14 // The go code is a simplified version of the original C.
15 //
16 //     sin.c
17 //
18 //     Circular sine
19 //
20 // SYNOPSIS:
21 //
22 // double x, y, sin();
23 // y = sin( x );
24 //
25 // DESCRIPTION:
26 //
27 // Range reduction is into intervals of pi/4. The reduction
28 // eliminated by contriving an extended precision modular ar
29 //
30 // Two polynomial approximating functions are employed.
31 // Between 0 and pi/4 the sine is approximated by
32 //     x + x**3 P(x**2).
33 // Between pi/4 and pi/2 the cosine is represented as
34 //     1 - x**2 Q(x**2).
35 //
36 // ACCURACY:
37 //
38 //                                     Relative error:
39 // arithmetic    domain    # trials    peak        rms
40 //     DEC        0, 10     150000    3.0e-17     7.8e-18
41 //     IEEE -1.07e9,+1.07e9  130000    2.1e-16     5.4e-17
42 //
43 // Partial loss of accuracy begins to occur at x = 2**30 = 1
44 // is not gradual, but jumps suddenly to about 1 part in 10e
```

```

45 // be meaningless for x > 2**49 = 5.6e14.
46 //
47 //     cos.c
48 //
49 //     Circular cosine
50 //
51 // SYNOPSIS:
52 //
53 // double x, y, cos();
54 // y = cos( x );
55 //
56 // DESCRIPTION:
57 //

60 //          -(i+1)
61 //          si + 2 <= yi
62 //          i          i
63 //
64 //      The advantage of (3) is that si and yi can be computed
65 //          i          i
66 //      the following recurrence formula:
67 //      if (3) is false
68 //
69 //          si+1 = si ,          yi+1 = yi ;
70 //          i+1    i          i+1    i
71 //
72 //      otherwise,
73 //          -i          -(i+1)
74 //          si+1 = si + 2 ,          yi+1 = yi - si - 2
75 //          i+1    i          i+1    i          i
76 //
77 //      One may easily use induction to prove (4) and (5).
78 //      Note. Since the left hand side of (3) contain only i
79 //      it does not necessary to do a full (53-bit) computation
80 //      in (3).
81 //      3. Final rounding
82 //      After generating the 53 bits result, we compute one
83 //      Together with the remainder, we can decide whether the
84 //      result is exact, bigger than 1/2ulp, or less than 1/
85 //      (it will never equal to 1/2ulp).
86 //      The rounding mode can be detected by checking whether
87 //      huge + tiny is equal to huge, and whether huge - tiny
88 //      equal to huge for some floating point number "huge"
89 //
90 //
91 //      Notes: Rounding mode detection omitted. The constants "
92 //      and "bias" are found in src/pkg/math/bits.go
93 //
94 //      Sqrt returns the square root of x.

15 //
16 //     tan.c
17 //
18 //     Circular tangent
19 //
20 // SYNOPSIS:
21 //
22 // double x, y, tan();
23 // y = tan( x );
24 //
25 // DESCRIPTION:
26 //
27 // Returns the circular tangent of the radian argument x.
28 //
29 // Range reduction is modulo pi/4. A rational function
30 //  $x + x^3 P(x^2)/Q(x^2)$ 
31 // is employed in the basic interval  $[0, \pi/4]$ .
32 //
33 // ACCURACY:
34 //
35 //                                     Relative error:
36 // arithmetic    domain    # trials    peak       rms
37 //   DEC         +-1.07e9    44000     4.1e-17    1.0e-17
38 //   IEEE        +-1.07e9    30000     2.9e-16    8.1e-17
39 //
40 // Partial loss of accuracy begins to occur at  $x = 2^{30} = 1$ 
41 // is not gradual, but jumps suddenly to about 1 part in  $10^e$ 
42 // be meaningless for  $x > 2^{49} = 5.6e14$ .
43 // [Accuracy loss statement from sin.go comments.]
44 //

31 // Complex circular tangent
32 //
33 // DESCRIPTION:
34 //
35 // If
36 //      $z = x + iy,$ 
37 //
38 // then
39 //
40 //      $w = \frac{\sin 2x + i \sinh 2y}{\cos 2x + \cosh 2y}.$ 
41 //
42 //
43 //
44 // On the real axis the denominator is zero at odd multiples
```

```

45 // of PI/2. The denominator is evaluated by its Taylor
46 // series near these points.
47 //
48 // ctan(z) = -i ctanh(iz).
49 //
50 // ACCURACY:
51 //
52 //                               Relative error:
53 // arithmetic   domain   # trials   peak           rms
54 //   DEC        -10,+10   5200      7.1e-17        1.6e-17
55 //   IEEE       -10,+10  30000     7.2e-16        1.2e-16

