Contents: Space-separated list of CSS style class(es) to be applied when this element is rendered. This value must be passed through as the "class" attribute on generated markup.

---

**setStyleClass**

```java
public void setStyleClass(String styleClass)
```

Set the value of the styleClass property.

---

**getTabindex**

```java
public String getTabindex()
```

Return the value of the tabindex property.

Contents: Position of this element in the tabbing order for the current document. This value must be an integer between 0 and 32767.

---

**setTabindex**

```java
public void setTabindex(String tabindex)
```

Set the value of the tabindex property.

---

**getTitle**

```java
public String getTitle()
```

Return the value of the title property.

Contents: Advisory title information about markup elements generated for this component.
setTitle

public void setTitle(String title)

Set the value of the title property.

saveState

public Object saveState(FacesContext _context)

**Description copied from interface: StateHolder**

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. **This method must not save the state of children and facets.** That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

component should be the same as before executing it.

The return from this method must be Serializable

**Specified by:**
(saveState in interface StateHolder)

**Overrides:**
(saveState in class UIInput)

restoreState

public void restoreState(FacesContext _context, Object _state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreStatejavax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by:
    restoreState in interface StateHolder

Overrides:
    restoreState in class UIInput
javax.faces.component.html  Class HtmlSelectOneRadio

java.lang.Object
  ▼ javax.faces.component.UIComponent
      ▼ javax.faces.component.UIComponentBase
          ▼ javax.faces.component.UIOutput
              ▼ javax.faces.component.UIInput
                  ▼ javax.faces.component.UISelectOne
                      ▼ javax.faces.component.html.HtmlSelectOneRadio

All Implemented Interfaces:
  EditableValueHolder, StateHolder, ValueHolder

public class HtmlSelectOneRadio
  extends UISelectOne

Extends: UIComponent > UIComponentBase > UIOutput > UIInput > UISelectOne

radio HTML input

renderertype "javax.faces.Radio" setRendererType()

Represents a single-selection component that is rendered as a set of HTML input elements of type radio.

By default, the renderertype property must be set to "javax.faces.Radio". This value can be changed by calling the setRendererType() method.

---

**Field Detail**

**COMPONENT_TYPE**

```java
class HtmlSelectOneRadio {
    public static final String COMPONENT_TYPE = "html_select_one_radio";
}
```

The standard component type for this component.

**See Also:**
- [Constant Field Values](#)

**Constructor Detail**

```java
class HtmlSelectOneRadio {
    public HtmlSelectOneRadio() {
    }
}
```

**Method Detail**

```java
public String getAccesskey() {
    return accesskey;
}
```

getAccesskey
public String getAccesskey() {
    Return the value of the accesskey property.
    Contents: Access key that, when pressed, transfers focus to this element.
}

public void setAccesskey(String accesskey) {
    accesskey
}

setAccesskey

public void setAccesskey(String accesskey) {
    Set the value of the accesskey property.
}

public int getBorder() {
    border
}

getBorder

public int getBorder() {
    Return the value of the border property.
    Contents: Width (in pixels) of the border to be drawn around the table containing the options list.
}
public void setBorder(int border)

    border

setBorder

public void setBorder(int border)

    Set the value of the border property.

public String getDir()

    dir

"LTR"left-to-right "RTL"right-to-left

getDir

public String getDir()

    Return the value of the dir property.

    Contents: Direction indication for text that does not inherit directionality. Valid values are "LTR" (left-to-right) and "RTL" (right-to-left).

public void setDir(String dir)

    dir
setDir

public void setDir(String dir)

Set the value of the dir property.

public boolean isDisabled()

disabled

false true disabled="disabled"

isDisabled

public boolean isDisabled()

Return the value of the disabled property.

Contents: Flag indicating that this element must never receive focus or be included in a subsequent submit. A value of false causes no attribute to be rendered, while a value of true causes the attribute to be rendered as disabled="disabled".

public void setDisabled(boolean disabled)

disabled

setDisabled

public void setDisabled(boolean disabled)

Set the value of the disabled property.
public String getDisabledClass()

disabledClass

CSS

getDisabledClass

public String getDisabledClass()

Return the value of the disabledClass property.

Contents: CSS style class to apply to the rendered label on disabled options.

public void setDisabledClass(String disabledClass)

disabledClass

setDisabledClass

public void setDisabledClass(String disabledClass)

Set the value of the disabledClass property.

public String getEnabledClass()

enabledClass

CSS
**getEnabledClass**

```java
public String getEnabledClass()
```

Return the value of the `enabledClass` property.

Contents: CSS style class to apply to the rendered label on enabled options.

**setEnabledClass**

```java
public void setEnabledClass(String enabledClass)
```

`enabledClass`

**setLabel**

```java
public String getLabel()
```

`label`

**getLabel**

```java
public String getLabel()
```

Return the value of the `label` property.
Contents: A localized user presentable name for this component.

public void setLabel(String label)

    label

setLabel

public void setLabel(String label)

    Set the value of the label property.

public String getLang()

    lang

gGetLang

public String getLang()

    Return the value of the lang property.

    Contents: Code describing the language used in the generated markup for this component.

public void setLang(String lang)

    lang
setLang

public void setLang(String lang)

Set the value of the lang property.

public String getLayout()

Return the value of the layout property.

Contents: Orientation of the options list to be created. Valid values are "pageDirection" (list is laid out vertically), or "lineDirection" (list is laid out horizontally). If not specified, the default value is "lineDirection".

public void setLayout(String layout)

public void setLayout(String layout)

Set the value of the layout property.

public String getOnblur()

onblur

Javascript

getOnblur

public String getOnblur()

Return the value of the onblur property.

Contents: Javascript code executed when this element loses focus.

public void setOnblur(String onblur)

onblur

setOnblur

public void setOnblur(String onblur)

Set the value of the onblur property.

public String getOnchange()

onchange
getOnchange

public String getOnchange()

    Return the value of the onchange property.

    Contents: Javascript code executed when this element loses focus and its value has been modified since gaining focus.

public void setOnchange(String onchange)

    onchange

setOnchange

public void setOnchange(String onchange)

    Set the value of the onchange property.

public String getOnclick()

    onclick

getOnclick

public String getOnclick()
Return the value of the onclick property.

Contents: Javascript code executed when a pointer button is clicked over this element.

```java
public void setOnclick(String onclick)
 onclick
```

setOnclick

```java
public void setOnclick(String onclick)
    Set the value of the onclick property.
```

```java
public String getOndblclick()
 ondblclick
```

Javascript

getOndblclick

```java
public String getOndblclick()
    Return the value of the ondblclick property.
    Contents: Javascript code executed when a pointer button is double clicked over this element.
```

```java
public void setOndblclick(String ondblclick)
```
**setOndblclick**

```java
public void setOndblclick(String ondblclick)
```

Set the value of the ondblclick property.

---

**public String getOnfocus()**

```java
onfocus
```

**Javascript**

---

**getOnfocus**

```java
public String getOnfocus()
```

Return the value of the onfocus property.

Contents: Javascript code executed when this element receives focus.

---

**public void setOnfocus(String onfocus)**

```java
onfocus
```

---

**setOnfocus**

```java
public void setOnfocus(String onfocus)
```
Set the value of the `onfocus` property.

```
public String getOnkeydown()
```

`onkeydown`

Javascript

**getOnkeydown**

```
public String getOnkeydown()
```

Return the value of the `onkeydown` property.

Contents: Javascript code executed when a key is pressed down over this element.

```
public void setOnkeydown(String onkeydown)
```

`onkeydown`

**setOnkeydown**

```
public void setOnkeydown(String onkeydown)
```

Set the value of the `onkeydown` property.

```
public String getOnkeypress()
```

`onkeypress`
Javascript

getOnkeypress

public String getOnkeypress()

Return the value of the onkeypress property.
Contents: Javascript code executed when a key is pressed and released over this element.

--------------------

public void setOnkeypress(String onkeypress)

onkeypress

setOnkeypress

public void setOnkeypress(String onkeypress)

Set the value of the onkeypress property.
--------------------

public String getOnkeyup()

onkeyup

Javascript

getOnkeyup

public String getOnkeyup()
Return the value of the `onkeyup` property.

Contents: Javascript code executed when a key is released over this element.

```java
public void setOnkeyup(String onkeyup)
  onkeyup
```

`setOnkeyup`

```java
public void setOnkeyup(String onkeyup)
  Set the value of the `onkeyup` property.
```

```java
public String getOnmousedown()
  onmousedown
```

`getOnmousedown`

```java
public String getOnmousedown()
  Return the value of the `onmousedown` property.
  Contents: Javascript code executed when a pointer button is pressed down over this element.
```

```java
public void setOnmousedown(String onmousedown)
```
onmousedown

setOnmousedown

public void setOnmousedown(String onmousedown)

Set the value of the onmousedown property.

public String getOnmousemove()

onmousemove

Javascript

getOnmousemove

public String getOnmousemove()

Return the value of the onmousemove property.

Contents: Javascript code executed when a pointer button is moved within this element.

public void setOnmousemove(String onmousemove)

onmousemove

setOnmousemove

public void setOnmousemove(String onmousemove)
Set the value of the onmousemove property.

public String getOnmouseout()

onmouseout

Javascript

getOnmouseout

public String getOnmouseout()

Return the value of the onmouseout property.

Contents: Javascript code executed when a pointer button is moved away from this element.

public void setOnmouseout(String onmouseout)

onmouseout

setOnmouseout

public void setOnmouseout(String onmouseout)

Set the value of the onmouseout property.

public String getOnmouseover()
Javascript

getOnmouseover

public String getOnmouseover()

    Return the value of the onmouseover property.

    Contents: Javascript code executed when a pointer button is moved onto this element.

-------------------------------------------------------------------------------------------------------------------

public void setOnmouseover(String onmouseover)

    onmouseover

setOnmouseover

public void setOnmouseover(String onmouseover)

    Set the value of the onmouseover property.

-------------------------------------------------------------------------------------------------------------------

public String getOnmouseup()

    onmouseup

Javascript

getOnmouseup

public String getOnmouseup()
Return the value of the `onmouseup` property.

Contents: Javascript code executed when a pointer button is released over this element.

```java
public void setOnmouseup(String onmouseup)

onmouseup
```

`setOnmouseup`

```java
public void setOnmouseup(String onmouseup)

Set the value of the `onmouseup` property.
```

`getOnselect`

```java
public String getOnselect()

onselect
```

`getOnselect`

```java
public String getOnselect()

Return the value of the `onselect` property.

Contents: Javascript code executed when text within this element is selected by the user.
```

```java
public void setOnselect(String onselect)
```
onselect

setOnselect

public void setOnselect(String onselect)

Set the value of the onselect property.

public boolean isReadonly()

readonly

false true readonly="readonly"

isReadonly

public boolean isReadonly()

Return the value of the readonly property.

Contents: Flag indicating that this component will prohibit changes by the user. The element may receive focus unless it has also been disabled. A value of false causes no attribute to be rendered, while a value of true causes the attribute to be rendered as readonly="readonly".

public void setReadonly(boolean readonly)

readonly
**setReadonly**

public void setReadonly(boolean readonly)

Set the value of the readonly property.

---

**public String getStyle()**

style

CSS

**getStyle**

public String getStyle()

Return the value of the style property.

Contents: CSS style(s) to be applied when this component is rendered.

---

**public void setStyle(String style)**

style

**setStyle**

public void setStyle(String style)

Set the value of the style property.
public String getStyleClass()

  styleClass

CSS "class"

getStyleClass

public String getStyleClass()

  Return the value of the styleClass property.

  Contents: Space-separated list of CSS style class(es) to be applied when this element is rendered. This value must be passed through as the "class" attribute on generated markup.

public void setStyleClass(String styleClass)

  styleClass

setStyleClass

public void setStyleClass(String styleClass)

  Set the value of the styleClass property.

public String getTabindex()

  tabindex

Tab 0 32767
**getTabindex**

public String getTabindex()

Return the value of the `tabindex` property.

Contents: Position of this element in the tabbing order for the current document. This value must be an integer between 0 and 32767.

---

**public void setTabindex(String tabindex)**

`tabindex`

**setTabindex**

public void setTabindex(String `tabindex`)

Set the value of the `tabindex` property.

---

**public String getTitle()**

`title`

**getTitle**

public String getTitle()

Return the value of the `title` property.
public void setTitle(String title)

title

setTitle

public void setTitle(String title)

Set the value of the title property.

public Object saveState(FacesContext _context)

saveState

public Object saveState(FacesContext _context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

Object state = component.saveState(facesContext);
component should be the same as before executing it.

The return from this method must be Serializable

Specified by:
    saveState in interface StateHolder

Overrides:
    saveState in class UIInput

public void restoreState(FacesContext _context, Object _state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by:
    restoreState in interface StateHolder

Overrides:
    restoreState in class UIInput
Submit a bug or feature

PS:
public interface HTTPBinding

extends Binding

Implements: Binding

HTTPBinding XML/HTTP

since JAX-WS 2.0

The HTTPBinding interface is an abstraction for the XML/HTTP binding.

Since:

JAX-WS 2.0

Field Summary

<table>
<thead>
<tr>
<th>static String</th>
<th>HTTP_BINDING</th>
</tr>
</thead>
<tbody>
<tr>
<td>A constant representing the identity of the XML/HTTP binding.</td>
<td></td>
</tr>
</tbody>
</table>

Method Summary

Methods inherited from interface javax.xml.ws.Binding
getHandlerChain, setHandlerChain

Field Detail
HTTP_BINDING

static final String HTTP_BINDING

A constant representing the identity of the XML/HTTP binding.

See Also:
Constant Field Values
javax.xml.ws.http  Class HTTPException

java.lang.Object  
  | java.lang.Throwable  
  |   | java.lang.Exception  
  |   |   | java.lang.RuntimeException  
  |   |   | javax.xml.ws.WebServiceException  
  |   |   | javax.xml.ws.ProtocolException  
  |   |   | javax.xml.ws.http.HTTPException  

All Implemented Interfaces:
  Serializable

public class HTTPException
  extends ProtocolException

Extends: Throwable > Exception > RuntimeException > 
WebServiceException > ProtocolException

HTTPException  XML/HTTP

XML/HTTP  HTTP
  since  JAX-WS 2.0

The HTTPException exception represents a XML/HTTP fault.

Since there is no standard format for faults or exceptions in XML/HTTP messaging, only the HTTP status code is captured.

Since:  
  JAX-WS 2.0

See Also:  
  Serialized Form
Constructor Summary

**HttpException**

**(int statusCode)**

Constructor for the HTTPException

Method Summary

<table>
<thead>
<tr>

- wait

Constructor Detail

```java
public HTTPException(int statusCode)
```

**HttpException**

**Parameters:**

- **statusCode**: int for the HTTP status code
public int getStatusCode()
HTTP

    return
HTTP

getStatusCode

public int getStatusCode()

    Gets the HTTP status code.

    Returns:
    HTTP status code
javax.servlet.jsp Interface HttpJspPage

All Superinterfaces:

JspPage, Servlet

public interface HttpJspPage

extends JspPage

Implements: JspPage

HttpJspPage HTTP JSP

JspPage _jspService Java

See also javax.servlet.jsp.JspPage

The HttpJspPage interface describes the interaction that a JSP Page Implementation Class must satisfy when using the HTTP protocol.

The behaviour is identical to that of the JspPage, except for the signature of the _jspService method, which is now expressible in the Java type system and included explicitly in the interface.

See Also:

JspPage

Method Detail

public void _jspService(HttpServletRequest request, HttpServletResponse response) throws ServletException, java.io.IOException
_jspService()  JSP  JSP  JSP

_jjspService()  service()  JSP
JSP_Engine
    request  JSP
    response  JSP
    Throws  ServletException:  JSP
    Throws  java.io.IOException:

_jjspService

void _jspService(HttpServletRequest request,
        HttpServletResponse response)
    throws  ServletException,
            IOException

The _jspService() method corresponds to the body of the JSP page. This method is defined automatically by the JSP container and should never be defined by the JSP page author.

If a superclass is specified using the extends attribute, that superclass may choose to perform some actions in its service() method before or after calling the _jspService() method. See using the extends attribute in the JSP_Engine chapter of the JSP
specification.

**Parameters:**

- request - Provides client request information to the JSP.
- response - Assists the JSP in sending a response to the client.

**Throws:**

- `ServletException` - Thrown if an error occurred during the processing of the JSP and that the container should take appropriate action to clean up the request.
- `IOException` - Thrown if an error occurred while writing the response for this page.

public abstract class HttpServlet

extends GenericServlet
implements Serializable

**Extends:** GenericServlet
**Implements:** java.io.Serializable

Provides an abstract class to be subclassed to create an HTTP servlet suitable for a Web site. A subclass of HttpServlet must override at least one method, usually one of these:
- `doGet`, if the servlet supports HTTP GET requests
- `doPost`, for HTTP POST requests
- `doPut`, for HTTP PUT requests
- `doDelete`, for HTTP DELETE requests
- `init` and `destroy`, to manage resources that are held for the life of the servlet
- `getServletInfo`, which the servlet uses to provide information about itself

There's almost no reason to override the `service` method. `service` handles standard HTTP requests by dispatching them to the handler methods for each HTTP request type (the `doXXX` methods listed above).

Likewise, there's almost no reason to override the `doOptions` and `doTrace` methods.

Servlets typically run on multithreaded servers, so be aware that a servlet must handle concurrent requests and be careful to synchronize access to shared resources. Shared resources include in-memory data such as instance or class variables and external objects such as files, database connections, and network connections. See the [Java Tutorial on Multithreaded Programming](https://docs.oracle.com/javase/tutorial/essential/concurrency/) for more information on handling multiple threads in a Java program.

</tr>
</tbody>
</table>
A servlet to handle a DELETE request.

```java
protected void doGet(HttpServletRequest req, HttpServletResponse resp)
```
Called by the server (via the service method) to allow a servlet to handle a GET request.

```java
protected void doHead(HttpServletRequest req, HttpServletResponse resp)
```
Receives an HTTP HEAD request from the protected service method and handles the request.

```java
protected void doOptions(HttpServletRequest req, HttpServletResponse resp)
```
Called by the server (via the service method) to allow a servlet to handle a OPTIONS request.

```java
protected void doPost(HttpServletRequest req, HttpServletResponse resp)
```
Called by the server (via the service method) to allow a servlet to handle a POST request.

```java
protected void doPut(HttpServletRequest req, HttpServletResponse resp)
```
Called by the server (via the service method) to allow a servlet to handle a PUT request.

```java
protected void doTrace(HttpServletRequest req, HttpServletResponse resp)
```
Called by the server (via the service method) to allow a servlet to handle a TRACE request.

```java
protected long getLastModified(HttpServletRequest req)
```
Returns the time the HttpServletRequest object was last modified, in milliseconds since midnight January 1, 1970 GMT.

```java
protected void service(HttpServletRequest req, HttpServletResponse resp)
```
Receives standard HTTP requests from the public service method and dispatches them to the doXXX methods defined in this class.

```java
void service(ServletRequest req, ServletResponse res)
```
Dispatches client requests to the protected service method.

Constructor Detail

public HttpServlet()

HttpServlet

public HttpServlet()

  Does nothing, because this is an abstract class.

Method Detail

protected void doGet(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException

  service servlet GET

  GET HTTP HEAD HEAD GET

    PrintWriter PrintWriter

  servlet HTTP

  Content-Length

  javax.servlet.ServletResponse#setContentLength

  servlet

  HTTP 1.1 Transfer-Encoding Content-Length
GET HTTP

GET

doGet   HTTP "Bad Request"

req     servlet HttpServletRequest
resp    servlet HttpServletResponse

Throws  java.io.IOException: servlet  GET
Throws  ServletException: GET
See also  setContentType

doGet

protected void doGet(HttpServletRequest req,
                       HttpServletResponse resp)
              throws ServletException,
                        IOException

Called by the server (via the service method) to allow a servlet to handle a GET request.

Overriding this method to support a GET request also automatically supports an HTTP HEAD request. A HEAD request is a GET request that returns no body in the response, only the request header fields.

When overriding this method, read the request data, write the response headers, get the response's writer or output stream object, and finally, write the response data. It's best to include content type and encoding. When using a PrintWriter object to return the response, set the content type before accessing the PrintWriter object.

The servlet container must write the headers before committing the response, because in HTTP the headers must be sent before the response body.

Where possible, set the Content-Length header (with the
ServletResponse.setContentLength(int) method), to allow the servlet container to use a persistent connection to return its response to the client, improving performance. The content length is automatically set if the entire response fits inside the response buffer.

When using HTTP 1.1 chunked encoding (which means that the response has a Transfer-Encoding header), do not set the Content-Length header.

The GET method should be safe, that is, without any side effects for which users are held responsible. For example, most form queries have no side effects. If a client request is intended to change stored data, the request should use some other HTTP method.

The GET method should also be idempotent, meaning that it can be safely repeated. Sometimes making a method safe also makes it idempotent. For example, repeating queries is both safe and idempotent, but buying a product online or modifying data is neither safe nor idempotent.

If the request is incorrectly formatted, doGet returns an HTTP "Bad Request" message.

**Parameters:**

req - an HttpServletResponse object that contains the request the client has made of the servlet
resp - an HttpServletRequest object that contains the response the servlet sends to the client

**Throws:**

IOException - if an input or output error is detected when the servlet handles the GET request
ServletException - if the request for the GET could not be handled

**See Also:**

ServletResponse.setContentType(java.lang.String)

---

protected long getLastModified(HttpServletRequest req)
getLastModified

protected long getLastModified(HttpServletRequest req)

Returns the time the HttpServletRequest object was last modified, in milliseconds since midnight January 1, 1970 GMT. If the time is unknown, this method returns a negative number (the default).

Servlets that support HTTP GET requests and can quickly determine their last modification time should override this method. This makes browser and proxy caches work more effectively, reducing the load on server and network resources.

Parameters:
- req - the HttpServletRequest object that is sent to the servlet

Returns:
- a long integer specifying the time the HttpServletRequest object was last modified, in milliseconds since midnight, January 1, 1970 GMT, or -1 if the time is not known

protected void doHead(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException

service HTTP HEAD Content-Type
Content-Length HEAD HTTP HEAD
Content-Length
doHead  HTTP HEAD

HTTP HEAD  doHead  HTTP "Bad Request"

- req  servlet
- resp  servlet

Throws  java.io.IOException:

Throws  ServletException: HEAD

doHead

protected void doHead(HttpServletResponse req, HttpServletRequest resp)
throws ServletException, IOException

 Receives an HTTP HEAD request from the protected service method and handles the request. The client sends a HEAD request when it wants to see only the headers of a response, such as Content-Type or Content-Length. The HTTP HEAD method counts the output bytes in the response to set the Content-Length header accurately.

If you override this method, you can avoid computing the response body and just set the response headers directly to improve performance. Make sure that the doHead method you write is both safe and idempotent (that is, protects itself from being called multiple times for one HTTP HEAD request).

If the HTTP HEAD request is incorrectly formatted, doHead returns an HTTP "Bad Request" message.

Parameters:
- req - the request object that is passed to the servlet
- resp - the response object that the servlet uses to return the headers to the client

Throws:
- IOException - if an input or output error occurs
ServletException - if the request for the HEAD could not be handled

protected void doPost(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException

service servlet POST

Web

PrintWriter PrintWriter

servlet HTTP

Content-Length
javax.servlet.ServletResponse#setContentLength

servlet

HTTP 1.1 Transfer-Encoding Content-Length

POST

HTTP POST doPost HTTP "Bad Request"

req servlet HttpServletRequest
resp servlet HttpServletResponse

Throws java.io.IOException: servlet

Throws ServletException: POST

See also javax.servlet.ServletOutputStream, setContentLength

doPost

protected void doPost(HttpServletRequest req, HttpServletResponse resp)
throws ServletException, IOException

Called by the server (via the service method) to allow a servlet to handle a POST request. The HTTP POST method allows the client to send data of unlimited length to the Web server a single time and is useful when posting information such as credit card numbers.

When overriding this method, read the request data, write the response headers, get the response's writer or output stream object, and finally, write the response data. It's best to include content type and encoding. When using a PrintWriter object to return the response, set the content type before accessing the PrintWriter object.

The servlet container must write the headers before committing the response, because in HTTP the headers must be sent before the response body.

Where possible, set the Content-Length header (with the ServletResponse.setContentLength(int) method), to allow the servlet container to use a persistent connection to return its response to the client, improving performance. The content length is automatically set if the entire response fits inside the response buffer.

When using HTTP 1.1 chunked encoding (which means that the response has a Transfer-Encoding header), do not set the Content-Length header.

This method does not need to be either safe or idempotent. Operations requested through POST can have side effects for which the user can be held accountable, for example, updating stored data or buying items online.

If the HTTP POST request is incorrectly formatted, doPost returns an HTTP "Bad Request" message.

Parameters:

req - an HttpServletResponse object that contains the request the
client has made of the servlet
resp - an HttpServletResponse object that contains the response the servlet sends to the client

Throws:
IOException - if an input or output error is detected when the servlet handles the request
ServletException - if the request for the POST could not be handled

See Also:
ServletOutputStream,
ServletResponse.setContentType(java.lang.String)

protected void doGet(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException

service servlet PUT

Content-LengthContent-TypeContent-Transfer-EncodingContent-EncodingContent-BaseContent-LanguageContent-LocationContent-MD5  Content-Range (HTTP 501 - Not Implemented) HTTP 1.1 RFC 2616

doPut URL

HTTP PUT doGet HTTP "Bad Request"

req servlet HttpServletRequest
resp servlet HttpServletResponse

Throws java.io.IOException: servlet PUT
Throws ServletException: PUT

doPut
protected void doPost(HttpServletRequest req, HttpServletResponse resp) throws ServletException, IOException

Called by the server (via the service method) to allow a servlet to handle a PUT request. The PUT operation allows a client to place a file on the server and is similar to sending a file by FTP.

When overriding this method, leave intact any content headers sent with the request (including Content-Length, Content-Type, Content-Transfer-Encoding, Content-Encoding, Content-Base, Content-Language, Content-Location, Content-MD5, and Content-Range). If your method cannot handle a content header, it must issue an error message (HTTP 501 - Not Implemented) and discard the request. For more information on HTTP 1.1, see RFC 2616.

This method does not need to be either safe or idempotent. Operations that doPost performs can have side effects for which the user can be held accountable. When using this method, it may be useful to save a copy of the affected URL in temporary storage.

If the HTTP PUT request is incorrectly formatted, doPost returns an HTTP "Bad Request" message.

Parameters:
- req - the HttpServletRequest object that contains the request the client made of the servlet
- resp - the HttpServletResponse object that contains the response the servlet returns to the client

Throws:
- IOException - if an input or output error occurs while the servlet is handling the PUT request
- ServletException - if the request for the PUT cannot be handled

protected void doDelete(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException
HTTP DELETE  
doDelete  HTTP "Bad Request"

protected void doDelete(HttpServletRequest req, HttpServletResponse resp) throws ServletException, IOException

Called by the server (via the service method) to allow a servlet to handle a DELETE request. The DELETE operation allows a client to remove a document or Web page from the server.

This method does not need to be either safe or idempotent. Operations requested through DELETE can have side effects for which users can be held accountable. When using this method, it may be useful to save a copy of the affected URL in temporary storage.

If the HTTP DELETE request is incorrectly formatted, doDelete returns an HTTP "Bad Request" message.

Parameters:
- req - the HttpServletRequest object that contains the request the client made of the servlet
- resp - the HttpServletResponse object that contains the
response the servlet returns to the client

**Throws:**
- `IOException` - if an input or output error occurs while the servlet is handling the DELETE request
- `ServletException` - if the request for the DELETE cannot be handled

```java
protected void doOptions(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException {
    service servlet OPTIONS
    doGet
    Allow: GET, HEAD, TRACE, OPTIONS
}
```

**doOptions**

```java
protected void doOptions(HttpServletRequest req, HttpServletResponse resp) throws ServletException, IOException {
    bodyParser
    doPost
    Allow: GET, HEAD, TRACE, OPTIONS
}
```
There's no need to override this method unless the servlet implements new HTTP methods, beyond those implemented by HTTP 1.1.

**Parameters:**
- `req` - the `HttpServletRequest` object that contains the request the client made of the servlet
- `resp` - the `HttpServletResponse` object that contains the response the servlet returns to the client

**Throws:**
- `IOException` - if an input or output error occurs while the servlet is handling the OPTIONS request
- `ServletException` - if the request for the OPTIONS cannot be handled

---

```java
protected void doTrace(HttpServletRequest req, HttpServletResponse resp) throws ServletException, IOException {
    // Called by the server (via the service method) to allow a servlet to handle a TRACE request. A TRACE returns the headers sent with the TRACE request to the client, so that they can be used in debugging. There's no need to override this method.
}
```
Parameters:

req - the HttpServletRequest object that contains the request the client made of the servlet
resp - the HttpServletResponse object that contains the response the servlet returns to the client

Throws:

IOException - if an input or output error occurs while the servlet is handling the TRACE request
ServletException - if the request for the TRACE cannot be handled

protected void service(HttpServletRequest req, HttpServletResponse resp) throws ServletException, java.io.IOException
public service HTTP doXXX
javax.servlet.Servlet#service HTTP

req servlet HttpServletRequest
resp servlet HttpServletResponse

Throws java.io.IOException: HTTP
Throws ServletException: HTTP
See also

service

protected void service(HttpServletRequest req, HttpServletResponse resp)
throws ServletException, IOException

 Receives standard HTTP requests from the public service method and dispatches them to the doXXX methods defined in this class. This method is an HTTP-specific version of the Servlet.service(javax.servlet.ServletRequest, javax.servlet.ServletResponse) method. There's no need to override this method.
public void service(ServletRequest req, ServletResponse res) throws ServletException, IOException

service

Dispenses client requests to the protected service method. There's no need to override this method.

Specified by: service in interface Servlet
Specified by: service in class GenericServlet
Parameters:
req - the HttpServletRequest object that contains the request the client made of the servlet
res - the HttpServletResponse object that contains the response the servlet returns to the client

Throws:
IOException - if an input or output error occurs while the servlet is handling the HTTP request
ServletException - if the HTTP request cannot be handled

See Also:
Servlet.service(javax.servlet.ServletRequest, javax.servlet.ServletResponse)
Interface HttpServletRequest

All Superinterfaces:

- ServletRequest

All Known Implementing Classes:

- HttpServletRequestWrapper

```java
public interface HttpServletRequest extendsServletRequest

Implements: ServletRequest
Implemented by: HttpServletRequestWrapper
```

Extends the ServletRequest interface to provide request information for HTTP servlets.

The servlet container creates an HttpServletRequest object and passes it as an argument to the servlet's service methods (doGet, doPost, etc).

### Field Summary

<table>
<thead>
<tr>
<th>static String</th>
<th>BASIC_AUTH</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>String identifier for Basic authentication.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>static String</th>
<th>CLIENT_CERT_AUTH</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
String identifier for Client Certificate authentication.

static String DIGEST_AUTH
  String identifier for Digest authentication.

static String FORM_AUTH
  String identifier for Form authentication.

## Method Summary

**getAuthType()**

Returns the name of the authentication scheme used to protect the servlet.

**getContextPath()**

Returns the portion of the request URI that indicates the context of the request.

**getCookies()**

Returns an array containing all of the Cookie objects the client sent with this request.

**getDateHeader(String name)**

Returns the value of the specified request header as a long value that represents a Date object.

**getHeader(String name)**

Returns the value of the specified request header as a String.

**getHeaderNames()**

Returns an enumeration of all the header names this request contains.

**getHeaders(String name)**

Returns all the values of the specified request header as an Enumeration of String objects.

**getIntHeader(String name)**

Returns the value of the specified request header as an int.

**getMethod()**

Returns the name of the HTTP method with which this request was made, for example, GET, POST, or PUT.
<table>

Field Detail

BASIC_AUTH

static final String BASIC_AUTH

String identifier for Basic authentication. Value "BASIC"

See Also:
Constant Field Values

FORM_AUTH

static final String FORM_AUTH

String identifier for Form authentication. Value "FORM"

See Also:
Constant Field Values

CLIENT_CERT_AUTH

static final String CLIENT_CERT_AUTH

String identifier for Client Certificate authentication. Value "CLIENT_CERT"

See Also:
Constant Field Values

DIGEST_AUTH

static final String DIGEST_AUTH

String identifier for Digest authentication. Value "DIGEST"

See Also:
Constant Field Values
public String getAuthType()

    servlet servlet basicform client certificate
digest servlet

    CGI AUTH_TYPE
    return BASIC_AUTHFORM_AUTHCLIENT_CERT_AUTH
    DIGEST_AUTH ==

getAuthType

String getAuthType()

    Returns the name of the authentication scheme used to protect the
servlet. All servlet containers support basic, form and client
certificate authentication, and may additionally support digest
authentication. If the servlet is not authenticated null is returned.

    Same as the value of the CGI variable AUTH_TYPE.

    Returns:
    one of the static members BASIC_AUTH, FORM_AUTH,
CLIENT_CERT_AUTH, DIGEST_AUTH (suitable for ==
comparison) or the container-specific string indicating the
authentication scheme, or null if the request was not
authenticated.

public Cookie[] getCookies()

    Cookie cookie

    return null
getCookies

Cookie[] getCookies()

Returns an array containing all of the Cookie objects the client sent with this request. This method returns null if no cookies were sent.

Returns:
an array of all the Cookies included with this request, or null if the request has no cookies

public long getDateHeader(String name)

Date  long  If-Modified-Since

1970 1 1

-1 IllegalArgumentException

name String
return long 1970 1 1 -1

Throws IllegalArgumentException:

getDateHeader

long getDateHeader(String name)

Returns the value of the specified request header as a long value that represents a Date object. Use this method with headers that contain dates, such as If-Modified-Since.

The date is returned as the number of milliseconds since January 1, 1970 GMT. The header name is case insensitive.

If the request did not have a header of the specified name, this method returns -1. If the header can't be converted to a date, the method throws an IllegalArgumentException.
Parameters:
   name - a String specifying the name of the header

Returns:
   a long value representing the date specified in the header expressed as the number of milliseconds since January 1, 1970 GMT, or -1 if the named header was not included with the request

Throws:
   IllegalArgumentException - If the header value can't be converted to a date

public String getHeader(String name)

Parameters:
   name - a String specifying the header name

Returns:
   a String containing the value of the requested header, or null if the request does not have a header of that name

getHeader

Returns the value of the specified request header as a String. If the request did not include a header of the specified name, this method returns null. If there are multiple headers with the same name, this method returns the first head in the request. The header name is case insensitive. You can use this method with any request header.

public java.utilEnumeration\<E\> getHeaders(String name)
Accept-Language

Enumeration

name String
return Enumeration null

getHeaders

Enumeration getHeaders(String name)

Returns all the values of the specified request header as an Enumeration of String objects.

Some headers, such as Accept-Language can be sent by clients as several headers each with a different value rather than sending the header as a comma separated list.

If the request did not include any headers of the specified name, this method returns an empty Enumeration. The header name is case insensitive. You can use this method with any request header.

Parameters:
name - a String specifying the header name

Returns:
an Enumeration containing the values of the requested header. If the request does not have any headers of that name return an empty enumeration. If the container does not allow access to header information, return null

public java.util Enumeration<E> getHeaderNames()

servlet servlet null
return servlet servlet
getHeaderNames

`Enumeration getHeaderNames()`

Returns an enumeration of all the header names this request contains. If the request has no headers, this method returns an empty enumeration.

Some servlet containers do not allow servlets to access headers using this method, in which case this method returns `null`.

**Returns:**

an enumeration of all the header names sent with this request; if the request has no headers, an empty enumeration; if the servlet container does not allow servlets to use this method, `null`

---

`public int getIntHeader(String name)`

```
int -1
NumberFormatException
```

```
name String
return -1
Throws NumberFormatException: int
```

getIntHeader

`int getIntHeader(String name)`

Returns the value of the specified request header as an `int`. If the request does not have a header of the specified name, this method returns `-1`. If the header cannot be converted to an integer, this method throws a `NumberFormatException`.
The header name is case insensitive.

Parameters:
- name - a String specifying the name of a request header

Returns:
- an integer expressing the value of the request header or -1 if the request doesn't have a header of this name

Throws:
- NumberFormatException - If the header value can't be converted to an int

---

```java
public String getMethod()

HTTP GET POST PUT CGI
REQUEST_METHOD

return String
```

getMethod

```java
String getMethod()

Returns the name of the HTTP method with which this request was made, for example, GET, POST, or PUT. Same as the value of the CGI variable REQUEST_METHOD.

Returns:
- a String specifying the name of the method with which this request was made
```

---

```java
public String getPathInfo()

URL servlet "/"

null

CGI PATH_INFO

return
```
**getPathInfo**

```java
String getPathInfo()
```

Returns any extra path information associated with the URL the client sent when it made this request. The extra path information follows the servlet path but precedes the query string and will start with a "/" character.

This method returns `null` if there was no extra path information.

Same as the value of the CGI variable PATH_INFO.

**Returns:**
- a `String`, decoded by the web container, specifying extra path information that comes after the servlet path but before the query string in the request URL; or `null` if the URL does not have any extra path information.

---

**public String getPathTranslated()**

```java
servlet CGI PATH_TRANSLATED
```

**getPathTranslated**

```java
String getPathTranslated()
```

Returns any extra path information after the servlet name but before the query string, and translates it to a real path. Same as the value
of the CGI variable PATH_TRANSLATED.

If the URL does not have any extra path information, this method returns null or the servlet container cannot translate the virtual path to a real path for any reason (such as when the web application is executed from an archive). The web container does not decode this string.

Returns:
- a String specifying the real path, or null if the URL does not have any extra path information

```java
public String getContextPath()
```

URI URI "/" "/" servlet

```java
return URI String
```

See also `getContextPath()`

`getContextPath()`

```java
String getContextPath()
```

Returns the portion of the request URI that indicates the context of the request. The context path always comes first in a request URI. The path starts with a "/" character but does not end with a "/" character. For servlets in the default (root) context, this method returns "/". The container does not decode this string.

It is possible that a servlet container may match a context by more than one context path. In such cases this method will return the actual context path used by the request and it may differ from the path returned by the `ServletContext.getContextPath()` method. The
context path returned by `ServletContext.getContextPath()` should be considered as the prime or preferred context path of the application.

**Returns:**
a String specifying the portion of the request URI that indicates the context of the request

**See Also:**
`ServletContext.getContextPath()`

```
public String getQueryString()
URL URL

    return String URL null

getQueryString

String getQueryString()

Returns the query string that is contained in the request URL after the path. This method returns null if the URL does not have a query string. Same as the value of the CGI variable QUERY_STRING.

**Returns:**
a String containing the query string or null if the URL contains no query string. The value is not decoded by the container.

```

```
public String getRemoteUser()

    return String null

getRemoteUser

String getRemoteUser()
```
Returns the login of the user making this request, if the user has been authenticated, or null if the user has not been authenticated. Whether the user name is sent with each subsequent request depends on the browser and type of authentication. Same as the value of the CGI variable REMOTE_USER.

**Returns:**

- a String specifying the login of the user making this request, or null if the user login is not known

---

```java
public boolean isUserInRole(String role)
```

**Parameters:**

- role - a String specifying the name of the role

**Returns:**

- a boolean indicating whether the authenticated user is included in the specified logical "role". Roles and role membership can be defined using deployment descriptors. If the user has not been authenticated, the method returns false.

