    ProtoMajor  int    // e.g. 1
    ProtoMinor  int

    // Header maps header keys to values. If the response had multi
    // headers with the same key, they will be concatenated, with co
    // delimiters. (Section 4.2 of RFC 2616 requires that multiple
    // be semantically equivalent to a comma-delimited sequence.) Va
    // duplicated by other fields in this struct (e.g., ContentLengt
    // omitted from Header.
    //
    // Keys in the map are canonicalized (see CanonicalHeaderKey).
    Header Header

    // Body represents the response body.
    //
    // The http Client and Transport guarantee that Body is always
    // non-nil, even on responses without a body or responses with
    // a zero-lengthed body.
    Body io.ReadCloser

    // ContentLength records the length of the associated content.
    // value -1 indicates that the length is unknown. Unless Reques
    // is "HEAD", values >= 0 indicate that the given number of byte
    // be read from Body.
    ContentLength int64

    // Contains transfer encodings from outer-most to inner-most. Va
    // nil, means that "identity" encoding is used.
    TransferEncoding []string

    // Close records whether the header directed that the connection
    // closed after reading Body. The value is advice for clients:
    // ReadResponse nor Response.Write ever closes a connection.
    Close bool

    // Trailer maps trailer keys to values, in the same
    // format as the header.
    Trailer Header

    // The Request that was sent to obtain this Response.
    // Request's Body is nil (having already been consumed).
```

```
    // This is only populated for Client requests.  
    Request *Request  
}
```

Response represents the response from an HTTP request.

func [Get](#)

```
func Get(url string) (r *Response, err error)
```

Get issues a GET to the specified URL. If the response is one of the following redirect codes, Get follows the redirect, up to a maximum of 10 redirects:

```
301 (Moved Permanently)  
302 (Found)  
303 (See Other)  
307 (Temporary Redirect)
```

Caller should close r.Body when done reading from it.

Get is a wrapper around DefaultClient.Get.

? Example

? Example

Code:

```
res, err := http.Get("http://www.google.com/robots.txt")  
if err != nil {  
    log.Fatal(err)  
}  
robots, err := ioutil.ReadAll(res.Body)  
if err != nil {  
    log.Fatal(err)  
}  
res.Body.Close()  
fmt.Printf("%s", robots)
```

func [Head](#)

```
func Head(url string) (r *Response, err error)
```

Head issues a HEAD to the specified URL. If the response is one of the

following redirect codes, Head follows the redirect after calling the Client's CheckRedirect function.

301 (Moved Permanently)
302 (Found)
303 (See Other)
307 (Temporary Redirect)

Head is a wrapper around DefaultClient.Head

func [Post](#)

```
func Post(url string, bodyType string, body io.Reader) (r *Response,
```

Post issues a POST to the specified URL.

Caller should close r.Body when done reading from it.

Post is a wrapper around DefaultClient.Post

func [PostForm](#)

```
func PostForm(url string, data url.Values) (r *Response, err error)
```

PostForm issues a POST to the specified URL, with data's keys and values urlencoded as the request body.

Caller should close r.Body when done reading from it.

PostForm is a wrapper around DefaultClient.PostForm

func [ReadResponse](#)

```
func ReadResponse(r *bufio.Reader, req *Request) (resp *Response, er
```

ReadResponse reads and returns an HTTP response from r. The req parameter specifies the Request that corresponds to this Response. Clients must call resp.Body.Close when finished reading resp.Body. After that call, clients can inspect resp.Trailer to find key/value pairs included in the response trailer.

func (*Response) [Cookies](#)

```
func (r *Response) Cookies() []*Cookie
```

Cookies parses and returns the cookies set in the Set-Cookie headers.

func (*Response) [Location](#)

```
func (r *Response) Location() (*url.URL, error)
```

Location returns the URL of the response's "Location" header, if present. Relative redirects are resolved relative to the Response's Request. ErrNoLocation is returned if no Location header is present.

func (*Response) [ProtoAtLeast](#)

```
func (r *Response) ProtoAtLeast(major, minor int) bool
```

ProtoAtLeast returns whether the HTTP protocol used in the response is at least major.minor.

func (*Response) [Write](#)

```
func (r *Response) Write(w io.Writer) error
```

Writes the response (header, body and trailer) in wire format. This method consults the following fields of the response:

StatusCode

ProtoMajor

ProtoMinor

RequestMethod

TransferEncoding

Trailer

Body

ContentLength

Header, values for non-canonical keys will have unpredictable behavi

type ResponseWriter

```
type ResponseWriter interface {
    // Header returns the header map that will be sent by WriteHeader
    // Changing the header after a call to WriteHeader (or Write) has
    // no effect.
    Header() Header

    // Write writes the data to the connection as part of an HTTP response
    // If WriteHeader has not yet been called, Write calls WriteHeader
    // before writing the data. If the Header does not contain a
    // Content-Type line, Write adds a Content-Type set to the response
    // the initial 512 bytes of written data to DetectContentType.
    Write([]byte) (int, error)

    // WriteHeader sends an HTTP response header with status code.
    // If WriteHeader is not called explicitly, the first call to Write
    // will trigger an implicit WriteHeader(http.StatusOK).
    // Thus explicit calls to WriteHeader are mainly used to
    // send error codes.
    WriteHeader(int)
}
```

A ResponseWriter interface is used by an HTTP handler to construct an HTTP response.

type [RoundTripper](#)

```
type RoundTripper interface {  
    // RoundTrip executes a single HTTP transaction, returning  
    // the Response for the request req. RoundTrip should not  
    // attempt to interpret the response. In particular,  
    // RoundTrip must return err == nil if it obtained a response,  
    // regardless of the response's HTTP status code. A non-nil  
    // err should be reserved for failure to obtain a response.  
    // Similarly, RoundTrip should not attempt to handle  
    // higher-level protocol details such as redirects,  
    // authentication, or cookies.  
    //  
    // RoundTrip should not modify the request, except for  
    // consuming the Body. The request's URL and Header fields  
    // are guaranteed to be initialized.  
    RoundTrip(*Request) (*Response, error)  
}
```

RoundTripper is an interface representing the ability to execute a single HTTP transaction, obtaining the Response for a given Request.

A RoundTripper must be safe for concurrent use by multiple goroutines.

```
var DefaultTransport RoundTripper = &Transport{Proxy: ProxyFromEnvir
```

DefaultTransport is the default implementation of Transport and is used by DefaultClient. It establishes a new network connection for each call to Do and uses HTTP proxies as directed by the \$HTTP_PROXY and \$NO_PROXY (or \$http_proxy and \$no_proxy) environment variables.

func [NewFileTransport](#)

```
func NewFileTransport(fs FileSystem) RoundTripper
```

NewFileTransport returns a new RoundTripper, serving the provided FileSystem. The returned RoundTripper ignores the URL host in its incoming requests, as well as most other properties of the request.

The typical use case for NewFileTransport is to register the "file" protocol with a Transport, as in:

```
t := &http.Transport{}
t.RegisterProtocol("file", http.NewFileTransport(http.Dir("/")))
c := &http.Client{Transport: t}
res, err := c.Get("file:///etc/passwd")
...
```

type [ServeMux](#)

```
type ServeMux struct {  
    // contains filtered or unexported fields  
}
```

ServeMux is an HTTP request multiplexer. It matches the URL of each incoming request against a list of registered patterns and calls the handler for the pattern that most closely matches the URL.

Patterns named fixed, rooted paths, like `"/favicon.ico"`, or rooted subtrees, like `"/images/"` (note the trailing slash). Longer patterns take precedence over shorter ones, so that if there are handlers registered for both `"/images/"` and `"/images/thumbnails/"`, the latter handler will be called for paths beginning `"/images/thumbnails/"` and the former will receive requests for any other paths in the `"/images/"` subtree.

Patterns may optionally begin with a host name, restricting matches to URLs on that host only. Host-specific patterns take precedence over general patterns, so that a handler might register for the two patterns `"/codesearch"` and `"codesearch.google.com/"` without also taking over requests for ["http://www.google.com/"](http://www.google.com/).

ServeMux also takes care of sanitizing the URL request path, redirecting any request containing `.` or `..` elements to an equivalent `.-` and `..-` free URL.

func [NewServeMux](#)

```
func NewServeMux() *ServeMux
```

NewServeMux allocates and returns a new ServeMux.

func (*ServeMux) [Handle](#)

```
func (mux *ServeMux) Handle(pattern string, handler Handler)
```

Handle registers the handler for the given pattern. If a handler already exists for pattern, Handle panics.

func (*ServeMux) [HandleFunc](#)

```
func (mux *ServeMux) HandleFunc(pattern string, handler func(Response
```

HandleFunc registers the handler function for the given pattern.

func (*ServeMux) [ServeHTTP](#)

```
func (mux *ServeMux) ServeHTTP(w ResponseWriter, r *Request)
```

ServeHTTP dispatches the request to the handler whose pattern most closely matches the request URL.

type [Server](#)

```
type Server struct {
    Addr          string          // TCP address to listen on, ":http"
    Handler       Handler        // handler to invoke, http.DefaultS
    ReadTimeout   time.Duration  // maximum duration before timing o
    WriteTimeout  time.Duration  // maximum duration before timing o
    MaxHeaderBytes int            // maximum size of request headers,
    TLSConfig     *tls.Config    // optional TLS config, used by Lis
}
```

A `Server` defines parameters for running an HTTP server.

func ([*Server](#)) [ListenAndServe](#)

```
func (srv *Server) ListenAndServe() error
```

`ListenAndServe` listens on the TCP network address `srv.Addr` and then calls `Serve` to handle requests on incoming connections. If `srv.Addr` is blank, `":http"` is used.

func ([*Server](#)) [ListenAndServeTLS](#)

```
func (srv *Server) ListenAndServeTLS(certFile, keyFile string) error
```

`ListenAndServeTLS` listens on the TCP network address `srv.Addr` and then calls `Serve` to handle requests on incoming TLS connections.

Filename containing a certificate and matching private key for the server must be provided. If the certificate is signed by a certificate authority, the `certFile` should be the concatenation of the server's certificate followed by the CA's certificate.

If `srv.Addr` is blank, `":https"` is used.

func ([*Server](#)) [Serve](#)

```
func (srv *Server) Serve(l net.Listener) error
```

`Serve` accepts incoming connections on the `Listener l`, creating a new service

thread for each. The service threads read requests and then call `srv.Handler` to reply to them.

type [Transport](#)

```
type Transport struct {  
  
    // Proxy specifies a function to return a proxy for a given  
    // Request. If the function returns a non-nil error, the  
    // request is aborted with the provided error.  
    // If Proxy is nil or returns a nil *URL, no proxy is used.  
    Proxy func(*Request) (*url.URL, error)  
  
    // Dial specifies the dial function for creating TCP  
    // connections.  
    // If Dial is nil, net.Dial is used.  
    Dial func(net, addr string) (c net.Conn, err error)  
  
    // TLSClientConfig specifies the TLS configuration to use with  
    // tls.Client. If nil, the default configuration is used.  
    TLSClientConfig *tls.Config  
  
    DisableKeepAlives bool  
    DisableCompression bool  
  
    // MaxIdleConnsPerHost, if non-zero, controls the maximum idle  
    // (keep-alive) to keep to keep per-host. If zero,  
    // DefaultMaxIdleConnsPerHost is used.  
    MaxIdleConnsPerHost int  
    // contains filtered or unexported fields  
}
```

Transport is an implementation of RoundTripper that supports http, https, and http proxies (for either http or https with CONNECT). Transport can also cache connections for future re-use.

func (*Transport) [CloseIdleConnections](#)

```
func (t *Transport) CloseIdleConnections()
```

CloseIdleConnections closes any connections which were previously connected from previous requests but are now sitting idle in a "keep-alive" state. It does not interrupt any connections currently in use.

func (*Transport) [RegisterProtocol](#)

```
func (t *Transport) RegisterProtocol(scheme string, rt RoundTripper)
```

RegisterProtocol registers a new protocol with scheme. The Transport will pass requests using the given scheme to rt. It is rt's responsibility to simulate HTTP request semantics.

RegisterProtocol can be used by other packages to provide implementations of protocol schemes like "ftp" or "file".

func (*Transport) [RoundTrip](#)

```
func (t *Transport) RoundTrip(req *Request) (resp *Response, err error)
```

RoundTrip implements the RoundTripper interface.

Package cgi

```
import "net/http/cgi"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package cgi implements CGI (Common Gateway Interface) as specified in RFC 3875.

Note that using CGI means starting a new process to handle each request, which is typically less efficient than using a long-running server. This package is intended primarily for compatibility with existing systems.

Index

[func Request\(\) \(*http.Request, error\)](#)

[func RequestFromMap\(params map\[string\]string\) \(*http.Request, error\)](#)

[func Serve\(handler http.Handler\) error](#)

[type Handler](#)

[func \(h *Handler\) ServeHTTP\(rw http.ResponseWriter, req *http.Request\)](#)

Package files

[child.go](#) [host.go](#)

func [Request](#)

```
func Request() (*http.Request, error)
```

Request returns the HTTP request as represented in the current environment. This assumes the current program is being run by a web server in a CGI environment. The returned Request's Body is populated, if applicable.

func [RequestFromMap](#)

```
func RequestFromMap(params map[string]string) (*http.Request, error)
```

RequestFromMap creates an http.Request from CGI variables. The returned Request's Body field is not populated.

func [Serve](#)

```
func Serve(handler http.Handler) error
```

Serve executes the provided Handler on the currently active CGI request, if any. If there's no current CGI environment an error is returned. The provided handler may be nil to use `http.DefaultServeMux`.

type [Handler](#)

```
type Handler struct {
    Path string // path to the CGI executable
    Root string

    // Dir specifies the CGI executable's working directory.
    // If Dir is empty, the base directory of Path is used.
    // If Path has no base directory, the current working
    // directory is used.
    Dir string

    Env      []string // extra environment variables to set, if
    InheritEnv []string // environment variables to inherit from
    Logger    *log.Logger // optional log for errors or nil to use
    Args     []string

    // PathLocationHandler specifies the root http Handler that
    // should handle internal redirects when the CGI process
    // returns a Location header value starting with a "/", as
    // specified in RFC 3875 6.3.2. This will likely be
    // http.DefaultServeMux.
    //
    // If nil, a CGI response with a local URI path is instead sent
    // back to the client and not redirected internally.
    PathLocationHandler http.Handler
}
```

Handler runs an executable in a subprocess with a CGI environment.

func (*Handler) [ServeHTTP](#)

```
func (h *Handler) ServeHTTP(rw http.ResponseWriter, req *http.Request)
```

Build version go1.0.1.

[func Serve\(l net.Listener, handler http.Handler\) error](#)

Package files

[child.go](#) [fcgi.go](#)

func [Serve](#)

```
func Serve(l net.Listener, handler http.Handler) error
```

Serve accepts incoming FastCGI connections on the listener `l`, creating a new goroutine for each. The goroutine reads requests and then calls `handler` to reply to them. If `l` is `nil`, Serve accepts connections from `os.Stdin`. If `handler` is `nil`, `http.DefaultServeMux` is used.

Build version go1.0.1.

type ResponseRecorder

func NewRecorder() *ResponseRecorder

func (rw *ResponseRecorder) Flush()

func (rw *ResponseRecorder) Header() http.Header

func (rw *ResponseRecorder) Write(buf []byte) (int, error)

func (rw *ResponseRecorder) WriteHeader(code int)

type Server

func NewServer(handler http.Handler) *Server

func NewTLSHandler(handler http.Handler) *Server

func NewUnstartedServer(handler http.Handler) *Server

func (s *Server) Close()

func (s *Server) CloseClientConnections()

func (s *Server) Start()

func (s *Server) StartTLS()

Package files

[recorder.go](#) [server.go](#)

Constants

```
const DefaultRemoteAddr = "1.2.3.4"
```

DefaultRemoteAddr is the default remote address to return in RemoteAddr if an explicit DefaultRemoteAddr isn't set on ResponseRecorder.

type [ResponseRecorder](#)

```
type ResponseRecorder struct {  
    Code      int           // the HTTP response code from WriteHead  
    HeaderMap http.Header  // the HTTP response headers  
    Body      *bytes.Buffer // if non-nil, the bytes.Buffer to appen  
    Flushed   bool  
}
```

ResponseRecorder is an implementation of `http.ResponseWriter` that records its mutations for later inspection in tests.

func [NewRecorder](#)

```
func NewRecorder() *ResponseRecorder
```

NewRecorder returns an initialized ResponseRecorder.

func (*ResponseRecorder) [Flush](#)

```
func (rw *ResponseRecorder) Flush()
```

Flush sets `rw.Flushed` to true.

func (*ResponseRecorder) [Header](#)

```
func (rw *ResponseRecorder) Header() http.Header
```

Header returns the response headers.

func (*ResponseRecorder) [Write](#)

```
func (rw *ResponseRecorder) Write(buf []byte) (int, error)
```

Write always succeeds and writes to `rw.Body`, if not nil.

func (*ResponseRecorder) [WriteHeader](#)

```
func (rw *ResponseRecorder) WriteHeader(code int)
```

WriteHeader sets rw.Code.

type [Server](#)

```
type Server struct {
    URL      string // base URL of form http://ipaddr:port with no t
    Listener net.Listener
    TLS      *tls.Config

    // Config may be changed after calling NewUnstartedServer and
    // before Start or StartTLS.
    Config *http.Server
    // contains filtered or unexported fields
}
```

A `Server` is an HTTP server listening on a system-chosen port on the local loopback interface, for use in end-to-end HTTP tests.

func [NewServer](#)

```
func NewServer(handler http.Handler) *Server
```

`NewServer` starts and returns a new `Server`. The caller should call `Close` when finished, to shut it down.

func [NewTLSServer](#)

```
func NewTLSServer(handler http.Handler) *Server
```

`NewTLSServer` starts and returns a new `Server` using TLS. The caller should call `Close` when finished, to shut it down.

func [NewUnstartedServer](#)

```
func NewUnstartedServer(handler http.Handler) *Server
```

`NewUnstartedServer` returns a new `Server` but doesn't start it.

After changing its configuration, the caller should call `Start` or `StartTLS`.

The caller should call `Close` when finished, to shut it down.

func (*Server) [Close](#)

```
func (s *Server) Close()
```

Close shuts down the server and blocks until all outstanding requests on this server have completed.

func (*Server) [CloseClientConnections](#)

```
func (s *Server) CloseClientConnections()
```

CloseClientConnections closes any currently open HTTP connections to the test Server.

func (*Server) [Start](#)

```
func (s *Server) Start()
```

Start starts a server from NewUnstartedServer.

func (*Server) [StartTLS](#)

```
func (s *Server) StartTLS()
```

StartTLS starts TLS on a server from NewUnstartedServer.

Build version go1.0.1.

Package files

[chunked.go](#) [dump.go](#) [persist.go](#) [reverseproxy.go](#)

Variables

```
var (  
    ErrPersistEOF = &http.ProtocolError{ErrorString: "persistent con  
    ErrClosed      = &http.ProtocolError{ErrorString: "connection clo  
    ErrPipeline    = &http.ProtocolError{ErrorString: "pipeline error  
)  
  
var ErrLineTooLong = errors.New("header line too long")
```

func [DumpRequest](#)

```
func DumpRequest(req *http.Request, body bool) (dump []byte, err error)
```

DumpRequest returns the as-received wire representation of req, optionally including the request body, for debugging. DumpRequest is semantically a no-op, but in order to dump the body, it reads the body data into memory and changes req.Body to refer to the in-memory copy. The documentation for `http.Request.Write` details which fields of req are used.

func [DumpRequestOut](#)

```
func DumpRequestOut(req *http.Request, body bool) ([]byte, error)
```

DumpRequestOut is like DumpRequest but includes headers that the standard http.Transport adds, such as User-Agent.

func DumpResponse

```
func DumpResponse(resp *http.Response, body bool) (dump []byte, err
```

DumpResponse is like DumpRequest but dumps a response.

func [NewChunkedReader](#)

```
func NewChunkedReader(r io.Reader) io.Reader
```

NewChunkedReader returns a new chunkedReader that translates the data read from r out of HTTP "chunked" format before returning it. The chunkedReader returns io.EOF when the final 0-length chunk is read.

NewChunkedReader is not needed by normal applications. The http package automatically decodes chunking when reading response bodies.

func [NewChunkedWriter](#)

```
func NewChunkedWriter(w io.Writer) io.WriteCloser
```

NewChunkedWriter returns a new chunkedWriter that translates writes into HTTP "chunked" format before writing them to w. Closing the returned chunkedWriter sends the final 0-length chunk that marks the end of the stream.

NewChunkedWriter is not needed by normal applications. The http package adds chunking automatically if handlers don't set a Content-Length header. Using NewChunkedWriter inside a handler would result in double chunking or chunking with a Content-Length length, both of which are wrong.

type [ClientConn](#)

```
type ClientConn struct {  
    // contains filtered or unexported fields  
}
```

A ClientConn sends request and receives headers over an underlying connection, while respecting the HTTP keepalive logic. ClientConn supports hijacking the connection calling Hijack to regain control of the underlying net.Conn and deal with it as desired.

ClientConn is low-level and should not be needed by most applications. See Client.

func [NewClientConn](#)

```
func NewClientConn(c net.Conn, r *bufio.Reader) *ClientConn
```

NewClientConn returns a new ClientConn reading and writing c. If r is not nil, it is the buffer to use when reading c.

func [NewProxyClientConn](#)

```
func NewProxyClientConn(c net.Conn, r *bufio.Reader) *ClientConn
```

NewProxyClientConn works like NewClientConn but writes Requests using Request's WriteProxy method.

func (*ClientConn) [Close](#)

```
func (cc *ClientConn) Close() error
```

Close calls Hijack and then also closes the underlying connection

func (*ClientConn) [Do](#)

```
func (cc *ClientConn) Do(req *http.Request) (resp *http.Response, er
```

Do is convenience method that writes a request and reads a response.

func (*ClientConn) [Hijack](#)

```
func (cc *ClientConn) Hijack() (c net.Conn, r *bufio.Reader)
```

Hijack detaches the ClientConn and returns the underlying connection as well as the read-side bufio which may have some left over data. Hijack may be called before the user or Read have signaled the end of the keep-alive logic. The user should not call Hijack while Read or Write is in progress.

func (*ClientConn) [Pending](#)

```
func (cc *ClientConn) Pending() int
```

Pending returns the number of unanswered requests that have been sent on the connection.

func (*ClientConn) [Read](#)

```
func (cc *ClientConn) Read(req *http.Request) (resp *http.Response,
```

Read reads the next response from the wire. A valid response might be returned together with an ErrPersistEOF, which means that the remote requested that this be the last request serviced. Read can be called concurrently with Write, but not with another Read.

func (*ClientConn) [Write](#)

```
func (cc *ClientConn) Write(req *http.Request) (err error)
```

Write writes a request. An ErrPersistEOF error is returned if the connection has been closed in an HTTP keepalive sense. If req.Close equals true, the keepalive connection is logically closed after this request and the opposing server is informed. An ErrUnexpectedEOF indicates the remote closed the underlying TCP connection, which is usually considered as graceful close.

type [ReverseProxy](#)

```
type ReverseProxy struct {
    // Director must be a function which modifies
    // the request into a new request to be sent
    // using Transport. Its response is then copied
    // back to the original client unmodified.
    Director func(*http.Request)

    // The transport used to perform proxy requests.
    // If nil, http.DefaultTransport is used.
    Transport http.RoundTripper

    // FlushInterval specifies the flush interval
    // to flush to the client while copying the
    // response body.
    // If zero, no periodic flushing is done.
    FlushInterval time.Duration
}
```

ReverseProxy is an HTTP Handler that takes an incoming request and sends it to another server, proxying the response back to the client.

func [NewSingleHostReverseProxy](#)

```
func NewSingleHostReverseProxy(target *url.URL) *ReverseProxy
```

NewSingleHostReverseProxy returns a new ReverseProxy that rewrites URLs to the scheme, host, and base path provided in target. If the target's path is "/base" and the incoming request was for "/dir", the target request will be for /base/dir.

func (***ReverseProxy**) [ServeHTTP](#)

```
func (p *ReverseProxy) ServeHTTP(rw http.ResponseWriter, req *http.R
```

type [ServerConn](#)

```
type ServerConn struct {  
    // contains filtered or unexported fields  
}
```

A `ServerConn` reads requests and sends responses over an underlying connection, until the HTTP keepalive logic commands an end. `ServerConn` also allows hijacking the underlying connection by calling `Hijack` to regain control over the connection. `ServerConn` supports pipe-lining, i.e. requests can be read out of sync (but in the same order) while the respective responses are sent.

`ServerConn` is low-level and should not be needed by most applications. See `Server`.

func [NewServerConn](#)

```
func NewServerConn(c net.Conn, r *bufio.Reader) *ServerConn
```

`NewServerConn` returns a new `ServerConn` reading and writing `c`. If `r` is not nil, it is the buffer to use when reading `c`.

func (*ServerConn) [Close](#)

```
func (sc *ServerConn) Close() error
```

`Close` calls `Hijack` and then also closes the underlying connection

func (*ServerConn) [Hijack](#)

```
func (sc *ServerConn) Hijack() (c net.Conn, r *bufio.Reader)
```

`Hijack` detaches the `ServerConn` and returns the underlying connection as well as the read-side `bufio` which may have some left over data. `Hijack` may be called before `Read` has signaled the end of the keep-alive logic. The user should not call `Hijack` while `Read` or `Write` is in progress.

func (*ServerConn) [Pending](#)

```
func (sc *ServerConn) Pending() int
```

Pending returns the number of unanswered requests that have been received on the connection.

func (*ServerConn) [Read](#)

```
func (sc *ServerConn) Read() (req *http.Request, err error)
```

Read returns the next request on the wire. An ErrPersistEOF is returned if it is gracefully determined that there are no more requests (e.g. after the first request on an HTTP/1.0 connection, or after a Connection:close on a HTTP/1.1 connection).

func (*ServerConn) [Write](#)

```
func (sc *ServerConn) Write(req *http.Request, resp *http.Response)
```

Write writes resp in response to req. To close the connection gracefully, set the Response.Close field to true. Write should be considered operational until it returns an error, regardless of any errors returned on the Read side.

Build version go1.0.1.

Package pprof

```
import "net/http/pprof"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package pprof serves via its HTTP server runtime profiling data in the format expected by the pprof visualization tool. For more information about pprof, see <http://code.google.com/p/google-perftools/>.

The package is typically only imported for the side effect of registering its HTTP handlers. The handled paths all begin with /debug/pprof/.

To use pprof, link this package into your program:

```
import _ "net/http/pprof"
```

Then use the pprof tool to look at the heap profile:

```
go tool pprof http://localhost:6060/debug/pprof/heap
```

Or to look at a 30-second CPU profile:

```
go tool pprof http://localhost:6060/debug/pprof/profile
```

Or to view all available profiles:

```
go tool pprof http://localhost:6060/debug/pprof/
```

For a study of the facility in action, visit

<http://blog.golang.org/2011/06/profiling-go-programs.html>

[func Handler\(name string\) http.Handler](#)

[func Index\(w http.ResponseWriter, r *http.Request\)](#)

[func Profile\(w http.ResponseWriter, r *http.Request\)](#)

[func Symbol\(w http.ResponseWriter, r *http.Request\)](#)

Package files

[pprof.go](#)

func [Cmdline](#)

```
func Cmdline(w http.ResponseWriter, r *http.Request)
```

Cmdline responds with the running program's command line, with arguments separated by NUL bytes. The package initialization registers it as `/debug/pprof/cmdline`.

func [Handler](#)

```
func Handler(name string) http.Handler
```

Handler returns an HTTP handler that serves the named profile.

func [Index](#)

```
func Index(w http.ResponseWriter, r *http.Request)
```

Index responds with the pprof-formatted profile named by the request. For example, `"/debug/pprof/heap"` serves the "heap" profile. Index responds to a request for `"/debug/pprof/"` with an HTML page listing the available profiles.

func [Profile](#)

```
func Profile(w http.ResponseWriter, r *http.Request)
```

Profile responds with the pprof-formatted cpu profile. The package initialization registers it as `/debug/pprof/profile`.

func [Symbol](#)

```
func Symbol(w http.ResponseWriter, r *http.Request)
```

Symbol looks up the program counters listed in the request, responding with a table mapping program counters to function names. The package initialization registers it as `/debug/pprof/symbol`.

Build version go1.0.1.

Package mail

```
import "net/mail"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package mail implements parsing of mail messages.

For the most part, this package follows the syntax as specified by RFC 5322.

Notable divergences:

- * Obsolete address formats are not parsed, including addresses with embedded route information.
- * Group addresses are not parsed.
- * The full range of spacing (the CFWS syntax element) is not support such as breaking addresses across lines.

Index

Variables

type Address

func (a *Address) String() string

type Header

func (h Header) AddressList(key string) ([]*Address, error)

func (h Header) Date() (time.Time, error)

func (h Header) Get(key string) string

type Message

func ReadMessage(r io.Reader) (msg *Message, err error)

Package files

[message.go](#)

Variables

```
var ErrHeaderNotPresent = errors.New("mail: header not in message")
```

type [Address](#)

```
type Address struct {  
    Name    string // Proper name; may be empty.  
    Address string // user@domain  
}
```

Address represents a single mail address. An address such as "Barry Gibbs <bg@example.com>" is represented as `Address{Name: "Barry Gibbs", Address: "bg@example.com"}`.

func (*Address) [String](#)

```
func (a *Address) String() string
```

String formats the address as a valid RFC 5322 address. If the address's name contains non-ASCII characters the name will be rendered according to RFC 2047.

type [Header](#)

```
type Header map[string][]string
```

A Header represents the key-value pairs in a mail message header.

func (Header) [AddressList](#)

```
func (h Header) AddressList(key string) ([]*Address, error)
```

AddressList parses the named header field as a list of addresses.

func (Header) [Date](#)

```
func (h Header) Date() (time.Time, error)
```

Date parses the Date header field.

func (Header) [Get](#)

```
func (h Header) Get(key string) string
```

Get gets the first value associated with the given key. If there are no values associated with the key, Get returns "".

type [Message](#)

```
type Message struct {  
    Header Header  
    Body   io.Reader  
}
```

A Message represents a parsed mail message.

func [ReadMessage](#)

```
func ReadMessage(r io.Reader) (msg *Message, err error)
```

ReadMessage reads a message from r. The headers are parsed, and the body of the message will be reading from r.

Build version go1.0.1.

Package rpc

```
import "net/rpc"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `rpc` provides access to the exported methods of an object across a network or other I/O connection. A server registers an object, making it visible as a service with the name of the type of the object. After registration, exported methods of the object will be accessible remotely. A server may register multiple objects (services) of different types but it is an error to register multiple objects of the same type.

Only methods that satisfy these criteria will be made available for remote access; other methods will be ignored:

- the method is exported.
- the method has two arguments, both exported (or builtin) types.
- the method's second argument is a pointer.
- the method has return type `error`.

In effect, the method must look schematically like

```
func (t *T) MethodName(argType T1, replyType *T2) error
```

where `T`, `T1` and `T2` can be marshaled by encoding/gob. These requirements apply even if a different codec is used. (In future, these requirements may soften for custom codecs.)

The method's first argument represents the arguments provided by the caller; the second argument represents the result parameters to be returned to the caller. The method's return value, if non-nil, is passed back as a string that the client sees as if created by `errors.New`.

The server may handle requests on a single connection by calling `ServeConn`. More typically it will create a network listener and call `Accept` or, for an HTTP listener, `HandleHTTP` and `http.Serve`.

A client wishing to use the service establishes a connection and then invokes `NewClient` on the connection. The convenience function `Dial` (`DialHTTP`) performs both steps for a raw network connection (an HTTP connection). The resulting `Client` object has two methods, `Call` and `Go`, that specify the service and method to call, a pointer containing the arguments, and a pointer to receive

the result parameters.

The Call method waits for the remote call to complete while the Go method launches the call asynchronously and signals completion using the Call structure's Done channel.

Unless an explicit codec is set up, package encoding/gob is used to transport the data.

Here is a simple example. A server wishes to export an object of type Arith:

```
package server

type Args struct {
    A, B int
}

type Quotient struct {
    Quo, Rem int
}

type Arith int

func (t *Arith) Multiply(args *Args, reply *int) error {
    *reply = args.A * args.B
    return nil
}

func (t *Arith) Divide(args *Args, quo *Quotient) error {
    if args.B == 0 {
        return errors.New("divide by zero")
    }
    quo.Quo = args.A / args.B
    quo.Rem = args.A % args.B
    return nil
}
```

The server calls (for HTTP service):

```
arith := new(Arith)
rpc.Register(arith)
rpc.HandleHTTP()
l, e := net.Listen("tcp", ":1234")
if e != nil {
    log.Fatal("listen error:", e)
}
go http.Serve(l, nil)
```

At this point, clients can see a service "Arith" with methods "Arith.Multiply" and "Arith.Divide". To invoke one, a client first dials the server:

```
client, err := rpc.DialHTTP("tcp", serverAddress + ":1234")
if err != nil {
    log.Fatal("dialing:", err)
}
```

Then it can make a remote call:

```
// Synchronous call
args := &server.Args{7,8}
var reply int
err = client.Call("Arith.Multiply", args, &reply)
if err != nil {
    log.Fatal("arith error:", err)
}
fmt.Printf("Arith: %d*%d=%d", args.A, args.B, reply)
```

or

```
// Asynchronous call
quotient := new(Quotient)
divCall := client.Go("Arith.Divide", args, &quotient, nil)
replyCall := <-divCall.Done // will be equal to divCall
// check errors, print, etc.
```

A server implementation will often provide a simple, type-safe wrapper for the client.

```

Package files

[client.go](#) [debug.go](#) [server.go](#)

Constants

```
const (  
    // Defaults used by HandleHTTP  
    DefaultRPCPath    = "/_goRPC_"  
    DefaultDebugPath = "/debug/rpc"  
)
```

Variables

```
var DefaultServer = NewServer()
```

DefaultServer is the default instance of *Server.

```
var ErrShutdown = errors.New("connection is shut down")
```

func [Accept](#)

```
func Accept(lis net.Listener)
```

Accept accepts connections on the listener and serves requests to DefaultServer for each incoming connection. Accept blocks; the caller typically invokes it in a go statement.

func [HandleHTTP](#)

```
func HandleHTTP()
```

HandleHTTP registers an HTTP handler for RPC messages to DefaultServer on DefaultRPCPath and a debugging handler on DefaultDebugPath. It is still necessary to invoke `http.Serve()`, typically in a `go` statement.

func Register

```
func Register(rcvr interface{}) error
```

Register publishes the receiver's methods in the DefaultServer.

func RegisterName

```
func RegisterName(name string, rcvr interface{}) error
```

RegisterName is like Register but uses the provided name for the type instead of the receiver's concrete type.

func [ServeCodec](#)

```
func ServeCodec(codec ServerCodec)
```

ServeCodec is like ServeConn but uses the specified codec to decode requests and encode responses.

func [ServeConn](#)

```
func ServeConn(conn io.ReadWriteCloser)
```

ServeConn runs the DefaultServer on a single connection. ServeConn blocks, serving the connection until the client hangs up. The caller typically invokes ServeConn in a go statement. ServeConn uses the gob wire format (see package gob) on the connection. To use an alternate codec, use ServeCodec.

func [ServeRequest](#)

```
func ServeRequest(codec ServerCodec) error
```

ServeRequest is like ServeCodec but synchronously serves a single request. It does not close the codec upon completion.

type [Call](#)

```
type Call struct {
    ServiceMethod string // The name of the service and method
    Args          interface{} // The argument to the function (*stru
    Reply         interface{} // The reply from the function (*struc
    Error         error      // After completion, the error status.
    Done         chan *Call // Strobes when call is complete.
}
```

Call represents an active RPC.

type [Client](#)

```
type Client struct {  
    // contains filtered or unexported fields  
}
```

Client represents an RPC Client. There may be multiple outstanding Calls associated with a single Client, and a Client may be used by multiple goroutines simultaneously.

func [Dial](#)

```
func Dial(network, address string) (*Client, error)
```

Dial connects to an RPC server at the specified network address.

func [DialHTTP](#)

```
func DialHTTP(network, address string) (*Client, error)
```

DialHTTP connects to an HTTP RPC server at the specified network address listening on the default HTTP RPC path.

func [DialHTTPPath](#)

```
func DialHTTPPath(network, address, path string) (*Client, error)
```

DialHTTPPath connects to an HTTP RPC server at the specified network address and path.

func [NewClient](#)

```
func NewClient(conn io.ReadWriteCloser) *Client
```

NewClient returns a new Client to handle requests to the set of services at the other end of the connection. It adds a buffer to the write side of the connection so the header and payload are sent as a unit.

func [NewClientWithCodec](#)

```
func NewClientWithCodec(codec ClientCodec) *Client
```

NewClientWithCodec is like NewClient but uses the specified codec to encode requests and decode responses.

func (*Client) [Call](#)

```
func (client *Client) Call(serviceMethod string, args interface{}, r
```

Call invokes the named function, waits for it to complete, and returns its error status.

func (*Client) [Close](#)

```
func (client *Client) Close() error
```

func (*Client) [Go](#)

```
func (client *Client) Go(serviceMethod string, args interface{}, rep
```

Go invokes the function asynchronously. It returns the Call structure representing the invocation. The done channel will signal when the call is complete by returning the same Call object. If done is nil, Go will allocate a new channel. If non-nil, done must be buffered or Go will deliberately crash.

type [ClientCodec](#)

```
type ClientCodec interface {
    WriteRequest(*Request, interface{}) error
    ReadResponseHeader(*Response) error
    ReadResponseBody(interface{}) error

    Close() error
}
```

A ClientCodec implements writing of RPC requests and reading of RPC responses for the client side of an RPC session. The client calls WriteRequest to write a request to the connection and calls ReadResponseHeader and ReadResponseBody in pairs to read responses. The client calls Close when finished with the connection. ReadResponseBody may be called with a nil argument to force the body of the response to be read and then discarded.

type [Request](#)

```
type Request struct {  
    ServiceMethod string // format: "Service.Method"  
    Seq           uint64 // sequence number chosen by client  
    // contains filtered or unexported fields  
}
```

Request is a header written before every RPC call. It is used internally but documented here as an aid to debugging, such as when analyzing network traffic.

type [Response](#)

```
type Response struct {
    ServiceMethod string // echoes that of the Request
    Seq           uint64 // echoes that of the request
    Error         string // error, if any.
    // contains filtered or unexported fields
}
```

Response is a header written before every RPC return. It is used internally but documented here as an aid to debugging, such as when analyzing network traffic.

type [Server](#)

```
type Server struct {  
    // contains filtered or unexported fields  
}
```

Server represents an RPC Server.

func [NewServer](#)

```
func NewServer() *Server
```

NewServer returns a new Server.

func (*Server) [Accept](#)

```
func (server *Server) Accept(lis net.Listener)
```

Accept accepts connections on the listener and serves requests for each incoming connection. Accept blocks; the caller typically invokes it in a go statement.

func (*Server) [HandleHTTP](#)

```
func (server *Server) HandleHTTP(rpcPath, debugPath string)
```

HandleHTTP registers an HTTP handler for RPC messages on rpcPath, and a debugging handler on debugPath. It is still necessary to invoke http.Serve(), typically in a go statement.

func (*Server) [Register](#)

```
func (server *Server) Register(rcvr interface{}) error
```

Register publishes in the server the set of methods of the receiver value that satisfy the following conditions:

- exported method
- two arguments, both pointers to exported structs
- one return value, of type error

It returns an error if the receiver is not an exported type or has no suitable methods. The client accesses each method using a string of the form "Type.Method", where Type is the receiver's concrete type.

func (*Server) [RegisterName](#)

```
func (server *Server) RegisterName(name string, rcvr interface{}) error
```

RegisterName is like Register but uses the provided name for the type instead of the receiver's concrete type.

func (*Server) [ServeCodec](#)

```
func (server *Server) ServeCodec(codec ServerCodec)
```

ServeCodec is like ServeConn but uses the specified codec to decode requests and encode responses.

func (*Server) [ServeConn](#)

```
func (server *Server) ServeConn(conn io.ReadWriteCloser)
```

ServeConn runs the server on a single connection. ServeConn blocks, serving the connection until the client hangs up. The caller typically invokes ServeConn in a go statement. ServeConn uses the gob wire format (see package gob) on the connection. To use an alternate codec, use ServeCodec.

func (*Server) [ServeHTTP](#)

```
func (server *Server) ServeHTTP(w http.ResponseWriter, req *http.Request)
```

ServeHTTP implements an http.Handler that answers RPC requests.

func (*Server) [ServeRequest](#)

```
func (server *Server) ServeRequest(codec ServerCodec) error
```

ServeRequest is like ServeCodec but synchronously serves a single request. It does not close the codec upon completion.

type [ServerCodec](#)

```
type ServerCodec interface {  
    ReadRequestHeader(*Request) error  
    ReadRequestBody(interface{}) error  
    WriteResponse(*Response, interface{}) error  
  
    Close() error  
}
```

A `ServerCodec` implements reading of RPC requests and writing of RPC responses for the server side of an RPC session. The server calls `ReadRequestHeader` and `ReadRequestBody` in pairs to read requests from the connection, and it calls `WriteResponse` to write a response back. The server calls `Close` when finished with the connection. `ReadRequestBody` may be called with a `nil` argument to force the body of the request to be read and discarded.

type [ServerError](#)

```
type ServerError string
```

ServerError represents an error that has been returned from the remote side of the RPC connection.

func (ServerError) [Error](#)

```
func (e ServerError) Error() string
```

func NewClient(conn io.ReadWriteCloser) *rpc.Client
```

NewClient returns a new `rpc.Client` to handle requests to the set of services at the other end of the connection.

func [NewClientCodec](#)

```
func NewClientCodec(conn io.ReadWriteCloser) rpc.ClientCodec
```

NewClientCodec returns a new rpc.ClientCodec using JSON-RPC on conn.

func [NewServerCodec](#)

```
func NewServerCodec(conn io.ReadWriteCloser) rpc.ServerCodec
```

NewServerCodec returns a new rpc.ServerCodec using JSON-RPC on conn.

func [ServeConn](#)

```
func ServeConn(conn io.ReadWriteCloser)
```

ServeConn runs the JSON-RPC server on a single connection. ServeConn blocks, serving the connection until the client hangs up. The caller typically invokes ServeConn in a go statement.

Build version go1.0.1.

Package smtp

```
import "net/smtp"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package smtp implements the Simple Mail Transfer Protocol as defined in RFC 5321. It also implements the following extensions:

8BITMIME	RFC 1652
AUTH	RFC 2554
STARTTLS	RFC 3207

Additional extensions may be handled by clients.

[type ServerInfo](#)

Package files

[auth.go smtp.go](#)

func [SendMail](#)

```
func SendMail(addr string, a Auth, from string, to []string, msg []b
```

SendMail connects to the server at addr, switches to TLS if possible, authenticates with mechanism a if possible, and then sends an email from address from, to addresses to, with message msg.

type [Auth](#)

```
type Auth interface {
    // Start begins an authentication with a server.
    // It returns the name of the authentication protocol
    // and optionally data to include in the initial AUTH message
    // sent to the server. It can return proto == "" to indicate
    // that the authentication should be skipped.
    // If it returns a non-nil error, the SMTP client aborts
    // the authentication attempt and closes the connection.
    Start(server *ServerInfo) (proto string, toServer []byte, err error)

    // Next continues the authentication. The server has just sent
    // the fromServer data. If more is true, the server expects a
    // response, which Next should return as toServer; otherwise
    // Next should return toServer == nil.
    // If Next returns a non-nil error, the SMTP client aborts
    // the authentication attempt and closes the connection.
    Next(fromServer []byte, more bool) (toServer []byte, err error)
}
```

Auth is implemented by an SMTP authentication mechanism.

func [CRAMMD5Auth](#)

```
func CRAMMD5Auth(username, secret string) Auth
```

CRAMMD5Auth returns an Auth that implements the CRAM-MD5 authentication mechanism as defined in RFC 2195. The returned Auth uses the given username and secret to authenticate to the server using the challenge-response mechanism.

func [PlainAuth](#)

```
func PlainAuth(identity, username, password, host string) Auth
```

PlainAuth returns an Auth that implements the PLAIN authentication mechanism as defined in RFC 4616. The returned Auth uses the given username and password to authenticate on TLS connections to host and act as identity. Usually identity will be left blank to act as username.

type [Client](#)

```
type Client struct {  
    // Text is the textproto.Conn used by the Client. It is exported  
    // clients to add extensions.  
    Text *textproto.Conn  
    // contains filtered or unexported fields  
}
```

A Client represents a client connection to an SMTP server.

func [Dial](#)

```
func Dial(addr string) (*Client, error)
```

Dial returns a new Client connected to an SMTP server at addr.

func [NewClient](#)

```
func NewClient(conn net.Conn, host string) (*Client, error)
```

NewClient returns a new Client using an existing connection and host as a server name to be used when authenticating.

func (***Client**) [Auth](#)

```
func (c *Client) Auth(a Auth) error
```

Auth authenticates a client using the provided authentication mechanism. A failed authentication closes the connection. Only servers that advertise the AUTH extension support this function.

func (***Client**) [Data](#)

```
func (c *Client) Data() (io.WriteCloser, error)
```

Data issues a DATA command to the server and returns a writer that can be used to write the data. The caller should close the writer before calling any more methods on c. A call to Data must be preceded by one or more calls to Rcpt.

func (*Client) [Extension](#)

```
func (c *Client) Extension(ext string) (bool, string)
```

Extension reports whether an extension is supported by the server. The extension name is case-insensitive. If the extension is supported, Extension also returns a string that contains any parameters the server specifies for the extension.

func (*Client) [Mail](#)

```
func (c *Client) Mail(from string) error
```

Mail issues a MAIL command to the server using the provided email address. If the server supports the 8BITMIME extension, Mail adds the BODY=8BITMIME parameter. This initiates a mail transaction and is followed by one or more Rcpt calls.

func (*Client) [Quit](#)

```
func (c *Client) Quit() error
```

Quit sends the QUIT command and closes the connection to the server.

func (*Client) [Rcpt](#)

```
func (c *Client) Rcpt(to string) error
```

Rcpt issues a RCPT command to the server using the provided email address. A call to Rcpt must be preceded by a call to Mail and may be followed by a Data call or another Rcpt call.

func (*Client) [Reset](#)

```
func (c *Client) Reset() error
```

Reset sends the RSET command to the server, aborting the current mail transaction.

func (*Client) [StartTLS](#)

```
func (c *Client) StartTLS(config *tls.Config) error
```

StartTLS sends the STARTTLS command and encrypts all further communication. Only servers that advertise the STARTTLS extension support this function.

func (*Client) [Verify](#)

```
func (c *Client) Verify(addr string) error
```

Verify checks the validity of an email address on the server. If Verify returns nil, the address is valid. A non-nil return does not necessarily indicate an invalid address. Many servers will not verify addresses for security reasons.

type [ServerInfo](#)

```
type ServerInfo struct {  
    Name string    // SMTP server name  
    TLS  bool       // using TLS, with valid certificate for Name  
    Auth []string  // advertised authentication mechanisms  
}
```

ServerInfo records information about an SMTP server.

Build version go1.0.1.