49
50 // A pollServer helps FDs determine when to retry a non-bloc
51 // read or write after they get EAGAIN. When an FD needs to
52 // send the fd on s.cr (for a read) or s.cw (for a write) to
53 // request to the poll server. Then receive on fd.cr/fd.cw.
54 // When the pollServer finds that i/o on FD should be possib
55 // again, it will send fd on fd.cr/fd.cw to wake any waiting
56 // This protocol is implemented as s.WaitRead() and s.WaitWr
57 //
58 // There is one subtlety: when sending on s.cr/s.cw, the
59 // poll server is probably in a system call, waiting for an
60 // to become ready. It's not looking at the request channel
61 // To resolve this, the poll server waits not just on the FD
62 // been given but also its own pipe. After sending on the
63 // buffered channel s.cr/s.cw, WaitRead/WaitWrite writes a
64 // byte to the pipe, causing the pollServer's poll system ca
65 // return. In response to the pipe being readable, the poll
66 // re-polls its request channels.
67 //
68 // Note that the ordering is "send request" and then "wake u
69 // If the operations were reversed, there would be a race: t
70 // server might wake up and look at the request channel, see
71 // was empty, and go back to sleep, all before the requester
72 // to send the request. Because the send must complete befo
73 // the request channel must be buffered. A buffer of size 1
74 // for any request load. If many processes are trying to su
75 // one will succeed, the pollServer will read the request, a
76 // channel will be empty for the next process's request. A
77 // might help batch requests.
78 //
79 // To avoid races in closing, all fd operations are locked a
80 // refcounted. when netFD.Close() is called, it calls syscal
81 // and sets a closing flag. Only when the last reference is
82 // will the fd be closed.

5 /*
6 Package net provides a portable interface for network I/O, i
7 TCP/IP, UDP, domain name resolution, and Unix domain sockets
8
9 Although the package provides access to low-level networking
10 primitives, most clients will need only the basic interface
11 by the Dial, Listen, and Accept functions and the associated
12 Conn and Listener interfaces. The crypto/tls package uses
13 the same interfaces and similar Dial and Listen functions.
14
15 The Dial function connects to a server:
16
17     conn, err := net.Dial("tcp", "google.com:80")
18     if err != nil {
19         // handle error
20     }
21     fmt.Fprintf(conn, "GET / HTTP/1.0\r\n\r\n")
22     status, err := bufio.NewReader(conn).ReadString('\n')
23     // ...
24
25 The Listen function creates servers:
26
27     ln, err := net.Listen("tcp", ":8080")
28     if err != nil {
29         // handle error
30     }
31     for {
32         conn, err := ln.Accept()
33         if err != nil {
34             // handle error
35             continue
36         }
37         go handleConnection(conn)
38     }
39 */
40 package net

5 /*
6 Package http provides HTTP client and server implementations
7
8 Get, Head, Post, and PostForm make HTTP requests:
9
10     resp, err := http.Get("http://example.com/")
11     ...
12     resp, err := http.Post("http://example.com/upload",
13     ...
14     resp, err := http.PostForm("http://example.com/form"
15         url.Values{"key": {"Value"}, "id": {"123"}})
16
17 The client must close the response body when finished with it:
18
19     resp, err := http.Get("http://example.com/")
20     if err != nil {
21         // handle error
22     }
23     defer resp.Body.Close()
24     body, err := ioutil.ReadAll(resp.Body)
25     // ...
26
27 For control over HTTP client headers, redirect policy, and other
28 settings, create a Client:
29
30     client := &http.Client{
31         CheckRedirect: redirectPolicyFunc,
32     }
33
34     resp, err := client.Get("http://example.com")
35     // ...
36
37     req, err := http.NewRequest("GET", "http://example.com",
38     // ...
39     req.Header.Add("If-None-Match", `W/"wyzzy"`)
40     resp, err := client.Do(req)
41     // ...
42
43 For control over proxies, TLS configuration, keep-alives,
44 compression, and other settings, create a Transport:
```