---

```java
public java.security.Principal getUserPrincipal()
```

**Returns:**

- java.security.Principal
**getUserPrincipal**

```java
Principal getUserPrincipal()
```

Returns a `java.security.Principal` object containing the name of the current authenticated user. If the user has not been authenticated, the method returns `null`.

**Returns:**

- a `java.security.Principal` containing the name of the user making this request; `null` if the user has not been authenticated

---

**public String getRequestedSessionId()**

```java
String getRequestedSessionId()
```

Returns the session ID specified by the client. This may not be the same as the ID of the current valid session for this request. If the client did not specify a session ID, this method returns `null`.

**Returns:**

- a `String` specifying the session ID, or `null` if the request did not specify a session ID

**See Also:**

- `isRequestedSessionIdValid()`

---

**public String getRequestURI()**

```java
URL getRequestURI()
```

**POST /some/path.html HTTP/1.1 /some/path.html**
GET http://foo.bar/a.html HTTP/1.0 /a.html
HEAD /xyz?a=b HTTP/1.1 /xyz

**URL**

```java
HttpUtils#getRequestURL
```

- `return` `URL`
- `String`

**See also**

`getRequestURL`

---

**getRequestURI**

```java
String getRequestURI()
```

Returns the part of this request's URL from the protocol name up to the query string in the first line of the HTTP request. The web container does not decode this String. For example:

<table>
<thead>
<tr>
<th>First line of HTTP request</th>
<th>Returned Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>POST /some/path.html HTTP/1.1</td>
<td>/some/path.html</td>
</tr>
<tr>
<td>GET <a href="http://foo.bar/a.html">http://foo.bar/a.html</a> HTTP/1.0</td>
<td>/a.html</td>
</tr>
<tr>
<td>HEAD /xyz?a=b HTTP/1.1</td>
<td>/xyz</td>
</tr>
</tbody>
</table>

To reconstruct an URL with a scheme and host, use `HttpUtils.getRequestURL(javax.servlet.http.HttpServletRequest)`.

**Returns:**

- a `String` containing the part of the URL from the protocol name up to the query string

**See Also:**

`HttpUtils.getRequestURL(javax.servlet.http.HttpServletRequest)`

---

**public StringBuffer getRequestURL()**

```java
URL URL
```

```java
javas.servlet.RequestDispatcher#forward URL
```
getRequestURL

StringBuffer getRequestURL()

Reconstructs the URL the client used to make the request. The returned URL contains a protocol, server name, port number, and server path, but it does not include query string parameters.

If this request has been forwarded using RequestDispatcher.forward(javax.servlet.ServletRequest, javax.servlet.ServletResponse), the server path in the reconstructed URL must reflect the path used to obtain the RequestDispatcher, and not the server path specified by the client.

Because this method returns a StringBuffer, not a string, you can modify the URL easily, for example, to append query parameters.

This method is useful for creating redirect messages and for reporting errors.

Returns:

- a StringBuffer object containing the reconstructed URL
returns  

servlet  

String URL  servlet  "/*"  

getServletPath

String getServletPath()

Returns the part of this request's URL that calls the servlet. This path starts with a "/" character and includes either the servlet name or a path to the servlet, but does not include any extra path information or a query string. Same as the value of the CGI variable SCRIPT_NAME.

This method will return an empty string ("") if the servlet used to process this request was matched using the "/*" pattern.

Returns:

a String containing the name or path of the servlet being called, as specified in the request URL, decoded, or an empty string if the servlet used to process the request is matched using the "/*" pattern.

public HttpSession getSession(boolean create)

HttpSession create true

create false HttpSession null

cookie IllegalStateException

create true false null

return HttpSession create false null

See also HttpSession

getSession

getSession
HttpSession getSession(boolean create)

Returns the current HttpSession associated with this request or, if there is no current session and create is true, returns a new session.

If create is false and the request has no valid HttpSession, this method returns null.

To make sure the session is properly maintained, you must call this method before the response is committed. If the container is using cookies to maintain session integrity and is asked to create a new session when the response is committed, an IllegalStateException is thrown.

Parameters:
create - true to create a new session for this request if necessary; false to return null if there's no current session

Returns:
the HttpSession associated with this request or null if create is false and the request has no valid session

See Also:
getSession()
public boolean isRequestedSessionIdValid() 

ID

false
return id
See also 
getRequestedSessionId, getSession, javax.servlet.http.HttpSessionContext

isRequestedSessionIdValid

boolean isRequestedSessionIdValid() 

Checks whether the requested session ID is still valid. 

If the client did not specify any session ID, this method returns false.

Returns: 
true if this request has an id for a valid session in the current session context; false otherwise
See Also: 
getRequestedSessionId(), getSession(boolean), HttpSessionContext

public boolean isRequestedSessionIdFromCookie() 

ID  cookie
return ID cookie
See also 
getSession

isRequestedSessionIdFromCookie
boolean isRequestedSessionIdFromCookie()

Checks whether the requested session ID came in as a cookie.

**Returns:**
true if the session ID came in as a cookie; otherwise, false

**See Also:**
getSession(boolean)

---

public boolean isRequestedSessionIdFromURL()

**ID** URL

return ID URL true false

See also getSession

---

isRequestedSessionIdFromURL

boolean isRequestedSessionIdFromURL()

Checks whether the requested session ID came in as part of the request URL.

**Returns:**
true if the session ID came in as part of a URL; otherwise, false

**See Also:**
getSession(boolean)

---

public boolean isRequestedSessionIdFromUrl()

**deprecated**

Java Servlet API 2.1

#isRequestedSessionIdFromURL

---

isRequestedSessionIdFromUrl

boolean isRequestedSessionIdFromUrl()

**Deprecated.** As of Version 2.1 of the Java Servlet API, use
isRequestedSessionIdFromURL() instead.
javax.servlet.http

Class HttpServletRequestWrapper

java.lang.Object
  ↓ javax.servlet.ServletRequestWrapper
     ↓ javax.servlet.http.HttpServletRequestWrapper

All Implemented Interfaces:
HttpServletRequest, ServletRequest

public class HttpServletRequestWrapper

extends ServletRequestWrapper
implements HttpServletRequest

Extends: ServletRequestWrapper
Implements: HttpServletRequest

HttpServletRequest Servlet Wrapper Decorator

since v 2.3
See also javax.servlet.http.HttpServletRequest

Provides a convenient implementation of the HttpServletRequest interface that can be subclassed by developers wishing to adapt the request to a Servlet. This class implements the Wrapper or Decorator pattern. Methods default to calling through to the wrapped request object.

Since: v 2.3
See Also: HttpServletRequest
Fields inherited from interface javax.servlet.http.HttpServletRequest

BASIC_AUTH, CLIENT_CERT_AUTH, DIGEST_AUTH, FORM_AUTH

Constructor Summary

HttpServletRequestWrapper(HttpServletRequest request)
Constructs a request object wrapping the given request.

Methods inherited from class `javax.servlet.ServletRequestWrapper`:

- `getAttribute`, `getAttributeNames`, `getCharacterEncoding`, `getContentType`, `getInputStream`, `getLocalAddr`, `getLocale`, `getLocales`, `getLocalName`, `getLocalPort`, `getParameter`, `getParameterMap`, `getParameterNames`, `getParameterValues`, `getProtocol`, `getReader`, `getRealPath`, `getRemoteAddr`, `getRemoteHost`, `getRemotePort`, `getRequestDispatcher`, `getScheme`, `getServerName`, `getServerPort`, `isSecure`, `removeAttribute`, `setAttribute`, `setCharacterEncoding`, `setRequest`.

Methods inherited from class `java.lang.Object`:

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`.

Methods inherited from interface `javax.servlet.ServletRequest`:

- `getAttribute`, `getAttributeNames`, `getCharacterEncoding`, `getContentType`, `getInputStream`, `getLocalAddr`, `getLocale`, `getLocales`, `getLocalName`, `getLocalPort`, `getParameter`, `getParameterMap`, `getParameterNames`, `getParameterValues`, `getProtocol`, `getReader`, `getRealPath`, `getRemoteAddr`, `getRemoteHost`. 
Constructor Detail

public HttpServletRequestWrapper(HttpServletRequest request)

Throws IllegalArgumentException: request null

HttpServletRequestWrapper

public HttpServletRequestWrapper(HttpServletRequest request)

Constructs a request object wrapping the given request.

Throws:
IllegalArgumentException - if the request is null

Method Detail

public String getAuthType()
getAuthType()

getAuthType

public String getAuthType()

The default behavior of this method is to return getAuthType() on the wrapped request object.

Specified by:
getAuthType in interface HttpServletRequest

Returns:
one of the static members BASIC_AUTH, FORM_AUTH, CLIENT_CERT_AUTH, DIGEST_AUTH (suitable for == comparison) or the container-specific string indicating the authentication scheme, or null if the request was not authenticated.

gpublic Cookie[] get Cookies()
ggetCookies()

gCookies

gpublic Cookie[] get Cookies()

getCookies

The default behavior of this method is to return getCookies() on the wrapped request object.

Specified by:
    getCookies in interface HttpServletRequest

Returns:
an array of all the Cookies included with this request, or null if the request has no cookies

gpublic long getDateHeader(String name)
ggetDateHeader(String name)

getDateHeader

public long getDateHeader(String name)

getDateHeader

The default behavior of this method is to return getDateHeader(String name) on the wrapped request object.
Specified by: 
**getDateTimeHeader** in interface [HttpServletRequest](https://docs.oracle.com/en/java/javase/11/docs/api/index.html)

Parameters: 
- **name** - a **String** specifying the name of the header

Returns: 
a long value representing the date specified in the header expressed as the number of milliseconds since January 1, 1970 GMT, or -1 if the named header was not included with the request.

---

**public String** **getHeader** (String name)

**getHeader(String name)**

**getHeader**

**public String** **getHeader**(String name)

The default behavior of this method is to return **getHeader(String name)** on the wrapped request object.

Specified by: 
**getHeader** in interface [HttpServletRequest](https://docs.oracle.com/en/java/javase/11/docs/api/index.html)

Parameters: 
- **name** - a **String** specifying the header name

Returns: 
a String containing the value of the requested header, or **null** if the request does not have a header of that name.

---

**public java.util.Enumeration<E>** **getHeaders** (String name)

**getHeaders(String name)**

**getHeaders**

**public Enumeration** **getHeaders**(String name)

---
The default behavior of this method is to return getHeaders(String name) on the wrapped request object.

**Specified by:**
getHeaders in interface HttpServletRequest

**Parameters:**
name - a String specifying the header name

**Returns:**
an Enumeration containing the values of the requested header. If the request does not have any headers of that name return an empty enumeration. If the container does not allow access to header information, return null

```java
public java.util.Enumeration<E> getHeaderNames()

getHeaderNames()
```

**getHeaderNames**

```java
public Enumeration getHeaderNames()

 The default behavior of this method is to return getHeaderNames() on the wrapped request object.

**Specified by:**
getHeaderNames in interface HttpServletRequest

**Returns:**
an enumeration of all the header names sent with this request; if the request has no headers, an empty enumeration; if the servlet container does not allow servlets to use this method, null

```java
public int getIntHeader(String name)

getIntHeader(String name)
```
**getIntHeader**

```java
class HttpRequest {
    public int getIntHeader(String name) {
        // Implementation...
    }
}
```

The default behavior of this method is to return `getIntHeader(String name)` on the wrapped request object.

**Specified by:**
`getIntHeader` in interface `HttpServletRequest`

**Parameters:**
- `name` - a String specifying the name of a request header

**Returns:**
- an integer expressing the value of the request header or -1 if the request doesn't have a header of this name

---

**public String getMethod()**

```java
class HttpRequest {
    public String getMethod() {
        // Implementation...
    }
}
```

The default behavior of this method is to return `getMethod()` on the wrapped request object.

**Specified by:**
`getMethod` in interface `HttpServletRequest`

**Returns:**
- a String specifying the name of the method with which this request was made

---

**public String getPathInfo()**

```java
class HttpRequest {
    public String getPathInfo() {
        // Implementation...
    }
}
```
**getPathInfo**

public String getPathInfo()

The default behavior of this method is to return getPathInfo() on the wrapped request object.

**Specified by:**
getPathInfo in interface HttpServletRequest

**Returns:**
a String, decoded by the web container, specifying extra path information that comes after the servlet path but before the query string in the request URL; or null if the URL does not have any extra path information

---

**public String getPathTranslated()**

**getPathTranslated()**

**getPathTranslated**

public String getPathTranslated()

The default behavior of this method is to return getPathTranslated() on the wrapped request object.

**Specified by:**
getPathTranslated in interface HttpServletRequest

**Returns:**
a String specifying the real path, or null if the URL does not have any extra path information

---

**public String getContextPath()**

**getContextPath()**
**getContextPath**

public String getContextPath()

The default behavior of this method is to return getContextPath() on the wrapped request object.

**Specified by:**
getContextPath in interface HttpServletRequest

**Returns:**
a String specifying the portion of the request URI that indicates the context of the request

**See Also:**
ServletContext.getContextPath()

---

**public String getQueryString()**

getQueryString()

---

**getQueryString**

public String getQueryString()

The default behavior of this method is to return getQueryString() on the wrapped request object.

**Specified by:**
getQueryString in interface HttpServletRequest

**Returns:**
a String containing the query string or null if the URL contains no query string. The value is not decoded by the container.

---

**public String getRemoteUser()**

getRemoteUser()
getRemoteUser

public String getRemoteUser()

    The default behavior of this method is to return getRemoteUser() on the wrapped request object.

    Specified by:
        getRemoteUser in interface HttpServletRequest

    Returns:
        a String specifying the login of the user making this request, or null if the user login is not known

____________________________

g瓤lic boolean isUserInRole(String role)

    The default behavior of this method is to return isUserInRole(String role) on the wrapped request object.

    Specified by:
        isUserInRole in interface HttpServletRequest

    Parameters:
        role - a String specifying the name of the role

    Returns:
        a boolean indicating whether the user making this request belongs to a given role; false if the user has not been authenticated

____________________________

public java.security.Principal getUserPrincipal()

    getUserPrincipal()
**getUserPrincipal**

```java
gpublic Principal getUserPrincipal()
```

The default behavior of this method is to return `getUserPrincipal()` on the wrapped request object.

**Specified by:**
`getUserPrincipal` in interface `HttpServletRequest`

**Returns:**
a `java.security.Principal` containing the name of the user making this request; `null` if the user has not been authenticated

---

**public String getRequestedSessionId()**

```
gpublic String getRequestedSessionId()
```

**getRequestedSessionId**

```java
gpublic String getRequestedSessionId()
```

The default behavior of this method is to return `getRequestedSessionId()` on the wrapped request object.

**Specified by:**
`getRequestedSessionId` in interface `HttpServletRequest`

**Returns:**
a `String` specifying the session ID, or `null` if the request did not specify a session ID

**See Also:**
`HttpServletRequest.isRequestedSessionIdValid()`

---

**public String getRequestURI()**

```
gpublic String getRequestURI()
```

**getRequestURI**

```java
gpublic String getRequestURI()
```

---
getRequestURI

public String getRequestURI()

The default behavior of this method is to return getRequestURI() on the wrapped request object.

Specified by: 
    getRequestURI in interface HttpServletRequest

Returns: 
a String containing the part of the URL from the protocol name up to the query string

See Also: 
    HttpUtils.getRequestURL(javax.servlet.http.HttpServletRequest)

getRequestURL

public StringBuffer getRequestURL()

The default behavior of this method is to return getRequestURL() on the wrapped request object.

Specified by: 
    getRequestURL in interface HttpServletRequest

Returns: 
a StringBuffer object containing the reconstructed URL

getServletPath

public String getServletPath()

getServletPath
public String getServletPath()

    The default behavior of this method is to return getServletPath() on the wrapped request object.

    Specified by:
    getServletPath in interface HttpServletRequest

    Returns:
    a String containing the name or path of the servlet being called, as specified in the request URL, decoded, or an empty string if the servlet used to process the request is matched using the "/\*" pattern.

public HttpSession getSession(boolean create)
getSession(boolean create)

getSession

public HttpSession getSession(boolean create)

    The default behavior of this method is to return getSession(boolean create) on the wrapped request object.

    Specified by:
    getSession in interface HttpServletRequest

    Parameters:
    create - true to create a new session for this request if necessary; false to return null if there's no current session

    Returns:
    the HttpSession associated with this request or null if create is false and the request has no valid session

    See Also:
    HttpServletRequest.getSession()
getSession

public HttpSession getSession()

The default behavior of this method is to return getSession() on the wrapped request object.

Specified by:
    getSession in interface HttpServletRequest

Returns:
    the HttpSession associated with this request

See Also:
    HttpServletRequest.getSession(boolean)

isRequestedSessionIdValid

public boolean isRequestedSessionIdValid()

isRequestedSessionIdValid

public boolean isRequestedSessionIdValid()

The default behavior of this method is to return isRequestedSessionIdValid() on the wrapped request object.

Specified by:
    isRequestedSessionIdValid in interface HttpServletRequest

Returns:
    true if this request has an id for a valid session in the current session context; false otherwise

See Also:
    HttpServletRequest.getRequestedSessionId(), HttpServletRequest.getSession(boolean), HttpSessionContext

public boolean isRequestedSessionIdFromCookie()
isRequestedSessionIdFromCookie

isRequestedSessionIdFromCookie

public boolean isRequestedSessionIdFromCookie()

The default behavior of this method is to return
isRequestedSessionIdFromCookie() on the wrapped request object.

Specified by:
    isRequestedSessionIdFromCookie in interface HttpServletRequest
Returns:
    true if the session ID came in as a cookie; otherwise, false
See Also:
    HttpServletRequest.getSession(boolean)

isRequestedSessionIdFromURL

isRequestedSessionIdFromURL

public boolean isRequestedSessionIdFromURL()

The default behavior of this method is to return
isRequestedSessionIdFromURL() on the wrapped request object.

Specified by:
    isRequestedSessionIdFromURL in interface HttpServletRequest
Returns:
    true if the session ID came in as part of a URL; otherwise, false
See Also:
    HttpServletRequest.getSession(boolean)

isRequestedSessionIdFromUrl

isRequestedSessionIdFromUrl

public boolean isRequestedSessionIdFromUrl()
public boolean isRequestedSessionIdFromUrl()

The default behavior of this method is to return
isRequestedSessionIdFromUrl() on the wrapped request object.

Specified by:
   isRequestedSessionIdFromUrl in interface HttpServletRequest

javax.servlet.http  Interface HttpServletResponse

All Superinterfaces:  
   ServletException

All Known Implementing Classes:  
   HttpServletResponseWrapper

public interface HttpServletResponse  
extends ServletException

Implements: ServletException  
Implemented by: HttpServletResponseWrapper

   ServletException  HTTP  HTTP  cookie

servlet  HttpServletResponse  servlet  service  doGet doPost

See also  
  javax.servlet.ServletResponse

Extends the ServletException interface to provide HTTP-specific functionality in sending a response. For example, it has methods to access HTTP headers and cookies.

The servlet container creates an HttpServletResponse object and passes it as an argument to the servlet's service methods (doGet, doPost, etc).

</table>
void setDateHeader(String name, long date)
Sets a response header with the given name and date-value.

void setHeader(String name, String value)
Sets a response header with the given name and value.

void setIntHeader(String name, int value)
Sets a response header with the given name and integer value.

void setStatus(int sc)
Sets the status code for this response.

void setStatus(int sc, String sm)
Deprecated. As of version 2.1, due to ambiguous meaning of the message parameter. To set a status code use setStatus(int), to send an error with a description use sendError(int, String). Sets the status code and message for this response.

Methods inherited from interface javax.servlet.ServletResponse
flushBuffer, getBufferSize, getCharacterEncoding, getContentType, getLocale, getOutputStream, getWriter, isCommitted, reset, resetBuffer, setBufferSize, setCharacterEncoding, setContentLength, setContentType, setLocale

Field Detail

SC_CONTINUE

static final int SC_CONTINUE
Status code (100) indicating the client can continue.

See Also:
Constant Field Values
SC_SWITCHING_PROTOCOLS

static final int SC_SWITCHING_PROTOCOLS

    Status code (101) indicating the server is switching protocols according to Upgrade header.

    See Also:
    Constant Field Values

SC_OK

static final int SC_OK

    Status code (200) indicating the request succeeded normally.

    See Also:
    Constant Field Values

SC_CREATED

static final int SC_CREATED

    Status code (201) indicating the request succeeded and created a new resource on the server.

    See Also:
    Constant Field Values
SC_ACCEPTED

static final int SC_ACCEPTED

Status code (202) indicating that a request was accepted for processing, but was not completed.

See Also:
   Constant Field Values

---

SC_NON_AUTHORITATIVE_INFORMATION

static final int SC_NON_AUTHORITATIVE_INFORMATION

Status code (203) indicating that the meta information presented by the client did not originate from the server.

See Also:
   Constant Field Values

---

SC_NO_CONTENT

static final int SC_NO_CONTENT

Status code (204) indicating that the request succeeded but that there was no new information to return.

See Also:
   Constant Field Values

---

SC_RESET_CONTENT
static final int SC_RESET_CONTENT

Status code (205) indicating that the agent SHOULD reset the document view which caused the request to be sent.

See Also:
Constant Field Values

---

SC_PARTIAL_CONTENT

static final int SC_PARTIAL_CONTENT

Status code (206) indicating that the server has fulfilled the partial GET request for the resource.

See Also:
Constant Field Values

---

SC_MULTIPLE_CHOICES

static final int SC_MULTIPLE_CHOICES

Status code (300) indicating that the requested resource corresponds to any one of a set of representations, each with its own specific location.

See Also:
Constant Field Values

---

SC_MOVED_PERMANENTLY
static final int SC_MOVED_PERMANENTLY

Status code (301) indicating that the resource has permanently moved to a new location, and that future references should use a new URI with their requests.

See Also:
Constant Field Values

---

SC_MOVED_TEMPORARILY

static final int SC_MOVED_TEMPORARILY

Status code (302) indicating that the resource has temporarily moved to another location, but that future references should still use the original URI to access the resource. This definition is being retained for backwards compatibility. SC_FOUND is now the preferred definition.

See Also:
Constant Field Values

---

SC_FOUND

static final int SC_FOUND

Status code (302) indicating that the resource reside temporarily under a different URI. Since the redirection might be altered on occasion, the client should continue to use the Request-URI for future requests. (HTTP/1.1) To represent the status code (302), it is recommended to use this variable.

See Also:
Constant Field Values
SC_SEE_OTHER

**static final int SC_SEE_OTHER**

Status code (303) indicating that the response to the request can be found under a different URI.

**See Also:**
- [Constant Field Values](#)

SC_NOT_MODIFIED

**static final int SC_NOT_MODIFIED**

Status code (304) indicating that a conditional GET operation found that the resource was available and not modified.

**See Also:**
- [Constant Field Values](#)

SC_USE_PROXY

**static final int SC_USE_PROXY**

Status code (305) indicating that the requested resource *MUST* be accessed through the proxy given by the *Location* field.

**See Also:**
- [Constant Field Values](#)
SC_TEMPORARY_REDIRECT

static final int SC_TEMPORARY_REDIRECT

Status code (307) indicating that the requested resource resides temporarily under a different URI. The temporary URI SHOULD be given by the Location field in the response.

See Also:
Constant Field Values

SC_BAD_REQUEST

static final int SC_BAD_REQUEST

Status code (400) indicating the request sent by the client was syntactically incorrect.

See Also:
Constant Field Values

SC_UNAUTHORIZED

static final int SC_UNAUTHORIZED

Status code (401) indicating that the request requires HTTP authentication.

See Also:
Constant Field Values
SC_PAYMENT_REQUIRED

static final int SC_PAYMENT_REQUIRED

Status code (402) reserved for future use.

See Also:
Constant Field Values

SC_FORBIDDEN

static final int SC_FORBIDDEN

Status code (403) indicating the server understood the request but refused to fulfill it.

See Also:
Constant Field Values

SC_NOT_FOUND

static final int SC_NOT_FOUND

Status code (404) indicating that the requested resource is not available.

See Also:
Constant Field Values
SC_METHOD_NOT_ALLOWED

static final int SC_METHOD_NOT_ALLOWED

Status code (405) indicating that the method specified in the Request-Line is not allowed for the resource identified by the Request-URI.

See Also:
Constant Field Values

SC_NOT_ACCEPTABLE

static final int SC_NOT_ACCEPTABLE

Status code (406) indicating that the resource identified by the request is only capable of generating response entities which have content characteristics not acceptable according to the accept headers sent in the request.

See Also:
Constant Field Values

SC_PROXY_AUTHENTICATION_REQUIRED

static final int SC_PROXY_AUTHENTICATION_REQUIRED

Status code (407) indicating that the client MUST first authenticate itself with the proxy.

See Also:
Constant Field Values
SC_REQUEST_TIMEOUT

static final int SC_REQUEST_TIMEOUT

Status code (408) indicating that the client did not produce a request within the time that the server was prepared to wait.

See Also:
Constant Field Values

SC_CONFLICT

static final int SC_CONFLICT

Status code (409) indicating that the request could not be completed due to a conflict with the current state of the resource.

See Also:
Constant Field Values

SC_GONE

static final int SC_GONE

Status code (410) indicating that the resource is no longer available at the server and no forwarding address is known. This condition SHOULD be considered permanent.

See Also:
Constant Field Values
SC_LENGTH_REQUIRED

static final int SC_LENGTH_REQUIRED

Status code (411) indicating that the request cannot be handled without a defined Content-Length.

See Also:
Constant Field Values

SC_PRECONDITION_FAILED

static final int SC_PRECONDITION_FAILED

Status code (412) indicating that the precondition given in one or more of the request-header fields evaluated to false when it was tested on the server.

See Also:
Constant Field Values

SC_REQUEST_ENTITY_TOO_LARGE

static final int SC_REQUEST_ENTITY_TOO_LARGE

Status code (413) indicating that the server is refusing to process the request because the request entity is larger than the server is willing or able to process.

See Also:
Constant Field Values
SC_REQUEST_URI_TOO_LONG

static final int SC_REQUEST_URI_TOO_LONG

Status code (414) indicating that the server is refusing to service the request because the Request-URI is longer than the server is willing to interpret.

See Also:
Constant Field Values

---

SC_UNSUPPORTED_MEDIA_TYPE

static final int SC_UNSUPPORTED_MEDIA_TYPE

Status code (415) indicating that the server is refusing to service the request because the entity of the request is in a format not supported by the requested resource for the requested method.

See Also:
Constant Field Values

---

SC_REQUESTED_RANGE_NOT_SATISFIABLE

static final int SC_REQUESTED_RANGE_NOT_SATISFIABLE

Status code (416) indicating that the server cannot serve the requested byte range.

See Also:
Constant Field Values
SC_EXPECTATION_FAILED

static final int SC_EXPECTATION_FAILED

Status code (417) indicating that the server could not meet the expectation given in the Expect request header.

See Also:
Constant Field Values

SC_INTERNAL_SERVER_ERROR

static final int SC_INTERNAL_SERVER_ERROR

Status code (500) indicating an error inside the HTTP server which prevented it from fulfilling the request.

See Also:
Constant Field Values

SC_NOT_IMPLEMENTED

static final int SC_NOT_IMPLEMENTED

Status code (501) indicating the HTTP server does not support the functionality needed to fulfill the request.

See Also:
Constant Field Values
SC_BAD_GATEWAY

static final int SC_BAD_GATEWAY

Status code (502) indicating that the HTTP server received an invalid response from a server it consulted when acting as a proxy or gateway.

See Also:
Constant Field Values

SC_SERVICE_UNAVAILABLE

static final int SC_SERVICE_UNAVAILABLE

Status code (503) indicating that the HTTP server is temporarily overloaded, and unable to handle the request.

See Also:
Constant Field Values

SC_GATEWAY_TIMEOUT

static final int SC_GATEWAY_TIMEOUT

Status code (504) indicating that the server did not receive a timely response from the upstream server while acting as a gateway or proxy.

See Also:
Constant Field Values
SC_HTTP_VERSION_NOT_SUPPORTED

static final int SC_HTTP_VERSION_NOT_SUPPORTED

Status code (505) indicating that the server does not support or refuses to support the HTTP protocol version that was used in the request message.

See Also:
Constant Field Values

### Method Detail

**public void addCookie(Cookie cookie)**

```java
public void addCookie(Cookie cookie)
```

Adds the specified cookie to the response. This method can be called multiple times to set more than one cookie.

**Parameters:**
- `cookie` - the Cookie to return to the client

**public boolean containsHeader(String name)**

```java
public boolean containsHeader(String name)
```

**ContainsHeader**

```java
public boolean containsHeader(String name)
```
boolean `containsHeader(String name)`

Returns a boolean indicating whether the named response header has already been set.

**Parameters:**
- `name` - the header name

**Returns:**
- `true` if the named response header has already been set; `false` otherwise

---

`public String encodeURL(String url)`

Encodes the specified URL by including the session ID in it, or, if encoding is not needed, returns the URL unchanged. The implementation of this method includes the logic to determine whether the session ID needs to be encoded in the URL. For example, if the browser supports cookies, or session tracking is turned off, URL encoding is unnecessary.

For robust session tracking, all URLs emitted by a servlet should be run through this method. Otherwise, URL rewriting cannot be used with browsers which do not support cookies.

**Parameters:**
public String encodeRedirectURL(String url)

Encodes the specified URL for use in the `sendRedirect` method or, if encoding is not needed, returns the URL unchanged. The implementation of this method includes the logic to determine whether the session ID needs to be encoded in the URL. Because the rules for making this determination can differ from those used to decide whether to encode a normal link, this method is separated from the `encodeURL` method.

All URLs sent to the `HttpServletResponse.sendRedirect` method should be run through this method. Otherwise, URL rewriting cannot be used with browsers which do not support cookies.

**Parameters:**

- `url` - the url to be encoded.

**Returns:**

- the encoded URL if encoding is needed; the unchanged URL
See Also:

`sendRedirect(java.lang.String), encodeUrl(java.lang.String)`

---

**public String encodeUrl(String url)**

deprecated 2.1 `encodeURL(String url)`

```
url
return
```

**encodeUrl**

`String encodeUrl(String url)`

**Deprecated. As of version 2.1, use encodeURL(String url) instead**

**Parameters:**

`url` - the url to be encoded.

**Returns:**

the encoded URL if encoding is needed; the unchanged URL otherwise.

---

**public String encodeRedirectUrl(String url)**

deprecated 2.1 `encodeRedirectURL(String url)`

```
url
return
```

**encodeRedirectUrl**

`String encodeRedirectUrl(String url)`

**Deprecated. As of version 2.1, use encodeRedirectURL(String url) instead**

**Parameters:**
url - the url to be encoded.

**Returns:**
the encoded URL if encoding is needed; the unchanged URL otherwise.

```java
public void sendError(int sc, String msg) throws java.io.IOException
HTML  "text/html" cookie
msg

IllegalStateException
  sc
  msg
Throws java.io.IOException:
Throws IllegalArgumentException:

sendError

void sendError(int sc,
  String msg)
throws IOException

Sends an error response to the client using the specified status. The server defaults to creating the response to look like an HTML-formatted server error page containing the specified message, setting the content type to "text/html", leaving cookies and other headers unmodified. If an error-page declaration has been made for the web application corresponding to the status code passed in, it will be served back in preference to the suggested msg parameter.

If the response has already been committed, this method throws an IllegalStateException. After using this method, the response should be considered to be committed and should not be written to.

**Parameters:**
public void sendError(int sc) throws java.io.IOException

IllegalStateException

Throws java.io.IOException:

Throws IllegalStateException:

sendError

void sendError(int sc)
throws IOException

Sends an error response to the client using the specified status code and clearing the buffer.

If the response has already been committed, this method throws an IllegalStateException. After using this method, the response should be considered to be committed and should not be written to.

Parameters:
sc - the error status code

Throws:
IOException - If an input or output exception occurs
IllegalStateException - If the response was committed before this method call

public void sendRedirect(String location) throws
java.io.IOException
URL URLservlet URL URL '/'
URI '/' servlet

IllegalStateException

Throws java.io.IOException:
Throwss IllegalStateException: URL URL

sendRedirect

void sendRedirect(String location)
throws IOException

Sends a temporary redirect response to the client using the specified redirect location URL. This method can accept relative URLs; the servlet container must convert the relative URL to an absolute URL before sending the response to the client. If the location is relative without a leading '/' the container interprets it as relative to the current request URI. If the location is relative with a leading '/' the container interprets it as relative to the servlet container root.

If the response has already been committed, this method throws an IllegalStateException. After using this method, the response should be considered to be committed and should not be written to.

Parameters:
location - the redirect location URL

Throws:
IOException - If an input or output exception occurs
IllegalStateException - If the response was committed or if a partial URL is given and cannot be converted into a valid URL

public void setDateHeader(String name, long date)
void setDateHeader(String name, long date)

Sets a response header with the given name and date-value. The date is specified in terms of milliseconds since the epoch. If the header had already been set, the new value overwrites the previous one. The containsHeader method can be used to test for the presence of a header before setting its value.

Parameters:
- name - the name of the header to set
- date - the assigned date value

See Also:
- containsHeader(java.lang.String)
- addDateHeader(java.lang.String, long)

public void addDateHeader(String name, long date)

void addDateHeader(String name, long date)

Adds a response header with the given name and date-value. The date is specified in terms of milliseconds since the epoch. This method allows response headers to have multiple values.
public void setHeader(String name, String value)

Sets a response header with the given name and value. If the header had already been set, the new value overwrites the previous one. The containsHeader method can be used to test for the presence of a header before setting its value.

Parameters:

name - the name of the header
value - the header value If it contains octet string, it should be encoded according to RFC 2047 (http://www.ietf.org/rfc/rfc2047.txt)

See Also:

containsHeader(java.lang.String),
addHeader(java.lang.String, java.lang.String)
addHeader

void addHeader(String name, String value)

Adds a response header with the given name and value. This method allows response headers to have multiple values.

Parameters:
   name - the name of the header
   value - the additional header value If it contains octet string, it should be encoded according to RFC 2047 (http://www.ietf.org/rfc/rfc2047.txt)

See Also:
setHeader(java.lang.String, java.lang.String)

public void setIntHeader(String name, int value)

Sets a response header with the given name and integer value. If the header had already been set, the new value overwrites the previous one. The containsHeader method can be used to test for the presence of a header before setting its value.

Parameters:
   name - the name of the header
public void addIntHeader(String name, int value)

   name
   value
 See also      setIntHeader

addIntHeader

void addIntHeader(String name,
                  int value)

   Adds a response header with the given name and integer value. This method allows response headers to have multiple values.

Parameters:

   name - the name of the header
   value - the assigned integer value
See Also:

   setIntHeader(java.lang.String, int)

public void setStatus(int sc)

SC_OK  SC_MOVED_TEMPORARILY Web

   sendError

Location  cookie

   sc
 See also      sendError
setStatus

void setStatus(int sc)

Sets the status code for this response. This method is used to set the return status code when there is no error (for example, for the status codes SC_OK or SC_MOVED_TEMPORARILY). If there is an error, and the caller wishes to invoke an error-page defined in the web application, the sendError method should be used instead.

The container clears the buffer and sets the Location header, preserving cookies and other headers.

Parameters:

  sc - the status code

See Also:

  sendError(int, java.lang.String)

public void setStatus(int sc, String sm)

deprecated 2.1

Sets the status code and message for this response.

Parameters:

  sc - the status code
  sm - the status message

Deprecated. As of version 2.1, due to ambiguous meaning of the message parameter. To set a status code use setStatus(int), to send an error with a description use sendError(int, String). Sets the status code and message for this response.

PS:
javax.servlet.http Class HttpServletResponseWrapper

java.lang.Object
   ▼ javax.servlet.ServletResponseWrapper
      ▼ javax.servlet.http.HttpServletResponseWrapper

All Implemented Interfaces:
   HttpServletResponse, ServletResponse

public class HttpServletResponseWrapper

extends ServletResponseWrapper
implements HttpServletResponse

Extends: ServletResponseWrapper
Implements: HttpServletResponse

HttpServletResponse Servlet Wrapper Decorator

   since v 2.3

See also javax.servlet.http.HttpServletResponse

Provides a convenient implementation of the HttpServletResponse interface that can be subclassed by developers wishing to adapt the response from a Servlet. This class implements the Wrapper or Decorator pattern. Methods default to calling through to the wrapped response object.

Since:
   v 2.3

Author:
   Various

**Constructor Detail**

class **public HttpServletServletResponseWrapper**(HttpServletRequest response)

Throws IllegalArgumentException: response null
HttpServletResponseWrapper

public HttpServletResponseWrapper(HttpServletResponse response)

Constructs a response adaptor wrapping the given response.

Throws:

IllegalArgumentException - if the response is null

Method Detail

public void addCookie(Cookie cookie)

addCookie(Cookie cookie)

addCookie

public void addCookie(Cookie cookie)

The default behavior of this method is to call addCookie(Cookie cookie) on the wrapped response object.

Specified by:

addCookie in interface HttpServletResponse

Parameters:

cookie - the Cookie to return to the client

public boolean containsHeader(String name)

containsHeader(String name)

containsHeader

public boolean containsHeader(String name)

The default behavior of this method is to call containsHeader(String
name) on the wrapped response object.

**Specified by:**
- `containsHeader` in interface `HttpServletResponse`

**Parameters:**
- `name` - the header name

**Returns:**
- `true` if the named response header has already been set; `false` otherwise

---

```java
public String encodeURL(String url)
```

**encodeURL**

```java
public String encodeURL(String url)
```

The default behavior of this method is to call `encodeURL(String url)` on the wrapped response object.

**Specified by:**
- `encodeURL` in interface `HttpServletResponse`

**Parameters:**
- `url` - the url to be encoded.

**Returns:**
- the encoded URL if encoding is needed; the unchanged URL otherwise.

---

```java
public String encodeRedirectURL(String url)
```

**encodeRedirectURL**

```java
public String encodeRedirectURL(String url)
```

The default behavior of this method is to call `encodeRedirectURL(String url)` on the wrapped response object.

**Specified by:**
- `encodeRedirectURL` in interface `HttpServletResponse`

**Parameters:**
- `url` - the url to be encoded.

**Returns:**
- the encoded URL if encoding is needed; the unchanged URL otherwise.
The default behavior of this method is to return encodeRedirectURL(String url) on the wrapped response object.

**Specified by:**
   encodeRedirectURL in interface HttpServletResponse

**Parameters:**
url - the url to be encoded.

**Returns:**
the encoded URL if encoding is needed; the unchanged URL otherwise.

**See Also:**
   HttpServletResponse.sendRedirect(java.lang.String),
   HttpServletResponse.encodeUrl(java.lang.String)

---

public String encodeUrl(String url)
encodeUrl(String url)

codeUrl

public String encodeUrl(String url)

The default behavior of this method is to call encodeUrl(String url) on the wrapped response object.

**Specified by:**
   encodeUrl in interface HttpServletResponse

**Parameters:**
url - the url to be encoded.

**Returns:**
the encoded URL if encoding is needed; the unchanged URL otherwise.

---

public String encodeRedirectUrl(String url)
encodeRedirectUrl(String url)
**encodeRedirectUrl**

public String encodeRedirectUrl(String url)

The default behavior of this method is to return encodeRedirectUrl(String url) on the wrapped response object.

**Specified by:**
  
  `encodeRedirectUrl` in interface `HttpServletResponse`

**Parameters:**

  url - the url to be encoded.

**Returns:**

  the encoded URL if encoding is needed; the unchanged URL otherwise.