Package textproto

```
import "net/textproto"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package textproto implements generic support for text-based request/response protocols in the style of HTTP, NNTP, and SMTP.

The package provides:

Error, which represents a numeric error response from a server.

Pipeline, to manage pipelined requests and responses in a client.

Reader, to read numeric response code lines, key: value headers, lines wrapped with leading spaces on continuation lines, and whole text blocks ending with a dot on a line by itself.

Writer, to write dot-encoded text blocks.

Conn, a convenient packaging of Reader, Writer, and Pipeline for use with a single network connection.

[func \(w *Writer\) PrintfLine\(format string, args ...interface{}\) error](#)

[Bugs](#)

Package files

[header.go](#) [pipeline.go](#) [reader.go](#) [textproto.go](#) [writer.go](#)

func [CanonicalMIMEHeaderKey](#)

```
func CanonicalMIMEHeaderKey(s string) string
```

CanonicalMIMEHeaderKey returns the canonical format of the MIME header key s. The canonicalization converts the first letter and any letter following a hyphen to upper case; the rest are converted to lowercase. For example, the canonical key for "accept-encoding" is "Accept-Encoding".

type [Conn](#)

```
type Conn struct {
    Reader
    Writer
    Pipeline
    // contains filtered or unexported fields
}
```

A Conn represents a textual network protocol connection. It consists of a Reader and Writer to manage I/O and a Pipeline to sequence concurrent requests on the connection. These embedded types carry methods with them; see the documentation of those types for details.

func [Dial](#)

```
func Dial(network, addr string) (*Conn, error)
```

Dial connects to the given address on the given network using net.Dial and then returns a new Conn for the connection.

func [NewConn](#)

```
func NewConn(conn io.ReadWriteCloser) *Conn
```

NewConn returns a new Conn using conn for I/O.

func (***Conn**) [Close](#)

```
func (c *Conn) Close() error
```

Close closes the connection.

func (***Conn**) [Cmd](#)

```
func (c *Conn) Cmd(format string, args ...interface{}) (id uint, err
```

Cmd is a convenience method that sends a command after waiting its turn in the pipeline. The command text is the result of formatting format with args and

appending `\r\n`. `Cmd` returns the id of the command, for use with `StartResponse` and `EndResponse`.

For example, a client might run a `HELP` command that returns a dot-body by using:

```
id, err := c.Cmd("HELP")
if err != nil {
    return nil, err
}

c.StartResponse(id)
defer c.EndResponse(id)

if _, _, err = c.ReadCodeLine(110); err != nil {
    return nil, err
}
text, err := c.ReadDotAll()
if err != nil {
    return nil, err
}
return c.ReadCodeLine(250)
```

type [Error](#)

```
type Error struct {  
    Code int  
    Msg  string  
}
```

An Error represents a numeric error response from a server.

func (*Error) [Error](#)

```
func (e *Error) Error() string
```

type [MIMEHeader](#)

```
type MIMEHeader map[string][]string
```

A MIMEHeader represents a MIME-style header mapping keys to sets of values.

func (MIMEHeader) [Add](#)

```
func (h MIMEHeader) Add(key, value string)
```

Add adds the key, value pair to the header. It appends to any existing values associated with key.

func (MIMEHeader) [Del](#)

```
func (h MIMEHeader) Del(key string)
```

Del deletes the values associated with key.

func (MIMEHeader) [Get](#)

```
func (h MIMEHeader) Get(key string) string
```

Get gets the first value associated with the given key. If there are no values associated with the key, Get returns "". Get is a convenience method. For more complex queries, access the map directly.

func (MIMEHeader) [Set](#)

```
func (h MIMEHeader) Set(key, value string)
```

Set sets the header entries associated with key to the single element value. It replaces any existing values associated with key.

type [Pipeline](#)

```
type Pipeline struct {  
    // contains filtered or unexported fields  
}
```

A Pipeline manages a pipelined in-order request/response sequence.

To use a Pipeline `p` to manage multiple clients on a connection, each client should run:

```
id := p.Next() // take a number  
  
p.StartRequest(id) // wait for turn to send request  
?send request?  
p.EndRequest(id) // notify Pipeline that request is sent  
  
p.StartResponse(id) // wait for turn to read response  
?read response?  
p.EndResponse(id) // notify Pipeline that response is read
```

A pipelined server can use the same calls to ensure that responses computed in parallel are written in the correct order.

func (*Pipeline) [EndRequest](#)

```
func (p *Pipeline) EndRequest(id uint)
```

`EndRequest` notifies `p` that the request with the given `id` has been sent (or, if this is a server, received).

func (*Pipeline) [EndResponse](#)

```
func (p *Pipeline) EndResponse(id uint)
```

`EndResponse` notifies `p` that the response with the given `id` has been received (or, if this is a server, sent).

func (*Pipeline) [Next](#)

```
func (p *Pipeline) Next() uint
```

Next returns the next id for a request/response pair.

func (*Pipeline) [StartRequest](#)

```
func (p *Pipeline) StartRequest(id uint)
```

StartRequest blocks until it is time to send (or, if this is a server, receive) the request with the given id.

func (*Pipeline) [StartResponse](#)

```
func (p *Pipeline) StartResponse(id uint)
```

StartResponse blocks until it is time to receive (or, if this is a server, send) the request with the given id.

type [ProtocolError](#)

```
type ProtocolError string
```

A ProtocolError describes a protocol violation such as an invalid response or a hung-up connection.

func (ProtocolError) [Error](#)

```
func (p ProtocolError) Error() string
```

type [Reader](#)

```
type Reader struct {  
    R *bufio.Reader  
    // contains filtered or unexported fields  
}
```

A Reader implements convenience methods for reading requests or responses from a text protocol network connection.

func [NewReader](#)

```
func NewReader(r *bufio.Reader) *Reader
```

NewReader returns a new Reader reading from r.

func (***Reader**) [DotReader](#)

```
func (r *Reader) DotReader() io.Reader
```

DotReader returns a new Reader that satisfies Reads using the decoded text of a dot-encoded block read from r. The returned Reader is only valid until the next call to a method on r.

Dot encoding is a common framing used for data blocks in text protocols such as SMTP. The data consists of a sequence of lines, each of which ends in "\r\n". The sequence itself ends at a line containing just a dot: ".\r\n". Lines beginning with a dot are escaped with an additional dot to avoid looking like the end of the sequence.

The decoded form returned by the Reader's Read method rewrites the "\r\n" line endings into the simpler "\n", removes leading dot escapes if present, and stops with error io.EOF after consuming (and discarding) the end-of-sequence line.

func (***Reader**) [ReadCodeLine](#)

```
func (r *Reader) ReadCodeLine(expectCode int) (code int, message str
```

ReadCodeLine reads a response code line of the form

code message

where code is a 3-digit status code and the message extends to the rest of the line. An example of such a line is:

```
220 plan9.bell-labs.com ESMTTP
```

If the prefix of the status does not match the digits in `expectCode`, `ReadCodeLine` returns with `err` set to `&Error{code, message}`. For example, if `expectCode` is 31, an error will be returned if the status is not in the range [310,319].

If the response is multi-line, `ReadCodeLine` returns an error.

An `expectCode <= 0` disables the check of the status code.

func (*Reader) [ReadContinuedLine](#)

```
func (r *Reader) ReadContinuedLine() (string, error)
```

`ReadContinuedLine` reads a possibly continued line from `r`, eliding the final trailing ASCII white space. Lines after the first are considered continuations if they begin with a space or tab character. In the returned data, continuation lines are separated from the previous line only by a single space: the newline and leading white space are removed.

For example, consider this input:

```
Line 1
  continued...
Line 2
```

The first call to `ReadContinuedLine` will return "Line 1 continued..." and the second will return "Line 2".

A line consisting of only white space is never continued.

func (*Reader) [ReadContinuedLineBytes](#)

```
func (r *Reader) ReadContinuedLineBytes() ([]byte, error)
```

ReadContinuedLineBytes is like ReadContinuedLine but returns a []byte instead of a string.

func (*Reader) [ReadDotBytes](#)

```
func (r *Reader) ReadDotBytes() ([]byte, error)
```

ReadDotBytes reads a dot-encoding and returns the decoded data.

See the documentation for the DotReader method for details about dot-encoding.

func (*Reader) [ReadDotLines](#)

```
func (r *Reader) ReadDotLines() ([]string, error)
```

ReadDotLines reads a dot-encoding and returns a slice containing the decoded lines, with the final \r\n or \n elided from each.

See the documentation for the DotReader method for details about dot-encoding.

func (*Reader) [ReadLine](#)

```
func (r *Reader) ReadLine() (string, error)
```

ReadLine reads a single line from r, eliding the final \n or \r\n from the returned string.

func (*Reader) [ReadLineBytes](#)

```
func (r *Reader) ReadLineBytes() ([]byte, error)
```

ReadLineBytes is like ReadLine but returns a []byte instead of a string.

func (*Reader) [ReadMIMEHeader](#)

```
func (r *Reader) ReadMIMEHeader() (MIMEHeader, error)
```

ReadMIMEHeader reads a MIME-style header from r. The header is a sequence of possibly continued Key: Value lines ending in a blank line. The returned map m maps CanonicalMIMEHeaderKey(key) to a sequence of values in the same

order encountered in the input.

For example, consider this input:

```
My-Key: Value 1
Long-Key: Even
         Longer Value
My-Key: Value 2
```

Given that input, `ReadMIMEHeader` returns the map:

```
map[string][]string{
    "My-Key": {"Value 1", "Value 2"},
    "Long-Key": {"Even Longer Value"},
}
```

func (*Reader) [ReadResponse](#)

```
func (r *Reader) ReadResponse(expectCode int) (code int, message string, err error)
```

`ReadResponse` reads a multi-line response of the form:

```
code-message line 1
code-message line 2
...
code message line n
```

where `code` is a 3-digit status code. The first line starts with the code and a hyphen. The response is terminated by a line that starts with the same code followed by a space. Each line in `message` is separated by a newline (`\n`).

See page 36 of RFC 959 (<http://www.ietf.org/rfc/rfc959.txt>) for details.

If the prefix of the status does not match the digits in `expectCode`, `ReadResponse` returns with `err` set to `&Error{code, message}`. For example, if `expectCode` is 31, an error will be returned if the status is not in the range [310,319].

An `expectCode` ≤ 0 disables the check of the status code.

type [Writer](#)

```
type Writer struct {
    w *bufio.Writer
    // contains filtered or unexported fields
}
```

A `Writer` implements convenience methods for writing requests or responses to a text protocol network connection.

func [NewWriter](#)

```
func NewWriter(w *bufio.Writer) *Writer
```

`NewWriter` returns a new `Writer` writing to `w`.

func (*Writer) [DotWriter](#)

```
func (w *Writer) DotWriter() io.WriteCloser
```

`DotWriter` returns a writer that can be used to write a dot-encoding to `w`. It takes care of inserting leading dots when necessary, translating line-ending `\n` into `\r\n`, and adding the final `.\r\n` line when the `DotWriter` is closed. The caller should close the `DotWriter` before the next call to a method on `w`.

See the documentation for `Reader`'s `DotReader` method for details about dot-encoding.

func (*Writer) [PrintfLine](#)

```
func (w *Writer) PrintfLine(format string, args ...interface{}) error
```

`PrintfLine` writes the formatted output followed by `\r\n`.

Bugs

To let callers manage exposure to denial of service attacks, Reader should allow them to set and reset a limit on the number of bytes read from the connection.

 [func \(v Values\) Get\(key string\) string](#)
 [func \(v Values\) Set\(key, value string\)](#)

Examples

[URL](#)
[Values](#)

Package files

[url.go](#)

func [QueryEscape](#)

```
func QueryEscape(s string) string
```

QueryEscape escapes the string so it can be safely placed inside a URL query.

func [QueryUnescape](#)

```
func QueryUnescape(s string) (string, error)
```

QueryUnescape does the inverse transformation of QueryEscape, converting %AB into the byte 0xAB and '+' into ' ' (space). It returns an error if any % is not followed by two hexadecimal digits.

type [Error](#)

```
type Error struct {  
    Op string  
    URL string  
    Err error  
}
```

Error reports an error and the operation and URL that caused it.

func (***Error**) [Error](#)

```
func (e *Error) Error() string
```

type [EscapeError](#)

type EscapeError string

func (EscapeError) [Error](#)

func (e EscapeError) Error() string

type [URL](#)

```
type URL struct {
    Scheme    string
    Opaque    string    // encoded opaque data
    User      *UserInfo // username and password information
    Host      string
    Path      string
    RawQuery  string // encoded query values, without '?'
    Fragment  string // fragment for references, without '#'
}
```

A URL represents a parsed URL (technically, a URI reference). The general form represented is:

```
scheme://[userinfo@]host/path[?query][#fragment]
```

URLs that do not start with a slash after the scheme are interpreted as:

```
scheme:opaque[?query][#fragment]
```

? Example

? Example

Code:

```
u, err := url.Parse("http://bing.com/search?q=dotnet")
if err != nil {
    log.Fatal(err)
}
u.Scheme = "https"
u.Host = "google.com"
q := u.Query()
q.Set("q", "golang")
u.RawQuery = q.Encode()
fmt.Println(u)
```

Output:

```
https://google.com/search?q=golang
```

func [Parse](#)

```
func Parse(rawurl string) (url *URL, err error)
```

Parse parses rawurl into a URL structure. The rawurl may be relative or absolute.

func [ParseRequestURI](#)

```
func ParseRequestURI(rawurl string) (url *URL, err error)
```

ParseRequestURI parses rawurl into a URL structure. It assumes that rawurl was received in an HTTP request, so the rawurl is interpreted only as an absolute URI or an absolute path. The string rawurl is assumed not to have a #fragment suffix. (Web browsers strip #fragment before sending the URL to a web server.)

func (*URL) [IsAbs](#)

```
func (u *URL) IsAbs() bool
```

IsAbs returns true if the URL is absolute.

func (*URL) [Parse](#)

```
func (u *URL) Parse(ref string) (*URL, error)
```

Parse parses a URL in the context of the receiver. The provided URL may be relative or absolute. Parse returns nil, err on parse failure, otherwise its return value is the same as ResolveReference.

func (*URL) [Query](#)

```
func (u *URL) Query() Values
```

Query parses RawQuery and returns the corresponding values.

func (*URL) [RequestURI](#)

```
func (u *URL) RequestURI() string
```

RequestURI returns the encoded path?query or opaque?query string that would be used in an HTTP request for u.

func (*URL) [ResolveReference](#)

```
func (u *URL) ResolveReference(ref *URL) *URL
```

ResolveReference resolves a URI reference to an absolute URI from an absolute base URI, per RFC 2396 Section 5.2. The URI reference may be relative or absolute. ResolveReference always returns a new URL instance, even if the returned URL is identical to either the base or reference. If ref is an absolute URL, then ResolveReference ignores base and returns a copy of ref.

func (*URL) [String](#)

```
func (u *URL) String() string
```

String reassembles the URL into a valid URL string.

type [Userinfo](#)

```
type Userinfo struct {  
    // contains filtered or unexported fields  
}
```

The `Userinfo` type is an immutable encapsulation of username and password details for a URL. An existing `Userinfo` value is guaranteed to have a username set (potentially empty, as allowed by RFC 2396), and optionally a password.

func [User](#)

```
func User(username string) *Userinfo
```

`User` returns a `Userinfo` containing the provided username and no password set.

func [UserPassword](#)

```
func UserPassword(username, password string) *Userinfo
```

`UserPassword` returns a `Userinfo` containing the provided username and password. This functionality should only be used with legacy web sites. RFC 2396 warns that interpreting `Userinfo` this way “is NOT RECOMMENDED, because the passing of authentication information in clear text (such as URI) has proven to be a security risk in almost every case where it has been used.”

func (*Userinfo) [Password](#)

```
func (u *Userinfo) Password() (string, bool)
```

`Password` returns the password in case it is set, and whether it is set.

func (*Userinfo) [String](#)

```
func (u *Userinfo) String() string
```

`String` returns the encoded userinfo information in the standard form of "username[:password]".

func (*Userinfo) [Username](#)

```
func (u *Userinfo) Username() string
```

Username returns the username.

type [Values](#)

```
type Values map[string][]string
```

Values maps a string key to a list of values. It is typically used for query parameters and form values. Unlike in the `http.Header` map, the keys in a `Values` map are case-sensitive.

? Example

? Example

Code:

```
v := url.Values{}
v.Set("name", "Ava")
v.Add("friend", "Jess")
v.Add("friend", "Sarah")
v.Add("friend", "Zoe")
// v.Encode() == "name=Ava&friend=Jess&friend=Sarah&friend=Zoe"
fmt.Println(v.Get("name"))
fmt.Println(v.Get("friend"))
fmt.Println(v["friend"])
```

Output:

```
Ava
Jess
[Jess Sarah Zoe]
```

func [ParseQuery](#)

```
func ParseQuery(query string) (m Values, err error)
```

`ParseQuery` parses the URL-encoded query string and returns a map listing the values specified for each key. `ParseQuery` always returns a non-nil map containing all the valid query parameters found; `err` describes the first decoding error encountered, if any.

func (Values) [Add](#)

```
func (v Values) Add(key, value string)
```

Add adds the key to value. It appends to any existing values associated with key.

func (Values) [Del](#)

```
func (v Values) Del(key string)
```

Del deletes the values associated with key.

func (Values) [Encode](#)

```
func (v Values) Encode() string
```

Encode encodes the values into “URL encoded” form. e.g. "foo=bar&bar=baz"

func (Values) [Get](#)

```
func (v Values) Get(key string) string
```

Get gets the first value associated with the given key. If there are no values associated with the key, Get returns the empty string. To access multiple values, use the map directly.

func (Values) [Set](#)

```
func (v Values) Set(key, value string)
```

Set sets the key to value. It replaces any existing values.

Build version go1.0.1.

Package os

```
import "os"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `os` provides a platform-independent interface to operating system functionality. The design is Unix-like, although the error handling is Go-like; failing calls return values of type `error` rather than error numbers. Often, more information is available within the error. For example, if a call that takes a file name fails, such as `Open` or `Stat`, the error will include the failing file name when printed and will be of type `*PathError`, which may be unpacked for more information.

The `os` interface is intended to be uniform across all operating systems. Features not generally available appear in the system-specific package `syscall`.

Here is a simple example, opening a file and reading some of it.

```
file, err := os.Open("file.go") // For read access.
if err != nil {
    log.Fatal(err)
}
```

If the open fails, the error string will be self-explanatory, like

```
open file.go: no such file or directory
```

The file's data can then be read into a slice of bytes. `Read` and `Write` take their byte counts from the length of the argument slice.

```
data := make([]byte, 100)
count, err := file.Read(data)
if err != nil {
    log.Fatal(err)
}
fmt.Printf("read %d bytes: %q\n", count, data[:count])
```

Package files

[dir_unix.go](#) [doc.go](#) [env.go](#) [error.go](#) [error_posix.go](#) [exec.go](#) [exec_posix.go](#) [exec_unix.go](#) [file.go](#) [file_posix.go](#) [file_unix.go](#) [getwd.go](#) [path.go](#) [path_unix.go](#) [proc.go](#) [stat_linux.go](#) [sys_linux.go](#) [types.go](#)

Constants

```
const (  
    O_RDONLY int = syscall.O_RDONLY // open the file read-only.  
    O_WRONLY int = syscall.O_WRONLY // open the file write-only.  
    O_RDWR  int = syscall.O_RDWR  // open the file read-write.  
    O_APPEND int = syscall.O_APPEND // append data to the file when  
    O_CREATE int = syscall.O_CREAT  // create a new file if none exist  
    O_EXCL   int = syscall.O_EXCL   // used with O_CREATE, file must  
    O_SYNC   int = syscall.O_SYNC   // open for synchronous I/O.  
    O_TRUNC  int = syscall.O_TRUNC  // if possible, truncate file when  
)
```

Flags to Open wrapping those of the underlying system. Not all flags may be implemented on a given system.

```
const (  
    SEEK_SET int = 0 // seek relative to the origin of the file  
    SEEK_CUR int = 1 // seek relative to the current offset  
    SEEK_END int = 2 // seek relative to the end  
)
```

Seek whence values.

```
const (  
    PathSeparator      = '/' // OS-specific path separator  
    PathListSeparator = ':' // OS-specific path list separator  
)  
  
const DevNull = "/dev/null"
```

DevNull is the name of the operating system's “null device.” On Unix-like systems, it is “/dev/null”; on Windows, “NUL”.

Variables

```
var (  
    ErrInvalid      = errors.New("invalid argument")  
    ErrPermission  = errors.New("permission denied")  
    ErrExist       = errors.New("file already exists")  
    ErrNotExist    = errors.New("file does not exist")  
)
```

Portable analogs of some common system call errors.

```
var (  
    Stdin  = NewFile(uintptr(syscall.Stdin), "/dev/stdin")  
    Stdout = NewFile(uintptr(syscall.Stdout), "/dev/stdout")  
    Stderr = NewFile(uintptr(syscall.Stderr), "/dev/stderr")  
)
```

Stdin, Stdout, and Stderr are open Files pointing to the standard input, standard output, and standard error file descriptors.

```
var Args []string
```

Args hold the command-line arguments, starting with the program name.

func [Chdir](#)

```
func Chdir(dir string) error
```

Chdir changes the current working directory to the named directory. If there is an error, it will be of type `*PathError`.

func [Chmod](#)

```
func Chmod(name string, mode FileMode) error
```

Chmod changes the mode of the named file to mode. If the file is a symbolic link, it changes the mode of the link's target. If there is an error, it will be of type *PathError.

func [Chown](#)

```
func Chown(name string, uid, gid int) error
```

Chown changes the numeric uid and gid of the named file. If the file is a symbolic link, it changes the uid and gid of the link's target. If there is an error, it will be of type `*PathError`.

func [Chtimes](#)

```
func Chtimes(name string, atime time.Time, mtime time.Time) error
```

Chtimes changes the access and modification times of the named file, similar to the Unix `utime()` or `utimes()` functions.

The underlying filesystem may truncate or round the values to a less precise time unit. If there is an error, it will be of type `*PathError`.

func [Clearenv](#)

```
func Clearenv()
```

Clearenv deletes all environment variables.

func Environ

```
func Environ() []string
```

Environ returns a copy of strings representing the environment, in the form "key=value".

func [Exit](#)

```
func Exit(code int)
```

Exit causes the current program to exit with the given status code. Conventionally, code zero indicates success, non-zero an error.

func [Expand](#)

```
func Expand(s string, mapping func(string) string) string
```

Expand replaces `${var}` or `$var` in the string based on the mapping function. Invocations of undefined variables are replaced with the empty string.

func [ExpandEnv](#)

```
func ExpandEnv(s string) string
```

ExpandEnv replaces `${var}` or `$var` in the string according to the values of the current environment variables. References to undefined variables are replaced by the empty string.

func [Getegid](#)

```
func Getegid() int
```

Getegid returns the numeric effective group id of the caller.

func [Getenv](#)

```
func Getenv(key string) string
```

Getenv retrieves the value of the environment variable named by the key. It returns the value, which will be empty if the variable is not present.

func [Geteuid](#)

```
func Geteuid() int
```

Geteuid returns the numeric effective user id of the caller.

func [Getgid](#)

```
func Getgid() int
```

Getgid returns the numeric group id of the caller.

func Getgroups

```
func Getgroups() ([]int, error)
```

Getgroups returns a list of the numeric ids of groups that the caller belongs to.

func [Getpagesize](#)

```
func Getpagesize() int
```

Getpagesize returns the underlying system's memory page size.

func [Getpid](#)

```
func Getpid() int
```

Getpid returns the process id of the caller.

func [Getppid](#)

```
func Getppid() int
```

Getppid returns the process id of the caller's parent.

func [Getuid](#)

```
func Getuid() int
```

Getuid returns the numeric user id of the caller.

func [Getwd](#)

```
func Getwd() (pwd string, err error)
```

Getwd returns a rooted path name corresponding to the current directory. If the current directory can be reached via multiple paths (due to symbolic links), Getwd may return any one of them.

func [Hostname](#)

```
func Hostname() (name string, err error)
```

Hostname returns the host name reported by the kernel.

func [IsExist](#)

```
func IsExist(err error) bool
```

IsExist returns whether the error is known to report that a file or directory already exists. It is satisfied by ErrExist as well as some syscall errors.

func [IsNotExist](#)

```
func IsNotExist(err error) bool
```

IsNotExist returns whether the error is known to report that a file or directory does not exist. It is satisfied by ErrNotExist as well as some syscall errors.

func IsPathSeparator

```
func IsPathSeparator(c uint8) bool
```

IsPathSeparator returns true if c is a directory separator character.

func IsPermission

```
func IsPermission(err error) bool
```

IsPermission returns whether the error is known to report that permission is denied. It is satisfied by ErrPermission as well as some syscall errors.

func [Lchown](#)

```
func Lchown(name string, uid, gid int) error
```

Lchown changes the numeric uid and gid of the named file. If the file is a symbolic link, it changes the uid and gid of the link itself. If there is an error, it will be of type `*PathError`.

func [Link](#)

```
func Link(oldname, newname string) error
```

Link creates newname as a hard link to the oldname file. If there is an error, it will be of type *LinkError.

func [Mkdir](#)

```
func Mkdir(name string, perm FileMode) error
```

Mkdir creates a new directory with the specified name and permission bits. If there is an error, it will be of type *PathError.

func [MkdirAll](#)

```
func MkdirAll(path string, perm FileMode) error
```

MkdirAll creates a directory named path, along with any necessary parents, and returns nil, or else returns an error. The permission bits perm are used for all directories that MkdirAll creates. If path is already a directory, MkdirAll does nothing and returns nil.

func [NewSyscallError](#)

```
func NewSyscallError(syscall string, err error) error
```

NewSyscallError returns, as an error, a new SyscallError with the given system call name and error details. As a convenience, if err is nil, NewSyscallError returns nil.

func [Readlink](#)

```
func Readlink(name string) (string, error)
```

Readlink returns the destination of the named symbolic link. If there is an error, it will be of type `*PathError`.

func [Remove](#)

```
func Remove(name string) error
```

Remove removes the named file or directory. If there is an error, it will be of type `*PathError`.

func [RemoveAll](#)

```
func RemoveAll(path string) error
```

RemoveAll removes path and any children it contains. It removes everything it can but returns the first error it encounters. If the path does not exist, RemoveAll returns nil (no error).

func [Rename](#)

```
func Rename(oldname, newname string) error
```

Rename renames a file.

func [SameFile](#)

```
func SameFile(fi1, fi2 FileInfo) bool
```

SameFile reports whether fi1 and fi2 describe the same file. For example, on Unix this means that the device and inode fields of the two underlying structures are identical; on other systems the decision may be based on the path names. SameFile only applies to results returned by this package's Stat. It returns false in other cases.

func [Setenv](#)

```
func Setenv(key, value string) error
```

Setenv sets the value of the environment variable named by the key. It returns an error, if any.

func [SymLink](#)

```
func SymLink(oldname, newname string) error
```

SymLink creates newname as a symbolic link to oldname. If there is an error, it will be of type *LinkError.

func [TempDir](#)

```
func TempDir() string
```

TempDir returns the default directory to use for temporary files.

func [Truncate](#)

```
func Truncate(name string, size int64) error
```

Truncate changes the size of the named file. If the file is a symbolic link, it changes the size of the link's target. If there is an error, it will be of type `*PathError`.

type [File](#)

```
type File struct {  
    // contains filtered or unexported fields  
}
```

File represents an open file descriptor.

func [Create](#)

```
func Create(name string) (file *File, err error)
```

Create creates the named file mode 0666 (before umask), truncating it if it already exists. If successful, methods on the returned File can be used for I/O; the associated file descriptor has mode O_RDWR. If there is an error, it will be of type *PathError.

func [NewFile](#)

```
func NewFile(fd uintptr, name string) *File
```

NewFile returns a new File with the given file descriptor and name.

func [Open](#)

```
func Open(name string) (file *File, err error)
```

Open opens the named file for reading. If successful, methods on the returned file can be used for reading; the associated file descriptor has mode O_RDONLY. If there is an error, it will be of type *PathError.

func [OpenFile](#)

```
func OpenFile(name string, flag int, perm FileMode) (file *File, err
```

OpenFile is the generalized open call; most users will use Open or Create instead. It opens the named file with specified flag (O_RDONLY etc.) and perm, (0666 etc.) if applicable. If successful, methods on the returned File can be used for I/O. If there is an error, it will be of type *PathError.

func [Pipe](#)

```
func Pipe() (r *File, w *File, err error)
```

Pipe returns a connected pair of Files; reads from r return bytes written to w. It returns the files and an error, if any.

func (*File) [Chdir](#)

```
func (f *File) Chdir() error
```

Chdir changes the current working directory to the file, which must be a directory. If there is an error, it will be of type *PathError.

func (*File) [Chmod](#)

```
func (f *File) Chmod(mode FileMode) error
```

Chmod changes the mode of the file to mode. If there is an error, it will be of type *PathError.

func (*File) [Chown](#)

```
func (f *File) Chown(uid, gid int) error
```

Chown changes the numeric uid and gid of the named file. If there is an error, it will be of type *PathError.

func (*File) [Close](#)

```
func (f *File) Close() error
```

Close closes the File, rendering it unusable for I/O. It returns an error, if any.

func (*File) [Fd](#)

```
func (f *File) Fd() uintptr
```

Fd returns the integer Unix file descriptor referencing the open file.

func (*File) [Name](#)

```
func (f *File) Name() string
```

Name returns the name of the file as presented to Open.

func (*File) [Read](#)

```
func (f *File) Read(b []byte) (n int, err error)
```

Read reads up to len(b) bytes from the File. It returns the number of bytes read and an error, if any. EOF is signaled by a zero count with err set to io.EOF.

func (*File) [ReadAt](#)

```
func (f *File) ReadAt(b []byte, off int64) (n int, err error)
```

ReadAt reads len(b) bytes from the File starting at byte offset off. It returns the number of bytes read and the error, if any. ReadAt always returns a non-nil error when $n < \text{len}(b)$. At end of file, that error is io.EOF.

func (*File) [Readdir](#)

```
func (f *File) Readdir(n int) (fi []FileInfo, err error)
```

Readdir reads the contents of the directory associated with file and returns an array of up to n FileInfo values, as would be returned by Lstat, in directory order. Subsequent calls on the same file will yield further FileInfos.

If $n > 0$, Readdir returns at most n FileInfo structures. In this case, if Readdir returns an empty slice, it will return a non-nil error explaining why. At the end of a directory, the error is io.EOF.

If $n \leq 0$, Readdir returns all the FileInfo from the directory in a single slice. In this case, if Readdir succeeds (reads all the way to the end of the directory), it returns the slice and a nil error. If it encounters an error before the end of the directory, Readdir returns the FileInfo read until that point and a non-nil error.

func (*File) [Readdirnames](#)

```
func (f *File) Readdirnames(n int) (names []string, err error)
```

Readdirnames reads and returns a slice of names from the directory f.

If $n > 0$, Readdirnames returns at most n names. In this case, if Readdirnames returns an empty slice, it will return a non-nil error explaining why. At the end of a directory, the error is `io.EOF`.

If $n \leq 0$, Readdirnames returns all the names from the directory in a single slice. In this case, if Readdirnames succeeds (reads all the way to the end of the directory), it returns the slice and a nil error. If it encounters an error before the end of the directory, Readdirnames returns the names read until that point and a non-nil error.

func (*File) [Seek](#)

```
func (f *File) Seek(offset int64, whence int) (ret int64, err error)
```

Seek sets the offset for the next Read or Write on file to offset, interpreted according to whence: 0 means relative to the origin of the file, 1 means relative to the current offset, and 2 means relative to the end. It returns the new offset and an error, if any.

func (*File) [Stat](#)

```
func (f *File) Stat() (fi FileInfo, err error)
```

Stat returns the FileInfo structure describing file. If there is an error, it will be of type `*PathError`.

func (*File) [Sync](#)

```
func (f *File) Sync() (err error)
```

Sync commits the current contents of the file to stable storage. Typically, this means flushing the file system's in-memory copy of recently written data to disk.

func (*File) [Truncate](#)

```
func (f *File) Truncate(size int64) error
```

Truncate changes the size of the file. It does not change the I/O offset. If there is an error, it will be of type `*PathError`.

func (*File) [Write](#)

```
func (f *File) Write(b []byte) (n int, err error)
```

Write writes `len(b)` bytes to the File. It returns the number of bytes written and an error, if any. Write returns a non-nil error when `n != len(b)`.

func (*File) [WriteAt](#)

```
func (f *File) WriteAt(b []byte, off int64) (n int, err error)
```

WriteAt writes `len(b)` bytes to the File starting at byte offset `off`. It returns the number of bytes written and an error, if any. WriteAt returns a non-nil error when `n != len(b)`.

func (*File) [WriteString](#)

```
func (f *File) WriteString(s string) (ret int, err error)
```

WriteString is like Write, but writes the contents of string `s` rather than an array of bytes.

type [FileInfo](#)

```
type FileInfo interface {  
    Name() string        // base name of the file  
    Size() int64         // length in bytes for regular files; system  
    Mode() FileMode     // file mode bits  
    ModTime() time.Time // modification time  
    IsDir() bool        // abbreviation for Mode().IsDir()  
    Sys() interface{}   // underlying data source (can return nil)  
}
```

A FileInfo describes a file and is returned by Stat and Lstat

func [Lstat](#)

```
func Lstat(name string) (fi FileInfo, err error)
```

Lstat returns a FileInfo describing the named file. If the file is a symbolic link, the returned FileInfo describes the symbolic link. Lstat makes no attempt to follow the link. If there is an error, it will be of type *PathError.

func [Stat](#)

```
func Stat(name string) (fi FileInfo, err error)
```

Stat returns a FileInfo describing the named file. If there is an error, it will be of type *PathError.

type [FileMode](#)

```
type FileMode uint32
```

A FileMode represents a file's mode and permission bits. The bits have the same definition on all systems, so that information about files can be moved from one system to another portably. Not all bits apply to all systems. The only required bit is ModeDir for directories.

```
const (  
    // The single letters are the abbreviations  
    // used by the String method's formatting.  
    ModeDir          FileMode = 1 << (32 - 1 - iota) // d: is a direct  
    ModeAppend       // a: append-only  
    ModeExclusive    // l: exclusive u  
    ModeTemporary    // T: temporary f  
    ModeSymlink      // L: symbolic li  
    ModeDevice       // D: device file  
    ModeNamedPipe    // p: named pipe  
    ModeSocket       // S: Unix domain  
    ModeSetuid       // u: setuid  
    ModeSetgid       // g: setgid  
    ModeCharDevice   // c: Unix charac  
    ModeSticky  
  
    // Mask for the type bits. For regular files, none will be set.  
    ModeType = ModeDir | ModeSymlink | ModeNamedPipe | ModeSocket |  
  
    ModePerm FileMode = 0777 // permission bits  
)
```

The defined file mode bits are the most significant bits of the FileMode. The nine least-significant bits are the standard Unix `rw-rw-rw-` permissions. The values of these bits should be considered part of the public API and may be used in wire protocols or disk representations: they must not be changed, although new bits might be added.

func (FileMode) [IsDir](#)

```
func (m FileMode) IsDir() bool
```

IsDir reports whether `m` describes a directory. That is, it tests for the ModeDir bit being set in `m`.

func (FileMode) [Perm](#)

```
func (m FileMode) Perm() FileMode
```

Perm returns the Unix permission bits in m.

func (FileMode) [String](#)

```
func (m FileMode) String() string
```

type [LinkError](#)

```
type LinkError struct {  
    Op string  
    Old string  
    New string  
    Err error  
}
```

LinkError records an error during a link or symlink or rename system call and the paths that caused it.

func (*LinkError) [Error](#)

```
func (e *LinkError) Error() string
```

type [PathError](#)

```
type PathError struct {  
    Op    string  
    Path string  
    Err  error  
}
```

PathError records an error and the operation and file path that caused it.

func (*PathError) [Error](#)

```
func (e *PathError) Error() string
```

type [ProcAttr](#)

```
type ProcAttr struct {
    // If Dir is non-empty, the child changes into the directory before
    // creating the process.
    Dir string
    // If Env is non-nil, it gives the environment variables for the
    // new process in the form returned by Environ.
    // If it is nil, the result of Environ will be used.
    Env []string
    // Files specifies the open files inherited by the new process.
    // first three entries correspond to standard input, standard output,
    // standard error. An implementation may support additional entries
    // depending on the underlying operating system. A nil entry corresponds
    // to that file being closed when the process starts.
    Files []*File

    // Operating system-specific process creation attributes.
    // Note that setting this field means that your program
    // may not execute properly or even compile on some
    // operating systems.
    Sys *syscall.SysProcAttr
}
```

ProcAttr holds the attributes that will be applied to a new process started by StartProcess.

type [Process](#)

```
type Process struct {
    Pid int
    // contains filtered or unexported fields
}
```

Process stores the information about a process created by StartProcess.

func [FindProcess](#)

```
func FindProcess(pid int) (p *Process, err error)
```

FindProcess looks for a running process by its pid. The Process it returns can be used to obtain information about the underlying operating system process.

func [StartProcess](#)

```
func StartProcess(name string, argv []string, attr *ProcAttr) (*Proc
```

StartProcess starts a new process with the program, arguments and attributes specified by name, argv and attr.

StartProcess is a low-level interface. The os/exec package provides higher-level interfaces.

If there is an error, it will be of type *PathError.

func (*Process) [Kill](#)

```
func (p *Process) Kill() error
```

Kill causes the Process to exit immediately.

func (*Process) [Release](#)

```
func (p *Process) Release() error
```

Release releases any resources associated with the Process p, rendering it

unusable in the future. Release only needs to be called if Wait is not.

func (*Process) [Signal](#)

```
func (p *Process) Signal(sig Signal) error
```

Signal sends a signal to the Process.

func (*Process) [Wait](#)

```
func (p *Process) Wait() (*ProcessState, error)
```

Wait waits for the Process to exit, and then returns a ProcessState describing its status and an error, if any. Wait releases any resources associated with the Process.

type [ProcessState](#)

```
type ProcessState struct {  
    // contains filtered or unexported fields  
}
```

ProcessState stores information about a process, as reported by Wait.

func (***ProcessState**) [Exited](#)

```
func (p *ProcessState) Exited() bool
```

Exited returns whether the program has exited.

func (***ProcessState**) [Pid](#)

```
func (p *ProcessState) Pid() int
```

Pid returns the process id of the exited process.

func (***ProcessState**) [String](#)

```
func (p *ProcessState) String() string
```

func (***ProcessState**) [Success](#)

```
func (p *ProcessState) Success() bool
```

Success reports whether the program exited successfully, such as with exit status 0 on Unix.

func (***ProcessState**) [Sys](#)

```
func (p *ProcessState) Sys() interface{}
```

Sys returns system-dependent exit information about the process. Convert it to the appropriate underlying type, such as syscall.WaitStatus on Unix, to access its contents.

func (*ProcessState) [SysUsage](#)

```
func (p *ProcessState) SysUsage() interface{}
```

SysUsage returns system-dependent resource usage information about the exited process. Convert it to the appropriate underlying type, such as `*syscall.Rusage` on Unix, to access its contents.

func (*ProcessState) [SystemTime](#)

```
func (p *ProcessState) SystemTime() time.Duration
```

SystemTime returns the system CPU time of the exited process and its children.

func (*ProcessState) [UserTime](#)

```
func (p *ProcessState) UserTime() time.Duration
```

UserTime returns the user CPU time of the exited process and its children.

type [Signal](#)

```
type Signal interface {
    String() string
    Signal() // to distinguish from other Stringers
}
```

A Signal represents an operating system signal. The usual underlying implementation is operating system-dependent: on Unix it is syscall.Signal.

```
var (
    Interrupt Signal = syscall.SIGINT
    Kill       Signal = syscall.SIGKILL
)
```

The only signal values guaranteed to be present on all systems are Interrupt (send the process an interrupt) and Kill (force the process to exit).

type [SyscallError](#)

```
type SyscallError struct {  
    Syscall string  
    Err     error  
}
```

SyscallError records an error from a specific system call.

func (*SyscallError) [Error](#)

```
func (e *SyscallError) Error() string
```

Package exec

```
import "os/exec"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package exec runs external commands. It wraps `os.StartProcess` to make it easier to remap stdin and stdout, connect I/O with pipes, and do other adjustments.

Index

[Cmd.Start](#)

[Cmd.StdoutPipe](#)

[Command](#)

[LookPath](#)

Package files

[exec.go](#) [lp_unix.go](#)

Variables

```
var ErrNotFound = errors.New("executable file not found in $PATH")
```

ErrNotFound is the error resulting if a path search failed to find an executable file.

func [LookPath](#)

```
func LookPath(file string) (string, error)
```

LookPath searches for an executable binary named file in the directories named by the PATH environment variable. If file contains a slash, it is tried directly and the PATH is not consulted.

? Example

? Example

Code:

```
path, err := exec.LookPath("fortune")
if err != nil {
    log.Fatal("installing fortune is in your future")
}
fmt.Printf("fortune is available at %s\n", path)
```

type Cmd

```
type Cmd struct {
    // Path is the path of the command to run.
    //
    // This is the only field that must be set to a non-zero
    // value.
    Path string

    // Args holds command line arguments, including the command as A
    // If the Args field is empty or nil, Run uses {Path}.
    //
    // In typical use, both Path and Args are set by calling Command
    Args []string

    // Env specifies the environment of the process.
    // If Env is nil, Run uses the current process's environment.
    Env []string

    // Dir specifies the working directory of the command.
    // If Dir is the empty string, Run runs the command in the
    // calling process's current directory.
    Dir string

    // Stdin specifies the process's standard input. If Stdin is
    // nil, the process reads from the null device (os.DevNull).
    Stdin io.Reader

    // Stdout and Stderr specify the process's standard output and e
    //
    // If either is nil, Run connects the corresponding file descrip
    // to the null device (os.DevNull).
    //
    // If Stdout and Stderr are the same writer, at most one
    // goroutine at a time will call Write.
    Stdout io.Writer
    Stderr io.Writer

    // ExtraFiles specifies additional open files to be inherited by
    // new process. It does not include standard input, standard out
    // standard error. If non-nil, entry i becomes file descriptor 3
    //
    // BUG: on OS X 10.6, child processes may sometimes inherit unwa
    // http://golang.org/issue/2603
    ExtraFiles []*os.File

    // SysProcAttr holds optional, operating system-specific attribu
```

```

// Run passes it to os.StartProcess as the os.ProcAttr's Sys file
SysProcAttr *syscall.SysProcAttr

// Process is the underlying process, once started.
Process *os.Process

// ProcessState contains information about an exited process,
// available after a call to Wait or Run.
ProcessState *os.ProcessState
// contains filtered or unexported fields
}

```

Cmd represents an external command being prepared or run.

func [Command](#)

```
func Command(name string, arg ...string) *Cmd
```

Command returns the Cmd struct to execute the named program with the given arguments.

It sets Path and Args in the returned structure and zeroes the other fields.

If name contains no path separators, Command uses LookPath to resolve the path to a complete name if possible. Otherwise it uses name directly.

The returned Cmd's Args field is constructed from the command name followed by the elements of arg, so arg should not include the command name itself. For example, Command("echo", "hello")

? Example

? Example

Code:

```

cmd := exec.Command("tr", "a-z", "A-Z")
cmd.Stdin = strings.NewReader("some input")
var out bytes.Buffer
cmd.Stdout = &out
err := cmd.Run()
if err != nil {
    log.Fatal(err)
}

```

```
fmt.Printf("in all caps: %q\n", out.String())
```

func (*Cmd) [CombinedOutput](#)

```
func (c *Cmd) CombinedOutput() ([]byte, error)
```

CombinedOutput runs the command and returns its combined standard output and standard error.

func (*Cmd) [Output](#)

```
func (c *Cmd) Output() ([]byte, error)
```

Output runs the command and returns its standard output.

? Example

? Example

Code:

```
out, err := exec.Command("date").Output()
if err != nil {
    log.Fatal(err)
}
fmt.Printf("The date is %s\n", out)
```

func (*Cmd) [Run](#)

```
func (c *Cmd) Run() error
```

Run starts the specified command and waits for it to complete.

The returned error is nil if the command runs, has no problems copying stdin, stdout, and stderr, and exits with a zero exit status.

If the command fails to run or doesn't complete successfully, the error is of type *ExitError. Other error types may be returned for I/O problems.

func (*Cmd) [Start](#)

```
func (c *Cmd) Start() error
```

Start starts the specified command but does not wait for it to complete.

? Example

? Example

Code:

```
cmd := exec.Command("sleep", "5")
err := cmd.Start()
if err != nil {
    log.Fatal(err)
}
log.Printf("Waiting for command to finish...")
err = cmd.Wait()
log.Printf("Command finished with error: %v", err)
```

func (*Cmd) [StderrPipe](#)

```
func (c *Cmd) StderrPipe() (io.ReadCloser, error)
```

StderrPipe returns a pipe that will be connected to the command's standard error when the command starts. The pipe will be closed automatically after Wait sees the command exit.

func (*Cmd) [StdinPipe](#)

```
func (c *Cmd) StdinPipe() (io.WriteCloser, error)
```

StdinPipe returns a pipe that will be connected to the command's standard input when the command starts.

func (*Cmd) [StdoutPipe](#)

```
func (c *Cmd) StdoutPipe() (io.ReadCloser, error)
```

StdoutPipe returns a pipe that will be connected to the command's standard output when the command starts. The pipe will be closed automatically after Wait sees the command exit.

? Example

? Example

Code:

```
cmd := exec.Command("echo", "-n", `{"Name": "Bob", "Age": 32}`)
stdout, err := cmd.StdoutPipe()
if err != nil {
    log.Fatal(err)
}
if err := cmd.Start(); err != nil {
    log.Fatal(err)
}
var person struct {
    Name string
    Age  int
}
if err := json.NewDecoder(stdout).Decode(&person); err != nil {
    log.Fatal(err)
}
if err := cmd.Wait(); err != nil {
    log.Fatal(err)
}
fmt.Printf("%s is %d years old\n", person.Name, person.Age)
```

func (*Cmd) [Wait](#)

```
func (c *Cmd) Wait() error
```

Wait waits for the command to exit. It must have been started by Start.

The returned error is nil if the command runs, has no problems copying stdin, stdout, and stderr, and exits with a zero exit status.

If the command fails to run or doesn't complete successfully, the error is of type *ExitError. Other error types may be returned for I/O problems.

type [Error](#)

```
type Error struct {  
    Name string  
    Err  error  
}
```

Error records the name of a binary that failed to be executed and the reason it failed.

func (*Error) [Error](#)

```
func (e *Error) Error() string
```

type [ExitError](#)

```
type ExitError struct {  
    *os.ProcessState  
}
```

An ExitError reports an unsuccessful exit by a command.

func (***ExitError**) [Error](#)

```
func (e *ExitError) Error() string
```

Package signal

```
import "os/signal"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package signal implements access to incoming signals.

Index

[func Notify\(c chan<- os.Signal, sig ...os.Signal\)](#)

[Bugs](#)

Package files

[signal.go](#) [signal_unix.go](#)

func [Notify](#)

```
func Notify(c chan<- os.Signal, sig ...os.Signal)
```

Notify causes package signal to relay incoming signals to c. If no signals are listed, all incoming signals will be relayed to c. Otherwise, just the listed signals will.

Package signal will not block sending to c: the caller must ensure that c has sufficient buffer space to keep up with the expected signal rate. For a channel used for notification of just one signal value, a buffer of size 1 is sufficient.

Bugs

This package is not yet implemented on Plan 9 and Windows.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).

Overview ?

Overview ?

Package user allows user account lookups by name or id.

Index

[type UnknownUserError](#)

[func \(e UnknownUserError\) Error\(\) string](#)

[type UnknownUserIdError](#)

[func \(e UnknownUserIdError\) Error\(\) string](#)

[type User](#)

[func Current\(\) \(*User, error\)](#)

[func Lookup\(username string\) \(*User, error\)](#)

[func LookupId\(uid string\) \(*User, error\)](#)

Package files

[lookup_unix.go](#) [user.go](#)

type UnknownUserError

```
type UnknownUserError string
```

UnknownUserError is returned by Lookup when a user cannot be found.

func (UnknownUserError) Error

```
func (e UnknownUserError) Error() string
```

type [UnknownUserIdError](#)

```
type UnknownUserIdError int
```

UnknownUserIdError is returned by LookupId when a user cannot be found.

func (UnknownUserIdError) [Error](#)

```
func (e UnknownUserIdError) Error() string
```

type [User](#)

```
type User struct {
    Uid      string // user id
    Gid      string // primary group id
    Username string
    Name     string
    HomeDir  string
}
```

User represents a user account.

On posix systems Uid and Gid contain a decimal number representing uid and gid. On windows Uid and Gid contain security identifier (SID) in a string format.

func [Current](#)

```
func Current() (*User, error)
```

Current returns the current user.

func [Lookup](#)

```
func Lookup(username string) (*User, error)
```

Lookup looks up a user by username. If the user cannot be found, the returned error is of type `UnknownUserError`.

func [LookupId](#)

```
func LookupId(uid string) (*User, error)
```

LookupId looks up a user by userid. If the user cannot be found, the returned error is of type `UnknownUserIdError`.

Build version go1.0.1.