```

45
46     tr := &http.Transport{
47         TLSClientConfig: &tls.Config{RootCAs: poc
48         DisableCompression: true,
49     }
50     client := &http.Client{Transport: tr}
51     resp, err := client.Get("https://example.com")
52
53 Clients and Transports are safe for concurrent use by multip
54 goroutines and for efficiency should only be created once an
55
56 ListenAndServe starts an HTTP server with a given address an
57 The handler is usually nil, which means to use DefaultServeM
58 Handle and HandleFunc add handlers to DefaultServeMux:
59
60     http.Handle("/foo", fooHandler)
61
62     http.HandleFunc("/bar", func(w http.ResponseWriter,
63         fmt.Fprintf(w, "Hello, %q", html.EscapeStrin
64     })
65
66     log.Fatal(http.ListenAndServe(":8080", nil))
67
68 More control over the server's behavior is available by crea
69 custom Server:
70
71     s := &http.Server{
72         Addr:         ":8080",
73         Handler:      myHandler,
74         ReadTimeout:  10 * time.Second,
75         WriteTimeout: 10 * time.Second,
76         MaxHeaderBytes: 1 << 20,
77     }
78     log.Fatal(s.ListenAndServe())
79 */
80 package http

```

5 // Package pprof serves via its HTTP server runtime profilin
6 // in the format expected by the pprof visualization tool.
7 // For more information about pprof, see
8 // http://code.google.com/p/google-perftools/.
9 //
10 // The package is typically only imported for the side effect
11 // registering its HTTP handlers.
12 // The handled paths all begin with /debug/pprof/.
13 //
14 // To use pprof, link this package into your program:
15 //     import _ "net/http/pprof"
16 //
17 // Then use the pprof tool to look at the heap profile:
18 //
19 //     go tool pprof http://localhost:6060/debug/pprof/heap
20 //
21 // Or to look at a 30-second CPU profile:
22 //
23 //     go tool pprof http://localhost:6060/debug/pprof/profile
24 //
25 // Or to view all available profiles:
26 //
27 //     go tool pprof http://localhost:6060/debug/pprof/
28 //
29 // For a study of the facility in action, visit
30 //
31 //     http://blog.golang.org/2011/06/profiling-go-programs
32 //

5 /*
6     Package rpc provides access to the exported methods
7     network or other I/O connection. A server registers
8     as a service with the name of the type of the object
9     methods of the object will be accessible remotely.
10    objects (services) of different types but it is an e
11    objects of the same type.
12
13    Only methods that satisfy these criteria will be mad
14    other methods will be ignored:
15
16        - the method is exported.
17        - the method has two arguments, both exporte
18        - the method's second argument is a pointer.
19        - the method has return type error.
20
21    In effect, the method must look schematically like
22
23        func (t *T) MethodName(argType T1, replyType
24
25    where T, T1 and T2 can be marshaled by encoding/gob.
26    These requirements apply even if a different codec i
27    (In future, these requirements may soften for custom
28
29    The method's first argument represents the arguments
30    second argument represents the result parameters to
31    The method's return value, if non-nil, is passed bac
32    sees as if created by errors.New.
33
34    The server may handle requests on a single connectio
35    typically it will create a network listener and call
36    listener, HandleHTTP and http.Serve.
37
38    A client wishing to use the service establishes a co
39    NewClient on the connection. The convenience functi
40    both steps for a raw network connection (an HTTP con
41    Client object has two methods, Call and Go, that spe
42    call, a pointer containing the arguments, and a poin
43    parameters.
44
```

45 The Call method waits for the remote call to complet
46 launches the call asynchronously and signals complet
47 structure's Done channel.

48

49 Unless an explicit codec is set up, package encoding
50 transport the data.

51

52 Here is a simple example. A server wishes to export

53

```
54 package server
```

55

```
56 type Args struct {
```

```
57     A, B int
```

58 }

59

```
60 type Quotient struct {
```

```
61     Quo, Rem int
```

62 }

63

```
64 type Arith int
```

65

```
66 func (t *Arith) Multiply(args *Args, reply *
```

```
67     *reply = args.A * args.B
```

```
68     return nil
```

69 }

70

```
71 func (t *Arith) Divide(args *Args, quo *Quot
```

```
72     if args.B == 0 {
```

```
73         return errors.New("divide by
```

74 }

```
75     quo.Quo = args.A / args.B
```

```
76     quo.Rem = args.A % args.B
```

```
77     return nil
```

78 }

79

80 The server calls (for HTTP service):

81

```
82     arith := new(Arith)
```

```
83     rpc.Register(arith)
```

```
84     rpc.HandleHTTP()
```

```
85     l, e := net.Listen("tcp", ":1234")
```

```
86     if e != nil {
```

```
87         log.Fatal("listen error:", e)
```