---

**sendError**

public void sendError(int sc, String msg) throws IOException

**sendError(int sc, String msg)**

**sendError**

public void sendError(int sc, String msg) throws IOException

The default behavior of this method is to call sendError(int sc, String msg) on the wrapped response object.

**Specified by:**

  `sendError` in interface `HttpServletResponse`

**Parameters:**

  sc - the error status code
  
  msg - the descriptive message

**Throws:**

  `IOException` - If an input or output exception occurs
public void sendError(int sc) throws java.io.IOException
sendError(int sc)

sendError

public void sendError(int sc)
    throws IOException

    The default behavior of this method is to call sendError(int sc) on the wrapped response object.

    Specified by:
        sendError in interface HttpServletResponse

    Parameters:
        sc - the error status code

    Throws:
        IOException - If an input or output exception occurs

public void sendRedirect(String location) throws java.io.IOException
sendRedirect(String location)

sendRedirect

public void sendRedirect(String location)
    throws IOException

    The default behavior of this method is to return sendRedirect(String location) on the wrapped response object.

    Specified by:
        sendRedirect in interface HttpServletResponse

    Parameters:
        location - the redirect location URL

    Throws:
        IOException - If an input or output exception occurs
public void setDateHeader(String name, long date)
setDateHeader(String name, long date)

setDateHeader

public void setDateHeader(String name, long date)

The default behavior of this method is to call setDateHeader(String name, long date) on the wrapped response object.

Specified by:
   setDateHeader in interface HttpServletResponse
Parameters:
   name - the name of the header to set
date - the assigned date value
See Also:
   HttpServletResponse.containsHeader(java.lang.String),
   HttpServletResponse.addDateHeader(java.lang.String, long)

public void addDateHeader(String name, long date)
addDateHeader(String name, long date)

addDateHeader

public void addDateHeader(String name, long date)

The default behavior of this method is to call addDateHeader(String name, long date) on the wrapped response object.

Specified by:
   addDateHeader in interface HttpServletResponse
Parameters:
   name - the name of the header to set
date - the additional date value

See Also:
HttpServletResponse.setDateHeader(java.lang.String, long)

public void setHeader(String name, String value)
setHeader(String name, String value)

setHeader

public void setHeader(String name, String value)

The default behavior of this method is to return setHeader(String name, String value) on the wrapped response object.

Specified by:
setHeader in interface HttpServletResponse

Parameters:
name - the name of the header
class value - the header value If it contains octet string, it should be encoded according to RFC 2047 (http://www.ietf.org/rfc/rfc2047.txt)

See Also:
HttpServletResponse.containsHeader(java.lang.String),
HttpServletResponse.addHeader(java.lang.String, java.lang.String)

public void addHeader(String name, String value)
addHeader(String name, String value)

addHeader

public void addHeader(String name, String value)
The default behavior of this method is to return `addHeader(String name, String value)` on the wrapped response object.

**Specified by:**
- `addHeader` in interface `HttpServletResponse`

**Parameters:**
- `name` - the name of the header
- `value` - the additional header value If it contains octet string, it should be encoded according to RFC 2047 (http://www.ietf.org/rfc/rfc2047.txt)

**See Also:**
- `HttpServletResponse.setHeader(java.lang.String, java.lang.String)`

---

```java
public void setIntHeader(String name, int value)
```

`setIntHeader` method

```java
public void setIntHeader(String name, int value)
```

The default behavior of this method is to call `setIntHeader(String name, int value)` on the wrapped response object.

**Specified by:**
- `setIntHeader` in interface `HttpServletResponse`

**Parameters:**
- `name` - the name of the header
- `value` - the assigned integer value

**See Also:**
- `HttpServletResponse.containsHeader(java.lang.String)`, `HttpServletResponse.addIntHeader(java.lang.String, int)`

---

```java
public void addIntHeader(String name, int value)
```

`addIntHeader` method

```java
public void addIntHeader(String name, int value)
```

---
addIntHeader

public void addIntHeader(String name, int value)

The default behavior of this method is to call addIntHeader(String name, int value) on the wrapped response object.

Specified by:
   addIntHeader in interface HttpServletResponse

Parameters:
   name - the name of the header
   value - the assigned integer value

See Also:
   HttpServletResponse.setIntHeader(java.lang.String, int)

public void setStatus(int sc)

setStatus(int sc)

setStatus

public void setStatus(int sc)

The default behavior of this method is to call setStatus(int sc) on the wrapped response object.

Specified by:
   setStatus in interface HttpServletResponse

Parameters:
   sc - the status code

See Also:
   HttpServletResponse.sendError(int, java.lang.String)

public void setStatus(int sc, String sm)
setStatus(int sc, String sm)

The default behavior of this method is to call setStatus(int sc, String sm) on the wrapped response object.

Parameters:
- sc - the status code
- sm - the status message

Specified by:
- setStatus in interface HttpServletResponse

**javax.servlet.http**  
**Interface HttpSession**

```java
public interface HttpSession
```

Web

```java
Web
```

```java
servlet HTTP HTTP cookie URL
```

```java
servlet
```

```java
HttpSessionBindingListener
```

```java
VM
```

```java
HttpSessionActivationListener
```

```java
servlet cookieisNew true
```

```java
true
```

```java
Web (ServletContext)
```

```java
See javax.servlet.http.HttpSessionBindingListener,
```

```java
also javax.servlet.http.HttpSessionContext
```

Provides a way to identify a user across more than one page request or visit to a Web site and to store information about that user.

The servlet container uses this interface to create a session between an HTTP client and an HTTP server. The session persists for a specified time period, across more than one connection or page request from the user. A session usually corresponds to one user, who may visit a site many times. The server can maintain a session in many ways such as using cookies or rewriting URLs.

This interface allows servlets to
• View and manipulate information about a session, such as the session identifier, creation time, and last accessed time
• Bind objects to sessions, allowing user information to persist across multiple user connections

When an application stores an object in or removes an object from a session, the session checks whether the object implements HttpSessionBindingListener. If it does, the servlet notifies the object that it has been bound to or unbound from the session. Notifications are sent after the binding methods complete. For session that are invalidated or expire, notifications are sent after the session has been invalidated or expired.

When container migrates a session between VMs in a distributed container setting, all session attributes implementing the HttpSessionActivationListener interface are notified.

A servlet should be able to handle cases in which the client does not choose to join a session, such as when cookies are intentionally turned off. Until the client joins the session, isNew returns true. If the client chooses not to join the session, getSession will return a different session on each request, and isNew will always return true.

Session information is scoped only to the current web application (ServletContext), so information stored in one context will not be directly visible in another.

### Method Detail

#### public long getCreationTime()

1970 1 1

<table>
<thead>
<tr>
<th>return</th>
<th>long 1970 1 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>IllegalStateException:</td>
</tr>
</tbody>
</table>

**getCreationTime**

long getCreationTime()

Returns the time when this session was created, measured in
milliseconds since midnight January 1, 1970 GMT.

**Returns:**

A `long` specifying when this session was created, expressed in milliseconds since 1/1/1970 GMT

**Throws:**

`IllegalStateException` - if this method is called on an invalidated session

---

```java
public String getId()
```

**getld**

```java
String getId()
```

Returns a string containing the unique identifier assigned to this session. The identifier is assigned by the servlet container and is implementation dependent.

**Returns:**

A string specifying the identifier assigned to this session

---

```java
public long getLastAccessedTime()
```

**getLastAccessedTime**

```java
long getLastAccessedTime()
```

Returns: A `long` specifying when this session was last accessed, expressed in milliseconds since 1/1/1970 GMT

**Throws**

`IllegalStateException`
long **getLastAccessedTime()**

Returns the last time the client sent a request associated with this session, as the number of milliseconds since midnight January 1, 1970 GMT, and marked by the time the container received the request.

Actions that your application takes, such as getting or setting a value associated with the session, do not affect the access time.

**Returns:**
- a `long` representing the last time the client sent a request associated with this session, expressed in milliseconds since 1/1/1970 GMT

**Throws:**
- `IllegalStateException` - if this method is called on an invalidated session

---

```java
public **ServletContext** **getServletContext()**

**ServletContext**

```return``` Web **ServletContext**

since 2.3
```

**getServletContext**

**ServletContext** **getServletContext()**

Returns the ServletContext to which this session belongs.

**Returns:**
- The ServletContext object for the web application

**Since:**
- 2.3

---

```java
public **void** **setMaxInactiveInterval**(int interval)
```

**setMaxInactiveInterval(int interval)**
setMaxInactiveInterval

void setMaxInactiveInterval(int interval)

Specifies the time, in seconds, between client requests before the servlet container will invalidate this session. A negative time indicates the session should never timeout.

Parameters:
  interval - An integer specifying the number of seconds

getMaxInactiveInterval

public int getMaxInactiveInterval()

Returns the maximum time interval, in seconds, that the servlet container will keep this session open between client accesses. After this interval, the servlet container will invalidate the session. The maximum time interval can be set with the setMaxInactiveInterval method. A negative time indicates the session should never timeout.

Returns:
  an integer specifying the number of seconds this session remains open between client requests

See Also:
  setMaxInactiveInterval(int)
public HttpSessionContext getSessionContext()

Deprecated. As of Version 2.1, this method is deprecated and has no replacement. It will be removed in a future version of the Java Servlet API.

public Object getAttribute(String name)

name
return

Throws

IllegalStateException: 

getAttribute

Object getAttribute(String name)

Returns the object bound with the specified name in this session, or null if no object is bound under the name.

Parameters:

name - a string specifying the name of the object

Returns:

the object with the specified name

Throws:

IllegalStateException - if this method is called on an invalidated session
public Object getValue(String name)

Deprecated. As of Version 2.2, this method is replaced by
getAttribute(java.lang.String).

Parameters:
   name - a string specifying the name of the object

Returns:
   the object with the specified name

Throws:
   IllegalAccessException - if this method is called on an
   invalidated session

public java.util.Enumeration&lt;E&gt; getAttributeNames()

return String Enumeration

Throws IllegalAccessException:

getAttributeNames

Enumeration getAttributeNames()

Returns an Enumeration of String objects containing the names of all
the objects bound to this session.

Returns:
   an Enumeration of String objects specifying the names of all the
objects bound to this session

Throws:
IllegalStateException - if this method is called on an invalidated session

public String[] getValueNames()

return

Throws
IllegalStateException:

getValueNames

String[] getValueNames()

Deprecated. As of Version 2.2, this method is replaced by getAttributeNames()

Returns:
an array of String objects specifying the names of all the objects bound to this session

Throws:
IllegalStateException - if this method is called on an invalidated session

public void setAttribute(String name, Object value)

setTextAttribute

setAttribute

String

setAttribute

IllegalStateException

setAttribute

IllegalStateException - if this method is called on an invalidated session
setAttribute

void `setAttribute(String name, Object value)`

Binds an object to this session, using the name specified. If an object of the same name is already bound to the session, the object is replaced.

After this method executes, and if the new object implements `HttpSessionBindingListener`, the container calls `HttpSessionBindingListener.valueBound`. The container then notifies any `HttpSessionAttributeListener`s in the web application.

If an object was already bound to this session of this name that implements `HttpSessionBindingListener`, its `HttpSessionBindingListener.valueUnbound` method is called.

If the value passed in is null, this has the same effect as calling `removeAttribute()`.

**Parameters:**

- `name` - the name to which the object is bound; cannot be null
- `value` - the object to be bound

**Throws:**

- `IllegalStateException` - if this method is called on an invalidated session

public void `putValue(String name, Object value)`

deprecated 2.2

`#setAttribute`
**putValue**

```java
void putValue(String name, Object value)
```

**Deprecated. As of Version 2.2, this method is replaced by setAttribute(java.lang.String, java.lang.Object)**

**Parameters:**
- `name` - the name to which the object is bound; cannot be null
- `value` - the object to be bound; cannot be null

**Throws:**
- `IllegalStateException` - if this method is called on an invalidated session

---

**public void removeAttribute(String name)**

```java
HttpSessionBindingListener
HttpSessionBindingListener.valueUnbound Web
HttpSessionAttributeListener
name
```

**Throws**
- `IllegalStateException`: null

---

**removeAttribute**

```java
void removeAttribute(String name)
```

Removes the object bound with the specified name from this session. If the session does not have an object bound with the specified name, this method does nothing.
After this method executes, and if the object implements HttpSessionBindingListener, the container calls HttpSessionBindingListener.valueUnbound. The container then notifies any HttpSessionAttributeListeners in the web application.

**Parameters:**
- name - the name of the object to remove from this session

**Throws:**
- `IllegalStateException` - if this method is called on an invalidated session

---

```java
public void removeValue(String name)
```

Deprecated: As of Version 2.2, this method is replaced by `removeAttribute(java.lang.String)`

**Parameters:**
- name - the name of the object to remove from this session

**Throws:**
- `IllegalStateException` - if this method is called on an invalidated session

---

```java
public void invalidate()
```

**Throws:**
- `IllegalStateException`
void invalidate()

Invalidates this session then unbinds any objects bound to it.

**Throws:**
- `IllegalStateException` - if this method is called on an already invalidated session

---

**public boolean isNew()**

public boolean isNew()

return true

Throws

IllegalStateException:

---

**isNew**

boolean isNew()

returns true if the client does not yet know about the session or if the client chooses not to join the session. For example, if the server used only cookie-based sessions, and the client had disabled the use of cookies, then a session would be new on each request.

**Returns:**
- true if the server has created a session, but the client has not yet joined

**Throws:**
- `IllegalStateException` - if this method is called on an already invalidated session

---

PS:
Interface

HttpSessionActivationListener

All Superinterfaces:
  EventListener

public interface HttpSessionActivationListener
extends EventListener

Implements: java.util.EventListener

VM HttpSessionActivationListener

   since 2.3

Objects that are bound to a session may listen to container events notifying them that sessions will be passivated and that session will be activated. A container that migrates session between VMs or persists sessions is required to notify all attributes bound to sessions implementing HttpSessionActivationListener.

Since:
   2.3

Class HttpSessionBindingEvent

java.lang.Object
  ▼ java.util.EventObject
    ▼ javax.servlet.http.HttpSessionEvent
        ▼ javax.servlet.http.HttpSessionBindingEvent

All Implemented Interfaces:
  Serializable

public class HttpSessionBindingEvent
  extends HttpSessionEvent

Extends: java.util.EventObject > HttpSessionEvent

HttpSession.setAttribute    HttpSession.removeAttribute

See also
javax.servlet.http.HttpSession,
javax.servlet.http.HttpSessionBindingListener,
javax.servlet.http.HttpSessionAttributeListener

Events of this type are either sent to an object that implements
HttpSessionBindingListener when it is bound or unbound from a session,
or to a HttpSessionAttributeListener that has been configured in the
deployment descriptor when any attribute is bound, unbound or replaced
in a session.

The session binds the object by a call to HttpSession.setAttribute and
unbinds the object by a call to HttpSession.removeAttribute.

Constructor Detail

public HttpSessionBindingEvent(HttpSession session, String name)

session
ame
See also
getName, getSession

HttpSessionBindingEvent

public HttpSessionBindingEvent(HttpSession session, String name)

Constructs an event that notifies an object that it has been bound to or unbound from a session. To receive the event, the object must implement HttpSessionBindingListener.

Parameters:
  session - the session to which the object is bound or unbound
  name - the name with which the object is bound or unbound

See Also:
  getName(), getSession()

public HttpSessionBindingEvent(HttpSession session, String name, Object value)

session
name
See also
getName, getSession
HttpSessionBindingEvent

public HttpSessionBindingEvent(HttpSession session, String name, Object value)

Constructs an event that notifies an object that it has been bound to or unbound from a session. To receive the event, the object must implement HttpSessionBindingListener.

Parameters:
   session - the session to which the object is bound or unbound
   name - the name with which the object is bound or unbound

See Also:
   getName(), getSession()

Method Detail

public HttpSession getSession()

getSession

public HttpSession getSession()

Return the session that changed.

Overrides:
   getSession in class HttpSessionEvent

public String getName()

return
getName

public String getName()

    Returns the name with which the attribute is bound to or unbound from the session.

    Returns:
    a string specifying the name with which the object is bound to or unbound from the session

public Object getValue()

    since 2.3

getValue

public Object getValue()

    Returns the value of the attribute that has been added, removed or replaced. If the attribute was added (or bound), this is the value of the attribute. If the attribute was removed (or unbound), this is the value of the removed attribute. If the attribute was replaced, this is the old value of the attribute.

    Since:
    2.3

</table>
with key-value pairs.

Methods inherited from class java.lang.Object:
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Constructor Detail

public HttpUtils()
    HttpUtils

HttpUtils

public HttpUtils()
    Deprecated.
    Constructs an empty HttpUtils object.

Method Detail

public static java.util.Hashtable<K, V> parseQueryString(String s)
    -        HashTable
          GE

+ %xx ASCII

S
return
Throws
IllegalArgumentException:
parseQueryString

public static Hashtable parseQueryString(String s)

Deprecated.
 Parses a query string passed from the client to the server and builds
a HashTable object with key-value pairs. The query string should be
in the form of a string packaged by the GET or POST method, that
is, it should have key-value pairs in the form key=value, with each
pair separated from the next by a & character.

A key can appear more than once in the query string with different
values. However, the key appears only once in the hashtable, with its
value being an array of strings containing the multiple values sent by
the query string.

The keys and values in the hashtable are stored in their decoded
form, so any + characters are converted to spaces, and characters
sent in hexadecimal notation (like %xx) are converted to ASCII
characters.

Parameters:
   s - a string containing the query to be parsed

Returns:
   a HashTable object built from the parsed key-value pairs

Throws:
   IllegalArgumentException - if the query string is invalid

parsePostData

public static java.util.Hashtable<K, V> parsePostData(int len,
            ServletInputStream in)

HTML  HTTP POST  application/x-www-urlencoded MIME

POST - POST  POST
parsePostData

public static Hashtable parsePostData(int len, ServletInputStream in)

Deprecated.

Parses data from an HTML form that the client sends to the server using the HTTP POST method and the application/x-www-form-urlencoded MIME type.

The data sent by the POST method contains key-value pairs. A key can appear more than once in the POST data with different values. However, the key appears only once in the hashtable, with its value being an array of strings containing the multiple values sent by the POST method.

The keys and values in the hashtable are stored in their decoded form, so any + characters are converted to spaces, and characters sent in hexadecimal notation (like %xx) are converted to ASCII characters.

Parameters:
  - len - an integer specifying the length, in characters, of the ServletInputStream object that is also passed to this method
  - in - the ServletInputStream object that contains the data sent from the client

Returns:
  - a HashTable object built from the parsed key-value pairs

Throws:
  - IllegalArgumentException - if the data sent by the POST method is invalid
public static StringBuffer getRequestURL(HttpServletRequest req)

HttpServletRequest URL URL

StringBuffer URL

getRequestURL

public static StringBuffer getRequestURL(HttpServletRequest req)

Deprecated.
Reconstructs the URL the client used to make the request, using information in the HttpServletRequest object. The returned URL contains a protocol, server name, port number, and server path, but it does not include query string parameters.

Because this method returns a StringBuffer, not a string, you can modify the URL easily, for example, to append query parameters.

This method is useful for creating redirect messages and for reporting errors.

Parameters:
req - a HttpServletRequest object containing the client's request

Returns:
a StringBuffer object containing the reconstructed URL

javax.jms Class IllegalStateException

java.lang.Object
   ↓ java.lang.Throwable
      ↓ java.lang.Exception
       ↓ javax.jms.JMSException
          ↓ javax.jms.IllegalStateException

All Implemented Interfaces:
   Serializable

public class IllegalStateException
extends JMSException

Extends: Throwable > Exception > JMSException

version April 9, 2002

This exception is thrown when a method is invoked at an illegal or inappropriate time or if the provider is not in an appropriate state for the requested operation. For example, this exception must be thrown if Session.commit is called on a non-transacted session. This exception is also called when a domain inappropriate method is called, such as calling TopicSession.CreateQueueBrowser.

public IllegalStateException()

null

**IllegalStateException**

public IllegalStateException()
Constructs a new instance with null as its detail message.

```java
public IllegalStateException(String message)

message
```

**IllegalStateException**

```java
public IllegalStateException(String message)

message
```

Constructs a new instance with the specified detail message.

**Parameters:**

- `message`: the detail message.

```java
public IllegalStateException(Throwable cause)

cause
```

```java
cause
```

**IllegalStateException**

```java
public IllegalStateException(Throwable cause)

cause
```

Constructs a new throwable with the specified cause.

**Parameters:**

- `cause`: a chained exception of type `Throwable`.

```java
public IllegalStateException(String message, Throwable cause)

message
```

```java
cause
```
IllegalStateException

public IllegalStateException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public IllegalStateException(String message, String errorCode)
throwable

message
errorCode

IllegalStateException

public IllegalStateException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

IllegalWriteException

s

IllegalWriteException
public IllegalWriteException(String s)

Constructs a IllegalWriteException with the specified detail message.

**Parameters:**
- s - the detail message
public class ImplicitObjectELResolver
extends ELResolver

Defines variable resolution behavior for the EL implicit objects defined in the JSP specification.

The following variables are resolved by this ELResolver, as per the JSP specification:

- `pageContext` - the `PageContext` object.
- `pageScope` - a Map that maps page-scoped attribute names to their values.
- `requestScope` - a Map that maps request-scoped attribute names to their values.
- `sessionScope` - a Map that maps session-scoped attribute names to their values.
- `applicationScope` - a Map that maps application-scoped attribute names to their values.
- `param` - a Map that maps parameter names to a single String parameter value (obtained by calling `ServletRequest.getParameter(String name)`).
- `paramValues` - a Map that maps parameter names to a String[] of all values for that parameter (obtained by calling `ServletRequest.getParameterValues(String name)`).
- `header` - a Map that maps header names to a single String header value (obtained by calling `HttpServletRequest.getHeader(String name)`).
- `headerValues` - a Map that maps header names to a String[] of all values for that header (obtained by calling `HttpServletRequest.getHeaders(String)`).
- `cookie` - a Map that maps cookie names to a single `Cookie` object.
Cookies are retrieved according to the semantics of HttpServletRequest.getCookies(). If the same name is shared by multiple cookies, an implementation must use the first one encountered in the array of Cookie objects returned by the get_cookies() method. However, users of the cookie implicit object must be aware that the ordering of cookies is currently unspecified in the servlet specification.

- initParam - a Map that maps context initialization parameter names to their String parameter value (obtained by calling ServletContext.getInitParameter(String name)).

Since:
- JSP 2.1

See Also:
- ELResolver

</tbody>
</table>
returns an `Iterator` containing `FeatureDescriptor` objects with information about each JSP implicit object resolved by this resolver.

### `getType` Method (Class `object`)

```java
public ELContext getType(ELContext context, Object base, Object property)
```

- If the base object is `null`, and the property matches the name of a JSP implicit object, returns `null` to indicate that no types are ever accepted to `setValue()`.

### `getValue` Method (Object `object`)

```java
public Object getValue(ELContext context, Object base, Object property)
```

- If the base object is `null`, and the property matches the name of a JSP implicit object, returns the implicit object.

### `isReadOnly` Method (Boolean `object`)

```java
public boolean isReadOnly(ELContext context, Object base, Object property)
```

- If the base object is `null`, and the property matches the name of a JSP implicit object, returns `true` to indicate that implicit objects cannot be overwritten.

### `setValue` Method (Void `object`)

```java
public void setValue(ELContext context, Object base, Object property, Object val)
```

- If the base object is `null`, and the property matches the name of a JSP implicit object, throws `PropertyNotWritableException` to indicate that implicit objects cannot be overwritten.

---

**Methods inherited from class java.lang.Object**

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
public ImplicitObjectELResolver()

**Method Detail**

**getValue**

public Object getValue(ELContext context, Object base, Object property)

If the base object is `null`, and the property matches the name of a JSP implicit object, returns the implicit object.

The `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver before returning if an implicit object is matched. If this property is not `true` after this method is called, the caller should ignore the return value.

**Specified by:**
getValue in class ELResolver

**Parameters:**
- context - The context of this evaluation.
- base - Only `null` is handled by this resolver. Other values will result in an immediate return.
- property - The name of the implicit object to resolve.

**Returns:**
- If the `propertyResolved` property of `ELContext` was set to `true`, then the implicit object; otherwise undefined.

**Throws:**
- NullPointerException - if context is `null`
- ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

**getType**

public Class getType(ELContext context, Object base,
If the base object is `null`, and the property matches the name of a JSP implicit object, returns `null` to indicate that no types are ever accepted to `setValue()`.

The `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver before returning if an implicit object is matched. If this property is not `true` after this method is called, the caller should ignore the return value.

Specified by:
`getType` in class `ELResolver`

Parameters:
- `context` - The context of this evaluation.
- `base` - Only `null` is handled by this resolver. Other values will result in an immediate return.
- `property` - The name of the implicit object to resolve.

Returns:
If the `propertyResolved` property of `ELContext` was set to `true`, then `null`; otherwise undefined.

Throws:
- `NullPointerException` - if `context` is `null`
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

**setValue**

```java
public void setValue(ELContext context,
                     Object base,
                     Object property,
                     Object val)
```

If the base object is `null`, and the property matches the name of a JSP implicit object, throws `PropertyNotWritableException` to indicate that implicit objects cannot be overwritten.

The `propertyResolved` property of the `ELContext` object must be set to
true by this resolver before returning if an implicit object is matched. If this property is not true after this method is called, the caller should ignore the return value.

**Specified by:**
- `setValue` in class `ELResolver`

**Parameters:**
- `context` - The context of this evaluation.
- `base` - Only null is handled by this resolver. Other values will result in an immediate return.
- `property` - The name of the implicit object.
- `val` - The value to be associated with the implicit object.

**Throws:**
- `NullPointerException` - if context is null.
- `PropertyNotWritableException` - always thrown, if the implicit object name is recognized by this resolver.
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

**isReadOnly**

```java
public boolean isReadOnly(ELContext context,
                         Object base,
                         Object property)
```

If the base object is null, and the property matches the name of a JSP implicit object, returns `true` to indicate that implicit objects cannot be overwritten.

The `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver before returning if an implicit object is matched. If this property is not `true` after this method is called, the caller should ignore the return value.

**Specified by:**
- `isReadOnly` in class `ELResolver`

**Parameters:**
- `context` - The context of this evaluation.
base - Only null is handled by this resolver. Other values will result in an immediate return.

property - The name of the implicit object.

**Returns:**

If the `propertyResolved` property of `ELContext` was set to `true`, then `true`; otherwise undefined.

**Throws:**

- `NullPointerException` - if `context` is `null`.
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

**getFeatureDescriptors**

```java
public Iterator<FeatureDescriptor> getFeatureDescriptors(ELContext context, Object base)
```

If the base object is `null`, and the property matches the name of a JSP implicit object, returns an `Iterator` containing `FeatureDescriptor` objects with information about each JSP implicit object resolved by this resolver. Otherwise, returns `null`.

The `Iterator` returned must contain one instance of `FeatureDescriptor` for each of the EL implicit objects defined by the JSP spec. Each info object contains information about a single implicit object, and is initialized as follows:

- **displayName** - The name of the implicit object.
- **name** - Same as `displayName` property.
- **shortDescription** - A suitable description for the implicit object. Will vary by implementation.
- **expert** - `false`
- **hidden** - `false`
- **preferred** - `true`

In addition, the following named attributes must be set in the returned `FeatureDescriptor`s:

- **ELResolver.TYPE** - The runtime type of the implicit object.
- **ELResolver.RESOLVABLE_AT_DESIGN_TIME** - `true`.
getFeatureDescriptors

Parameters:
- context - The context of this evaluation.
- base - Only null is handled by this resolver. Other values will result in a null return value.

Returns:
An Iterator containing one FeatureDescriptor object for each implicit object, or null if base is not null.

See Also:
FeatureDescriptor

getCommonPropertyType

public void getCommonPropertyType(ELContext context, Object base)

If the base object is null, returns String.class. Otherwise, returns null.

Specified by:
getCommonPropertyType in class ELResolver

Parameters:
- context - The context of this evaluation.
- base - Only null is handled by this resolver. Other values will result in a null return value.

Returns:
null if base is not null; otherwise String.class.

public interface IndexedRecord
extends Record, List, Serializable

Implements: Record, java.util.List<E>, java.io.Serializable

IndexedRecord java.util.List Collection
   since 0.8

IndexedRecord represents an ordered collection of record elements based on the java.util.List interface. This interface allows a client to access elements by their integer index (position in the list) and search for elements in the List.

Since:
   0.8
Author:
   Rahul Sharma

javax.persistence Annotation Type Inheritance

@Target(value=TYPE)  
@Retention(value=RUNTIME)  
public @interface Inheritance

**Implements:** Annotation  
@Target(value=TYPE)  
@Retention(value=RUNTIME)

@Target(value=TYPE)  
@Retention(value=RUNTIME)

@Entity  
@Inheritance(strategy=JOINED)  
public class Customer { ... }

@Entity  
public class ValuedCustomer extends Customer { ... }

**since**  
Java Persistence 1.0  

Defines the inheritance strategy to be used for an entity class hierarchy. It is specified on the entity class that is the root of the entity class hierarchy.

Example:

@Entity  
@Inheritance(strategy=JOINED)  
public class Customer { ... }

@Entity  
public class ValuedCustomer extends Customer { ... }

**Since:**  
Java Persistence 1.0
abstract public InheritanceType strategy()

**strategy**

public abstract InheritanceType strategy

The strategy to be used

**Default:**

Enum Constant Detail

SINGLE_TABLE

public static final `InheritanceType` SINGLE_TABLE

A single table per class hierarchy

---

TABLE_PER_CLASS

public static final `InheritanceType` TABLE_PER_CLASS

A table per concrete entity class

---
public static final InheritanceType JOINED

A strategy in which fields that are specific to a subclass are mapped to a separate table than the fields that are common to the parent class, and a join is performed to instantiate the subclass.

Method Detail

final public static InheritanceType[] values()

values

public static final InheritanceType[] values()

    Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

    for(InheritanceType c : InheritanceType.values())
        System.out.println(c);

    Returns:
    an array containing the constants of this enum type, in the order they're declared

    public static InheritanceType valueOf(String name)

valueOf

public static InheritanceType valueOf(String name)

    Returns the enum constant of this type with the specified name. The
string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**

name - the name of the enum constant to be returned.

**Returns:**
the enum constant with the specified name

**Throws:**

IllegalArgumentException - if this enum type has no constant with the specified name

getAsObject

**Description copied from interface: Converter**

Convert the specified string value, which is associated with the specified UIComponent, into a model data object that is appropriate for being stored during the Apply Request Values phase of the request processing lifecycle.

**Specified by:** getAsObject in interface Converter

**Parameters:**
- context - FacesContext for the request being processed
- component - UIComponent with which this model object value is associated
- value - String value to be converted (may be null)

**Returns:**
- null if the value to convert is null, otherwise the result of the
public String getAsString(FacesContext context, UIComponent component, Object value)

Throws converterException - if conversion cannot be successfully performed

Throws NullPointerException - if context or component is null

Description copied from interface: Converter

Convert the specified model object value, which is associated with the specified UIComponent, into a String that is suitable for being included in the response generated during the Render Response phase of the request processing lifecycle.

Specified by: getAsString in interface Converter

Parameters:
context - FacesContext for the request being processed
component - UIComponent with which this model object value is associated
value - Model object value to be converted (may be null)

Returns:
a zero-length String if value is null, otherwise the result of the conversion

Throws:
converterException - if conversion cannot be successfully performed
performed

`NullPointerException` - if context or component is null

javax.resource.cci Interface Interaction

public interface Interaction

javax.resource.cci.Interaction EIS Interaction EIS

- Record Record InteractionSpec execute
  InteractionSpec EIS Record
- Record InteractionSpec execute InteractionSpec
  EIS Record

Interaction Connection Connection close Interaction
Interaction Connection

version 0.8
since 0.8
See also java.sql.ResultSet

The javax.resource.cci.Interaction enables a component to execute EIS functions. An Interaction instance supports the following ways of interacting with an EIS instance:

- execute method that takes an input Record, output Record and an InteractionSpec. This method executes the EIS function represented by the InteractionSpec and updates the output Record
- execute method that takes an input Record and an InteractionSpec. This method implementation executes the EIS function represented by the InteractionSpec and produces the output Record as a return value.

An Interaction instance is created from a Connection and is required to maintain its association with the Connection instance. The close method releases all resources maintained by the resource adapter for the Interaction. The close of an Interaction instance should not close the associated Connection instance.
Since: 0.8
Version: 0.8
Author: Rahul Sharma

### Method Detail

public void close() throws ResourceException
Interaction Interaction  Connection
**Interaction**

Throws [ResourceException](#): Interaction Interaction close

---

**close**

```java
void close() throws ResourceException
```

Closes the current Interaction and release all the resources held for this instance by the resource adapter. The close of an Interaction instance does not close the associated Connection instance. It is recommended that Interaction instances be closed explicitly to free any held resources.

**Throws:**

- [ResourceException](#) - Failed to close the Interaction instance. Invoking close on an already closed Interaction should also throw this exception.

---

**public Connection getConnection()**

**Returns:**

- Connection instance associated with the Interaction

---

**public boolean execute(InteractionSpec ispec, Record**
input, Record output) throws ResourceException

InteractionSpec Record Record

ispec EIS / InteractionSpec
input Record
output Record
return EIS Record true false

Throws:
- EIS
- InteractionSpec
- Record
- Interaction

throws NotSupportedException:

execute

boolean execute(InteractionSpec ispec,
                    Record input,
                    Record output)
    throws ResourceException

Executes an interaction represented by the InteractionSpec. This
form of invocation takes an input Record and updates the output
Record.

Parameters:
- ispec - InteractionSpec representing a target EIS data/function
  module
- input - Input Record
- output - Output Record

Returns:
- true if execution of the EIS function has been successful and
  output Record has been updated; false otherwise

Throws:
- ResourceException - Exception if execute operation fails.
Examples of error cases are:
- Resource adapter internal, EIS-specific or communication
error
• Invalid specification of an InteractionSpec, input or output record structure
• Errors in use of input or output Record
• Invalid connection associated with this Interaction

NotSupportedException - Operation not supported

public Record execute(InteractionSpec ispec, Record input) throws ResourceException

InteractionSpec Interaction Record

Record

execute

Record execute(InteractionSpec ispec, Record input)

throws ResourceException

Executes an interaction represented by the InteractionSpec. This form of invocation takes an input Record and returns an output Record if the execution of the Interaction has been successfull.

Parameters:
    ispec - InteractionSpec representing a target EIS data/function module
    input - Input Record
Returns:
output Record if execution of the EIS function has been successful; null otherwise

Throws:
ResourceException - Exception if execute operation fails.

Examples of error cases are:
- Resource adapter internal, EIS-specific or communication error
- Invalid specification of an InteractionSpec or input record structure
- Errors in use of input Record or creation of an output Record
- Invalid connection associated with this Interaction

NotSupportedException - Operation not supported

---

public ResourceWarning getWarnings() throws ResourceException

Interaction ResourceWarning

return ResourceWarning

Throws ResourceException: Interaction ResourceWarning

---

getWarnings

ResourceWarning getWarnings() throws ResourceException

Gets the first ResourceWarning from the chain of warnings associated with this Interaction instance.

Returns:
ResourceWarning at top of the warning chain

Throws:
ResourceException - Failed to get ResourceWarnings associated with Interaction
public void clearWarnings() throws ResourceException
Interaction Interaction getWarnings
null

Throws ResourceException: Interaction ResourceWarning

clearWarnings

void clearWarnings()
throws ResourceException

Clears all the warning reported by this Interaction instance. After a call to this method, the method getWarnings will return null until a new warning is reported for this Interaction.

Throws:
ResourceException - Failed to clear ResourceWarnings associated with Interaction
javax.resource.cci  Interface InteractionSpec

All Superinterfaces:
  Serializable

public interface InteractionSpec
extends Serializable

Implements: java.io.Serializable

InteractionSpec  EIS Interaction  InteractionSpec  EIS

CCI  InteractionSpec  EIS InteractionSpec

InteractionSpec  Java Bean

  • FunctionNameEIS
  • InteractionVerbEIS  SYNC_SENDSYNC_SEND_RECEIVE
  • ExecutionTimeoutInteraction  EIS

Interaction  ResultSet

  • FetchSize
  • FetchDirection
  • MaxFieldSize
  • ResultSetType
  • ResultSetConcurrency

InteractionSpec  CCI  EIS  CCI

InteractionSpec  JavaBean  InteractionSpec
InteractionSpec  java.io.Serializable

  version  0.8
An InteractionSpec holds properties for driving an Interaction with an EIS instance. An InteractionSpec is used by an Interaction to execute the specified function on an underlying EIS.

The CCI specification defines a set of standard properties for an InteractionSpec. An InteractionSpec implementation is not required to support a standard property if that property does not apply to its underlying EIS.

The InteractionSpec implementation class must provide getter and setter methods for each of its supported properties. The getter and setter methods convention should be based on the Java Beans design pattern.

The standard properties are as follows:

- FunctionName: name of an EIS function
- InteractionVerb: mode of interaction with an EIS instance: SYNC_SEND, SYNC_SEND_RECEIVE, SYNC_RECEIVE
- ExecutionTimeout: the number of milliseconds an Interaction will wait for an EIS to execute the specified function

The following standard properties are used to give hints to an Interaction instance about the ResultSet requirements:

- FetchSize
- FetchDirection
- MaxFieldSize
- ResultSetType
- ResultSetConcurrency

A CCI implementation can provide additional properties beyond that described in the InteractionSpec interface. Note that the format and type of the additional properties is specific to an EIS and is outside the scope of the CCI specification.
It is required that the InteractionSpec interface be implemented as a JavaBean for the toolability support. The properties on the InteractionSpec implementation class should be defined through the getter and setter methods pattern. An implementation class for InteractionSpec interface is required to implement the java.io.Serializable interface.

<td>Interaction Verb type: The execution of an Interaction sends a request to the EIS instance and receives response synchronously.</td>
</tr>
</tbody>
</table>

### Field Detail

SYNC_SEND
static final int `SYNC_SEND`

Interaction Verb type: The execution of an Interaction does only a send to the target EIS instance. The input record is sent to the EIS instance without any synchronous response in terms of an output Record or ResultSet.

See Also:
Constant Field Values

---------

SYNC_SEND_RECEIVE

static final int `SYNC_SEND_RECEIVE`

Interaction Verb type: The execution of an Interaction sends a request to the EIS instance and receives response synchronously. The input record is sent to the EIS instance with the output received either as Record or CCIResultSet.

See Also:
Constant Field Values

---------

SYNC_RECEIVE

static final int `SYNC_RECEIVE`

The execution of an Interaction results in a synchronous receive of an output Record. An example is: a session bean gets a method invocation and it uses this SEND_RECEIVE form of interaction to retrieve messages that have been delivered to a message queue.

javax.xml.registry.infomodel  Interface InternationalString

public interface InternationalString

Locale  String  String  String  InternationalString
LocalizedString  Collection  String  Locale
InternationalString  set/get  InternationalString  String

See also  javax.xml.registry.infomodel.LocalizedString

This interface represents a String that has been internationalized into several Locales. This interface is used as a replacement for the String type whenever a String attribute needs to be I18N capable. An instance of the InternationalString interface composes within it a Collection of LocalizedString instances, where each String is specific to a particular Locale. The InternationalString interface provides set/get methods for adding or getting locale specific String values for the InternationalString instance.

**Collection**

Returns the LocalizedStrings associated with this object.

**String**

- **getValue()**
  
  Gets the String value for the Locale returned by `Locale.getDefault()`.

- **getValue(Locale locale)**
  
  Gets the String value for the specified Locale.

- **removeLocalizedString(LocalizedString localizedString)**
  
  Removes a LocalizedString from this object.

- **removeLocalizedStrings(Collection localizedStrings)**
  
  Removes specified LocalizedStrings to this object.

- **setValue(Locale locale, String value)**
  
  Sets the String value for the specified Locale.

- **setValue(String value)**
  
  Sets the String value for the Locale returned by `Locale.getDefault()`.

---

**Method Detail**

**public String getValue() throws JAXRException**

Locale.getDefault()  Locale  String

0

    return Locale.getDefault()  Locale  String

Throws JAXRException: JAXR

**getValue**

String getValue() throws JAXRException

Gets the String value for the Locale returned by `Locale.getDefault()`.
public String getValue(java.util.Locale locale) throws JAXRException
Locale String null

locale	Locale
return Locale String
Throws JAXRException: JAXR

getValue

String getValue(Locale locale)
throws JAXRException

Gets the String value for the specified Locale. Return null if no locale specific value is found for the specified locale.

Capability Level: 0

Parameters:
locale - The Locale for the desired value

Returns:
the String value for the specified Locale

Throws:
JAXRException - If the JAXR provider encounters an internal error
public void setValue(String value) throws JAXRException
Locale.getDefault()  Locale  String

Sets the String value for the Locale returned by Locale.getDefault().

**Capability Level:** 0

**Parameters:**
value - the String value for the Locale returned by Locale.getDefault()

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

-------------

public void setValue(java.util.Locale locale, String value)
throws JAXRException
Locale  String

locale
value

**Throws**  
JAXRException:  JAXR
setValue

void setValue(Locale locale, String value) throws JAXRException

Sets the String value for the specified Locale.

**Capability Level:** 0

**Parameters:**
- locale - The locale for this value being set
- value - The value being set

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

public void addLocalizedString(LocalizedString localizedString) throws JAXRException

LocalizedString

0

LocalizedString

Throws JAXRException: JAXR

addLocalizedString

void addLocalizedString(LocalizedString localizedString) throws JAXRException

Adds a LocalizedString to this object.

**Capability Level:** 0

**Parameters:**
- localizedString - the LocalizedString being added to this object
Throws:

`JAXRException` - If the JAXR provider encounters an internal error

```
public void addLocalizedStrings(java.util.Collection<E> localizedStrings) throws JAXRException
LocalizedString

@localizedStrings
LocalizedString Collection
@throws JAXRException: JAXR
```

`addLocalizedStrings`

```
void addLocalizedStrings(Collection localizedStrings)
throws JAXRException

Adds many LocalizedStrings to this object.