[func Clean\(path string\) string](#)

[func Dir\(path string\) string](#)

[func Ext\(path string\) string](#)

[func IsAbs\(path string\) bool](#)

[func Join\(elem ...string\) string](#)

[func Match\(pattern, name string\) \(matched bool, err error\)](#)

[func Split\(path string\) \(dir, file string\)](#)

Examples

[Base](#)

[Clean](#)

[Dir](#)

[Ext](#)

[IsAbs](#)

[Join](#)

[Split](#)

Package files

[match.go](#) [path.go](#)

Variables

```
var ErrBadPattern = errors.New("syntax error in pattern")
```

ErrBadPattern indicates a globbing pattern was malformed.

func [Base](#)

```
func Base(path string) string
```

Base returns the last element of path. Trailing slashes are removed before extracting the last element. If the path is empty, Base returns ".". If the path consists entirely of slashes, Base returns "/".

? Example

? Example

Code:

```
fmt.Println(path.Base("/a/b"))
```

Output:

b

func [Clean](#)

```
func Clean(path string) string
```

Clean returns the shortest path name equivalent to path by purely lexical processing. It applies the following rules iteratively until no further processing can be done:

1. Replace multiple slashes with a single slash.
2. Eliminate each . path name element (the current directory).
3. Eliminate each inner .. path name element (the parent directory) along with the non-.. element that precedes it.
4. Eliminate .. elements that begin a rooted path: that is, replace "../" by "/" at the beginning of a path.

The returned path ends in a slash only if it is the root "/".

If the result of this process is an empty string, Clean returns the string ".".

See also Rob Pike, "Lexical File Names in Plan 9 or Getting Dot-Dot Right," <http://plan9.bell-labs.com/sys/doc/lexnames.html>

? Example

? Example

Code:

```
paths := []string{
    "a/c",
    "a//c",
    "a/c/.",
    "a/c/b/..",
    "../a/c",
    "../a/b/../../../../c",
}

for _, p := range paths {
    fmt.Printf("Clean(%q) = %q\n", p, path.Clean(p))
}
```

Output:

```
Clean("a/c") = "a/c"  
Clean("a//c") = "a/c"  
Clean("a/c/.") = "a/c"  
Clean("a/c/b/..") = "a/c"  
Clean("../a/c") = "/a/c"  
Clean("../a/b/../../c") = "/a/c"
```

func [Dir](#)

```
func Dir(path string) string
```

Dir returns all but the last element of path, typically the path's directory. The path is Cleaned and trailing slashes are removed before processing. If the path is empty, Dir returns ".". If the path consists entirely of slashes followed by non-slash bytes, Dir returns a single slash. In any other case, the returned path does not end in a slash.

? Example

? Example

Code:

```
fmt.Println(path.Dir("/a/b/c"))
```

Output:

```
/a/b
```

func [Ext](#)

```
func Ext(path string) string
```

Ext returns the file name extension used by path. The extension is the suffix beginning at the final dot in the final slash-separated element of path; it is empty if there is no dot.

? Example

? Example

Code:

```
fmt.Println(path.Ext("/a/b/c/bar.css"))
```

Output:

```
.css
```

func [IsAbs](#)

```
func IsAbs(path string) bool
```

IsAbs returns true if the path is absolute.

? Example

? Example

Code:

```
fmt.Println(path.IsAbs("/dev/null"))
```

Output:

```
true
```

func [Join](#)

```
func Join(elem ...string) string
```

Join joins any number of path elements into a single path, adding a separating slash if necessary. The result is Cleaned; in particular, all empty strings are ignored.

? Example

? Example

Code:

```
fmt.Println(path.Join("a", "b", "c"))
```

Output:

a/b/c

func Match

func Match(pattern, name string) (matched bool, err error)

Match returns true if name matches the shell file name pattern. The pattern syntax is:

pattern:

{ term }

term:

'*'	matches any sequence of non-/ characters
'?'	matches any single non-/ character
'[' ['^']	{ character-range } ']'
	character class (must be non-empty)
c	matches character c (c != '*', '?', '\\', '[')
'\\' c	matches character c

character-range:

c	matches character c (c != '\\', '-', ']')
'\\' c	matches character c
lo '-' hi	matches character c for lo <= c <= hi

Match requires pattern to match all of name, not just a substring. The only possible returned error is ErrBadPattern, when pattern is malformed.

func [Split](#)

```
func Split(path string) (dir, file string)
```

Split splits path immediately following the final slash. separating it into a directory and file name component. If there is no slash path, Split returns an empty dir and file set to path. The returned values have the property that path = dir+file.

? Example

? Example

Code:

```
fmt.Println(path.Split("static/myfile.css"))
```

Output:

```
static/ myfile.css
```

Subdirectories

```
const (  
    Separator      = os.PathSeparator  
    ListSeparator = os.PathListSeparator  
)
```

Variables

```
var ErrBadPattern = errors.New("syntax error in pattern")
```

ErrBadPattern indicates a globbing pattern was malformed.

```
var SkipDir = errors.New("skip this directory")
```

SkipDir is used as a return value from WalkFuncs to indicate that the directory named in the call is to be skipped. It is not returned as an error by any function.

func [Abs](#)

```
func Abs(path string) (string, error)
```

Abs returns an absolute representation of path. If the path is not absolute it will be joined with the current working directory to turn it into an absolute path. The absolute path name for a given file is not guaranteed to be unique.

func Base

```
func Base(path string) string
```

Base returns the last element of path. Trailing path separators are removed before extracting the last element. If the path is empty, Base returns ".". If the path consists entirely of separators, Base returns a single separator.

func Clean

```
func Clean(path string) string
```

Clean returns the shortest path name equivalent to path by purely lexical processing. It applies the following rules iteratively until no further processing can be done:

1. Replace multiple Separator elements with a single one.
2. Eliminate each . path name element (the current directory)
3. Eliminate each inner .. path name element (the parent dir along with the non-.. element that precedes it.)
4. Eliminate .. elements that begin a rooted path: that is, replace "../.." by "/" at the beginning of a path, assuming Separator is '/'.

The returned path ends in a slash only if it represents a root directory, such as "/" on Unix or `C:\` on Windows.

If the result of this process is an empty string, Clean returns the string ".".

See also Rob Pike, "Lexical File Names in Plan 9 or Getting Dot-Dot Right," <http://plan9.bell-labs.com/sys/doc/lexnames.html>

func [Dir](#)

```
func Dir(path string) string
```

Dir returns all but the last element of path, typically the path's directory. Trailing path separators are removed before processing. If the path is empty, Dir returns ".". If the path consists entirely of separators, Dir returns a single separator. The returned path does not end in a separator unless it is the root directory.

func [EvalSymlinks](#)

```
func EvalSymlinks(path string) (string, error)
```

EvalSymlinks returns the path name after the evaluation of any symbolic links. If path is relative the result will be relative to the current directory, unless one of the components is an absolute symbolic link.

func [Ext](#)

```
func Ext(path string) string
```

Ext returns the file name extension used by path. The extension is the suffix beginning at the final dot in the final element of path; it is empty if there is no dot.

func [FromSlash](#)

```
func FromSlash(path string) string
```

FromSlash returns the result of replacing each slash (/) character in path with a separator character. Multiple slashes are replaced by multiple separators.

func [Glob](#)

```
func Glob(pattern string) (matches []string, err error)
```

Glob returns the names of all files matching pattern or nil if there is no matching file. The syntax of patterns is the same as in Match. The pattern may describe hierarchical names such as /usr/*/bin/ed (assuming the Separator is '/').

func [HasPrefix](#)

```
func HasPrefix(p, prefix string) bool
```

HasPrefix exists for historical compatibility and should not be used.

func [IsAbs](#)

```
func IsAbs(path string) bool
```

IsAbs returns true if the path is absolute.

func [Join](#)

```
func Join(elem ...string) string
```

Join joins any number of path elements into a single path, adding a Separator if necessary. The result is Cleaned, in particular all empty strings are ignored.

func [Match](#)

func Match(pattern, name string) (matched bool, err error)

Match returns true if name matches the shell file name pattern. The pattern syntax is:

pattern:

{ term }

term:

'*'	matches any sequence of non-Separator characters
'?'	matches any single non-Separator character
'[' ['^']	{ character-range } ']'
	character class (must be non-empty)
c	matches character c (c != '*', '?', '\\', '[')
'\\' c	matches character c

character-range:

c	matches character c (c != '\\', '-', ']')
'\\' c	matches character c
lo '-' hi	matches character c for lo <= c <= hi

Match requires pattern to match all of name, not just a substring. The only possible returned error is ErrBadPattern, when pattern is malformed.

On Windows, escaping is disabled. Instead, '\\' is treated as path separator.

func [Rel](#)

```
func Rel(basepath, targpath string) (string, error)
```

Rel returns a relative path that is lexically equivalent to targpath when joined to basepath with an intervening separator. That is, `Join(basepath, Rel(basepath, targpath))` is equivalent to targpath itself. On success, the returned path will always be relative to basepath, even if basepath and targpath share no elements. An error is returned if targpath can't be made relative to basepath or if knowing the current working directory would be necessary to compute it.

func [Split](#)

```
func Split(path string) (dir, file string)
```

Split splits path immediately following the final Separator, separating it into a directory and file name component. If there is no Separator in path, Split returns an empty dir and file set to path. The returned values have the property that path = dir+file.

func [SplitList](#)

```
func SplitList(path string) []string
```

SplitList splits a list of paths joined by the OS-specific ListSeparator, usually found in PATH or GOPATH environment variables. Unlike strings.Split, SplitList returns an empty slice when passed an empty string.

func [ToSlash](#)

```
func ToSlash(path string) string
```

ToSlash returns the result of replacing each separator character in path with a slash ('/') character. Multiple separators are replaced by multiple slashes.

func [VolumeName](#)

```
func VolumeName(path string) string
```

VolumeName returns the leading volume name on Windows. It returns "" elsewhere.

func [Walk](#)

```
func Walk(root string, walkFn WalkFunc) error
```

Walk walks the file tree rooted at root, calling walkFn for each file or directory in the tree, including root. All errors that arise visiting files and directories are filtered by walkFn. The files are walked in lexical order, which makes the output deterministic but means that for very large directories Walk can be inefficient.

type [WalkFunc](#)

```
type WalkFunc func(path string, info os.FileInfo, err error) error
```

WalkFunc is the type of the function called for each file or directory visited by Walk. If there was a problem walking to the file or directory named by path, the incoming error will describe the problem and the function can decide how to handle that error (and Walk will not descend into that directory). If an error is returned, processing stops. The sole exception is that if path is a directory and the function returns the special value SkipDir, the contents of the directory are skipped and processing continues as usual on the next file.

Package reflect

```
import "reflect"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `reflect` implements run-time reflection, allowing a program to manipulate objects with arbitrary types. The typical use is to take a value with static type `interface{}` and extract its dynamic type information by calling `TypeOf`, which returns a `Type`.

A call to `ValueOf` returns a `Value` representing the run-time data. `Zero` takes a `Type` and returns a `Value` representing a zero value for that type.

See "The Laws of Reflection" for an introduction to reflection in Go:
http://golang.org/doc/articles/laws_of_reflection.html

Package files

[deepequal.go](#) [type.go](#) [value.go](#)

func Copy

```
func Copy(dst, src Value) int
```

Copy copies the contents of src into dst until either dst has been filled or src has been exhausted. It returns the number of elements copied. Dst and src each must have kind Slice or Array, and dst and src must have the same element type.

func [DeepEqual](#)

```
func DeepEqual(a1, a2 interface{}) bool
```

DeepEqual tests for deep equality. It uses normal == equality where possible but will scan members of arrays, slices, maps, and fields of structs. It correctly handles recursive types. Functions are equal only if they are both nil.

type [ChanDir](#)

```
type ChanDir int
```

ChanDir represents a channel type's direction.

```
const (  
    RecvDir ChanDir          = 1 << iota // <-chan  
    SendDir                  // chan<-  
    BothDir = RecvDir | SendDir // chan  
)
```

func (ChanDir) [String](#)

```
func (d ChanDir) String() string
```

type [Kind](#)

```
type Kind uint
```

A Kind represents the specific kind of type that a Type represents. The zero Kind is not a valid kind.

```
const (  
    Invalid Kind = iota  
    Bool  
    Int  
    Int8  
    Int16  
    Int32  
    Int64  
    Uint  
    Uint8  
    Uint16  
    Uint32  
    Uint64  
    Uintptr  
    Float32  
    Float64  
    Complex64  
    Complex128  
    Array  
    Chan  
    Func  
    Interface  
    Map  
    Ptr  
    Slice  
    String  
    Struct  
    UnsafePointer  
)
```

func (Kind) [String](#)

```
func (k Kind) String() string
```

type [Method](#)

```
type Method struct {
    // Name is the method name.
    // PkgPath is the package path that qualifies a lower case (unex
    // method name. It is empty for upper case (exported) method na
    // The combination of PkgPath and Name uniquely identifies a met
    // in a method set.
    // See http://golang.org/ref/spec#Uniqueness\_of\_identifiers
    Name    string
    PkgPath string

    Type Type // method type
    Func Value // func with receiver as first argument
    Index int    // index for Type.Method
}
```

Method represents a single method.

type [SliceHeader](#)

```
type SliceHeader struct {  
    Data uintptr  
    Len  int  
    Cap  int  
}
```

`SliceHeader` is the runtime representation of a slice. It cannot be used safely or portably.

type [StringHeader](#)

```
type StringHeader struct {  
    Data uintptr  
    Len  int  
}
```

StringHeader is the runtime representation of a string. It cannot be used safely or portably.

type StructField

```
type StructField struct {
    // Name is the field name.
    // PkgPath is the package path that qualifies a lower case (unex
    // field name. It is empty for upper case (exported) field name
    // See http://golang.org/ref/spec#Uniqueness\_of\_identifiers
    Name      string
    PkgPath   string

    Type      Type      // field type
    Tag       StructTag // field tag string
    Offset    uintptr  // offset within struct, in bytes
    Index     []int    // index sequence for Type.FieldByIndex
    Anonymous bool      // is an anonymous field
}
```

A StructField describes a single field in a struct.

type [StructTag](#)

```
type StructTag string
```

A StructTag is the tag string in a struct field.

By convention, tag strings are a concatenation of optionally space-separated key:"value" pairs. Each key is a non-empty string consisting of non-control characters other than space (U+0020 ' '), quote (U+0022 ""), and colon (U+003A ':'). Each value is quoted using U+0022 "" characters and Go string literal syntax.

func (**StructTag**) [Get](#)

```
func (tag StructTag) Get(key string) string
```

Get returns the value associated with key in the tag string. If there is no such key in the tag, Get returns the empty string. If the tag does not have the conventional format, the value returned by Get is unspecified.

type Type

```
type Type interface {

    // Align returns the alignment in bytes of a value of
    // this type when allocated in memory.
    Align() int

    // FieldAlign returns the alignment in bytes of a value of
    // this type when used as a field in a struct.
    FieldAlign() int

    // Method returns the i'th method in the type's method set.
    // It panics if i is not in the range [0, NumMethod()).
    //
    // For a non-interface type T or *T, the returned Method's Type
    // fields describe a function whose first argument is the receiver.
    //
    // For an interface type, the returned Method's Type field gives
    // method signature, without a receiver, and the Func field is nil.
    Method(int) Method

    // MethodByName returns the method with that name in the type's
    // method set and a boolean indicating if the method was found.
    //
    // For a non-interface type T or *T, the returned Method's Type
    // fields describe a function whose first argument is the receiver.
    //
    // For an interface type, the returned Method's Type field gives
    // method signature, without a receiver, and the Func field is nil.
    MethodByName(string) (Method, bool)

    // NumMethod returns the number of methods in the type's method
    // set.
    NumMethod() int

    // Name returns the type's name within its package.
    // It returns an empty string for unnamed types.
    Name() string

    // PkgPath returns a named type's package path, that is, the import
    // path that uniquely identifies the package, such as "encoding/base64".
    // If the type was predeclared (string, error) or unnamed (*T, slice),
    // the package path will be the empty string.
    PkgPath() string

    // Size returns the number of bytes needed to store
    // a value of the given type; it is analogous to unsafe.Sizeof.
```

```

Size() uintptr

// String returns a string representation of the type.
// The string representation may use shortened package names
// (e.g., base64 instead of "encoding/base64") and is not
// guaranteed to be unique among types. To test for equality,
// compare the Types directly.
String() string

// Kind returns the specific kind of this type.
Kind() Kind

// Implements returns true if the type implements the interface
Implements(u Type) bool

// AssignableTo returns true if a value of the type is assignabl
AssignableTo(u Type) bool

// Bits returns the size of the type in bits.
// It panics if the type's Kind is not one of the
// sized or unsized Int, Uint, Float, or Complex kinds.
Bits() int

// ChanDir returns a channel type's direction.
// It panics if the type's Kind is not Chan.
ChanDir() ChanDir

// IsVariadic returns true if a function type's final input para
// is a "... " parameter. If so, t.In(t.NumIn() - 1) returns the
// implicit actual type []T.
//
// For concreteness, if t represents func(x int, y ... float64),
//
// t.NumIn() == 2
// t.In(0) is the reflect.Type for "int"
// t.In(1) is the reflect.Type for "[]float64"
// t.IsVariadic() == true
//
// IsVariadic panics if the type's Kind is not Func.
IsVariadic() bool

// Elem returns a type's element type.
// It panics if the type's Kind is not Array, Chan, Map, Ptr, or
Elem() Type

// Field returns a struct type's i'th field.
// It panics if the type's Kind is not Struct.
// It panics if i is not in the range [0, NumField()).
Field(i int) StructField

```

```

// FieldByIndex returns the nested field corresponding
// to the index sequence. It is equivalent to calling Field
// successively for each index i.
// It panics if the type's Kind is not Struct.
FieldByIndex(index []int) StructField

// FieldByName returns the struct field with the given name
// and a boolean indicating if the field was found.
FieldByName(name string) (StructField, bool)

// FieldByNameFunc returns the first struct field with a name
// that satisfies the match function and a boolean indicating if
// the field was found.
FieldByNameFunc(match func(string) bool) (StructField, bool)

// In returns the type of a function type's i'th input parameter
// It panics if the type's Kind is not Func.
// It panics if i is not in the range [0, NumIn()).
In(i int) Type

// Key returns a map type's key type.
// It panics if the type's Kind is not Map.
Key() Type

// Len returns an array type's length.
// It panics if the type's Kind is not Array.
Len() int

// NumField returns a struct type's field count.
// It panics if the type's Kind is not Struct.
NumField() int

// NumIn returns a function type's input parameter count.
// It panics if the type's Kind is not Func.
NumIn() int

// NumOut returns a function type's output parameter count.
// It panics if the type's Kind is not Func.
NumOut() int

// Out returns the type of a function type's i'th output paramet
// It panics if the type's Kind is not Func.
// It panics if i is not in the range [0, NumOut()).
Out(i int) Type
// contains filtered or unexported methods
}

```

Type is the representation of a Go type.

Not all methods apply to all kinds of types. Restrictions, if any, are noted in the documentation for each method. Use the `Kind` method to find out the kind of type before calling kind-specific methods. Calling a method inappropriate to the kind of type causes a run-time panic.

func [PtrTo](#)

```
func PtrTo(t Type) Type
```

`PtrTo` returns the pointer type with element `t`. For example, if `t` represents type `Foo`, `PtrTo(t)` represents `*Foo`.

func [TypeOf](#)

```
func TypeOf(i interface{}) Type
```

`TypeOf` returns the reflection `Type` of the value in the `interface{}`. `TypeOf(nil)` returns `nil`.

type [Value](#)

```
type Value struct {  
    // contains filtered or unexported fields  
}
```

Value is the reflection interface to a Go value.

Not all methods apply to all kinds of values. Restrictions, if any, are noted in the documentation for each method. Use the Kind method to find out the kind of value before calling kind-specific methods. Calling a method inappropriate to the kind of type causes a run time panic.

The zero Value represents no value. Its IsValid method returns false, its Kind method returns Invalid, its String method returns "<invalid Value>", and all other methods panic. Most functions and methods never return an invalid value. If one does, its documentation states the conditions explicitly.

A Value can be used concurrently by multiple goroutines provided that the underlying Go value can be used concurrently for the equivalent direct operations.

func [Append](#)

```
func Append(s Value, x ...Value) Value
```

Append appends the values x to a slice s and returns the resulting slice. As in Go, each x's value must be assignable to the slice's element type.

func [AppendSlice](#)

```
func AppendSlice(s, t Value) Value
```

AppendSlice appends a slice t to a slice s and returns the resulting slice. The slices s and t must have the same element type.

func [Indirect](#)

```
func Indirect(v Value) Value
```

Indirect returns the value that v points to. If v is a nil pointer, Indirect returns a zero Value. If v is not a pointer, Indirect returns v.

func [MakeChan](#)

```
func MakeChan(typ Type, buffer int) Value
```

MakeChan creates a new channel with the specified type and buffer size.

func [MakeMap](#)

```
func MakeMap(typ Type) Value
```

MakeMap creates a new map of the specified type.

func [MakeSlice](#)

```
func MakeSlice(typ Type, len, cap int) Value
```

MakeSlice creates a new zero-initialized slice value for the specified slice type, length, and capacity.

func [New](#)

```
func New(typ Type) Value
```

New returns a Value representing a pointer to a new zero value for the specified type. That is, the returned Value's Type is PtrTo(t).

func [NewAt](#)

```
func NewAt(typ Type, p unsafe.Pointer) Value
```

NewAt returns a Value representing a pointer to a value of the specified type, using p as that pointer.

func [ValueOf](#)

```
func ValueOf(i interface{}) Value
```

ValueOf returns a new Value initialized to the concrete value stored in the interface i. ValueOf(nil) returns the zero Value.

func [Zero](#)

```
func Zero(typ Type) Value
```

Zero returns a Value representing a zero value for the specified type. The result is different from the zero value of the Value struct, which represents no value at all. For example, Zero(.TypeOf(42)) returns a Value with Kind Int and value 0.

func (Value) [Addr](#)

```
func (v Value) Addr() Value
```

Addr returns a pointer value representing the address of v. It panics if CanAddr() returns false. Addr is typically used to obtain a pointer to a struct field or slice element in order to call a method that requires a pointer receiver.

func (Value) [Bool](#)

```
func (v Value) Bool() bool
```

Bool returns v's underlying value. It panics if v's kind is not Bool.

func (Value) [Bytes](#)

```
func (v Value) Bytes() []byte
```

Bytes returns v's underlying value. It panics if v's underlying value is not a slice of bytes.

func (Value) [Call](#)

```
func (v Value) Call(in []Value) []Value
```

Call calls the function v with the input arguments in. For example, if len(in) == 3, v.Call(in) represents the Go call v(in[0], in[1], in[2]). Call panics if v's Kind is not Func. It returns the output results as Values. As in Go, each input argument must be assignable to the type of the function's corresponding input parameter. If

v is a variadic function, Call creates the variadic slice parameter itself, copying in the corresponding values.

func (Value) [CallSlice](#)

```
func (v Value) CallSlice(in []Value) []Value
```

CallSlice calls the variadic function v with the input arguments in, assigning the slice in[len(in)-1] to v's final variadic argument. For example, if len(in) == 3, v.Call(in) represents the Go call v(in[0], in[1], in[2]...). Call panics if v's Kind is not Func or if v is not variadic. It returns the output results as Values. As in Go, each input argument must be assignable to the type of the function's corresponding input parameter.

func (Value) [CanAddr](#)

```
func (v Value) CanAddr() bool
```

CanAddr returns true if the value's address can be obtained with Addr. Such values are called addressable. A value is addressable if it is an element of a slice, an element of an addressable array, a field of an addressable struct, or the result of dereferencing a pointer. If CanAddr returns false, calling Addr will panic.

func (Value) [CanInterface](#)

```
func (v Value) CanInterface() bool
```

CanInterface returns true if Interface can be used without panicking.

func (Value) [CanSet](#)

```
func (v Value) CanSet() bool
```

CanSet returns true if the value of v can be changed. A Value can be changed only if it is addressable and was not obtained by the use of unexported struct fields. If CanSet returns false, calling Set or any type-specific setter (e.g., SetBool, SetInt64) will panic.

func (Value) [Cap](#)

```
func (v Value) Cap() int
```

Cap returns v's capacity. It panics if v's Kind is not Array, Chan, or Slice.

func (Value) [Close](#)

```
func (v Value) Close()
```

Close closes the channel v. It panics if v's Kind is not Chan.

func (Value) [Complex](#)

```
func (v Value) Complex() complex128
```

Complex returns v's underlying value, as a complex128. It panics if v's Kind is not Complex64 or Complex128

func (Value) [Elem](#)

```
func (v Value) Elem() Value
```

Elem returns the value that the interface v contains or that the pointer v points to. It panics if v's Kind is not Interface or Ptr. It returns the zero Value if v is nil.

func (Value) [Field](#)

```
func (v Value) Field(i int) Value
```

Field returns the i'th field of the struct v. It panics if v's Kind is not Struct or i is out of range.

func (Value) [FieldByIndex](#)

```
func (v Value) FieldByIndex(index []int) Value
```

FieldByIndex returns the nested field corresponding to index. It panics if v's Kind is not struct.

func (Value) [FieldByName](#)

```
func (v Value) FieldByName(name string) Value
```

FieldByName returns the struct field with the given name. It returns the zero Value if no field was found. It panics if v's Kind is not struct.

func (Value) [FieldByNameFunc](#)

```
func (v Value) FieldByNameFunc(match func(string) bool) Value
```

FieldByNameFunc returns the struct field with a name that satisfies the match function. It panics if v's Kind is not struct. It returns the zero Value if no field was found.

func (Value) [Float](#)

```
func (v Value) Float() float64
```

Float returns v's underlying value, as a float64. It panics if v's Kind is not Float32 or Float64

func (Value) [Index](#)

```
func (v Value) Index(i int) Value
```

Index returns v's i'th element. It panics if v's Kind is not Array or Slice or i is out of range.

func (Value) [Int](#)

```
func (v Value) Int() int64
```

Int returns v's underlying value, as an int64. It panics if v's Kind is not Int, Int8, Int16, Int32, or Int64.

func (Value) [Interface](#)

```
func (v Value) Interface() (i interface{})
```

Interface returns v's current value as an interface{}. It is equivalent to:

```
var i interface{} = (v's underlying value)
```

If `v` is a method obtained by invoking `Value.Method` (as opposed to `Type.Method`), `Interface` cannot return an interface value, so it panics. It also panics if the `Value` was obtained by accessing unexported struct fields.

func (Value) [InterfaceData](#)

```
func (v Value) InterfaceData() [2]uintptr
```

`InterfaceData` returns the interface `v`'s value as a `uintptr` pair. It panics if `v`'s `Kind` is not `Interface`.

func (Value) [IsNil](#)

```
func (v Value) IsNil() bool
```

`IsNil` returns true if `v` is a nil value. It panics if `v`'s `Kind` is not `Chan`, `Func`, `Interface`, `Map`, `Ptr`, or `Slice`.

func (Value) [IsValid](#)

```
func (v Value) IsValid() bool
```

`IsValid` returns true if `v` represents a value. It returns false if `v` is the zero `Value`. If `IsValid` returns false, all other methods except `String` panic. Most functions and methods never return an invalid value. If one does, its documentation states the conditions explicitly.

func (Value) [Kind](#)

```
func (v Value) Kind() Kind
```

`Kind` returns `v`'s `Kind`. If `v` is the zero `Value` (`IsValid` returns false), `Kind` returns `Invalid`.

func (Value) [Len](#)

```
func (v Value) Len() int
```

Len returns v's length. It panics if v's Kind is not Array, Chan, Map, Slice, or String.

func (Value) [MapIndex](#)

```
func (v Value) MapIndex(key Value) Value
```

MapIndex returns the value associated with key in the map v. It panics if v's Kind is not Map. It returns the zero Value if key is not found in the map or if v represents a nil map. As in Go, the key's value must be assignable to the map's key type.

func (Value) [MapKeys](#)

```
func (v Value) MapKeys() []Value
```

MapKeys returns a slice containing all the keys present in the map, in unspecified order. It panics if v's Kind is not Map. It returns an empty slice if v represents a nil map.

func (Value) [Method](#)

```
func (v Value) Method(i int) Value
```

Method returns a function value corresponding to v's i'th method. The arguments to a Call on the returned function should not include a receiver; the returned function will always use v as the receiver. Method panics if i is out of range.

func (Value) [MethodByName](#)

```
func (v Value) MethodByName(name string) Value
```

MethodByName returns a function value corresponding to the method of v with the given name. The arguments to a Call on the returned function should not include a receiver; the returned function will always use v as the receiver. It returns the zero Value if no method was found.

func (Value) [NumField](#)

```
func (v Value) NumField() int
```

NumField returns the number of fields in the struct v. It panics if v's Kind is not Struct.

func (Value) [NumMethod](#)

```
func (v Value) NumMethod() int
```

NumMethod returns the number of methods in the value's method set.

func (Value) [OverflowComplex](#)

```
func (v Value) OverflowComplex(x complex128) bool
```

OverflowComplex returns true if the complex128 x cannot be represented by v's type. It panics if v's Kind is not Complex64 or Complex128.

func (Value) [OverflowFloat](#)

```
func (v Value) OverflowFloat(x float64) bool
```

OverflowFloat returns true if the float64 x cannot be represented by v's type. It panics if v's Kind is not Float32 or Float64.

func (Value) [OverflowInt](#)

```
func (v Value) OverflowInt(x int64) bool
```

OverflowInt returns true if the int64 x cannot be represented by v's type. It panics if v's Kind is not Int, Int8, int16, Int32, or Int64.

func (Value) [OverflowUint](#)

```
func (v Value) OverflowUint(x uint64) bool
```

OverflowUint returns true if the uint64 x cannot be represented by v's type. It panics if v's Kind is not Uint, Uintptr, Uint8, Uint16, Uint32, or Uint64.

func (Value) [Pointer](#)

```
func (v Value) Pointer() uintptr
```

Pointer returns v's value as a uintptr. It returns uintptr instead of unsafe.Pointer so that code using reflect cannot obtain unsafe.Pointers without importing the unsafe package explicitly. It panics if v's Kind is not Chan, Func, Map, Ptr, Slice, or UnsafePointer.

func (Value) [Recv](#)

```
func (v Value) Recv() (x Value, ok bool)
```

Recv receives and returns a value from the channel v. It panics if v's Kind is not Chan. The receive blocks until a value is ready. The boolean value ok is true if the value x corresponds to a send on the channel, false if it is a zero value received because the channel is closed.

func (Value) [Send](#)

```
func (v Value) Send(x Value)
```

Send sends x on the channel v. It panics if v's kind is not Chan or if x's type is not the same type as v's element type. As in Go, x's value must be assignable to the channel's element type.

func (Value) [Set](#)

```
func (v Value) Set(x Value)
```

Set assigns x to the value v. It panics if CanSet returns false. As in Go, x's value must be assignable to v's type.

func (Value) [SetBool](#)

```
func (v Value) SetBool(x bool)
```

SetBool sets v's underlying value. It panics if v's Kind is not Bool or if CanSet() is false.

func (Value) [SetBytes](#)

```
func (v Value) SetBytes(x []byte)
```

SetBytes sets v's underlying value. It panics if v's underlying value is not a slice of bytes.

func (Value) [SetComplex](#)

```
func (v Value) SetComplex(x complex128)
```

SetComplex sets v's underlying value to x. It panics if v's Kind is not Complex64 or Complex128, or if CanSet() is false.

func (Value) [SetFloat](#)

```
func (v Value) SetFloat(x float64)
```

SetFloat sets v's underlying value to x. It panics if v's Kind is not Float32 or Float64, or if CanSet() is false.

func (Value) [SetInt](#)

```
func (v Value) SetInt(x int64)
```

SetInt sets v's underlying value to x. It panics if v's Kind is not Int, Int8, Int16, Int32, or Int64, or if CanSet() is false.

func (Value) [SetLen](#)

```
func (v Value) SetLen(n int)
```

SetLen sets v's length to n. It panics if v's Kind is not Slice or if n is negative or greater than the capacity of the slice.

func (Value) [SetMapIndex](#)

```
func (v Value) SetMapIndex(key, val Value)
```

SetMapIndex sets the value associated with key in the map v to val. It panics if v's Kind is not Map. If val is the zero Value, SetMapIndex deletes the key from the map. As in Go, key's value must be assignable to the map's key type, and val's value must be assignable to the map's value type.

func (Value) [SetPointer](#)

```
func (v Value) SetPointer(x unsafe.Pointer)
```

SetPointer sets the unsafe.Pointer value v to x. It panics if v's Kind is not UnsafePointer.

func (Value) [SetString](#)

```
func (v Value) SetString(x string)
```

SetString sets v's underlying value to x. It panics if v's Kind is not String or if CanSet() is false.

func (Value) [SetUint](#)

```
func (v Value) SetUint(x uint64)
```

SetUint sets v's underlying value to x. It panics if v's Kind is not Uint, Uintptr, Uint8, Uint16, Uint32, or Uint64, or if CanSet() is false.

func (Value) [Slice](#)

```
func (v Value) Slice(beg, end int) Value
```

Slice returns a slice of v. It panics if v's Kind is not Array or Slice.

func (Value) [String](#)

```
func (v Value) String() string
```

String returns the string v's underlying value, as a string. String is a special case because of Go's String method convention. Unlike the other getters, it does not panic if v's Kind is not String. Instead, it returns a string of the form "<T value>" where T is v's type.

func (Value) [TryRecv](#)

```
func (v Value) TryRecv() (x Value, ok bool)
```

TryRecv attempts to receive a value from the channel v but will not block. It panics if v's Kind is not Chan. If the receive cannot finish without blocking, x is the zero Value. The boolean ok is true if the value x corresponds to a send on the channel, false if it is a zero value received because the channel is closed.

func (Value) [TrySend](#)

```
func (v Value) TrySend(x Value) bool
```

TrySend attempts to send x on the channel v but will not block. It panics if v's Kind is not Chan. It returns true if the value was sent, false otherwise. As in Go, x's value must be assignable to the channel's element type.

func (Value) [Type](#)

```
func (v Value) Type() Type
```

Type returns v's type.

func (Value) [Uint](#)

```
func (v Value) Uint() uint64
```

Uint returns v's underlying value, as a uint64. It panics if v's Kind is not Uint, Uintptr, Uint8, Uint16, Uint32, or Uint64.

func (Value) [UnsafeAddr](#)

```
func (v Value) UnsafeAddr() uintptr
```

UnsafeAddr returns a pointer to v's data. It is for advanced clients that also import the "unsafe" package. It panics if v is not addressable.

type [ValueError](#)

```
type ValueError struct {  
    Method string  
    Kind    Kind  
}
```

A `ValueError` occurs when a `Value` method is invoked on a `Value` that does not support it. Such cases are documented in the description of each method.

func (*[ValueError](#)) [Error](#)

```
func (e *ValueError) Error() string
```

Package regexp

```
import "regexp"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `regexp` implements regular expression search.

The syntax of the regular expressions accepted is the same general syntax used by Perl, Python, and other languages. More precisely, it is the syntax accepted by RE2 and described at <http://code.google.com/p/re2/wiki/Syntax>, except for `\C`.

All characters are UTF-8-encoded code points.

There are 16 methods of `Regexp` that match a regular expression and identify the matched text. Their names are matched by this regular expression:

```
Find(All)?(String)?(Submatch)?(Index)?
```

If `'All'` is present, the routine matches successive non-overlapping matches of the entire expression. Empty matches abutting a preceding match are ignored. The return value is a slice containing the successive return values of the corresponding non-`'All'` routine. These routines take an extra integer argument, `n`; if `n >= 0`, the function returns at most `n` matches/submatches.

If `'String'` is present, the argument is a string; otherwise it is a slice of bytes; return values are adjusted as appropriate.

If `'Submatch'` is present, the return value is a slice identifying the successive submatches of the expression. Submatches are matches of parenthesized subexpressions within the regular expression, numbered from left to right in order of opening parenthesis. Submatch 0 is the match of the entire expression, submatch 1 the match of the first parenthesized subexpression, and so on.

If `'Index'` is present, matches and submatches are identified by byte index pairs within the input string: `result[2*n:2*n+1]` identifies the indexes of the `n`th submatch. The pair for `n==0` identifies the match of the entire expression. If `'Index'` is not present, the match is identified by the text of the match/submatch. If an index is negative, it means that subexpression did not match any string in the input.

There is also a subset of the methods that can be applied to text read from a `RuneReader`:

MatchReader, FindReaderIndex, FindReaderSubmatchIndex

This set may grow. Note that regular expression matches may need to examine text beyond the text returned by a match, so the methods that match text from a RuneReader may read arbitrarily far into the input before returning.

(There are a few other methods that do not match this pattern.)

Package files

exec.go regex.go

func [Match](#)

```
func Match(pattern string, b []byte) (matched bool, error error)
```

Match checks whether a textual regular expression matches a byte slice. More complicated queries need to use `Compile` and the full `Regexp` interface.

func [MatchReader](#)

```
func MatchReader(pattern string, r io.RuneReader) (matched bool, err
```

MatchReader checks whether a textual regular expression matches the text read by the RuneReader. More complicated queries need to use Compile and the full Regexp interface.

func [MatchString](#)

`func MatchString(pattern string, s string) (matched bool, error error)`

MatchString checks whether a textual regular expression matches a string. More complicated queries need to use Compile and the full Regexp interface.

func [QuoteMeta](#)

```
func QuoteMeta(s string) string
```

QuoteMeta returns a string that quotes all regular expression metacharacters inside the argument text; the returned string is a regular expression matching the literal text. For example, `QuoteMeta(`[foo]`)` returns ``\[foo\]``.

type [Regexp](#)

```
type Regexp struct {  
    // contains filtered or unexported fields  
}
```

Regexp is the representation of a compiled regular expression. The public interface is entirely through methods. A Regexp is safe for concurrent use by multiple goroutines.

func [Compile](#)

```
func Compile(expr string) (*Regexp, error)
```

Compile parses a regular expression and returns, if successful, a Regexp object that can be used to match against text.

When matching against text, the regexp returns a match that begins as early as possible in the input (leftmost), and among those it chooses the one that a backtracking search would have found first. This so-called leftmost-first matching is the same semantics that Perl, Python, and other implementations use, although this package implements it without the expense of backtracking. For POSIX leftmost-longest matching, see [CompilePOSIX](#).

func [CompilePOSIX](#)

```
func CompilePOSIX(expr string) (*Regexp, error)
```

CompilePOSIX is like [Compile](#) but restricts the regular expression to POSIX ERE (egrep) syntax and changes the match semantics to leftmost-longest.

That is, when matching against text, the regexp returns a match that begins as early as possible in the input (leftmost), and among those it chooses a match that is as long as possible. This so-called leftmost-longest matching is the same semantics that early regular expression implementations used and that POSIX specifies.

However, there can be multiple leftmost-longest matches, with different submatch choices, and here this package diverges from POSIX. Among the

possible leftmost-longest matches, this package chooses the one that a backtracking search would have found first, while POSIX specifies that the match be chosen to maximize the length of the first subexpression, then the second, and so on from left to right. The POSIX rule is computationally prohibitive and not even well-defined. See <http://swtch.com/~rsc/regexp/regexp2.html#posix> for details.

func [MustCompile](#)

```
func MustCompile(str string) *Regexp
```

MustCompile is like Compile but panics if the expression cannot be parsed. It simplifies safe initialization of global variables holding compiled regular expressions.

func [MustCompilePOSIX](#)

```
func MustCompilePOSIX(str string) *Regexp
```

MustCompilePOSIX is like CompilePOSIX but panics if the expression cannot be parsed. It simplifies safe initialization of global variables holding compiled regular expressions.

func (*Regexp) [Expand](#)

```
func (re *Regexp) Expand(dst []byte, template []byte, src []byte, ma
```

Expand appends template to dst and returns the result; during the append, Expand replaces variables in the template with corresponding matches drawn from src. The match slice should have been returned by FindSubmatchIndex.

In the template, a variable is denoted by a substring of the form \$name or \${name}, where name is a non-empty sequence of letters, digits, and underscores. A purely numeric name like \$1 refers to the submatch with the corresponding index; other names refer to capturing parentheses named with the (?P<name>...) syntax. A reference to an out of range or unmatched index or a name that is not present in the regular expression is replaced with an empty string.

In the \$name form, name is taken to be as long as possible: \$1x is equivalent to

`${1x}`, not `${1}x`, and, `$10` is equivalent to `${10}`, not `${1}0`.

To insert a literal `$` in the output, use `$$` in the template.

func (*Regex) [ExpandString](#)

```
func (re *Regex) ExpandString(dst []byte, template string, src stri
```

`ExpandString` is like `Expand` but the template and source are strings. It appends to and returns a byte slice in order to give the calling code control over allocation.

func (*Regex) [Find](#)

```
func (re *Regex) Find(b []byte) []byte
```

`Find` returns a slice holding the text of the leftmost match in `b` of the regular expression. A return value of `nil` indicates no match.

func (*Regex) [FindAll](#)

```
func (re *Regex) FindAll(b []byte, n int) [][]byte
```

`FindAll` is the 'All' version of `Find`; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of `nil` indicates no match.

func (*Regex) [FindAllIndex](#)

```
func (re *Regex) FindAllIndex(b []byte, n int) [][]int
```

`FindAllIndex` is the 'All' version of `FindIndex`; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of `nil` indicates no match.

func (*Regex) [FindAllString](#)

```
func (re *Regex) FindAllString(s string, n int) []string
```

`FindAllString` is the 'All' version of `FindString`; it returns a slice of all successive

matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindAllStringIndex](#)

```
func (re *Regex) FindAllStringIndex(s string, n int) [][]int
```

FindAllStringIndex is the 'All' version of FindStringIndex; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindAllStringSubmatch](#)

```
func (re *Regex) FindAllStringSubmatch(s string, n int) [][]string
```

FindAllStringSubmatch is the 'All' version of FindStringSubmatch; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindAllStringSubmatchIndex](#)

```
func (re *Regex) FindAllStringSubmatchIndex(s string, n int) [][]int
```

FindAllStringSubmatchIndex is the 'All' version of FindStringSubmatchIndex; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindAllSubmatch](#)

```
func (re *Regex) FindAllSubmatch(b []byte, n int) [][][]byte
```

FindAllSubmatch is the 'All' version of FindSubmatch; it returns a slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindAllSubmatchIndex](#)

```
func (re *Regex) FindAllSubmatchIndex(b []byte, n int) [][]int
```

FindAllSubmatchIndex is the 'All' version of FindSubmatchIndex; it returns a

slice of all successive matches of the expression, as defined by the 'All' description in the package comment. A return value of nil indicates no match.

func (*Regex) [FindIndex](#)

```
func (re *Regex) FindIndex(b []byte) (loc []int)
```

FindIndex returns a two-element slice of integers defining the location of the leftmost match in b of the regular expression. The match itself is at b[loc[0]:loc[1]]. A return value of nil indicates no match.

func (*Regex) [FindReaderIndex](#)

```
func (re *Regex) FindReaderIndex(r io.RuneReader) (loc []int)
```

FindReaderIndex returns a two-element slice of integers defining the location of the leftmost match of the regular expression in text read from the RuneReader. The match itself is at s[loc[0]:loc[1]]. A return value of nil indicates no match.

func (*Regex) [FindReaderSubmatchIndex](#)

```
func (re *Regex) FindReaderSubmatchIndex(r io.RuneReader) []int
```

FindReaderSubmatchIndex returns a slice holding the index pairs identifying the leftmost match of the regular expression of text read by the RuneReader, and the matches, if any, of its subexpressions, as defined by the 'Submatch' and 'Index' descriptions in the package comment. A return value of nil indicates no match.

func (*Regex) [FindString](#)

```
func (re *Regex) FindString(s string) string
```

FindString returns a string holding the text of the leftmost match in s of the regular expression. If there is no match, the return value is an empty string, but it will also be empty if the regular expression successfully matches an empty string. Use FindStringIndex or FindStringSubmatch if it is necessary to distinguish these cases.

func (*Regex) [FindStringIndex](#)

```
func (re *Regexp) FindStringIndex(s string) (loc []int)
```

FindStringIndex returns a two-element slice of integers defining the location of the leftmost match in s of the regular expression. The match itself is at s[loc[0]:loc[1]]. A return value of nil indicates no match.

func (*Regexp) [FindStringSubmatch](#)

```
func (re *Regexp) FindStringSubmatch(s string) []string
```

FindStringSubmatch returns a slice of strings holding the text of the leftmost match of the regular expression in s and the matches, if any, of its subexpressions, as defined by the 'Submatch' description in the package comment. A return value of nil indicates no match.

func (*Regexp) [FindStringSubmatchIndex](#)

```
func (re *Regexp) FindStringSubmatchIndex(s string) []int
```

FindStringSubmatchIndex returns a slice holding the index pairs identifying the leftmost match of the regular expression in s and the matches, if any, of its subexpressions, as defined by the 'Submatch' and 'Index' descriptions in the package comment. A return value of nil indicates no match.

func (*Regexp) [FindSubmatch](#)

```
func (re *Regexp) FindSubmatch(b []byte) [][]byte
```

FindSubmatch returns a slice of slices holding the text of the leftmost match of the regular expression in b and the matches, if any, of its subexpressions, as defined by the 'Submatch' descriptions in the package comment. A return value of nil indicates no match.

func (*Regexp) [FindSubmatchIndex](#)

```
func (re *Regexp) FindSubmatchIndex(b []byte) []int
```

FindSubmatchIndex returns a slice holding the index pairs identifying the leftmost match of the regular expression in b and the matches, if any, of its subexpressions, as defined by the 'Submatch' and 'Index' descriptions in the

package comment. A return value of nil indicates no match.

func (*Regexp) [LiteralPrefix](#)

```
func (re *Regexp) LiteralPrefix() (prefix string, complete bool)
```

LiteralPrefix returns a literal string that must begin any match of the regular expression re. It returns the boolean true if the literal string comprises the entire regular expression.

func (*Regexp) [Match](#)

```
func (re *Regexp) Match(b []byte) bool
```

Match returns whether the Regexp matches the byte slice b. The return value is a boolean: true for match, false for no match.

func (*Regexp) [MatchReader](#)

```
func (re *Regexp) MatchReader(r io.RuneReader) bool
```

MatchReader returns whether the Regexp matches the text read by the RuneReader. The return value is a boolean: true for match, false for no match.

func (*Regexp) [MatchString](#)

```
func (re *Regexp) MatchString(s string) bool
```

MatchString returns whether the Regexp matches the string s. The return value is a boolean: true for match, false for no match.

func (*Regexp) [NumSubexp](#)

```
func (re *Regexp) NumSubexp() int
```

NumSubexp returns the number of parenthesized subexpressions in this Regexp.

func (*Regexp) [ReplaceAll](#)

```
func (re *Regexp) ReplaceAll(src, repl []byte) []byte
```

ReplaceAll returns a copy of src, replacing matches of the Regexp with the replacement string repl. Inside repl, \$ signs are interpreted as in Expand, so for instance \$1 represents the text of the first submatch.

func (*Regexp) [ReplaceAllFunc](#)

```
func (re *Regexp) ReplaceAllFunc(src []byte, repl func([]byte) []byte)
```

ReplaceAllFunc returns a copy of src in which all matches of the Regexp have been replaced by the return value of of function repl applied to the matched byte slice. The replacement returned by repl is substituted directly, without using Expand.

func (*Regexp) [ReplaceAllLiteral](#)

```
func (re *Regexp) ReplaceAllLiteral(src, repl []byte) []byte
```

ReplaceAllLiteral returns a copy of src, replacing matches of the Regexp with the replacement bytes repl. The replacement repl is substituted directly, without using Expand.

func (*Regexp) [ReplaceAllLiteralString](#)

```
func (re *Regexp) ReplaceAllLiteralString(src, repl string) string
```

ReplaceAllStringLiteral returns a copy of src, replacing matches of the Regexp with the replacement string repl. The replacement repl is substituted directly, without using Expand.

func (*Regexp) [ReplaceAllString](#)

```
func (re *Regexp) ReplaceAllString(src, repl string) string
```

ReplaceAllString returns a copy of src, replacing matches of the Regexp with the replacement string repl. Inside repl, \$ signs are interpreted as in Expand, so for instance \$1 represents the text of the first submatch.

func (*Regexp) [ReplaceAllStringFunc](#)

```
func (re *Regexp) ReplaceAllStringFunc(src string, repl func(string))
```

ReplaceAllStringFunc returns a copy of src in which all matches of the Regexp have been replaced by the return value of of function repl applied to the matched substring. The replacement returned by repl is substituted directly, without using Expand.

func (*Regexp) [String](#)

```
func (re *Regexp) String() string
```

String returns the source text used to compile the regular expression.

func (*Regexp) [SubexpNames](#)

```
func (re *Regexp) SubexpNames() []string
```

SubexpNames returns the names of the parenthesized subexpressions in this Regexp. The name for the first sub-expression is names[1], so that if m is a match slice, the name for m[i] is SubexpNames()[i]. Since the Regexp as a whole cannot be named, names[0] is always the empty string. The slice should not be modified.