88 }

```
89     go http.Serve(l, nil)
```

90

91 At this point, clients can see a service "Arith" wit
92 "Arith.Divide". To invoke one, a client first dials

93

```
94     client, err := rpc.DialHTTP("tcp", serverAdd
```

```

95         if err != nil {
96             log.Fatal("dialing:", err)
97         }
98
99     Then it can make a remote call:
100
101         // Synchronous call
102         args := &server.Args{7,8}
103         var reply int
104         err = client.Call("Arith.Multiply", args, &r
105         if err != nil {
106             log.Fatal("arith error:", err)
107         }
108         fmt.Printf("Arith: %d*d=%d", args.A, args.B
109
110     or
111
112         // Asynchronous call
113         quotient := new(Quotient)
114         divCall := client.Go("Arith.Divide", args, &
115         replyCall := <-divCall.Done // will be e
116         // check errors, print, etc.
117
118     A server implementation will often provide a simple,
119     client.

5 // Package os provides a platform-independent interface to o
6 // functionality. The design is Unix-like, although the erro
7 // Go-like; failing calls return values of type error rather
8 // Often, more information is available within the error. Fo
9 // if a call that takes a file name fails, such as Open or S
10 // will include the failing file name when printed and will
11 // *PathError, which may be unpacked for more information.
12 //
13 // The os interface is intended to be uniform across all ope
14 // Features not generally available appear in the system-spe
15 //
16 // Here is a simple example, opening a file and reading some
17 //
18 //     file, err := os.Open("file.go") // For read access.
19 //     if err != nil {
20 //         log.Fatal(err)
21 //     }
22 //
23 // If the open fails, the error string will be self-explanat
24 //
25 //     open file.go: no such file or directory
26 //
27 // The file's data can then be read into a slice of bytes. R
28 // Write take their byte counts from the length of the argum
29 //
30 //     data := make([]byte, 100)
31 //     count, err := file.Read(data)

5 // Package regexp implements regular expression search.
6 //
7 // The syntax of the regular expressions accepted is the same
8 // general syntax used by Perl, Python, and other languages.
9 // More precisely, it is the syntax accepted by RE2 and described
10 // at http://code.google.com/p/re2/wiki/Syntax, except for \C.
11 //
12 // All characters are UTF-8-encoded code points.
13 //
14 // There are 16 methods of Regexp that match a regular expression
15 // and return the matched text. Their names are matched by this regular
16 // expression:
17 //     Find(All)?(String)?(Submatch)?(Index)?
18 //
19 // If 'All' is present, the routine matches successive non-overlapping
20 // matches of the entire expression. Empty matches (whenever the
21 // expression is empty) are ignored. The return value is a slice containing
22 // the return values of the corresponding non-'All' routine. The
23 // routine takes an extra integer argument, n; if n >= 0, the function returns
24 // at most n matches/submatches.
25 //
26 // If 'String' is present, the argument is a string; otherwise, it is a
27 // slice of bytes; return values are adjusted as appropriate.
28 //
29 // If 'Submatch' is present, the return value is a slice identifying
30 // successive submatches of the expression. Submatches are identified by
31 // parenthesized subexpressions within the regular expression. The
32 // slice is ordered left to right in order of opening parenthesis. Submatch
33 // 0 is the entire expression, submatch 1 the match of the first
34 // parenthesized subexpression, and so on.
35 //
36 // If 'Index' is present, matches and submatches are identified by
37 // byte index pairs within the input string: result[2*n:2*n+1] identifies
38 // the nth submatch. The pair for n==0 identifies the match of the
39 // entire expression. If 'Index' is not present, the match is identified
40 // by the text of the match/submatch. If an index is negative, it
41 // indicates that the subexpression did not match any string in the input.
42 //
43 // There is also a subset of the methods that can be applied to a
44 // RuneReader:
```

```

45 //
46 //      MatchReader, FindReaderIndex, FindReaderSubmatchInde
47 //
48 // This set may grow. Note that regular expression matches
49 // examine text beyond the text returned by a match, so the
50 // match text from a RuneReader may read arbitrarily far int
51 // before returning.
52 //
53 // (There are a few other methods that do not match this pat
54 //

5 // This file implements binary search.
6
7 package sort
8
9 // Search uses binary search to find and return the smallest
10 // in [0, n) at which f(i) is true, assuming that on the ran
11 // f(i) == true implies f(i+1) == true. That is, Search req
12 // f is false for some (possibly empty) prefix of the input
13 // and then true for the (possibly empty) remainder; Search
14 // the first true index. If there is no such index, Search
15 // Search calls f(i) only for i in the range [0, n).
16 //
17 // A common use of Search is to find the index i for a value
18 // a sorted, indexable data structure such as an array or sl
19 // In this case, the argument f, typically a closure, captur
20 // to be searched for, and how the data structure is indexed
21 // ordered.
22 //
23 // For instance, given a slice data sorted in ascending orde
24 // the call Search(len(data), func(i int) bool { return data
25 // returns the smallest index i such that data[i] >= 23. If
26 // wants to find whether 23 is in the slice, it must test da
27 // separately.
28 //
29 // Searching data sorted in descending order would use the <
30 // operator instead of the >= operator.
31 //
32 // To complete the example above, the following code tries t
33 // x in an integer slice data sorted in ascending order:
34 //
35 //     x := 23
36 //     i := sort.Search(len(data), func(i int) bool { retur
37 //     if i < len(data) && data[i] == x {
38 //         // x is present at data[i]
39 //     } else {
40 //         // x is not present in data,
41 //         // but i is the index where it would be inse
42 //     }

10
11 import (
12     "runtime"
13     "sync"
14     "unsafe"
15 )
16
17 // Lock synchronizing creation of new file descriptors with
18 //
19 // We want the child in a fork/exec sequence to inherit only
20 // file descriptors we intend. To do that, we mark all file
21 // descriptors close-on-exec and then, in the child, explici
22 // unmark the ones we want the exec'ed program to keep.
23 // Unix doesn't make this easy: there is, in general, no way
24 // allocate a new file descriptor close-on-exec. Instead yo
25 // have to allocate the descriptor and then mark it close-on
26 // If a fork happens between those two events, the child's e
27 // will inherit an unwanted file descriptor.
28 //
29 // This lock solves that race: the create new fd/mark close-
30 // operation is done holding ForkLock for reading, and the f
31 // is done holding ForkLock for writing. At least, that's t
32 // There are some complications.
33 //
34 // Some system calls that create new file descriptors can bl
35 // for arbitrarily long times: open on a hung NFS server or
36 // pipe, accept on a socket, and so on. We can't reasonably
37 // the lock across those operations.
38 //
39 // It is worse to inherit some file descriptors than others.
40 // If a non-malicious child accidentally inherits an open or
41 // that's not a big deal. On the other hand, if a long-live
```

```

42 // accidentally inherits the write end of a pipe, then the r
43 // of that pipe will not see EOF until that child exits, pot
44 // causing the parent program to hang. This is a common pro
45 // in threaded C programs that use popen.
46 //
47 // Luckily, the file descriptors that are most important not
48 // inherit are not the ones that can take an arbitrarily lon
49 // to create: pipe returns instantly, and the net package us
50 // non-blocking I/O to accept on a listening socket.
51 // The rules for which file descriptor-creating operations u
52 // ForkLock are as follows:
53 //
54 // 1) Pipe.      Does not block.  Use the ForkLock.
55 // 2) Socket.   Does not block.  Use the ForkLock.
56 // 3) Accept.   If using non-blocking mode, use the ForkLock.
57 //             Otherwise, live with the race.
58 // 4) Open.     Can block.  Use O_CLOEXEC if available (Linux
59 //             Otherwise, live with the race.
60 // 5) Dup.      Does not block.  Use the ForkLock.
61 //             On Linux, could use fcntl F_DUPFD_CLOEXEC
62 //             instead of the ForkLock, but only for dup(fd,

5 // Package testing provides support for automated testing of