Capability Level: 0

Parameters:

`localizedStrings` - the Collection of LocalizedStrings being added to this object

Throws:

`JAXRException` - If the JAXR provider encounters an internal error
```

```
public void removeLocalizedString(LocalizedString localizedString) throws JAXRException
LocalizedString

0
```
removeLocalizedString

void removeLocalizedString(LocalizedString localizedString)
throws JAXRException

Removes a LocalizedString from this object.

Capability Level: 0

Parameters:
 localizedString - the LocalizedString being removed from this object

Throws:
 JAXRException - If the JAXR provider encounters an internal error

---

public void removeLocalizedStrings(java.util.Collection<E> localizedStrings) throws JAXRException

Removes specified LocalizedStrings to this object.
public LocalizedString getLocalizedString(java.util.Locale locale, String charsetName) throws JAXRException

Locale charsetName LocalizedString

Throws: JAXRException: JAXR

getLocalizedString

LocalizedString getLocalizedString(Locale locale, String charsetName) throws JAXRException

Gets the LocalizedString for the specified Locale and charsetName.

Capability Level: 0

Parameters:
locale - The locale for the desired LocalizedStrings
charsetName - The character set name for the desired LocalizedStrings

Returns:
the LocalizedString that matches specified locale and character
Throws: `JAXRException` - If the JAXR provider encounters an internal error.

```java
public java.util.Collection<E> getLocalizedStrings() throws JAXRException
LocalizedString

0

return LocalizedString CollectionCollection null
Throws `JAXRException`: JAXR
See also `javax.xml.registry.infomodel.LocalizedString`

getLocalizedStrings

`Collection` getLocalizedStrings() throws `JAXRException`

Returns the LocalizedStrings associated with this object.

**Capability Level: 0**

**Returns:**
Collection of LocalizedString instances. The Collection may be empty but not null.

**Throws:**
`JAXRException` - If the JAXR provider encounters an internal error.

**See Also:**
`LocalizedString`

javax.mail.internet Class InternetAddress

java.lang.Object  
  javax.mail.Address  
  javax.mail.internet.InternetAddress

All Implemented Interfaces: 
Serializable, Cloneable

public class InternetAddress
  extends Address
  implements Cloneable

Extends: Address 
Implements: Cloneable

RFC822 Internet "user@host.domain" "Personal Name"

This class represents an Internet email address using the syntax of RFC822. Typical address syntax is of the form "user@host.domain" or "Personal Name".

void validate()
    Validate that this address conforms to the syntax rules of RFC 822.

Methods inherited from class java.lang.Object
final, getClass, notify, notifyAll, wait, wait, wait

Field Detail

address
protected String address

personal
protected String personal
    The personal name.

encodedPersonal
protected String encodedPersonal
    The RFC 2047 encoded version of the personal name.
    This field and the personal field track each other, so if a subclass sets one of these fields directly, it should set the other to null, so that it is suitably recomputed.
public InternetAddress()

Default constructor.

public InternetAddress(String address) throws AddressException

Constructor.

Parse the given string and create an InternetAddress. See the parse method for details of the parsing. The address is parsed using "strict" parsing. This constructor does not perform the additional syntax checks that the InternetAddress(String address, boolean strict) constructor does when strict is true. This constructor is equivalent
public InternetAddress(String address, boolean strict)
throws AddressException

Parameters:
address - the address in RFC822 format
strict - enforce RFC822 syntax

Throws:
AddressException - if the parse failed

Since:
JavaMail 1.3

Parse the given string and create an InternetAddress. If strict is false, the detailed syntax of the address isn't checked.

public InternetAddress(String address, String personal)
throws java.io.UnsupportedEncodingException

Parameters:
address - the address in RFC822 format
personal - the personal part of the address

Since:
JavaMail 1.3
InternetAddress

public InternetAddress(String address, String personal)
throws UnsupportedEncodingException

Construct an InternetAddress given the address and personal name. The address is assumed to be a syntactically valid RFC822 address.

Parameters:
address - the address in RFC822 format
personal - the personal name

Throws:
UnsupportedEncodingException

public InternetAddress(String address, String personal, String charset)
throws java.io.UnsupportedEncodingException

Construct an InternetAddress given the address and personal name. The address is assumed to be a syntactically valid RFC822 address.
Parameters:
  address - the address in RFC822 format
  personal - the personal name
  charset - the MIME charset for the name

Throws:
  UnsupportedEncodingException

Method Detail

public Object clone()

InternetAddress

since JavaMail 1.2

clone

public Object clone()

Return a copy of this InternetAddress object.

Overrides:
  clone in class Object

Since:
  JavaMail 1.2

public String getType()

InternetAddress "rfc822"

getype

public String getType()

Return the type of this address. The type of an InternetAddress is "rfc822".
**setAddress**

```java
public void setAddress(String address)
```

*address*

**setAddress**

```java
public void setAddress(String address)
```

Set the email address.

**Parameters:**

- `address` - email address

**setPersonal**

```java
public void setPersonal(String name, String charset)
```

**Throws**

**See also**

- setPersonal(String)

**setPersonal**

```java
public void setPersonal(String name, String charset)
```
Set the personal name. If the name contains non US-ASCII characters, then the name will be encoded using the specified charset as per RFC 2047. If the name contains only US-ASCII characters, no encoding is done and the name is used as is.

Parameters:
- name - personal name
- charset - MIME charset to be used to encode the name as per RFC 2047

Throws:
- UnsupportedEncodingException - if the charset encoding fails.

See Also:
- setPersonal(String)

---

```java
public void setPersonal(String name) throws java.io.UnsupportedEncodingException
```

name

Throws java.io.UnsupportedEncodingException:

See also setPersonal(String name, String charset)

---

```java
public void setPersonal(String name)
```

Set the personal name. If the name contains non US-ASCII characters, then the name will be encoded using the platform's default charset. If the name contains only US-ASCII characters, no encoding is done and the name is used as is.

Parameters:
- name - personal name
Throws:
UnsupportedEncodingException - if the charset encoding fails.

See Also:
setPersonal(String name, String charset)

public String getAddress()

    return

getAddress

public String getAddress()

    Get the email address.

    Returns:
    email address

public String getPersonal()

RFC 2047  Unicode

    return

getPersonal

public String getPersonal()

    Get the personal name. If the name is encoded as per RFC 2047, it is decoded and converted into Unicode. If the decoding or conversion fails, the raw data is returned as is.

    Returns:
    personal name
public String toString()
RFC 822 / RFC 2047  US-ASCII

    return

**toString**

```java
public String toString()
```

Convert this address into a RFC 822 / RFC 2047 encoded address. The resulting string contains only US-ASCII characters, and hence is mail-safe.

**Specified by:**
```
toString in class Address
```

**Returns:**
```
possibly encoded address string
```

---

public String toUnicodeString()
Unicode RFC 822

    return
    since     Unicode
              JavaMail 1.2

**toUnicodeString**

```java
public String toUnicodeString()
```

Returns a properly formatted address (RFC 822 syntax) of Unicode characters.

**Returns:**
```
Unicode address string
```

**Since:**
```
JavaMail 1.2
```
public boolean equals(Object a)

equals

public boolean equals(Object a)

The equality operator.

Specified by:

equals in class Address

Parameters:

a - Address object

public int hashCode()

hashCode

public int hashCode()

Compute a hash code for the address.

Overrides:

hashCode in class Object

public static String toString(Address[] addresses)

InternetAddress US-ASCII

addresses InternetAddress

Throws

ClassCastException,; InternetAddress

return

RuntimeException
public static String toString(Address[] addresses)

Convert the given array of InternetAddress objects into a comma separated sequence of address strings. The resulting string contains only US-ASCII characters, and hence is mail-safe.

Parameters:
addresses - array of InternetAddress objects

Returns:
comma separated string of addresses

Throws:
ClassCastException, - if any address object in the given array is not an InternetAddress object. Note that this is a RuntimeException.

public static String toString(Address[] addresses, int used)

Convert the given array of InternetAddress objects into a comma separated sequence of address strings. The resulting string contains only US-ASCII characters, and hence is mail-safe.

Parameters:
addresses - array of InternetAddress objects
used - index of the last used address

Returns:
comma separated string of addresses

Throws:
ClassCastException, - if any address object in the given array is not an InternetAddress object. Note that this is a RuntimeException.
separated sequence of address strings. The resulting string contains only US-ASCII characters, and hence is mail-safe.

The 'used' parameter specifies the number of character positions already taken up in the field into which the resulting address sequence string is to be inserted. It is used to determine the line-break positions in the resulting address sequence string.

**Parameters:**
- addresses - array of InternetAddress objects
- used - number of character positions already used, in the field into which the address string is to be inserted.

**Returns:**
- comma separated string of addresses

**Throws:**
- ClassCastException, - if any address object in the given array is not an InternetAddress object. Note that this is a RuntimeException.

```java
public static InternetAddress getLocalAddress(Session session)

InternetAddress "mail.from" "mail.user"
"mail.host" "user.name"
InetAddress.getLocalHost null
    session               Session
    return

getLocalAddress

public static InternetAddress getLocalAddress(Session session)

Return an InternetAddress object representing the current user. The entire email address may be specified in the "mail.from" property. If not set, the "mail.user" and "mail.host" properties are tried. If those are not set, the "user.name" property and InetAddress.getLocalHost method are tried. Security exceptions that may occur while
accessing this information are ignored. If it is not possible to determine an email address, null is returned.

**Parameters:**
- session - Session object used for property lookup

**Returns:**
- current user’s email address

---

```java
public static InternetAddress[] parse(String addresslist)
throws AddressException
```

**InternetAddress RFC822**

**addresslist**

`return` - return InternetAddress

**Throws:**
- `AddressException`:

`parse`

---

```java
public static InternetAddress[] parse(String addresslist)
throws AddressException
```

**Parse** the given comma separated sequence of addresses into InternetAddress objects. Addresses must follow RFC822 syntax.

**Parameters:**
- addresslist - comma separated address strings

**Returns:**
- array of InternetAddress objects

**Throws:**
- `AddressException` - if the parse failed

---

```java
public static InternetAddress[] parse(String addresslist, boolean strict)
throws AddressException
```

**InternetAddress**

`strict` - false

`trueRFC822` - stri
Parse the given sequence of addresses into InternetAddress objects. If strict is false, simple email addresses separated by spaces are also allowed. If strict is true, many (but not all) of the RFC822 syntax rules are enforced. In particular, even if strict is true, addresses composed of simple names (with no "@domain" part) are allowed. Such "illegal" addresses are not uncommon in real messages.

Non-strict parsing is typically used when parsing a list of mail addresses entered by a human. Strict parsing is typically used when parsing address headers in mail messages.

**Parameters:**
- addresslist - comma separated address strings
- strict - enforce RFC822 syntax

**Returns:**
- array of InternetAddress objects

**Throws:**
- AddressException - if the parse failed
public static InternetAddress[] parseHeader(String addresslist, boolean strict) throws AddressException

Parse the given sequence of addresses into InternetAddress objects. If strict is false, the full syntax rules for individual addresses are not enforced. If strict is true, many (but not all) of the RFC822 syntax rules are enforced.

To better support the range of "invalid" addresses seen in real messages, this method enforces fewer syntax rules than the parse method when the strict flag is false and enforces more rules when the strict flag is true. If the strict flag is false and the parse is successful in separating out an email address or addresses, the syntax of the addresses themselves is not checked.

Parameters:
  addresslist - comma separated address strings
  strict - enforce RFC822 syntax

Returns:
  array of InternetAddress objects

Throws:
public void validate() throws AddressException
RFC 822

Throws
AddressException:
since
JavaMail 1.3

validate

public void validate()
throws AddressException

Validate that this address conforms to the syntax rules of RFC 822. The current implementation checks many, but not all, syntax rules. Note that even though the syntax of the address may be correct, there's no guarantee that a mailbox of that name exists.

Throws:
AddressException - if the address isn't valid.
Since:
JavaMail 1.3

public boolean isGroup()
RFC 822  RFC 822

return true
since
JavaMail 1.3

isGroup
Indicates whether this address is an RFC 822 group address. Note that a group address is different than the mailing list addresses supported by most mail servers. Group addresses are rarely used; see RFC 822 for details.

**Returns:**
true if this address represents a group

**Since:**
JavaMail 1.3

```java
public InternetAddress[] getGroup(boolean strict) throws AddressException
0 1 null
parseHeader
    return
    internetAddress null
    throws AddressException:
    since JavaMail 1.3
```

PS:
InternetHeaders is a utility class that manages RFC822 style headers. Given an RFC822 format message stream, it reads lines until the blank line that indicates end of header. The input stream is positioned at the start of the body. The lines are stored within the object and can be extracted as either Strings or Header objects.

This class is mostly intended for service providers. MimeMessage and MimeBody use this class for holding their headers.

A note on RFC822 and MIME headers
RFC822 and MIME header fields must contain only US-ASCII characters. If a header contains non US-ASCII characters, it must be encoded as per the rules in RFC 2047. The MimeUtility class provided in this package can be used to to achieve this. Callers of the setHeader, addHeader, and addHeaderLine methods are responsible for enforcing the MIME requirements for the specified headers. In addition, these header fields must be folded (wrapped) before being sent if they exceed the line length limitation for the transport (1000 bytes for SMTP). Received headers may have been folded. The application is responsible for folding and unfolding headers as appropriate.

Field Detail

headers

protected `List` `headers`

The actual list of Headers, including placeholder entries. Placeholder entries are Headers with a null value and are never seen by clients of the InternetHeaders class. Placeholder entries are used to keep track of the preferred order of headers. Headers are never actually removed from the list, they're converted into placeholder entries. New headers are added after existing headers of the same name (or before in the case of `Received` and `Return-Path` headers). If no existing header or placeholder for the header is found, new headers are added after the special placeholder with the name `"."`.

Since:
JavaMail 1.4

Constructor Detail

`public InternetHeaders()`

`InternetHeaders`

`public InternetHeaders()`

Create an empty `InternetHeaders` object. Placeholder entries are
public InternetHeaders(java.io.InputStream is) throws MessagingException

RFC822

BufferedInputStream

\[is\] RFC822

InternetHeaders

public InternetHeaders(InputStream is) throws MessagingException

Read and parse the given RFC822 message stream till the blank line separating the header from the body. The input stream is left positioned at the start of the body. The header lines are stored internally.

For efficiency, wrap a BufferedInputStream around the actual input stream and pass it as the parameter.

No placeholder entries are inserted; the original order of the headers is preserved.

Parameters:
  \textit{is} - RFC822 input stream

Throws:
  MessagingException

Method Detail
public void load(InputStream is) throws MessagingException
RFC822 InternetHeaders

InternetHeaders

load

public void load(InputStream is)
throws MessagingException

Read and parse the given RFC822 message stream till the blank line separating the header from the body. Store the header lines inside this InternetHeaders object. The order of header lines is preserved.

Note that the header lines are added into this InternetHeaders object, so any existing headers in this object will not be affected. Headers are added to the end of the existing list of headers, in order.

Parameters:
    is - RFC822 input stream

Throws:
    MessagingException

public String[] getHeader(String name)
String

getHeader

public String[] getHeader(String name)
Return all the values for the specified header. The values are String objects. Returns null if no headers with the specified name exist.

**Parameters:**
- `name` - header name

**Returns:**
- array of header values, or null if none

```
public String getHeader(String name, String delimiter)
```

Get all the headers for this header name, returned as a single String, with headers separated by the delimiter. If the delimiter is null, only the first header is returned. Returns null if no headers with the specified name exist.

**Parameters:**
- `name` - header name
- `delimiter` - delimiter

**Returns:**
- the value fields for all headers with this name, or null if none

```
public void setHeader(String name, String value)
```

RFC822 US-ASCII
setHeader

public void setHeader(String name, String value)

Change the first header line that matches name to have value, adding a new header if no existing header matches. Remove all matching headers but the first.

Note that RFC822 headers can only contain US-ASCII characters

Parameters:
  name - header name
  value - header value

addHeader

public void addHeader(String name, String value)

Add a header with the specified name and value to the header list.
The current implementation knows about the preferred order of most well-known headers and will insert headers in that order. In addition, it knows that Received headers should be inserted in reverse order (newest before oldest), and that they should appear at the beginning of the headers, preceded only by a possible Return-Path header.

Note that RFC822 headers can only contain US-ASCII characters.

**Parameters:**
- name - header name
- value - header value

```java
public void removeHeader(String name)
```

**removeHeader**

```java
public void removeHeader(String name)
```

Remove all header entries that match the given name

**Parameters:**
- name - header name

```java
public java.util.Enumeration<E> getAllHeaders()
```

**getAllHeaders**

```java
public Enumeration getAllHeaders()
```

Return all the headers as an Enumeration of `Header` objects.
Returns:
Header objects

public java.util.Enumeration<E>
getMatchingHeaders(String[] names)

javax.mail.Header
return Header

getMatchingHeaders

public Enumeration getMatchingHeaders(String[] names)

Return all matching Header objects.

Returns:
matching Header objects

public java.util.Enumeration<E>
getNonMatchingHeaders(String[] names)

javax.mail.Header
return Header

getNonMatchingHeaders

public Enumeration getNonMatchingHeaders(String[] names)

Return all non-matching Header objects.

Returns:
non-matching Header objects

public void addHeaderLine(String line)
addHeaderLine

public void addHeaderLine(String line)

Add an RFC822 header line to the header store. If the line starts with a space or tab (a continuation line), add it to the last header line in the list. Otherwise, append the new header line to the list.

Note that RFC822 headers can only contain US-ASCII characters

Parameters:
    line - raw RFC822 header line

public java.utilEnumeration<String> getAllHeaderLines()

Return all the header lines as an Enumeration of Strings.

getAllHeaderLines

public Enumeration getAllHeaderLines()

getMatchingHeaderLines(String[] names)

String
getMatchingHeaderLines

public Enumeration getMatchingHeaderLines(String[] names)

    Return all matching header lines as an Enumeration of Strings.

getNonMatchingHeaderLines

public java.util Enumeration<E>
getNonMatchingHeaderLines(String[] names)

getNonMatchingHeaderLines

public Enumeration getNonMatchingHeaderLines(String[] names)

    Return all non-matching header lines

PS :
An individual internet header. This class is only used by subclasses of InternetHeaders.

An InternetHeader object with a null value is used as a placeholder for headers of that name, to preserve the order of headers. A placeholder InternetHeader object with a name of "::" marks the location in the list of headers where new headers are added by default.

Since:
JavaMail 1.4

reason
errorCode

InvalidClientIDException

public InvalidClientIDException(String reason, String errorCode)

Constructs an InvalidClientIDException with the specified reason
and error code.

**Parameters:**
- reason - a description of the exception
- errorCode - a string specifying the vendor-specific error code

```java
public InvalidClientIDException(String reason)
```

InvalidClientIDException

```java
public InvalidClientIDException(String reason)
```

Constructs an InvalidClientIDException with the specified reason. The error code defaults to null.

**Parameters:**
- reason - a description of the exception

Create an InvalidPropertyException.

public InvalidPropertyException(String message)
InvalidPropertyException

message

InvalidPropertyException

public InvalidPropertyException(String message)

Create an InvalidPropertyException.

Parameters:
message - a description of the exception

InvalidPropertyException

public InvalidPropertyException(Throwable cause)
cause throwable

cause

InvalidPropertyException

public InvalidPropertyException(Throwable cause)

Constructs a new throwable with the specified cause.

Parameters:
cause - a chained exception of type Throwable.

InvalidPropertyException

public InvalidPropertyException(String message,
InvalidPropertyException

public InvalidPropertyException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public InvalidPropertyException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.
public void setInvalidPropertyDescriptors(PropertyDescriptor[] invalidProperties)

Set a list of invalid properties.

public java.beans.PropertyDescriptor[] getInvalidPropertyDescriptors()

Get the list of invalid properties.

public InvalidRequestException()
        Throwable JAXRException

InvalidRequestException

public InvalidRequestException()

    Constructs a JAXRException object with no reason or embedded Throwable.

public InvalidRequestException(String reason)

    JAXRException String reason

InvalidRequestException

public InvalidRequestException(String reason)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown.

    Parameters:
        reason - a description of what caused the exception

public InvalidRequestException(String reason, Throwable cause)

    JAXRException String Throwable
    Throwable reason
    cause JAXRException Throwable
public InvalidRequestException(String reason, Throwable cause)

Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

Parameters:
reason - a description of what caused the exception
cause - a Throwable object that is to be embedded in this JAXRException object

public InvalidRequestException(Throwable cause)

Throwable JAXRException
cause Exception Throwable

InvalidRequestException

public InvalidRequestException(Throwable cause)

Constructs a JAXRException object initialized with the given Throwable object.

Parameters:
cause - the Throwable that caused this Exception

public InvalidTransactionException(String msg)
javax.interceptor  Interface InvocationContext

public interface InvocationContext

AroundInvoke  Interceptor

Context information passed to AroundInvoke and Interceptor-class lifecycle callback methods.

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
</table>
| Map<String, Object>       | **getContextData()**  
|                           | Returns the context data associated with this invocation or lifecycle callback. |
| Method                    | **getMethod()**  
|                           | Returns the method of the bean class for which the interceptor was invoked. |
| Object[]                  | **getParameters()**  
|                           | Returns the parameters that will be used to invoke the business method. |
| Object                    | **getTarget()**  
|                           | Returns the target instance. |
| Object                    | **proceed()**  
|                           | Proceed to the next entry in the interceptor chain. |
| void                      | **setParameters(Object[] params)**  
|                           | Sets the parameters that will be used to invoke the business method. |

Method Detail
public Object getTarget()

getTarget

Object getTarget()

Returns the target instance.

public Method getMethod()
Interceptor Bean AroundInvoke Bean
null

getMethod

Method getMethod()

Returns the method of the bean class for which the interceptor was invoked. For AroundInvoke methods, this is the business method on the bean class. For lifecycle callback methods, returns null.

public Object[] getParameters()
setParameters getParameters()

Throws IllegalStateException:

getParameters

Object[] getParameters()

Returns the parameters that will be used to invoke the business method. If setParameters has been called, getParameters() returns the values to which the parameters have been set.
Throws:

- **IllegalStateException** - if invoked within a lifecycle callback method.

---

public void setParameters(Object[] params)

**Throws**

- IllegalStateException
- IllegalArgumentException

### setParameters

Sets the parameters that will be used to invoke the business method.

**Throws:**

- **IllegalStateException** - if invoked within a lifecycle callback method.
- **IllegalArgumentException** - if the parameter types do not match the types for the business method, or the number of parameters supplied does not equal the number of parameters for the business method.

---

public java.util.Map<K, V> getContextData()

**Map**

### getContextData

Returns the context data associated with this invocation or lifecycle callback. If there is no context data, an empty Map object will be returned.
public Object proceed() throws Exception
Interceptor proceed  void proceed
null

proceed

**Object**  **proceed()**

throws  **Exception**

Proceed to the next entry in the interceptor chain. The proceed method returns the result of the next method invoked. If the method returns void, proceed returns null.

**Throws:**  **Exception**
javax.servlet.jsp.tagext  Interface IterationTag

All Superinterfaces:
   JspTag, Tag

All Known Subinterfaces:
   BodyTag

All Known Implementing Classes:
   AttributeTag, BodyTagSupport, ConverterELTag, ConverterTag, FacetTag, TagSupport, UICOMPONENTBODYTag, UICOMPONENTCLASSTAGBase, UICOMPONENTELTag, UICOMPONENTTag, ValidatorELTag, ValidatorTag

public interface IterationTag
   extends Tag

Implements: Tag
Implemented by: BodyTag, TagSupport

IterationTag Tag
   doStartTag() doEndTag() Tag IterationTag
      doAfterBody()

   doAfterBody() doAfterBody()
   IterationTag.EVAL_BODY_AGAIN doAfterBody()
   Tag.SKIP_BODY doEndTag()

   Tag
   doAfterBody()

   doStartTag()BODY doAfterBody() TryCatchFinally
The `IterationTag` interface extends `Tag` by defining one additional method that controls the reevaluation of its body.

A tag handler that implements `IterationTag` is treated as one that implements `Tag` regarding the `doStartTag()` and `doEndTag()` methods. `IterationTag` provides a new method: `doAfterBody()`.

The `doAfterBody()` method is invoked after every body evaluation to control whether the body will be reevaluated or not. If `doAfterBody()` returns `IterationTag.EVAL_BODY_AGAIN`, then the body will be reevaluated. If `doAfterBody()` returns `Tag.SKIP_BODY`, then the body will be skipped and `doEndTag()` will be evaluated instead.

**Properties** There are no new properties in addition to those in `Tag`.

**Methods** There is one new methods: `doAfterBody()`.

**Lifecycle**

Lifecycle details are described by the transition diagram below. Exceptions that are thrown during the computation of `doStartTag()`, `BODY` and `doAfterBody()` interrupt the execution sequence and are propagated up the stack, unless the tag handler implements the `TryCatchFinally` interface; see that interface for details.
Empty and Non-Empty Action

If the TagLibraryDescriptor file indicates that the action must always have an empty element body, by a `<body-content>` entry of "empty", then the `doStartTag()` method must return `SKIP_BODY`.

Note that which methods are invoked after the `doStartTag()` depends on both the return value and on if the custom action element is empty or not in the JSP page, not on how it's declared in the TLD.

If `SKIP_BODY` is returned the body is not evaluated, and then `doEndTag()` is invoked.

If `EVAL_BODY_INCLUDE` is returned, and the custom action element is not empty, the body is evaluated and "passed through" to the current out, then `doAfterBody()` is invoked and, after zero or more iterations, `doEndTag()` is invoked.

---

**Field Summary**

<table>
<thead>
<tr>
<th>static int</th>

</tbody>
</table>

**Methods inherited from interface** `javax.servlet.jsp.tagext.Tag`

`doEndTag`, `doStartTag`, `getParent`, `release`, `setPageContext`, `setParent`
**Field Detail**

EVAL_BODY_AGAIN

static final int EVAL_BODY_AGAIN

Request the reevaluation of some body. Returned from doAfterBody. For compatibility with JSP 1.1, the value is carefully selected to be the same as the, now deprecated, BodyTag.EVAL_BODY_TAG,

See Also:
Constant Field Values

**Method Detail**

```java
public int doAfterBody() throws JspException
```

BodyEvaluation JSP

doAfterBody EVAL_BODY_AGAIN
doAfterBody doAfterBody SKIP_BODY
doEndTag

BodyTag doAfterBody SKIP_BODY doEndTag
pageContext popBody out

doAfterBody() JSP AT_BEGIN NESTED
TagExtraInfo TLD

return

Throws JspException:
doAfterBody

int doAfterBody() throws JspException

Process body (re)evaluation. This method is invoked by the JSP Page implementation object after every evaluation of the body into the BodyEvaluation object. The method is not invoked if there is no body evaluation.

If doAfterBody returns EVAL_BODY_AGAIN, a new evaluation of the body will happen (followed by another invocation of doAfterBody). If doAfterBody returns SKIP_BODY, no more body evaluations will occur, and the doEndTag method will be invoked.

If this tag handler implements BodyTag and doAfterBody returns SKIP_BODY, the value of out will be restored using the popBody method in pageContext prior to invoking doEndTag.

The method re-invocations may be lead to different actions because there might have been some changes to shared state, or because of external computation.

The JSP container will resynchronize the values of any AT_BEGIN and NESTED variables (defined by the associated TagExtraInfo or TLD) after the invocation of doAfterBody().

Returns:
whether additional evaluations of the body are desired

Throws:
JspException - if an error occurred while processing this tag
PS:
public interface **J2eeApplicationObject**

extends **DeployableObject**

**Implements:** **DeployableObject**

J2eeApplicationObject is an interface that represents a J2EE application (EAR); it maintains a DeployableObject for each module in the archive.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>void addXPathListener(ModuleType type, String xpath, XpathListener xpl)</strong></td>
<td>Register a listener for changes in XPath that are related to this deployableObject.</td>

</tr>
</tbody>
</table>
getModuleUris

Return the list of URIs for all modules in the application.

getModuleUris(ModuleType type)

Return the list of URIs of the designated module type.

getText(ModuleType type, String xpath)

Return the text value from the XPath; search only the deployment descriptors of the specified type.

removeXPathListener(ModuleType type, String xpath, XpathListener xpl)

Unregister the listener for an XPath.

Methods inherited from interface javax.enterprise.deploy.model.DeployableObject
entries, getChildBean, getClassFromScope, getDDBeanRoot, getDDBeanRoot, getEntry, getModuleDTDVersion, getText, getType

Method Detail

public DeployableObject getDeployableObject(String uri)

URI DeployableObject

uri

return URI J2EE DeployableObject ‘null'

getDeployableObject

DeployableObject getDeployableObject(String uri)

Return the DeployableObject of the specified URI designator.

Parameters:

uri - Describes where to get the module from.
Returns:
the DeployableObject describing the j2ee module at this uri or 'null' if there is not match.

public DeployableObject[] getDeployableObjects(ModuleType type)
DeployableObject
    type
    return URI J2EE DeployableObject 'null'

defgetDeployableObjects
DeployableObject[] getDeployableObjects(ModuleType type)

    return URI J2EE DeployableObject 'null'

defgetDeployableObjects
    return URI J2EE DeployableObject 'null'

defgetDeployableObjects

    return URI J2EE DeployableObject 'null'
public String[] getModuleUris(ModuleType type)

URI

type
return

URI 'null'

getModuleUris

String[] getModuleUris(ModuleType type)

Return the list of URIs of the designated module type.

Parameters:
  type - The type of module to return.

Returns:
  the URIs of the contained modules or 'null' if there are no matches.

public String[] getModuleUris()

URI

return

URI 'null'

getModuleUris

String[] getModuleUris()

Return the list of URIs for all modules in the application.

Returns:
  the URIs of the contained modules or 'null' if there are no matches.
public **DDBean**[] getChildBean(**ModuleType** type, String xpath)

**XPath DDBean**

* type
* xpath  
* return DDBeans 'null'

**getChildBean**

**DDBean**[] **getChildBean**(**ModuleType** type, **String** xpath)

Return a list of DDBean based upon an XPath; all deployment descriptors of the specified type are searched.

**Parameters:**
* type - The type of deployment descriptor to query.
* xpath - An XPath string referring to a location in the deployment descriptor

**Returns:**
The list of DDBeans or 'null' of there are no matches.

---

public **String**[] getText(**ModuleType** type, String xpath)

**XPath**

* type
* xpath  
* return XPath 'null'

**getText**

**String**[] **getText**(**ModuleType** type, **String** xpath)

Return the text value from the XPath; search only the deployment descriptors of the specified type.
Parameters:
| type   | The type of deployment descriptor to query. |
| xpath  | An xpath string referring to a location in the deployment descriptor |

Returns:
The text values of this xpath or 'null' if there are no matches.

---

public void addXpathListener(ModuleType type, String xpath, XpathListener xpl)

addXpathListener

Register a listener for changes in XPath that are related to this deployableObject.

Parameters:
| type   | The type of deployment descriptor to query. |
| xpath  | The xpath to listen for. |
| xpl    | The listener. |

---

public void removeXpathListener(ModuleType type, String xpath, XpathListener xpl)

XPath

removeXpathListener

void removeXpathListener(ModuleType type, String xpath, XpathListener xpl)

Remove the listener for changes in XPath that are related to this deployableObject.
removeXpathListener

void removeXpathListener(ModuleType type, String xpath, XpathListener xpl)

Unregister the listener for an XPath.

Parameters:
- type - The type of deployment descriptor to query.
- xpath - The XPath to listen for
- xpl - The listener

XML

JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );

// unmarshal from foo.xml
Unmarshaller u = jc.createUnmarshaller();
FooObject fooObj = (FooObject)u.unmarshal( new File( "foo.xml" ) );

// marshal to System.out
Marshaller m = jc.createMarshaller();
m.marshal( fooObj, System.out );
The JAXBContext class provides the client's entry point to the JAXB API. It provides an abstraction for managing the XML/Java binding information necessary to implement the JAXB binding framework operations: unmarshal, marshal and validate.

A client application normally obtains new instances of this class using one of these two styles for newInstance methods, although there are other specialized forms of the method available:

- **JAXBContext.newInstance("com.acme.foo:com.acme.bar")**
  The JAXBContext instance is initialized from a list of colon separated Java package names. Each java package contains JAXB mapped classes, schema-derived classes and/or user annotated classes. Additionally, the java package may contain JAXB package annotations that must be processed. (see JLS 3rd Edition, Section 7.4.1. Package Annotations).

- **JAXBContext.newInstance(com.acme.foo.Foo.class)**
  The JAXBContext instance is initialized with class(es) passed as parameter(s) and classes that are statically reachable from these class(es). See newInstance(Class...) for details.

**SPEC REQUIREMENT:** the provider must supply an implementation
class containing the following method signatures:

```java
public static JAXBContext createContext(String contextPath, ClassLoader classLoader, Map properties)
public static JAXBContext createContext(Class[] classes, Map properties) throws JAXBException
```

The following JAXB 1.0 requirement is only required for schema to java interface/implementation binding. It does not apply to JAXB annotated classes. JAXB Providers must generate a `jaxb.properties` file in each package containing schema derived classes. The property file must contain a property named `javax.xml.bind.context.factory` whose value is the name of the class that implements the `createContext` APIs.

The class supplied by the provider does not have to be assignable to `javax.xml.bind.JAXBContext`, it simply has to provide a class that implements the `createContext` APIs.

In addition, the provider must call the `DatatypeConverter.setDatatypeConverter` api prior to any client invocations of the marshal and unmarshal methods. This is necessary to configure the datatype converter that will be used during these operations.

**Unmarshalling**

The `Unmarshaller` class provides the client application the ability to convert XML data into a tree of Java content objects. The unmarshal method allows for any global XML element declared in the schema to be unmarshalled as the root of an instance document. Additionally, the unmarshal method allows for an unrecognized root element that has an xsi:type attribute's value that references a type definition declared in the schema to be unmarshalled as the root of an instance document. The `JAXBContext` object allows the merging of global elements and type definitions across a set of schemas (listed in the `contextPath`). Since each schema in the schema set can belong to distinct namespaces, the unification of schemas to an unmarshalling context should be namespace independent. This means that a client application is able to unmarshal XML documents that are instances of any of the schemas listed in the `contextPath`. 
For example:

```java
JAXBContext jc = JAXBContext.newInstance( "com.acme.foo:com.acme.bar" );
Unmarshaller u = jc.createUnmarshaller();
FooObject fooObj = (FooObject)u.unmarshal( new File( "foo.xml" ) );
BarObject barObj = (BarObject)u.unmarshal( new File( "bar.xml" ) );
BazObject bazObj = (BazObject)u.unmarshal( new File( "baz.xml" ) );
```

The client application may also generate Java content trees explicitly rather than unmarshalling existing XML data. For all JAXB-annotated value classes, an application can create content using constructors. For schema-derived interface/implementation classes and for the creation of elements that are not bound to a JAXB-annotated class, an application needs to have access and knowledge about each of the schema derived ObjectFactory classes that exist in each of java packages contained in the contextPath. For each schema derived java class, there is a static factory method that produces objects of that type. For example, assume that after compiling a schema, you have a package `com.acme.foo` that contains a schema derived interface named `PurchaseOrder`. In order to create objects of that type, the client application would use the factory method like this:

```java
com.acme.foo.PurchaseOrder po =
    com.acme.foo.ObjectFactory.createPurchaseOrder();
```

Once the client application has an instance of the schema derived object, it can use the mutator methods to set content on it.

For more information on the generated ObjectFactory classes, see Section 4.2 Java Package of the specification.

**SPEC REQUIREMENT:** the provider must generate a class in each package that contains all of the necessary object factory methods for that package named ObjectFactory as well as the static newInstance( javaContentInterface ) method

**Marshalling**

The `Marshaller` class provides the client application the ability to convert a Java content tree back into XML data. There is no
difference between marshalling a content tree that is created manually using the factory methods and marshalling a content tree that is the result an unmarshal operation. Clients can marshal a java content tree back to XML data to a java.io.OutputStream or a java.io.Writer. The marshalling process can alternatively produce SAX2 event streams to a registered ContentHandler or produce a DOM Node object. Client applications have control over the output encoding as well as whether or not to marshal the XML data as a complete document or as a fragment.

Here is a simple example that unmarshals an XML document and then marshals it back out:

```java
JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" )

// unmarshal from foo.xml
Unmarshaller u = jc.createUnmarshaller();
FooObject fooObj = (FooObject) u.unmarshal( new File( "foo.xml" ) )