Package syntax

```
import "regexp/syntax"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `syntax` parses regular expressions into parse trees and compiles parse trees into programs. Most clients of regular expressions will use the facilities of package `regexp` (such as `Compile` and `Match`) instead of this package.

func IsWordChar

```
func IsWordChar(r rune) bool
```

IsWordChar reports whether r is consider a “word character” during the evaluation of the \b and \B zero-width assertions. These assertions are ASCII-only: the word characters are [A-Za-z0-9_].

type [EmptyOp](#)

```
type EmptyOp uint8
```

An EmptyOp specifies a kind or mixture of zero-width assertions.

```
const (  
    EmptyBeginLine EmptyOp = 1 << iota  
    EmptyEndLine  
    EmptyBeginText  
    EmptyEndText  
    EmptyWordBoundary  
    EmptyNoWordBoundary  
)
```

func [EmptyOpContext](#)

```
func EmptyOpContext(r1, r2 rune) EmptyOp
```

EmptyOpContext returns the zero-width assertions satisfied at the position between the runes r1 and r2. Passing r1 == -1 indicates that the position is at the beginning of the text. Passing r2 == -1 indicates that the position is at the end of the text.

type [Error](#)

```
type Error struct {  
    Code ErrorCode  
    Expr string  
}
```

An Error describes a failure to parse a regular expression and gives the offending expression.

func (***Error**) [Error](#)

```
func (e *Error) Error() string
```

type [ErrorCode](#)

```
type ErrorCode string
```

An ErrorCode describes a failure to parse a regular expression.

```
const (  
    // Unexpected error  
    ErrInternalError ErrorCode = "regexp/syntax: internal error"  
  
    // Parse errors  
    ErrInvalidCharClass      ErrorCode = "invalid character class"  
    ErrInvalidCharRange     ErrorCode = "invalid character class ra  
    ErrInvalidEscape         ErrorCode = "invalid escape sequence"  
    ErrInvalidNamedCapture  ErrorCode = "invalid named capture"  
    ErrInvalidPerlOp        ErrorCode = "invalid or unsupported Per  
    ErrInvalidRepeatOp      ErrorCode = "invalid nested repetition"  
    ErrInvalidRepeatSize    ErrorCode = "invalid repeat count"  
    ErrInvalidUTF8          ErrorCode = "invalid UTF-8"  
    ErrMissingBracket       ErrorCode = "missing closing ]"  
    ErrMissingParen         ErrorCode = "missing closing )"  
    ErrMissingRepeatArgument ErrorCode = "missing argument to repeti  
    ErrTrailingBackslash    ErrorCode = "trailing backslash at end  
)
```

func (ErrorCode) [String](#)

```
func (e ErrorCode) String() string
```

type Flags

type Flags uint16

Flags control the behavior of the parser and record information about regexp context.

```
const (
    FoldCase      Flags = 1 << iota // case-insensitive match
    Literal       // treat pattern as literal string
    ClassNL       // allow character classes like
    DotNL         // allow . to match newline
    OneLine       // treat ^ and $ as only matching
    NonGreedy     // make repetition operators default
    PerlX         // allow Perl extensions
    UnicodeGroups // allow \p{Han}, \P{Han} for Unicode
    WasDollar     // regexp OpEndText was $, not \
    Simple        // regexp contains no counted repeats

    MatchNL = ClassNL | DotNL

    Perl      = ClassNL | OneLine | PerlX | UnicodeGroups // as class
    POSIX Flags = 0 // POSIX
)
```

type [Inst](#)

```
type Inst struct {
    Op    InstOp
    Out   uint32 // all but InstMatch, InstFail
    Arg   uint32 // InstAlt, InstAltMatch, InstCapture, InstEmptyWidt
    Rune  []rune
}
```

An Inst is a single instruction in a regular expression program.

func (*Inst) [MatchEmptyWidth](#)

```
func (i *Inst) MatchEmptyWidth(before rune, after rune) bool
```

MatchEmptyWidth returns true if the instruction matches an empty string between the runes before and after. It should only be called when `i.Op == InstEmptyWidth`.

func (*Inst) [MatchRune](#)

```
func (i *Inst) MatchRune(r rune) bool
```

MatchRune returns true if the instruction matches (and consumes) `r`. It should only be called when `i.Op == InstRune`.

func (*Inst) [String](#)

```
func (i *Inst) String() string
```

type [InstOp](#)

```
type InstOp uint8
```

An InstOp is an instruction opcode.

```
const (  
    InstAlt InstOp = iota  
    InstAltMatch  
    InstCapture  
    InstEmptyWidth  
    InstMatch  
    InstFail  
    InstNop  
    InstRune  
    InstRune1  
    InstRuneAny  
    InstRuneAnyNotNL  
)
```

type [Op](#)

```
type Op uint8
```

An Op is a single regular expression operator.

```
const (
    OpNoMatch          Op = 1 + iota // matches no strings
    OpEmptyMatch      // matches empty string
    OpLiteral          // matches Runes sequence
    OpCharClass        // matches Runes interpreted as r
    OpAnyCharNotNL    // matches any character
    OpAnyChar          // matches any character
    OpBeginLine        // matches empty string at beginn
    OpEndLine          // matches empty string at end of
    OpBeginText        // matches empty string at beginn
    OpEndText          // matches empty string at end of
    OpWordBoundary     // matches word boundary `b`
    OpNoWordBoundary  // matches word non-boundary `B`
    OpCapture          // capturing subexpression with i
    OpStar             // matches Sub[0] zero or more ti
    OpPlus            // matches Sub[0] one or more tir
    OpQuest           // matches Sub[0] zero or one tir
    OpRepeat          // matches Sub[0] at least Min ti
    OpConcat          // matches concatenation of Subs
    OpAlternate       // matches alternation of Subs
)
```

type [Prog](#)

```
type Prog struct {
    Inst    []Inst
    Start  int // index of start instruction
    NumCap int // number of InstCapture insts in re
}
```

A Prog is a compiled regular expression program.

func [Compile](#)

```
func Compile(re *Regexp) (*Prog, error)
```

Compile compiles the regexp into a program to be executed. The regexp should have been simplified already (returned from re.Simplify).

func (*Prog) [Prefix](#)

```
func (p *Prog) Prefix() (prefix string, complete bool)
```

Prefix returns a literal string that all matches for the regexp must start with. Complete is true if the prefix is the entire match.

func (*Prog) [StartCond](#)

```
func (p *Prog) StartCond() EmptyOp
```

StartCond returns the leading empty-width conditions that must be true in any match. It returns ^EmptyOp(0) if no matches are possible.

func (*Prog) [String](#)

```
func (p *Prog) String() string
```

type [Regexp](#)

```
type Regexp struct {
    Op      Op // operator
    Flags   Flags
    Sub     []*Regexp // subexpressions, if any
    Sub0    [1]*Regexp // storage for short Sub
    Rune    []rune    // matched runes, for OpLiteral, OpCharClass
    Rune0   [2]rune   // storage for short Rune
    Min, Max int       // min, max for OpRepeat
    Cap     int       // capturing index, for OpCapture
    Name    string    // capturing name, for OpCapture
}
```

A Regexp is a node in a regular expression syntax tree.

func [Parse](#)

```
func Parse(s string, flags Flags) (*Regexp, error)
```

Parse parses a regular expression string *s*, controlled by the specified *Flags*, and returns a regular expression parse tree. The syntax is described in the top-level comment for package `regexp`.

func (*Regexp) [CapNames](#)

```
func (re *Regexp) CapNames() []string
```

CapNames walks the regexp to find the names of capturing groups.

func (*Regexp) [Equal](#)

```
func (x *Regexp) Equal(y *Regexp) bool
```

Equal returns true if *x* and *y* have identical structure.

func (*Regexp) [MaxCap](#)

```
func (re *Regexp) MaxCap() int
```

MaxCap walks the regexp to find the maximum capture index.

func (*Regex) [Simplify](#)

```
func (re *Regex) Simplify() *Regex
```

Simplify returns a regexp equivalent to re but without counted repetitions and with various other simplifications, such as rewriting `/(?:a+)+/` to `/a+/`. The resulting regexp will execute correctly but its string representation will not produce the same parse tree, because capturing parentheses may have been duplicated or removed. For example, the simplified form for `/(x){1,2}/` is `/(x)(x)?/` but both parentheses capture as `$1`. The returned regexp may share structure with or be the original.

func (*Regex) [String](#)

```
func (re *Regex) String() string
```

Overview ?

Overview ?

Package runtime contains operations that interact with Go's runtime system, such as functions to control goroutines. It also includes the low-level type information used by the reflect package; see reflect's documentation for the programmable interface to the run-time type system.

[zruntime_defs_linux_amd64.go](#) [zversion.go](#)

Constants

```
const Compiler = "gc"
```

Compiler is the name of the compiler toolchain that built the running binary.
Known toolchains are:

```
gc      The 5g/6g/8g compiler suite at code.google.com/p/go.  
gccgo   The gccgo front end, part of the GCC compiler suite.
```

```
const GOARCH string = theGoarch
```

GOARCH is the running program's architecture target: 386, amd64, or arm.

```
const GOOS string = theGoos
```

GOOS is the running program's operating system target: one of darwin, freebsd, linux, and so on.

Variables

```
var MemProfileRate int = 512 * 1024
```

MemProfileRate controls the fraction of memory allocations that are recorded and reported in the memory profile. The profiler aims to sample an average of one allocation per MemProfileRate bytes allocated.

To include every allocated block in the profile, set MemProfileRate to 1. To turn off profiling entirely, set MemProfileRate to 0.

The tools that process the memory profiles assume that the profile rate is constant across the lifetime of the program and equal to the current value. Programs that change the memory profiling rate should do so just once, as early as possible in the execution of the program (for example, at the beginning of main).

func Breakpoint

func Breakpoint()

Breakpoint() executes a breakpoint trap.

func [CPUProfile](#)

```
func CPUProfile() []byte
```

CPUProfile returns the next chunk of binary CPU profiling stack trace data, blocking until data is available. If profiling is turned off and all the profile data accumulated while it was on has been returned, CPUProfile returns nil. The caller must save the returned data before calling CPUProfile again. Most clients should use the runtime/pprof package or the testing package's `-test.cpuprofile` flag instead of calling CPUProfile directly.

func [Caller](#)

```
func Caller(skip int) (pc uintptr, file string, line int, ok bool)
```

Caller reports file and line number information about function invocations on the calling goroutine's stack. The argument skip is the number of stack frames to ascend, with 1 identifying the caller of Caller. (For historical reasons the meaning of skip differs between Caller and Callers.) The return values report the program counter, file name, and line number within the file of the corresponding call. The boolean ok is false if it was not possible to recover the information.

func [Callers](#)

```
func Callers(skip int, pc []uintptr) int
```

Callers fills the slice pc with the program counters of function invocations on the calling goroutine's stack. The argument skip is the number of stack frames to skip before recording in pc, with 0 starting at the caller of Callers. It returns the number of entries written to pc.

func [GC](#)

func GC()

GC runs a garbage collection.

func GOMAXPROCS

```
func GOMAXPROCS(n int) int
```

GOMAXPROCS sets the maximum number of CPUs that can be executing simultaneously and returns the previous setting. If $n < 1$, it does not change the current setting. The number of logical CPUs on the local machine can be queried with NumCPU. This call will go away when the scheduler improves.

func GOROOT

```
func GOROOT() string
```

GOROOT returns the root of the Go tree. It uses the GOROOT environment variable, if set, or else the root used during the Go build.

func [Goexit](#)

```
func Goexit()
```

Goexit terminates the goroutine that calls it. No other goroutine is affected. Goexit runs all deferred calls before terminating the goroutine.

func [GoroutineProfile](#)

```
func GoroutineProfile(p []StackRecord) (n int, ok bool)
```

GoroutineProfile returns n, the number of records in the active goroutine stack profile. If $\text{len}(p) \geq n$, GoroutineProfile copies the profile into p and returns n, true. If $\text{len}(p) < n$, GoroutineProfile does not change p and returns n, false.

Most clients should use the runtime/pprof package instead of calling GoroutineProfile directly.

func [Gosched](#)

```
func Gosched()
```

Gosched yields the processor, allowing other goroutines to run. It does not suspend the current goroutine, so execution resumes automatically.

func LockOSThread

```
func LockOSThread()
```

LockOSThread wires the calling goroutine to its current operating system thread. Until the calling goroutine exits or calls `UnlockOSThread`, it will always execute in that thread, and no other goroutine can.

func [MemProfile](#)

```
func MemProfile(p []MemProfileRecord, inuseZero bool) (n int, ok bool)
```

MemProfile returns n, the number of records in the current memory profile. If len(p) >= n, MemProfile copies the profile into p and returns n, true. If len(p) < n, MemProfile does not change p and returns n, false.

If inuseZero is true, the profile includes allocation records where r.AllocBytes > 0 but r.AllocBytes == r.FreeBytes. These are sites where memory was allocated, but it has all been released back to the runtime.

Most clients should use the runtime/pprof package or the testing package's -test.memprofile flag instead of calling MemProfile directly.

func [NumCPU](#)

```
func NumCPU() int
```

NumCPU returns the number of logical CPUs on the local machine.

func [NumCgoCall](#)

```
func NumCgoCall() int64
```

NumCgoCall returns the number of cgo calls made by the current process.

func [NumGoroutine](#)

```
func NumGoroutine() int
```

NumGoroutine returns the number of goroutines that currently exist.

func [ReadMemStats](#)

```
func ReadMemStats(m *MemStats)
```

ReadMemStats populates m with memory allocator statistics.

func [SetCPUProfileRate](#)

```
func SetCPUProfileRate(hz int)
```

SetCPUProfileRate sets the CPU profiling rate to hz samples per second. If hz ≤ 0 , SetCPUProfileRate turns off profiling. If the profiler is on, the rate cannot be changed without first turning it off. Most clients should use the runtime/pprof package or the testing package's -test.cpuprofile flag instead of calling SetCPUProfileRate directly.

func [SetFinalizer](#)

```
func SetFinalizer(x, f interface{})
```

SetFinalizer sets the finalizer associated with `x` to `f`. When the garbage collector finds an unreachable block with an associated finalizer, it clears the association and runs `f(x)` in a separate goroutine. This makes `x` reachable again, but now without an associated finalizer. Assuming that SetFinalizer is not called again, the next time the garbage collector sees that `x` is unreachable, it will free `x`.

SetFinalizer(`x`, nil) clears any finalizer associated with `x`.

The argument `x` must be a pointer to an object allocated by calling `new` or by taking the address of a composite literal. The argument `f` must be a function that takes a single argument of `x`'s type and can have arbitrary ignored return values. If either of these is not true, SetFinalizer aborts the program.

Finalizers are run in dependency order: if `A` points at `B`, both have finalizers, and they are otherwise unreachable, only the finalizer for `A` runs; once `A` is freed, the finalizer for `B` can run. If a cyclic structure includes a block with a finalizer, that cycle is not guaranteed to be garbage collected and the finalizer is not guaranteed to run, because there is no ordering that respects the dependencies.

The finalizer for `x` is scheduled to run at some arbitrary time after `x` becomes unreachable. There is no guarantee that finalizers will run before a program exits, so typically they are useful only for releasing non-memory resources associated with an object during a long-running program. For example, an `os.File` object could use a finalizer to close the associated operating system file descriptor when a program discards an `os.File` without calling `Close`, but it would be a mistake to depend on a finalizer to flush an in-memory I/O buffer such as a `bufio.Writer`, because the buffer would not be flushed at program exit.

A single goroutine runs all finalizers for a program, sequentially. If a finalizer must run for a long time, it should do so by starting a new goroutine.

func [Stack](#)

```
func Stack(buf []byte, all bool) int
```

Stack formats a stack trace of the calling goroutine into buf and returns the number of bytes written to buf. If all is true, Stack formats stack traces of all other goroutines into buf after the trace for the current goroutine.

func [ThreadCreateProfile](#)

```
func ThreadCreateProfile(p []StackRecord) (n int, ok bool)
```

ThreadCreateProfile returns n, the number of records in the thread creation profile. If $\text{len}(p) \geq n$, ThreadCreateProfile copies the profile into p and returns n, true. If $\text{len}(p) < n$, ThreadCreateProfile does not change p and returns n, false.

Most clients should use the runtime/pprof package instead of calling ThreadCreateProfile directly.

func [UnlockOSThread](#)

```
func UnlockOSThread()
```

UnlockOSThread unwires the calling goroutine from its fixed operating system thread. If the calling goroutine has not called LockOSThread, UnlockOSThread is a no-op.

func [Version](#)

```
func Version() string
```

Version returns the Go tree's version string. It is either a sequence number or, when possible, a release tag like "release.2010-03-04". A trailing + indicates that the tree had local modifications at the time of the build.

type [Error](#)

```
type Error interface {
    error

    // RuntimeError is a no-op function but
    // serves to distinguish types that are runtime
    // errors from ordinary errors: a type is a
    // runtime error if it has a RuntimeError method.
    RuntimeError()
}
```

The Error interface identifies a run time error.

type [Func](#)

```
type Func struct {  
    // contains filtered or unexported fields  
}
```

func [FuncForPC](#)

```
func FuncForPC(pc uintptr) *Func
```

FuncForPC returns a *Func describing the function that contains the given program counter address, or else nil.

func (*Func) [Entry](#)

```
func (f *Func) Entry() uintptr
```

Entry returns the entry address of the function.

func (*Func) [FileLine](#)

```
func (f *Func) FileLine(pc uintptr) (file string, line int)
```

FileLine returns the file name and line number of the source code corresponding to the program counter pc. The result will not be accurate if pc is not a program counter within f.

func (*Func) [Name](#)

```
func (f *Func) Name() string
```

Name returns the name of the function.

type [MemProfileRecord](#)

```
type MemProfileRecord struct {
    AllocBytes, FreeBytes    int64        // number of bytes allocat
    AllocObjects, FreeObjects int64        // number of objects alloc
    Stack0                  [32]uintptr // stack trace for this re
}
```

A MemProfileRecord describes the live objects allocated by a particular call sequence (stack trace).

func (*MemProfileRecord) [InUseBytes](#)

```
func (r *MemProfileRecord) InUseBytes() int64
```

InUseBytes returns the number of bytes in use (AllocBytes - FreeBytes).

func (*MemProfileRecord) [InUseObjects](#)

```
func (r *MemProfileRecord) InUseObjects() int64
```

InUseObjects returns the number of objects in use (AllocObjects - FreeObjects).

func (*MemProfileRecord) [Stack](#)

```
func (r *MemProfileRecord) Stack() []uintptr
```

Stack returns the stack trace associated with the record, a prefix of r.Stack0.

type [MemStats](#)

```
type MemStats struct {
    // General statistics.
    Alloc      uint64 // bytes allocated and still in use
    TotalAlloc uint64 // bytes allocated (even if freed)
    Sys        uint64 // bytes obtained from system (should be sum o
    Lookups    uint64 // number of pointer lookups
    Mallocs    uint64 // number of mallocs
    Frees      uint64

    // Main allocation heap statistics.
    HeapAlloc   uint64 // bytes allocated and still in use
    HeapSys     uint64 // bytes obtained from system
    HeapIdle    uint64 // bytes in idle spans
    HeapInuse   uint64 // bytes in non-idle span
    HeapReleased uint64 // bytes released to the OS
    HeapObjects uint64

    // Low-level fixed-size structure allocator statistics.
    // Inuse is bytes used now.
    // Sys is bytes obtained from system.
    StackInuse uint64 // bootstrap stacks
    StackSys   uint64
    MSpanInuse uint64 // mspan structures
    MSpanSys   uint64
    MCacheInuse uint64 // mcache structures
    MCacheSys   uint64
    BuckHashSys uint64

    // Garbage collector statistics.
    NextGC      uint64 // next run in HeapAlloc time (bytes)
    LastGC      uint64 // last run in absolute time (ns)
    PauseTotalNs uint64
    PauseNs     [256]uint64 // most recent GC pause times
    NumGC       uint32
    EnableGC    bool
    DebugGC     bool

    // Per-size allocation statistics.
    // 61 is NumSizeClasses in the C code.
    BySize [61]struct {
        Size      uint32
        Mallocs   uint64
        Frees     uint64
    }
}
```

A MemStats records statistics about the memory allocator.

type [StackRecord](#)

```
type StackRecord struct {  
    Stack0 [32]uintptr // stack trace for this record; ends at first  
}
```

A StackRecord describes a single execution stack.

func (*StackRecord) [Stack](#)

```
func (r *StackRecord) Stack() []uintptr
```

Stack returns the stack trace associated with the record, a prefix of r.Stack0.

type [TypeAssertionError](#)

```
type TypeAssertionError struct {  
    // contains filtered or unexported fields  
}
```

A TypeAssertionError explains a failed type assertion.

func (*TypeAssertionError) [Error](#)

```
func (e *TypeAssertionError) Error() string
```

func (*TypeAssertionError) [RuntimeError](#)

```
func (*TypeAssertionError) RuntimeError()
```

[func PrintStack\(\)](#)
[func Stack\(\) \[\]byte](#)

Package files

[stack.go](#)

func [PrintStack](#)

```
func PrintStack()
```

PrintStack prints to standard error the stack trace returned by Stack.

func [Stack](#)

```
func Stack() []byte
```

Stack returns a formatted stack trace of the goroutine that calls it. For each routine, it includes the source line information and PC value, then attempts to discover, for Go functions, the calling function or method and the text of the line containing the invocation.

Build version go1.0.1.

[Bugs](#)

Package files

[pprof.go](#)

func [Profiles](#)

```
func Profiles() []*Profile
```

Profiles returns a slice of all the known profiles, sorted by name.

func [StartCPUProfile](#)

```
func StartCPUProfile(w io.Writer) error
```

StartCPUProfile enables CPU profiling for the current process. While profiling, the profile will be buffered and written to w. StartCPUProfile returns an error if profiling is already enabled.

func [StopCPUProfile](#)

```
func StopCPUProfile()
```

StopCPUProfile stops the current CPU profile, if any. StopCPUProfile only returns after all the writes for the profile have completed.

func [WriteHeapProfile](#)

```
func WriteHeapProfile(w io.Writer) error
```

WriteHeapProfile is shorthand for `Lookup("heap").WriteTo(w, 0)`. It is preserved for backwards compatibility.

type [Profile](#)

```
type Profile struct {  
    // contains filtered or unexported fields  
}
```

A Profile is a collection of stack traces showing the call sequences that led to instances of a particular event, such as allocation. Packages can create and maintain their own profiles; the most common use is for tracking resources that must be explicitly closed, such as files or network connections.

A Profile's methods can be called from multiple goroutines simultaneously.

Each Profile has a unique name. A few profiles are predefined:

```
goroutine    - stack traces of all current goroutines  
heap         - a sampling of all heap allocations  
threadcreate - stack traces that led to the creation of new OS threa
```

These predefined profiles maintain themselves and panic on an explicit Add or Remove method call.

The CPU profile is not available as a Profile. It has a special API, the StartCPUProfile and StopCPUProfile functions, because it streams output to a writer during profiling.

func [Lookup](#)

```
func Lookup(name string) *Profile
```

Lookup returns the profile with the given name, or nil if no such profile exists.

func [NewProfile](#)

```
func NewProfile(name string) *Profile
```

NewProfile creates a new profile with the given name. If a profile with that name already exists, NewProfile panics. The convention is to use a 'import/path.' prefix to create separate name spaces for each package.

func (*Profile) [Add](#)

```
func (p *Profile) Add(value interface{}, skip int)
```

Add adds the current execution stack to the profile, associated with value. Add stores value in an internal map, so value must be suitable for use as a map key and will not be garbage collected until the corresponding call to Remove. Add panics if the profile already contains a stack for value.

The skip parameter has the same meaning as runtime.Caller's skip and controls where the stack trace begins. Passing skip=0 begins the trace in the function calling Add. For example, given this execution stack:

```
Add  
called from rpc.NewClient  
called from mypkg.Run  
called from main.main
```

Passing skip=0 begins the stack trace at the call to Add inside rpc.NewClient. Passing skip=1 begins the stack trace at the call to NewClient inside mypkg.Run.

func (*Profile) [Count](#)

```
func (p *Profile) Count() int
```

Count returns the number of execution stacks currently in the profile.

func (*Profile) [Name](#)

```
func (p *Profile) Name() string
```

Name returns this profile's name, which can be passed to Lookup to reobtain the profile.

func (*Profile) [Remove](#)

```
func (p *Profile) Remove(value interface{})
```

Remove removes the execution stack associated with value from the profile. It is a no-op if the value is not in the profile.

func (*Profile) [WriteTo](#)

```
func (p *Profile) WriteTo(w io.Writer, debug int) error
```

WriteTo writes a pprof-formatted snapshot of the profile to w. If a write to w returns an error, WriteTo returns that error. Otherwise, WriteTo returns nil.

The debug parameter enables additional output. Passing debug=0 prints only the hexadecimal addresses that pprof needs. Passing debug=1 adds comments translating addresses to function names and line numbers, so that a programmer can read the profile without tools.

The predefined profiles may assign meaning to other debug values; for example, when printing the "goroutine" profile, debug=2 means to print the goroutine stacks in the same form that a Go program uses when dying due to an unrecovered panic.

Bugs

A bug in the OS X Snow Leopard 64-bit kernel prevents CPU profiling from giving accurate results on that system.

Build version go1.0.1.

Examples

[Interface](#)

[Interface \(Reverse\)](#)
[Ints](#)

Package files

[search.go](#) [sort.go](#)

func [Float64s](#)

```
func Float64s(a []float64)
```

Float64s sorts a slice of float64s in increasing order.

func [Float64sAreSorted](#)

```
func Float64sAreSorted(a []float64) bool
```

Float64sAreSorted tests whether a slice of float64s is sorted in increasing order.

func [Ints](#)

```
func Ints(a []int)
```

Ints sorts a slice of ints in increasing order.

? Example

? Example

Code:

```
s := []int{5, 2, 6, 3, 1, 4} // unsorted
sort.Ints(s)
fmt.Println(s)
```

Output:

```
[1 2 3 4 5 6]
```

func IntsAreSorted

```
func IntsAreSorted(a []int) bool
```

IntsAreSorted tests whether a slice of ints is sorted in increasing order.

func IsSorted

```
func IsSorted(data Interface) bool
```

IsSorted reports whether data is sorted.

func [Search](#)

```
func Search(n int, f func(int) bool) int
```

Search uses binary search to find and return the smallest index i in $[0, n)$ at which $f(i)$ is true, assuming that on the range $[0, n)$, $f(i) == \text{true}$ implies $f(i+1) == \text{true}$. That is, Search requires that f is false for some (possibly empty) prefix of the input range $[0, n)$ and then true for the (possibly empty) remainder; Search returns the first true index. If there is no such index, Search returns n . Search calls $f(i)$ only for i in the range $[0, n)$.

A common use of Search is to find the index i for a value x in a sorted, indexable data structure such as an array or slice. In this case, the argument f , typically a closure, captures the value to be searched for, and how the data structure is indexed and ordered.

For instance, given a slice `data` sorted in ascending order, the call `Search(len(data), func(i int) bool { return data[i] >= 23 })` returns the smallest index i such that `data[i] >= 23`. If the caller wants to find whether 23 is in the slice, it must test `data[i] == 23` separately.

Searching data sorted in descending order would use the `<=` operator instead of the `>=` operator.

To complete the example above, the following code tries to find the value x in an integer slice `data` sorted in ascending order:

```
x := 23
i := sort.Search(len(data), func(i int) bool { return data[i] >= x })
if i < len(data) && data[i] == x {
    // x is present at data[i]
} else {
    // x is not present in data,
    // but i is the index where it would be inserted.
}
```

As a more whimsical example, this program guesses your number:

```
func GuessingGame() {
    var s string
    fmt.Printf("Pick an integer from 0 to 100.\n")
}
```

```
    answer := sort.Search(100, func(i int) bool {
        fmt.Printf("Is your number <= %d? ", i)
        fmt.Scanf("%s", &s)
        return s != "" && s[0] == 'y'
    })
    fmt.Printf("Your number is %d.\n", answer)
}
```

func [SearchFloat64s](#)

```
func SearchFloat64s(a []float64, x float64) int
```

SearchFloat64s searches for x in a sorted slice of float64s and returns the index as specified by Search. The slice must be sorted in ascending order.

func [SearchInts](#)

```
func SearchInts(a []int, x int) int
```

SearchInts searches for x in a sorted slice of ints and returns the index as specified by Search. The slice must be sorted in ascending order.

func [SearchStrings](#)

```
func SearchStrings(a []string, x string) int
```

SearchStrings searches for x slice a sorted slice of strings and returns the index as specified by Search. The slice must be sorted in ascending order.

func [Sort](#)

```
func Sort(data Interface)
```

Sort sorts data. It makes one call to data.Len to determine n, and $O(n \cdot \log(n))$ calls to data.Less and data.Swap. The sort is not guaranteed to be stable.

func Strings

```
func Strings(a []string)
```

Strings sorts a slice of strings in increasing order.

func StringsAreSorted

```
func StringsAreSorted(a []string) bool
```

StringsAreSorted tests whether a slice of strings is sorted in increasing order.

type [Float64Slice](#)

```
type Float64Slice []float64
```

Float64Slice attaches the methods of Interface to []float64, sorting in increasing order.

func (Float64Slice) [Len](#)

```
func (p Float64Slice) Len() int
```

func (Float64Slice) [Less](#)

```
func (p Float64Slice) Less(i, j int) bool
```

func (Float64Slice) [Search](#)

```
func (p Float64Slice) Search(x float64) int
```

Search returns the result of applying SearchFloat64s to the receiver and x.

func (Float64Slice) [Sort](#)

```
func (p Float64Slice) Sort()
```

Sort is a convenience method.

func (Float64Slice) [Swap](#)

```
func (p Float64Slice) Swap(i, j int)
```

type [IntSlice](#)

```
type IntSlice []int
```

IntSlice attaches the methods of Interface to []int, sorting in increasing order.

func (IntSlice) [Len](#)

```
func (p IntSlice) Len() int
```

func (IntSlice) [Less](#)

```
func (p IntSlice) Less(i, j int) bool
```

func (IntSlice) [Search](#)

```
func (p IntSlice) Search(x int) int
```

Search returns the result of applying SearchInts to the receiver and x.

func (IntSlice) [Sort](#)

```
func (p IntSlice) Sort()
```

Sort is a convenience method.

func (IntSlice) [Swap](#)

```
func (p IntSlice) Swap(i, j int)
```

type [Interface](#)

```
type Interface interface {
    // Len is the number of elements in the collection.
    Len() int
    // Less returns whether the element with index i should sort
    // before the element with index j.
    Less(i, j int) bool
    // Swap swaps the elements with indexes i and j.
    Swap(i, j int)
}
```

A type, typically a collection, that satisfies `sort.Interface` can be sorted by the routines in this package. The methods require that the elements of the collection be enumerated by an integer index.

? Example

? Example

Code:

```
package sort_test

import (
    "fmt"
    "sort"
)

type Grams int

func (g Grams) String() string { return fmt.Sprintf("%dg", int(g)) }

type Organ struct {
    Name    string
    Weight  Grams
}

type Organs []*Organ

func (s Organs) Len() int      { return len(s) }
func (s Organs) Swap(i, j int) { s[i], s[j] = s[j], s[i] }

// ByName implements sort.Interface by providing Less and using the
// Swap methods of the embedded Organs value.
```

```

type ByName struct{ Organs }

func (s ByName) Less(i, j int) bool { return s.Organs[i].Name < s.Or

// ByWeight implements sort.Interface by providing Less and using th
// Swap methods of the embedded Organs value.
type ByWeight struct{ Organs }

func (s ByWeight) Less(i, j int) bool { return s.Organs[i].Weight <

func ExampleInterface() {
    s := []*Organ{
        {"brain", 1340},
        {"heart", 290},
        {"liver", 1494},
        {"pancreas", 131},
        {"prostate", 62},
        {"spleen", 162},
    }

    sort.Sort(ByWeight{s})
    fmt.Println("Organs by weight:")
    printOrgans(s)

    sort.Sort(ByName{s})
    fmt.Println("Organs by name:")
    printOrgans(s)

    // Output:
    // Organs by weight:
    // prostate (62g)
    // pancreas (131g)
    // spleen (162g)
    // heart (290g)
    // brain (1340g)
    // liver (1494g)
    // Organs by name:
    // brain (1340g)
    // heart (290g)
    // liver (1494g)
    // pancreas (131g)
    // prostate (62g)
    // spleen (162g)
}

func printOrgans(s []*Organ) {
    for _, o := range s {
        fmt.Printf("%-8s (%v)\n", o.Name, o.Weight)
    }
}

```

```
}
```

? Example (Reverse)

? Example (Reverse)

Code:

```
package sort_test

import (
    "fmt"
    "sort"
)

// Reverse embeds a sort.Interface value and implements a reverse so
// that value.
type Reverse struct {
    // This embedded Interface permits Reverse to use the methods of
    // another Interface implementation.
    sort.Interface
}

// Less returns the opposite of the embedded implementation's Less m
func (r Reverse) Less(i, j int) bool {
    return r.Interface.Less(j, i)
}

func ExampleInterface_reverse() {
    s := []int{5, 2, 6, 3, 1, 4} // unsorted
    sort.Sort(Reverse{sort.IntSlice(s)})
    fmt.Println(s)
    // Output: [6 5 4 3 2 1]
}
```

type [StringSlice](#)

```
type StringSlice []string
```

StringSlice attaches the methods of Interface to []string, sorting in increasing order.

func (StringSlice) [Len](#)

```
func (p StringSlice) Len() int
```

func (StringSlice) [Less](#)

```
func (p StringSlice) Less(i, j int) bool
```

func (StringSlice) [Search](#)

```
func (p StringSlice) Search(x string) int
```

Search returns the result of applying SearchStrings to the receiver and x.

func (StringSlice) [Sort](#)

```
func (p StringSlice) Sort()
```

Sort is a convenience method.

func (StringSlice) [Swap](#)

```
func (p StringSlice) Swap(i, j int)
```

Build version go1.0.1.

Constants

```
const IntSize = intSize // number of bits in int, uint (32 or 64)
```

Variables

```
var ErrRange = errors.New("value out of range")
```

ErrRange indicates that a value is out of range for the target type.

```
var ErrSyntax = errors.New("invalid syntax")
```

ErrSyntax indicates that a value does not have the right syntax for the target type.

func AppendBool

```
func AppendBool(dst []byte, b bool) []byte
```

AppendBool appends "true" or "false", according to the value of b, to dst and returns the extended buffer.

func [AppendFloat](#)

```
func AppendFloat(dst []byte, f float64, fmt byte, prec int, bitSize
```

AppendFloat appends the string form of the floating-point number `f`, as generated by `FormatFloat`, to `dst` and returns the extended buffer.

func [AppendInt](#)

```
func AppendInt(dst []byte, i int64, base int) []byte
```

AppendInt appends the string form of the integer *i*, as generated by `FormatInt`, to *dst* and returns the extended buffer.

func [AppendQuote](#)

```
func AppendQuote(dst []byte, s string) []byte
```

AppendQuote appends a double-quoted Go string literal representing s, as generated by Quote, to dst and returns the extended buffer.

func [AppendQuoteRune](#)

```
func AppendQuoteRune(dst []byte, r rune) []byte
```

AppendQuoteRune appends a single-quoted Go character literal representing the rune, as generated by QuoteRune, to dst and returns the extended buffer.

func [AppendQuoteRuneToASCII](#)

```
func AppendQuoteRuneToASCII(dst []byte, r rune) []byte
```

AppendQuoteRune appends a single-quoted Go character literal representing the rune, as generated by QuoteRuneToASCII, to dst and returns the extended buffer.

func [AppendQuoteToASCII](#)

```
func AppendQuoteToASCII(dst []byte, s string) []byte
```

AppendQuoteToASCII appends a double-quoted Go string literal representing s, as generated by QuoteToASCII, to dst and returns the extended buffer.

func [AppendUint](#)

```
func AppendUint(dst []byte, i uint64, base int) []byte
```

AppendUint appends the string form of the unsigned integer *i*, as generated by `FormatUint`, to *dst* and returns the extended buffer.

func [Atoi](#)

```
func Atoi(s string) (i int, err error)
```

Atoi is shorthand for `ParseInt(s, 10, 0)`.

func [CanBackquote](#)

```
func CanBackquote(s string) bool
```

CanBackquote returns whether the string `s` would be a valid Go string literal if enclosed in backquotes.

func FormatBool

```
func FormatBool(b bool) string
```

FormatBool returns "true" or "false" according to the value of b

func [FormatFloat](#)

```
func FormatFloat(f float64, fmt byte, prec, bitSize int) string
```

FormatFloat converts the floating-point number `f` to a string, according to the format `fmt` and precision `prec`. It rounds the result assuming that the original was obtained from a floating-point value of `bitSize` bits (32 for float32, 64 for float64).

The format `fmt` is one of 'b' (-ddddpddd, a binary exponent), 'e' (-d.ddddedd, a decimal exponent), 'E' (-d.ddddEdd, a decimal exponent), 'f' (-ddd.dddd, no exponent), 'g' ('e' for large exponents, 'f' otherwise), or 'G' ('E' for large exponents, 'f' otherwise).

The precision `prec` controls the number of digits (excluding the exponent) printed by the 'e', 'E', 'f', 'g', and 'G' formats. For 'e', 'E', and 'f' it is the number of digits after the decimal point. For 'g' and 'G' it is the total number of digits. The special precision -1 uses the smallest number of digits necessary such that ParseFloat will return `f` exactly.

func [FormatInt](#)

```
func FormatInt(i int64, base int) string
```

FormatInt returns the string representation of i in the given base.

func [FormatUint](#)

```
func FormatUint(i uint64, base int) string
```

FormatUint returns the string representation of i in the given base.

func [IsPrint](#)

```
func IsPrint(r rune) bool
```

IsPrint reports whether the rune is defined as printable by Go, with the same definition as `unicode.IsPrint`: letters, numbers, punctuation, symbols and ASCII space.

func [Itoa](#)

```
func Itoa(i int) string
```

Itoa is shorthand for `FormatInt(i, 10)`.

func [ParseBool](#)

```
func ParseBool(str string) (value bool, err error)
```

ParseBool returns the boolean value represented by the string. It accepts 1, t, T, TRUE, true, True, 0, f, F, FALSE, false, False. Any other value returns an error.

func [ParseFloat](#)

```
func ParseFloat(s string, bitSize int) (f float64, err error)
```

ParseFloat converts the string `s` to a floating-point number with the precision specified by `bitSize`: 32 for `float32`, or 64 for `float64`. When `bitSize=32`, the result still has type `float64`, but it will be convertible to `float32` without changing its value.

If `s` is well-formed and near a valid floating point number, ParseFloat returns the nearest floating point number rounded using IEEE754 unbiased rounding.

The errors that ParseFloat returns have concrete type `*NumError` and include `err.Num = s`.

If `s` is not syntactically well-formed, ParseFloat returns `err.Error = ErrSyntax`.

If `s` is syntactically well-formed but is more than 1/2 ULP away from the largest floating point number of the given size, ParseFloat returns `f = Inf`, `err.Error = ErrRange`.

func [ParseInt](#)

```
func ParseInt(s string, base int, bitSize int) (i int64, err error)
```

ParseInt interprets a string `s` in the given base (2 to 36) and returns the corresponding value `i`. If `base == 0`, the base is implied by the string's prefix: base 16 for "0x", base 8 for "0", and base 10 otherwise.

The `bitSize` argument specifies the integer type that the result must fit into. Bit sizes 0, 8, 16, 32, and 64 correspond to `int`, `int8`, `int16`, `int32`, and `int64`.

The errors that ParseInt returns have concrete type `*NumError` and include `err.Num = s`. If `s` is empty or contains invalid digits, `err.Error = ErrSyntax`; if the value corresponding to `s` cannot be represented by a signed integer of the given size, `err.Error = ErrRange`.

func [ParseUint](#)

```
func ParseUint(s string, b int, bitSize int) (n uint64, err error)
```

ParseUint is like ParseInt but for unsigned numbers.

func [Quote](#)

```
func Quote(s string) string
```

Quote returns a double-quoted Go string literal representing s. The returned string uses Go escape sequences (`\t`, `\n`, `\xFF`, `\u0100`) for control characters and non-printable characters as defined by `IsPrint`.

func [QuoteRune](#)

```
func QuoteRune(r rune) string
```

QuoteRune returns a single-quoted Go character literal representing the rune. The returned string uses Go escape sequences (`\t`, `\n`, `\xFF`, `\u0100`) for control characters and non-printable characters as defined by `IsPrint`.

func QuoteRuneToASCII

```
func QuoteRuneToASCII(r rune) string
```

QuoteRuneToASCII returns a single-quoted Go character literal representing the rune. The returned string uses Go escape sequences (`\t`, `\n`, `\xFF`, `\u0100`) for non-ASCII characters and non-printable characters as defined by `IsPrint`.

func QuoteToASCII

```
func QuoteToASCII(s string) string
```

QuoteToASCII returns a double-quoted Go string literal representing s. The returned string uses Go escape sequences (`\t`, `\n`, `\xFF`, `\u0100`) for non-ASCII characters and non-printable characters as defined by `IsPrint`.

func [Unquote](#)

```
func Unquote(s string) (t string, err error)
```

Unquote interprets s as a single-quoted, double-quoted, or backquoted Go string literal, returning the string value that s quotes. (If s is single-quoted, it would be a Go character literal; Unquote returns the corresponding one-character string.)

func UnquoteChar

`func UnquoteChar(s string, quote byte) (value rune, multibyte bool,`

`UnquoteChar` decodes the first character or byte in the escaped string or character literal represented by the string `s`. It returns four values:

- 1) `value`, the decoded Unicode code point or byte value;
- 2) `multibyte`, a boolean indicating whether the decoded character requires a multibyte escape;
- 3) `tail`, the remainder of the string after the character; and
- 4) an error that will be `nil` if the character is syntactically valid.

The second argument, `quote`, specifies the type of literal being parsed and therefore which escaped quote character is permitted. If set to a single quote, it permits the sequence `\'` and disallows unescaped `'`. If set to a double quote, it permits `\"` and disallows unescaped `"`. If set to zero, it does not permit either escape and allows both quote characters to appear unescaped.

type [NumError](#)

```
type NumError struct {  
    Func string // the failing function (ParseBool, ParseInt, ParseU  
    Num  string // the input  
    Err  error   // the reason the conversion failed (ErrRange, ErrSy  
}
```

A NumError records a failed conversion.

func (*NumError) [Error](#)

```
func (e *NumError) Error() string
```

func Contains

func Contains(s, substr string) bool

Contains returns true if substr is within s.

? Example

? Example

Code:

```
fmt.Println(strings.Contains("seafood", "foo"))
fmt.Println(strings.Contains("seafood", "bar"))
fmt.Println(strings.Contains("seafood", ""))
fmt.Println(strings.Contains("", ""))
```

Output:

```
true
false
true
true
```

func ContainsAny

```
func ContainsAny(s, chars string) bool
```

ContainsAny returns true if any Unicode code points in chars are within s.

? Example

? Example

Code:

```
fmt.Println(strings.ContainsAny("team", "i"))  
fmt.Println(strings.ContainsAny("failure", "u & i"))  
fmt.Println(strings.ContainsAny("foo", ""))  
fmt.Println(strings.ContainsAny("", ""))
```

Output:

```
false  
true  
false  
false
```

func ContainsRune

```
func ContainsRune(s string, r rune) bool
```

ContainsRune returns true if the Unicode code point `r` is within `s`.

func [Count](#)

```
func Count(s, sep string) int
```

Count counts the number of non-overlapping instances of sep in s.

? Example

? Example

Code:

```
fmt.Println(strings.Count("cheese", "e"))  
fmt.Println(strings.Count("five", "")) // before & after each rune
```

Output:

```
3  
5
```

func [EqualFold](#)

```
func EqualFold(s, t string) bool
```

EqualFold reports whether s and t, interpreted as UTF-8 strings, are equal under Unicode case-folding.

? Example

? Example

Code:

```
fmt.Println(strings.EqualFold("Go", "go"))
```

Output:

```
true
```

func [Fields](#)

```
func Fields(s string) []string
```

Fields splits the string `s` around each instance of one or more consecutive white space characters, returning an array of substrings of `s` or an empty list if `s` contains only white space.

? Example

? Example

Code:

```
fmt.Printf("Fields are: %q", strings.Fields("  foo bar  baz  "))
```

Output:

```
Fields are: ["foo" "bar" "baz"]
```

func [FieldsFunc](#)

```
func FieldsFunc(s string, f func(rune) bool) []string
```

FieldsFunc splits the string `s` at each run of Unicode code points `c` satisfying `f(c)` and returns an array of slices of `s`. If all code points in `s` satisfy `f(c)` or the string is empty, an empty slice is returned.

func [HasPrefix](#)

```
func HasPrefix(s, prefix string) bool
```

HasPrefix tests whether the string `s` begins with `prefix`.

func [HasSuffix](#)

```
func HasSuffix(s, suffix string) bool
```

HasSuffix tests whether the string `s` ends with `suffix`.

func [Index](#)

func Index(s, sep string) int

Index returns the index of the first instance of sep in s, or -1 if sep is not present in s.

? Example

? Example

Code:

```
fmt.Println(strings.Index("chicken", "ken"))  
fmt.Println(strings.Index("chicken", "dmr"))
```

Output:

```
4  
-1
```

func [IndexAny](#)

```
func IndexAny(s, chars string) int
```

IndexAny returns the index of the first instance of any Unicode code point from chars in s, or -1 if no Unicode code point from chars is present in s.

func [IndexFunc](#)

```
func IndexFunc(s string, f func(rune) bool) int
```

IndexFunc returns the index into s of the first Unicode code point satisfying f(c), or -1 if none do.

func [IndexRune](#)

```
func IndexRune(s string, r rune) int
```

IndexRune returns the index of the first instance of the Unicode code point `r`, or `-1` if `rune` is not present in `s`.

? Example

? Example

Code:

```
fmt.Println(strings.IndexRune("chicken", 'k'))  
fmt.Println(strings.IndexRune("chicken", 'd'))
```

Output:

```
4  
-1
```

func [Join](#)

```
func Join(a []string, sep string) string
```

Join concatenates the elements of a to create a single string. The separator string sep is placed between elements in the resulting string.

? Example

? Example

Code:

```
s := []string{"foo", "bar", "baz"}  
fmt.Println(strings.Join(s, ", "))
```

Output:

```
foo, bar, baz
```

func [LastIndex](#)

```
func LastIndex(s, sep string) int
```

LastIndex returns the index of the last instance of sep in s, or -1 if sep is not present in s.

? Example

? Example

Code:

```
fmt.Println(strings.Index("go gopher", "go"))  
fmt.Println(strings.LastIndex("go gopher", "go"))  
fmt.Println(strings.LastIndex("go gopher", "rodent"))
```

Output:

```
0  
3  
-1
```

func [LastIndexAny](#)

```
func LastIndexAny(s, chars string) int
```

LastIndexAny returns the index of the last instance of any Unicode code point from chars in s, or -1 if no Unicode code point from chars is present in s.

func [LastIndexFunc](#)

```
func LastIndexFunc(s string, f func(rune) bool) int
```

LastIndexFunc returns the index into s of the last Unicode code point satisfying f(c), or -1 if none do.

func Map

```
func Map(mapping func(rune) rune, s string) string
```

Map returns a copy of the string `s` with all its characters modified according to the mapping function. If mapping returns a negative value, the character is dropped from the string with no replacement.

? Example

? Example

Code:

```
rot13 := func(r rune) rune {
    switch {
    case r >= 'A' && r <= 'Z':
        return 'A' + (r-'A'+13)%26
    case r >= 'a' && r <= 'z':
        return 'a' + (r-'a'+13)%26
    }
    return r
}
fmt.Println(strings.Map(rot13, "'Twas brillig and the slithy gopher.
```

Output:

```
'Gjnf oevyyvt naq gur fyvgul tbcure...
```

func Repeat

```
func Repeat(s string, count int) string
```

Repeat returns a new string consisting of count copies of the string s.

? Example

? Example

Code:

```
fmt.Println("ba" + strings.Repeat("na", 2))
```

Output:

banana

func [Replace](#)

```
func Replace(s, old, new string, n int) string
```

Replace returns a copy of the string `s` with the first `n` non-overlapping instances of `old` replaced by `new`. If `n < 0`, there is no limit on the number of replacements.

? Example

? Example

Code:

```
fmt.Println(strings.Replace("oink oink oink", "k", "ky", 2))  
fmt.Println(strings.Replace("oink oink oink", "oink", "moo", -1))
```

Output:

```
oinky oinky oink  
moo moo moo
```

func [Split](#)

```
func Split(s, sep string) []string
```

Split slices `s` into all substrings separated by `sep` and returns a slice of the substrings between those separators. If `sep` is empty, Split splits after each UTF-8 sequence. It is equivalent to SplitN with a count of -1.

? Example

? Example

Code:

```
fmt.Printf("%q\n", strings.Split("a,b,c", ","))
fmt.Printf("%q\n", strings.Split("a man a plan a canal panama", "a "))
fmt.Printf("%q\n", strings.Split(" xyz ", ""))
fmt.Printf("%q\n", strings.Split("", "Bernardo O'Higgins"))
```

Output:

```
["a" "b" "c"]
["" "man " "plan " "canal panama"]
[" " "x" "y" "z" " "]
[""]
```

func [SplitAfter](#)

```
func SplitAfter(s, sep string) []string
```

`SplitAfter` slices `s` into all substrings after each instance of `sep` and returns a slice of those substrings. If `sep` is empty, `SplitAfter` splits after each UTF-8 sequence. It is equivalent to `SplitAfterN` with a count of `-1`.

? Example

? Example

Code:

```
fmt.Printf("%q\n", strings.SplitAfter("a,b,c", ","))
```

Output:

```
["a," "b," "c"]
```

func [SplitAfterN](#)

```
func SplitAfterN(s, sep string, n int) []string
```

SplitAfterN slices s into substrings after each instance of sep and returns a slice of those substrings. If sep is empty, SplitAfterN splits after each UTF-8 sequence. The count determines the number of substrings to return:

n > 0: at most n substrings; the last substring will be the unsplit

n == 0: the result is nil (zero substrings)

n < 0: all substrings

? Example

? Example

Code:

```
fmt.Printf("%q\n", strings.SplitAfterN("a,b,c", ",", 2))
```

Output:

```
["a," "b,c"]
```

func [SplitN](#)

```
func SplitN(s, sep string, n int) []string
```

SplitN slices s into substrings separated by sep and returns a slice of the substrings between those separators. If sep is empty, SplitN splits after each UTF-8 sequence. The count determines the number of substrings to return:

n > 0: at most n substrings; the last substring will be the unsplit
n == 0: the result is nil (zero substrings)
n < 0: all substrings

? Example

? Example

Code:

```
fmt.Printf("%q\n", strings.SplitN("a,b,c", ",", 2))  
z := strings.SplitN("a,b,c", ",", 0)  
fmt.Printf("%q (nil = %v)\n", z, z == nil)
```

Output:

```
["a" "b,c"]  
[] (nil = true)
```

func [Title](#)

```
func Title(s string) string
```

Title returns a copy of the string `s` with all Unicode letters that begin words mapped to their title case.

? Example

? Example

Code:

```
fmt.Println(strings.Title("her royal highness"))
```

Output:

```
Her Royal Highness
```

func [ToLower](#)

```
func ToLower(s string) string
```

ToLower returns a copy of the string `s` with all Unicode letters mapped to their lower case.

? Example

? Example

Code:

```
fmt.Println(strings.ToLower("Gopher"))
```

Output:

```
gopher
```

func [ToLowerSpecial](#)

```
func ToLowerSpecial(_case unicode.SpecialCase, s string) string
```

ToLowerSpecial returns a copy of the string `s` with all Unicode letters mapped to their lower case, giving priority to the special casing rules.

func [ToTitle](#)

```
func ToTitle(s string) string
```

ToTitle returns a copy of the string s with all Unicode letters mapped to their title case.

? Example

? Example

Code:

```
fmt.Println(strings.ToTitle("loud noises"))  
fmt.Println(strings.ToTitle("ᵀ"))
```

Output:

```
LOUD NOISES
```

func [ToTitleSpecial](#)

```
func ToTitleSpecial(_case unicode.SpecialCase, s string) string
```

ToTitleSpecial returns a copy of the string `s` with all Unicode letters mapped to their title case, giving priority to the special casing rules.

func [ToUpper](#)

```
func ToUpper(s string) string
```

ToUpper returns a copy of the string `s` with all Unicode letters mapped to their upper case.

? Example

? Example

Code:

```
fmt.Println(strings.ToUpper("Gopher"))
```

Output:

```
GOPHER
```

func [ToUpperSpecial](#)

```
func ToUpperSpecial(_case unicode.SpecialCase, s string) string
```

ToUpperSpecial returns a copy of the string `s` with all Unicode letters mapped to their upper case, giving priority to the special casing rules.

func [Trim](#)

```
func Trim(s string, cutset string) string
```

Trim returns a slice of the string `s` with all leading and trailing Unicode code points contained in `cutset` removed.

? Example

? Example

Code:

```
fmt.Printf("[%q]", strings.Trim(" !!! Achtung !!! ", "! "))
```

Output:

```
["Achtung"]
```

func [TrimFunc](#)

```
func TrimFunc(s string, f func(rune) bool) string
```

TrimFunc returns a slice of the string s with all leading and trailing Unicode code points c satisfying f(c) removed.

func [TrimLeft](#)

```
func TrimLeft(s string, cutset string) string
```

TrimLeft returns a slice of the string s with all leading Unicode code points contained in cutset removed.

func [TrimLeftFunc](#)

```
func TrimLeftFunc(s string, f func(rune) bool) string
```

TrimLeftFunc returns a slice of the string `s` with all leading Unicode code points `c` satisfying `f(c)` removed.

func [TrimRight](#)

```
func TrimRight(s string, cutset string) string
```

TrimRight returns a slice of the string s, with all trailing Unicode code points contained in cutset removed.

func [TrimRightFunc](#)

```
func TrimRightFunc(s string, f func(rune) bool) string
```

TrimRightFunc returns a slice of the string s with all trailing Unicode code points c satisfying f(c) removed.

func [TrimSpace](#)

```
func TrimSpace(s string) string
```

TrimSpace returns a slice of the string s, with all leading and trailing white space removed, as defined by Unicode.

? Example

? Example

Code:

```
fmt.Println(strings.TrimSpace(" \t\n a lone gopher \n\t\r\n"))
```

Output:

```
a lone gopher
```

type [Reader](#)

```
type Reader struct {  
    // contains filtered or unexported fields  
}
```

A Reader implements the `io.Reader`, `io.ReaderAt`, `io.Seeker`, `io.ByteScanner`, and `io.RuneScanner` interfaces by reading from a string.

func [NewReader](#)

```
func NewReader(s string) *Reader
```

`NewReader` returns a new Reader reading from `s`. It is similar to `bytes.NewBufferString` but more efficient and read-only.

func (***Reader**) [Len](#)

```
func (r *Reader) Len() int
```

`Len` returns the number of bytes of the unread portion of the string.

func (***Reader**) [Read](#)

```
func (r *Reader) Read(b []byte) (n int, err error)
```

func (***Reader**) [ReadAt](#)

```
func (r *Reader) ReadAt(b []byte, off int64) (n int, err error)
```

func (***Reader**) [ReadByte](#)

```
func (r *Reader) ReadByte() (b byte, err error)
```

func (***Reader**) [ReadRune](#)

```
func (r *Reader) ReadRune() (ch rune, size int, err error)
```

func (***Reader**) [Seek](#)

```
func (r *Reader) Seek(offset int64, whence int) (int64, error)
```

Seek implements the io.Seeker interface.

func (*Reader) [UnreadByte](#)

```
func (r *Reader) UnreadByte() error
```

func (*Reader) [UnreadRune](#)

```
func (r *Reader) UnreadRune() error
```

type [Replacer](#)

```
type Replacer struct {  
    // contains filtered or unexported fields  
}
```

A Replacer replaces a list of strings with replacements.

func [NewReplacer](#)

```
func NewReplacer(oldnew ...string) *Replacer
```

NewReplacer returns a new Replacer from a list of old, new string pairs. Replacements are performed in order, without overlapping matches.

? Example

? Example

Code:

```
r := strings.NewReplacer("<", "&lt;", ">", "&gt;")  
fmt.Println(r.Replace("This is <b>HTML</b>!"))
```

Output:

```
This is &lt;b&gt;HTML&lt;/b&gt;!
```

func (*Replacer) [Replace](#)

```
func (r *Replacer) Replace(s string) string
```

Replace returns a copy of s with all replacements performed.

func (*Replacer) [WriteString](#)

```
func (r *Replacer) WriteString(w io.Writer, s string) (n int, err error)
```

WriteString writes s to w with all replacements performed.

Bugs

The rule Title uses for word boundaries does not handle Unicode punctuation properly.

Build version go1.0.1.

Package sync

```
import "sync"
```

[Overview](#)

[Index](#)

[Examples](#)

[Subdirectories](#)

Overview ?

Overview ?

Package sync provides basic synchronization primitives such as mutual exclusion locks. Other than the Once and WaitGroup types, most are intended for use by low-level library routines. Higher-level synchronization is better done via channels and communication.

Values containing the types defined in this package should not be copied.

Examples

[Once](#)

[WaitGroup](#)

Package files

[cond.go](#) [mutex.go](#) [once.go](#) [runtime.go](#) [rwmutex.go](#) [waitgroup.go](#)

type [Cond](#)

```
type Cond struct {  
    L Locker // held while observing or changing the condition  
    // contains filtered or unexported fields  
}
```

Cond implements a condition variable, a rendezvous point for goroutines waiting for or announcing the occurrence of an event.

Each Cond has an associated Locker L (often a *Mutex or *RWMutex), which must be held when changing the condition and when calling the Wait method.

func [NewCond](#)

```
func NewCond(l Locker) *Cond
```

NewCond returns a new Cond with Locker l.

func (***Cond**) [Broadcast](#)

```
func (c *Cond) Broadcast()
```

Broadcast wakes all goroutines waiting on c.

It is allowed but not required for the caller to hold c.L during the call.

func (***Cond**) [Signal](#)

```
func (c *Cond) Signal()
```

Signal wakes one goroutine waiting on c, if there is any.

It is allowed but not required for the caller to hold c.L during the call.

func (***Cond**) [Wait](#)

```
func (c *Cond) Wait()
```

Wait atomically unlocks c.L and suspends execution of the calling goroutine. After later resuming execution, Wait locks c.L before returning. Unlike in other systems, Wait cannot return unless awoken by Broadcast or Signal.

Because c.L is not locked when Wait first resumes, the caller typically cannot assume that the condition is true when Wait returns. Instead, the caller should Wait in a loop:

```
c.L.Lock()
for !condition() {
    c.Wait()
}
... make use of condition ...
c.L.Unlock()
```

type Locker

```
type Locker interface {  
    Lock()  
    Unlock()  
}
```

A Locker represents an object that can be locked and unlocked.

type [Mutex](#)

```
type Mutex struct {  
    // contains filtered or unexported fields  
}
```

A Mutex is a mutual exclusion lock. Mutexes can be created as part of other structures; the zero value for a Mutex is an unlocked mutex.

func (*Mutex) [Lock](#)

```
func (m *Mutex) Lock()
```

Lock locks m. If the lock is already in use, the calling goroutine blocks until the mutex is available.

func (*Mutex) [Unlock](#)

```
func (m *Mutex) Unlock()
```

Unlock unlocks m. It is a run-time error if m is not locked on entry to Unlock.

A locked Mutex is not associated with a particular goroutine. It is allowed for one goroutine to lock a Mutex and then arrange for another goroutine to unlock it.

type [Once](#)

```
type Once struct {  
    // contains filtered or unexported fields  
}
```

Once is an object that will perform exactly one action.

? Example

? Example

Code:

```
var once sync.Once  
onceBody := func() {  
    fmt.Printf("Only once\n")  
}  
done := make(chan bool)  
for i := 0; i < 10; i++ {  
    go func() {  
        once.Do(onceBody)  
        done <- true  
    }()  
}  
for i := 0; i < 10; i++ {  
    <-done  
}
```

Output:

Only once

func (*Once) [Do](#)

```
func (o *Once) Do(f func())
```

Do calls the function f if and only if the method is being called for the first time with this receiver. In other words, given

```
var once Once
```

if `once.Do(f)` is called multiple times, only the first call will invoke f, even if f

has a different value in each invocation. A new instance of `Once` is required for each function to execute.

`Do` is intended for initialization that must be run exactly once. Since `f` is niladic, it may be necessary to use a function literal to capture the arguments to a function to be invoked by `Do`:

```
config.once.Do(func() { config.init(filename) })
```

Because no call to `Do` returns until the one call to `f` returns, if `f` causes `Do` to be called, it will deadlock.

type [RWMutex](#)

```
type RWMutex struct {  
    // contains filtered or unexported fields  
}
```

An RWMutex is a reader/writer mutual exclusion lock. The lock can be held by an arbitrary number of readers or a single writer. RWMutexes can be created as part of other structures; the zero value for a RWMutex is an unlocked mutex.

func (*RWMutex) [Lock](#)

```
func (rw *RWMutex) Lock()
```

Lock locks rw for writing. If the lock is already locked for reading or writing, Lock blocks until the lock is available. To ensure that the lock eventually becomes available, a blocked Lock call excludes new readers from acquiring the lock.

func (*RWMutex) [RLock](#)

```
func (rw *RWMutex) RLock()
```

RLock locks rw for reading.

func (*RWMutex) [RLocker](#)

```
func (rw *RWMutex) RLocker() Locker
```

RLocker returns a Locker interface that implements the Lock and Unlock methods by calling rw.RLock and rw.RUnlock.

func (*RWMutex) [RUnlock](#)

```
func (rw *RWMutex) RUnlock()
```

RUnlock undoes a single RLock call; it does not affect other simultaneous readers. It is a run-time error if rw is not locked for reading on entry to RUnlock.

func (*RWMutex) [Unlock](#)

```
func (rw *RWMutex) Unlock()
```

Unlock unlocks rw for writing. It is a run-time error if rw is not locked for writing on entry to Unlock.

As with Mutexes, a locked RWMutex is not associated with a particular goroutine. One goroutine may RLock (Lock) an RWMutex and then arrange for another goroutine to RUnlock (Unlock) it.

type [WaitGroup](#)

```
type WaitGroup struct {  
    // contains filtered or unexported fields  
}
```

A `WaitGroup` waits for a collection of goroutines to finish. The main goroutine calls `Add` to set the number of goroutines to wait for. Then each of the goroutines runs and calls `Done` when finished. At the same time, `Wait` can be used to block until all goroutines have finished.

? Example

? Example

This example fetches several URLs concurrently, using a `WaitGroup` to block until all the fetches are complete.

Code:

```
var wg sync.WaitGroup  
var urls = []string{  
    "http://www.golang.org/",  
    "http://www.google.com/",  
    "http://www.somestupidname.com/",  
}  
for _, url := range urls {  
    // Increment the WaitGroup counter.  
    wg.Add(1)  
    // Launch a goroutine to fetch the URL.  
    go func(url string) {  
        // Fetch the URL.  
        http.Get(url)  
        // Decrement the counter.  
        wg.Done()  
    }(url)  
}  
// Wait for all HTTP fetches to complete.  
wg.Wait()
```

func (*[WaitGroup](#)) [Add](#)

```
func (wg *WaitGroup) Add(delta int)
```

Add adds delta, which may be negative, to the WaitGroup counter. If the counter becomes zero, all goroutines blocked on Wait() are released.

func (*WaitGroup) [Done](#)

```
func (wg *WaitGroup) Done()
```

Done decrements the WaitGroup counter.

func (*WaitGroup) [Wait](#)

```
func (wg *WaitGroup) Wait()
```

Wait blocks until the WaitGroup counter is zero.

Package atomic

```
import "sync/atomic"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `atomic` provides low-level atomic memory primitives useful for implementing synchronization algorithms.

These functions require great care to be used correctly. Except for special, low-level applications, synchronization is better done with channels or the facilities of the `sync` package. Share memory by communicating; don't communicate by sharing memory.

The compare-and-swap operation, implemented by the `CompareAndSwapT` functions, is the atomic equivalent of:

```
if *val == old {
    *val = new
    return true
}
return false
```

func [AddInt32](#)

```
func AddInt32(val *int32, delta int32) (new int32)
```

AddInt32 atomically adds delta to *val and returns the new value.

func [AddInt64](#)

```
func AddInt64(val *int64, delta int64) (new int64)
```

AddInt64 atomically adds delta to *val and returns the new value.

func [AddUint32](#)

```
func AddUint32(val *uint32, delta uint32) (new uint32)
```

AddUint32 atomically adds delta to *val and returns the new value.

func [AddUint64](#)

```
func AddUint64(val *uint64, delta uint64) (new uint64)
```

AddUint64 atomically adds delta to *val and returns the new value.

func [AddUintptr](#)

```
func AddUintptr(val *uintptr, delta uintptr) (new uintptr)
```

AddUintptr atomically adds delta to *val and returns the new value.

func [CompareAndSwapInt32](#)

```
func CompareAndSwapInt32(val *int32, old, new int32) (swapped bool)
```

CompareAndSwapInt32 executes the compare-and-swap operation for an int32 value.

func [CompareAndSwapInt64](#)

```
func CompareAndSwapInt64(val *int64, old, new int64) (swapped bool)
```

CompareAndSwapInt64 executes the compare-and-swap operation for an int64 value.

func CompareAndSwapPointer

```
func CompareAndSwapPointer(val *unsafe.Pointer, old, new unsafe.Poin
```

CompareAndSwapPointer executes the compare-and-swap operation for a `unsafe.Pointer` value.

func [CompareAndSwapUint32](#)

`func CompareAndSwapUint32(val *uint32, old, new uint32) (swapped bool)`

`CompareAndSwapUint32` executes the compare-and-swap operation for a `uint32` value.

func [CompareAndSwapUint64](#)

```
func CompareAndSwapUint64(val *uint64, old, new uint64) (swapped bool)
```

CompareAndSwapUint64 executes the compare-and-swap operation for a uint64 value.

func CompareAndSwapUintptr

```
func CompareAndSwapUintptr(val *uintptr, old, new uintptr) (swapped
```

CompareAndSwapUintptr executes the compare-and-swap operation for a uintptr value.

func LoadInt32

```
func LoadInt32(addr *int32) (val int32)
```

LoadInt32 atomically loads *addr.

func [LoadInt64](#)

```
func LoadInt64(addr *int64) (val int64)
```

LoadInt64 atomically loads *addr.

func LoadPointer

```
func LoadPointer(addr *unsafe.Pointer) (val unsafe.Pointer)
```

LoadPointer atomically loads *addr.

func [LoadUint32](#)

```
func LoadUint32(addr *uint32) (val uint32)
```

LoadUint32 atomically loads *addr.

func [LoadUint64](#)

```
func LoadUint64(addr *uint64) (val uint64)
```

LoadUint64 atomically loads *addr.

func LoadUintptr

```
func LoadUintptr(addr *uintptr) (val uintptr)
```

LoadUintptr atomically loads *addr.

func [StoreInt32](#)

```
func StoreInt32(addr *int32, val int32)
```

StoreInt32 atomically stores val into *addr.

func [StoreInt64](#)

```
func StoreInt64(addr *int64, val int64)
```

StoreInt64 atomically stores val into *addr.

func StorePointer

```
func StorePointer(addr *unsafe.Pointer, val unsafe.Pointer)
```

StorePointer atomically stores val into *addr.

func [StoreUint32](#)

```
func StoreUint32(addr *uint32, val uint32)
```

StoreUint32 atomically stores val into *addr.

func [StoreUint64](#)

```
func StoreUint64(addr *uint64, val uint64)
```

StoreUint64 atomically stores val into *addr.

func [StoreUintptr](#)

```
func StoreUintptr(addr *uintptr, val uintptr)
```

StoreUintptr atomically stores val into *addr.

Bugs

On ARM, the 64-bit functions use instructions unavailable before ARM 11.

On x86-32, the 64-bit functions use instructions unavailable before the Pentium MMX.

Build version go1.0.1.

Package syscall

```
import "syscall"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `syscall` contains an interface to the low-level operating system primitives. The details vary depending on the underlying system. Its primary use is inside other packages that provide a more portable interface to the system, such as `"os"`, `"time"` and `"net"`. Use those packages rather than this one if you can. For details of the functions and data types in this package consult the manuals for the appropriate operating system. These calls return `err == nil` to indicate success; otherwise `err` is an operating system error describing the failure. On most systems, that error has type `syscall.Errno`.

```
var (  
    Stdin  = 0  
    Stdout = 1  
    Stderr = 2  
)  
  
var ForkLock sync.RWMutex  
  
var SocketDisableIPv6 bool
```

For testing: clients can set this flag to force creation of IPv6 sockets to return EAFNOSUPPORT.

func [Accept](#)

```
func Accept(fd int) (nfd int, sa Sockaddr, err error)
```

func [Access](#)

```
func Access(path string, mode uint32) (err error)
```

func [Acct](#)

```
func Acct(path string) (err error)
```

func [Adjtimex](#)

```
func Adjtimex(buf *Timex) (state int, err error)
```

func [AttachLsf](#)

```
func AttachLsf(fd int, i []SockFilter) error
```

func [Bind](#)

```
func Bind(fd int, sa Sockaddr) (err error)
```

func [BindToDevice](#)

```
func BindToDevice(fd int, device string) (err error)
```

BindToDevice binds the socket associated with fd to device.

func [Chdir](#)

```
func Chdir(path string) (err error)
```

func [Chmod](#)

```
func Chmod(path string, mode uint32) (err error)
```

func [Chown](#)

```
func Chown(path string, uid int, gid int) (err error)
```

func [Chroot](#)

```
func Chroot(path string) (err error)
```

func [Clearenv](#)

func Clearenv()

func Close

```
func Close(fd int) (err error)
```

func CloseOnExec

```
func CloseOnExec(fd int)
```

func CmsgLen

```
func CmsgLen(dataLen int) int
```

CmsgLen returns the value to store in the Len field of the CmsgHdr structure, taking into account any necessary alignment.

func CmsgSpace

```
func CmsgSpace(dataLen int) int
```

CmsgSpace returns the number of bytes an ancillary element with payload of the passed data length occupies.

func [Connect](#)

```
func Connect(fd int, sa Sockaddr) (err error)
```

func [Creat](#)

```
func Creat(path string, mode uint32) (fd int, err error)
```

func DetachLsf

func DetachLsf(fd int) error

func Dup

```
func Dup(oldfd int) (fd int, err error)
```

func Dup2

```
func Dup2(oldfd int, newfd int) (err error)
```

func Environ

```
func Environ() []string
```

func EpollCreate

```
func EpollCreate(size int) (fd int, err error)
```

func [EpollCreate1](#)

```
func EpollCreate1(flag int) (fd int, err error)
```

func [EpollCtl](#)

```
func EpollCtl(epfd int, op int, fd int, event *EpollEvent) (err error)
```

func [EpollWait](#)

```
func EpollWait(epfd int, events []EpollEvent, msec int) (n int, err
```

func [Exec](#)

```
func Exec(argv0 string, argv []string, envv []string) (err error)
```

Ordinary exec.

func [Exit](#)

```
func Exit(code int)
```

func [Faccessat](#)

func Faccessat(dirfd int, path string, mode uint32, flags int) (err

func Fallocate

func Fallocate(fd int, mode uint32, off int64, len int64) (err error)

func [Fchdir](#)

```
func Fchdir(fd int) (err error)
```

func [Fchmod](#)

func Fchmod(fd int, mode uint32) (err error)

func [Fchmodat](#)

`func Fchmodat(dirfd int, path string, mode uint32, flags int) (err e`

func [Fchown](#)

```
func Fchown(fd int, uid int, gid int) (err error)
```

func [Fchownat](#)

```
func Fchownat(dirfd int, path string, uid int, gid int, flags int) (
```

func [Fdatasync](#)

```
func Fdatasync(fd int) (err error)
```

func Flock

```
func Flock(fd int, how int) (err error)
```

func [ForkExec](#)

```
func ForkExec(argv0 string, argv []string, attr *ProcAttr) (pid int,
```

Combination of fork and exec, careful to be thread safe.

func Fstat

```
func Fstat(fd int, stat *Stat_t) (err error)
```

func [Fstatfs](#)

func Fstatfs(fd int, buf *Statfs_t) (err error)

func [Fsync](#)

```
func Fsync(fd int) (err error)
```

func [Ftruncate](#)

```
func Ftruncate(fd int, length int64) (err error)
```

func Futimes

```
func Futimes(fd int, tv []Timeval) (err error)
```

func [Futimesat](#)

```
func Futimesat(dirfd int, path string, tv []Timeval) (err error)
```

```
sys futimesat(dirfd int, path *byte, times *[2]Timeval) (err error)
```

func [Getcwd](#)

```
func Getcwd(buf []byte) (n int, err error)
```

func [Getdents](#)

```
func Getdents(fd int, buf []byte) (n int, err error)
```

func [Getegid](#)

```
func Getegid() (egid int)
```

func [Getenv](#)

```
func Getenv(key string) (value string, found bool)
```

func Geteuid

```
func Geteuid() (euid int)
```

func [Getgid](#)

```
func Getgid() (gid int)
```

func Getgroups

```
func Getgroups() (gids []int, err error)
```

func [Getpagesize](#)

```
func Getpagesize() int
```

func [Getpgid](#)

```
func Getpgid(pid int) (pgid int, err error)
```

func [Getpgrp](#)

```
func Getpgrp() (pid int)
```

func [Getpid](#)

```
func Getpid() (pid int)
```

func [Getppid](#)

```
func Getppid() (ppid int)
```

func [Getrlimit](#)

```
func Getrlimit(resource int, rlim *Rlimit) (err error)
```

func Getrusage

```
func Getrusage(who int, rusage *Rusage) (err error)
```

func [GetsockoptInet4Addr](#)

func GetsockoptInet4Addr(fd, level, opt int) (value [4]byte, err error)

func [GetsockoptInt](#)

```
func GetsockoptInt(fd, level, opt int) (value int, err error)
```

func [Gettid](#)

```
func Gettid() (tid int)
```

func [Gettimeofday](#)

```
func Gettimeofday(tv *Timeval) (err error)
```

func Getuid

```
func Getuid() (uid int)
```

func [Getwd](#)

func Getwd() (wd string, err error)

sys Getcwd(buf []byte) (n int, err error)

func InotifyAddWatch

```
func InotifyAddWatch(fd int, pathname string, mask uint32) (watchdes
```

func InotifyInit

```
func InotifyInit() (fd int, err error)
```

func [InotifyInit1](#)

```
func InotifyInit1(flags int) (fd int, err error)
```

func InotifyRmWatch

```
func InotifyRmWatch(fd int, watchdesc uint32) (success int, err error)
```

func Ioperm

```
func Ioperm(from int, num int, on int) (err error)
```

func Iopl

```
func Iopl(level int) (err error)
```

func [Kill](#)

```
func Kill(pid int, sig Signal) (err error)
```

func [Klogctl](#)

```
func Klogctl(typ int, buf []byte) (n int, err error)
```

func [Lchown](#)

```
func Lchown(path string, uid int, gid int) (err error)
```

func [Link](#)

```
func Link(oldpath string, newpath string) (err error)
```

func Listen

```
func Listen(s int, n int) (err error)
```

func [LsfSocket](#)

```
func LsfSocket(ifindex, proto int) (int, error)
```

func Lstat

```
func Lstat(path string, stat *Stat_t) (err error)
```

func [Madvise](#)

```
func Madvise(b []byte, advice int) (err error)
```

func [Mkdir](#)

```
func Mkdir(path string, mode uint32) (err error)
```

func [Mkdirat](#)

```
func Mkdirat(dirfd int, path string, mode uint32) (err error)
```

func [Mkfifo](#)

```
func Mkfifo(path string, mode uint32) (err error)
```

func [Mknod](#)

```
func Mknod(path string, mode uint32, dev int) (err error)
```

func [Mknodat](#)

```
func Mknodat(dirfd int, path string, mode uint32, dev int) (err error)
```

func Mlock

```
func Mlock(b []byte) (err error)
```

func Mlockall

func Mlockall(flags int) (err error)

func [Mmap](#)

func Mmap(fd int, offset int64, length int, prot int, flags int) (da

func [Mount](#)

```
func Mount(source string, target string, fstype string, flags uintpt
```

```
sys mount(source string, target string, fstype string, flags uintptr, data *byte) (err  
error)
```

func [Mprotect](#)

```
func Mprotect(b []byte, prot int) (err error)
```

func [Munlock](#)

```
func Munlock(b []byte) (err error)
```

func [Munlockall](#)

func Munlockall() (err error)

func [Munmap](#)

func Munmap(b []byte) (err error)

func [Nanosleep](#)

```
func Nanosleep(time *Timespec, leftover *Timespec) (err error)
```

func [NetlinkRIB](#)

```
func NetlinkRIB(proto, family int) ([]byte, error)
```

NetlinkRIB returns routing information base, as known as RIB, which consists of network facility information, states and parameters.

func [Open](#)

```
func Open(path string, mode int, perm uint32) (fd int, err error)
```

```
sys open(path string, mode int, perm uint32) (fd int, err error)
```

func [Openat](#)

```
func Openat(dirfd int, path string, flags int, mode uint32) (fd int,  
sys openat(dirfd int, path string, flags int, mode uint32) (fd int, err error)
```

func ParseDirent

```
func ParseDirent(buf []byte, max int, names []string) (consumed int,
```

func ParseNetlinkMessage

```
func ParseNetlinkMessage(buf []byte) ([]NetlinkMessage, error)
```

ParseNetlinkMessage parses buf as netlink messages and returns the slice containing the NetlinkMessage structs.

func ParseNetlinkRouteAttr

```
func ParseNetlinkRouteAttr(msg *NetlinkMessage) ([]NetlinkRouteAttr,
```

ParseNetlinkRouteAttr parses msg's payload as netlink route attributes and returns the slice containing the NetlinkRouteAttr structs.

func ParseSocketControlMessage

```
func ParseSocketControlMessage(buf []byte) ([]SocketControlMessage,
```

func [ParseUnixRights](#)

```
func ParseUnixRights(msg *SocketControlMessage) ([]int, error)
```

ParseUnixRights decodes a socket control message that contains an integer array of open file descriptors from another process.

func Pause

func Pause() (err error)

func [Pipe](#)

func Pipe(p []int) (err error)

sysnb pipe(p *[2]_C_int) (err error)

func PivotRoot

```
func PivotRoot(newroot string, putold string) (err error)
```

func Pread

```
func Pread(fd int, p []byte, offset int64) (n int, err error)
```

func PtraceAttach

func PtraceAttach(pid int) (err error)

func [PtraceCont](#)

```
func PtraceCont(pid int, signal int) (err error)
```

func [PtraceDetach](#)

```
func PtraceDetach(pid int) (err error)
```

func [PtraceGetEventMsg](#)

```
func PtraceGetEventMsg(pid int) (msg uint, err error)
```

func [PtraceGetRegs](#)

```
func PtraceGetRegs(pid int, regsout *PtraceRegs) (err error)
```

func PtracePeekData

```
func PtracePeekData(pid int, addr uintptr, out []byte) (count int, e
```

func PtracePeekText

```
func PtracePeekText(pid int, addr uintptr, out []byte) (count int, e
```

func PtracePokeData

```
func PtracePokeData(pid int, addr uintptr, data []byte) (count int,
```

func PtracePokeText

```
func PtracePokeText(pid int, addr uintptr, data []byte) (count int,
```

func PtraceSetOptions

```
func PtraceSetOptions(pid int, options int) (err error)
```

func [PtraceSetRegs](#)

```
func PtraceSetRegs(pid int, regs *PtraceRegs) (err error)
```

func [PtraceSingleStep](#)

```
func PtraceSingleStep(pid int) (err error)
```

func [Pwrite](#)

```
func Pwrite(fd int, p []byte, offset int64) (n int, err error)
```

func [RawSyscall](#)

```
func RawSyscall(trap, a1, a2, a3 uintptr) (r1, r2 uintptr, err Errno
```

func [RawSyscall6](#)

```
func RawSyscall6(trap, a1, a2, a3, a4, a5, a6 uintptr) (r1, r2 uintptr)
```

func Read

```
func Read(fd int, p []byte) (n int, err error)
```

func [ReadDirent](#)

```
func ReadDirent(fd int, buf []byte) (n int, err error)
```

func [Readlink](#)

```
func Readlink(path string, buf []byte) (n int, err error)
```

func [Reboot](#)

```
func Reboot(cmd int) (err error)
```

```
sys reboot(magic1 uint, magic2 uint, cmd int, arg string) (err error)
```

func Recvfrom

func Recvfrom(fd int, p []byte, flags int) (n int, from Sockaddr, err error)

func Recvmsg

func Recvmsg(fd int, p, oob []byte, flags int) (n, oobn int, recvfla

func [Rename](#)

```
func Rename(oldpath string, newpath string) (err error)
```

func [Renameat](#)

```
func Renameat(olddirfd int, oldpath string, newdirfd int, newpath st
```

func [Rmdir](#)

```
func Rmdir(path string) (err error)
```

func [Seek](#)

```
func Seek(fd int, offset int64, whence int) (off int64, err error)
```

func [Select](#)

```
func Select(nfd int, r *FdSet, w *FdSet, e *FdSet, timeout *Timeval)
```

func [Sendfile](#)

```
func Sendfile(outfd int, infd int, offset *int64, count int) (writte
```

func [Sendmsg](#)

func Sendmsg(fd int, p, oob []byte, to Sockaddr, flags int) (err err

func [Sendto](#)

```
func Sendto(fd int, p []byte, flags int, to Sockaddr) (err error)
```

func [SetLsfPromisc](#)

```
func SetLsfPromisc(name string, m bool) error
```

func [SetNonblock](#)

```
func SetNonblock(fd int, nonblocking bool) (err error)
```

func [Setdomainname](#)

func Setdomainname(p []byte) (err error)

func [Setenv](#)

func Setenv(key, value string) error

func [Setfsgid](#)

```
func Setfsgid(gid int) (err error)
```

func [Setfsuid](#)

```
func Setfsuid(uid int) (err error)
```

func [Setgid](#)

```
func Setgid(gid int) (err error)
```

func Setgroups

```
func Setgroups(gids []int) (err error)
```

func [Sethostname](#)

```
func Sethostname(p []byte) (err error)
```

func [Setpgid](#)

func Setpgid(pid int, pgid int) (err error)

func [Setregid](#)

```
func Setregid(rgid int, egid int) (err error)
```

func [Setresgid](#)

func Setresgid(rgid int, egid int, sgid int) (err error)

func [Setresuid](#)

```
func Setresuid(ruid int, euid int, suid int) (err error)
```

func [Setreuid](#)

```
func Setreuid(ruid int, euid int) (err error)
```

func [Setrlimit](#)

```
func Setrlimit(resource int, rlim *Rlimit) (err error)
```

func [Setsid](#)

```
func Setsid() (pid int, err error)
```

func [SetsockoptIPMreq](#)

```
func SetsockoptIPMreq(fd, level, opt int, mreq *IPMreq) (err error)
```

func [SetsockoptIPMreqn](#)

```
func SetsockoptIPMreqn(fd, level, opt int, mreq *IPMreqn) (err error
```

func [SetsockoptIPv6Mreq](#)

```
func SetsockoptIPv6Mreq(fd, level, opt int, mreq *IPv6Mreq) (err err
```

func [SetsockoptInet4Addr](#)

func SetsockoptInet4Addr(fd, level, opt int, value [4]byte) (err err

func [SetsockoptInt](#)

```
func SetsockoptInt(fd, level, opt int, value int) (err error)
```

func [SetsockoptLinger](#)

```
func SetsockoptLinger(fd, level, opt int, l *Linger) (err error)
```

func [SetsockoptString](#)

```
func SetsockoptString(fd, level, opt int, s string) (err error)
```

func [SetsockoptTimeval](#)

```
func SetsockoptTimeval(fd, level, opt int, tv *Timeval) (err error)
```

func [Settimeofday](#)

```
func Settimeofday(tv *Timeval) (err error)
```

func [Setuid](#)

```
func Setuid(uid int) (err error)
```

func Shutdown

```
func Shutdown(fd int, how int) (err error)
```

func [Socket](#)

```
func Socket(domain, typ, proto int) (fd int, err error)
```

func [Socketpair](#)

```
func Socketpair(domain, typ, proto int) (fd [2]int, err error)
```

func [Splice](#)

```
func Splice(rfd int, roff *int64, wfd int, woff *int64, len int, fla
```

func [StartProcess](#)

```
func StartProcess(argv0 string, argv []string, attr *ProcAttr) (pid
```

StartProcess wraps ForkExec for package os.

func [Stat](#)

```
func Stat(path string, stat *Stat_t) (err error)
```

func [Statfs](#)

```
func Statfs(path string, buf *Statfs_t) (err error)
```

func [StringBytePtr](#)

```
func StringBytePtr(s string) *byte
```

StringBytePtr returns a pointer to a NUL-terminated array of bytes containing the text of s.

func [StringByteSlice](#)

```
func StringByteSlice(s string) []byte
```

StringByteSlice returns a NUL-terminated slice of bytes containing the text of s.

func [StringSlicePtr](#)

```
func StringSlicePtr(ss []string) []*byte
```

Convert array of string to array of NUL-terminated byte pointer.

func [SymLink](#)

```
func SymLink(oldpath string, newpath string) (err error)
```

func Sync

func Sync()

func SyncFileRange

func SyncFileRange(fd int, off int64, n int64, flags int) (err error

func Syscall

```
func Syscall(trap, a1, a2, a3 uintptr) (r1, r2 uintptr, err Errno)
```

func [Syscall6](#)

```
func Syscall6(trap, a1, a2, a3, a4, a5, a6 uintptr) (r1, r2 uintptr,
```

func [Sysinfo](#)

```
func Sysinfo(info *Sysinfo_t) (err error)
```

func Tee

```
func Tee(rfd int, wfd int, len int, flags int) (n int64, err error)
```

func Tgkill

```
func Tgkill(tgid int, tid int, sig Signal) (err error)
```

func [Times](#)

```
func Times(tms *Tms) (ticks uintptr, err error)
```

func TimespecToNsec

```
func TimespecToNsec(ts Timespec) int64
```

func [TimevalToNsec](#)

```
func TimevalToNsec(tv Timeval) int64
```

func [Truncate](#)

```
func Truncate(path string, length int64) (err error)
```

func Umask

func Umask(mask int) (oldmask int)

func [Uname](#)

```
func Uname(buf *Utsname) (err error)
```

func [UnixCredentials](#)

```
func UnixCredentials(ucred *Ucred) []byte
```

UnixCredentials encodes credentials into a socket control message for sending to another process. This can be used for authentication.

func [UnixRights](#)

```
func UnixRights(fds ...int) []byte
```

UnixRights encodes a set of open file descriptors into a socket control message for sending to another process.

func [Unlink](#)

```
func Unlink(path string) (err error)
```

func [Unlinkat](#)

```
func Unlinkat(dirfd int, path string) (err error)
```

func Unmount

```
func Unmount(target string, flags int) (err error)
```

func [Unshare](#)

```
func Unshare(flags int) (err error)
```

func [Ustat](#)

func Ustat(dev int, ubuf *Ustat_t) (err error)

func [Utime](#)

```
func Utime(path string, buf *Utimbuf) (err error)
```

func [Utimes](#)

```
func Utimes(path string, tv []Timeval) (err error)
```

```
sys utimes(path string, times *[2]Timeval) (err error)
```

func [Wait4](#)

```
func Wait4(pid int, wstatus *WaitStatus, options int, rusage *Rusage
```

```
sys wait4(pid int, wstatus *_C_int, options int, rusage *Rusage) (wpid int, err  
error)
```

func [Write](#)

```
func Write(fd int, p []byte) (n int, err error)
```

type [CmsgHdr](#)

```
type CmsgHdr struct {  
    Len          uint64  
    Level        int32  
    Type         int32  
    X__cmsg_data [0]byte  
}
```

func (*CmsgHdr) [SetLen](#)

```
func (cmsg *CmsgHdr) SetLen(length int)
```

type [Credential](#)

```
type Credential struct {  
    Uid    uint32    // User ID.  
    Gid    uint32    // Group ID.  
    Groups []uint32 // Supplementary group IDs.  
}
```

Credential holds user and group identities to be assumed by a child process started by `StartProcess`.

type [Dirent](#)

```
type Dirent struct {  
    Ino      uint64  
    Off      int64  
    Reclen   uint16  
    Type     uint8  
    Name     [256]int8  
    Pad_cgo_0 [5]byte  
}
```

type EpollEvent

```
type EpollEvent struct {  
    Events uint32  
    Fd      int32  
    Pad     int32  
}
```

type [Errno](#)

```
type Errno uintptr
```

An Errno is an unsigned number describing an error condition. It implements the error interface. The zero Errno is by convention a non-error, so code to convert from Errno to error should use:

```
err = nil
if errno != 0 {
    err = errno
}
```

func (Errno) [Error](#)

```
func (e Errno) Error() string
```

func (Errno) [Temporary](#)

```
func (e Errno) Temporary() bool
```

func (Errno) [Timeout](#)

```
func (e Errno) Timeout() bool
```

type [FdSet](#)

```
type FdSet struct {  
    Bits [16]int64  
}
```

type [Fsid](#)

```
type Fsid struct {  
    X__val [2]int32  
}
```

type [IPMreq](#)

```
type IPMreq struct {  
    Multiaddr [4]byte /* in_addr */  
    Interface [4]byte /* in_addr */  
}
```

func [GetsockoptIPMreq](#)

```
func GetsockoptIPMreq(fd, level, opt int) (*IPMreq, error)
```

type [IPMreqn](#)

```
type IPMreqn struct {  
    Multiaddr [4]byte /* in_addr */  
    Address   [4]byte /* in_addr */  
    Ifindex   int32  
}
```

func [GetsockoptIPMreqn](#)

```
func GetsockoptIPMreqn(fd, level, opt int) (*IPMreqn, error)
```

type [IPv6Mreq](#)

```
type IPv6Mreq struct {  
    Multiaddr [16]byte /* in6_addr */  
    Interface uint32  
}
```

func [GetsockoptIPv6Mreq](#)

```
func GetsockoptIPv6Mreq(fd, level, opt int) (*IPv6Mreq, error)
```

type [IfAddrmsg](#)

```
type IfAddrmsg struct {  
    Family      uint8  
    Prefixlen   uint8  
    Flags       uint8  
    Scope       uint8  
    Index       uint32  
}
```

type IfInfomsg

```
type IfInfomsg struct {  
    Family      uint8  
    X__ifi_pad  uint8  
    Type        uint16  
    Index       int32  
    Flags       uint32  
    Change      uint32  
}
```

type [Inet4Pktinfo](#)

```
type Inet4Pktinfo struct {  
    Ifindex  int32  
    Spec_dst [4]byte /* in_addr */  
    Addr     [4]byte /* in_addr */  
}
```

type Inet6Pktinfo

```
type Inet6Pktinfo struct {  
    Addr    [16]byte /* in6_addr */  
    Ifindex uint32  
}
```

type InotifyEvent

```
type InotifyEvent struct {  
    Wd      int32  
    Mask    uint32  
    Cookie  uint32  
    Len     uint32  
    Name    [0]byte  
}
```

type [Iovec](#)

```
type Iovec struct {  
    Base *byte  
    Len  uint64  
}
```

func (*Iovec) [SetLen](#)

```
func (iov *Iovec) SetLen(length int)
```

type Linger

```
type Linger struct {  
    Onoff int32  
    Linger int32  
}
```

type [Msghdr](#)

```
type Msghdr struct {
    Name      *byte
    Namelen   uint32
    Pad_cgo_0 [4]byte
    Iov       *Iovec
    Iovlen    uint64
    Control   *byte
    Controllen uint64
    Flags     int32
    Pad_cgo_1 [4]byte
}
```

func (*Msghdr) [SetControllen](#)

```
func (msghdr *Msghdr) SetControllen(length int)
```

type [NetlinkMessage](#)

```
type NetlinkMessage struct {  
    Header NlMsgHdr  
    Data []byte  
}
```

NetlinkMessage represents the netlink message.

type [NetlinkRouteAttr](#)

```
type NetlinkRouteAttr struct {  
    Attr RtAttr  
    Value []byte  
}
```

NetlinkRouteAttr represents the netlink route attribute.

type [NetlinkRouteRequest](#)

```
type NetlinkRouteRequest struct {  
    Header NlMsgHdr  
    Data    RtGenmsg  
}
```

NetlinkRouteRequest represents the request message to receive routing and link states from the kernel.

type [NlAttr](#)

```
type NlAttr struct {  
    Len  uint16  
    Type uint16  
}
```

type [NlMsgerr](#)

```
type NlMsgerr struct {  
    Error int32  
    Msg   NlMsghdr  
}
```

type [NlMsgHdr](#)

```
type NlMsgHdr struct {  
    Len    uint32  
    Type   uint16  
    Flags  uint16  
    Seq    uint32  
    Pid    uint32  
}
```

type [ProcAttr](#)

```
type ProcAttr struct {
    Dir    string    // Current working directory.
    Env    []string   // Environment.
    Files  []uintptr  // File descriptors.
    Sys    *SysProcAttr
}
```

ProcAttr holds attributes that will be applied to a new process started by StartProcess.

type [PtraceRegs](#)

```
type PtraceRegs struct {  
    R15      uint64  
    R14      uint64  
    R13      uint64  
    R12      uint64  
    Rbp      uint64  
    Rbx      uint64  
    R11      uint64  
    R10      uint64  
    R9       uint64  
    R8       uint64  
    Rax      uint64  
    Rcx      uint64  
    Rdx      uint64  
    Rsi      uint64  
    Rdi      uint64  
    Orig_rax uint64  
    Rip      uint64  
    Cs       uint64  
    Eflags   uint64  
    Rsp      uint64  
    Ss       uint64  
    Fs_base  uint64  
    Gs_base  uint64  
    Ds       uint64  
    Es       uint64  
    Fs       uint64  
    Gs       uint64  
}
```

func (*PtraceRegs) [PC](#)

```
func (r *PtraceRegs) PC() uint64
```

func (*PtraceRegs) [SetPC](#)

```
func (r *PtraceRegs) SetPC(pc uint64)
```

type [RawSockaddr](#)

```
type RawSockaddr struct {  
    Family uint16  
    Data   [14]int8  
}
```

type [RawSockaddrAny](#)

```
type RawSockaddrAny struct {  
    Addr RawSockaddr  
    Pad  [96]int8  
}
```

type [RawSockaddrInet4](#)

```
type RawSockaddrInet4 struct {
    Family uint16
    Port    uint16
    Addr    [4]byte /* in_addr */
    Zero    [8]uint8
}
```

type [RawSockaddrInet6](#)

```
type RawSockaddrInet6 struct {
    Family    uint16
    Port      uint16
    Flowinfo  uint32
    Addr      [16]byte /* in6_addr */
    Scope_id  uint32
}
```

type [RawSockaddrLinklayer](#)

```
type RawSockaddrLinklayer struct {  
    Family    uint16  
    Protocol  uint16  
    Ifindex   int32  
    Hatype    uint16  
    Pkttype   uint8  
    Halen     uint8  
    Addr      [8]uint8  
}
```

type [RawSockaddrNetlink](#)

```
type RawSockaddrNetlink struct {  
    Family uint16  
    Pad    uint16  
    Pid    uint32  
    Groups uint32  
}
```

type [RawSockaddrUnix](#)

```
type RawSockaddrUnix struct {  
    Family uint16  
    Path   [108]int8  
}
```

type Rlimit

```
type Rlimit struct {  
    Cur uint64  
    Max uint64  
}
```

type [RtAttr](#)

```
type RtAttr struct {  
    Len  uint16  
    Type uint16  
}
```

type [RtGenmsg](#)