6 // It is intended to be used in concert with the ``go test''
7 // execution of any function of the form
8 //     func TestXxx(*testing.T)
9 // where Xxx can be any alphanumeric string (but the first 1
10 // [a-z]) and serves to identify the test routine.
11 // These TestXxx routines should be declared within the pack
12 //
13 // Functions of the form
14 //     func BenchmarkXxx(*testing.B)
15 // are considered benchmarks, and are executed by the "go te
16 // the -test.bench flag is provided.
17 //
18 // A sample benchmark function looks like this:
19 //     func BenchmarkHello(b *testing.B) {
20 //         for i := 0; i < b.N; i++ {
21 //             fmt.Sprintf("hello")
22 //         }
23 //     }
24 //
25 // The benchmark package will vary b.N until the benchmark f
26 // long enough to be timed reliably. The output
27 //     testing.BenchmarkHello    10000000    282 ns/op
28 // means that the loop ran 10000000 times at a speed of 282
29 //
30 // If a benchmark needs some expensive setup before running,
31 // may be stopped:
32 //     func BenchmarkBigLen(b *testing.B) {
33 //         b.StopTimer()
34 //         big := NewBig()
35 //         b.StartTimer()
36 //         for i := 0; i < b.N; i++ {
37 //             big.Len()
38 //         }
39 //     }
40 //
41 // The package also runs and verifies example code. Example
42 // include a concluding comment that begins with "Output:" a
43 // the standard output of the function when the tests are ru
44 // examples of an example:
```

```

45 //
46 //     func ExampleHello() {
47 //         fmt.Println("hello")
48 //         // Output: hello
49 //     }
50 //
51 //     func ExampleSalutations() {
52 //         fmt.Println("hello, and")
53 //         fmt.Println("goodbye")
54 //         // Output:
55 //         // hello, and
56 //         // goodbye
57 //     }
58 //
59 // Example functions without output comments are compiled by
60 //
61 // The naming convention to declare examples for a function
62 // method M on type T are:
63 //
64 //     func ExampleF() { ... }
65 //     func ExampleT() { ... }
66 //     func ExampleT_M() { ... }
67 //
68 // Multiple example functions for a type/function/method may
69 // append a distinct suffix to the name. The suffix must
70 // lower-case letter.
71 //
72 //     func ExampleF_suffix() { ... }
73 //     func ExampleT_suffix() { ... }
74 //     func ExampleT_M_suffix() { ... }
75 //
76 // The entire test file is presented as the example when it
77 // example function, at least one other function, type, vari
78 // declaration, and no test or benchmark functions.

5 // Package scanner provides a scanner and tokenizer for UTF-
6 // It takes an io.Reader providing the source, which then ca
7 // through repeated calls to the Scan function. For compati
8 // existing tools, the NUL character is not allowed.
9 //
10 // By default, a Scanner skips white space and Go comments a
11 // literals as defined by the Go language specification. It
12 // customized to recognize only a subset of those literals a
13 // different white space characters.
14 //
15 // Basic usage pattern:
16 //
17 //     var s scanner.Scanner
18 //     s.Init(src)
19 //     tok := s.Scan()
20 //     for tok != scanner.EOF {
21 //         // do something with tok
22 //         tok = s.Scan()
23 //     }
24 //

31 }
32
33 // A Writer is a filter that inserts padding around tab-deli
34 // columns in its input to align them in the output.
35 //
36 // The Writer treats incoming bytes as UTF-8 encoded text co
37 // of cells terminated by (horizontal or vertical) tabs or l
38 // breaks (newline or formfeed characters). Cells in adjacen
39 // constitute a column. The Writer inserts padding as needed
40 // make all cells in a column have the same width, effective
41 // aligning the columns. It assumes that all characters have
```

```

42 // same width except for tabs for which a tabwidth must be s
43 // Note that cells are tab-terminated, not tab-separated: tr
44 // non-tab text at the end of a line does not form a column
45 //
46 // The Writer assumes that all Unicode code points have the
47 // this may not be true in some fonts.
48 //
49 // If DiscardEmptyColumns is set, empty columns that are ter
50 // entirely by vertical (or "soft") tabs are discarded. Colu
51 // terminated by horizontal (or "hard") tabs are not affecte
52 // this flag.
53 //
54 // If a Writer is configured to filter HTML, HTML tags and e
55 // are passed through. The widths of tags and entities are
56 // assumed to be zero (tags) and one (entities) for formatti
57 //
58 // A segment of text may be escaped by bracketing it with Es
59 // characters. The tabwriter passes escaped text segments th
60 // unchanged. In particular, it does not interpret any tabs
61 // breaks within the segment. If the StripEscape flag is set
62 // Escape characters are stripped from the output; otherwise
63 // are passed through as well. For the purpose of formatting
64 // width of the escaped text is always computed excluding th
65 // characters.
66 //
67 // The formfeed character ('\f') acts like a newline but it
68 // terminates all columns in the current line (effectively c
69 // Flush). Cells in the next line start new columns. Unless
70 // inside an HTML tag or inside an escaped text segment, for
71 // characters appear as newlines in the output.
72 //

6 Package template implements data-driven templates for genera
7
8 To generate HTML output, see package html/template, which ha
9 as this package but automatically secures HTML output agains
10
11 Templates are executed by applying them to a data structure.
12 template refer to elements of the data structure (typically
13 or a key in a map) to control execution and derive values to
14 Execution of the template walks the structure and sets the c
15 by a period '.' and called "dot", to the value at the curren
16 structure as execution proceeds.
17
18 The input text for a template is UTF-8-encoded text in any f
19 "Actions"--data evaluations or control structures--are delir
20 "{{" and "}}"; all text outside actions is copied to the out
21 Actions may not span newlines, although comments can.
22
23 Once constructed, a template may be executed safely in paral
24
25 Here is a trivial example that prints "17 items are made of
26
27         type Inventory struct {
28             Material string
29             Count    uint
30         }
31         sweaters := Inventory{"wool", 17}
32         tmpl, err := template.New("test").Parse("{{.Count}}
33         if err != nil { panic(err) }
34         err = tmpl.Execute(os.Stdout, sweaters)
35         if err != nil { panic(err) }
36
37 More intricate examples appear below.
38
39 Actions
40
41 Here is the list of actions. "Arguments" and "pipelines" are
```

```

42 data, defined in detail below.
43
44 */
45 //      {{{/* a comment */}}}
46 //      A comment; discarded. May contain newlines.

92             If the value of the pipeline is empty, dot i
93             is executed; otherwise, dot is set to the va
94             and T1 is executed.
95
96 Arguments
97
98 An argument is a simple value, denoted by one of the followi
99
100 - A boolean, string, character, integer, floating-po
101   or complex constant in Go syntax. These behave lik
102   constants, although raw strings may not span newli
103 - The character '.' (period):
104   .
105   The result is the value of dot.
106 - A variable name, which is a (possibly empty) alpha
107   preceded by a dollar sign, such as
108     $piOver2
109   or
110     $
111   The result is the value of the variable.
112   Variables are described below.
113 - The name of a field of the data, which must be a s
114   by a period, such as
115     .Field
116   The result is the value of the field. Field invoca
117   chained:
118     .Field1.Field2
119   Fields can also be evaluated on variables, includi
120     $x.Field1.Field2
121 - The name of a key of the data, which must be a map
122   by a period, such as
123     .Key
124   The result is the map element value indexed by the
125   Key invocations may be chained and combined with f
126   depth:
127     .Field1.Key1.Field2.Key2
128   Although the key must be an alphanumeric identifie
129   field names they do not need to start with an uppe
130   Keys can also be evaluated on variables, including
131     $x.key1.key2
132 - The name of a niladic method of the data, preceded
133   such as
134     .Method
135   The result is the value of invoking the method wit
136   receiver, dot.Method(). Such a method must have on
137   any type) or two return values, the second of whic
138   If it has two and the returned error is non-nil, e
139   and an error is returned to the caller as the valu
140   Method invocations may be chained and combined wit