// marshal to System.out
Marshaller m = jc.createMarshaller();
m.marshal( fooObj, System.out );
```

**Validation**

Validation has been changed significantly since JAXB 1.0. The `Validator` class has been deprecated and made optional. This means that you are advised not to use this class and, in fact, it may not even be available depending on your JAXB provider. JAXB 1.0 client applications that rely on `Validator` will still work properly when deployed with the JAXB 1.0 runtime system. In JAXB 2.0, the `Unmarshaller` has included convenince methods that expose the JAXP 1.3 `javax.xml.validation` framework. Please refer to the `Unmarshaller.setSchema(javax.xml.validation.Schema)` API for more information.

**JAXB Runtime Binding Framework Compatibility**

The following JAXB 1.0 restriction only applies to binding schema to interfaces/implementation classes. Since this binding does not require a common runtime system, a JAXB client application must
not attempt to mix runtime objects (JAXBContext, Marshaller, etc.) from different providers. This does not mean that the client application isn't portable, it simply means that a client has to use a runtime system provided by the same provider that was used to compile the schema.

Method Detail

public static JAXBContext newInstance(String contextPath) throws JAXBException

    JAXBContext
    newInstance
    Thread.setContextClassLoader()

api

newInstance

JAXBException: JAXBContext

    1. ObjectFactory.class  jaxb.index
    2. contextPath
    3. contextPath
    4. contextPath

newInstance

public static JAXBContext newInstance(String contextPath) throws JAXBException

    Obtain a new instance of a JAXBContext class.

    This is a convenience method for the newInstance method. It uses
the context class loader of the current thread. To specify the use of a
different class loader, either set it via the
Thread.setContextClassLoader() api or use the newInstance method.

Throws:

JAXBException - if an error was encountered while creating the
JAXBContext such as

1. failure to locate either ObjectFactory.class or jaxb.index in
   the packages
2. an ambiguity among global elements contained in the
   contextPath
3. failure to locate a value for the context factory provider
   property
4. mixing schema derived packages from different providers
   on the same contextPath

1. ObjectFactory.class jaxb.index

Throws
2. contextPath
3.
4. contextPath

newInstance

public static JAXBContext newInstance(String contextPath, ClassLoader classLoader)
throws JAXBException

Obtain a new instance of a JAXBContext class.

The client application must supply a context path which is a list of colon (':', \u003A) separated java package names that contain
schema-derived classes and/or fully qualified JAXB-annotated classes. Schema-derived code is registered with the JAXBContext by the ObjectFactory.class generated per package. Alternatively than being listed in the context path, programmer annotated JAXB mapped classes can be listed in a jaxb.index resource file, format described below. Note that a java package can contain both schema-derived classes and user annotated JAXB classes. Additionally, the java package may contain JAXB package annotations that must be processed. (see JLS 3rd Edition, Section 7.4.1. "Package Annotations").

Every package listed on the contextPath must meet **one or both** of the following conditions otherwise a JAXBException will be thrown:

1. it must contain ObjectFactory.class
2. it must contain jaxb.index

**Format for jaxb.index**

The file contains a newline-separated list of class names. Space and tab characters, as well as blank lines, are ignored. The comment character is '#' (0x23); on each line all characters following the first comment character are ignored. The file must be encoded in UTF-8. Classes that are reachable, as defined in newInstance(Class...), from the listed classes are also registered with JAXBContext.

Constraints on class name occuring in a jaxb.index file are:

- Must not end with ".class".
- Class names are resolved relative to package containing jaxb.index file. Only classes occuring directly in package containing jaxb.index file are allowed.
- Fully qualified class names are not allowed. A qualified class name,relative to current package, is only allowed to specify a nested or inner class.

To maintain compatibility with JAXB 1.0 schema to java interface/implementation binding, enabled by schema customization, the JAXB provider will ensure that each package on the context path has a jaxb.properties file which contains a value for the
javax.xml.bind.context.factory property and that all values resolve to the same provider. This requirement does not apply to JAXB annotated classes.

If there are any global XML element name collisions across the various packages listed on the contextPath, a JAXBException will be thrown.

Mixing generated interface/implement bindings from multiple JAXB Providers in the same context path may result in a JAXBException being thrown.

**Parameters:**
- `contextPath` - list of java package names that contain schema derived class and/or java to schema (JAXB-annotated) mapped classes
- `classLoader` - This class loader will be used to locate the implementation classes.

**Returns:**
- a new instance of a JAXBContext

**Throws:**
- JAXBException - if an error was encountered while creating the JAXBContext such as
  1. failure to locate either ObjectFactory.class or jaxb.index in the packages
  2. an ambiguity among global elements contained in the contextPath
  3. failure to locate a value for the context factory provider property
  4. mixing schema derived packages from different providers on the same contextPath

```java
newInstance

public static JAXBContext newInstance(String contextPath, ClassLoader classLoader, Map<String,?> properties)
```
Obtain a new instance of a JAXBContext class.

This is mostly the same as `newInstance(String, ClassLoader)`, but this version allows you to pass in provider-specific properties to configure the instanciation of JAXBContext.

The interpretation of properties is up to implementations.

**Parameters:**
- `contextPath` - list of java package names that contain schema derived classes
- `classLoader` - This class loader will be used to locate the implementation classes.
- `properties` - provider-specific properties

**Returns:**
a new instance of a JAXBContext

**Throws:**
- `JAXBException` - if an error was encountered while creating the JAXBContext such as
  1. failure to locate either ObjectFactory.class or jaxb.index in the packages
  2. an ambiguity among global elements contained in the contextPath
  3. failure to locate a value for the context factory provider property
  4. mixing schema derived packages from different providers on the same contextPath

**Since:**
JAXB2.0

```java
public static JAXBContext newInstance(Class<T>[] classesToBeBound) throws JAXBException

JAXBContext
```
newInstance(Foo.class)  JAXBContext  Foo
Bar  Zot  FooBar

class Foo {
    @XmlTransient FooBar c;
    Bar b;
}
class Bar { int x; }
class Zot extends Bar { int y; }
class FooBar { }

JAXBContext java JLS 3 7.4.1

```
newInstance null

JAXBContext
JAXBException

return

JAXB

Throws

1. JAXB
2. JAXB
3. JAXB
4. JAXB

Throws

IllegalArgumentException:

null

newInstance(null);

since

JAXB2.0

newInstance

public static JAXBContext newInstance(Class... classesToBeBound) throws JAXBException

Obtain a new instance of a JAXBContext class.

The client application must supply a list of classes that the new context object needs to recognize. Not only the new context will
recognize all the classes specified, but it will also recognize any
classes that are directly/indirectly referenced statically from the
specified classes. Subclasses of referenced classes nor
@XmlTransient referenced classes are not registered with
JAXBContext. For example, in the following Java code, if you do
newInstance(Foo.class), the newly created JAXBContext will
recognize both Foo and Bar, but not Zot Or FooBar:

class Foo {
    @XmlTransient FooBar c;
    Bar b;
}
class Bar { int x; }
class Zot extends Bar { int y; }
class FooBar { }

Therefore, a typical client application only needs to specify the top-
level classes, but it needs to be careful.

Note that for each java package registered with JAXBContext, when
the optional package annotations exist, they must be processed.
(see JLS 3rd Edition, Section 7.4.1. "Package Annotations").

Parameters:
    classesToBeBound - list of java classes to be recognized by the
new JAXBContext. Can be empty, in which case a JAXBContext
that only knows about spec-defined classes will be returned.

Returns:
A new instance of a JAXBContext. Always non-null valid object.

Throws:
    JAXBException - if an error was encountered while creating the
JAXBContext, such as (but not limited to):
    1. No JAXB implementation was discovered
    2. Classes use JAXB annotations incorrectly
    3. Classes have colliding annotations (i.e., two classes with
the same type name)
    4. The JAXB implementation was unable to locate provider-
specific out-of-band information (such as additional files
generated at the development time.)
    IllegalArgumentException - if the parameter contains null (i.e.,
newInstance

public static JAXBContext newInstance(Class[] classesToBeBound, Map<String,?> properties)
    throws JAXBException

Obtain a new instance of a JAXBContext class.

An overloading of newInstance(Class...) to configure 'properties' for this instantiation of JAXBContext.

The interpretation of properties is implementation specific.

Parameters:
  classesToBeBound - list of java classes to be recognized by the new JAXBContext. Can be empty, in which case a JAXBContext that only knows about spec-defined classes will be returned.

Returns:
  A new instance of a JAXBContext. Always non-null valid object.

Throws:
  JAXBException - if an error was encountered while creating the JAXBContext, such as (but not limited to):
  1. No JAXB implementation was discovered
  2. Classes use JAXB annotations incorrectly
  3. Classes have colliding annotations (i.e., two classes with the same type name)
  4. The JAXB implementation was unable to locate provider-specific out-of-band information (such as additional files generated at the development time.)
  IllegalArgumentException - if the parameter contains null (i.e., newInstance(null);

Since:
  JAXB2.0

   - javax.xml.bind.JAXBElement<T>

All Implemented Interfaces:
   Serializable

public class JAXBElement<T>
   extends Object
   implements Serializable

Implements: java.io.Serializable
Inner classes: JAXBElement.GlobalScope

Xml JAXB

Xml xml

   • xml name
   • value
   • declaredType xs:element @type
   • scope
   • boolean nil xsi:nil
declaredType scope xml JAXB

Scope  GlobalScope Java

   value null nil true nil nil true value
   null nil

   since  JAXB 2.0

JAXB representation of an Xml Element.
This class represents information about an Xml Element from both the element declaration within a schema and the element instance value within an xml document with the following properties

- element's xml tag **name**
- **value** represents the element instance's attribute(s) and content model
- element declaration's **declaredType** (xs:element @type attribute)
- **scope** of element declaration
- boolean **nil** property. (element instance's xsi:nil attribute)

The **declaredType** and **scope** property are the JAXB class binding for the xml type definition.

**Scope** is either **JAXBElement.GlobalScope** or the Java class representing the complex type definition containing the schema element declaration.

There is a property constraint that if **value** is null, then **nil** must be true. The converse is not true to enable representing a nil element with attribute(s). If **nil** is true, it is possible that **value** is non-null so it can hold the value of the attributes associated with a nil element.

**Since:**
JAXB 2.0

getName

public QName getName()

    Returns the xml element tag name.

setValue

public void setValue(T t)

    Set the content model and attributes of this xml element.

    When this property is set to null, isNil() must be true. Details of
    constraint are described at isNil().

    See Also:
    isTypeSubstituted()

public Object getValue()

    null #isNil()

getValue

public T getValue()

    Return the content model and attribute values for this element.

    See isNil() for a description of a property constraint when this value
    is null
public Class<T> getScope()

xml

    return GlobalScope.class

See also isGlobalScope()

getScope

public Class getScope()

    Returns scope of xml element declaration.

    Returns: GlobalScope.class if this element is of global scope.

    See Also: isGlobalScope()

public boolean isNil()

    nil true

    #getValue() null true true #getValue()

    null nil xml

isNil

public boolean isNil()

    Returns true iff this element instance content model is nil.

    This property always returns true when getValue() is null. Note that
the converse is not true, when this property is true, getValue() can
contain a non-null value for attribute(s). It is valid for a nil xml
element to have attribute(s).
public void setNil(boolean value)

nil

See also

setNil

public void setNil(boolean value)

Set whether this element has nil content.

See Also:

isNil()

-----------

public boolean isGlobalScope()

xml true

isGlobalScope

public boolean isGlobalScope()

Returns true iff this xml element declaration is global.

-----------

public boolean isTypeSubstituted()

xml xml true

isTypeSubstituted

public boolean isTypeSubstituted()

Returns true iff this xml element instance's value has a different type than xml element declaration's declared type.

### Constructor Detail

**public JAXBException(String message)**

JAXBException

**errorCode**

**linkedException**

**null**

**message**

---

**JAXBException**

**public JAXBException(String message)**

Construct a JAXBException with the specified detail message. The errorCode and linkedException will default to null.

**Parameters:**

message - a description of the exception
public JAXBException(String message, String errorCode)

errorCode JAXBException linkedException null

message
errorCode

JAXBException

public JAXBException(String message, String errorCode)

Construct a JAXBException with the specified detail message and vendor specific errorCode. The linkedException will default to null.

Parameters:
    message - a description of the exception
    errorCode - a string specifying the vendor specific error code

public JAXBException(Throwable exception)

linkedException JAXBException errorCode null

exception

JAXBException

public JAXBException(Throwable exception)

Construct a JAXBException with a linkedException. The detail message and vendor specific errorCode will default to null.

Parameters:
    exception - the linked exception

public JAXBException(String message, Throwable exception)

public JAXBException(String message, String errorCode, Throwable exception)

Construct a JAXBException with the specified detail message, vendor specific errorCode, and linkedException.

Parameters:
  - message - a description of the exception
  - errorCode - a string specifying the vendor specific error code

public JAXBException(String message, Throwable exception)

Construct a JAXBException with the specified detail message and linkedException. The errorCode will default to null.

Parameters:
  - message - a description of the exception
  - exception - the linked exception
public String getErrorCode()

    return

genericCode

genericCode

public Throwable getLinkedException()

    return null

getLinkedException

public void setLinkedException(Throwable exception)

    exception null
setLinkedException

public void setLinkedException(Throwable exception)

Add a linked Exception.

Parameters:
  exception - the linked Exception (A null value is permitted and indicates that the linked exception does not exist or is unknown).

public String toString()

JAXBException

toString

public String toString()

JAXBException

Returns a short description of this JAXBException.

Overrides:
  toString in class Throwable

public void printStackTrace(java.io.PrintStream s)

JAXBException PrintStream null

linkedException
  s          PrintStream

printStackTrace

public void printStackTrace(PrintStream s)

Prints this JAXBException and its stack trace (including the stack
trace of the linkedException if it is non-null) to the PrintStream.

Overrides:

printStackTrace in class Throwable

Parameters:

s - PrintStream to use for output

public void printStackTrace()
JAXBException System.err null
linkedException

printStackTrace

public void printStackTrace()

Prints this JAXBException and its stack trace (including the stack trace of the linkedException if it is non-null) to System.err.

Overrides:

printStackTrace in class Throwable

public void printStackTrace(java.io.PrintWriter s)
JAXBException PrintWriter null
linkedException
s PrintWriter

printStackTrace

public void printStackTrace(PrintWriter s)

Prints this JAXBException and its stack trace (including the stack trace of the linkedException if it is non-null) to the PrintWriter.

Overrides:
printStackTrace in class Throwable

Parameters:
   s - PrintWriter to use for output

getCause

public Throwable getCause()

Overrides:
   getCause in class Throwable

PS:
javax.xml.bind  **Class JAXBIntrospector**

```java
java.lang.Object
  `javax.xml.bind.JAXBIntrospector`
```

```java
public abstract class JAXBIntrospector extends Object
```

JAXB  JAXB xml

JAXB xml java schema schema java  
JAXB XML  
createJAXBIntrospector()  

```java
since  JAXB2.0  
See also  createJAXBIntrospector()
```

Provide access to JAXB xml binding data for a JAXB object.

Initially, the intent of this class is to just conceptualize how a JAXB application developer can access xml binding information, independent if binding model is java to schema or schema to java. Since accessing the XML element name related to a JAXB element is a highly requested feature, demonstrate access to this binding information. The factory method to get a JAXBIntrospector instance is `JAXBContext.createJAXBIntrospector()`.

**Since:**  
JAXB2.0  
**See Also:**  
`JAXBContext.createJAXBIntrospector()`

Constructor Detail

public JAXBIntrospector()

JAXBIntrospector

public JAXBIntrospector()

Method Detail

abstract public boolean isElement(Object object)

object JAXB true

object JAXB
1.(javax.xml.bind.JAXBElement)
2.(object)

See also

getElementName(Object)

isElement

public abstract boolean isElement(Object object)

Return true iff object represents a JAXB element.

Parameter object is a JAXB element for following cases:

1. It is an instance of javax.xml.bind.JAXBElement.
2. The class of object is annotated with @XmlRootElement.

See Also:

g getElementName(Object)

abstract public javax.xml.namespace.QName
getElementName(Object jaxbElement)

jaxbElement xml qname

jaxbElement #isElement(Object) true
return jaxbElement xml qname
JAXB null

getElementName

public abstract QName getElementName(Object jaxbElement)

Get xml element qname for jaxbElement.

Parameters:
jaxbElement - is an object that isElement(Object) returned true.

Returns:
xml element qname associated with jaxbElement; null if jaxbElement is not a JAXB Element.

public static Object getValue(Object jaxbElement)

JAXB

javax.xml.bind.JAXBElemet >@XmlRootElement
Java

jaxbElement #isElement(Object) true
return jaxbElement

getValue

public static Object getValue(Object jaxbElement)

Get the element value of a JAXB element.

Convenience method to abstract whether working with either a javax.xml.bind.JAXBElemet instance or an instance of @XmlRootElement annotated Java class.

Parameters:
jaxbElement - object that #isElement(Object) returns true.

Returns:
The element value of the jaxbElement.

SUMMARY:
NESTED | FIELD | CONSTR | METHOD

DETAIL:
FIELD | CONSTR | METHOD
javax.xml.bind.util Class JAXBResult

java.lang.Object  
   ↓ javax.xml.transform.sax.SAXResult  
   ↓ javax.xml.bind.util.JAXBResult

All Implemented Interfaces:
   Result

public class JAXBResult
extends SAXResult

Extends: javax.xml.transform.sax.SAXResult

JAXB JAXP  
   ↓ javax.xml.transform.Result

JAXB Java/XML

JAXB XSLT

   JAXBResult result = new JAXBResult(JAXBContext.newInstance("org.acme.foo"));

   // set up XSLT transformation
   TransformerFactory tf = TransformerFactory.newInstance();
   Transformer t = tf.newTransformer(new StreamSource("test.xsl"));

   // run transformation
   t.transform(new StreamSource("document.xml"),result);

   // obtain the unmarshalled content tree
   Object o = result.getResult();

SAXResult JAXBResult SAXResult

setHandler setLexicalHandler setSystemId
JAXP Result implementation that unmarshals a JAXB object.

This utility class is useful to combine JAXB with other Java/XML technologies.

The following example shows how to use JAXB to unmarshal a document resulting from an XSLT transformation.

```java
JAXBResult result = new JAXBResult(
    JAXBContext.newInstance("org.acme.foo")
);

// set up XSLT transformation
TransformerFactory tf = TransformerFactory.newInstance();
Transformer t = tf.newTransformer(new StreamSource("test.xs"));

// run transformation
    t.transform(new StreamSource("document.xml"),result);

// obtain the unmarshalled content tree
Object o = result.getResult();
```

The fact that JAXBResult derives from SAXResult is an implementation detail. Thus in general applications are strongly discouraged from accessing methods defined on SAXResult.

In particular it shall never attempt to call the setHandler, setLexicalHandler, and setSystemId methods.

### Constructor Detail

```java
public JAXBResult(JAXBContext context) throws JAXBException
```

**JAXBContext**

```java
context Unmarshaller JAXBContext null
```

**Throws**

- JAXBException: JAXBResult null

JAXBResult
public JAXBResult(JAXBContext context) throws JAXBException

Creates a new instance that uses the specified JAXBContext to unmarshal.

**Parameters:**
- context - The JAXBContext that will be used to create the necessary Unmarshaller. This parameter must not be null.

**Throws:**
- JAXBException - if an error is encountered while creating the JAXBResult or if the context parameter is null.

public JAXBResult(Unmarshaller _unmarshaller) throws JAXBException

Unmarshal

**JAXBResult Unmarshaller Unmarshaller Unmarshaller**

Unmarshal

**Unmarshaller JAXBContext**

_unmarshaller    Unmarshaller null

**Throws**
- JAXBException: JAXBResult Unmarshaller null

**JAXBResult**

public JAXBResult(Unmarshaller _unmarshaller) throws JAXBException

Creates a new instance that uses the specified Unmarshaller to unmarshal an object.

This JAXBResult object will use the specified Unmarshaller instance. It is the caller's responsibility not to use the same Unmarshaller for other purposes while it is being used by this object.
The primary purpose of this method is to allow the client to configure Unmarshaller. Unless you know what you are doing, it's easier and safer to pass a JAXBContext.

**Parameters:**

_unmarshaller - the unmarshaller. This parameter must not be null.

**Throws:**

[JAXBException](#) - if an error is encountered while creating the JAXBResult or the Unmarshaller parameter is null.

**Method Detail**

```java
public Object getResult() throws JAXBException
```

```java
return null

Throws

IllegalStateException: Always return a non-null object.

Throws

JAXBException: SAXException
```

**getResult**

```java
public Object getResult() throws JAXBException
```

Gets the unmarshalled object created by the transformation.

**Returns:**

Always return a non-null object.

**Throws:**

[IllegalStateException](#) - if this method is called before an object is unmarshalled.

[JAXBException](#) - if there is any unmarshalling error. Note that the implementation is allowed to throw SAXException during the parsing when it finds an error.

PS :
javax.xml.bind.util Class JAXBSource

java.lang.Object
  ↓ javax.xml.transform.sax.SAXSource
   ↓ javax.xml.bind.util.JAXBSource

All Implemented Interfaces:
  Source

public class JAXBSource
extends SAXSource

Extends: javax.xml.transform.sax.SAXSource

JAXB JAXP

JAXB Java/XML

JAXB XSLT

MyObject o = // get JAXB content tree

// jaxbContext is a JAXBContext object from which 'o' is created.
JAXBSource source = new JAXBSource( jaxbContext, o );

// set up XSLT transformation
TransformerFactory tf = TransformerFactory.newInstance();
Transformer t = tf.newTransformer(new StreamSource("test.xsl"));

// run transformation
t.transform(source,new StreamResult(System.out));

SAXSource JAXBSource SAXSource
setXMLReader setInputSource getXMLReader XMLReader
getInputSource InputSource XMLReader

getInputSource InputSource getXMLReader XMLReader
JAXP Source implementation that marshals a JAXB-generated object.

This utility class is useful to combine JAXB with other Java/XML technologies.

The following example shows how to use JAXB to marshal a document for transformation by XSLT.

```java
MyObject o = // get JAXB content tree

// jaxbContext is a JAXBContext object from which 'o' is cr
JAXBSource source = new JAXBSource( jaxbContext, o );

// set up XSLT transformation
TransformerFactory tf = TransformerFactory.newInstance();
Transformer t = tf.newTransformer(new StreamSource("test.xs

// run transformation
t.transform(source,new StreamResult(System.out));
```

The fact that JAXBSource derives from SAXSource is an implementation detail. Thus in general applications are strongly discouraged from accessing methods defined on SAXSource. In particular, the setXMLReader and setInputSource methods shall never be called. The XMLReader object obtained by the getXMLReader method shall be used only for parsing the InputSource object returned by the getInputSource method.

Similarly the InputSource object obtained by the getInputSource method shall be used only for being parsed by the XMLReader object returned by the getXMLReader.

#### Methods inherited from class `java.lang.Object`
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`

### Constructor Detail

```java
public JAXBSource(JAXBContext context, Object contentObject) throws JAXBException
```

- `context` - `javax.xml.transform.Source`  
- `contentObject` - JAXBContext marshaller null  
- `contentObject` - `javax.xml.transform.Source` XML null  

**Throws**
- `JAXBException`: JAXBSource null
public JAXBSource(JAXBContext context, Object contentObject) throws JAXBException

Creates a new Source for the given content object.

Parameters:
- context - JAXBContext that was used to create contentObject. This context is used to create a new instance of marshaller and must not be null.
- contentObject - An instance of a JAXB-generated class, which will be used as a Source (by marshalling it into XML). It must not be null.

Throws:
- JAXBException - if an error is encountered while creating the JAXBSource or if either of the parameters are null.

public JAXBSource(Marshaller marshaller, Object contentObject) throws JAXBException

javax.xml.transform.Source marshaller contentObject XML marshaller contentObject JAXBContext null

Throws JAXBException: JAXBSource null

JAXBSource

public JAXBSource(Marshaller marshaller, Object contentObject) throws JAXBException

Creates a new Source for the given content object.

Parameters:
- marshaller - A marshaller instance that will be used to marshal contentObject into XML. This must be created from a
JAXBContext that was used to build `contentObject` and must not be null.

`contentObject` - An instance of a JAXB-generated class, which will be used as a `Source` (by marshalling it into XML). It must not be null.

**Throws:**

`JAXBException` - if an error is encountered while creating the JAXBSource or if either of the parameters are null.

**Constructor Detail**

- **public JAXRException()**
  - `Throwable` JAXRException

  **JAXRException**

- **public JAXRException()**
  - Constructs a JAXRException object with no reason or embedded Throwable.
public JAXRException(String reason)

JAXRException  String  reason

JAXRException

public JAXRException(String reason)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown.

    Parameters:
    reason - a description of what caused the exception

public JAXRException(String reason, Throwable cause)

    Throwable  String  Throwable
    reason     cause     JAXRException  Throwable

JAXRException

public JAXRException(String reason, Throwable cause)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

    Parameters:
    reason - a description of what caused the exception
    cause - a Throwable object that is to be embedded in this JAXRException object
public JAXRException(Throwable cause)

    Throwable JAXRException
    cause Exception Throwable

JAXRException

public JAXRException(Throwable cause)

    Constructs a JAXRException object initialized with the given Throwable object.

Parameters:
    cause - the Throwable that caused this Exception

Method Detail

public String getMessage()

    JAXRException

    Throwable return JAXRException Throwable

getMessage

public String getMessage()

    Returns the detail message for this JAXRException object.

    If there is an embedded Throwable, and if the JAXRException object has no detail message of its own, this method will return the detail message from the embedded Throwable.

    Overrides:
        getMessage in class Throwable
Returns:
the error or warning message for this JAXRException or, if it has none, the message of the embedded Throwable, if there is one.

```
public Throwable getCause()

JAXRException Throwable null
return Throwable Throwable null
```

getcause

```
public Throwable getCause()

Returns the Throwable embedded in this JAXRException if there is one. Otherwise, this method returns null.

Overrides:
getcause in class Throwable

>Returns:
the embedded Throwable or null if there is none
```

```
public Throwable initCause(Throwable cause)

throwable cause cause throwable
throwable

#JAXRException(Throwable)  #JAXRException(String,Throwable)

cause #getCause() null
return Throwable
Throws IllegalArgumentException: cause
IllegalStateException: throwable
Throws #JAXRException(Throwable) #JAXRException(String,Throwable)
throwable
**initCause**

public Throwable initCause(Throwable cause)

Initializes the cause of this throwable to the specified value. (The cause is the throwable that caused this throwable to get thrown.)

This method can be called at most once. It is generally called from within the constructor, or immediately after creating the throwable. If this throwable was created with JAXRException(Throwable) or JAXRException(String, Throwable), this method cannot be called even once.

Overrides:

initCause in class Throwable

Parameters:

cause - the cause (which is saved for later retrieval by the getCause() method). (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

Returns:

a reference to this Throwable instance.

Throws:

IllegalArgumentException - if cause is this throwable. (A throwable cannot be its own cause.)

IllegalStateException - if this throwable was created with JAXRException(Throwable) or JAXRException(String, Throwable), or this method has already been called on this throwable.

---

**public String getRequestId()**

getRequestId

public String getRequestId()
Returns the unique id for the request that generated this response.

**Capability Level:** 0

**Specified by:**
- `getRequestId` in interface `JAXRResponse`

**Returns:**
- the request id

---

```java
public int getStatus()
```

**getStatus**

```java
public int getStatus()
```

**Description copied from interface:** `JAXRResponse`
Returns the status for this response.

**Capability Level:** 0

**Specified by:**
- `getStatus` in interface `JAXRResponse`

**Returns:**
- the status which is an integer enumerated value

**See Also:**
- `JAXRResponse.STATUS_SUCCESS`

---

```java
public boolean isAvailable() throws JAXRException
```

**isAvailable**

```java
public boolean isAvailable()
```

**isAvailable**

```java
throws JAXRException
```
Returns true if a response is available, false otherwise. This is a polling method and must not block.

**Specified by:**  
`isAvailable` in interface `JAXRResponse`

**Returns:**  
true if the response is available; false otherwise

**Throws:**  
`JAXRException` - If the JAXR provider encounters an internal error

<tr>
<th>ClassMethod</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JAXRPCException()</td>
<td>Constructs a new exception with null as its detail message.</td>
</tr>
<tr>
<td>JAXRPCException(String message)</td>
<td></td>
</tr>
</tbody>
</table>

Constructs a new exception with the specified detail message.

**JAXRPCException** *(String message, Throwable cause)*

Constructs a new exception with the specified detail message and cause.

**JAXRPCException** *(Throwable cause)*

Constructs a new JAXRPCException with the specified cause and a detail message of `(cause==null ? null : null) ?`.

### Method Summary

<table>
<thead>
<tr>
<th>Throwable</th>
<th>getLinkedCause()</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Gets the Linked cause</td>

### Constructor Detail

**public JAXRPCException()**

nullcause

**JAXRPCException**

**public JAXRPCException()**

Constructs a new exception with null as its detail message. The cause is not initialized.
public JAXRPCException(String message)

Constructs a new exception with the specified detail message. The cause is not initialized.

Parameters:
message - The detail message which is later retrieved using the getMessage method

public JAXRPCException(String message, Throwable cause)

Constructs a new exception with the specified detail message and cause.

Parameters:
message - The detail message which is later retrieved using the getMessage method
cause - The cause which is saved for the later retrieval throw by the getCause method
public JAXRPCException(Throwables cause)
JAXRPCException cause
    (cause
    : cause.toString() cause
    cause cause getCause
    null cause

JAXRPCException

public JAXRPCException(Throwables cause)

Constructs a new JAXRPCException with the specified cause and a detail message of (cause==null ? null : cause.toString()) (which typically contains the class and detail message of cause).

Parameters:
  cause - The cause which is saved for the later retrieval throw by the getCause method. (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

Method Detail

public Throwable getLinkedCause()

getLinkedCause

public Throwable getLinkedCause()

Gets the Linked cause

Returns:
  The cause of this Exception or null if the cause is nonexistent or unknown

Method Detail

public String getRequestId() throws JAXRException

ID

0

return ID

Throws JAXRException: JAXR
getRequestId

```java
StringgetRequestId()
throws JAXRException
```

Returns the unique id for the request that generated this response.

**Capability Level: 0**

**Returns:**
- the request id

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

```java
public int getStatus() throws JAXRException
```

0

```java
    return
```

**Throws**
- `JAXRException`: JAXR

**See also**
- `STATUS_SUCCESS`

---

getStatus

```java
int getStatus()
throws JAXRException
```

Returns the status for this response.

**Capability Level: 0**

**Returns:**
- the status which is an integer enumerated value

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error
public boolean isAvailable() throws JAXRException
true false

0

return true false

Throws JAXRException: JAXR

isAvailable

boolean isAvailable() throws JAXRException

Returns true if a response is available, false otherwise. This is a polling method and must not block.

Capability Level: 0

Returns:
true if the response is available; false otherwise

Throws:
JAXRException - If the JAXR provider encounters an internal error

javax.jms Class JMSException

java.lang.Object
   ↓ java.lang.Throwable
      ↓ java.lang.Exception
         ↓ javax.jms.JMSException

All Implemented Interfaces:
   Serializable

Direct Known Subclasses:
   IllegalStateException, InvalidClientIDException, InvalidDestinationException, InvalidSelectorException, JMSSecurityException, MessageEOFException, MessageFormatException, MessageNotReadableException, MessageNotWriteableException, ResourceAllocationException, TransactionInProgressException, TransactionRolledBackException

public class JMSException
extends Exception

Extends: Throwable > Exception
Extended by: IllegalStateException, InvalidClientIDException, InvalidDestinationException, InvalidSelectorException, JMSSecurityException, MessageEOFException, MessageFormatException, MessageNotReadableException, MessageNotWriteableException, ResourceAllocationException, TransactionInProgressException, TransactionRolledBackException

JMS API

• getMessage

•

• JMS API
This is the root class of all JMS API exceptions.

It provides the following information:

- A provider-specific string describing the error. This string is the standard exception message and is available via the `getMessage` method.
- A provider-specific string error code
- A reference to another exception. Often a JMS API exception will be the result of a lower-level problem. If appropriate, this lower-level exception can be linked to the JMS API exception.

### Constructor Summary

**`JMSException(String reason)`**

Constructs a `JMSException` with the specified reason and with the error code defaulting to null.

**`JMSException(String reason, String errorCode)`**

Constructs a `JMSException` with the specified reason and error code.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>String getErrorCode()</code></td>
<td>Gets the vendor-specific error code.</td>
</tr>
<tr>
<td><code>Exception getLinkedException()</code></td>
<td>Gets the exception linked to this one.</td>
</tr>
</tbody>
</table>
void setLinkedException(Exception ex)

    Adds a linked Exception.

Methods inherited from class java.lang.Throwable
fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, initCause, printStackTrace, printStackTrace, printStackTrace, setStackTrace, toString

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait

Constructor Detail

public JMSException(String reason, String errorCode)

JMSException

public JMSException(String reason)

null JMSException

Parameters:
reason - a description of the exception
errorCode - a string specifying the vendor-specific error code

public JMSException(String reason)
JMSException

public JMSException(String reason)

Constructs a JMSException with the specified reason and with the error code defaulting to null.

Parameters:
reason - a description of the exception

Method Detail

public String getErrorCode()

    return

getAddress

public String getErrorCode()

    Gets the vendor-specific error code.

Returns:
a string specifying the vendor-specific error code

public Exception getLinkedException()

    return Exception null

getLinkedException

public Exception getLinkedException()
Gets the exception linked to this one.

**Returns:**
the linked Exception, null if none

```java
public void setLinkedException(Exception ex)
```

**setLinkedException**

```java
public void setLinkedException(Exception ex)
```

Adds a linked Exception.

**Parameters:**
- `ex` - the linked Exception

### Method Detail

#### public JMSProducerStats[] getProducers()

Returns an array of JMSProducerStats that provide statistics about the message producers associated with the referencing JMS session statistics.

#### public JMSConsumerStats[] getConsumers()

Returns an array of JMSConsumerStats that provide statistics about the message consumers associated with the referencing JMS session statistics.

Methods inherited from interface javax.management.j2ee.statistics.Stats

- getStatistic, getStatisticNames, getStatistics
public CountStatistic getMessageCount()

getMessageCount

CountStatistic getMessageCount()

Number of messages exchanged.

public CountStatistic getPendingMessageCount()

getPendingMessageCount

CountStatistic getPendingMessageCount()

Number of pending messages.

public CountStatistic getExpiredMessageCount()

getExpiredMessageCount

CountStatistic getExpiredMessageCount()

Number of expired messages.

public TimeStatistic getMessageWaitTime()
getMessageWaitTime

TimeStatistic getMessageWaitTime()

Time spent by a message before being delivered.

public CountStatistic getDurableSubscriptionCount()

getDurableSubscriptionCount

CountStatistic getDurableSubscriptionCount()

Number of durable subscriptions.

getStatistic, getStatisticNames, getStatistics

Method Detail

public JMSConnectionStats[] getConnections()
JMSConnectionStats  JMS

getConnections

JMSConnectionStats[] getConnections()

Returns an array of JMSConnectionStats that provide statistics about the connections associated with the referencing JMS resource.
javax.persistence Annotation Type JoinColumn

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface JoinColumn

**Implements:** Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

@ManyToOne
@JoinColumn(name="ADDR_ID")
public Address getAddress() { return address; }

**since** Java Persistence 1.0

Is used to specify a mapped column for joining an entity association.

Example:

@ManyToOne
@JoinColumn(name="ADDR_ID")
public Address getAddress() { return address; }

**Since:**
Java Persistence 1.0

---

**Optional Element Summary**

<table>
<thead>
<tr>
<th>String</th>
<th>columnDefinition</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>(Optional) The SQL fragment that is used when generating the DDL for the column.</td>
</tr>
<tr>
<td>Field</td>
<td>Description</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>boolean insertable</td>
<td>(Optional) Whether the column is included in SQL INSERT statements generated by the persistence provider.</td>
</tr>
<tr>
<td>String name</td>
<td>(Optional) The name of the foreign key column.</td>
</tr>
<tr>
<td>boolean nullable</td>
<td>(Optional) Whether the foreign key column is nullable.</td>
</tr>
<tr>
<td>String referencedColumnName</td>
<td>(Optional) The name of the column referenced by this foreign key column.</td>
</tr>
<tr>
<td>String table</td>
<td>(Optional) The name of the table that contains the column.</td>
</tr>
<tr>
<td>boolean unique</td>
<td>(Optional) Whether the property is a unique key.</td>
</tr>
<tr>
<td>boolean updatable</td>
<td>(Optional) Whether the column is included in SQL UPDATE statements generated by the persistence provider.</td>
</tr>
</tbody>
</table>

abstract public String name()
OneToOne  Many-ToOne
ManyToMany                “ _”“ _”

name

public abstract String name

(Optional) The name of the foreign key column. The table in which it is found depends upon the context. If the join is for a OneToOne or Many-ToOne mapping, the foreign key column is in the table of the source entity. If the join is for a ManyToMany, the foreign key is in a join table. Default (only applies if a single join column is used): The concatenation of the following: the name of the referencing relationship property or field of the referencing entity; " _"; the name of the referenced primary key column. If there is no such referencing
relationship property or field in the entity, the join column name is formed as the concatenation of the following: the name of the entity; "_"; the name of the referenced primary key column.

**Default:**

```

```

**abstract public String referencedColumnName()**

**JoinTable**

**referencedColumnName**

```java
public abstract String referencedColumnName
```

(Optional) The name of the column referenced by this foreign key column. When used with relationship mappings, the referenced column is in the table of the target entity. When used inside a JoinTable annotation, the referenced key column is in the entity table of the owning entity, or inverse entity if the join is part of the inverse join definition. Default (only applies if single join column is being used): The same name as the primary key column of the referenced table.

**Default:**

```

```

**abstract public boolean unique()**

**UniqueConstraint**

**unique**

```java
public abstract boolean unique
```

(Optional) Whether the property is a unique key. This is a shortcut for
the UniqueConstraint annotation at the table level and is useful for when the unique key constraint is only a single field. It is not necessary to explicitly specify this for a join column that corresponds to a primary key that is part of a foreign key.

**Default:**
false

```java
abstract public boolean nullable()
null

nullable
```

```java
public abstract boolean nullable

(Optional) Whether the foreign key column is nullable.

**Default:**
true
```

```java
abstract public boolean insertable()
SQL INSERT

insertable
```

```java
public abstract boolean insertable

(Optional) Whether the column is included in SQL INSERT statements generated by the persistence provider.

**Default:**
true
abstract public boolean updatable()
SQL UPDATE

updatable

public abstract boolean updatable

(Optional) Whether the column is included in SQL UPDATE statements generated by the persistence provider.

Default:
true

abstract public String columnDefinition()
DDL SQL

SQL

columnDefinition

public abstract String columnDefinition

(Optional) The SQL fragment that is used when generating the DDL for the column.

Defaults to the generated SQL for the column.

Default:
"

abstract public String table()
public abstract String table

(Optional) The name of the table that contains the column. If a table is not specified, the column is assumed to be in the primary table of the applicable entity.