```
type RtGenmsg struct {  
    Family uint8  
}
```

type RtMsg

```
type RtMsg struct {  
    Family    uint8  
    Dst_len   uint8  
    Src_len   uint8  
    Tos       uint8  
    Table     uint8  
    Protocol  uint8  
    Scope     uint8  
    Type      uint8  
    Flags     uint32  
}
```

type [RtNextHop](#)

```
type RtNextHop struct {  
    Len      uint16  
    Flags    uint8  
    Hops     uint8  
    Ifindex  int32  
}
```

type Rusage

```
type Rusage struct {
    Utime    Timeval
    Stime    Timeval
    Maxrss   int64
    Ixrss    int64
    Idrss    int64
    Isrss    int64
    Minflt   int64
    Majflt   int64
    Nswap    int64
    Inblock  int64
    Oublock  int64
    Msgsnd   int64
    Msgrcv   int64
    Nsignals int64
    Nvcsw    int64
    Nivcsw   int64
}
```

type [Signal](#)

```
type Signal int
```

A Signal is a number describing a process signal. It implements the `os.Signal` interface.

func (Signal) [Signal](#)

```
func (s Signal) Signal()
```

func (Signal) [String](#)

```
func (s Signal) String() string
```

type [SockFilter](#)

```
type SockFilter struct {  
    Code uint16  
    Jt    uint8  
    Jf    uint8  
    K     uint32  
}
```

func [LsfJump](#)

```
func LsfJump(code, k, jt, jf int) *SockFilter
```

func [LsfStmt](#)

```
func LsfStmt(code, k int) *SockFilter
```

type [SockFprog](#)

```
type SockFprog struct {  
    Len      uint16  
    Pad_cgo_0 [6]byte  
    Filter    *SockFilter  
}
```

type [Sockaddr](#)

```
type Sockaddr interface {  
    // contains filtered or unexported methods  
}
```

func [Getpeername](#)

```
func Getpeername(fd int) (sa Sockaddr, err error)
```

func [Getsockname](#)

```
func Getsockname(fd int) (sa Sockaddr, err error)
```

type [SockaddrInet4](#)

```
type SockaddrInet4 struct {  
    Port int  
    Addr [4]byte  
    // contains filtered or unexported fields  
}
```

type [SockaddrInet6](#)

```
type SockaddrInet6 struct {
    Port    int
    ZoneId  uint32
    Addr    [16]byte
    // contains filtered or unexported fields
}
```

type [SockaddrLinklayer](#)

```
type SockaddrLinklayer struct {
    Protocol uint16
    Ifindex  int
    Hatype   uint16
    Pkttype  uint8
    Halen    uint8
    Addr     [8]byte
    // contains filtered or unexported fields
}
```

type [SockaddrNetlink](#)

```
type SockaddrNetlink struct {  
    Family uint16  
    Pad    uint16  
    Pid    uint32  
    Groups uint32  
    // contains filtered or unexported fields  
}
```

type [SockaddrUnix](#)

```
type SockaddrUnix struct {  
    Name string  
    // contains filtered or unexported fields  
}
```

type [SocketControlMessage](#)

```
type SocketControlMessage struct {  
    Header CmsgHdr  
    Data   []byte  
}
```

type [Stat_t](#)

```
type Stat_t struct {
    Dev      uint64
    Ino      uint64
    Nlink    uint64
    Mode     uint32
    Uid      uint32
    Gid      uint32
    X__pad0  int32
    Rdev     uint64
    Size     int64
    Blksize  int64
    Blocks   int64
    Atim     Timespec
    Mtim     Timespec
    Ctim     Timespec
    X__unused [3]int64
}
```

type [Statfs_t](#)

```
type Statfs_t struct {
    Type      int64
    Bsize     int64
    Blocks    uint64

    Files     uint64
    Ffree     uint64
    Fsid      Fsid
    Namelen   int64
    Fsize     int64
    Flags     int64
    Spare     [4]int64
}
```

type [SysProcAttr](#)

```
type SysProcAttr struct {
    Chroot      string    // Chroot.
    Credential  *Credential // Credential.
   Ptrace      bool      // Enable tracing.
   Setsid      bool      // Create session.
   Setpgid     bool      // Set process group ID to new pid (SYSV
   Setctty     bool      // Set controlling terminal to fd 0
   Noctty      bool      // Detach fd 0 from controlling terminal
   Pdeathsig   Signal    // Signal that the process will get when
}
```

type Sysinfo_t

```
type Sysinfo_t struct {
    Uptime      int64
    Loads       [3]uint64
    Totalram    uint64
    Freeram     uint64
    Sharedram   uint64
    Bufferram   uint64
    Totalswap   uint64
    Freeswap    uint64
    Procs       uint16
    Pad         uint16
    Pad_cgo_0   [4]byte
    Totalhigh   uint64
    Freehigh    uint64
    Unit        uint32
    X_f         [0]byte
    Pad_cgo_1   [4]byte
}
```

type [Termios](#)

```
type Termios struct {
    Iflag      uint32
    Oflag      uint32
    Cflag      uint32
    Lflag      uint32
    Line       uint8
    Cc         [32]uint8
    Pad_cgo_0  [3]byte
    Ispeed     uint32
    Ospeed     uint32
}
```

type [Time_t](#)

```
type Time_t int64
```

func [Time](#)

```
func Time(t *Time_t) (tt Time_t, err error)
```

type [Timespec](#)

```
type Timespec struct {  
    Sec  int64  
    Nsec int64  
}
```

func [NsecToTimespec](#)

```
func NsecToTimespec(nsec int64) (ts Timespec)
```

func (***Timespec**) [Nano](#)

```
func (ts *Timespec) Nano() int64
```

func (***Timespec**) [Unix](#)

```
func (ts *Timespec) Unix() (sec int64, nsec int64)
```

type [Timeval](#)

```
type Timeval struct {  
    Sec  int64  
    Usec int64  
}
```

func [NsecToTimeval](#)

```
func NsecToTimeval(nsec int64) (tv Timeval)
```

func (*Timeval) [Nano](#)

```
func (tv *Timeval) Nano() int64
```

func (*Timeval) [Unix](#)

```
func (tv *Timeval) Unix() (sec int64, nsec int64)
```

type Timex

```
type Timex struct {
    Modes      uint32
    Pad_cgo_0  [4]byte
    Offset     int64
    Freq       int64
    Maxerror   int64
    Esterror   int64
    Status     int32
    Pad_cgo_1  [4]byte
    Constant   int64
    Precision  int64
    Tolerance  int64
    Time       Timeval
    Tick       int64
    Ppsfreq   int64
    Jitter     int64
    Shift      int32
    Pad_cgo_2  [4]byte
    Stabil     int64
    Jitcnt     int64
    Calcnt     int64
    Errcnt     int64
    Stbcnt     int64
    Tai        int32
    Pad_cgo_3  [44]byte
}
```

type Tms

```
type Tms struct {  
    Utime  int64  
    Stime  int64  
    Ctime  int64  
    Cstime int64  
}
```

type [Ucred](#)

```
type Ucred struct {  
    Pid int32  
    Uid uint32  
    Gid uint32  
}
```

func [ParseUnixCredentials](#)

```
func ParseUnixCredentials(msg *SocketControlMessage) (*Ucred, error)
```

ParseUnixCredentials decodes a socket control message that contains credentials in a Ucred structure. To receive such a message, the SO_PASSCRED option must be enabled on the socket.

type Ustat_t

```
type Ustat_t struct {
    Tfree      int32
    Pad_cgo_0  [4]byte
    Tinode     uint64
    Fname      [6]int8
    Fpack      [6]int8
    Pad_cgo_1  [4]byte
}
```

type Utimbuf

```
type Utimbuf struct {  
    Actime  int64  
    Modtime int64  
}
```

type Utsname

```
type Utsname struct {
    Sysname    [65]int8
    Nodename   [65]int8
    Release    [65]int8
    Version    [65]int8
    Machine    [65]int8
    Domainname [65]int8
}
```

type [WaitStatus](#)

type WaitStatus uint32

func (WaitStatus) [Continued](#)

func (w WaitStatus) Continued() bool

func (WaitStatus) [CoreDump](#)

func (w WaitStatus) CoreDump() bool

func (WaitStatus) [ExitStatus](#)

func (w WaitStatus) ExitStatus() int

func (WaitStatus) [Exited](#)

func (w WaitStatus) Exited() bool

func (WaitStatus) [Signal](#)

func (w WaitStatus) Signal() Signal

func (WaitStatus) [Signaled](#)

func (w WaitStatus) Signaled() bool

func (WaitStatus) [StopSignal](#)

func (w WaitStatus) StopSignal() Signal

func (WaitStatus) [Stopped](#)

func (w WaitStatus) Stopped() bool

func (WaitStatus) [TrapCause](#)

```
func (w WaitStatus) TrapCause() int
```

Package testing

```
import "testing"
```

[Overview](#)

[Index](#)

[Subdirectories](#)

Overview ?

Overview ?

Package testing provides support for automated testing of Go packages. It is intended to be used in concert with the “go test” command, which automates execution of any function of the form

```
func TestXxx(*testing.T)
```

where Xxx can be any alphanumeric string (but the first letter must not be in [a-z]) and serves to identify the test routine. These TestXxx routines should be declared within the package they are testing.

Functions of the form

```
func BenchmarkXxx(*testing.B)
```

are considered benchmarks, and are executed by the "go test" command when the -test.bench flag is provided.

A sample benchmark function looks like this:

```
func BenchmarkHello(b *testing.B) {  
    for i := 0; i < b.N; i++ {  
        fmt.Sprintf("hello")  
    }  
}
```

The benchmark package will vary b.N until the benchmark function lasts long enough to be timed reliably. The output

```
testing.BenchmarkHello    10000000    282 ns/op
```

means that the loop ran 10000000 times at a speed of 282 ns per loop.

If a benchmark needs some expensive setup before running, the timer may be stopped:

```
func BenchmarkBigLen(b *testing.B) {  
    b.StopTimer()  
    big := NewBig()  
    b.StartTimer()  
    for i := 0; i < b.N; i++ {
```

```

        big.Len()
    }
}

```

The package also runs and verifies example code. Example functions may include a concluding comment that begins with "Output:" and is compared with the standard output of the function when the tests are run, as in these examples of an example:

```

func ExampleHello() {
    fmt.Println("hello")
    // Output: hello
}

func ExampleSalutations() {
    fmt.Println("hello, and")
    fmt.Println("goodbye")
    // Output:
    // hello, and
    // goodbye
}

```

Example functions without output comments are compiled but not executed.

The naming convention to declare examples for a function F, a type T and method M on type T are:

```

func ExampleF() { ... }
func ExampleT() { ... }
func ExampleT_M() { ... }

```

Multiple example functions for a type/function/method may be provided by appending a distinct suffix to the name. The suffix must start with a lower-case letter.

```

func ExampleF_suffix() { ... }
func ExampleT_suffix() { ... }
func ExampleT_M_suffix() { ... }

```

The entire test file is presented as the example when it contains a single example function, at least one other function, type, variable, or constant declaration, and no test or benchmark functions.

Package files

[benchmark.go](#) [example.go](#) [testing.go](#)

func [Main](#)

```
func Main(matchString func(pat, str string) (bool, error), tests []I
```

An internal function but exported because it is cross-package; part of the implementation of the "go test" command.

func [RunBenchmarks](#)

```
func RunBenchmarks(matchString func(pat, str string) (bool, error),
```

An internal function but exported because it is cross-package; part of the implementation of the "go test" command.

func [RunExamples](#)

```
func RunExamples(matchString func(pat, str string) (bool, error), ex
```

func [RunTests](#)

```
func RunTests(matchString func(pat, str string) (bool, error), tests
```

func [Short](#)

```
func Short() bool
```

Short reports whether the `-test.short` flag is set.

type [B](#)

```
type B struct {  
    N int  
    // contains filtered or unexported fields  
}
```

B is a type passed to Benchmark functions to manage benchmark timing and to specify the number of iterations to run.

func (*B) [Error](#)

```
func (c *B) Error(args ...interface{})
```

Error is equivalent to Log() followed by Fail().

func (*B) [Errorf](#)

```
func (c *B) Errorf(format string, args ...interface{})
```

Errorf is equivalent to Logf() followed by Fail().

func (*B) [Fail](#)

```
func (c *B) Fail()
```

Fail marks the function as having failed but continues execution.

func (*B) [FailNow](#)

```
func (c *B) FailNow()
```

FailNow marks the function as having failed and stops its execution. Execution will continue at the next test or benchmark.

func (*B) [Failed](#)

```
func (c *B) Failed() bool
```

Failed returns whether the function has failed.

func (*B) [Fatal](#)

```
func (c *B) Fatal(args ...interface{})
```

Fatal is equivalent to Log() followed by FailNow().

func (*B) [Fatalf](#)

```
func (c *B) Fatalf(format string, args ...interface{})
```

Fatalf is equivalent to Logf() followed by FailNow().

func (*B) [Log](#)

```
func (c *B) Log(args ...interface{})
```

Log formats its arguments using default formatting, analogous to Println(), and records the text in the error log.

func (*B) [Logf](#)

```
func (c *B) Logf(format string, args ...interface{})
```

Logf formats its arguments according to the format, analogous to Printf(), and records the text in the error log.

func (*B) [ResetTimer](#)

```
func (b *B) ResetTimer()
```

ResetTimer sets the elapsed benchmark time to zero. It does not affect whether the timer is running.

func (*B) [SetBytes](#)

```
func (b *B) SetBytes(n int64)
```

SetBytes records the number of bytes processed in a single operation. If this is

called, the benchmark will report ns/op and MB/s.

func (*B) [StartTimer](#)

```
func (b *B) StartTimer()
```

StartTimer starts timing a test. This function is called automatically before a benchmark starts, but it can also be used to resume timing after a call to StopTimer.

func (*B) [StopTimer](#)

```
func (b *B) StopTimer()
```

StopTimer stops timing a test. This can be used to pause the timer while performing complex initialization that you don't want to measure.

type [BenchmarkResult](#)

```
type BenchmarkResult struct {  
    N      int           // The number of iterations.  
    T      time.Duration // The total time taken.  
    Bytes  int64           // Bytes processed in one iteration.  
}
```

The results of a benchmark run.

func [Benchmark](#)

```
func Benchmark(f func(b *B)) BenchmarkResult
```

Benchmark benchmarks a single function. Useful for creating custom benchmarks that do not use the "go test" command.

func (BenchmarkResult) [NsPerOp](#)

```
func (r BenchmarkResult) NsPerOp() int64
```

func (BenchmarkResult) [String](#)

```
func (r BenchmarkResult) String() string
```

type InternalBenchmark

```
type InternalBenchmark struct {  
    Name string  
    F     func(b *B)  
}
```

An internal type but exported because it is cross-package; part of the implementation of the "go test" command.

type [InternalExample](#)

```
type InternalExample struct {  
    Name    string  
    F       func()  
    Output  string  
}
```

type [InternalTest](#)

```
type InternalTest struct {  
    Name string  
    F     func(*T)  
}
```

An internal type but exported because it is cross-package; part of the implementation of the "go test" command.

type [T](#)

```
type T struct {  
    // contains filtered or unexported fields  
}
```

T is a type passed to Test functions to manage test state and support formatted test logs. Logs are accumulated during execution and dumped to standard error when done.

func (*T) [Error](#)

```
func (c *T) Error(args ...interface{})
```

Error is equivalent to Log() followed by Fail().

func (*T) [Errorf](#)

```
func (c *T) Errorf(format string, args ...interface{})
```

Errorf is equivalent to Logf() followed by Fail().

func (*T) [Fail](#)

```
func (c *T) Fail()
```

Fail marks the function as having failed but continues execution.

func (*T) [FailNow](#)

```
func (c *T) FailNow()
```

FailNow marks the function as having failed and stops its execution. Execution will continue at the next test or benchmark.

func (*T) [Failed](#)

```
func (c *T) Failed() bool
```

Failed returns whether the function has failed.

func (*T) [Fatal](#)

```
func (c *T) Fatal(args ...interface{})
```

Fatal is equivalent to Log() followed by FailNow().

func (*T) [Fatalf](#)

```
func (c *T) Fatalf(format string, args ...interface{})
```

Fatalf is equivalent to Logf() followed by FailNow().

func (*T) [Log](#)

```
func (c *T) Log(args ...interface{})
```

Log formats its arguments using default formatting, analogous to Println(), and records the text in the error log.

func (*T) [Logf](#)

```
func (c *T) Logf(format string, args ...interface{})
```

Logf formats its arguments according to the format, analogous to Printf(), and records the text in the error log.

func (*T) [Parallel](#)

```
func (t *T) Parallel()
```

Parallel signals that this test is to be run in parallel with (and only with) other parallel tests in this CPU group.

Package files

[logger.go](#) [reader.go](#) [writer.go](#)

Variables

```
var ErrTimeout = errors.New("timeout")
```

func [DataErrReader](#)

```
func DataErrReader(r io.Reader) io.Reader
```

DataErrReader returns a Reader that returns the final error with the last data read, instead of by itself with zero bytes of data.

func HalfReader

```
func HalfReader(r io.Reader) io.Reader
```

HalfReader returns a Reader that implements Read by reading half as many requested bytes from r.

func [NewReadLogger](#)

```
func NewReadLogger(prefix string, r io.Reader) io.Reader
```

NewReadLogger returns a reader that behaves like r except that it logs (using log.Print) each read to standard error, printing the prefix and the hexadecimal data written.

func [NewWriteLogger](#)

```
func NewWriteLogger(prefix string, w io.Writer) io.Writer
```

NewWriteLogger returns a writer that behaves like w except that it logs (using log.Printf) each write to standard error, printing the prefix and the hexadecimal data written.

func OneByteReader

```
func OneByteReader(r io.Reader) io.Reader
```

OneByteReader returns a Reader that implements each non-empty Read by reading one byte from r.

func TimeoutReader

```
func TimeoutReader(r io.Reader) io.Reader
```

TimeoutReader returns ErrTimeout on the second read with no data. Subsequent calls to read succeed.

func [TruncateWriter](#)

```
func TruncateWriter(w io.Writer, n int64) io.Writer
```

TruncateWriter returns a Writer that writes to w but stops silently after n bytes.

Build version go1.0.1.

Package files

quick.go

func [Check](#)

```
func Check(function interface{}, config *Config) (err error)
```

Check looks for an input to f, any function that returns bool, such that f returns false. It calls f repeatedly, with arbitrary values for each argument. If f returns false on a given input, Check returns that input as a *CheckError. For example:

```
func TestOddMultipleOfThree(t *testing.T) {
    f := func(x int) bool {
        y := OddMultipleOfThree(x)
        return y%2 == 1 && y%3 == 0
    }
    if err := quick.Check(f, nil); err != nil {
        t.Error(err)
    }
}
```

func [CheckEqual](#)

```
func CheckEqual(f, g interface{}, config *Config) (err error)
```

CheckEqual looks for an input on which f and g return different results. It calls f and g repeatedly with arbitrary values for each argument. If f and g return different answers, CheckEqual returns a *CheckEqualError describing the input and the outputs.

func [Value](#)

```
func Value(t reflect.Type, rand *rand.Rand) (value reflect.Value, ok
```

Value returns an arbitrary value of the given type. If the type implements the Generator interface, that will be used. Note: To create arbitrary values for structs, all the fields must be exported.

type [CheckEqualError](#)

```
type CheckEqualError struct {  
    CheckError  
    Out1 []interface{}  
    Out2 []interface{}  
}
```

A CheckEqualError is the result CheckEqual finding an error.

func (*CheckEqualError) [Error](#)

```
func (s *CheckEqualError) Error() string
```

type [CheckError](#)

```
type CheckError struct {  
    Count int  
    In    []interface{ }  
}
```

A CheckError is the result of Check finding an error.

func (*CheckError) [Error](#)

```
func (s *CheckError) Error() string
```

type [Config](#)

```
type Config struct {
    // MaxCount sets the maximum number of iterations. If zero,
    // MaxCountScale is used.
    MaxCount int
    // MaxCountScale is a non-negative scale factor applied to the d
    // maximum. If zero, the default is unchanged.
    MaxCountScale float64
    // If non-nil, rand is a source of random numbers. Otherwise a d
    // pseudo-random source will be used.
    Rand *rand.Rand
    // If non-nil, the Values function generates a slice of arbitrar
    // reflect.Values that are congruent with the arguments to the f
    // being tested. Otherwise, the top-level Values function is use
    // to generate them.
    Values func([]reflect.Value, *rand.Rand)
}
```

A Config structure contains options for running a test.

type Generator

```
type Generator interface {  
    // Generate returns a random instance of the type on which it is  
    // method using the size as a size hint.  
    Generate(rand *rand.Rand, size int) reflect.Value  
}
```

A Generator can generate random values of its own type.

type [SetupError](#)

```
type SetupError string
```

A SetupError is the result of an error in the way that check is being used, independent of the functions being tested.

func (SetupError) [Error](#)

```
func (s SetupError) Error() string
```

Package scanner

```
import "text/scanner"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package scanner provides a scanner and tokenizer for UTF-8-encoded text. It takes an `io.Reader` providing the source, which then can be tokenized through repeated calls to the `Scan` function. For compatibility with existing tools, the NUL character is not allowed.

By default, a Scanner skips white space and Go comments and recognizes all literals as defined by the Go language specification. It may be customized to recognize only a subset of those literals and to recognize different white space characters.

Basic usage pattern:

```
var s scanner.Scanner
s.Init(src)
tok := s.Scan()
for tok != scanner.EOF {
    // do something with tok
    tok = s.Scan()
}
```

Package files

[scanner.go](#)

Constants

```
const (  
    ScanIdents      = 1 << -Ident  
    ScanInts        = 1 << -Int  
    ScanFloats      = 1 << -Float // includes Ints  
    ScanChars       = 1 << -Char  
    ScanStrings     = 1 << -String  
    ScanRawStrings  = 1 << -RawString  
    ScanComments    = 1 << -Comment  
    SkipComments    = 1 << -skipComment // if set with ScanComments,  
    GoTokens        = ScanIdents | ScanFloats | ScanChars | ScanStrin  
)
```

Predefined mode bits to control recognition of tokens. For instance, to configure a Scanner such that it only recognizes (Go) identifiers, integers, and skips comments, set the Scanner's Mode field to:

```
ScanIdents | ScanInts | SkipComments
```

```
const (  
    EOF = -(iota + 1)  
    Ident  
    Int  
    Float  
    Char  
    String  
    RawString  
    Comment  
)
```

The result of Scan is one of the following tokens or a Unicode character.

```
const GoWhitespace = 1<<'\t' | 1<<'\n' | 1<<'\r' | 1<<' '
```

GoWhitespace is the default value for the Scanner's Whitespace field. Its value selects Go's white space characters.

func [TokenString](#)

```
func TokenString(tok rune) string
```

TokenString returns a printable string for a token or Unicode character.

type [Position](#)

```
type Position struct {
    Filename string // filename, if any
    Offset   int    // byte offset, starting at 0
    Line     int    // line number, starting at 1
    Column   int    // column number, starting at 1 (character count)
}
```

A source position is represented by a Position value. A position is valid if Line > 0.

func (*Position) [IsValid](#)

```
func (pos *Position) IsValid() bool
```

IsValid returns true if the position is valid.

func (Position) [String](#)

```
func (pos Position) String() string
```

type [Scanner](#)

```
type Scanner struct {  
  
    // Error is called for each error encountered. If no Error  
    // function is set, the error is reported to os.Stderr.  
    Error func(s *Scanner, msg string)  
  
    // ErrorCount is incremented by one for each error encountered.  
    ErrorCount int  
  
    // The Mode field controls which tokens are recognized. For inst  
    // to recognize Ints, set the ScanInts bit in Mode. The field ma  
    // changed at any time.  
    Mode uint  
  
    // The Whitespace field controls which characters are recognized  
    // as white space. To recognize a character ch <= ' ' as white s  
    // set the ch'th bit in Whitespace (the Scanner's behavior is un  
    // for values ch > ' '). The field may be changed at any time.  
    Whitespace uint64  
  
    // Start position of most recently scanned token; set by Scan.  
    // Calling Init or Next invalidates the position (Line == 0).  
    // The Filename field is always left untouched by the Scanner.  
    // If an error is reported (via Error) and Position is invalid,  
    // the scanner is not inside a token. Call Pos to obtain an erro  
    // position in that case.  
    Position  
    // contains filtered or unexported fields  
}
```

A Scanner implements reading of Unicode characters and tokens from an io.Reader.

func (*Scanner) [Init](#)

```
func (s *Scanner) Init(src io.Reader) *Scanner
```

Init initializes a Scanner with a new source and returns s. Error is set to nil, ErrorCount is set to 0, Mode is set to GoTokens, and Whitespace is set to GoWhitespace.

func (*Scanner) [Next](#)

```
func (s *Scanner) Next() rune
```

Next reads and returns the next Unicode character. It returns EOF at the end of the source. It reports a read error by calling `s.Error`, if not nil; otherwise it prints an error message to `os.Stderr`. Next does not update the Scanner's Position field; use `Pos()` to get the current position.

func (*Scanner) [Peek](#)

```
func (s *Scanner) Peek() rune
```

Peek returns the next Unicode character in the source without advancing the scanner. It returns EOF if the scanner's position is at the last character of the source.

func (*Scanner) [Pos](#)

```
func (s *Scanner) Pos() (pos Position)
```

Pos returns the position of the character immediately after the character or token returned by the last call to `Next` or `Scan`.

func (*Scanner) [Scan](#)

```
func (s *Scanner) Scan() rune
```

Scan reads the next token or Unicode character from source and returns it. It only recognizes tokens `t` for which the respective Mode bit (`1<<-t`) is set. It returns EOF at the end of the source. It reports scanner errors (read and token errors) by calling `s.Error`, if not nil; otherwise it prints an error message to `os.Stderr`.

func (*Scanner) [TokenText](#)

```
func (s *Scanner) TokenText() string
```

TokenText returns the string corresponding to the most recently scanned token. Valid after calling `Scan()`.

Build version go1.0.1.

Package tabwriter

```
import "text/tabwriter"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package tabwriter implements a write filter (tabwriter.Writer) that translates tabbed columns in input into properly aligned text.

The package is using the Elastic Tabstops algorithm described at <http://nickgravgaard.com/elasticstops/index.html>.

Index

Constants

type Writer

func NewWriter(output io.Writer, minwidth, tabwidth, padding int, padchar byte, flags uint) *Writer

func (b *Writer) Flush() (err error)

func (b *Writer) Init(output io.Writer, minwidth, tabwidth, padding int, padchar byte, flags uint) *Writer

func (b *Writer) Write(buf []byte) (n int, err error)

Examples

Writer.Init

Package files

tabwriter.go

Constants

```
const (  
    // Ignore html tags and treat entities (starting with '&'   
    // and ending in ';') as single characters (width = 1).   
    FilterHTML uint = 1 << iota   
  
    // Strip Escape characters bracketing escaped text segments   
    // instead of passing them through unchanged with the text.   
    StripEscape   
  
    // Force right-alignment of cell content.   
    // Default is left-alignment.   
    AlignRight   
  
    // Handle empty columns as if they were not present in   
    // the input in the first place.   
    DiscardEmptyColumns   
  
    // Always use tabs for indentation columns (i.e., padding of   
    // leading empty cells on the left) independent of padchar.   
    TabIndent   
  
    // Print a vertical bar ('|') between columns (after formatting)   
    // Discarded columns appear as zero-width columns ("||").   
    Debug   
)
```

Formatting can be controlled with these flags.

```
const Escape = '\xff'
```

To escape a text segment, bracket it with Escape characters. For instance, the tab in this string "Ignore this tab: \xff\t\xff" does not terminate a cell and constitutes a single character of width one for formatting purposes.

The value 0xff was chosen because it cannot appear in a valid UTF-8 sequence.

type [Writer](#)

```
type Writer struct {  
    // contains filtered or unexported fields  
}
```

A `Writer` is a filter that inserts padding around tab-delimited columns in its input to align them in the output.

The `Writer` treats incoming bytes as UTF-8 encoded text consisting of cells terminated by (horizontal or vertical) tabs or line breaks (newline or formfeed characters). Cells in adjacent lines constitute a column. The `Writer` inserts padding as needed to make all cells in a column have the same width, effectively aligning the columns. It assumes that all characters have the same width except for tabs for which a `tabwidth` must be specified. Note that cells are tab-terminated, not tab-separated: trailing non-tab text at the end of a line does not form a column cell.

The `Writer` assumes that all Unicode code points have the same width; this may not be true in some fonts.

If `DiscardEmptyColumns` is set, empty columns that are terminated entirely by vertical (or "soft") tabs are discarded. Columns terminated by horizontal (or "hard") tabs are not affected by this flag.

If a `Writer` is configured to filter HTML, HTML tags and entities are passed through. The widths of tags and entities are assumed to be zero (tags) and one (entities) for formatting purposes.

A segment of text may be escaped by bracketing it with Escape characters. The `tabwriter` passes escaped text segments through unchanged. In particular, it does not interpret any tabs or line breaks within the segment. If the `StripEscape` flag is set, the Escape characters are stripped from the output; otherwise they are passed through as well. For the purpose of formatting, the width of the escaped text is always computed excluding the Escape characters.

The formfeed character (`\f`) acts like a newline but it also terminates all columns in the current line (effectively calling `Flush`). Cells in the next line start new columns. Unless found inside an HTML tag or inside an escaped text segment,

formfeed characters appear as newlines in the output.

The Writer must buffer input internally, because proper spacing of one line may depend on the cells in future lines. Clients must call Flush when done calling Write.

func [NewWriter](#)

```
func NewWriter(output io.Writer, minwidth, tabwidth, padding int, pa
```

NewWriter allocates and initializes a new tabwriter.Writer. The parameters are the same as for the the Init function.

func (*Writer) [Flush](#)

```
func (b *Writer) Flush() (err error)
```

Flush should be called after the last call to Write to ensure that any data buffered in the Writer is written to output. Any incomplete escape sequence at the end is considered complete for formatting purposes.

func (*Writer) [Init](#)

```
func (b *Writer) Init(output io.Writer, minwidth, tabwidth, padding
```

A Writer must be initialized with a call to Init. The first parameter (output) specifies the filter output. The remaining parameters control the formatting:

minwidth	minimal cell width including any padding
tabwidth	width of tab characters (equivalent number of spaces
padding	padding added to a cell before computing its width
padchar	ASCII char used for padding if padchar == '\t', the Writer will assume that the width of a '\t' in the formatted output is tabwidth, and cells are left-aligned independent of align_left (for correct-looking results, tabwidth must correspo
flags	formatting control

? Example

? Example

Code:

```
w := new(tabwriter.Writer)

// Format in tab-separated columns with a tab stop of 8.
w.Init(os.Stdout, 0, 8, 0, '\t', 0)
fmt.Fprintln(w, "a\tb\tc\td\t.")
fmt.Fprintln(w, "123\t12345\t1234567\t123456789\t.")
fmt.Fprintln(w)
w.Flush()

// Format right-aligned in space-separated columns of minimal width
// and at least one blank of padding (so wider column entries do not
// touch each other).
w.Init(os.Stdout, 5, 0, 1, ' ', tabwriter.AlignRight)
fmt.Fprintln(w, "a\tb\tc\td\t.")
fmt.Fprintln(w, "123\t12345\t1234567\t123456789\t.")
fmt.Fprintln(w)
w.Flush()
```

Output:

```
a      b      c      d      .
123    12345  1234567 123456789 .

      a      b      c      d.
    123 12345 1234567 123456789.
```

func (*Writer) [Write](#)

```
func (b *Writer) Write(buf []byte) (n int, err error)
```

Write writes buf to the writer b. The only errors returned are ones encountered while writing to the underlying output stream.

Build version go1.0.1.

[Terms of Service](#) | [Privacy Policy](#)

Package template

```
import "text/template"
```

[Overview](#)

[Index](#)

[Examples](#)

[Subdirectories](#)

Overview ?

Overview ?

Package `template` implements data-driven templates for generating textual output.

To generate HTML output, see package `html/template`, which has the same interface as this package but automatically secures HTML output against certain attacks.

Templates are executed by applying them to a data structure. Annotations in the template refer to elements of the data structure (typically a field of a struct or a key in a map) to control execution and derive values to be displayed. Execution of the template walks the structure and sets the cursor, represented by a period '.' and called "dot", to the value at the current location in the structure as execution proceeds.

The input text for a template is UTF-8-encoded text in any format. "Actions"--data evaluations or control structures--are delimited by "{{" and "}}"; all text outside actions is copied to the output unchanged. Actions may not span newlines, although comments can.

Once constructed, a template may be executed safely in parallel.

Here is a trivial example that prints "17 items are made of wool".

```
type Inventory struct {
    Material string
    Count    uint
}
sweaters := Inventory{"wool", 17}
tmpl, err := template.New("test").Parse("{{.Count}} items are made of")
if err != nil { panic(err) }
err = tmpl.Execute(os.Stdout, sweaters)
if err != nil { panic(err) }
```

More intricate examples appear below.

Actions

Here is the list of actions. "Arguments" and "pipelines" are evaluations of data,

defined in detail below.

```
{{/* a comment */}}
```

A comment; discarded. May contain newlines.
Comments do not nest.

```
{{pipeline}}
```

The default textual representation of the value of the pipeline is copied to the output.

```
{{if pipeline}} T1 {{end}}
```

If the value of the pipeline is empty, no output is generated; otherwise, T1 is executed. The empty values are false, 0, a nil pointer or interface value, and any array, slice, map, or string of length zero.
Dot is unaffected.

```
{{if pipeline}} T1 {{else}} T0 {{end}}
```

If the value of the pipeline is empty, T0 is executed; otherwise, T1 is executed. Dot is unaffected.

```
{{range pipeline}} T1 {{end}}
```

The value of the pipeline must be an array, slice, or map. If the value of the pipeline has length zero, nothing is output; otherwise, dot is set to the successive elements of the array, slice, or map and T1 is executed. If the value is a map and keys are of basic type with a defined order ("comparable"), elements will be visited in sorted key order.

```
{{range pipeline}} T1 {{else}} T0 {{end}}
```

The value of the pipeline must be an array, slice, or map. If the value of the pipeline has length zero, dot is unaffected; T0 is executed; otherwise, dot is set to the successive elements of the array, slice, or map and T1 is executed.

```
{{template "name"}}
```

The template with the specified name is executed with nil as dot.

```
{{template "name" pipeline}}
```

The template with the specified name is executed with dot set to the value of the pipeline.

```
{{with pipeline}} T1 {{end}}
```

If the value of the pipeline is empty, no output is generated; otherwise, dot is set to the value of the pipeline and T1 is executed.

```
{{with pipeline}} T1 {{else}} T0 {{end}}
```

If the value of the pipeline is empty, dot is unaffected and T0 is executed; otherwise, dot is set to the value of the pipeline and T1 is executed.

is executed; otherwise, dot is set to the value of the pipel and T1 is executed.

Arguments

An argument is a simple value, denoted by one of the following.

- A boolean, string, character, integer, floating-point, imaginary or complex constant in Go syntax. These behave like Go's untyped constants, although raw strings may not span newlines.
- The character '.' (period):

`.`
The result is the value of dot.

- A variable name, which is a (possibly empty) alphanumeric string preceded by a dollar sign, such as
`$piOver2`

or

`$`

The result is the value of the variable.
Variables are described below.

- The name of a field of the data, which must be a struct, preceded by a period, such as
`.Field`

The result is the value of the field. Field invocations may be chained:

`.Field1.Field2`

Fields can also be evaluated on variables, including chaining:
`$x.Field1.Field2`

- The name of a key of the data, which must be a map, preceded by a period, such as
`.Key`

The result is the map element value indexed by the key.
Key invocations may be chained and combined with fields to any depth:

`.Field1.Key1.Field2.Key2`

Although the key must be an alphanumeric identifier, unlike with field names they do not need to start with an upper case letter.
Keys can also be evaluated on variables, including chaining:

`$x.key1.key2`

- The name of a niladic method of the data, preceded by a period, such as

`.Method`

The result is the value of invoking the method with dot as the receiver, `dot.Method()`. Such a method must have one return value (any type) or two return values, the second of which is an error. If it has two and the returned error is non-nil, execution terminates and an error is returned to the caller as the value of `Execute`. Method invocations may be chained and combined with fields and key

to any depth:

```
.Field1.Key1.Method1.Field2.Key2.Method2
```

Methods can also be evaluated on variables, including chaining:

```
$x.Method1.Field
```

- The name of a niladic function, such as
fun

The result is the value of invoking the function, fun(). The return types and values behave as in methods. Functions and function names are described below.

Arguments may evaluate to any type; if they are pointers the implementation automatically indirections to the base type when required. If an evaluation yields a function value, such as a function-valued field of a struct, the function is not invoked automatically, but it can be used as a truth value for an if action and the like. To invoke it, use the call function, defined below.

A pipeline is a possibly chained sequence of "commands". A command is a simple value (argument) or a function or method call, possibly with multiple arguments:

Argument

The result is the value of evaluating the argument.

```
.Method [Argument...]
```

The method can be alone or the last element of a chain but, unlike methods in the middle of a chain, it can take arguments. The result is the value of calling the method with the arguments:

```
dot.Method(Argument1, etc.)
```

```
functionName [Argument...]
```

The result is the value of calling the function associated with the name:

```
function(Argument1, etc.)
```

Functions and function names are described below.

Pipelines

A pipeline may be "chained" by separating a sequence of commands with pipeline characters '|'. In a chained pipeline, the result of the each command is passed as the last argument of the following command. The output of the final command in the pipeline is the value of the pipeline.

The output of a command will be either one value or two values, the second of which has type error. If that second value is present and evaluates to non-nil, execution terminates and the error is returned to the caller of Execute.

Variables

A pipeline inside an action may initialize a variable to capture the result. The initialization has syntax

```
$variable := pipeline
```

where `$variable` is the name of the variable. An action that declares a variable produces no output.

If a "range" action initializes a variable, the variable is set to the successive elements of the iteration. Also, a "range" may declare two variables, separated by a comma:

```
$index, $element := pipeline
```

in which case `$index` and `$element` are set to the successive values of the array/slice index or map key and element, respectively. Note that if there is only one variable, it is assigned the element; this is opposite to the convention in Go range clauses.

A variable's scope extends to the "end" action of the control structure ("if", "with", or "range") in which it is declared, or to the end of the template if there is no such control structure. A template invocation does not inherit variables from the point of its invocation.

When execution begins, `$` is set to the data argument passed to `Execute`, that is, to the starting value of `dot`.

Examples

Here are some example one-line templates demonstrating pipelines and variables. All produce the quoted word "output":

```
{{"\output\"}}  
    A string constant.  
{{`output`}}  
    A raw string constant.  
{{printf "%q" "output"}}  
    A function call.  
{{"output" | printf "%q"}}  
    A function call whose final argument comes from the previous
```

```

    command.
{{"put" | printf "%s%s" "out" | printf "%q"}}
    A more elaborate call.
{{"output" | printf "%s" | printf "%q"}}
    A longer chain.
{{with "output"}}{{printf "%q" .}}{{end}}
    A with action using dot.
{{with $x := "output" | printf "%q"}}{{{$x}}}}{{end}}
    A with action that creates and uses a variable.
{{with $x := "output"}}{{printf "%q" $x}}}}{{end}}
    A with action that uses the variable in another action.
{{with $x := "output"}}{{{$x | printf "%q"}}}}}}{{end}}
    The same, but pipelined.

```

Functions

During execution functions are found in two function maps: first in the template, then in the global function map. By default, no functions are defined in the template but the Funcs method can be used to add them.

Predefined global functions are named as follows.

and

Returns the boolean AND of its arguments by returning the first empty argument or the last argument, that is, "and x y" behaves as "if x then y else x". All the arguments are evaluated.

call

Returns the result of calling the first argument, which must be a function, with the remaining arguments as parameters. Thus "call .X.Y 1 2" is, in Go notation, dot.X.Y(1, 2) where Y is a func-valued field, map entry, or the like. The first argument must be the result of an evaluation that yields a value of function type (as distinct from a predefined function such as print). The function must return either one or two result values, the second of which is of type error. If the arguments don't match the function or the returned error value is non-nil, execution stops.

html

Returns the escaped HTML equivalent of the textual representation of its arguments.

index

Returns the result of indexing its first argument by the following arguments. Thus "index x 1 2 3" is, in Go syntax, x[1][2][3]. Each indexed item must be a map, slice, or array

js

Returns the escaped JavaScript equivalent of the textual

representation of its arguments.

`len` Returns the integer length of its argument.

`not` Returns the boolean negation of its single argument.

`or` Returns the boolean OR of its arguments by returning the first non-empty argument or the last argument, that is, "or x y" behaves as "if x then x else y". All the arguments are evaluated.

`print` An alias for `fmt.Sprint`

`printf` An alias for `fmt.Sprintf`

`println` An alias for `fmt.Sprintln`

`urlquery` Returns the escaped value of the textual representation of its arguments in a form suitable for embedding in a URL query

The boolean functions take any zero value to be false and a non-zero value to be true.

Associated templates

Each template is named by a string specified when it is created. Also, each template is associated with zero or more other templates that it may invoke by name; such associations are transitive and form a name space of templates.

A template may use a template invocation to instantiate another associated template; see the explanation of the "template" action above. The name must be that of a template associated with the template that contains the invocation.

Nested template definitions

When parsing a template, another template may be defined and associated with the template being parsed. Template definitions must appear at the top level of the template, much like global variables in a Go program.

The syntax of such definitions is to surround each template declaration with a "define" and "end" action.

The define action names the template being created by providing a string

constant. Here is a simple example:

```
`{{define "T1"}}ONE{{end}}
{{define "T2"}}TWO{{end}}
{{define "T3"}}{{template "T1"}} {{template "T2"}}{{end}}
{{template "T3"}}`
```

This defines two templates, T1 and T2, and a third T3 that invokes the other two when it is executed. Finally it invokes T3. If executed this template will produce the text

```
ONE TWO
```

By construction, a template may reside in only one association. If it's necessary to have a template addressable from multiple associations, the template definition must be parsed multiple times to create distinct *Template values, or must be copied with the Clone or AddParseTree method.

Parse may be called multiple times to assemble the various associated templates; see the ParseFiles and ParseGlob functions and methods for simple ways to parse related templates stored in files.

A template may be executed directly or through ExecuteTemplate, which executes an associated template identified by name. To invoke our example above, we might write,

```
err := tmpl.Execute(os.Stdout, "no data needed")
if err != nil {
    log.Fatalf("execution failed: %s", err)
}
```

or to invoke a particular template explicitly by name,

```
err := tmpl.ExecuteTemplate(os.Stdout, "T2", "no data needed")
if err != nil {
    log.Fatalf("execution failed: %s", err)
}
```

[Template \(Helpers\)](#)

[Template \(Share\)](#)

Package files

[doc.go](#) [exec.go](#) [funcs.go](#) [helper.go](#) [template.go](#)

func [HTMLEscape](#)

```
func HTMLEscape(w io.Writer, b []byte)
```

HTMLEscape writes to w the escaped HTML equivalent of the plain text data b.

func [HTMLEscapeString](#)

```
func HTMLEscapeString(s string) string
```

HTMLEscapeString returns the escaped HTML equivalent of the plain text data s.

func [HTMLEscaper](#)

```
func HTMLEscaper(args ...interface{}) string
```

HTMLEscaper returns the escaped HTML equivalent of the textual representation of its arguments.

func [JSEscape](#)

```
func JSEscape(w io.Writer, b []byte)
```

JSEscape writes to w the escaped JavaScript equivalent of the plain text data b.

func [JSEscapeString](#)

```
func JSEscapeString(s string) string
```

JSEscapeString returns the escaped JavaScript equivalent of the plain text data s.

func [JSEscaper](#)

```
func JSEscaper(args ...interface{}) string
```

JSEscaper returns the escaped JavaScript equivalent of the textual representation of its arguments.

func [URLQueryEscaper](#)

```
func URLQueryEscaper(args ...interface{}) string
```

URLQueryEscaper returns the escaped value of the textual representation of its arguments in a form suitable for embedding in a URL query.

type [FuncMap](#)

```
type FuncMap map[string]interface{}
```

FuncMap is the type of the map defining the mapping from names to functions. Each function must have either a single return value, or two return values of which the second has type error. In that case, if the second (error) argument evaluates to non-nil during execution, execution terminates and Execute returns that error.

type [Template](#)

```
type Template struct {
    *parse.Tree
    // contains filtered or unexported fields
}
```

Template is the representation of a parsed template. The `*parse.Tree` field is exported only for use by `html/template` and should be treated as unexported by all other clients.

? Example

? Example

Code:

```
// Define a template.
const letter = `
Dear {{.Name}},
{{if .Attended}}
It was a pleasure to see you at the wedding.{{else}}
It is a shame you couldn't make it to the wedding.{{end}}
{{with .Gift}}Thank you for the lovely {{.}}.
{{end}}
Best wishes,
Josie
`

// Prepare some data to insert into the template.
type Recipient struct {
    Name, Gift string
    Attended bool
}
var recipients = []Recipient{
    {"Aunt Mildred", "bone china tea set", true},
    {"Uncle John", "moleskin pants", false},
    {"Cousin Rodney", "", false},
}

// Create a new template and parse the letter into it.
t := template.Must(template.New("letter").Parse(letter))

// Execute the template for each recipient.
for _, r := range recipients {
```

```
    err := t.Execute(os.Stdout, r)
    if err != nil {
        log.Println("executing template:", err)
    }
}
```

Output:

Dear Aunt Mildred,

It was a pleasure to see you at the wedding.
Thank you for the lovely bone china tea set.

Best wishes,
Josie

Dear Uncle John,

It is a shame you couldn't make it to the wedding.
Thank you for the lovely moleskin pants.

Best wishes,
Josie

Dear Cousin Rodney,

It is a shame you couldn't make it to the wedding.

Best wishes,
Josie

? Example (Func)

? Example (Func)

This example demonstrates a custom function to process template text. It installs the `strings.Title` function and uses it to Make Title Text Look Good In Our Template's Output.

Code:

```
// First we create a FuncMap with which to register the function.
funcMap := template.FuncMap{
    // The name "title" is what the function will be called in the t
    "title": strings.Title,
}
```

```

// A simple template definition to test our function.
// We print the input text several ways:
// - the original
// - title-cased
// - title-cased and then printed with %q
// - printed with %q and then title-cased.
const templateText = `
Input: {{printf "%q" .}}
Output 0: {{title .}}
Output 1: {{title . | printf "%q"}}
Output 2: {{printf "%q" . | title}}
`

// Create a template, add the function map, and parse the text.
tmpl, err := template.New("titleTest").Funcs(funcMap).Parse(templateText)
if err != nil {
    log.Fatalf("parsing: %s", err)
}

// Run the template to verify the output.
err = tmpl.Execute(os.Stdout, "the go programming language")
if err != nil {
    log.Fatalf("execution: %s", err)
}

```

Output:

```

Input: "the go programming language"
Output 0: The Go Programming Language
Output 1: "The Go Programming Language"
Output 2: "The Go Programming Language"

```

? Example (Glob)

? Example (Glob)

Here we demonstrate loading a set of templates from a directory.

Code:

```

// Here we create a temporary directory and populate it with our sam
// template definition files; usually the template files would alrea
// exist in some location known to the program.
dir := createTestDir([]templateFile{
    // T0.tmpl is a plain template file that just invokes T1.

```

```

    {"T0.tpl", `T0 invokes T1: ({{template "T1"}})`},
    // T1.tpl defines a template, T1 that invokes T2.
    {"T1.tpl", `{{define "T1"}}T1 invokes T2: ({{template "T2"}}){{
    // T2.tpl defines a template T2.
    {"T2.tpl", `{{define "T2"}}This is T2{{end}}`},
    })
// Clean up after the test; another quirk of running as an example.
defer os.RemoveAll(dir)

// pattern is the glob pattern used to find all the template files.
pattern := filepath.Join(dir, "*.tpl")

// Here starts the example proper.
// T0.tpl is the first name matched, so it becomes the starting tem
// the value returned by ParseGlob.
tpl := template.Must(template.ParseGlob(pattern))

err := tpl.Execute(os.Stdout, nil)
if err != nil {
    log.Fatalf("template execution: %s", err)
}

```

Output:

```
T0 invokes T1: (T1 invokes T2: (This is T2))
```

? Example (Helpers)

? Example (Helpers)

This example demonstrates one way to share some templates and use them in different contexts. In this variant we add multiple driver templates by hand to an existing bundle of templates.

Code:

```

// Here we create a temporary directory and populate it with our sam
// template definition files; usually the template files would alrea
// exist in some location known to the program.
dir := createTestDir([]templateFile{
    // T1.tpl defines a template, T1 that invokes T2.
    {"T1.tpl", `{{define "T1"}}T1 invokes T2: ({{template "T2"}}){{
    // T2.tpl defines a template T2.
    {"T2.tpl", `{{define "T2"}}This is T2{{end}}`},
    })
// Clean up after the test; another quirk of running as an example.
defer os.RemoveAll(dir)

```

```

// pattern is the glob pattern used to find all the template files.
pattern := filepath.Join(dir, "*.tmpl")

// Here starts the example proper.
// Load the helpers.
templates := template.Must(template.ParseGlob(pattern))
// Add one driver template to the bunch; we do this with an explicit
_, err := templates.Parse("{{define `driver1`}}Driver 1 calls T1: ({{
if err != nil {
    log.Fatal("parsing driver1: ", err)
}
// Add another driver template.
_, err = templates.Parse("{{define `driver2`}}Driver 2 calls T2: ({{
if err != nil {
    log.Fatal("parsing driver2: ", err)
}
// We load all the templates before execution. This package does not
// that behavior but html/template's escaping does, so it's a good h
err = templates.ExecuteTemplate(os.Stdout, "driver1", nil)
if err != nil {
    log.Fatalf("driver1 execution: %s", err)
}
err = templates.ExecuteTemplate(os.Stdout, "driver2", nil)
if err != nil {
    log.Fatalf("driver2 execution: %s", err)
}
}

```

Output:

```

Driver 1 calls T1: (T1 invokes T2: (This is T2))
Driver 2 calls T2: (This is T2)

```

? Example (Share)

? Example (Share)

This example demonstrates how to use one group of driver templates with distinct sets of helper templates.

Code:

```

// Here we create a temporary directory and populate it with our sam
// template definition files; usually the template files would alrea
// exist in some location known to the program.
dir := createTestDir([]templateFile{
    // T0.tmpl is a plain template file that just invokes T1.

```

```

    {"T0.tpl", "T0 ({{.}} version) invokes T1: ({{template `T1`}})\
    // T1.tpl defines a template, T1 that invokes T2. Note T2 is no
    {"T1.tpl", `{{define "T1"}}T1 invokes T2: ({{template "T2"}}){{
}})
// Clean up after the test; another quirk of running as an example.
defer os.RemoveAll(dir)

// pattern is the glob pattern used to find all the template files.
pattern := filepath.Join(dir, "*.tpl")

// Here starts the example proper.
// Load the drivers.
drivers := template.Must(template.ParseGlob(pattern))

// We must define an implementation of the T2 template. First we clo
// the drivers, then add a definition of T2 to the template name spa

// 1. Clone the helper set to create a new name space from which to
first, err := drivers.Clone()
if err != nil {
    log.Fatal("cloning helpers: ", err)
}
// 2. Define T2, version A, and parse it.
_, err = first.Parse("{{define `T2`}}T2, version A{{end}}")
if err != nil {
    log.Fatal("parsing T2: ", err)
}

// Now repeat the whole thing, using a different version of T2.
// 1. Clone the drivers.
second, err := drivers.Clone()
if err != nil {
    log.Fatal("cloning drivers: ", err)
}
// 2. Define T2, version B, and parse it.
_, err = second.Parse("{{define `T2`}}T2, version B{{end}}")
if err != nil {
    log.Fatal("parsing T2: ", err)
}

// Execute the templates in the reverse order to verify the
// first is unaffected by the second.
err = second.ExecuteTemplate(os.Stdout, "T0.tpl", "second")
if err != nil {
    log.Fatalf("second execution: %s", err)
}
err = first.ExecuteTemplate(os.Stdout, "T0.tpl", "first")
if err != nil {
    log.Fatalf("first: execution: %s", err)
}

```

Output:

```
T0 (second version) invokes T1: (T1 invokes T2: (T2, version B))
T0 (first version) invokes T1: (T1 invokes T2: (T2, version A))
```

func [Must](#)

```
func Must(t *Template, err error) *Template
```

Must is a helper that wraps a call to a function returning (*Template, error) and panics if the error is non-nil. It is intended for use in variable initializations such as

```
var t = template.Must(template.New("name").Parse("text"))
```

func [New](#)

```
func New(name string) *Template
```

New allocates a new template with the given name.

func [ParseFiles](#)

```
func ParseFiles(filenamees ...string) (*Template, error)
```

ParseFiles creates a new Template and parses the template definitions from the named files. The returned template's name will have the (base) name and (parsed) contents of the first file. There must be at least one file. If an error occurs, parsing stops and the returned *Template is nil.

func [ParseGlob](#)

```
func ParseGlob(pattern string) (*Template, error)
```

ParseGlob creates a new Template and parses the template definitions from the files identified by the pattern, which must match at least one file. The returned template will have the (base) name and (parsed) contents of the first file matched by the pattern. ParseGlob is equivalent to calling ParseFiles with the list of files matched by the pattern.

func (*Template) [AddParseTree](#)

```
func (t *Template) AddParseTree(name string, tree *parse.Tree) (*Tem
```

AddParseTree creates a new template with the name and parse tree and associates it with t.

func (*Template) [Clone](#)

```
func (t *Template) Clone() (*Template, error)
```

Clone returns a duplicate of the template, including all associated templates. The actual representation is not copied, but the name space of associated templates is, so further calls to Parse in the copy will add templates to the copy but not to the original. Clone can be used to prepare common templates and use them with variant definitions for other templates by adding the variants after the clone is made.

func (*Template) [Delims](#)

```
func (t *Template) Delims(left, right string) *Template
```

Delims sets the action delimiters to the specified strings, to be used in subsequent calls to Parse, ParseFiles, or ParseGlob. Nested template definitions will inherit the settings. An empty delimiter stands for the corresponding default: {{ or }}. The return value is the template, so calls can be chained.

func (*Template) [Execute](#)

```
func (t *Template) Execute(wr io.Writer, data interface{}) (err error)
```

Execute applies a parsed template to the specified data object, and writes the output to wr.

func (*Template) [ExecuteTemplate](#)

```
func (t *Template) ExecuteTemplate(wr io.Writer, name string, data i
```

ExecuteTemplate applies the template associated with t that has the given name to the specified data object and writes the output to wr.

func (*Template) [Funcs](#)

```
func (t *Template) Funcs(funcMap FuncMap) *Template
```

Funcs adds the elements of the argument map to the template's function map. It panics if a value in the map is not a function with appropriate return type. However, it is legal to overwrite elements of the map. The return value is the template, so calls can be chained.

func (*Template) [Lookup](#)

```
func (t *Template) Lookup(name string) *Template
```

Lookup returns the template with the given name that is associated with t, or nil if there is no such template.

func (*Template) [Name](#)

```
func (t *Template) Name() string
```

Name returns the name of the template.

func (*Template) [New](#)

```
func (t *Template) New(name string) *Template
```

New allocates a new template associated with the given one and with the same delimiters. The association, which is transitive, allows one template to invoke another with a `{{template}}` action.

func (*Template) [Parse](#)

```
func (t *Template) Parse(text string) (*Template, error)
```

Parse parses a string into a template. Nested template definitions will be associated with the top-level template t. Parse may be called multiple times to parse definitions of templates to associate with t. It is an error if a resulting template is non-empty (contains content other than template definitions) and would replace a non-empty template with the same name. (In multiple calls to Parse with the same receiver template, only one call can contain text other than

space, comments, and template definitions.)

func (*Template) [ParseFiles](#)

```
func (t *Template) ParseFiles(filenamees ...string) (*Template, error)
```

ParseFiles parses the named files and associates the resulting templates with t. If an error occurs, parsing stops and the returned template is nil; otherwise it is t. There must be at least one file.

func (*Template) [ParseGlob](#)

```
func (t *Template) ParseGlob(pattern string) (*Template, error)
```

ParseGlob parses the template definitions in the files identified by the pattern and associates the resulting templates with t. The pattern is processed by filepath.Glob and must match at least one file. ParseGlob is equivalent to calling t.ParseFiles with the list of files matched by the pattern.

func (*Template) [Templates](#)

```
func (t *Template) Templates() []*Template
```

Templates returns a slice of the templates associated with t, including t itself.

Package parse

```
import "text/template/parse"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package parse builds parse trees for templates as defined by text/template and html/template. Clients should use those packages to construct templates rather than this one, which provides shared internal data structures not intended for general use.

Package files

[lex.go](#) [node.go](#) [parse.go](#)

func IsEmptyTree

```
func IsEmptyTree(n Node) bool
```

IsEmptyTree reports whether this tree (node) is empty of everything but space.

func [Parse](#)

```
func Parse(name, text, leftDelim, rightDelim string, funcs ...map[st
```

Parse returns a map from template name to `parse.Tree`, created by parsing the templates described in the argument string. The top-level template will be given the specified name. If an error is encountered, parsing stops and an empty map is returned with the error.

type [ActionNode](#)

```
type ActionNode struct {  
    NodeType  
    Line int          // The line number in the input.  
    Pipe *PipeNode // The pipeline in the action.  
}
```

ActionNode holds an action (something bounded by delimiters). Control actions have their own nodes; ActionNode represents simple ones such as field evaluations.

func (*ActionNode) [Copy](#)

```
func (a *ActionNode) Copy() Node
```

func (*ActionNode) [String](#)

```
func (a *ActionNode) String() string
```

type [BoolNode](#)

```
type BoolNode struct {  
    NodeType  
    True bool // The value of the boolean constant.  
}
```

BoolNode holds a boolean constant.

func (***BoolNode**) [Copy](#)

```
func (b *BoolNode) Copy() Node
```

func (***BoolNode**) [String](#)

```
func (b *BoolNode) String() string
```

type [BranchNode](#)

```
type BranchNode struct {
    NodeType
    Line      int          // The line number in the input.
    Pipe      *PipeNode // The pipeline to be evaluated.
    List      *ListNode // What to execute if the value is non-empty.
    ElseList  *ListNode // What to execute if the value is empty (nil)
}
```

BranchNode is the common representation of if, range, and with.

func (*BranchNode) [String](#)

```
func (b *BranchNode) String() string
```

type [CommandNode](#)

```
type CommandNode struct {  
    NodeType  
    Args []Node // Arguments in lexical order: Identifier, field, or  
}
```

CommandNode holds a command (a pipeline inside an evaluating action).

func (*CommandNode) [Copy](#)

```
func (c *CommandNode) Copy() Node
```

func (*CommandNode) [String](#)

```
func (c *CommandNode) String() string
```

type [DotNode](#)

```
type DotNode bool
```

DotNode holds the special identifier '!'. It is represented by a nil pointer.

func (*DotNode) [Copy](#)

```
func (d *DotNode) Copy() Node
```

func (*DotNode) [String](#)

```
func (d *DotNode) String() string
```

func (*DotNode) [Type](#)

```
func (d *DotNode) Type() NodeType
```

type [FieldNode](#)

```
type FieldNode struct {  
    NodeType  
    Ident []string // The identifiers in lexical order.  
}
```

FieldNode holds a field (identifier starting with '.'). The names may be chained ('.x.y'). The period is dropped from each ident.

func (***FieldNode**) [Copy](#)

```
func (f *FieldNode) Copy() Node
```

func (***FieldNode**) [String](#)

```
func (f *FieldNode) String() string
```

type [IdentifierNode](#)

```
type IdentifierNode struct {  
    NodeType  
    Ident string // The identifier's name.  
}
```

IdentifierNode holds an identifier.

func [NewIdentifier](#)

```
func NewIdentifier(ident string) *IdentifierNode
```

NewIdentifier returns a new IdentifierNode with the given identifier name.

func (*IdentifierNode) [Copy](#)

```
func (i *IdentifierNode) Copy() Node
```

func (*IdentifierNode) [String](#)

```
func (i *IdentifierNode) String() string
```

type [IfNode](#)

```
type IfNode struct {  
    BranchNode  
}
```

IfNode represents an `{{if}}` action and its commands.

func (*IfNode) [Copy](#)

```
func (i *IfNode) Copy() Node
```

type [ListNode](#)

```
type ListNode struct {  
    NodeType  
    Nodes []Node // The element nodes in lexical order.  
}
```

ListNode holds a sequence of nodes.

func (*ListNode) [Copy](#)

```
func (l *ListNode) Copy() Node
```

func (*ListNode) [CopyList](#)

```
func (l *ListNode) CopyList() *ListNode
```

func (*ListNode) [String](#)

```
func (l *ListNode) String() string
```

type [Node](#)

```
type Node interface {
    Type() NodeType
    String() string
    // Copy does a deep copy of the Node and all its components.
    // To avoid type assertions, some XxxNodes also have specialized
    // CopyXxx methods that return *XxxNode.
    Copy() Node
}
```

A node is an element in the parse tree. The interface is trivial.

type [NodeType](#)

```
type NodeType int
```

NodeType identifies the type of a parse tree node.

```
const (  
    NodeText      NodeType = iota // Plain text.  
    NodeAction    // A simple action such as field eval  
    NodeBool      // A boolean constant.  
    NodeCommand   // An element of a pipeline.  
    NodeDot       // The cursor, dot.  
  
    NodeField     // A field or method name.  
    NodeIdentifier // An identifier; always a function name.  
    NodeIf        // An if action.  
    NodeList      // A list of Nodes.  
    NodeNumber    // A numerical constant.  
    NodePipe      // A pipeline of commands.  
    NodeRange     // A range action.  
    NodeString    // A string constant.  
    NodeTemplate  // A template invocation action.  
    NodeVariable  // A $ variable.  
    NodeWith      // A with action.  
)
```

func (NodeType) [Type](#)

```
func (t NodeType) Type() NodeType
```

Type returns itself and provides an easy default implementation for embedding in a Node. Embedded in all non-trivial Nodes.

type [NumberNode](#)

```
type NumberNode struct {
    NodeType
    IsInt      bool        // Number has an integral value.
    IsUint     bool        // Number has an unsigned integral value.
    IsFloat    bool        // Number has a floating-point value.
    IsComplex  bool        // Number is complex.
    Int64      int64       // The signed integer value.
    Uint64     uint64      // The unsigned integer value.
    Float64    float64    // The floating-point value.
    Complex128 complex128 // The complex value.
    Text       string      // The original textual representation fro
}
```

NumberNode holds a number: signed or unsigned integer, float, or complex. The value is parsed and stored under all the types that can represent the value. This simulates in a small amount of code the behavior of Go's ideal constants.

func (*NumberNode) [Copy](#)

```
func (n *NumberNode) Copy() Node
```

func (*NumberNode) [String](#)

```
func (n *NumberNode) String() string
```

type [PipeNode](#)

```
type PipeNode struct {
    NodeType
    Line int           // The line number in the input.
    Decl []*VariableNode // Variable declarations in lexical order.
    Cmds []*CommandNode // The commands in lexical order.
}
```

PipeNode holds a pipeline with optional declaration

func (*PipeNode) [Copy](#)

```
func (p *PipeNode) Copy() Node
```

func (*PipeNode) [CopyPipe](#)

```
func (p *PipeNode) CopyPipe() *PipeNode
```

func (*PipeNode) [String](#)

```
func (p *PipeNode) String() string
```

type [RangeNode](#)

```
type RangeNode struct {  
    BranchNode  
}
```

RangeNode represents a {{range}} action and its commands.

func (*RangeNode) [Copy](#)

```
func (r *RangeNode) Copy() Node
```

type [StringNode](#)

```
type StringNode struct {  
    NodeType  
    Quoted string // The original text of the string, with quotes.  
    Text    string // The string, after quote processing.  
}
```

StringNode holds a string constant. The value has been "unquoted".

func (*StringNode) [Copy](#)

```
func (s *StringNode) Copy() Node
```

func (*StringNode) [String](#)

```
func (s *StringNode) String() string
```

type [TemplateNode](#)

```
type TemplateNode struct {
    NodeType
    Line int        // The line number in the input.
    Name string     // The name of the template (unquoted).
    Pipe *PipeNode // The command to evaluate as dot for the templat
}
```

TemplateNode represents a {{template}} action.

func (*TemplateNode) [Copy](#)

```
func (t *TemplateNode) Copy() Node
```

func (*TemplateNode) [String](#)

```
func (t *TemplateNode) String() string
```

type [TextNode](#)

```
type TextNode struct {  
    NodeType  
    Text []byte // The text; may span newlines.  
}
```

TextNode holds plain text.

func (*TextNode) [Copy](#)

```
func (t *TextNode) Copy() Node
```

func (*TextNode) [String](#)

```
func (t *TextNode) String() string
```

type [Tree](#)

```
type Tree struct {
    Name string    // name of the template represented by the tree.
    Root *ListNode // top-level root of the tree.
    // Parsing only; cleared after parse.
    // contains filtered or unexported fields
}
```

Tree is the representation of a single parsed template.

func [New](#)

```
func New(name string, funcs ...map[string]interface{}) *Tree
```

New allocates a new parse tree with the given name.

func (***Tree**) [Parse](#)

```
func (t *Tree) Parse(s, leftDelim, rightDelim string, treeSet map[st
```

Parse parses the template definition string to construct a representation of the template for execution. If either action delimiter string is empty, the default ("{" or "}") is used. Embedded template definitions are added to the treeSet map.

type [VariableNode](#)

```
type VariableNode struct {  
    NodeType  
    Ident []string // Variable names in lexical order.  
}
```

VariableNode holds a list of variable names. The dollar sign is part of the name.

func (*VariableNode) [Copy](#)

```
func (v *VariableNode) Copy() Node
```

func (*VariableNode) [String](#)

```
func (v *VariableNode) String() string
```

type [WithNode](#)

```
type WithNode struct {  
    BranchNode  
}
```

WithNode represents a `{{with}}` action and its commands.

func (*WithNode) [Copy](#)

```
func (w *WithNode) Copy() Node
```

Build version go1.0.1.

Package time

```
import "time"
```

[Overview](#)

[Index](#)

[Examples](#)

Overview ?

Overview ?

Package time provides functionality for measuring and displaying time.

The calendrical calculations always assume a Gregorian calendar.

Constants

```
const (  
  ANSIC           = "Mon Jan _2 15:04:05 2006"  
  UnixDate       = "Mon Jan _2 15:04:05 MST 2006"  
  RubyDate       = "Mon Jan 02 15:04:05 -0700 2006"  
  RFC822         = "02 Jan 06 15:04 MST"  
  RFC822Z        = "02 Jan 06 15:04 -0700" // RFC822 with numeric zon  
  RFC850         = "Monday, 02-Jan-06 15:04:05 MST"  
  RFC1123        = "Mon, 02 Jan 2006 15:04:05 MST"  
  RFC1123Z       = "Mon, 02 Jan 2006 15:04:05 -0700" // RFC1123 with  
  RFC3339        = "2006-01-02T15:04:05Z07:00"  
  RFC3339Nano    = "2006-01-02T15:04:05.999999999Z07:00"  
  Kitchen        = "3:04PM"  
  // Handy time stamps.  
  Stamp          = "Jan _2 15:04:05"  
  StampMilli     = "Jan _2 15:04:05.000"  
  StampMicro     = "Jan _2 15:04:05.000000"  
  StampNano      = "Jan _2 15:04:05.000000000"  
)
```

These are predefined layouts for use in `Time.Format`. The standard time used in the layouts is:

```
Mon Jan 2 15:04:05 MST 2006
```

which is Unix time 1136243045. Since MST is GMT-0700, the standard time can be thought of as

```
01/02 03:04:05PM '06 -0700
```

To define your own format, write down what the standard time would look like formatted your way; see the values of constants like `ANSIC`, `StampMicro` or `Kitchen` for examples.

Within the format string, an underscore `_` represents a space that may be replaced by a digit if the following number (a day) has two digits; for compatibility with fixed-width Unix time formats.

A decimal point followed by one or more zeros represents a fractional second, printed to the given number of decimal places. A decimal point followed by one or more nines represents a fractional second, printed to the given number of

decimal places, with trailing zeros removed. When parsing (only), the input may contain a fractional second field immediately after the seconds field, even if the layout does not signify its presence. In that case a decimal point followed by a maximal series of digits is parsed as a fractional second.

Numeric time zone offsets format as follows:

-0700 hhmm
-07:00 hh:mm

Replacing the sign in the format with a Z triggers the ISO 8601 behavior of printing Z instead of an offset for the UTC zone. Thus:

Z0700 Z or hhmm
Z07:00 Z or hh:mm

func [After](#)

```
func After(d Duration) <-chan Time
```

After waits for the duration to elapse and then sends the current time on the returned channel. It is equivalent to `NewTimer(d).C`.

? Example

? Example

Code:

```
select {
case m := <-c:
    handle(m)
case <-time.After(5 * time.Minute):
    fmt.Println("timed out")
}
```

func [Sleep](#)

```
func Sleep(d Duration)
```

Sleep pauses the current goroutine for the duration d.

? Example

? Example

Code:

```
time.Sleep(100 * time.Millisecond)
```

func [Tick](#)

```
func Tick(d Duration) <-chan Time
```

Tick is a convenience wrapper for NewTicker providing access to the ticking channel only. Useful for clients that have no need to shut down the ticker.

? Example

? Example

Code:

```
c := time.Tick(1 * time.Minute)
for now := range c {
    fmt.Printf("%v %s\n", now, statusUpdate())
}
```

type [Duration](#)

```
type Duration int64
```

A Duration represents the elapsed time between two instants as an int64 nanosecond count. The representation limits the largest representable duration to approximately 290 years.

```
const (  
    Nanosecond Duration = 1  
    Microsecond      = 1000 * Nanosecond  
    Millisecond       = 1000 * Microsecond  
    Second            = 1000 * Millisecond  
    Minute            = 60 * Second  
    Hour              = 60 * Minute  
)
```

Common durations. There is no definition for units of Day or larger to avoid confusion across daylight savings time zone transitions.

To count the number of units in a Duration, divide:

```
second := time.Second  
fmt.Print(int64(second/time.Millisecond)) // prints 1000
```

To convert an integer number of units to a Duration, multiply:

```
seconds := 10  
fmt.Print(time.Duration(seconds)*time.Second) // prints 10s
```

? Example

? Example

Code:

```
t0 := time.Now()  
expensiveCall()  
t1 := time.Now()  
fmt.Printf("The call took %v to run.\n", t1.Sub(t0))
```

func [ParseDuration](#)

```
func ParseDuration(s string) (Duration, error)
```

ParseDuration parses a duration string. A duration string is a possibly signed sequence of decimal numbers, each with optional fraction and a unit suffix, such as "300ms", "-1.5h" or "2h45m". Valid time units are "ns", "us" (or "?s"), "ms", "s", "m", "h".

func [Since](#)

```
func Since(t Time) Duration
```

Since returns the time elapsed since t. It is shorthand for `time.Now().Sub(t)`.

func (Duration) [Hours](#)

```
func (d Duration) Hours() float64
```

Hours returns the duration as a floating point number of hours.

func (Duration) [Minutes](#)

```
func (d Duration) Minutes() float64
```

Minutes returns the duration as a floating point number of minutes.

func (Duration) [Nanoseconds](#)

```
func (d Duration) Nanoseconds() int64
```

Nanoseconds returns the duration as an integer nanosecond count.

func (Duration) [Seconds](#)

```
func (d Duration) Seconds() float64
```

Seconds returns the duration as a floating point number of seconds.

func (Duration) [String](#)

```
func (d Duration) String() string
```

String returns a string representing the duration in the form "72h3m0.5s". Leading zero units are omitted. As a special case, durations less than one second format use a smaller unit (milli-, micro-, or nanoseconds) to ensure that the leading digit is non-zero. The zero duration formats as 0, with no unit.

type [Location](#)

```
type Location struct {  
    // contains filtered or unexported fields  
}
```

A Location maps time instants to the zone in use at that time. Typically, the Location represents the collection of time offsets in use in a geographical area, such as CEST and CET for central Europe.

```
var Local *Location = &localLoc
```

Local represents the system's local time zone.

```
var UTC *Location = &utcLoc
```

UTC represents Universal Coordinated Time (UTC).

func [FixedZone](#)

```
func FixedZone(name string, offset int) *Location
```

FixedZone returns a Location that always uses the given zone name and offset (seconds east of UTC).

func [LoadLocation](#)

```
func LoadLocation(name string) (*Location, error)
```

LoadLocation returns the Location with the given name.

If the name is "" or "UTC", LoadLocation returns UTC. If the name is "Local", LoadLocation returns Local.

Otherwise, the name is taken to be a location name corresponding to a file in the IANA Time Zone database, such as "America/New_York".

The time zone database needed by LoadLocation may not be present on all systems, especially non-Unix systems. LoadLocation looks in the directory or uncompressed zip file named by the ZONEINFO environment variable, if any,

then looks in known installation locations on Unix systems, and finally looks in \$GOROOT/lib/time/zoneinfo.zip.

func (*Location) [String](#)

```
func (l *Location) String() string
```

String returns a descriptive name for the time zone information, corresponding to the argument to LoadLocation.

type [Month](#)

```
type Month int
```

A Month specifies a month of the year (January = 1, ...).

```
const (  
    January Month = 1 + iota  
    February  
    March  
    April  
    May  
    June  
    July  
    August  
    September  
    October  
    November  
    December  
)
```

? Example

? Example

Code:

```
_, month, day := time.Now().Date()  
if month == time.November && day == 10 {  
    fmt.Println("Happy Go day!")  
}
```

func (Month) [String](#)

```
func (m Month) String() string
```

String returns the English name of the month ("January", "February", ...).

type [ParseError](#)

```
type ParseError struct {  
    Layout      string  
    Value       string  
    LayoutElem  string  
    ValueElem   string  
    Message     string  
}
```

ParseError describes a problem parsing a time string.

func (*ParseError) [Error](#)

```
func (e *ParseError) Error() string
```

Error returns the string representation of a ParseError.

type [Ticker](#)

```
type Ticker struct {  
    C <-chan Time // The channel on which the ticks are delivered.  
    // contains filtered or unexported fields  
}
```

A Ticker holds a synchronous channel that delivers `ticks' of a clock at intervals.

func [NewTicker](#)

```
func NewTicker(d Duration) *Ticker
```

NewTicker returns a new Ticker containing a channel that will send the time with a period specified by the duration argument. It adjusts the intervals or drops ticks to make up for slow receivers. The duration d must be greater than zero; if not, NewTicker will panic.

func (***Ticker**) [Stop](#)

```
func (t *Ticker) Stop()
```

Stop turns off a ticker. After Stop, no more ticks will be sent.

type [Time](#)

```
type Time struct {  
    // contains filtered or unexported fields  
}
```

A `Time` represents an instant in time with nanosecond precision.

Programs using times should typically store and pass them as values, not pointers. That is, time variables and struct fields should be of type `time.Time`, not `*time.Time`. A `Time` value can be used by multiple goroutines simultaneously.

Time instants can be compared using the `Before`, `After`, and `Equal` methods. The `Sub` method subtracts two instants, producing a `Duration`. The `Add` method adds a `Time` and a `Duration`, producing a `Time`.

The zero value of type `Time` is January 1, year 1, 00:00:00.000000000 UTC. As this time is unlikely to come up in practice, the `IsZero` method gives a simple way of detecting a time that has not been initialized explicitly.

Each `Time` has associated with it a `Location`, consulted when computing the presentation form of the time, such as in the `Format`, `Hour`, and `Year` methods. The methods `Local`, `UTC`, and `In` return a `Time` with a specific location. Changing the location in this way changes only the presentation; it does not change the instant in time being denoted and therefore does not affect the computations described in earlier paragraphs.

func [Date](#)

```
func Date(year int, month Month, day, hour, min, sec, nsec int, loc
```

`Date` returns the `Time` corresponding to

```
yyyy-mm-dd hh:mm:ss + nsec nanoseconds
```

in the appropriate zone for that time in the given location.

The month, day, hour, min, sec, and nsec values may be outside their usual

ranges and will be normalized during the conversion. For example, October 32 converts to November 1.

A daylight savings time transition skips or repeats times. For example, in the United States, March 13, 2011 2:15am never occurred, while November 6, 2011 1:15am occurred twice. In such cases, the choice of time zone, and therefore the time, is not well-defined. `Date` returns a time that is correct in one of the two zones involved in the transition, but it does not guarantee which.

`Date` panics if `loc` is `nil`.

? Example

? Example

Code:

```
t := time.Date(2009, time.November, 10, 23, 0, 0, 0, time.UTC)
fmt.Printf("Go launched at %s\n", t.Local())
```

Output:

```
Go launched at 2009-11-10 15:00:00 -0800 PST
```

func [Now](#)

```
func Now() Time
```

`Now` returns the current local time.

func [Parse](#)

```
func Parse(layout, value string) (Time, error)
```

`Parse` parses a formatted string and returns the time value it represents. The layout defines the format by showing the representation of the standard time,

```
Mon Jan 2 15:04:05 -0700 MST 2006
```

which is then used to describe the string to be parsed. Predefined layouts `ANSIC`, `UnixDate`, `RFC3339` and others describe standard representations. For

more information about the formats and the definition of the standard time, see the documentation for ANSIC.

Elements omitted from the value are assumed to be zero or, when zero is impossible, one, so parsing "3:04pm" returns the time corresponding to Jan 1, year 0, 15:04:00 UTC. Years must be in the range 0000..9999. The day of the week is checked for syntax but it is otherwise ignored.

func [Unix](#)

```
func Unix(sec int64, nsec int64) Time
```

Unix returns the local Time corresponding to the given Unix time, sec seconds and nsec nanoseconds since January 1, 1970 UTC. It is valid to pass nsec outside the range [0, 999999999].

func (Time) [Add](#)

```
func (t Time) Add(d Duration) Time
```

Add returns the time t+d.

func (Time) [AddDate](#)

```
func (t Time) AddDate(years int, months int, days int) Time
```

AddDate returns the time corresponding to adding the given number of years, months, and days to t. For example, AddDate(-1, 2, 3) applied to January 1, 2011 returns March 4, 2010.

AddDate normalizes its result in the same way that Date does, so, for example, adding one month to October 31 yields December 1, the normalized form for November 31.

func (Time) [After](#)

```
func (t Time) After(u Time) bool
```

After reports whether the time instant t is after u.

func (Time) [Before](#)

```
func (t Time) Before(u Time) bool
```

Before reports whether the time instant `t` is before `u`.

func (Time) [Clock](#)

```
func (t Time) Clock() (hour, min, sec int)
```

Clock returns the hour, minute, and second within the day specified by `t`.

func (Time) [Date](#)

```
func (t Time) Date() (year int, month Month, day int)
```

Date returns the year, month, and day in which `t` occurs.

func (Time) [Day](#)

```
func (t Time) Day() int
```

Day returns the day of the month specified by `t`.

func (Time) [Equal](#)

```
func (t Time) Equal(u Time) bool
```

Equal reports whether `t` and `u` represent the same time instant. Two times can be equal even if they are in different locations. For example, 6:00 +0200 CEST and 4:00 UTC are Equal. This comparison is different from using `t == u`, which also compares the locations.

func (Time) [Format](#)

```
func (t Time) Format(layout string) string
```

Format returns a textual representation of the time value formatted according to `layout`. The layout defines the format by showing the representation of the standard time,

Mon Jan 2 15:04:05 -0700 MST 2006

which is then used to describe the time to be formatted. Predefined layouts ANSIC, UnixDate, RFC3339 and others describe standard representations. For more information about the formats and the definition of the standard time, see the documentation for ANSIC.

func (*Time) [GobDecode](#)

```
func (t *Time) GobDecode(buf []byte) error
```

GobDecode implements the gob.GobDecoder interface.

func (Time) [GobEncode](#)

```
func (t Time) GobEncode() ([]byte, error)
```

GobEncode implements the gob.GobEncoder interface.

func (Time) [Hour](#)

```
func (t Time) Hour() int
```

Hour returns the hour within the day specified by t, in the range [0, 23].

func (Time) [ISOWeek](#)

```
func (t Time) ISOWeek() (year, week int)
```

ISOWeek returns the ISO 8601 year and week number in which t occurs. Week ranges from 1 to 53. Jan 01 to Jan 03 of year n might belong to week 52 or 53 of year n-1, and Dec 29 to Dec 31 might belong to week 1 of year n+1.

func (Time) [In](#)

```
func (t Time) In(loc *Location) Time
```

In returns t with the location information set to loc.

In panics if loc is nil.

func (Time) [IsZero](#)

```
func (t Time) IsZero() bool
```

IsZero reports whether t represents the zero time instant, January 1, year 1, 00:00:00 UTC.

func (Time) [Local](#)

```
func (t Time) Local() Time
```

Local returns t with the location set to local time.

func (Time) [Location](#)

```
func (t Time) Location() *Location
```

Location returns the time zone information associated with t.

func (Time) [MarshalJSON](#)

```
func (t Time) MarshalJSON() ([]byte, error)
```

MarshalJSON implements the json.Marshaler interface. Time is formatted as RFC3339.

func (Time) [Minute](#)

```
func (t Time) Minute() int
```

Minute returns the minute offset within the hour specified by t, in the range [0, 59].

func (Time) [Month](#)

```
func (t Time) Month() Month
```

Month returns the month of the year specified by t.

func (Time) [Nanosecond](#)

```
func (t Time) Nanosecond() int
```

Nanosecond returns the nanosecond offset within the second specified by t, in the range [0, 999999999].

func (Time) [Second](#)

```
func (t Time) Second() int
```

Second returns the second offset within the minute specified by t, in the range [0, 59].

func (Time) [String](#)

```
func (t Time) String() string
```

String returns the time formatted using the format string

```
"2006-01-02 15:04:05.999999999 -0700 MST"
```

func (Time) [Sub](#)

```
func (t Time) Sub(u Time) Duration
```

Sub returns the duration t-u. To compute t-d for a duration d, use t.Add(-d).

func (Time) [UTC](#)

```
func (t Time) UTC() Time
```

UTC returns t with the location set to UTC.

func (Time) [Unix](#)

```
func (t Time) Unix() int64
```

Unix returns t as a Unix time, the number of seconds elapsed since January 1, 1970 UTC.

func (Time) [UnixNano](#)

```
func (t Time) UnixNano() int64
```

UnixNano returns t as a Unix time, the number of nanoseconds elapsed since January 1, 1970 UTC. The result is undefined if the Unix time in nanoseconds cannot be represented by an int64. Note that this means the result of calling UnixNano on the zero Time is undefined.

func (*Time) [UnmarshalJSON](#)

```
func (t *Time) UnmarshalJSON(data []byte) (err error)
```

UnmarshalJSON implements the json.Unmarshaler interface. Time is expected in RFC3339 format.

func (Time) [Weekday](#)

```
func (t Time) Weekday() Weekday
```

Weekday returns the day of the week specified by t.

func (Time) [Year](#)

```
func (t Time) Year() int
```

Year returns the year in which t occurs.

func (Time) [Zone](#)

```
func (t Time) Zone() (name string, offset int)
```

Zone computes the time zone in effect at time t, returning the abbreviated name of the zone (such as "CET") and its offset in seconds east of UTC.

type [Timer](#)

```
type Timer struct {  
    C <-chan Time  
    // contains filtered or unexported fields  
}
```

The `Timer` type represents a single event. When the `Timer` expires, the current time will be sent on `C`, unless the `Timer` was created by `AfterFunc`.

func [AfterFunc](#)

```
func AfterFunc(d Duration, f func()) *Timer
```

`AfterFunc` waits for the duration to elapse and then calls `f` in its own goroutine. It returns a `Timer` that can be used to cancel the call using its `Stop` method.

func [NewTimer](#)

```
func NewTimer(d Duration) *Timer
```

`NewTimer` creates a new `Timer` that will send the current time on its channel after at least duration `d`.

func (*Timer) [Stop](#)

```
func (t *Timer) Stop() (ok bool)
```

`Stop` prevents the `Timer` from firing. It returns `true` if the call stops the timer, `false` if the timer has already expired or stopped.

type [Weekday](#)

```
type Weekday int
```

A Weekday specifies a day of the week (Sunday = 0, ...).

```
const (  
    Sunday Weekday = iota  
    Monday  
    Tuesday  
    Wednesday  
    Thursday  
    Friday  
    Saturday  
)
```

func (Weekday) [String](#)

```
func (d Weekday) String() string
```

String returns the English name of the day ("Sunday", "Monday", ...).

Constants

```
const (  
    MaxRune          = '\U0010FFFF' // Maximum valid Unicode code poi  
    ReplacementChar = '\uFFFD'     // Represents invalid code points  
    MaxASCII        = '\u007F'     // maximum ASCII value.  
    MaxLatin1       = '\u00FF'     // maximum Latin-1 value.  
)
```

```
const (  
    UpperCase = iota  
    LowerCase  
    TitleCase  
    MaxCase  
)
```

Indices into the Delta arrays inside CaseRanges for case mapping.

```
const (  
    UpperLower = MaxRune + 1 // (Cannot be a valid delta.)  
)
```

If the Delta field of a CaseRange is UpperLower or LowerUpper, it means this CaseRange represents a sequence of the form (say) Upper Lower Upper Lower.

```
const Version = "6.0.0"
```

Version is the Unicode edition from which the tables are derived.

    "Lu":      foldLu,
    "M":       foldM,
    "Mn":      foldMn,
}

```

FoldCategory maps a category name to a table of code points outside the category that are equivalent under simple case folding to code points inside the category. If there is no entry for a category name, there are no such points.

```
var FoldScript = map[string]*RangeTable{}
```

FoldScript maps a script name to a table of code points outside the script that are equivalent under simple case folding to code points inside the script. If there is no entry for a script name, there are no such points.

```
var GraphicRanges = []*RangeTable{
    L, M, N, P, S, Zs,
}

```

GraphicRanges defines the set of graphic characters according to Unicode.

```
var PrintRanges = []*RangeTable{
    L, M, N, P, S,
}

```

PrintRanges defines the set of printable characters according to Go. ASCII space, U+0020, is handled separately.

```

Scripts is the set of Unicode script tables.

func [Is](#)

```
func Is(rangeTab *RangeTable, r rune) bool
```

Is tests whether rune is in the specified table of ranges.

func [IsControl](#)

```
func IsControl(r rune) bool
```

IsControl reports whether the rune is a control character. The C (Other) Unicode category includes more code points such as surrogates; use Is(C, r) to test for them.

func [IsDigit](#)

```
func IsDigit(r rune) bool
```

IsDigit reports whether the rune is a decimal digit.

func [IsGraphic](#)

```
func IsGraphic(r rune) bool
```

IsGraphic reports whether the rune is defined as a Graphic by Unicode. Such characters include letters, marks, numbers, punctuation, symbols, and spaces, from categories L, M, N, P, S, Zs.

func IsLetter

```
func IsLetter(r rune) bool
```

IsLetter reports whether the rune is a letter (category L).

func IsLower

```
func IsLower(r rune) bool
```

IsLower reports whether the rune is a lower case letter.

func IsMark

```
func IsMark(r rune) bool
```

IsMark reports whether the rune is a mark character (category M).

func IsNumber

```
func IsNumber(r rune) bool
```

IsNumber reports whether the rune is a number (category N).

func [IsOneOf](#)

```
func IsOneOf(set []*RangeTable, r rune) bool
```

IsOneOf reports whether the rune is a member of one of the ranges.

func [IsPrint](#)

```
func IsPrint(r rune) bool
```

IsPrint reports whether the rune is defined as printable by Go. Such characters include letters, marks, numbers, punctuation, symbols, and the ASCII space character, from categories L, M, N, P, S and the ASCII space character. This categorization is the same as IsGraphic except that the only spacing character is ASCII space, U+0020.

func [IsPunct](#)

```
func IsPunct(r rune) bool
```

IsPunct reports whether the rune is a Unicode punctuation character (category P).

func IsSpace

```
func IsSpace(r rune) bool
```

IsSpace reports whether the rune is a space character as defined by Unicode's White Space property; in the Latin-1 space this is

```
'\t', '\n', '\v', '\f', '\r', ' ', U+0085 (NEL), U+00A0 (NBSP).
```

Other definitions of spacing characters are set by category Z and property Pattern_White_Space.

func IsSymbol

```
func IsSymbol(r rune) bool
```

IsSymbol reports whether the rune is a symbolic character.

func [IsTitle](#)

```
func IsTitle(r rune) bool
```

IsTitle reports whether the rune is a title case letter.

func [IsUpper](#)

```
func IsUpper(r rune) bool
```

IsUpper reports whether the rune is an upper case letter.

func [SimpleFold](#)

```
func SimpleFold(r rune) rune
```

SimpleFold iterates over Unicode code points equivalent under the Unicode-defined simple case folding. Among the code points equivalent to rune (including rune itself), SimpleFold returns the smallest rune $\geq r$ if one exists, or else the smallest rune ≥ 0 .

For example:

```
SimpleFold('A') = 'a'
```

```
SimpleFold('a') = 'A'
```

```
SimpleFold('K') = 'k'
```

```
SimpleFold('k') = '\u212A' (Kelvin symbol, ?)
```

```
SimpleFold('\u212A') = 'K'
```

```
SimpleFold('1') = '1'
```

func To

```
func To(_case int, r rune) rune
```

To maps the rune to the specified case: UpperCase, LowerCase, or TitleCase.

func ToLower

```
func ToLower(r rune) rune
```

ToLower maps the rune to lower case.

func [ToTitle](#)

```
func ToTitle(r rune) rune
```

ToTitle maps the rune to title case.

func ToUpper

```
func ToUpper(r rune) rune
```

ToUpper maps the rune to upper case.

type [CaseRange](#)

```
type CaseRange struct {  
    Lo    uint32  
    Hi    uint32  
    Delta d  
}
```

CaseRange represents a range of Unicode code points for simple (one code point to one code point) case conversion. The range runs from Lo to Hi inclusive, with a fixed stride of 1. Deltas are the number to add to the code point to reach the code point for a different case for that character. They may be negative. If zero, it means the character is in the corresponding case. There is a special case representing sequences of alternating corresponding Upper and Lower pairs. It appears with a fixed Delta of

```
{UpperLower, UpperLower, UpperLower}
```

The constant UpperLower has an otherwise impossible delta value.

type [Range16](#)

```
type Range16 struct {  
    Lo      uint16  
    Hi      uint16  
    Stride  uint16  
}
```

Range16 represents of a range of 16-bit Unicode code points. The range runs from Lo to Hi inclusive and has the specified stride.

type [Range32](#)

```
type Range32 struct {  
    Lo      uint32  
    Hi      uint32  
    Stride  uint32  
}
```

Range32 represents a range of Unicode code points and is used when one or more of the values will not fit in 16 bits. The range runs from Lo to Hi inclusive and has the specified stride. Lo and Hi must always be $\geq 1 \ll 16$.

type [RangeTable](#)

```
type RangeTable struct {  
    R16 []Range16  
    R32 []Range32  
}
```

RangeTable defines a set of Unicode code points by listing the ranges of code points within the set. The ranges are listed in two slices to save space: a slice of 16-bit ranges and a slice of 32-bit ranges. The two slices must be in sorted order and non-overlapping. Also, R32 should contain only values $\geq 0x10000$ ($1 \ll 16$).

type [SpecialCase](#)

```
type SpecialCase []CaseRange
```

SpecialCase represents language-specific case mappings such as Turkish. Methods of SpecialCase customize (by overriding) the standard mappings.

```
var AzeriCase SpecialCase = _TurkishCase  
var TurkishCase SpecialCase = _TurkishCase
```

func (SpecialCase) [ToLower](#)

```
func (special SpecialCase) ToLower(r rune) rune
```

ToLower maps the rune to lower case giving priority to the special mapping.

func (SpecialCase) [ToTitle](#)

```
func (special SpecialCase) ToTitle(r rune) rune
```

ToTitle maps the rune to title case giving priority to the special mapping.

func (SpecialCase) [ToUpper](#)

```
func (special SpecialCase) ToUpper(r rune) rune
```

ToUpper maps the rune to upper case giving priority to the special mapping.

Bugs

There is no mechanism for full case folding, that is, for characters that involve multiple runes in the input or output.

Package utf16

```
import "unicode/utf16"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `utf16` implements encoding and decoding of UTF-16 sequences.

Index

[func Decode\(s \[\]uint16\) \[\]rune](#)
[func DecodeRune\(r1, r2 rune\) rune](#)
[func Encode\(s \[\]rune\) \[\]uint16](#)
[func EncodeRune\(r rune\) \(r1, r2 rune\)](#)
[func IsSurrogate\(r rune\) bool](#)

Package files

[utf16.go](#)

func [Decode](#)

```
func Decode(s []uint16) []rune
```

Decode returns the Unicode code point sequence represented by the UTF-16 encoding s.

func [DecodeRune](#)

```
func DecodeRune(r1, r2 rune) rune
```

DecodeRune returns the UTF-16 decoding of a surrogate pair. If the pair is not a valid UTF-16 surrogate pair, DecodeRune returns the Unicode replacement code point U+FFFD.

func [Encode](#)

```
func Encode(s []rune) []uint16
```

Encode returns the UTF-16 encoding of the Unicode code point sequence s.

func [EncodeRune](#)

```
func EncodeRune(r rune) (r1, r2 rune)
```

EncodeRune returns the UTF-16 surrogate pair r1, r2 for the given rune. If the rune is not a valid Unicode code point or does not need encoding, EncodeRune returns U+FFFD, U+FFFD.

func [IsSurrogate](#)

```
func IsSurrogate(r rune) bool
```

IsSurrogate returns true if the specified Unicode code point can appear in a surrogate pair.

Build version go1.0.1.

Package utf8

```
import "unicode/utf8"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package `utf8` implements functions and constants to support text encoded in UTF-8. It includes functions to translate between runes and UTF-8 byte sequences.

Index

Constants

[func DecodeLastRune\(p \[\]byte\) \(r rune, size int\)](#)

[func DecodeLastRuneInString\(s string\) \(r rune, size int\)](#)

[func DecodeRune\(p \[\]byte\) \(r rune, size int\)](#)

[func DecodeRuneInString\(s string\) \(r rune, size int\)](#)

[func EncodeRune\(p \[\]byte, r rune\) int](#)

[func FullRune\(p \[\]byte\) bool](#)

[func FullRuneInString\(s string\) bool](#)

[func RuneCount\(p \[\]byte\) int](#)

[func RuneCountInString\(s string\) \(n int\)](#)

[func RuneLen\(r rune\) int](#)

[func RuneStart\(b byte\) bool](#)

[func Valid\(p \[\]byte\) bool](#)

[func ValidString\(s string\) bool](#)

Package files

[utf8.go](#)

Constants

```
const (  
    RuneError = '\uFFFD'      // the "error" Rune or "Unicode replace  
    RuneSelf  = 0x80         // characters below Runeself are repres  
    MaxRune   = '\U0010FFFF' // Maximum valid Unicode code point.  
    UTFMax    = 4           // maximum number of bytes of a UTF-8 e  
)
```

Numbers fundamental to the encoding.

func DecodeLastRune

```
func DecodeLastRune(p []byte) (r rune, size int)
```

DecodeLastRune unpacks the last UTF-8 encoding in p and returns the rune and its width in bytes. If the encoding is invalid, it returns (RuneError, 1), an impossible result for correct UTF-8.

func [DecodeLastRuneInString](#)

```
func DecodeLastRuneInString(s string) (r rune, size int)
```

DecodeLastRuneInString is like DecodeLastRune but its input is a string. If the encoding is invalid, it returns (RuneError, 1), an impossible result for correct UTF-8.

func [DecodeRune](#)

```
func DecodeRune(p []byte) (r rune, size int)
```

DecodeRune unpacks the first UTF-8 encoding in p and returns the rune and its width in bytes. If the encoding is invalid, it returns (RuneError, 1), an impossible result for correct UTF-8.

func [DecodeRuneInString](#)

```
func DecodeRuneInString(s string) (r rune, size int)
```

DecodeRuneInString is like DecodeRune but its input is a string. If the encoding is invalid, it returns (RuneError, 1), an impossible result for correct UTF-8.

func [EncodeRune](#)

```
func EncodeRune(p []byte, r rune) int
```

EncodeRune writes into p (which must be large enough) the UTF-8 encoding of the rune. It returns the number of bytes written.

func [FullRune](#)

```
func FullRune(p []byte) bool
```

FullRune reports whether the bytes in p begin with a full UTF-8 encoding of a rune. An invalid encoding is considered a full Rune since it will convert as a width-1 error rune.

func [FullRuneInString](#)

```
func FullRuneInString(s string) bool
```

FullRuneInString is like FullRune but its input is a string.

func [RuneCount](#)

```
func RuneCount(p []byte) int
```

RuneCount returns the number of runes in p. Erroneous and short encodings are treated as single runes of width 1 byte.

func [RuneCountInString](#)

```
func RuneCountInString(s string) (n int)
```

RuneCountInString is like RuneCount but its input is a string.

func [RuneLen](#)

```
func RuneLen(r rune) int
```

RuneLen returns the number of bytes required to encode the rune.

func [RuneStart](#)

```
func RuneStart(b byte) bool
```

RuneStart reports whether the byte could be the first byte of an encoded rune. Second and subsequent bytes always have the top two bits set to 10.

func [Valid](#)

```
func Valid(p []byte) bool
```

Valid reports whether p consists entirely of valid UTF-8-encoded runes.

func [ValidString](#)

```
func ValidString(s string) bool
```

ValidString reports whether s consists entirely of valid UTF-8-encoded runes.