```

141 to any depth:
142 .Field1.Key1.Method1.Field2.Key2.Method2
143 Methods can also be evaluated on variables, includ
144 \$x.Method1.Field
145 - The name of a niladic function, such as
146 fun
147 The result is the value of invoking the function,
148 types and values behave as in methods. Functions a
149 names are described below.
150
151 Arguments may evaluate to any type; if they are pointers the
152 automatically indirects to the base type when required.
153 If an evaluation yields a function value, such as a function
154 field of a struct, the function is not invoked automatically
155 can be used as a truth value for an if action and the like.
156 it, use the call function, defined below.
157
158 A pipeline is a possibly chained sequence of "commands". A c
159 value (argument) or a function or method call, possibly with
160
161 Argument
162 The result is the value of evaluating the ar
163 .Method [Argument...]
164 The method can be alone or the last element
165 unlike methods in the middle of a chain, it
166 The result is the value of calling the metho
167 arguments:
168 dot.Method(Argument1, etc.)
169 functionName [Argument...]
170 The result is the value of calling the funct
171 with the name:
172 function(Argument1, etc.)
173 Functions and function names are described b
174
175 Pipelines
176
177 A pipeline may be "chained" by separating a sequence of comm
178 characters '|'. In a chained pipeline, the result of the eac
179 passed as the last argument of the following command. The ou
180 command in the pipeline is the value of the pipeline.
181
182 The output of a command will be either one value or two valu
183 which has type error. If that second value is present and ev
184 non-nil, execution terminates and the error is returned to t
185 Execute.
186
187 Variables
188
189 A pipeline inside an action may initialize a variable to cap