Default: 

""
javax.persistence  **Annotation Type JoinColumns**

```java
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface JoinColumns

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
```

```java
public @interface JoinColumns

JoinColumns  

JoinColumn

JoinColumns  JoinColumn  name  referencedColumnName

@ManyToOne
@JoinColumns(
    @JoinColumn(name="ADDR_ID", referencedColumnName="ID"),
    @JoinColumn(name="ADDR_ZIP", referencedColumnName="ZIP")
)
public Address getAddress() { return address; }

since  Java Persistence 1.0  

Defines mapping for the composite foreign keys. This annotation groups `JoinColumn` annotations for the same relationship.

When the `JoinColumns` annotation is used, both the `name` and the `referencedColumnName` elements must be specified in each such `JoinColumn` annotation.

Example:
@ManyToOne
@JoinColumns(
    @JoinColumn(name="ADDR_ID", referencedColumnName="ID"),
    @JoinColumn(name="ADDR_ZIP", referencedColumnName="ZIP")
)
public Address getAddress() { return address; }
```
### Required Element Summary

| JoinColumn[] | value |

### Element Detail

abstract public `JoinColumn[] value()`

**value**

public abstract `JoinColumn[] value`
javax.persistence  Annotation Type JoinTable

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface JoinTable

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

JoinTable

@JoinTable(
    name="CUST_PHONE",
    joinColumns=
        @JoinColumn(name="CUST_ID", referencedColumnName="ID"),
    inverseJoinColumns=
        @JoinColumn(name="PHONE_ID", referencedColumnName="ID")
  )

since Java Persistence 1.0

This annotation is used in the mapping of associations. It is specified on the owning side of a many-to-many association, or in a unidirectional one-to-many association.

If the JoinTable annotation is missing, the default values of the annotation elements apply. The name of the join table is assumed to be the table names of the associated primary tables concatenated together (owning side first) using an underscore.

Example:
@JoinTable(
    name="CUST_PHONE",
    joinColumns=
        @JoinColumn(name="CUST_ID", referencedColumnName="ID"),
    inverseJoinColumns=
        @JoinColumn(name="PHONE_ID", referencedColumnName="ID"),
    ...
```java
inverseJoinColumn=
   @JoinColumn(name="PHONE_ID", referencedColumnName="ID")
)

Since:
   Java Persistence 1.0

---

### Optional Element Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Element</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>catalog</td>
<td>(Optional) The catalog of the table.</td>
</tr>
<tr>
<td>JoinColumn[]</td>
<td>inverseJoinColumns</td>
<td>(Optional) The foreign key columns of the join table which reference the primary table of the entity that does not own the association (i.e. the inverse side of the association).</td>
</tr>
<tr>
<td>JoinColumn[]</td>
<td>joinColumns</td>
<td>(Optional) The foreign key columns of the join table which reference the primary table of the entity owning the association (i.e. the owning side of the association).</td>
</tr>
<tr>
<td>String</td>
<td>name</td>
<td>(Optional) The name of the join table.</td>
</tr>
<tr>
<td>String</td>
<td>schema</td>
<td>(Optional) The schema of the table.</td>
</tr>
<tr>
<td>UniqueConstraint[]</td>
<td>uniqueConstraints</td>
<td>(Optional) Unique constraints that are to be placed on the table.</td>
</tr>
</tbody>
</table>

abstract public String name()
name

public abstract String name

(Optional) The name of the join table.

Defaults to the concatenated names of the two associated primary entity tables, separated by an underscore.

Default:
""

-------------

abstract public String catalog()

catalog

public abstract String catalog

(Optional) The catalog of the table.

Defaults to the default catalog.

Default:
""

-------------

abstract public String schema()
schema

public abstract String schema

(Optional) The schema of the table.

Defaults to the default schema for user.

Default: ""

abstract public JoinColumn[] joinColumns()

JoinColumn

joinColumns

public abstract JoinColumn[] joinColumns

(Optional) The foreign key columns of the join table which reference the primary table of the entity owning the association (i.e. the owning side of the association).

Uses the same defaults as for JoinColumn.

Default:

{}

abstract public JoinColumn[] inverseJoinColumns()
JoinColumn

inverseJoinColumns

public abstract JoinColumn[] inverseJoinColumns

(Optional) The foreign key columns of the join table which reference the primary table of the entity that does not own the association (i.e. the inverse side of the association).

Uses the same defaults as for JoinColumn.

Default:

{}  

abstract public UniqueConstraint[] uniqueConstraints()

uniqueConstraints

public abstract UniqueConstraint[] uniqueConstraints

(Optional) Unique constraints that are to be placed on the table. These are only used if table generation is in effect.

Defaults to no additional constraints.

Default:

{}

PS :
public interface JspApplicationContext

Stores application-scoped information relevant to JSP containers.

The JSP container must create a single instance of JspApplicationContext for each ServletContext instance.

An instance of JspApplicationContext is obtained by invoking the static JspFactory.getJspApplicationContext(javax.servlet.ServletContext) method, passing the ServletContext of the corresponding web application.

The JspApplicationContext provides the following services to JSP applications:

- Allows registration of ELResolvers, which are used to resolve variables in EL expressions contained in JSP pages and tag files.
- Provides an instance of ExpressionFactory for those applications or frameworks that need to perform programmatic evaluation of EL expressions instead of allowing the JSP container to do it for them.
- Allows the attachment of ELContextListener instances for notification whenever a new ELContext is created. This is necessary when an application wishes to make custom context objects available to their pluggable ELResolvers.

Since: JSP 2.1

See Also: ServletContext, JspFactory, ELResolver, ExpressionFactory, ELContextListener

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>addELContextListener(ELContextListener listener)</td>
</tr>
</tbody>
</table>
void addELResolver(ELResolver resolver)

Adds an ELResolver to affect the way EL variables and properties are resolved for EL expressions appearing in JSP pages and tag files.

For example, in the EL expression `${employee.lastName}`, an ELResolver determines what object "employee" references and how to find its "lastName" property.

When evaluating an expression, the JSP container will consult a set of standard resolvers as well as any resolvers registered via this method. The set of resolvers are consulted in the following order:

- ImplicitObjectELResolver
- ListELResolver
- MapELResolver
- ArrayELResolver
- BeanELResolver
- **ScopedAttributeELResolver**

  It is illegal to register an ELResolver after the application has received any request from the client. If an attempt is made to register an ELResolver after that time, an IllegalStateException is thrown.

  This restriction is in place to allow the JSP container to optimize for the common case where no additional ELResolvers are in the chain, aside from the standard ones. It is permissible to add ELResolvers before or after initialization to a CompositeELResolver that is already in the chain.

  It is not possible to remove an ELResolver registered with this method, once it has been registered.

  **Parameters:**
  - resolver - The new ELResolver

  **Throws:**
  - [IllegalStateException](#) - if an attempt is made to call this method after all ServletContextListenerS have had their contextInitialized methods invoked.

---

**getExpressionFactory**

`ExpressionFactory getExpressionFactory()`

Returns a factory used to create ValueExpressions and MethodExpressionS so that EL expressions can be parsed and evaluated.

**Returns:**
A concrete implementation of the an ExpressionFactory.

---

**addELContextListener**

`void addELContextListener(ELContextListener listener)`

Registers a ELContextListeners so that context objects can be
added whenever a new ELContext is created.

At a minimum, the ELContext objects created will contain a reference to the JspContext for this request, which is added by the JSP container. This is sufficient for all the default ELResolvers listed in addELResolver(javax.el.ELResolver). Note that JspContext.class is used as the key to ELContext.putContext() for the JspContext object reference.

This method is generally used by frameworks and applications that register their own ELResolver that needs context other than JspContext. The listener will typically add the necessary context to the ELContext provided in the event object. Registering a listener that adds context allows the ELResolvers in the stack to access the context they need when they do a resolution.

**Parameters:**

- listener - The listener to be notified when a new ELContext is created.
javax.servlet.jsp  **Class JspContext**

**java.lang.Object**
  |_ javax.servlet.jsp.JspContext

**Direct Known Subclasses:**
  PageContext

```java
public abstract class JspContext
  extends Object

Extended by: PageContext
```

JspContext  PageContext  servlet / Servlet

JspContext /
  - API
  - JspWriter
  -

JspWriter  pushBody()  popBody()

**JSP**

Servlet JSP
  setAttribute()  getAttribute()  findAttribute()  removeAttribute()  getAt
  getAttributeNamesInScope()

getOut()

getExpressionEvaluator()  getVariableResolver()

since  2.0
JspContext serves as the base class for the PageContext class and abstracts all information that is not specific to servlets. This allows for Simple Tag Extensions to be used outside of the context of a request/response Servlet.

The JspContext provides a number of facilities to the page/component author and page implementor, including:

- a single API to manage the various scoped namespaces
- a mechanism to obtain the JspWriter for output
- a mechanism to expose page directive attributes to the scripting environment

Methods Intended for Container Generated Code

The following methods enable the management of nested JspWriter streams to implement Tag Extensions: pushBody() and popBody()

Methods Intended for JSP authors

Some methods provide uniform access to the diverse objects representing scopes. The implementation must use the underlying machinery corresponding to that scope, so information can be passed back and forth between the underlying environment (e.g. Servlets) and JSP pages. The methods are: setAttribute(), getAttribute(), findAttribute(), removeAttribute(), getAttributesScope() and getAttributeNamesInScope().

The following methods provide convenient access to implicit objects: getOut()

The following methods provide programmatic access to the Expression Language evaluator: getExpressionEvaluator(), getVariableResolver()

Since:

JSP 2.0
## Constructor Summary

**JspContext()**

Sole constructor.

Methods inherited from class java.lang.Object:
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
abstract public void setAttribute(String name, Object value)

null  removeAttribute

name
value  name  null
Throws  NullPointerException:  null

setAttribute

public abstract void setAttribute(String name, Object value)

Register the name and value specified with page scope semantics. If the value passed in is null, this has the same effect as calling removeAttribute( name, PageContext.PAGE_SCOPE ).

Parameters:
     name - the name of the attribute to set
     value - the value to associate with the name, or null if the attribute is to be removed from the page scope.

Throws:
     NullPointerException - if the name is null

abstract public void setAttribute(String name, Object value, int scope)

null  removeAttribute

name
value  name  null
scope  /
Throws  NullPointerException:  null
Throws  IllegalArgumentException:  scope
Throws  IllegalStateException:  scope
**Throws** PageContext.SESSION_SCOPE

### setAttribute

```java
public abstract void setAttribute(String name, Object value, int scope)
```

Register the name and value specified with appropriate scope semantics. If the value passed in is `null`, this has the same effect as calling `removeAttribute(name, scope)`.

**Parameters:**
- `name` - the name of the attribute to set
- `value` - the object to associate with the name, or `null` if the attribute is to be removed from the specified scope.
- `scope` - the scope with which to associate the name/object

**Throws:**
- `NullPointerException` - if the name is `null`
- `IllegalArgumentException` - if the scope is invalid
- `IllegalStateException` - if the scope is `PageContext.SESSION_SCOPE` but the page that was requested does not participate in a session or the session has been invalidated.

---

### abstract public Object getAttribute(String name)

```java
null
```

```java
    name
    return null
    Throws NullPointerException: null
```

### getAttribute

```java
public abstract Object getAttribute(String name)
```
Returns the object associated with the name in the page scope or null if not found.

**Parameters:**
- name - the name of the attribute to get

**Returns:**
the object associated with the name in the page scope or null if not found.

**Throws:**
- NullPointerException - if the name is null

abstract public Object getAttribute(String name, int scope)
null

name
scope /
return null

Throws
- NullPointerException: null
- IllegalArgumentException: scope
- IllegalStateException: scope
- PageContext.SESSION_SCOPE

**getAttribute**

public abstract Object getAttribute(String name, int scope)

Return the object associated with the name in the specified scope or null if not found.

**Parameters:**
- name - the name of the attribute to set
- scope - the scope with which to associate the name/object

**Returns:**
the object associated with the name in the specified scope or null if not found.

**Throws:**
NullPointerException - if the name is null
IllegalArgumentException - if the scope is invalid
IllegalStateException - if the scope is PageContext.SESSION_SCOPE but the page that was requested does not participate in a session or the session has been invalidated.

abstract public Object findAttribute(String name)
null

name
return null

Throws
NullPointerException: null

findAttribute

public abstract Object findAttribute(String name)

Searches for the named attribute in page, request, session (if valid), and application scope(s) in order and returns the value associated or null.

Parameters:
name - the name of the attribute to search for

Returns:
the value associated or null

Throws:
NullPointerException - if the name is null

abstract public void removeAttribute(String name)

name

Throws
NullPointerException: null
removeAttribute

public abstract void removeAttribute(String name)

Remove the object reference associated with the given name from all scopes. Does nothing if there is no such object.

Parameters:
    name - The name of the object to remove.

Throws:
    NullPointerException - if the name is null

abstract public void removeAttribute(String name, int scope)

    name
    scope

Throws
    IllegalArgumentException: scope
    IllegalStateException: scope
    PageContext.SESSION_SCOPE
    NullPointerException: null

removeAttribute

public abstract void removeAttribute(String name, int scope)

Remove the object reference associated with the specified name in the given scope. Does nothing if there is no such object.

Parameters:
    name - The name of the object to remove.
    scope - The scope where to look.

Throws:
    IllegalArgumentException - if the scope is invalid
    IllegalStateException - if the scope is
PageContext.SESSION_SCOPE but the page that was requested does not participate in a session or the session has been invalidated.

**NullPointerException** - if the name is null

---

**abstract public int getAttributesScope(String name)**

```
name
return 0
Throws NullPointerException: null
```

**getAttributesScope**

**public abstract int getAttributesScope(String name)**

Get the scope where a given attribute is defined.

**Parameters:**
- `name` - the name of the attribute to return the scope for

**Returns:**
- the scope of the object associated with the name specified or 0

**Throws:**
- `NullPointerException` - if the name is null

---

**abstract public java.util Enumeration<E> getAttributeNamesInScope(int scope)**

```
scope
return (java.lang.String)
Throws IllegalArgumentException: scope
Throws IllegalStateException: scope
Throws PageContext.SESSION_SCOPE
```

---
get AttributeNamesInScope

public abstract Enumeration<String> getAttributeNamesInScope(int scope)

Enumerate all the attributes in a given scope.

Parameters:
  scope - the scope to enumerate all the attributes for

Returns:
  an enumeration of names (java.lang.String) of all the attributes
  the specified scope

Throws:
  IllegalArgumentException - if the scope is invalid
  IllegalStateException - if the scope is
  PageContext.SESSION_SCOPE but the page that was
  requested does not participate in a session or the session has
  been invalidated.

abstract public JspWriter getOut()

out JspWriter

return JspWriter

getOut

public abstract JspWriter getOut()

The current value of the out object (a JspWriter).

Returns:
  the current JspWriter stream being used for client response

abstract public ExpressionEvaluator getExpressionEvaluator()

gExpressionEvaluator JSP_EL
ExpressionEvaluator
getExpressionEvaluator

public abstract ExpressionEvaluator getExpressionEvaluator()

**Deprecated. As of JSP 2.1, replaced by**

`JspApplicationContext.getExpressionFactory()`

Provides programmatic access to the ExpressionEvaluator. The JSP Container must return a valid instance of an ExpressionEvaluator that can parse EL expressions.

**Returns:**
A valid instance of an ExpressionEvaluator.

**Since:**
JSP 2.0

---

getVariableResolver

public abstract VariableResolver getVariableResolver()

**Deprecated. As of JSP 2.1, replaced by** `ELContext.getELResolver()`, which can be obtained by `jspContext.getELContext().getELResolver()`.

Returns an instance of a VariableResolver that provides access to the implicit objects specified in the JSP specification using this JspContext as the context object.
Returns:
A valid instance of a VariableResolver.

Since:
JSP 2.0

---

class JspContext

getELContext

public abstract ELContext getELContext()

Returns the ELContext associated with this JspContext.

The ELContext is created lazily and is reused if it already exists. There is a new ELContext for each JspContext.

The ELContext must contain the ELResolver described in the JSP specification (and in the javadocs for JspApplicationContext.addELResolver(javax.el.ELResolver)).

Returns:
The ELContext associated with this JspContext.

Since:
JSP 2.1

---

public JspWriter pushBody(java.io.Writer writer)

Writer  JspWriter "out"  JspWriter  "out"  JspContext  "out"

JspWriter

- clear() IOException
- clearBuffer()
- getBufferSize() 0
- getRemaining() 0
public JspWriter pushBody(Writer writer)

Return a new JspWriter object that sends output to the provided Writer. Saves the current "out" JspWriter, and updates the value of the "out" attribute in the page scope attribute namespace of the JspContext.

The returned JspWriter must implement all methods and behave as though it were unbuffered. More specifically:

- clear() must throw an IOException
- clearBuffer() does nothing
- getBufferSize() always returns 0
- getRemaining() always returns 0

Parameters:
- writer - The Writer for the returned JspWriter to send output to.

Returns:
a new JspWriter that writes to the given Writer.

Since:
JSP 2.0

public JspWriter popBody()
public JspWriter popBody()

Return the previous JspWriter "out" saved by the matching pushBody(), and update the value of the "out" attribute in the page scope attribute namespace of the JspContext.

Returns:
the saved JspWriter.
public abstract class JspEngineInfo
extends Object

JspEngineInfo JSP

The JspEngineInfo is an abstract class that provides information on the current JSP engine.

Constructor Summary

Constructor Detail
public JspEngineInfo()

JspEngineInfo

public JspEngineInfo()

    Sole constructor. (For invocation by subclass constructors, typically implicit.)

Method Detail

abstract public String getSpecificationVersion()

    "." "2.0" "1.2.3.4.5.6.7"

    return null

getSpecificationVersion

public abstract String getSpecificationVersion()

    Return the version number of the JSP specification that is supported by this JSP engine.

    Specification version numbers that consists of positive decimal integers separated by periods ".", for example, "2.0" or "1.2.3.4.5.6.7". This allows an extensible number to be used to represent major, minor, micro, etc versions. The version number must begin with a number.

    Returns:
    the specification version, null is returned if it is not known

PS:
javax.servlet.jsp  **Class JspException**

```java
java.lang.Object  
   \_ java.lang.Throwble  
      \_ java.lang.Exception  
         \_ javax.servlet.jsp.JspException
```

**All Implemented Interfaces:**

  Serializable

**Direct Known Subclasses:**

  JspTagException, SkipPageException

---

```java
public class JspException
extends Exception
```

**Extends:** Throwable > Exception

**Extended by:** JspTagException, SkipPageException

JSP  JspException  errorpage

A generic exception known to the JSP engine; uncaught JspExceptions will result in an invocation of the errorpage machinery.

**See Also:**

  Serialized Form

---

## Constructor Detail

**public JspException()**

*JspException*

**public JspException()**

Construct a JspException.

**public JspException(String msg)**

*JSP /

  msg  String*
JspException

public JspException(String msg)

Constructs a new JSP exception with the specified message. The message can be written to the server log and/or displayed for the user.

Parameters:
msg - a String specifying the text of the exception message

public JspException(String message, Throwable rootCause)

JSP   JSP “” JSP

message  String
rootCause  servlet  Throwable  servlet

JspException

public JspException(String message, Throwable cause)

Constructs a new JspException with the specified detail message and cause. The cause is saved for later retrieval by the Throwable.getCause() and getRootCause() methods.

See Also:
Exception.Exception(String, Throwable)

public JspException(Throwable rootCause)

JSP   JSP “” JSP

Throwable  getLocalizedMessage  JspException
public JspException(Throwable cause)

Constructs a new JspException with the specified cause. The cause is saved for later retrieval by the Throwable.getCause() andgetRootCause() methods.

See Also:
Exception.Exception(Throwable)

public ThrowablegetRootCause()

Returns the exception that caused this JspException.

Returns:
the Throwable that caused this JspException

Deprecated. As of JSP 2.1, replaced by Throwable.getCause()

PS:
The JspFactory is an abstract class that defines a number of factory methods available to a JSP page at runtime for the purposes of creating instances of various interfaces and classes used to support the JSP implementation.

A conformant JSP Engine implementation will, during its initialization instantiate an implementation dependent subclass of this class, and make it globally available for use by JSP implementation classes by registering the instance created with this class via the static setDefaultFactory() method.

The only implementation-dependent classes that can be created from the factory are: PageContext, JspEngineInfo, and JspApplicationContext.

With the exception of JspApplicationContext, JspFactory objects should not be used by JSP application developers.
### Constructor Summary

Methods inherited from class java.lang.Object:

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait
Constructor Detail

public JspFactory()

JspFactory

public JspFactory()

   Sole constructor. (For invocation by subclass constructors, typically implicit.)

Method Detail

public static void setDefaultFactory(JspFactory deflt)

   JSP

       deflt

setDefaultFactory

public static void setDefaultFactory(JspFactory deflt)

   set the default factory for this implementation. It is illegal for any principal other than the JSP Engine runtime to call this method.

   Parameters:
       deflt - The default factory implementation

public static JspFactory getDefaultFactory()}

   return
**getDefualtFactory**

public static JspFactory getDefaultFactory()

Returns the default factory for this implementation.

**Returns:**

the default factory for this implementation

---

**abstract public** PageContext getPageContext(Servlet servlet, ServletRequest request, ServletResponse response, String errorPageURL, boolean needsSession, int buffer, boolean autoflush)

Servlet  javservlet.jsp.PageContext

PageContext  JSP  _jspService()

PageContext.initialize()  PageContext

PageContext  releasePageContext()

```java
servlet
request
response
errorPageURL
needsSession
buffer
autoflush
return
```

JSP  URL null

JSP  true

PageContext.NO_BUFFER

PageContext.DEFAULT_BUFFER

IOException

See also  javaservlet.jsp.PageContext
getPageContext

```java
public abstract PageContext getPageContext(Servlet servlet,
                                      ServletRequest request,
                                      ServletResponse response,
                                      String errorPageURL,
                                      boolean needsSession,
                                      int buffer,
                                      boolean autoflush)
```

obtains an instance of an implementation dependent
javax.servlet.jsp.PageContext abstract class for the calling Servlet
and currently pending request and response.

This method is typically called early in the processing of the
_jspService() method of a JSP implementation class in order to
obtain a PageContext object for the request being processed.

Invoking this method shall result in the PageContext.initialize() method being invoked. The PageContext returned is properly initialized.

All PageContext objects obtained via this method shall be released
by invoking releasePageContext().

**Parameters:**
- `servlet` - the requesting servlet
- `request` - the current request pending on the servlet
- `response` - the current response pending on the servlet
- `errorPageURL` - the URL of the error page for the requesting JSP, or null
- `needsSession` - true if the JSP participates in a session
- `buffer` - size of buffer in bytes, PageContext.NO_BUFFER if no buffer, PageContext.DEFAULT_BUFFER if implementation default.
- `autoflush` - should the buffer autoflush to the output stream on buffer overflow, or throw an IOException?

**Returns:**
the page context

**See Also:**
PageContext
abstract public void releasePageContext(PageContext pc)

PageContext  PageContext.release()  JSP
  _jspService()

  pc             getPageContext()  PageContext

releasePageContext

public abstract void releasePageContext(PageContext pc)

called to release a previously allocated PageContext object. Results in PageContext.release() being invoked. This method should be invoked prior to returning from the _jspService() method of a JSP implementation class.

Parameters:
   pc - A PageContext previously obtained by getPageContext()

abstract public JspEngineInfo getEngineInfo()

JSP

  return       JSP  JspEngineInfo

g EngelInfo

public abstract JspEngineInfo getEngineInfo()

called to get implementation-specific information on the current JSP engine.

Returns:  
a JspEngineInfo object describing the current JSP engine
getJspApplicationContext

public abstract JspApplicationContext getJspApplicationContext(ServletContext context)

Obtains the JspApplicationContext instance associated with the web application for the given ServletContext.

Parameters:
context - The ServletContext for the web application the desired JspApplicationContext is associated with.

Returns:
The JspApplicationContext associated with the web application.

Since:
2.1
Encapsulates a portion of JSP code in an object that can be invoked as many times as needed. JSP Fragments are defined using JSP syntax as the body of a tag for an invocation to a SimpleTag handler, or as the body of a `<jsp:attribute>` standard action specifying the value of an attribute that is declared as a fragment, or to be of type JspFragment in the TLD.

The definition of the JSP fragment must only contain template text and JSP action elements. In other words, it must not contain scriptlets or scriptlet expressions. At translation time, the container generates an implementation of the JspFragment abstract class capable of executing the defined fragment.

A tag handler can invoke the fragment zero or more times, or pass it along to other tags, before returning. To communicate values to/from a
JSP fragment, tag handlers store/retrieve values in the JspContext associated with the fragment.

Note that tag library developers and page authors should not generate JspFragment implementations manually.

*Implementation Note:* It is not necessary to generate a separate class for each fragment. One possible implementation is to generate a single helper class for each page that implements JspFragment. Upon construction, a discriminator can be passed to select which fragment that instance will execute.

**Since:**
- JSP 2.0

### Constructor Summary

<table>
<thead>
<tr>
<th>JspFragment()</th>
</tr>
</thead>
</table>

### Method Summary

<table>
<thead>
<tr>
<th>JspContext</th>
<th>abstract getJspContext() Returns the JspContext that is bound to this JspFragment.</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>invoke(Writer out) Executes the fragment and directs all output to the given Writer, or the JspWriter returned by the getOut() method of the JspContext associated with the fragment if out is null.</td>
</tr>
</tbody>
</table>

Methods inherited from class java.lang.**Object**
- clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

### Constructor Detail
public JspFragment()

JspFragment

public JspFragment()

### Method Detail

abstract public void invoke(java.io.Writer out) throws JspException, java.io.IOException

Writer out  null JspContext  getOut()

JspWriter

```
out  Writer JspContext.getOut()  null
```

**Throws**

- JspException:
- SkipPageException: Tag.SKIP_PAGE
- SkipPageException
- java.io.IOException:

### invoke

public abstract void invoke(Writer out) throws JspException, IOException

Executes the fragment and directs all output to the given Writer, or
the JspWriter returned by the getOut() method of the JspContext
associated with the fragment if out is null.

**Parameters:**

- out - The Writer to output the fragment to, or null if output should
  be sent to JspContext.getOut().

**Throws:**

- JspException - Thrown if an error occurred while invoking this
  fragment.
- SkipPageException - Thrown if the page that (either directly or
indirectly) invoked the tag handler that invoked this fragment is to cease evaluation. The container must throw this exception if a Classic Tag Handler returned Tag.SKIP_PAGE or if a Simple Tag Handler threw SkipPageException.

IOException - If there was an error writing to the stream.

abstract public JspContext getJspContext()
JspFragment JspContext

getJspContext

public abstract JspContext getJspContext()

Returns the JspContext that is bound to this JspFragment.

Returns:
The JspContext used by this fragment at invocation time.
public interface JspIdConsumer

This interface indicates to the container that a tag handler wishes to be provided with a compiler generated ID.

The container sets the jspId attribute of the tag handler with an identification string, as part of tag property initialization. Each tag in a JSP page has a unique jspId, and a given tag in a JSP page always has the same jspId, even for multiple requests to the page.

Tag handler instances that implement JspIdConsumer cannot be reused.

Even though the jspId attribute is similar in concept to the jsp:id attribute of an XML view (see Section JSP.10.1.13 of the spec), they are not related. The jsp:id attribute is available only at translation time, and the jspId attribute is available only at request time.

The JSP container must provide a value for jspId that conforms to the following rules:

- It must start with a letter (as defined by the Character.isLetter() method) or underscore ('_').
- Subsequent characters may be letters (as defined by the Character.isLetter() method), digits (as defined by the Character.isDigit() method), dashes ('-'), or underscores ('_').

Note that the rules exclude colons ':' in a jspId, and that they are the same rules used for a component ID in JavaServer Faces.

Since:
   JSP 2.1
Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Signature</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>setJspId</td>
<td>void setJspId(String id)</td>
<td>Called by the container generated code to set a value for the jspId attribute.</td>
</tr>
</tbody>
</table>

Method Detail

setJspId

void setJspId(String id)

Called by the container generated code to set a value for the jspId attribute. An unique identification string, relative to this page, is generated at translation time.
javax.servlet.jsp  Interface JspPage

All Superinterfaces:
   Servlet

All Known Subinterfaces:
   HttpJspPage

public interface JspPage
extends Servlet

Implements: Servlet
Implemented by: HttpJspPage

JspPage  JSP  HTTP  HttpJspPage

jspInit()  jspDestroy()  _jspService()  Java

Servlet

jspInit()  jspDestroy()  JSP  _jspService()  JSP  JSP

_jjspService()

_jjspService()  JSP  JSP  JSP

_jjspService()  service()  JSP  JSP_Engine

JSP

public void _jspService(ServletRequestSubtype request,
ServletResponseSubtype response)
throws ServletException, IOException;
The JspPage interface describes the generic interaction that a JSP Page Implementation class must satisfy; pages that use the HTTP protocol are described by the HttpJspPage interface.

**Two plus One Methods**

The interface defines a protocol with 3 methods; only two of them: jspInit() and jspDestroy() are part of this interface as the signature of the third method: _jspService() depends on the specific protocol used and cannot be expressed in a generic way in Java.

A class implementing this interface is responsible for invoking the above methods at the appropriate time based on the corresponding Servlet-based method invocations.

The jspInit() and jspDestroy() methods can be defined by a JSP author, but the _jspService() method is defined automatically by the JSP processor based on the contents of the JSP page.

_**jspService()**_

The _jspService() method corresponds to the body of the JSP page. This method is defined automatically by the JSP container and should never be defined by the JSP page author.

If a superclass is specified using the extends attribute, that superclass may choose to perform some actions in its service() method before or after calling the _jspService() method. See using the extends attribute in the JSP_Engine chapter of the JSP specification.

The specific signature depends on the protocol supported by the JSP page.

    public void _jspService(ServletRequestSubtype request, ServletResponseSubtype response) throws ServletException, IOException;
## Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void jspDestroy()</td>
<td>The jspDestroy() method is invoked when the JSP page is about to be destroyed.</td>
</tr>
<tr>
<td>void jspInit()</td>
<td>The jspInit() method is invoked when the JSP page is initialized.</td>
</tr>
</tbody>
</table>

## Methods inherited from interface javax.servlet.Servlet

- destroy
- getServletConfig
- getServletInfo
- init
- service

## Method Detail

```java
public void jspInit()

dependencies:
jspInit() JSP
getServletConfig() JSP
jspInit JSP
```

### jspInit

```java
void jspInit()
```

The jspInit() method is invoked when the JSP page is initialized. It is the responsibility of the JSP implementation (and of the class mentioned by the extends attribute, if present) that at this point invocations to the getServletConfig() method will return the desired value. A JSP page can override this method by including a definition for it in a declaration element. A JSP page should redefine the init() method from Servlet.

```java
public void jspDestroy()

dependencies:
jspDestroy() JSP
```

### jspDestroy

```java
void jspDestroy()
```
jspDestroy

void jspDestroy()

The jspDestroy() method is invoked when the JSP page is about to be destroyed. A JSP page can override this method by including a definition for it in a declaration element. A JSP page should redefine the destroy() method from Servlet.
javax.servlet.jsp.tagext  Interface JspTag

All Known Subinterfaces:
    BodyTag, IterationTag, SimpleTag, Tag

All Known Implementing Classes:
    AttributeTag, BodyTagSupport, ConverterELTag, ConverterTag,
    FacetTag, SimpleTagSupport, TagAdapter, TagSupport,
    UIComponentBodyTag, UIComponentClassicTagBase,
    UIComponentELTag, UIComponentTag, UIComponentTagBase,
    ValidatorELTag, ValidatorTag

public interface JspTag

Implemented by: SimpleTag, Tag, UIComponentTagBase

Tag  SimpleTag

    since  2.0

Serves as a base class for Tag and SimpleTag. This is mostly for
organizational and type-safety purposes.

Since:
    JSP 2.0
PS :
javax.servlet.jsp  **Class JspTagException**

**java.lang.Object**
  └── **java.lang.Throwable**
      └── **java.lang.Exception**
          └── **javax.servlet.jsp.JspException**
              └── **javax.servlet.jsp.JspTagException**

**All Implemented Interfaces:**
  **Serializable**

```java
public class JspTagException
extends JspException

**Extends:** Throwable > Exception > JspException

JSP

Exception to be used by a Tag Handler to indicate some unrecoverable error. This error is to be caught by the top level of the JSP page and will result in an error page.

**Constructor Detail**

```java
public JspTagException(String msg)
```

```
JspTagException/

msg
String
```

**JspTagException**

```java
public JspTagException(String msg)
```

```
Constructs a new JspTagException with the specified message. The message can be written to the server log and/or displayed for the user.
```
Parameters:
- **msg** - a String specifying the text of the exception message

```java
public JspTagException()
JspTagException

JspTagException

public JspTagException()

Constructs a new JspTagException with no message.

public JspTagException(String message, Throwable rootCause)

Constructs a new JspTagException when the JSP Tag needs to throw an exception and include a message about the "root cause" exception that interfered with its normal operation, including a description message.

Parameters:
- **message** - a String containing the text of the exception message
- **rootCause** - the Throwable exception that interfered with the JSP Tag's normal operation, making this JSP Tag exception necessary
public JspTagException(Throwable rootCause)

Constructs a new JSP Tag exception when the JSP Tag needs to throw an exception and include a message about the "root cause" exception that interfered with its normal operation. The exception's message is based on the localized message of the underlying exception.

This method calls the `getLocalizedMessage` method on the `Throwable` exception to get a localized exception message. When subclassing `JspTagException`, this method can be overridden to create an exception message designed for a specific locale.

**Parameters:**
- `rootCause` - the `Throwable` exception that interfered with the JSP Tag's normal operation, making the JSP Tag exception necessary

**Since:**
- JSP 2.0

PS:
javax.servlet.jsp Class JspWriter

java.lang.Object
   java.io.Writer
      javax.servlet.jsp.JspWriter

All Implemented Interfaces:
   Closeable, Flushable, Appendable

Direct Known Subclasses:
   BodyContent

public abstract class JspWriter
   extends Writer

Extends: java.io.Writer
Extended by: BodyContent

JSP JspWriter out PageContext

   java.io.BufferedWriter java.io.PrintWriter print
   java.io.IOException PrintWriter

   JspWriter ServletResponse PrintWriter JspWriter
   PrintWriter getWriter() PrintWriter PrintWriter
   setContentType() JSP

   •
   •

   JSP autoFlush true JSP autoFlush false JSP autoFlush true
The actions and template data in a JSP page is written using the JspWriter object that is referenced by the implicit variable out which is initialized automatically using methods in the PageContext object.

This abstract class emulates some of the functionality found in the java.io.BufferedWriter and java.io.PrintWriter classes, however it differs in that it throws java.io.IOException from the print methods while PrintWriter does not.

Buffering

The initial JspWriter object is associated with the PrintWriter object of the ServletResponse in a way that depends on whether the page is or is not buffered. If the page is not buffered, output written to this JspWriter object will be written through to the PrintWriter directly, which will be created if necessary by invoking the getWriter() method on the response object. But if the page is buffered, the PrintWriter object will not be created until the buffer is flushed and operations like setContentType() are legal. Since this flexibility simplifies programming substantially, buffering is the default for JSP pages.

Buffering raises the issue of what to do when the buffer is exceeded. Two approaches can be taken:

- Exceeding the buffer is not a fatal error; when the buffer is exceeded, just flush the output.
- Exceeding the buffer is a fatal error; when the buffer is exceeded, raise an exception.

Both approaches are valid, and thus both are supported in the JSP technology. The behavior of a page is controlled by the autoFlush attribute, which defaults to true. In general, JSP pages that need to be
sure that correct and complete data has been sent to their client may want to set autoFlush to false, with a typical case being that where the client is an application itself. On the other hand, JSP pages that send data that is meaningful even when partially constructed may want to set autoFlush to true; such as when the data is sent for immediate display through a browser. Each application will need to consider their specific needs.

An alternative considered was to make the buffer size unbounded; but, this had the disadvantage that runaway computations would consume an unbounded amount of resources.

The "out" implicit variable of a JSP implementation class is of this type. If the page directive selects autoflush="true" then all the I/O operations on this class shall automatically flush the contents of the buffer if an overflow condition would result if the current operation were performed without a flush. If autoflush="false" then all the I/O operations on this class shall throw an IOException if performing the current operation would result in a buffer overflow condition.

                    boolean autoFlush)

Protected constructor.

Parameters:
  bufferSize - the size of the buffer to be used by the JspWriter
  autoFlush - whether the JspWriter should be autoflushing

Method Detail

abstract public void newLine() throws java.io.IOException

Throws
  java.io.IOException: I/O

newLine

public abstract void newLine()
    throws IOException

Write a line separator. The line separator string is defined by the system property line.separator, and is not necessarily a single newline ('\n') character.

Throws:
  IOException - If an I/O error occurs

abstract public void print(boolean b) throws java.io.IOException

boolean valueOf(boolean) JspWriter Writer

Throws
  java.io.IOException:
print

public abstract void print(boolean b) throws IOException

    Print a boolean value. The string produced by
    String.valueOf(boolean) is written to the JspWriter's buffer or, if no
    buffer is used, directly to the underlying writer.

Parameters:
    b - The boolean to be printed

Throws:
    IOException - If an error occurred while writing

abstract public void print(char c) throws java.io.IOException

    Print a character. The character is written to the JspWriter's buffer or,
    if no buffer is used, directly to the underlying writer.

Parameters:
    c - The char to be printed

Throws:
    IOException - If an error occurred while writing
abstract public void print(int i) throws java.io.IOException
    \text{valueOf(int)} JspWriter Writer
        \text{i} \quad \text{int}
    \text{Throws} \quad \text{java.io.IOException: toString(int)}

print

public abstract void print(int i)
    \text{throws IOException}

    Print an integer. The string produced by \text{String.valueOf(int)} is
    written to the JspWriter's buffer or, if no buffer is used, directly to the
    underlying writer.

Parameters:
    \text{i} - The \text{int} to be printed

Throws:
    \text{IOException} - If an error occurred while writing

See Also:
    \text{Integer.toString(int)}

abstract public void print(long l) throws java.io.IOException
    \text{valueOf(long)} JspWriter Writer
        \text{l} \quad \text{long}
    \text{Throws} \quad \text{java.io.IOException: toString(long)}

print

public abstract void print(long l)
    \text{throws IOException}

    Print a long integer. The string produced by \text{String.valueOf(long)} is
written to the JspWriter's buffer or, if no buffer is used, directly to the underlying writer.

**Parameters:**
- \( l \) - The long to be printed

**Throws:**
- \( 	ext{IOException} \) - If an error occurred while writing

**See Also:**
- \( 	ext{Long.toString(long)} \)

---

abstract public void print(float \( f \)) throws java.io.IOException

\( \text{valueOf(float)} \) JspWriter Writer

\( f \) float

**Throws**
- java.io.IOException:

**See also**
- \( 	ext{toString(float)} \)

---

**print**

public abstract void print(float \( f \))
throws IOException

Print a floating-point number. The string produced by \( \text{String.valueOf(float)} \) is written to the JspWriter's buffer or, if no buffer is used, directly to the underlying writer.

**Parameters:**
- \( f \) - The float to be printed

**Throws:**
- \( 	ext{IOException} \) - If an error occurred while writing

**See Also:**
- \( 	ext{Float.toString(float)} \)

---

abstract public void print(double \( d \)) throws java.io.IOException
valueOf(double)  JspWriter  Writer

\(d\)  \hspace{1cm} \text{double}

Throws  \hspace{1cm} \text{java.io.IOException: toString(double)}

See also

print

public abstract void print(double d)  
throws IOException

Print a double-precision floating-point number. The string produced by String.valueOf(double) is written to the JspWriter’s buffer or, if no buffer is used, directly to the underlying writer.

Parameters:

\(d\) - The double to be printed

Throws:

IOException - If an error occurred while writing

See Also:

Double.toString(double)

abstract public void print(char[] s) throws 
java.io.IOException  
JspWriter  Writer

\(s\)

Throws  \hspace{1cm} \text{NullPointerException: s null}

Throws  \hspace{1cm} \text{java.io.IOException:}

print

public abstract void print(char[] s)  
throws IOException

Print an array of characters. The characters are written to the JspWriter's buffer or, if no buffer is used, directly to the underlying
abstract public void print(String s) throws IOException

Print a string. If the argument is null then the string "null" is printed. Otherwise, the string's characters are written to the JspWriter's buffer or, if no buffer is used, directly to the underlying writer.

Parameters:
  s - The String to be printed

Throws:
  IOException - If an error occurred while writing

See also
  toString()
print

public abstract void print(Object obj)
    throws IOException

Print an object. The string produced by the String.valueOf(Object) method is written to the JspWriter's buffer or, if no buffer is used, directly to the underlying writer.

Parameters:
    obj - The object to be printed

Throws:
    IOException - If an error occurred while writing

See Also:
    Object.toString()

abstract public void println() throws java.io.IOException

Terminate the current line by writing the line separator string. The line separator string is defined by the system property line.separator, and is not necessarily a single newline character ('\n').

Throws:
    IOException - If an error occurred while writing

abstract public void println(boolean x) throws
javax.printing

---

**println**