Build version go1.0.1.

Except as [noted](#), the content of this page is licensed under the Creative Commons Attribution 3.0 License, and code is licensed under a [BSD license](#).
[Terms of Service](#) | [Privacy Policy](#)

Package unsafe

```
import "unsafe"
```

[Overview](#)

[Index](#)

Overview ?

Overview ?

Package unsafe contains operations that step around the type safety of Go programs.

Index

[func Alignof\(v ArbitraryType\) uintptr](#)
[func Offsetof\(v ArbitraryType\) uintptr](#)
[func Sizeof\(v ArbitraryType\) uintptr](#)
[type ArbitraryType](#)
[type Pointer](#)

Package files

[unsafe.go](#)

func [Alignof](#)

```
func Alignof(v ArbitraryType) uintptr
```

Alignof returns the alignment of the value v. It is the maximum value m such that the address of a variable with the type of v will always be zero mod m. If v is of the form structValue.field, it returns the alignment of field f within struct object obj.

func [Offsetof](#)

```
func Offsetof(v ArbitraryType) uintptr
```

Offsetof returns the offset within the struct of the field represented by v, which must be of the form structValue.field. In other words, it returns the number of bytes between the start of the struct and the start of the field.

func [Sizeof](#)

```
func Sizeof(v ArbitraryType) uintptr
```

Sizeof returns the size in bytes occupied by the value v. The size is that of the "top level" of the value only. For instance, if v is a slice, it returns the size of the slice descriptor, not the size of the memory referenced by the slice.

type [ArbitraryType](#)

```
type ArbitraryType int
```

ArbitraryType is here for the purposes of documentation only and is not actually part of the unsafe package. It represents the type of an arbitrary Go expression.

type [Pointer](#)

```
type Pointer *ArbitraryType
```

Pointer represents a pointer to an arbitrary type. There are three special operations available for type Pointer that are not available for other types.

- 1) A pointer value of any type can be converted to a Pointer.
- 2) A Pointer can be converted to a pointer value of any type.
- 3) A uintptr can be converted to a Pointer.
- 4) A Pointer can be converted to a uintptr.

Pointer therefore allows a program to defeat the type system and read and write arbitrary memory. It should be used with extreme care.

Build version go1.0.1.

Go Projects

These are external projects and not endorsed or supported by the Go project.

Projects

Submit a Project

Using this form you can submit a project to be included in the list.

Filter by tag: **all** [lib](#) [app](#) [tool](#) [cgo](#) [wontbuild](#)

Build Tools

- [GG](#) - A build tool for Go in Go tool
- [GVM](#) - GVM provides an interface to manage Go versions. lib
- [Gocheck](#) - Rich test framework with suites, fixtures, assertions, good error reporting, etc tool
- [SCons Go Tools](#) - A collection of builders that makes it easy to compile Go projects in SCons. tool
- [chimp](#) - Library to provide the "Go" language with automation tools. Can be used to write build scripts, deploy scripts, etc tool
- [fileembed-go](#) - This is a command-line utility to take a number of source files, and embed them into a Go package. tool
- [gb](#) - A(nother) build tool for go, with an emphasis on multi-package projects. tool
- [go-runner](#) - a simple runner for .go programs tool wontbuild
- [goam](#) - A simple project build tool for Go tool
- [gobbler](#) - Go build tool to build and test advanced multi-package projects with little configuration tool wontbuild
- [gobuild](#) - Automatic build tool aiming to replace Makefiles for simple Go projects tool
- [gobuild-fork](#) - A fork of gobuild tool wontbuild
- [godag](#) - A frontend to the Go compiler collection tool
- [goscons](#) - Another set of SCons builders for Go. tool
- [gotgo](#) - An experimental preprocessor to implement 'generics' tool wontbuild
- [makengo](#) - A build tool similar to Ruby's rake tool

Caching

- [gocache](#) - gocache app wontbuild

- [gomemcached](#) - A memcached server in go app

Command-line Option Parsers

- [ReadFlags](#) - Read flag values from text files lib
- [argcfg](#) - Use reflection to populate fields in a struct from command line arguments lib
- [gnuflag](#) - GNU-compatible flag parsing; substantially compatible with flag. lib
- [go-options](#) - A command line parsing library for Go lib
- [goopt](#) - a getopt clone to parse command-line flags lib
- [optarg](#) - An easy to use GNU-style command-line argument parsing with full validation and nice usage information. lib
- [optparse-go](#) - parses command-lines lib
- [opts.go](#) - lightweight POSIX- and GNU- style option parsing lib
- [pflag](#) - Drop-in replacement for Go's flag package, implementing POSIX/GNU-style --flags. lib

Command-line Tools

- [GoPasswordCreator](#) - A small tool, which creates random passwords tool
- [cron.go](#) - A small cron job system to handle scheduled tasks, such as optimizing databases or kicking idle users from chat. lib
- [gich](#) - A cross platform which utility written in Go tool
- [goblin](#) - a set of Plan9/unix utilities re-written in Go app
- [gocreate](#) - Command line utility that create files from templates. tool
- [jsonpp](#) - A fast command line JSON pretty printer. lib
- [tecla](#) - Command-line editing library lib

Compression

- [dgoz](#) - LZO bindings lib
- [go-lz4](#) - Port of LZ4 lossless compression algorithm to Go. lib
- [go-lzss](#) - Implementation of LZSS compression algorithm in Go lib
- [go-sevenz](#) - Package sevenzip implements access to 7-zip archives (wraps C interface of LZMA SDK) lib
- [lzma](#) - compress/lzma package for Go lib
- [snappy-go](#) - Google's Snappy compression algorithm in Go lib

- [yenc](#) - yenc decoder package lib
- [zip](#) - a library for reading ZIP archives. lib

Console User Interface

- [DevTodo2](#) - A small command-line per-project task list manager. tool
- [ansiterm](#) - pkg to drive text-only consoles that respond to ANSI escape sequences
- [curses.go](#) - GO binding for NCurses lib
- [g5t](#) - Gettext for Go, stripped down to the bare metal lib
- [getpass](#) - Password prompting from console lib
- [go-stfl](#) - a thin wrapper around STFL, an ncurses-based widget toolkit lib
- [go-term](#) - Wrapper and utilities related to Unix terminal lib
- [gockel](#) - a Twitter client for text terminals tool
- [gocurse](#) - Go bindings for NCurses cgo wontbuild
- [goncurses](#) - An ncurses library, including the form, menu and panel extensions lib
- [igo](#) - A simple interactive Go interpreter built on exp/eval with some readline refinements lib wontbuild
- [inline](#) - Library for line editing lib
- [oh](#) - A Unix shell written in Go app
- [pty](#) - obtain pseudo-terminal devices lib
- [tattr-go](#) - Thin wrapper around termios structure lib
- [termios](#) - Terminal support lib
- [termon](#) - Easy terminal-control-interface for Go. lib

Cryptography

- [BLAKE-256](#) - Go implementation of BLAKE-256 hash function lib
- [GoKoblitz](#) - An ECDSA library for Go supporting Koblitz curves (such as secp256k1) lib
- [GoSkein](#) - Implementation of Skein hash and Threefish crypto for Go lib
- [bcrypt](#) - Blowfish password hashing lib
- [dkeyczar](#) - Go port of Google'e Keyczar cryptography library lib
- [dkrcrypt](#) - Korean block ciphers: SEED and HIGHT lib
- [dskipjack](#) - Go implementation of the SKIPJACK encryption algorithm lib
- [go-rabbit](#) - Go implementation of Rabbit encryption algorithm lib
- [go-salsa20](#) - Go implementation of Salsa20 encryption algorithm lib

- [gopam](#) - PAM application API wrapper lib
- [ketama.go](#) - libketama-style consistent hashing lib
- [kindi](#) - encryption command line tool app
- [passwordhash](#) - Package passwordhash implements safe password hashing and comparison. lib
- [pbkdf2.go](#) - PBKDF2 password hashing lib
- [scpu](#) - SSH2 client application lib
- [scrypt](#) - Go implementation of Colin Percival's scrypt key derivation function lib
- [ssh.go](#) - SSH2 Client library lib

Data Structures

- [FSM](#) - Finite State Machine lib
- [GoLLRB](#) - A Left-Leaning Red-Black (LLRB) implementation of 2-3 balanced binary search trees in Google Go lib
- [Gokogiri](#) - A lightweight libxml wrapper library lib
- [Picugen](#) - A general-purpose hash/checksum digest generator. lib
- [Sortutil](#) - Nested, case-insensitive, and reverse sorting for Go. lib
- [asyncwr](#) - Asynchronous, non-blocking, wrapper for io.Writer lib
- [bigendian](#) - binary parsing and printing lib
- [btree](#) - Package btree implements B-trees with fixed size keys, <http://en.wikipedia.org/wiki/Btree> lib
- [deepcopy](#) - Make deep copies of data structures lib wontbuild
- [dgobloom](#) - A Bloom Filter implementation lib
- [epochdate](#) - Compact dates stored as days since the Unix epoch lib
- [go-avltree](#) - AVL tree (Adel'son-Vel'skii & Landis) with indexing added lib
- [go-darts](#) - Double-ARray Trie System for golang lib
- [go-extractor](#) - Go wrapper for GNU libextractor lib
- [go-maps](#) - Go maps generalized to interfaces lib
- [go-priority-queue](#) - An easy to use heap implementation with a conventional priority queue interface. lib
- [go-stree](#) - A segment tree implementation for range queries on intervals lib
- [gobson](#) - BSON (de)serializer lib
- [gohash](#) - A simple linked-list hashtable that implements sets and maps lib
- [goop](#) - Dynamic object-oriented programming support for Go lib
- [gopqueue](#) - Priority queue at top of container/heap lib
- [gorbt](#) - A simple red black tree lib
- [gotoc](#) - A protocol buffer compiler written in Go lib

- [goxml](#) - A thin wrapper around libxml2 lib
- [gringo](#) - A minimalist queue implemented using a stripped-down lock-free ringbuffer lib
- [libgob](#) - A low level library for generating gobs from other languages lib
- [seq](#) - Functional containers, sequential and concurrent lib
- [skip.go](#) - Fast ordered maps using skip lists lib
- [skiplist](#) - A skip list implementation. Highly customizable and easy to use. lib
- [sortutil](#) - Utilities supplemental to the Go standard "sort" package lib
- [timsort](#) - Fast, stable sort, uses external comparator lib
- [tribool](#) - Ternary (tree-valued) logic for Go lib
- [vcard](#) - Reading and writing vcard file in go. Implementation of RFC 2425 (A MIME Content-Type for Directory Information) and RFC 2426 (vCard MIME Directory Profile). lib
- [xlsx](#) - A library to help with extracting data from Microsoft Office Excel XLSX files. lib
- [xmlm](#) - Advanced XML marshalling/unmarshalling lib

Databases and Storage

- [CodeSearch](#) - Index and perform regex searches over large bodies of source code app
- [DBGo](#) - A light-weight relational flat-file database engine. app
- [Disky](#) - Home-grown, disk-backed key-value store tool
- [Go-Redis](#) - Client and Connectors for Redis key-value store lib
- [GoMySQL](#) - MySQL library for Go lib
- [GoMySQL-Client-Library](#) - Go MySQL Client Library lib
- [MyMySQL](#) - MySQL Client API written entirely in Go. lib
- [Optimus Cache Prime](#) - Smart cache preloader for websites with XML sitemaps. app
- [PostgreSQL bindings](#) - PostgreSQL bindings cgo
- [Radix](#) - Asynchronous Redis client lib
- [Tideland CGL Redis](#) - Powerful Redis client with pub/sub support. lib
- [Tideland Redis Database Client](#) - Simple but powerful client for the Redis key/value (and more) database. lib
- [Weed File System](#) - fast distributed key-file store app
- [cabinet](#) - Kyoto Cabinet bindings for go lib
- [cass](#) - Cassandra Client Lib lib
- [cdb.go](#) - Create and read cdb ("constant database") files lib

- [couch-go](#) - newer maintained CouchDB database binding lib
- [fswatch](#) - mac utility for watching the file system for changes tool
- [go datamapper](#) - ActiveRecord-like database wrapper lib
- [go-cache](#) - An in-memory key:value store/cache (similar to Memcached) library for Go, suitable for single-machine applications. app
- [go-db](#) - A generic database API lib
- [go-db-oracle](#) - GO interface to Oracle DB lib
- [go-dbd-mysql](#) - A MySQL driver implementation for go-dbi lib
- [go-dbi](#) - A database abstraction API in the spirit of Perl DBI et al lib
- [go-mongo](#) - a driver for MongoDB lib
- [go-mysql](#) - MySQL wrapper for Go cgo
- [go-mysql-driver](#) - A lightweight and fast MySQL-Driver for Go's database/sql package lib
- [go-notify](#) - GO bindings for the libnotify lib
- [go-odbc](#) - ODBC Driver for Go lib
- [go-pgsql](#) - A PostgreSQL client library for Go lib
- [go-sphinx](#) - A sphinx client package for Go, for full text search. lib
- [go-sqlite3](#) - Access SQLite3 databases from Go cgo
- [go-wikiparse](#) - mediawiki dump parser for working with wikipedia data tool
- [go.fsevents](#) - path event lib for mac lib
- [gocask](#) - Key-value store inspired by Riak Bitcask. Can be used as pure go implementation of dbm and other kv-stores. lib
- [gocouch](#) - a CouchDB client library lib
- [godbc](#) - Go ODBC Interface using unixODBC by Benoy R Nair cgo
- [godis](#) - Simple client for Redis lib
- [gofluid](#) - FluidDB client library for Go lib
- [gofluiddb](#) - A lightweight wrapper around the FluidDB API for clients written in Go lib
- [gographite](#) - statsd server in go (for feeding data to graphite) app
- [gokabinet](#) - Go bindings for Kyoto Cabinet DBM implementation lib
- [gomemcache](#) - a memcached client lib
- [gomongo](#) - driver for MongoDB lib
- [goprotodb](#) - A binding to Berkeley DB storing records encoded as Protocol Buffers. lib
- [goriak](#) - Database bindings for Riak lib
- [goriak](#) - Database driver for riak database (project homepage is now on bitbucket.org) lib
- [gorp](#) - SQL mapper for Go lib
- [gosqlite](#) - a trivial SQLite binding for Go. lib

- [gosqlite \(forked\)](#) - A fork of gosqlite lib
- [gosqlite3](#) - Go Interface for SQLite3 cgo
- [gotyrant](#) - A Go wrapper for tokyo tyrant cgo
- [hdfs.go](#) - go bindings for libhdfs lib
- [levigo](#) - levigo provides the ability to create and access LevelDB databases. lib
- [libmysqlgo](#) - Another wrapper for the MySQL C API cgo
- [mgo](#) - Rich MongoDB driver for Go lib
- [mgo \(package\)](#) - Rich MongoDB driver for Go (package reference for the Packages tab, please keep the other link since it has docs) lib
- [mysql-connector-go](#) - implements MySQL wire protocol lib
- [mysqlgo](#) - MySQL bindings cgo
- [persival](#) - Programatic, persistent, pseudo key-value storage app
- [pgsql.go](#) - PostgreSQL high-level client library wrapper lib
- [pq.go](#) - A pure Go Postgres driver lib
- [vitess](#) - Scaling MySQL databases for the web app

Development Tools

- [deifdef](#) - Removes #ifdef/#endif blocks from code based on a set of #defines tool
- [glib](#) - Bindings for GLib type system lib
- [gonew](#) - A tool to create new Go projects tool
- [gonow](#) - Tool to run Go scripts tool
- [gorun](#) - Enables Go source files to be used as scripts. tool
- [hamcrest](#) - Hamcrest matchers (and Asserters) for runtime check and JUnit-like testing tool lib
- [hsandbox](#) - Tool for quick experimentation with Go snippets tool
- [liccor](#) - A tool for updating license headers in Go source files tool
- [liteide](#) - An go auto build tools and qt-based ide for Go tool
- [trace](#) - a simple debug tracing tool

Distributed/Grid Computing

- [Cloud-Backups](#) - Small Go utilities to backup data from the cloud, to the cloud app
- [malus](#) - A Kademlia-compatible DHT(Distributed Hash Table) written in Go app

Documentation

- [Mango](#) - Automatically generate unix man pages from Go sources app
- [pkgdoc](#) - Pkgdoc generates HTML documentation for a Go package using a user specified template. tool
- [redoc](#) - Commands documentation for Redis tool

Editors

- [Go conTEXT](#) - Highlighter plugin for the conTEXT editor lib
- [Google Go for Idea](#) - Google Go language plugin for IntelliJ IDEA
- [goclipse](#) - An Eclipse-based IDE for Go. tool
- [gofinder](#) - (code) search tool for acme tool
- [tabby](#) - Source code editor app

Encodings

- [mimemagic](#) - Detect mime-types automatically based on file contents with no external dependencies lib

GUIs and Widget Toolkits

- [go-fltk](#) - FLTK2 GUI toolkit bindings for Go lib
- [go-gtk](#) - Bindings for GTK cgo
- [go-iup](#) - Bindings for Iup, a cross-platform native widget GUI toolkit lib
- [goosurface](#) - An interface to Cairo via GTK cgo
- [mdtwm](#) - Tiling window manager for X app
- [termbox](#) - A minimalist alternative to ncurses to build terminal-based user interfaces cgo

Games

- [ChessBuddy](#) - Play chess with Go, HTML5, WebSockets and random strangers! app
- [FlexBot](#) - A flexible bot for the Spring RTS engine implementing the 'lobby protocol' app
- [Gongo](#) - A program written in Go that plays Go app
- [godoku](#) - Go Sudoku Solver - example of "share by communicating" tool

- [gospeccy](#) - A ZX Spectrum 48k Emulator app
- [gotris](#) - A classic tetris game written in Go app
- [teratogen](#) - A rogue-like game using SDL app

Go Implementations

- [Express Go](#) - Interpreted Go implementation for Windows app

Graphics and Audio

- [Arclight](#) - Arclight is a tool for rendering images app
- [Go-OpenGL](#) - Go bindings for OpenGL cgo
- [Go-SDL](#) - Go bindings for SDL cgo
- [GoGL](#) - OpenGL binding generator lib
- [GoMacDraw](#) - A mac implementation of go.wde lib
- [Goop](#) - Audio synthesizer engine tool
- [Winhello](#) - An example Windows GUI hello world application app
- [allergro](#) - basic wrapper for the Allegro library cgo
- [alsa](#) - alsa is a Go wrapper package for C alsa library. lib
- [baukasten](#) - A modular game library. lib
- [blend](#) - Image processing library and rendering toolkit for Go. lib
- [bmp.go](#) - package for encoding/decoding Windows BMP files lib
- [chart](#) - Library to generate common chart (pie, bar, strip, scatter, histogram) in different output formats. lib
- [draw2d](#) - This package provide an API to draw 2d geometrical form on images. This library is largely inspired by postscript, cairo, HTML5 canvas. lib
- [freetype-go](#) - a Go implementation of FreeType lib
- [gmf](#) - Go Media Framework - a binding to ffmpeg to bring Media Processing to Google Go lib
- [go-gd](#) - Go bingings for GD lib
- [go-gnuplot](#) - go bindings for GNUPlot lib
- [go-graph](#) - Generic graph library for Go. lib
- [go-gtk3](#) - gtk3 bindings for go lib
- [go-heatmap](#) - A toolkit for making heatmaps lib
- [go-openal](#) - Experimental OpenAL bindings for Go cgo
- [go-opencl](#) - A go wrapper to the OpenCL heterogeneous parallel programming library lib

- [go-vlc](#) - Go bindings for libVLC lib
- [go.uik](#) - A UI kit for Go, in Go. lib
- [go.wde](#) - A windowing/drawing/event interface lib
- [gocairo](#) - Golang wrapper for cairo graphics library cgo
- [gofax](#) - CCITT fax library lib
- [goray](#) - Raytracer written in Go, based on Yafaray app
- [gosdl](#) - Go wrapper for SDL cgo
- [goxscr](#) - Go rewrites of xscreensaver ports app
- [gst](#) - Go bindings for GStreamer lib
- [hgui](#) - Gui toolkit based on http and gtk-webkit. lib
- [iascii](#) - retro-ASCII image encoder tool
- [id3tag](#) - id3tag is a Go wrapper around C libid3tag library. lib
- [math3d](#) - A linear algebra package optimized for OpenGL lib
- [ogg](#) - Go wrapper for C libogg library. lib cgo
- [pdfreader](#) - a library to read the contents of PDF files lib
- [portaudio](#) - A Go binding to PortAudio lib
- [postscript-go](#) - Postscript go implementation that uses draw2d to generate images. lib
- [pulsego](#) - Go binding for PulseAudio cgo
- [smallpt.go](#) - A port of the smallpt global illumination renderer to Go app
- [starfish](#) - A simple Go graphics and user input library, built on SDL lib
- [svgo](#) - a library for creating and outputting SVG lib
- [window](#) - Optimized moving window for real-time data lib
- [wingo](#) - A fully-featured window manager written in Go. app
- [wxGo](#) - Go Wrapper for the wxWidgets GUI lib
- [x-go-binding](#) - bindings for the X windowing system lib

Instant Messaging

- [Go-IRC-Client-Library](#) - blah lib
- [GoTY](#) - "Go Troll Yourself", minimalist client IRC library lib
- [calculon](#) - IRC bot with support for runtime (un)loadable modules and configurable via a web interface lib
- [go-bot](#) - (aka rndbot) - An irc-bot that executes Go code sent to it and print its output app
- [goirc](#) - event-based stateful IRC client framework lib
- [irc.go](#) - Go IRC bot framework lib

Mathematics

- [Bitcoin Calculator](#) - Bitcoin Mining, Power and Profitability Calculator, data fetching, json, scheduled tasks lib
- [GoStats](#) - Descriptive statistics and linear regression for Go lib
- [Tideland Go Numerical Library](#) - Helpful numerical types and functions. lib
- [bayesian](#) - Naive Bayesian Classification for Golang lib
- [blas](#) - Go implementation of BLAS (Basic Linear Algebra Subprograms) lib
- [cartconvert](#) - cartography functions for the Go programming language lib
- [ellipsoid](#) - ellipsoid.go performs latitude and longitude calculations on the surface of an ellipsoid. lib
- [geom](#) - 2d geometry. lib
- [go-fftw](#) - Go bindings for FFTW - The Fastest Fourier Transform in the West lib
- [go-fn](#) - Special functions that would not fit in "math" pkg lib
- [go-gt](#) - Graph theory algorithms lib
- [go-humanize](#) - Formatting numbers for humans. lib
- [go.matrix](#) - a linear algebra package (please remove gomatrix - i am its author and this is the same code) lib
- [gochipmunk](#) - Go bindings to the Chipmunk Physics library. lib
- [gocomplex](#) - a complex number library lib
- [gofrac](#) - A fractions library for go lib
- [gogmp](#) - GMP bindings for Go cgo
- [gomatrix](#) - a linear algebra package lib
- [imath](#) - Fast integer-only math routines lib
- [mathutil](#) - Package mathutil provides utilities supplementing the standard 'math' and 'rand' packages. lib
- [polyclip.go](#) - Go implementation of algorithm for Boolean operations on 2D polygons lib

Misc

- [ArBit](#) - Automated Bitcoin arbitrage trading program. tool
- [CGRates](#) - Rating system designed to be used in telecom carriers world
- [Go-PhysicsFS](#) - Go bindings for the PhysicsFS archive-access abstraction library. lib
- [Go-fuse](#) - Library to write FUSE filesystems in Go lib
- [GoLCS](#) - Solve Longest Common Sequence problem in go lib

- [GoTS](#) - a commandline tool for www.tinysong.com app
- [Gotgo](#) - A Go preprocessor that provides an implementation of generics tool
- [Hranoprovod](#) - Command-line calorie tracking tool
- [Perlito](#) - An implementation of a subset of Perl 6 with a Go (and other languages) backend tool
- [Tideland CGL Monitoring](#) - Flexible monitoring of your application lib
- [Tideland Common Go Library](#) - Many helpful packages for the daily Go development. lib
- [Tideland Event-Driven Cell Architecture](#) - Package for the development of event-driven architectures. lib
- [UbuntuTranslator](#) - a simple but useful translator for Ubuntu. app
- [atexit](#) - Simple atexit library lib
- [bencoding](#) - Go implementation of the bencoding protocol used by bittorrent lib
- [bio-go](#) - Basic bioinformatics functions for the Go language. lib
- [cpu](#) - A Go package that reports processor topology lib
- [dbus-go](#) - D-Bus Go library lib
- [desktop](#) - Open file/uri with default application (cross platform) lib
- [dump](#) - An utility that dumps Go variables, similar to PHP's var_dump tool
- [dupfinder](#) - Simple program that finds duplicate files app
- [errforce](#) - Utilities for working effectively with Go errors and UNIX errors lib
- [faker](#) - Generate fake data, names, text, addresses, etc. tool
- [fnv](#) - Go implementation for the Fowler-Noll-Vo hash function lib
- [functional](#) - Functional programming library including a lazy list implementation and some of the most usual functions. lib
- [fungo](#) - A library to help write 2D games in Go lib
- [go-amiando](#) - Wrapper for the Amiando event management API lib
- [go-bit](#) - An efficient and comprehensive bitset implementation with utility bit functions. lib
- [go-eco](#) - Functions for use in ecology lib
- [go-erx](#) - Extended error reporting library lib
- [go-ext](#) - Small utility library for Go lib
- [go-hyphenator](#) - A TeX-style hyphenation package. lib
- [go-idn](#) - a project to bring IDN support to Go, feature compatible with libidn lib
- [go-papi](#) - Go interface to the PAPI performance API lib
- [go-pkg-lastfm](#) - A library to access the entire Last.fm 2.0 webservice API, including the authenticated services lib

- [go-pkg-mpd](#) - A library to access the MPD music daemon lib
- [go-pkg-mtp](#) - Bindings for the libmtp implementation of the Media Transfer Protocol to interact with media devices like MP3 players cgo
- [go-pkg-njb](#) - Bindings for the libnjb (Nomad Juke Box) that interacts with older MP3 players cgo
- [go-pkg-xmlx](#) - Extension to the standard Go XML package. Maintains a node tree that allows forward/backwards browser and exposes some simple single/multi-node search functions lib
- [go-qrand](#) - Go client for quantum random bit generator service at random.irb.hr lib
- [go-repl](#) - A Go REPL; builds up a source .go file over time, compiles it for output tool
- [go-semvar](#) - Semantic versions (see <http://semver.org>) lib
- [go-taskstats](#) - Go interface for Linux taskstats lib
- [go-translate](#) - Google Language Translate library lib
- [go-uuid](#) - Universal Unique IDentifier generator and parser lib
- [go.pcsc-lite](#) - Go wrapper for pcsc-lite lib
- [goNI488](#) - A Go wrapper around National Instruments NI488.2 General Purpose Interface Bus (GPIB) driver. lib
- [goPromise](#) - Scheme-like delayed evaluation for Go lib
- [goagain](#) - Zero-downtime restarts in Go lib
- [goconf](#) - a configuration file parser lib
- [goconfig](#) - Configuration file parser for Go lib
- [gocsv](#) - Library for CSV parsing and emitting lib
- [goga](#) - A genetic algorithm framework lib
- [gogobject](#) - GObject-introspection based bindings generator lib
- [golife](#) - Implementation of Game of Life for command line app
- [gomagic](#) - Libmagic bindings cgo
- [gommap](#) - gommap enables Go programs to directly work with memory mapped files and devices in a very efficient way lib
- [goneuro](#) - Go driver for NeuroSky devices. lib
- [goplan9](#) - libraries for interacting with Plan 9 lib
- [goraphing](#) - A tool to generate a simple graph data structures from JSON data files app
- [goskirt](#) - Upskirt markdown library bindings for Go lib
- [gotaskqueue](#) - With gotaskqueue, a program could define several tasks and execute them separately at specific time points. lib
- [gotimer](#) - A simple way to time a function lib
- [gotweet](#) - A simple Twitter command line client app

- [gouuid](#) - Pure Go UUID v3, 4 and 5 generator compatible with RFC4122 lib
- [hasher](#) - Library to compute hash in user account passwords lib
- [iolaus-go](#) - A Go implementation of the 'iolaus' distributed version control system app
- [koans](#) - programming koans for go
- [lineup](#) - A minimalistic message queue server app
- [log4go](#) - Go logging package akin to log4j lib
- [magic](#) - wrapper around libmagic lib
- [mimeparse](#) - Simple library to handle mime-types Go lib
- [mitigation](#) - Package mitigation provides the possibility to prevent damage caused by bugs or exploits. lib
- [passwd](#) - A parser for the /etc/passwd file lib
- [primegen.go](#) - Sieve of Atkin prime number generator
- [seelog](#) - powerful and easy-to-learn logging framework that provides functionality for flexible dispatching, filtering, and formatting lib
- [selenium](#) - Selenium client tool
- [symutils](#) - Various tools and libraries to handle symbolic links lib
- [tamias](#) - a port of Chipmunk Physics lib
- [tideland-kmr](#) - Tideland Knowledge Management and Retrieval is a wiki app
- [trie](#) - A Trie structure implementation for Go, using Unicode runes as keys. Includes a customization for TeX-style hyphenation tries. lib
- [xplor](#) - Files tree browser for p9p acme app

Music

- [gompd](#) - A client interface for the MPD (Music Player Daemon) app

Networking

- [Go Ajax](#) - Go Ajax is a JSON-RPC implementation designed to create AJAX powered websites. lib
- [GoAWS](#) - Library for many AWS services (S3, SQS, EC2, etc) lib
- [GoPOP3](#) - Implements the POP3 protocol as specified in RFC 1939 lib
- [GoRTP](#) - RTP / RTCP stack implementation for Go lib
- [HTTP JSON-RPC](#) - An implementation of HTTP JSON-RPC protocol for Go lib

- [Skynet](#) - Skynet is distributed mesh of processes designed for highly scalable API type service provision. lib
- [Tonika](#) - Secure social networking platform app
- [Uniqush](#) - A free and open source software which provides a unified push service for server-side notification to apps on mobile devices. lib
- [cascadeauth](#) - Squid authenticator that consults multiple sources app
- [dmrigo](#) - Library for with Hadoop Streaming map/reduce lib
- [dns](#) - A DNS library in Go lib
- [doozerd](#) - A consistent distributed data store app
- [dyndnsd](#) - a configurable dyndns client tool
- [eventsourc](#) - Server-sent events for net/http server. lib
- [freeport](#) - Find a free port on the system. lib
- [ftp.go](#) - FTP client for Google Go language lib
- [ftp4go](#) - An FTP client for Go, started as a port of the standard Python FTP client library lib
- [gearman-go](#) - A native implementation for Gearman API with Go. lib
- [go-curl](#) - libcurl binding that supports go func callbacks lib
- [go-dbus](#) - A library to connect to the D-bus messaging system lib
- [go-icap](#) - ICAP (Internet Content Adaptation Protocol) server library lib
- [go-imap](#) - IMAP client library lib
- [go-irc](#) - Simple IRC client library lib
- [go-mail](#) - Email utilities including RFC822 messages and Google Mail defaults. lib
- [go-msgpack](#) - MsgPack library for Go, with pack/unpack and net/rpc codec support lib
- [go-nagios](#) - Library for writing Nagios plugins lib
- [go-nntp](#) - An NNTP client and server library for go lib
- [go-router](#) - implementation of remote channel communication lib
- [go-rpcgen](#) - ProtoBuf RPC binding generator for net/rpc and AppEngine lib
- [go-socket.io](#) - A Socket.IO backend implementation written in Go lib
- [go-xmlrpc](#) - Simple XML-RPC client/server library lib
- [go-xmpp](#) - XMPP client library lib
- [go9](#) - an implementation of the 9P distributed file system protocol lib
- [go9p](#) - 9p protocol implementation in Go lib
- [goauth](#) - A library for header-based OAuth over HTTP or HTTPS. lib
- [gobeanstalk](#) - Go Beanstalkd client library lib
- [gobir](#) - Extensible IRC bot with channel administration, seen support, and go documentation querying app
- [gocluster](#) - implementation of a clustering heuristic using a particle swarm

- optimization technique lib
- [godloader](#) - Collection of download tools that tries to follow the Unix philosophy app
- [godns](#) - A more complete DNS package lib
- [godns2](#) - A simple DNS resolution library with fine control over the messages lib
- [godwulf](#) - Gopher server written in Go app
- [goexmpp](#) - XMPP client implementation lib
- [goftp](#) - A FTP client library lib
- [gogammu](#) - Library for sending and receiving SMS lib
- [gonetbench](#) - Simple TCP benchmarking tool tool
- [gonoip](#) - No-IP client lib
- [gopcap](#) - A simple wrapper around libpcap cgo
- [goprotobuf](#) - the Go implementation of Google's Protocol Buffers lib
- [gorobot](#) - a modular IRC bot app
- [gosndfile](#) - Go binding for libsndfile lib
- [gostomp](#) - implementation of STOMP (Streaming Text Orientated Messaging Protocol) lib
- [gozmq](#) - Go Bindings for 0mq (zeromq/zmq) lib
- [grong](#) - Small authoritative DNS name server app
- [handlersocket-go](#) - Go native library to connect to HandlerSocket interface of InnoDB tables lib
- [jaid](#) - Just Another IRC Daemon app
- [kafka.go](#) - Producer & Consumer for the Kafka messaging system lib
- [ldap](#) - Basic LDAP v3 functionality for the GO programming language. lib
- [mdns](#) - Multicast DNS library for Go lib
- [netsnail](#) - A low-bandwidth simulator app
- [remotize](#) - A remotize package and command that helps remotizing methods without having to chaneg their signatures for rpc lib
- [replican-sync](#) - An rsync algorithm implementation in Go lib
- [rs232](#) - Serial interface for those of us who still have modems (or arduinos) lib
- [statsd.go](#) - Client library for statsd lib
- [stompngo](#) - A Stomp 1.1 Compliant Client lib
- [stompngo_examples](#) - Examples for stompngo. lib

Other Random Toys, Experiments and Example Code

- [go-crazy](#) - An experimental source-to-source compiler for go tool

- [go-hashmap](#) - A hash table in pure go as an experiment in Go performance app
- [gochat](#) - A 'stupid' chat server written in Go app
- [goconc](#) - A collection of useful concurrency idioms and functions for Go, compiled app
- [goplay](#) - A bunch of random small programs in Go app
- [lifegame-on-golang](#) - Game of Life in Go app
- [linear](#) - Playing around with the linear algebra app
- [project euler in go](#) - Solutions to Project Euler in Go also app
- [shadergo](#) - shader test using golang app

P2P and File Sharing

- [Taipei-Torrent](#) - Another BT client app
- [ed2kcrawler](#) - eDonkey2000 link crawler app
- [gobit](#) - Bittorrent Client in Go app
- [gop2p](#) - A simple p2p app to learn Go app
- [wgo](#) - A simple BitTorrent client based in part on the Taipei-Torrent and gobit code app

Programming

- [GoSpec](#) - a BDD framework lib
- [go-clang](#) - cgo bindings to the C-API of libclang lib
- [go-galib](#) - a library of Genetic Algorithms lib
- [go-intset](#) - a library to work with bounded sets of integers, including multiple alternative implementations lib
- [go-parse](#) - a Parsec-like parsing library lib
- [go-stringio](#) - implementation of the various file I/O interfaces using memory buffers instead of real files lib
- [godeferred](#) - port of jsdeferred: <http://cho45.stfuawsc.com/jsdeferred/> lib
- [gosets](#) - implementation of set types lib
- [gospecify](#) - another BDD framework lib
- [gowizard](#) - Tool to create skeleton of Go projects tool
- [iterutils](#) - functions from Python's itertools module lib

Source Code Management

- [hggofmt](#) - A Mercurial/hg extension with a hook to *gofmt* changed files automatically before a commit tool

Strings and Text

- [Black Friday](#) - A markdown processor lib
- [GoXML](#) - A basic libxml wrapper for Go lib cgo
- [Mahonia](#) - Character-set conversion library in Go lib
- [NTemplate](#) - Nested Templates lib
- [csvutil](#) - A heavy duty CSV reading and writing library. lib
- [dgohash](#) - Collection of string hashing functions, including Murmur3 and others lib
- [go-charset](#) - Conversion between character sets. Native Go. lib
- [go-guess](#) - Go wrapper for libguess lib
- [go-migemo](#) - migemo extension for go (Japanese incremental text search) lib
- [go-substrs](#) - A container for substrings resultant from pattern matching lib
- [go.stringmetrics](#) - String distance metrics implemented in Go lib
- [goini](#) - A go library to parse INI files. lib
- [gosphinx](#) - A Go client interface to the Sphinx standalone full-text search engine app
- [goyaml](#) - A port of LibYAML to Go lib
- [gpKMP](#) - String-matching in Golang using the Knuth  CMorris  CPratt algorithm lib
- [iconv-go](#) - iconv wrapper with Reader and Writer lib
- [inflect](#) - Word inflection library (similar to Ruby ActiveSupport::Inflector). Singularize(), Pluralize(), Underscore() etc. lib
- [kasia.go](#) - Templating system for HTML and other text documents lib
- [kview](#) - Simple wrapper for kasia.go templates. It helps to modularize content of a website lib
- [mail.go](#) - Parse email messages lib
- [neste](#) - Extended version of Go's template package for generating textual output from nested templates. lib
- [peg](#) - Parsing Expression Grammer Parser lib
- [pretty.go](#) - Pretty-printing for go values lib
- [rubex](#) - A simple regular expression library that supports Ruby's regex syntax. It is faster than Regexp. lib
- [scanner](#) - A text scanner that parses primitive types, analogous to Java's `java.util.Scanner` or C's `scanf(3)` lib

- [sre2](#) - RE2 in Go lib
- [strogonoff](#) - Stenography with Go lib
- [strutil](#) - Package strutil collects utils supplemental to the standard strings package. lib
- [uctricks](#) - Some silly text transformations via Unicode lib

Tag Generators

- [egotags](#) - ETags generator tool
- [gotags](#) - Generate a tags file for the Go Programming Language in the format used tool
- [tago](#) - Emacs TAGS generator for Go source tool

Testing

- [Tideland CGL Asserts](#) - Make asserts during testing and inside of your applications lib
- [assert](#) - helper functions for the built-in 'testing' package lib
- [go2xunit](#) - Convert "go test -v" output to xunit XML output tool
- [gomock](#) - a mocking framework for Go. tool

Virtual Machines and Languages

- [Gelo](#) - Extensible, embeddable interpreter app
- [GoForth](#) - A simple Forth parser app
- [GoLightly](#) - A flexible and lightweight virtual machine with runtime-configurable instruction set app
- [JavaScriptCore](#) - This is a wrapper for WebKit's javascript engine for Go. lib
- [RubyGoLightly](#) - An experimental port of TinyRb to Go app
- [The erGo? Compiler](#) - An independent implementation of the Go language. app
- [brainfuck](#) - A brainfuck virtual machine in Go app
- [forego](#) - Forth virtual machine tool
- [go-python](#) - go bindings for CPython C-API lib
- [go-scheme](#) - Scheme implementation in Go app
- [goheader](#) - Tool for translating C type declarations into its Go equivalent lib
- [golemon](#) - A port of the Lemon parser-generator lib

- [goll1e](#) - An LL(1) parser generator for the Go programming language. app
- [golua](#) - Go wrapper for LUA's C API cgo
- [golua-fork](#) - A fork of GoLua that works on current releases of Go lib
- [gotcl](#) - Tcl interpreter in Go lib
- [ngaro](#) - A ngaro virtual machine to run retroForth images app
- [prescript](#) - An experimental PostScript-like scripting language app
- [turing](#) - BF virtual machine more appropriate for school settings. lib

Web Applications

- [Digestw](#) - A Web Application - Twitter's Timeline Digest app
- [GoURLShortener](#) - A frontend for the <http://is.gd/> URL shortener app
- [J♦♦Vai Tarde](#) - Unfollows monitoring for Twitter app
- [fourohfourfound](#) - A fallback HTTP server that may redirect requests with runtime configurable redirections app
- [goals-calendar](#) - A web-based Seinfeld calendar implemented in Go app
- [goblog](#) - A static blog engine lib
- [goflash](#) - Flash player implementation in Go language app
- [gogallery](#) - simple web server with an emphasis on easily browsing images app
- [goof](#) - A simple http server to exchange files over http (upload/download) app
- [gopages](#) - A php-like web framework that allows embedding Go code in web pages app
- [gopaste](#) - The code that runs the gopaste.org pastebin app
- [goplot](#) - A graphing utility with some curve-fitting features, includes a web interface app
- [gowiki](#) - A simple wiki in Go using web.go and mustache.go app
- [htdigest-go](#) - Command line tool for managing htdigest files lib
- [kurz.go](#) - a url shortener based on web.go and redis app
- [now.go](#) - A simple HTTP-based to-do queue. app
- [sf_server](#) - a tiny send file server and client lib
- [webtf](#) - Web app to graphical visualization of twitter timelines using the HTML5 `<canvas>` tag app

Web Libraries

- [Cascadia](#) - CSS selector library lib

- [GOAuth](#) - OAuth Consumer lib
- [Go-OAuth](#) - OAuth 1.0 client lib
- [GoRest](#) - An extensive configuration(tags) based RESTful style web-services framework. lib
- [GoWeb](#) - Frameworklet that simplifies building API's in Go - has Ruby on Rails style routing lib
- [Goldorak.Go](#) - a web miniframework built using mustache.go, web.go and Go-Redis lib
- [HTML Transform](#) - A CSS selector based html scraping and transformation library lib
- [Kontl](#) - A client for kon.tl's URL shortening service lib
- [OAuth Consumer](#) - OAuth 1.0 consumer implementation lib
- [RSS-Go](#) - RSS and ATOM feed reader package for the Go programming language. lib
- [Stack on Go](#) - Go wrapper for Stack Exchange API lib
- [Tideland CGL Web](#) - Package for RESTful web applications lib
- [Tideland RESTful Web Framework](#) - A foundation for web applications and servers following the REST principles lib
- [Twister](#) - A framework and server for writing web applications. lib
- [app.go](#) - Web framework for google app engine lib
- [authcookie](#) - Package authcookie implements creation and verification of signed authentication cookies. lib
- [bwl](#) - a set of libraries to help build web sites lib
- [captcha](#) - Image and audio captcha generator and server lib
- [ddg](#) - DuckDuckGo API interface lib
- [dgoogauth](#) - Go port of Google's Authenticator library for one-time passwords lib
- [falcore](#) - Modular HTTP server framework lib
- [fcgigo](#) - a FastCGI implementation lib
- [gaerecords](#) - Lightweight wrapper around appengine/datastore providing Active Record and DBO style management of data lib
- [get2ch-go](#) - a library to access the 2channel Japanese web bulletin board lib
- [go-dealmap](#) - Go library for accessing TheDealMap's API lib
- [go-dropbox](#) - API library for dropbox lib
- [go-facebook](#) - Go implementations of facebook APIs. lib
- [go-fastweb](#) - aims to be a simple, small and clean MVC framework for go lib
- [go-flickr](#) - A wrapper for Flickr's API lib
- [go-gravatar](#) - Wrapper for the Gravatar API lib

- [go-gzip-file-server](#) - A net.http.Handler similar to FileServer that serves gzipped content lib
- [go-http-auth](#) - HTTP Basic and HTTP Digest authentication lib
- [go-libGeoIP](#) - GO Lib GeoIP API for Maxmind lib
- [go-pkg-rss](#) - a packages that reads RSS and Atom feeds lib
- [go-rss](#) - Simple RSS parser, tested with Wordpress feeds. lib
- [go-start](#) - A high level web-framework for Go lib
- [go-tripit](#) - Go API library for the TripIt web services lib
- [go-twitter](#) - another Twitter client lib
- [go-twitter-oauth](#) - a simple Twitter client (supports OAuth) lib
- [go-urlshortener](#) - interface to google's urlshorten API lib
- [go-webproject](#) - Modular web application framework and app server tool
- [godom](#) - a library that implements a small, non-compliant subset of the W3C DOM Core lib
- [gofastcgi](#) - another FastCGI implementation lib
- [gohaml](#) - An implementation of the popular XHTML Abstraction Markup Language using the Go language. lib
- [gojwt](#) - Json Web Tokens for Go lib
- [gomesh](#) - A simple HTML decoration library. lib
- [googtrans](#) - unofficial go bindings for Google Translate API v2 lib
- [gorilla](#) - Go web toolkit lib
- [gorouter](#) - Simple router for go to process url variables lib
- [goscribble](#) - An MPD Audioscrobble lib
- [goweb](#) - Lightweight web framework for Go providing Ruby on Rails style routing lib
- [htmlfiller](#) - Fills in html forms with default values and errors a la Ian Bicking's htmlfill for Python lib
- [http-gonsole](#) - Speak HTTP like a local. (the simple, intuitive HTTP console, golang version) lib
- [httplib.go](#) - 'Low level' client HTTP library that provides keep-alive connections and generic requests lib
- [justintv](#) - Justin.tv REST API with oauth lib
- [mango](#) - Mango is a modular web-application framework for Go, inspired by Rack, and PEP333. lib
- [mustache.go](#) - an implementation of the Mustache template language lib
- [passwordreset](#) - Creation and verification of secure tokens useful for implementation of "reset forgotten password" feature in web applications. lib
- [postmark](#) - Access postmark API from Go lib

- [pusher.go](#) - HTTP Server Push module for the standard http package lib
- [rest.go](#) - Library to simplify implementation of REST servers and clients. lib
- [rest.go \(forked\)](#) - forked rest.go for improvements and REST consistency lib
- [rest2go](#) - Based on rest.go, forked for improvements and REST consistency lib
- [robotstxt](#) - The robots.txt exclusion protocol implementation. Allows to parse and query robots.txt file. lib
- [routes.go](#) - http routing API similar to expressjs or sinatra lib
- [seshcookie](#) - A web session library inspired by Beaker lib
- [web](#) - A web framework with views for constructing web page, supports FCGI, CGI. lib
- [web.go](#) - a simple framework to write webapps lib
- [webdriver](#) - WebDriver (Selenium) client lib
- [webtestutil](#) - Web and HTTP functional testing utilities. Includes Gorilla testing support. lib
- [wfd](#) - Simple web framework designed for and written in go. Works with other languages as well, but not as well. lib
- [xmldom](#) - a library that implements a small, non-compliant subset of the W3C DOM Core lib
- [xsrfToken](#) - A package for generating and validating tokens used in preventing XSRF attacks. lib

Windows

- [gform](#) - An easy to use Windows GUI toolkit for Go lib
- [go-Windows-begin](#) - for the absolute Windows-Go beginner
- [go-ole](#) - win32 ole implementation for golang lib
- [w32](#) - Windows API wrapper for Go. lib
- [walk](#) - "Windows Application Library Kit" for the Go Programming Language lib

5 /*
6 Package zlib implements reading and writing of zlib format c
7 as specified in RFC 1950.
8
9 The implementation provides filters that uncompress during r
10 and compress during writing. For example, to write compress
11 to a buffer:
12
13     var b bytes.Buffer
14     w, err := zlib.NewWriter(&b)
15     w.Write([]byte("hello, world\n"))
16     w.Close()
17
18 and to read that data back:
19
20     r, err := zlib.NewReader(&b)
21     io.Copy(os.Stdout, r)
22     r.Close()
23 */