190 The initialization has syntax
191
192 \$variable := pipeline
193
194 where \$variable is the name of the variable. An action that
195 variable produces no output.
196
197 If a "range" action initializes a variable, the variable is
198 successive elements of the iteration. Also, a "range" may d
199 variables, separated by a comma:
200
201 \$index, \$element := pipeline
202
203 in which case \$index and \$element are set to the successive
204 array/slice index or map key and element, respectively. Not
205 only one variable, it is assigned the element; this is oppos
206 convention in Go range clauses.
207
208 A variable's scope extends to the "end" action of the contro
209 "with", or "range") in which it is declared, or to the end o
210 there is no such control structure. A template invocation d
211 variables from the point of its invocation.
212
213 When execution begins, \$ is set to the data argument passed
214 to the starting value of dot.
215
216 Examples
217
218 Here are some example one-line templates demonstrating pipel
219 All produce the quoted word "output":
220
221 {{"\\"output\\"}}
222 A string constant.
223 {{`"output"`}}
224 A raw string constant.
225 {{printf "%q" "output"}}
226 A function call.
227 {{"output" | printf "%q"}}
228 A function call whose final argument comes f
229 command.
230 {{"put" | printf "%s%s" "out" | printf "%q"}}
231 A more elaborate call.
232 {{"output" | printf "%s" | printf "%q"}}
233 A longer chain.
234 {{with "output"}}{{printf "%q" .}}{{end}}
235 A with action using dot.
236 {{with \$x := "output" | printf "%q"}}{{\$x}}{{end}}
237 A with action that creates and uses a variab
238 {{with \$x := "output"}}{{printf "%q" \$x}}{{end}}
239 A with action that uses the variable in anot

```
240         {{with $x := "output"}}{{ $x | printf "%q" }}{{end}}
241         The same, but pipelined.
242
243 Functions
244
245 During execution functions are found in two function maps: f
246 template, then in the global function map. By default, no fu
247 in the template but the Funcs method can be used to add them
248
249 Predefined global functions are named as follows.
250
251     and
252         Returns the boolean AND of its arguments by
253         first empty argument or the last argument, t
254         "and x y" behaves as "if x then y else x". A
255         arguments are evaluated.
256
257     call
258         Returns the result of calling the first argu
259         must be a function, with the remaining argum
260         Thus "call .X.Y 1 2" is, in Go notation, dot
261         Y is a func-valued field, map entry, or the
262         The first argument must be the result of an
263         that yields a value of function type (as dis
264         a predefined function such as print). The fu
265         return either one or two result values, the
266         is of type error. If the arguments don't mat
267         or the returned error value is non-nil, exec
268
269     html
270         Returns the escaped HTML equivalent of the t
271         representation of its arguments.
272
273     index
274         Returns the result of indexing its first arg
275         following arguments. Thus "index x 1 2 3" is
276         x[1][2][3]. Each indexed item must be a map,
277
278     js
279         Returns the escaped JavaScript equivalent of
280         representation of its arguments.
281
282     len
283         Returns the integer length of its argument.
284
285     not
286         Returns the boolean negation of its single a
287
288     or
289         Returns the boolean OR of its arguments by r
290         first non-empty argument or the last argumen
291         "or x y" behaves as "if x then x else y". Al
292         arguments are evaluated.
293
294     print
295         An alias for fmt.Sprint
296
297     printf
```