```java
public abstract void println(boolean x)
throws IOException
```

Print a boolean value and then terminate the line. This method behaves as though it invokes `print(boolean)` and then `println()`.

**Parameters:**
- `x` - the boolean to write

**Throws:**
- `IOException` - If an error occurred while writing

---

**abstract public void println(char x) throws java.io.IOException**

```java
public abstract void println(char x)
throws IOException
```

Print a character and then terminate the line. This method behaves as though it invokes `print(char)` and then `println()`.

**Parameters:**
- `x` - the char to write

**Throws:**
IOException - If an error occurred while writing

abstract public void println(int x) throws java.io.IOException

public abstract void println(int x) throws IOException

Print an integer and then terminate the line. This method behaves as though it invokes print(int) and then println().

Parameters:
x - the int to write

Throws:
IOException - If an error occurred while writing

abstract public void println(long x) throws java.io.IOException

public abstract void println(long x) throws IOException

Print a long integer and then terminate the line. This method behaves as though it invokes print(long) and then println().
abstract public void println(float x) throws IOException

print ln

public abstract void println(float x)
throws IOException

Print a floating-point number and then terminate the line. This method behaves as though it invokes print(float) and then println().

Parameters:
  x - the float to write

Throws:
  IOException - If an error occurred while writing

abstract public void println(double x) throws IOException

print ln

public abstract void println(double x)
throws IOException

Print a double-precision number and then terminate the line. This method behaves as though it invokes print(double) and then println().

Parameters:
  x - the double to write

Throws:
  IOException - If an error occurred while writing
public abstract void println(double x)  
   throws IOException

Print a double-precision floating-point number and then terminate the line. This method behaves as though it invokes print(double) and then println().

Parameters:
        x - the double to write

Throws:
       IOException - If an error occured while writing

abstract public void println(char[] x) throws java.io.IOException

print(char[]) prin
        x                         char[]
        char[]
Thros         java.io.IOException:

println

public abstract void println(char[] x)  
   throws IOException

Print an array of characters and then terminate the line. This method behaves as though it invokes print(char[]) and then println().

Parameters:
        x - the char[] to write

Throws:
       IOException - If an error occured while writing

abstract public void println(String x) throws java.io.IOException

String
        #print(String)   #pr

x                 String
Throws: java.io.IOException:

println

public abstract void println(String x) throws IOException

Print a String and then terminate the line. This method behaves as though it invokes print(String) and then println().

Parameters:
  x - the String to write

Throws:
  IOException - If an error occurred while writing

abstract public void println(Object x) throws java.io.IOException

Print an Object and then terminate the line. This method behaves as though it invokes print(Object) and then println().

Parameters:
  x - the Object to write

Throws:
  IOException - If an error occurred while writing
abstract public void clear() throws java.io.IOException

clear

epublic abstract void clear()
    throws IOException

    Clear the contents of the buffer. If the buffer has been already been flushed then the clear operation shall throw an IOException to signal the fact that some data has already been irrevocably written to the client response stream.

    Throws:
        IOException - If an I/O error occurs

------------------------------------------------------------------------

abstract public void clearBuffer() throws java.io.IOException

clearBuffer

epublic abstract void clearBuffer()
    throws IOException

    Clears the current contents of the buffer. Unlike clear(), this method will not throw an IOException if the buffer has already been flushed. It merely clears the current content of the buffer and returns.

    Throws:
        IOException - If an I/O error occurs
abstract public void flush() throws java.io.IOException

write()  flush()  Writer
OutputStream

write()  flush()  IOException

Throws

java.io.IOException: I/O

flush

public abstract void flush()

throws IOException

Flush the stream. If the stream has saved any characters from the various write() methods in a buffer, write them immediately to their intended destination. Then, if that destination is another character or byte stream, flush it. Thus one flush() invocation will flush all the buffers in a chain of Writers and OutputStreams.

The method may be invoked indirectly if the buffer size is exceeded.

Once a stream has been closed, further write() or flush() invocations will cause an IOException to be thrown.

Specified by:

flush in interface Flushable

Specified by:

flush in class Writer

Throws:

IOException - If an I/O error occurs

abstract public void close() throws java.io.IOException
JspWriter JSP close()
flush()

Throws java.io.IOException: I/O

close

public abstract void close()
    throws IOException

Close the stream, flushing it first.

This method needs not be invoked explicitly for the initial JspWriter as the code generated by the JSP container will automatically include a call to close().

Closing a previously-closed stream, unlike flush(), has no effect.

Specified by:
    close in interface Closeable
Specified by:
    close in class Writer
Throws:
    IOException - If an I/O error occurs

public int getBufferSize()
JspWriter

    return 0

getBufferSize

public int getBufferSize()

This method returns the size of the buffer used by the JspWriter.
abstract public int getRemaining()

    return

getRemaining

class public abstract int getRemaining()

    This method returns the number of unused bytes in the buffer.

    Returns:
    the number of bytes unused in the buffer

public boolean isAutoFlush()

    return  JspWriter  IOException

isAutoFlush

    This method indicates whether the JspWriter is autoFlushing.

    Returns:
    if this JspWriter is auto flushing or throwing IOExceptions on
    buffer overflow conditions

Method Detail

public String getId() throws JAXRException
Id NULL

    0

        return ID

Throws JAXRException: JAXR
**getld**

```java
String getId() throws JAXRException
```

Returns the unique Id of this key. Default is a NULL String.

**Capability Level: 0**

**Returns:**
- the id for this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public void setId(String id) throws JAXRException**

**ID**

```
0
```

```java
id
```

**Throws**
- `JAXRException`: JAXR

---

**setId**

```java
void setId(String id) throws JAXRException
```

Sets the unique id associated with this key.

**Capability Level: 0**

**Parameters:**
- `id` - the id being defined for this object

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

PS:
javax.resource.spi Interface LazyAssociatableConnectionManager

public interface LazyAssociatableConnectionManager

ConnectionManager
　version 1.0

This is a mix-in interface that may be optionally implemented by a ConnectionManager implementation. An implementation of this interface must support the lazy connection association optimization.

Version: 1.0
Author: Ram Jeyaraman

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void associateConnection(Object connection,</td>
<td>This method is called by a resource adapter (that is capable of lazy connection association optimization) in order to lazily associate a connection object with a ManagedConnection instance.</td>

Method Detail

public void associateConnection(Object connection, ManagedConnectionFactory mcf, ConnectionRequestInfo cxReqInfo) throws ResourceException
associateConnection

void associateConnection(Object connection,
                         ManagedConnectionFactory mcf,
                         ConnectionRequestInfo cxReqInfo)
throws ResourceException

This method is called by a resource adapter (that is capable of lazy connection association optimization) in order to lazily associate a connection object with a ManagedConnection instance.

Parameters:
connection - the connection object that is to be associated.
mcf - The ManagedConnectionFactory instance that was originally used to create the connection object.
cxReqInfo - connection request information. This information must be the same as that used to originally create the connection object.

Throws:
ResourceException - Generic exception.
ApplicationServerInternalException - Application server specific exception.
SecurityException - Security related error.
ResourceAllocationException - Failed to allocate system resources for connection request.
ResourceAdapterInternalException - Resource adapter related error condition.

</table>

Method Detail

public void lazyEnlist(ManagedConnection mc) throws ResourceException
    XA
        mc ManagedConnection
lazyEnlist

void lazyEnlist(ManagedConnection mc)
throws ResourceException

This method is called by a resource adapter (that is capable of lazy transaction enlistment optimization) in order to lazily enlist a connection object with a XA transaction.

Parameters:
  mc - The ManagedConnection instance that needs to be lazily associated.

Throws:
  ResourceException - Generic exception.
  ApplicationServerInternalException - Application server specific exception.
  ResourceAllocationException - Failed to allocate system resources for connection request.
  ResourceAdapterInternalException - Resource adapter related error condition.
public interface LazyEnlistableManagedConnection

ManagedConnection (enlistment)
version 1.0

This is a mix-in interface that may be optionally implemented by a ManagedConnection implementation. An implementation of this interface must support the lazy transaction enlistment optimization.

**javax.faces.validator**  **Class LengthValidator**

**java.lang.Object**

- javax.faces.validator.LengthValidator

**All Implemented Interfaces:**
  - `EventListener`, `StateHolder`, `Validator`

```java
public class LengthValidator
extends Object
implements Validator, StateHolder

Implements: Validator, StateHolder
```

**LengthValidator**  **Validator**  **String**

- `toString`  **String**
- `Validator`  `maximum`  **String**  **String**
  - `MAXIMUM_MESSAGE_ID`  **ValidatorException**
- `Validator`  `minimum`  **String**  **String**
  - `MINIMUM_MESSAGE_ID`  **ValidatorException**

**ValidatorException**  **ID**  **javax.faces.Number**  **Converter**  **Locale**

---

**LengthValidator** is a **Validator** that checks the number of characters in the String representation of the value of the associated component. The following algorithm is implemented:

- Convert the passed value to a String, if necessary, by calling its `toString()` method.
- If a `maximum` property has been configured on this **validator**, check the length of the converted String against this limit. If the String length is larger than the specified maximum, throw a
ValidatorException containing a a MAXIMUM_MESSAGE_ID message.
- If a minimum property has been configured on this validator, check the length of the converted String against this limit. If the String length is less than the specified minimum, throw a ValidatorException containing a a MINIMUM_MESSAGE_ID message.

For all of the above cases that cause a ValidatorException to be thrown, if there are parameters to the message that match up with validator parameters, the values of these parameters must be converted using the Converter registered in the application under the converter id javax.faces.Number. This allows the values to be localized according to the current Locale.

### Field Summary

**Methods inherited from class java.lang.Object**
VALIDATOR_ID

public static final String VALIDATOR_ID

The standard validator id for this validator.

See Also:
Constant Field Values

MAXIMUM_MESSAGE_ID

public static final String MAXIMUM_MESSAGE_ID

The message identifier of the FacesMessage to be created if the maximum length check fails. The message format string for this message may optionally include the following placeholders:

- `{0}` replaced by the configured maximum length.
- `{1}` replaced by a String whose value is the label of the input component that produced this message.

See Also:
Constant Field Values

MINIMUM_MESSAGE_ID
public static final String MINIMUM_MESSAGE_ID

The message identifier of the FacesMessage to be created if the minimum length check fails. The message format string for this message may optionally include the following placeholders:

- \{0\} replaced by the configured minimum length.
- \{1\} replaced by a string whose value is the label of the input component that produced this message.

See Also:
Constant Field Values

Constructor Detail

public LengthValidator()

Validator

LengthValidator

public LengthValidator()

Construct a Validator with no preconfigured limits.

public LengthValidator(int maximum)

Validator

maximum

LengthValidator
public LengthValidator(int maximum)

Construct a **Validator** with the specified preconfigured limit.

**Parameters:**
- `maximum` - Maximum value to allow

public LengthValidator(int maximum, int minimum)

**Validator**

```java
  public int getMaximum()
  
  getMaximum
```
Return the maximum length to be enforced by this `Validator`, or 0 if the maximum has not been set.

```java
public void setMaximum(int maximum)
```

Set the maximum length to be enforced by this `Validator`. 

**Parameters:**
- `maximum` - The new maximum value

```java
public int getMinimum()
```

Return the minimum length to be enforced by this `Validator`, or 0 if the minimum has not been set.

```java
public void setMinimum(int minimum)
```

```java
Validator
```
**setMinimum**

```java
public void setMinimum(int minimum)
```

Set the minimum length to be enforced by this **Validator**.

**Parameters:**

- `minimum` - The new minimum value

---

**public void validate(FacesContext context, UIComponent component, Object value) throws ValidatorException**

Throws

- `NullPointerException`: `NullPointerException`
- `context`: `null`
- `component`: `null`

Throws

- **ValidatorException**: `NullPointerException`

---

**validate**

```java
public void validate(FacesContext context, UIComponent component, Object value)
```

throws **ValidatorException**

**Description copied from interface:** Validator

Perform the correctness checks implemented by this **Validator** against the specified **UIComponent**. If any violations are found, a **ValidatorException** will be thrown containing the **FacesMessage** describing the failure.

**Specified by:**

- **validate** in interface **Validator**

**Parameters:**

- `context` - FacesContext for the request we are processing
- `component` - UIComponent we are checking for correctness
value - the value to validate

**Throws:**
- NullPointerException - if context or component is null
- ValidatorException - if validation fails

---

```java
public boolean equals(Object otherObj)
```

**equals**

```java
public boolean equals(Object otherObj)
```

**Overrides:**
- equals in class Object

---

```java
public int hashCode()
```

**hashCode**

```java
public int hashCode()
```

**Overrides:**
- hashCode in class Object

---

```java
public Object saveState(FacesContext context)
```

**saveState**

```java
public Object saveState(FacesContext context)
```

**Description copied from interface: StateHolder**

Gets the state of the instance as a Serializable Object.
If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext)` method on all those instances as well. **This method must not save the state of children and facets.** That is done via the `StateManager`.

This method must not alter the state of the implementing object. In other words, after executing this code:

```java
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be `Serializable`

**Specified by:**

`saveState` in interface `StateHolder`

```
public void restoreState(FacesContext context, Object state)
```

```
restoreState
```

```
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface:** `StateHolder`

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.
public boolean isTransient()

isTransient

public boolean isTransient()

  Description copied from interface: StateHolder

  If true, the Object implementing this interface must not participate in state saving or restoring.

  Specified by:
  isTransient in interface StateHolder

public void setTransient(boolean transientValue)

setTransient

public void setTransient(boolean transientValue)

  Description copied from interface: StateHolder

  Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

  Specified by:
  setTransient in interface StateHolder

Parameters:
  transientValue - boolean pass true if this Object will participate in state saving or restoring, otherwise pass false.

javax.faces.lifecycle Class Lifecycle

java.lang.Object
   javax.faces.lifecycle.Lifecycle

public abstract class Lifecycle
extends Object

Lifecycle  JavaServer Faces  JavaServer Faces

Lifecycle manages the processing of the entire lifecycle of a particular JavaServer Faces request. It is responsible for executing all of the phases that have been defined by the JavaServer Faces Specification, in the specified order, unless otherwise directed by activities that occurred during the execution of each phase.

An instance of Lifecycle is created by calling the getLifecycle() method of LifecycleFactory, for a specified lifecycle identifier. Because this instance is shared across multiple simultaneous requests, it must be implemented in a thread-safe manner.

Constructor Summary

| Lifecycle() |

Method Summary

<p>| addPhaseListener(PhaseListener listener) |
| Register a new PhaseListener instance that is |</p>
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>abstract void interested(FacesContext context)</code></td>
<td>Execute all of the phases of the request processing lifecycle, up to but not including the Render Response phase, as described in the JavaServer Faces Specification, in the specified order.</td>
</tr>
<tr>
<td><code>abstract void execute(FacesContext context)</code></td>
<td>Execute all of the phases of the request processing lifecycle, up to but not including the Render Response phase, as described in the JavaServer Faces Specification, in the specified order.</td>
</tr>
<tr>
<td><code>abstract void removePhaseListener(PhaseListener listener)</code></td>
<td>Deregister an existing PhaseListener instance that is no longer interested in being notified before and after the processing for standard phases of the request processing lifecycle.</td>
</tr>
<tr>
<td><code>abstract void render(FacesContext context)</code></td>
<td>Execute the Render Response phase of the request processing lifecycle, unless the responseComplete() method has been called on the FacesContext instance associated with the current request.</td>
</tr>
</tbody>
</table>

Methods inherited from class java.lang.Object

`clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
abstract public void addPhaseListener(PhaseListener listener)

*PhaseListener*

<table>
<thead>
<tr>
<th>listener</th>
<th>PhaseListener</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>NullPointerException: listener null</td>
</tr>
</tbody>
</table>

addPhaseListener

public abstract void addPhaseListener(PhaseListener listener)

Register a new PhaseListener instance that is interested in being notified before and after the processing for standard phases of the request processing lifecycle.

Parameters:

- listener - The PhaseListener to be registered

Throws:

- NullPointerException - if listener is null

abstract public void execute(FacesContext context) throws FacesException

JavaServer Faces

renderResponse() responseComplete()

<table>
<thead>
<tr>
<th>context</th>
<th>FacesContext</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>FacesException:</td>
</tr>
<tr>
<td>Throws</td>
<td>NullPointerException: context null</td>
</tr>
</tbody>
</table>
**execute**

```java
public abstract void execute(FacesContext context)
    throws FacesException
```

Execute all of the phases of the request processing lifecycle, up to but not including the *Render Response* phase, as described in the JavaServer Faces Specification, in the specified order. The processing flow can be affected (by the application, by components, or by event listeners) by calls to the `renderResponse()` or `responseComplete()` methods of the `FacesContext` instance associated with the current request.

**Parameters:**
- `context` - FacesContext for the request to be processed

**Throws:**
- `FacesException` - if thrown during the execution of the request processing lifecycle
- `NullPointerException` - if context is null

**abstract public PhaseListener[] getPhaseListeners()**

```java
Lifecycle PhaseListener 0
```

**getPhaseListeners**

```java
public abstract PhaseListener[] getPhaseListeners()
```

Return the set of registered `PhaseListener`s for this `Lifecycle` instance. If there are no registered listeners, a zero-length array is returned.

**abstract public void removePhaseListener(PhaseListener listener)**
**PhaseListener**

*listener*  
Throws  
NullPointerException: listener null

**removePhaseListener**

public abstract void removePhaseListener(*PhaseListener* listener)

Deregister an existing *PhaseListener* instance that is no longer interested in being notified before and after the processing for standard phases of the request processing lifecycle. If no such listener instance has been registered, no action is taken.

**Parameters:**
- listener - The *PhaseListener* to be deregistered

**Throws:**
- NullPointerException - if listener is null

**abstract public void render**(*FacesContext* context) throws *FacesException*

<table>
<thead>
<tr>
<th>context</th>
<th>FacesContext</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td><em>FacesException</em>:</td>
</tr>
<tr>
<td>Throws</td>
<td>NullPointerException: context null</td>
</tr>
</tbody>
</table>

**render**

public abstract void render(*FacesContext* context) throws *FacesException*

Execute the *Render Response* phase of the request processing lifecycle, unless the responseComplete() method has been called on
the `FacesContext` instance associated with the current request.

**Parameters:**
context - FacesContext for the request being processed

**Throws:**
- `FacesException` - if an exception is thrown during the execution of the request processing lifecycle
- `NullPointerException` - if context is null
javax.faces.lifecycle Class LifecycleFactory

java.lang.Object
  └─javax.faces.lifecycle.LifecycleFactory

public abstract class LifecycleFactory
  extends Object

LifecycleFactory Lifecycle JavaServer Faces Lifecycle Lifecycle

JavaServer Faces Web LifecycleFactory

LifecycleFactory factory = (LifecycleFactory)
FactoryFinder.getFactory(FactoryFinder.LIFECYCLE_FACTORY);

LifecycleFactory is a factory object that creates (if needed) and returns Lifecycle instances. Implementations of JavaServer Faces must provide at least a default implementation of Lifecycle. Advanced implementations (or external third party libraries) MAY provide additional Lifecycle implementations (keyed by lifecycle identifiers) for performing different types of request processing on a per-request basis.

There must be one LifecycleFactory instance per web application that is utilizing JavaServer Faces. This instance can be acquired, in a portable manner, by calling:

   LifecycleFactory factory = (LifecycleFactory)
     FactoryFinder.getFactory(FactoryFinder.LIFECYCLE_FACTORY);
### Constructor Summary

**LifecycleFactory()**

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>addLifecycle(String lifecycleId, Lifecycle lifecycle)</strong></td>
<td>Register a new Lifecycle instance, associated with the specified lifecycleId, to be supported by this LifecycleFactory.</td>
</tr>
<tr>
<td><strong>getLifecycle(String lifecycleId)</strong></td>
<td>Create (if needed) and return a Lifecycle instance for the specified lifecycle identifier.</td>
</tr>
<tr>
<td><strong>getLifecycleIds()</strong></td>
<td>Return an Iterator over the set of lifecycle identifiers supported by this factory.</td>
</tr>
</tbody>
</table>

### Methods inherited from class java.lang.Object

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

### Field Detail

**DEFAULT_LIFECYCLE**

public static final String DEFAULT_LIFECYCLE

The lifecycle identifier for the default Lifecycle instance for this JavaServer Faces implementation.
JavaServer Faces implementation.

See Also:
   Constant Field Values

### Constructor Detail

```java
public LifecycleFactory()
```

**LifecycleFactory**

```java
public LifecycleFactory()
```

### Method Detail

```java
abstract public void addLifecycle(String lifecycleId, Lifecycle lifecycle)
```

<table>
<thead>
<tr>
<th>lifecycleId</th>
<th>Lifecycle</th>
<th>LifecycleFactory</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lifecycle</td>
<td>Web</td>
<td></td>
</tr>
</tbody>
</table>

**Throws**  
IllegalArgumentException: lifecycleId  
NullPointerException: lifecycleId lifecycle null

```java
addLifecycle
```

public abstract void addLifecycle(String lifecycleId, Lifecycle lifecycle)

Register a new Lifecycle instance, associated with the specified lifecycleId, to be supported by this LifecycleFactory. This method may be called at any time, and makes the corresponding Lifecycle
instance available throughout the remaining lifetime of this web application.

**Parameters:**
- lifecycleId - Identifier of the new Lifecycle lifecycle - Lifecycle instance that we are registering

**Throws:**
- IllegalArgumentException - if a Lifecycle with the specified lifecycleId has already been registered
- NullPointerException - if lifecycleId or lifecycle is null

```java
abstract public Lifecycle getLifecycle(String lifecycleId)
```

```java
public abstract Lifecycle getLifecycle(String lifecycleId)
```

Create (if needed) and return a Lifecycle instance for the specified lifecycle identifier. The set of available lifecycle identifiers is available via the getLifecycleIds() method.

Each call to getLifecycle() for the same lifecycleId, from within the same web application, must return the same Lifecycle instance.

**Parameters:**
- lifecycleId - Lifecycle identifier of the requested Lifecycle instance

**Throws:**
IllegalArgumentException - if no Lifecycle instance can be returned for the specified identifier

NullPointerException - if lifecycleId is null

abstract public java.util.Iterator<E> getLifecycleIds()

Iterator LifecycleFactory.DEFAULT_LIFECYCLE

getLifecycleIds

public abstract Iterator<String> getLifecycleIds()

Return an Iterator over the set of lifecycle identifiers supported by this factory. This set must include the value specified by LifecycleFactory.DEFAULT_LIFECYCLE.
javax.xml.registry Interface LifeCycleManager

All Known Subinterfaces:
   BusinessLifeCycleManager

public interface LifeCycleManager

Implemented by: BusinessLifeCycleManager

LifeCycleManager API

JAXR UnsupportedCapabilityException

The LifeCycleManager interface is the main interface in the API for managing life cycle operations on objects defined by the information model.

The factory methods of this interface must throw an UnsupportedCapabilityException if the client attempts to create an instance of an infomodel interface that is not supported by the capability level of the JAXR provider.

### Method Detail

**public Object createObject(String interfaceName) throws JAXRException, InvalidRequestException, UnsupportedCapabilityException**

**Organization**

Organization org = (Organization)
lifeCycleMgr.createObject(LifeCycleManager.ORGANIZATION);

0

<table>
<thead>
<tr>
<th>interfaceName</th>
<th>javax.xml.registry.infomodel</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>Object</td>
</tr>
<tr>
<td>Throws</td>
<td>JAXRException: JAXR</td>
</tr>
<tr>
<td></td>
<td>InvalidRequestException: javax.xml.registry.infomodel</td>
</tr>
<tr>
<td></td>
<td>UnsupportedCapabilityException: JAXR</td>
</tr>
</tbody>
</table>

**createObject**

Object createObject(String interfaceName)

Throws JAXRException, InvalidRequestException, UnsupportedCapabilityException

Creates instances of information model interfaces (factory method).  
To create an Organization, use this method as follows:

Organization org = (Organization)
lifeCycleMgr.createObject(LifeCycleManager.ORGANIZATION);

**Capability Level: 0**
Parameters:
- `interfaceName` - the unqualified name of an interface in the `javax.xml.registry.infomodel` package

Returns:
an Object that can then be cast to an instance of the interface

Throws:
- `JAXRException` - if the JAXR provider encounters an internal error
- `InvalidRequestException` - if the interface is not an interface in the `javax.xml.registry.infomodel` package
- `UnsupportedCapabilityException` - if the client attempts to create an instance of an infomodel interface that is not supported by the capability level of the JAXR provider

```java
public Association createAssociation(RegistryObject targetObject, Concept associationType) throws JAXRException

Association sourceObject  null Association RegistryObject

UDDI  Organization  Association

0

targetObject  Association  RegistryObject
associationType  Association
return  Association
Throws  JAXRException:  JAXR
```

`createAssociation`

```java
Association createAssociation(RegistryObject targetObject, Concept associationType) throws JAXRException

Creates an Association instance using the specified parameters. The`
sourceObject is left null and will be set when the Association is added to a RegistryObject.

Note that for a UDDI provider an Association may only be created between Organizations.

**Capability Level: 0**

**Parameters:**
- targetObject - the target RegistryObject for the association
- associationType - the association type for the Association

**Returns:**
the Association instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

```java
public Classification createClassification(ClassificationScheme scheme, String name, String value) throws JAXRException
Classification createClassification(ClassificationScheme scheme, String name, String value)
```

<table>
<thead>
<tr>
<th>parameter</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>scheme</td>
<td>ClassificationScheme</td>
</tr>
<tr>
<td>name</td>
<td>String</td>
</tr>
<tr>
<td>value</td>
<td>String</td>
</tr>
<tr>
<td>return</td>
<td>Classification</td>
</tr>
</tbody>
</table>

**Throws**
- JAXRException: JAXR

**createClassification**

```java
classification createClassification(ClassificationScheme scheme, String name, String value)
```
throws JAXRException

Creates a Classification instance for an external Classification using the specified String name and String value that identify a taxonomy element within the specified ClassificationScheme.

**Capability Level: 0**

**Parameters:**
- `scheme` - the ClassificationScheme to be used
- `name` - the name of the taxonomy element (a String)
- `value` - the value of the taxonomy element

**Returns:**
the Classification instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

```java
public Classification createClassification(ClassificationScheme scheme, InternationalString name, String value) throws JAXRException {
    Classification return Classification
    \[\text{Scheme} \text{Classification} \text{InternationalString} \text{String} \text{ClassificationScheme}\]
    \[\text{0}\]
    \[\text{scheme} \text{Classification} \text{Scheme}\]
    \[\text{name} \text{InternationalString}\]
    \[\text{value} \text{InternationalString}\]
    \[\text{return} \text{Classification}\]
    \[\text{Throws} \text{JAXRException: JAXR}\]
```

createClassification
**Classification** createClassification(**ClassificationScheme** scheme, **InternationalString** name, **String** value)

throws **JAXRException**

Creates a Classification instance for an external Classification using the specified InternationalString name and String value that identify a taxonomy element within the specified ClassificationScheme.

**Capability Level:** 0

**Parameters:**
- `scheme` - the ClassificationScheme to be used
- `name` - the name of the taxonomy element (an InternationalString)
- `value` - the value of the taxonomy element

**Returns:**
- the Classification instance created

**Throws:**
- **JAXRException** - if the JAXR provider encounters an internal error

---

**public Classification** createClassification(**Concept** concept)

throws **JAXRException**, **InvalidRequestException**

Classification Classification Concept ClassificationScheme

0

```
  concept               Concept
  return               Classification
  Throws                JAXRException: JAXR
  Throws                InvalidRequestException: Concept ClassificationScheme
```

**createClassification**

**Classification** createClassification(**Concept** concept)
throws JAXRException, InvalidRequestException

Creates a Classification instance for an internal Classification using
the specified Concept that identifies a taxonomy element within an
internal ClassificationScheme.

**Capability Level: 0**

**Parameters:**
- concept - the Concept that identifies the taxonomy element

**Returns:**
- the Classification instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error
- InvalidRequestException - if the Concept is not under a ClassificationScheme

```java
public ClassificationScheme createClassificationScheme(String name, String description) throws JAXRException, InvalidRequestException

String  ClassificationScheme

0

name ClassificationScheme String
description ClassificationScheme String
return  ClassificationScheme
Throws JAXRException: JAXR
```

createClassificationScheme

```java
ClassificationScheme createClassificationScheme(String name, String description)
```
Creates a ClassificationScheme given the specified String parameters.

**Capability Level: 0**

**Parameters:**
- name - the name of the ClassificationScheme (a String)
- description - a description of the ClassificationScheme (a String)

**Returns:**
the ClassificationScheme instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error
- InvalidRequestException

```java
public ClassificationScheme createClassificationScheme(InternationalString name, InternationalString description) throws JAXRException, InvalidRequestException
  InternationalString ClassificationScheme

0

    name               ClassificationScheme  InternationalString
    description  ClassificationScheme  InternationalString
    return          ClassificationScheme
    Throws          JAXRException: JAXR
```

createClassificationScheme

```java
ClassificationScheme createClassificationScheme(InternationalString description) throws JAXRException
```
InvalidRequestException

Creates a ClassificationScheme given the specified InternationalString parameters.

**Capability Level: 0**

**Parameters:**
- name - the name of the ClassificationScheme (an InternationalString)
- description - a description of the ClassificationScheme (an InternationalString)

**Returns:**
- the ClassificationScheme instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error
- InvalidRequestException

```java
public ClassificationScheme createClassificationScheme(Concept concept) throws JAXRException, InvalidRequestException
ClassificationScheme Concept Concept ClassificationScheme

Concept ClassificationScheme

BusinessQueryManager findConcept Concept ClassificationScheme Concept ClassificationScheme

UDDI tModel tModel Concept tModel ClassificationScheme UDDI

0
```
createClassificationScheme

ClassificationScheme createClassificationScheme(Concept concept) throws JAXRException

Creates a ClassificationScheme from a Concept that has no ClassificationScheme or parent Concept.

This method is a special-case method to do a type-safe conversion from Concept to ClassificationScheme.

This method is provided to allow for Concepts returned by the BusinessQueryManager findConcepts call to be safely cast to ClassificationScheme. It is up to the programmer to make sure that the Concept is indeed semantically a ClassificationScheme.

This method is necessary because in the UDDI specification a tModel may serve multiple purposes, and there is no way to know when a tModel maps to a Concept and when it maps to a ClassificationScheme. The UDDI specification leaves the determination to the programmer, and consequently so does this method.

Capability Level: 0

Parameters:
  concept - the Concept to be used

Returns:
  the ClassificationScheme instance created

Throws:
  JAXRException - if the JAXR provider encounters an internal error
InvalidRequestException - if the Concept has a parent Concept or is under a ClassificationScheme

public Concept createConcept(RegistryObject parent, String name, String value) throws JAXRException
Concept name String

0

parent ClassificationScheme Concept
name Concept String
value Concept
return Concept
Throws JAXRException: JAXR

createConcept

Concept createConcept(RegistryObject parent, String name, String value)
throws JAXRException

Creates a Concept instance using the specified parameters, where the name is a String.

Capability Level: 0

Parameters:
  parent - a reference either to a parent ClassificationScheme or to a Concept
  name - the name of the concept (a String)
  value - the value of the concept

Returns:
  the Concept instance created

Throws:
  JAXRException - if the JAXR provider encounters an internal
public Concept createConcept(RegistryObject parent, InternationalString name, String value) throws JAXRException

Concept name InternationalString

0

parent ClassificationScheme Concept
name Concept InternationalString
value Concept
return Concept
Throws JAXRException: JAXR

createConcept

Concept createConcept(RegistryObject parent, InternationalString name, String value) throws JAXRException

Creates a Concept instance using the specified parameters, where the name is an InternationalString.

Capability Level: 0

Parameters:
parent - a reference either to a parent ClassificationScheme or to a Concept
name - the name of the concept (an InternationalString)
value - the value of the concept

Returns:
the Concept instance created

Throws:
JAXRException - if the JAXR provider encounters an internal
public EmailAddress createEmailAddress(String address) throws JAXRException
EmailAddress address

0

address
return EmailAddress
Throws JAXRException: JAXR

createEmailAddress

EmailAddress createEmailAddress(String address)
throws JAXRException

Creates an EmailAddress instance using an address as the parameter.

Capability Level: 0

Parameters:
address - the email address

Returns:
the EmailAddress instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

public EmailAddress createEmailAddress(String address, String type) throws JAXRException
EmailAddress address type
createEmailAddress

EmailAddress createEmailAddress(String address, String type) throws JAXRException

Creates an EmailAddress instance using both an address and a type as parameters.

Capability Level: 0

Parameters:
    address - the email address
    type  - the type of the address

Returns:
    the EmailAddress instance created

Throws:
    JAXRException - if the JAXR provider encounters an internal error

public ExternalIdentifier createExternalIdentifier(ClassificationScheme identificationScheme, String name, String value) throws JAXRException
    ExternalIdentifier name String
createExternalIdentifier

ExternalIdentifier createExternalIdentifier(ClassificationScheme identificationScheme, String name, String value) throws JAXRException

Creates an ExternalIdentifier instance using the specified parameters, where the name is a String.

Capability Level: 0

Parameters:
- identificationScheme - the ClassificationScheme used
- name - the name of the external identifier (a String)
- value - the value of the external identifier

Returns:
the ExternalIdentifier instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

---

public ExternalIdentifier createExternalIdentifier(ClassificationScheme identificationScheme, InternationalString name, String value) throws JAXRException

ExternalIdentifier name InternationalString

0

identificationScheme ClassificationScheme
createExternalIdentifier

```java
ExternalIdentifier createExternalIdentifier(ClassificationScheme ide
InternationalString name
String value)
throws JAXRException
```

Creates an ExternalIdentifier instance using the specified parameters, where the name is an InternationalString.

**Capability Level: 0**

**Parameters:**
- `identificationScheme` - the ClassificationScheme used
- `name` - the name of the external identifier (an InternationalString)
- `value` - the value of the external identifier

**Returns:**
- the ExternalIdentifier instance created

**Throws:**
- `JAXRException` - if the JAXR provider encounters an internal error

---

```java
public ExternalLink createExternalLink(String externalURI,
String description) throws JAXRException
```

**0**

- `externalURI` - URI
- `description` - String
- `return` - ExternalLink
createExternalLink

createExternalLink(String externalURI, String description) throws JAXRException

Creates an ExternalLink instance using the specified parameters, where the description is a String.

Capability Level: 0

Parameters:
- externalURI - the external URI
- description - a description of the link (a String)

Returns:
- the ExternalLink instance created

Throws:
- JAXRException - if the JAXR provider encounters an internal error

public ExternalLink createExternalLink(String externalURI, InternationalString description) throws JAXRException

Returns: ExternalLink description InternationalString

0

externalURI URI
description InternationalString
return ExternalLink
Throws JAXRException: JAXR

createExternalLink
**ExternalLink** `createExternalLink(String externalURI, InternationalString description) throws JAXRException`

Creates an ExternalLink instance using the specified parameters, where the description is an InternationalString.

**Capability Level: 0**

**Parameters:**
- `externalURI` - the external URI
- `description` - a description of the link (an InternationalString)

**Returns:**
- the ExternalLink instance created

**Throws:**
- `JAXRException` - if the JAXR provider encounters an internal error

---

```java
public ExtrinsicObject createExtrinsicObject(DataHandler repositoryItem) throws JAXRException
ExtrinsicObject
```

1

```java
repositoryItem DataHandler null
return ExtrinsicObject
Throws JAXRException JAXR
```

**createExtrinsicObject**

**ExtrinsicObject createExtrinsicObject(DataHandler repositoryItem) throws JAXRException**

Creates an ExtrinsicObject instance using the specified parameters.

**Capability Level: 1**
Parameters:
repositoryItem - the DataHandler for the repository item. Must not be null.

Returns:
the ExtrinsicObject instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

public InternationalString createInternationalString() throws JAXRException
InternationalString

return InternationalString

Throws JAXRException: JAXR

createInternationalString

InternationalString createInternationalString() throws JAXRException

Creates an empty InternationalString instance.

Capability Level: 0

Returns:
the InternationalString instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

public InternationalString createInternationalString(String s) throws JAXRException
createInternationalString

`createInternationalString(String s)` throws `JAXRException`

Creates an InternationalString instance using a String parameter and the default Locale.

**Capability Level**: 0

**Parameters:**

- `s` - the String from which to create the InternationalString

**Returns:**

the InternationalString instance created

**Throws:**

- `JAXRException` - if the JAXR provider encounters an internal error
createInternationalString

```java
InternationalString createInternationalString(Locale l, String s) throws JAXRException
```

Creates an InternationalString instance using the specified Locale and String parameters.

**Capability Level:** 0

**Parameters:**
- `l` - the Locale in which to create the InternationalString
- `s` - the String from which to create the InternationalString

**Returns:**
- the InternationalString instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

---

```java
public Key createKey(String id) throws JAXRException
```

**Key**

```
0
```

**Parameters:**
- `id` - Key ID

**Returns:**
- Key

**Throws:**
- JAXRException - JAXR

---

createKey

```java
Key createKey(String id) throws JAXRException
```
Creates a Key instance from an ID.

**Capability Level: 0**

**Parameters:**
- `id` - the ID string from which to create the Key

**Returns:**
- the Key instance created

**Throws:**
- `JAXRException` - if the JAXR provider encounters an internal error

```java
public LocalizedString createLocalizedString(java.util.Locale l, String s) throws JAXRException
Locale String LocalizedString

0

/ LocalizedString Locale
s LocalizedString String
return
Throws JAXRException: JAXR
```

**createLocalizedString**

```java
LocalizedString createLocalizedString(Locale l, String s) throws JAXRException
```

Creates a LocalizedString instance using the specified Locale and String parameters.

**Capability Level: 0**
public LocalizedString createLocalizedString(java.util.Locale l, String s, String charSetName) throws JAXRException

LocaleString LocalizedString

createLocalizedString

LocalizedString createLocalizedString(Locale l, String s, String charSetName) throws JAXRException

Creates a LocalizedString instance using the specified Locale, String, and character set parameters.

Capability Level: 0

Parameters:

1 - the Locale in which to create the LocalizedString
s - the String from which to create the LocalizedString
charSetName - the name of the character set to use

Returns:
the LocalizedString instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

public Organization createOrganization(String name) throws JAXRException
Organization name String
0

name Organization
return Organization

Throws JAXRException: JAXR

createOrganization

Organization createOrganization(String name) throws JAXRException

Creates an Organization instance using the specified name, where the name is a String.