289 An alias for fmt.Sprintf
 290 println
 291 An alias for fmt.Sprintln
 292 urlquery
 293 Returns the escaped value of the textual rep
 294 its arguments in a form suitable for embeddi
 295
 296 The boolean functions take any zero value to be false and a
 297 be true.
 298
 299 Associated templates
 300
 301 Each template is named by a string specified when it is crea
 302 template is associated with zero or more other templates tha
 303 name; such associations are transitive and form a name space
 304
 305 A template may use a template invocation to instantiate anot
 306 template; see the explanation of the "template" action above
 307 that of a template associated with the template that contain
 308
 309 Nested template definitions
 310
 311 When parsing a template, another template may be defined and
 312 template being parsed. Template definitions must appear at t
 313 template, much like global variables in a Go program.
 314
 315 The syntax of such definitions is to surround each template
 316 "define" and "end" action.
 317
 318 The define action names the template being created by provid
 319 constant. Here is a simple example:
 320
 321 `{{define "T1"}}ONE{{end}}
 322 {{define "T2"}}TWO{{end}}
 323 {{define "T3"}}{{template "T1"}} {{template "T2"}}{{
 324 {{template "T3"}}`
 325
 326 This defines two templates, T1 and T2, and a third T3 that i
 327 when it is executed. Finally it invokes T3. If executed this
 328 produce the text
 329
 330 ONE TWO
 331
 332 By construction, a template may reside in only one associati
 333 necessary to have a template addressable from multiple assoc
 334 template definition must be parsed multiple times to create
 335 values, or must be copied with the Clone or AddParseTree met
 336
 337 Parse may be called multiple times to assemble the various a

```
338 see the ParseFiles and ParseGlob functions and methods for s
339 related templates stored in files.
340
341 A template may be executed directly or through ExecuteTempla
342 an associated template identified by name. To invoke our exa
343 might write,
344
345     err := tmpl.Execute(os.Stdout, "no data needed")
346     if err != nil {
347         log.Fatalf("execution failed: %s", err)
348     }
349
350 or to invoke a particular template explicitly by name,
351
352     err := tmpl.ExecuteTemplate(os.Stdout, "T2", "no dat
353     if err != nil {
354         log.Fatalf("execution failed: %s", err)
355     }
356
357 */
358 package template

8
9 // These are predefined layouts for use in Time.Format.
10 // The standard time used in the layouts is:
11 //     Mon Jan 2 15:04:05 MST 2006
12 // which is Unix time 1136243045. Since MST is GMT-0700,
13 // the standard time can be thought of as
14 //     01/02 03:04:05PM '06 -0700
15 // To define your own format, write down what the standard t
16 // like formatted your way; see the values of constants like
17 // StampMicro or Kitchen for examples.
18 //
19 // Within the format string, an underscore _ represents a sp
20 // replaced by a digit if the following number (a day) has t
21 // compatibility with fixed-width Unix time formats.
22 //
23 // A decimal point followed by one or more zeros represents
24 // second, printed to the given number of decimal places. A
25 // followed by one or more nines represents a fractional sec
26 // the given number of decimal places, with trailing zeros r
27 // When parsing (only), the input may contain a fractional s
28 // field immediately after the seconds field, even if the la
29 // signify its presence. In that case a decimal point follow
30 // series of digits is parsed as a fractional second.
31 //
32 // Numeric time zone offsets format as follows:
33 //     -0700 ±hhmm
34 //     -07:00 ±hh:mm
35 // Replacing the sign in the format with a Z triggers
36 // the ISO 8601 behavior of printing Z instead of an
37 // offset for the UTC zone. Thus:
38 //     Z0700 Z or ±hhmm
39 //     Z07:00 Z or ±hh:mm

```

```
144 // representation. For example, to use the Unix epoch inter
145 // could define that to distinguish a zero value from Jan 1
146 // time would be represented by sec=-1, nsec=1e9. However,
147 // suggest a representation, namely using 1-1-1 00:00:00 UTC
148 // epoch, and that's what we do.
149 //
150 // The Add and Sub computations are oblivious to the choice
151 //
152 // The presentation computations - year, month, minute, and
153 // rely heavily on division and modulus by positive constant
154 // calendrical calculations we want these divisions to round
155 // for negative values, so that the remainder is always posi
156 // Go's division (like most hardware division instructions)
157 // zero. We can still do those computations and then adjust
158 // for a negative numerator, but it's annoying to write the
159 // over and over. Instead, we can change to a different epo
160 // ago that all the times we care about will be positive, an
161 // to zero and round down coincide. These presentation rout
162 // have to add the zone offset, so adding the translation to
163 // alternate epoch is cheap. For example, having a non-nega
164 // means that we can write
165 //
166 //     sec = t % 60
167 //
168 // instead of
169 //
170 //     sec = t % 60
171 //     if sec < 0 {
172 //         sec += 60
173 //     }
174 //
175 // everywhere.
176 //
177 // The calendar runs on an exact 400 year cycle: a 400-year
178 // printed for 1970-2469 will apply as well to 2470-2869. E
179 // of the week match up. It simplifies the computations to
180 // cycle boundaries so that the exceptional years are always
181 // long as possible. That means choosing a year equal to 1
182 // that the first leap year is the 4th year, the first misse
183 // is the 100th year, and the missed missed leap year is the
184 // So we'd prefer instead to print a calendar for 2001-2400
185 // for 2401-2800.
186 //
187 // Finally, it's convenient if the delta between the Unix ep
188 // long-ago epoch is representable by an int64 constant.
189 //
190 // These three considerations—choose an epoch as early as po
191 // uses a year equal to 1 mod 400, and that is no more than
192 // earlier than 1970—bring us to the year -292277022399. We
```

```

193 // this year as the absolute zero year, and to times measure
194 // seconds since this year as absolute times.
195 //
196 // Times measured as an int64 seconds since the year 1—the r
197 // used for Time's sec field—are called internal times.
198 //
199 // Times measured as an int64 seconds since the year 1970 ar
200 // times.
201 //
202 // It is tempting to just use the year 1 as the absolute epo
203 // that the routines are only valid for years >= 1. However
204 // routines would then be invalid when displaying the epoch
205 // west of UTC, since it is year 0. It doesn't seem tenable
206 // printing the zero time correctly isn't supported in half
207 // zones. By comparison, it's reasonable to mishandle some
208 // the year -292277022399.