Capability Level: 0

Parameters:
  name - the name of the Organization

Returns:
  the Organization instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error
public **Organization** createOrganization(**InternationalString** name) throws **JAXRException**

Organization name **InternationalString**

0

- **name**
- **Organization**
- **return**
- **Organization**
- **Throws**
  - **JAXRException**: JAXR

**createOrganization**

**Organization** createOrganization(**InternationalString** name) throws **JAXRException**

Creates an Organization instance using the specified name, where the name is an **InternationalString**.

**Capability Level**: 0

**Parameters:**
- **name** - the name of the Organization

**Returns:**
- the Organization instance created

**Throws:**
- **JAXRException** - if the JAXR provider encounters an internal error

---

public **PersonName** createPersonName(String firstName, String middleName, String lastName) throws **JAXRException**

**PersonName**

1
createPersonName

```java
PersonName createPersonName(String firstName,
String middleName,
String lastName)
throws JAXRException
```

Creates a PersonName instance using the specified first, middle, and last names.

**Capability Level: 1**

**Parameters:**
- `firstName` - the person's first name
- `middleName` - the person's middle name
- `lastName` - the person's last name

**Returns:**
- the PersonName instance created

**Throws:**
- `JAXRException` - if the JAXR provider encounters an internal error

```java
public PersonName createPersonName(String fullName)
throws JAXRException
PersonName
```

```java
fullName
```

```java
return PersonName
```
createPersonName

createPersonName(String fullName) throws JAXRException

Creates a PersonName instance using the specified full name.

Capability Level: 0

Parameters:
  fullName - the person's full name

Returns:
  the PersonName instance created

 Throws:
  JAXRException - if the JAXR provider encounters an internal error

---

public PostalAddress createPostalAddress(String streetNumber, String street, String city, String stateOrProvince, String country, String postalCode, String type) throws JAXRException

PostalAddress

0

streetNumber
street
city
stateOrProvince
country

US ZIP
type
return
PostalAddress
Throws

JAXRException: JAXR

createPostalAddress

PostalAddress createPostalAddress(String streetNumber,
    String street,
    String city,
    String stateOrProvince,
    String country,
    String postalCode,
    String type)
throws JAXRException

Creates a PostalAddress instance using the specified parameters.

Capability Level: 0

Parameters:
- streetNumber - the street number
- street - the street name
- city - the city name
- stateOrProvince - the state or province name
- country - the country name
- postalCode - the postal code (such as a US ZIP code)
- type - the type of the address

Returns:
the PostalAddress instance created

Throws:
  JAXRException - if the JAXR provider encounters an internal error

---

public RegistryPackage createRegistryPackage(String name) throws JAXRException
RegistryPackage name String

1

name String
createRegistryPackage

RegistryPackage createRegistryPackage(String name) throws JAXRException

Creates a RegistryPackage instance using the specified name, where the name is a String.

Capability Level: 1

Parameters:
name - the name of the registry package (a String)

Returns:
the RegistryPackage instance created

Throws:
JAXRException - if the JAXR provider encounters an internal error

public RegistryPackage createRegistryPackage(InternationalString name) throws JAXRException

RegistryPackage name InternationalString

1

name InternationalString
return RegistryPackage
Throws JAXRException: JAXR

createRegistryPackage

RegistryPackage createRegistryPackage(InternationalString name)
throws JAXRException

Creates a RegistryPackage instance using the specified name, where the name is an InternationalString.

**Capability Level: 1**

**Parameters:**
- **name** - the name of the registry package (an InternationalString)

**Returns:**
- the RegistryPackage instance created

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

```java
public Service createService(String name) throws JAXRException
```

Service name String

0

```
name Service String return Service
Throws JAXRException: JAXR
```

createService

```java
Service createService(String name)
```

Throws JAXRException

Creates a Service instance using the specified name, where the name is a String.

**Capability Level: 0**

**Parameters:**
- **name** - the name of the Service (a String)
Returns:
the Service instance created

Throws:

- **JAXRException** - if the JAXR provider encounters an internal error

```java
public Service createService(InternationalString name) throws JAXRException
Service name InternationalString

0

name Service InternationalString
return Service
Throws JAXRException: JAXR
```

### createService

**Service createService(InternationalString name)**

throws **JAXRException**

Creates a Service instance using the specified name, where the name is an InternationalString.

**Capability Level: 0**

**Parameters:**

- `name` - the name of the Service (an InternationalString)

**Returns:**

the Service instance created

**Throws:**

- **JAXRException** - if the JAXR provider encounters an internal error

```java
public ServiceBinding createServiceBinding() throws
```
**JAXRException**

ServiceBinding

0

```
return ServiceBinding
Throws JAXRException: JAXR
```

**createServiceBinding**

```java
createServiceBinding() throws JAXRException
```

Creates an empty ServiceBinding instance.

**Capability Level:** 0

**Returns:**
the ServiceBinding instance created

**Throws:**

- JAXRException - if the JAXR provider encounters an internal error

```
public Slot createSlot(String name, String value, String slotType) throws JAXRException
Slot value String
```

```
name Slot
value String
slotType Slot
return Slot
Throws JAXRException: JAXR
```
createSlot

```java
Slot createSlot(String name,
String value,
String slotType)
throws JAXRException
```

Creates a Slot instance using the specified parameters, where the value is a String.

**Capability Level: 0**

**Parameters:**
- `name` - the name of the Slot
- `value` - the value (a String)
- `slotType` - the slot type

**Returns:**
the Slot instance created

**Throws:**
- `JAXRException` - if the JAXR provider encounters an internal error

```java
public Slot createSlot(String name, java.util.Collection<E> values, String slotType) throws JAXRException
Slot value String String Collection
```

<table>
<thead>
<tr>
<th>name</th>
<th>Slot</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>String Collection</td>
</tr>
<tr>
<td>slotType</td>
<td>Slot</td>
</tr>
<tr>
<td>return</td>
<td>Slot</td>
</tr>
</tbody>
</table>

**Throws**

- `JAXRException`: JAXR
Slot createSlot(String name, Collection values, String slotType) throws JAXRException

Creates a Slot instance using the specified parameters, where the value is a Collection of Strings.

Capability Level: 0

Parameters:
- name - the name of the Slot
- value - the value (a Collection of Strings)
- slotType - the slot type

Returns:
- the Slot instance created

Throws:
- JAXRException - if the JAXR provider encounters an internal error

public SpecificationLink createSpecificationLink() throws JAXRException

SpecificationLink

0

return SpecificationLink

Throws JAXRException: JAXR

createSpecificationLink

SpecificationLink createSpecificationLink() throws JAXRException

Creates an empty SpecificationLink instance.

Capability Level: 0
public **TelephoneNumber** createTelephoneNumber() throws **JAXRException**

**TelephoneNumber**

0

    return **TelephoneNumber**

Throws **JAXRException**: JAXR

---

**createTelephoneNumber**

**TelephoneNumber** createTelephoneNumber() throws **JAXRException**

Creates an empty TelephoneNumber instance.

**Capability Level: 0**

**Returns:**

the TelephoneNumber instance created

**Throws:**

**JAXRException** - if the JAXR provider encounters an internal error

---

public **User** createUser() throws **JAXRException**

**User**

0
createElement

public BulkResponse saveObjects(java.util.Collection<E> objects) throws JAXRException
Object RegistryObject

0

objects RegistryObject Collection
return BulkResponse Collection SaveException
Throws JAXRException: JAXR

saveObjects

BulkResponse saveObjects(Collection objects) throws JAXRException
Saves one or more Objects to the registry. An object may be a RegistryObject subclass instance.

If an object is not in the registry, it is created in the registry. If it already exists in the registry and has been modified, then its state is updated (replaced) in the registry.

**Capability Level: 0**

**Parameters:**
- objects - a potentially heterogeneous Collection of RegistryObject instances

**Returns:**
- a BulkResponse containing the Collection of keys for those objects that were saved successfully and any SaveException that was encountered in case of partial commit

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

```java
public BulkResponse deprecateObjects(java.util.Collection<E> keys) throws JAXRException
"soon to be deleted"JAXR AssociationsClassifications  ExternalLinks API  JAXR  JAXRException java.lang.IllegalStateException

1

keys Collection
return BulkResponse Collection JAXRException
Throws JAXRException: JAXR

deprecateObjects
```
BulkResponse deprecateObjects(Collection keys)
throws JAXRException

Deprecates one or more previously submitted objects. Deprecation marks an object as "soon to be deleted". Once an object is deprecated, the JAXR provider must not allow any new references (e.g. new Associations, Classifications and ExternalLinks) to that object to be submitted. If a client makes an API call that results in a new reference to a deprecated object, the JAXR provider must throw a java.lang.IllegalStateException within a JAXRException. However, existing references to a deprecated object continue to function normally.

Capability Level: 1

Parameters:
keys - a Collection of keys for the objects to be deprecated

Returns:
a BulkResponse containing the Collection of keys for those objects that were deprecated successfully and any JAXRException that was encountered in case of partial commit

Throws:
JAXRException - if the JAXR provider encounters an internal error

public BulkResponse unDeprecateObjects(java.util.Collection<E> keys) throws JAXRException
JAXR Associations
Classifications ExternalLinks

keys Collection
return BulkResponse Collection JAXRException
Throws JAXRException: JAXR
unDeprecateObjects

BulkResponse unDeprecateObjects(Collection keys) throws JAXRException

Undeprecates one or more previously deprecated objects. If an object was not previously deprecated, it is not an error, and no exception is thrown. Once an object is undeprecated, the JAXR provider must again allow new references (e.g. new Associations, Classifications and ExternalLinks) to that object to be submitted.

Capability Level: 1

Parameters:
- keys - a Collection of keys for the objects to be undeprecated

Returns:
- a BulkResponse containing the Collection of keys for those objects that were deprecated successfully and any JAXRException that was encountered in case of partial commit

Throws:
- JAXRException - if the JAXR provider encounters an internal error

public BulkResponse deleteObjects(java.util.Collection<E> keys) throws JAXRException

1

keys Collection
return BulkResponse Collection DeleteException
Throws JAXRException: JAXR

deleteObjects

BulkResponse deleteObjects(Collection keys)
Deletes one or more previously submitted objects from the registry using the object keys.

**Capability Level: 1**

**Parameters:**
- keys - a Collection of keys for the objects to be deleted

**Returns:**
- a BulkResponse containing the Collection of keys for those objects that were deleted successfully and any DeleteException that was encountered in case of partial commit

**Throws:**
- JAXRException - if the JAXR provider encounters an internal error

```java
public BulkResponse deleteObjects(java.util.Collection<E> keys, String objectType) throws JAXRException
```

**deleteObjects**

BulkResponse deleteObjects(Collection keys, String objectType) throws JAXRException

Deletes one or more previously submitted objects from the registry using the object keys and a specified objectType attribute.
public RegistryService getRegistryService() throws JAXRException

RegistryService

0

return RegistryService

Throws JAXRException: JAXR

associates <javax.xml.registry.RegistryService>

getRegistryService

RegistryService getRegistryService() throws JAXRException

Returns the parent RegistryService that created this object.

Capability Level: 0

Returns:

the parent RegistryService

throws JAXRException

Throws:
JAXRException - if the JAXR provider encounters an internal error

javax.faces.model Class ListDataModel

java.lang.Object
   ↓ javax.faces.model.DataModel
      ↓ javax.faces.model.ListDataModel

public class ListDataModel
extends DataModel

Extends: DataModel

ListDataModel is a convenience implementation of DataModel that wraps an List of Java objects.

Constructor Summary

<table>
<thead>
<tr>
<th>Constructor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ListDataModel()</td>
<td>Construct a new ListDataModel with no specified wrapped data.</td>
</tr>
<tr>
<td>ListDataModel(List list)</td>
<td>Construct a new ListDataModel wrapping the specified list.</td>
</tr>
</tbody>
</table>

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int getRowCount()</td>
<td>If there is wrappedData available, return the length of the list.</td>
</tr>
<tr>
<td>Object getRowData()</td>
<td>If row data is available, return the array element at the index specified by rowIndex.</td>
</tr>
<tr>
<td>getRowIndex()</td>
<td></td>
</tr>
</tbody>
</table>
### Methods

**int**

Return the zero-relative index of the currently selected row.

**Object**

`getWrappedData()`

Return the object representing the data wrapped by this `DataModel`, if any.

**boolean**

`isRowAvailable()`

Return `true` if there is `wrappedData` available, and the current value of `rowIndex` is greater than or equal to zero, and less than the size of the list.

**void**

`setRowIndex(int rowIndex)`

Set the zero-relative index of the currently selected row, or `-1` to indicate that we are not positioned on a row.

`setWrappedData(Object data)`

Set the object representing the data collection wrapped by this `DataModel`.

---

**Methods inherited from class `javax.faces.model.DataModel`**

- `addDataModelListener`, `getDataModelListeners`, `removeDataModelListener`

**Methods inherited from class `java.lang.Object`**

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`

---

### Constructor Detail

**public ListDataModel()**

`ListDataModel`
public ListDataModel()

Construct a new ListDataModel with no specified wrapped data.

public ListDataModel(java.util.List<E> list)

ListDataModel

list

ListDataModel

public ListDataModel(List list)

Construct a new ListDataModel wrapping the specified list.

Parameters:
list - List to be wrapped (if any)

Method Detail

public boolean isRowAvailable()

wrappedData  rowIndex  0  true  false

Throws  FacesException:

isRowAvailable

public boolean isRowAvailable()

Return true if there is wrappedData available, and the current value of rowIndex is greater than or equal to zero, and less than the size of the list. Otherwise, return false.
public int getRowCount()

wrappedData     wrappedData -1

Throws            FacesException:

getRowCount

public int getRowCount()

If there is wrappedData available, return the length of the list. If no wrappedData is available, return -1.

Specified by:
    getRowCount in class DataModel
Throws:
    FacesException - if an error occurs getting the row count

public Object getRowData()

rowIndex         null

Throws            FacesException:
Throws            IllegalArgumentException:

getRowData

public Object getRowData()
If row data is available, return the array element at the index specified by rowIndex. If no wrapped data is available, return null.

**Specified by:**
getRowData in class DataModel

**Throws:**
FacesException - if an error occurs getting the row data
IllegalArgumentException - if now row data is available at the currently specified row index

```java
public int getRowIndex()

Throws  FacesException: NullPointerException
```

### getRowIndex

**Description copied from class:** DataModel

Return the zero-relative index of the currently selected row. If we are not currently positioned on a row, or no wrappedData is available, return -1.

**Specified by:**
getRowIndex in class DataModel

**Throws:**
FacesException - if an error occurs getting the row index

```java
public void setRowIndex(int rowIndex)

Throws  FacesException: NullPointerException
Throws  IllegalArgumentException: NullPointerException rowIndex
```

### setRowIndex

```java
setRowIndex
```
public void setRowIndex(int rowIndex)

**Description copied from class:** [DataModel](#)

Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row. It is possible to set the row index at a value for which the underlying data collection does not contain any row data. Therefore, callers may use the isRowAvailable() method to detect whether row data will be available for use by the getRowData() method.

If there is no wrappedData available when this method is called, the specified rowIndex is stored (and may be retrieved by a subsequent call to getRowData()), but no event is sent. Otherwise, if the currently selected row index is changed by this call, a DataModelEvent will be sent to the rowSelected() method of all registered DataModelListeners.

**Specified by:**
setRowIndex in class [DataModel](#)

**Parameters:**
- rowIndex - The new zero-relative index (must be non-negative)

**Throws:**
- [FacesException](#) - if an error occurs setting the row index
- [IllegalArgumentException](#) - if rowIndex is less than -1

---

public Object getWrappedData()

**getWrappedData**

public Object getWrappedData()

**Description copied from class:** [DataModel](#)

Return the object representing the data wrapped by this DataModel, if any.
specified by:

**getWrappedData** in class **DataModel**

---

**public void setWrappedData(Object data)**

Throws

**ClassCastException: data**

**List**

---

**setWrappedData**

**public void setWrappedData(Object data)**

Description copied from class: **DataModel**

Set the object representing the data collection wrapped by this **DataModel**. If the specified data is **null**, detach this **DataModel** from any previously wrapped data collection instead.

If data is non-null, the currently selected row index must be set to zero, and a **DataModelEvent** must be sent to the **rowSelected()** method of all registered **DataModelListener**s indicating that this row is now selected.

**Specified by:**

**setWrappedData** in class **DataModel**

**Parameters:**

data - Data collection to be wrapped, or **null** to detach from any previous data collection

**Throws:**

**ClassCastException** - if data is non-null and is not a **List**

java.util.List base

#isReadOnly true#setValue PropertyNotWritableException

ELResolver CompositeELResolver ELResolver

Javadoc

since JSP 2.1
See javax.el.CompositeELResolver, javax.el.ELResolver
also java.util.List

Defines property resolution behavior on instances of List.

This resolver handles base objects of type java.util.List. It accepts any object as a property and coerces that object into an integer index into the list. The resulting value is the value in the list at that index.

This resolver can be constructed in read-only mode, which means that isReadOnly will always return true and setValue(javax.el.ELContext, java.lang.Object, java.lang.Object, java.lang.Object) will always throw PropertyNotWritableException.

ELResolvers are combined together using CompositeELResolver, to
define rich semantics for evaluating an expression. See the javadocs for
ELResolver for details.

Since:
   JSP 2.1

### Constructor Detail

**public ListELResolver()**

/     ListELResolver

**ListELResolver**

**public ListELResolver()**

Creates a new read/write ListELResolver.

**public ListELResolver(boolean isReadOnly)**

ListELResolver

    isReadOnly true false
ListELResolver

public ListELResolver(boolean isReadOnly)

Creates a new ListELResolver whose read-only status is determined by the given parameter.

Parameters:
  isReadOnly - true if this resolver cannot modify lists; false otherwise.

Method Detail

getType

public Class<T> getType(ELContext context, Object base, Object property)

base             List   ELContext   propertyResolved   true
true             base               List               base

context
base
property
return            ELContext   propertyResolved   true

Throws            PropertyNotFoundException:
Throws            NullPointerException: context
Throws            ELException: cause

getType

public Class<?> getType(ELContext context,
If the base object is a list, returns the most general acceptable type for a value in this list.

If the base is a List, the propertyResolved property of the ELContext object must be set to true by this resolver, before returning. If this property is not true after this method is called, the caller should ignore the return value.

Assuming the base is a List, this method will always return Object.class. This is because lists accept any object as an element.

Specified by:

g getType in class ELResolver

Parameters:

context - The context of this evaluation.
base - The list to analyze. Only bases of type List are handled by this resolver.
property - The index of the element in the list to return the acceptable type for. Will be coerced into an integer, but otherwise ignored by this resolver.

Returns:

If the propertyResolved property of ELContext was set to true, then the most general acceptable type; otherwise undefined.

Throws:

PropertyNotFoundException - if the given index is out of bounds for this list.
NullPointerException - if context is null 
ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

public Object getValue(ELContext context, Object base, Object property)
IllegalArgumentException null

base List ELContext propertyResolved true
true

class

context
base
property
return ELContext propertyResolved true null

Throws IllegalArgumentException:
Throws NullPointerException: context null
Throws ELException: cause

getValue

public Object getValue(ELContext context,
Object base,
Object property)

If the base object is a list, returns the value at the given index. The index is specified by the property argument, and coerced into an integer. If the coercion could not be performed, an IllegalArgumentException is thrown. If the index is out of bounds, null is returned.

If the base is a List, the propertyResolved property of the ELContext object must be set to true by this resolver, before returning. If this property is not true after this method is called, the caller should ignore the return value.

Specified by:
getValue in class ELResolver

Parameters:
context - The context of this evaluation.
base - The list to be analyzed. Only bases of type List are handled by this resolver.
property - The index of the value to be returned. Will be coerced
into an integer.

**Returns:**
If the `propertyResolved` property of `ELContext` was set to `true`, then the value at the given index or `null` if the index was out of bounds. Otherwise, undefined.

**Throws:**
- `IllegalArgumentException` - if the property could not be coerced into an integer.
- `NullPointerException` - if `context` is `null`.
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

```java
public void setValue(ELContext context, Object base, Object property, Object val) throws IllegalArgumentException, PropertyNotFoundException, PropertyNotWritableException
```

```java
base List ELContext propertyResolved true
```

```java
PropertyNotWritableException
```

```java
java.util.Collections#unmodifiableList List
```

```java
PropertyNotWritableException Collection API
```

```java
List base
```

```java
context base property val
```

**Throws**
- `ClassCastException`
- `NullPointerException`
- `IllegalArgumentException`
- `PropertyNotWritableException`:
Throws `PropertyNotFoundException`:

Throws `ELException`: cause

```java
public void setValue(ELContext context, Object base, Object property, Object val)
```

If the base object is a list, attempts to set the value at the given index with the given value. The index is specified by the `property` argument, and coerced into an integer. If the coercion could not be performed, an `IllegalArgumentException` is thrown. If the index is out of bounds, a `PropertyNotFoundException` is thrown.

If the base is a `List`, the `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver, before returning. If this property is not `true` after this method is called, the caller can safely assume no value was set.

If this resolver was constructed in read-only mode, this method will always throw `PropertyNotWritableException`.

If a `List` was created using `Collections.unmodifiableList(java.util.List)`, this method must throw `PropertyNotWritableException`. Unfortunately, there is no Collections API method to detect this. However, an implementation can create a prototype unmodifiable `List` and query its runtime type to see if it matches the runtime type of the base object as a workaround.

**Specified by:**

`setValue` in class `ELResolver`

**Parameters:**

- `context` - The context of this evaluation.
- `base` - The list to be modified. Only bases of type `List` are handled by this resolver.
- `property` - The index of the value to be set. Will be coerced into
an integer.
val - The value to be set at the given index.

Throws:

- ClassCastException - if the class of the specified element prevents it from being added to this list.
- NullPointerException - if context is null, or if the value is null and this List does not support null elements.
- IllegalArgumentException - if the property could not be coerced into an integer, or if some aspect of the specified element prevents it from being added to this list.
- PropertyNotWritableException - if this resolver was constructed in read-only mode, or if the set operation is not supported by the underlying list.
- PropertyNotFoundException - if the given index is out of bounds for this list.
- ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

public boolean isReadOnly(ELContext context, Object base, Object property)
base

base List ELContext propertyResolved true
true

java.util.Collections#unmodifiableList List true

Collection API

collection
base List base
property

return ELContext propertyResolved true setValue true
false
Throws  `PropertyNotFoundException`
Throws  `NullPointerException: context null`
Throws  `ELException: cause`

isReadonly

```java
public boolean isReadonly(ELContext context,
                           Object base,
                           Object property)
```

If the base object is a list, returns whether a call to

If the base is a `List`, the `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver, before returning. If this property is not `true` after this method is called, the caller should ignore the return value.

If this resolver was constructed in read-only mode, this method will always return `true`.

If a `List` was created using `Collections.unmodifiableList(java.util.List)`, this method must return `true`. Unfortunately, there is no Collections API method to detect this. However, an implementation can create a prototype unmodifiable `List` and query its runtime type to see if it matches the runtime type of the base object as a workaround.

Specified by:
  `isReadonly` in class `ELResolver`

Parameters:
  context - The context of this evaluation.
  base - The list to analyze. Only bases of type `List` are handled by this resolver.
  property - The index of the element in the list to return the acceptable type for. Will be coerced into an integer, but otherwise ignored by this resolver.

Returns:
If the propertyResolved property of ELContext was set to true, then true if calling the setValue method will always fail or false if it is possible that such a call may succeed; otherwise undefined.

Throws:
- PropertyNotFoundException - if the given index is out of bounds for this list.
- NullPointerException - if context is null
- ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

```java
public java.util.Iterator<E> getFeatureDescriptors(ELContext context, Object base) null
#getCommonPropertyType
c
context
d
base
List base
e
return
null
f

getFeatureDescriptors
g
public Iterator<FeatureDescriptor> getFeatureDescriptors(ELContext c
Object base
d
Always returns null, since there is no reason to iterate through set
e
set of all integers.

The getCommonPropertyType(javax.el.ELContext, java.lang.Object) method returns sufficient information about what properties this resolver accepts.

Specified by:
- getFeatureDescriptors in class ELResolver
Parameters:
  
  - context - The context of this evaluation.
  - base - The list. Only bases of type List are handled by this resolver.

Returns:
  
  null.

See Also:
  
  FeatureDescriptor

---

public Class<T> getCommonPropertyType(ELContext context, Object base)
base property null

base List Integer.class List

context
base List base
return base List null Integer.class

getCommonPropertyType

public Class<?> getCommonPropertyType(ELContext context, Object base)

If the base object is a list, returns the most general type that this resolver accepts for the property argument. Otherwise, returns null.

Assuming the base is a List, this method will always return Integer.class. This is because Lists accept integers as their index.

Specified by:
  
  getCommonPropertyType in class ELResolver

Parameters:
  
  - context - The context of this evaluation.
  - base - The list to analyze. Only bases of type List are handled by this resolver.
Returns:

null if base is not a List; otherwise Integer.class.
javax.management.j2ee  Interface ListenerRegistration

All Superinterfaces:
   Serializable

public interface ListenerRegistration

extends Serializable

Implements: java.io.Serializable

ListenerRegistration  MEJB

ListenerRegistration defines the methods which clients of the MEJB use to add and remove event listeners.

<td>Add a listener to a registered managed object.</td>
</tr>
<tr>
<td>void removeNotificationListener(ObjectName name, NotificationListener listener)</td>
</tr>
<tr>
<td>Remove a listener from a registered managed object.</td>
</tr>
</tbody>
</table>
Add a listener to a registered managed object.

**Parameters:**

- `name`: The name of the managed object on which the listener should be added.
- `listener`: The listener object which will handle the notifications emitted by the registered managed object.
- `filter`: The filter object. If filter is null, no filtering will be performed before handling notifications.
- `handback`: The context to be sent to the listener when a notification is emitted.

**Throws:**

- `InstanceNotFoundException`: The managed object name provided does not match any of the registered managed objects.
- `RemoteException`: A communication exception occurred during
the execution of a remote method call

```java
public void removeNotificationListener(javax.management.ObjectName name, javax.management.NotificationListener listener)
    throws javax.management.InstanceNotFoundException,
            javax.management.ListenerNotFoundException,
            java.rmi.RemoteException
```

**name**

**listener**

**Throws** javax.management.InstanceNotFoundException:

**removeNotificationListener**

```java
void removeNotificationListener(ObjectName name, NotificationListener listener)
    throws InstanceNotFoundException,
            ListenerNotFoundException,
            RemoteException
```

Remove a listener from a registered managed object.

**Parameters:**

- **name** - The name of the managed object on which the listener should be removed.
- **listener** - The listener object which will handle the notifications emitted by the registered managed object. This method will remove all the information related to this listener.

**Throws:**

- **InstanceNotFoundException** - The managed object name provided does not match any of the registered managed objects.
- **ListenerNotFoundException** - The listener is not registered in the managed object.
RemoteException - A communication exception occurred during the execution of a remote method call

javax.persistence Annotation Type Lob

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface Lob

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

Lob Blob

@Lob @Basic(fetch=LAZY)
@Column(name="REPORT")
protected String report;

Since: Java Persistence 1.0

Specifies that a persistent property or field should be persisted as a large object to a database-supported large object type. The Lob annotation may be used in conjunction with the Basic annotation. A Lob may be either a binary or character type.

The Lob type is inferred from the type of the persistent field or property, and except for string and character-based types defaults to Blob.

Example:

@Lob @Basic(fetch=LAZY)
@Column(name="REPORT")
protected String report;

getCharsetName
String getCharsetName() throws JAXRException

Gets the canonical name for the charset for this object. Must return the default charset when there is no charset name defined.

**Capability Level: 0**

**Returns:**
the character set name for the character set used by this object

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

**See Also:**
DEFAULT_CHARSET_NAME

```java
public java.util.Locale getLocale() throws JAXRException

Locale Locale Locale Locale

0

return Locale

Throws JAXRException: JAXR

See also getDefault()
```

getLocale

Locale getLocale() throws JAXRException

Get the Locale for this object. Must return the default Locale when no Locale has been defined.

**Capability Level: 0**

**Returns:**
the Locale used by this object
Throws:

- `JAXRException` - If the JAXR provider encounters an internal error

See Also:

- `Locale.getDefault()`

---

```java
public String getValue() throws JAXRException

String

0

return

Throws

- `JAXRException`: JAXR

---

`getValue`

```java
String getValue() throws JAXRException

Get the String value for this object.

Capability Level: 0

Returns:

- the value defined by this object

Throws:

- `JAXRException` - If the JAXR provider encounters an internal error

---

```java
public void setCharsetName(String charsetName) throws JAXRException

0
```
**setCharsetName**

```java
void setCharsetName(String charsetName)
throws JAXRException
```

Set the canonical name for the charset for this object.

**Capability Level: 0**

**Parameters:**
- `charsetName` - the character set name for the character set used by this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public void setLocale(java.util.Locale locale) throws JAXRException**

**Locale**

```java
locale
```

**Throws**
- `JAXRException` - JAXR

---

**setLocale**

```java
void setLocale(Locale locale)
throws JAXRException
```

Set the Locale for this object.
public void setValue(String value) throws JAXRException

String

0

setValue

void setValue(String value)
throws JAXRException

Set the String value for the specified object.

Capability Level: 0

Parameters:
value - the value defined by this object

Throws:
JAXRException - If the JAXR provider encounters an internal error

PS:
public interface LocalTransaction

LocalTransaction

javax.resource.spi

CCI

Connection.getLocalTransaction

LocalTransaction

EIS

Connection

since 0.8

See also javax.resource.cci.Connection

The LocalTransaction defines a transaction demarcation interface for resource manager local transactions. Note that this interface is used for application level local transaction demarcation. The system contract level LocalTransaction interface (as defined in the javax.resource.spi package) is used by the container for local transaction management.

A local transaction is managed internal to a resource manager. There is no external transaction manager involved in the coordination of such transactions.

A CCI implementation can (but is not required to) implement the LocalTransaction interface. If the LocalTransaction interface is supported by a CCI implementation, then the method Connection.getLocalTransaction should return a LocalTransaction instance. A component can then use the returned LocalTransaction to demarcate a resource manager local transaction (associated with the Connection instance) on the underlying EIS instance.

Since:
### Method Summary

<table>

</table>

### Method Detail

**public void `begin()` throws `ResourceException`**

**EIS**

*ResourceException:*

**Throws:**
- EIS
- JTA

**begin**

**void `begin()` throws `ResourceException`**

Begins a local transaction on an EIS instance.

**Throws:**
- *ResourceException* - Failed to begin a local transaction.
Examples of error cases are:
- Resource adapter internal or EIS-specific error
- Connection is already participating in a local or JTA transaction

```java
public void commit() throws ResourceException
EIS

  ResourceException:
  • EIS
  Throws
  • JTA
  •
```

```java
commit
void commit()
  throws ResourceException

  Commits the current local transaction and release all locks held by the underlying EIS instance.

  Throws:
  ResourceException - Failed to commit a local transaction.
Examples of error cases are:
  • Resource adapter internal or EIS-specific error
  • Violation of integrity constraints, deadlock detection, communication failure during transaction completion, or any retry requirement
  • Connection is participating in an active JTA transaction
  • Invalid transaction context; commit operation invoked without an active transaction context
```

```java
public void rollback() throws ResourceException
```
**ResourceException:**

Throws

- EIS
- JTA

**rollback**

```java
void rollback()
throws ResourceException
```

Rollbacks the current resource manager local transaction.

**Throws:**

- ResourceException - Failed to rollback a local transaction.

Examples of error cases are:

- Resource adapter internal or EIS-specific error
- Connection is participating in an active JTA transaction
- Invalid transaction context; rollback operation invoked without an active transaction context
javax.resource.spi  Interface LocalTransaction

public interface LocalTransaction

LocalTransaction LocalTransaction
javax.resource.spi

CCI LocalTransaction CCI LocalTransaction
    Connection.getLocalTransaction LocalTransaction
LocalTransaction EIS Connection
    since 0.8
    See also  javax.resource.cci.Connection

LocalTransaction interface provides support for transactions that are managed internal to an EIS resource manager, and do not require an external transaction manager.

A resource adapter implements the javax.resource.spi.LocalTransaction interface to provide support for local transactions that are performed on the underlying resource manager.

If a resource adapter supports the LocalTransaction interface, then the application server can choose to perform local transaction optimization (uses local transaction instead of a JTA transaction for a single resource manager case).

public class LocalTransactionException
  extends ResourceException

Extends: Throwable > Exception > ResourceException

LocalTransactionException  Java Transaction API  XAResource
  javax.transaction.xa.XAException

LocalTransactionException

  • LocalTransaction  commit
  • LocalTransaction  commit
  • ManagedConnection
  •

  version  1.0

A LocalTransactionException represents various error conditions related to the local transaction management contract. The Java Transaction API specification specifies the javax.transaction.xa.XAException class for exceptions related to XAResource based transaction management contract.

The LocalTransactionException is used for the local transaction management contract to indicate the following common error conditions:
• Invalid transaction context when a transaction operation is executed. For example, calling commit method on LocalTransaction object without an active local transaction is an error condition.
• Transaction is rolled back instead of getting committed during a commit method call on the LocalTransaction object.
• An attempt to start a local transaction from the same thread on a ManagedConnection that is already associated with an active local transaction.
• Any resource adapter or resource manager specific error conditions related to local transaction management. Examples are violation of integrity of resources, deadlock detection, communication failure during transaction completion, retry required or any internal error in a resource manager.

**Constructor Detail**

public `LocalTransactionException()`

null

`LocalTransactionException`

public `LocalTransactionException()`

Constructs a new instance with null as its detail message.

public `LocalTransactionException(String message)`

`message`

`LocalTransactionException`
public LocalTransactionException(String message)

Constructs a new instance with the specified detail message.

Parameters:
message - the detail message.

public LocalTransactionException(Throwable cause)

cause throwable

cause Throwable

LocalTransactionException

public LocalTransactionException(Throwable cause)

Constructs a new throwable with the specified cause.

Parameters:
cause - a chained exception of type Throwable.

public LocalTransactionException(String message, Throwable cause)

cause throwable

message

cause Throwable

LocalTransactionException

public LocalTransactionException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.
Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public LocalTransactionException(String message, String errorCode)
throwable

message
errorCode

LocalTransactionException

public LocalTransactionException(String message, String errorCode)

Constructs a new throwable with the specified detail message and
an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

<tr>
<td>String <code>getSystemId()</code></td>
<td>Returns the system ID of the XML</td>
</tr>
</tbody>
</table>
public int getLineNumber()  
-1

    return

getLineNumber

int getLineNumber()  

    Return the line number where the current event ends, returns -1 if none is available.

    Returns:  
        the current line number

public int getColumnNumber()  
-1

    return

getColumnNumber

int getColumnNumber()  

    Return the column number where the current event ends, returns -1 if none is available.

    Returns:  
        the current column number

public int getCharacterOffset()  
-1
**getCharacterOffset**

```java
int getCharacterOffset()
```

Return the byte or character offset into the input source this location is pointing to. If the input source is a file or a byte stream then this is the byte offset into that stream, but if the input source is a character media then the offset is the character offset. Returns -1 if there is no offset available.

**Returns:**

the current offset

---

**public String getPublicId()**

```java
XML ID
```

```java
return ID null
```

**getPublicId**

```java
String getPublicId()
```

Returns the public ID of the XML

**Returns:**

the public ID, or null if not available

---

**public String getSystemId()**

```java
XML ID
```

```java
return ID null
```

**getSystemId**
String getSystemId()

Returns the system ID of the XML

**Returns:**
the system ID, or null if not available
javax.persistence Enum LockModeType

java.lang.Object
    - java.lang.Enum<LockModeType>
        - javax.persistence.LockModeType

All Implemented Interfaces:
    Serializable, Comparable&lt;LockModeType&gt;

public enum LockModeType
    extends Enum&lt;LockModeType&gt;

Extends: Enum&lt;E&gt;

    lock(EntityManager.lock())

    LockModeType.READ   LockModeType.WRITE

T1  lock(entity, LockModeType.READ)

    • P1 T1  T2  T1  T2  T1  T2
    • P2 T1  T2  T1

P1  P2

lock(entity, LockModeType.WRITE)

    lock(EntityManager.lock())

since  Java Persistence 1.0

Lock modes that can be specified by means of the EntityManager.lock() method.

The semantics of requesting locks of type LockModeType.READ and
LockModeType.WRITE are the following.

If transaction T1 calls lock(entity, LockModeType.READ) on a versioned object, the entity manager must ensure that neither of the following phenomena can occur:

- **P1 (Dirty read):** Transaction T1 modifies a row. Another transaction T2 then reads that row and obtains the modified value, before T1 has committed or rolled back. Transaction T2 eventually commits successfully; it does not matter whether T1 commits or rolls back and whether it does so before or after T2 commits.

- **P2 (Non-repeatable read):** Transaction T1 reads a row. Another transaction T2 then modifies or deletes that row, before T1 has committed. Both transactions eventually commit successfully.

Lock modes must always prevent the phenomena P1 and P2.

In addition, calling lock(entity, LockModeType.WRITE) on a versioned object, will also force an update (increment) to the entity's version column.

The persistence implementation is not required to support calling EntityManager.lock() on a non-versioned object. When it cannot support a such lock call, it must throw the PersistenceException.

Since:
Java Persistence 1.0

Enum Constant Detail

READ

public static final LockModeType READ

  Read lock

WRITE

public static final LockModeType WRITE

  Write lock

Method Detail
final public static LockModeType[] values()

values

public static final LockModeType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

for(LockModeType c : LockModeType.values())
    System.out.println(c);

Returns:
    an array containing the constants of this enum type, in the order they're declared

public static LockModeType valueOf(String name)

valueOf

public static LockModeType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

Parameters:
    name - the name of the enum constant to be returned.

Returns:
    the enum constant with the specified name

Throws:
    IllegalArgumentException - if this enum type has no constant with the specified name

PS :
javax.xml.ws Interface LogicalMessage

public interface LogicalMessage

LogicalMessage (protocol agnostic) XML

since JAX-WS 2.0

The LogicalMessage interface represents a protocol agnostic XML message and contains methods that provide access to the payload of the message.

Since:
JAX-WS 2.0

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;Source&gt;getPayload()&lt;br&gt;Gets the message payload as an XML source, may be called multiple times on the same LogicalMessage instance, always returns a new Source that may be used to retrieve the entire message payload.</td>
</tr>
<tr>
<td>&lt;Object&gt;getPayload(JAXBContext context)&lt;br&gt;Gets the message payload as a JAXB object.</td>
</tr>
<tr>
<td>void setPayload(Object payload, JAXBContext context)&lt;br&gt;Sets the message payload</td>
</tr>
<tr>
<td>void setPayload(Source payload)&lt;br&gt;Sets the message payload</td>
</tr>
</tbody>
</table>

Method Detail
public javax.xml.transform.Source getPayload()

XML LogicalMessage Source

Source DOMSource DOM Source
setPayload

return null

getPayload

getPayload()

Gets the message payload as an XML source, may be called multiple times on the same LogicalMessage instance, always returns a new Source that may be used to retrieve the entire message payload.

If the returned Source is an instance of DOMSource, then modifications to the encapsulated DOM tree change the message payload in-place, there is no need to subsequently call setPayload. Other types of Source provide only read access to the message payload.

Returns:
The contained message payload; returns null if no payload is present in this message.

public void setPayload(javax.xml.transform.Source payload)

payload

Throws WebServiceException:

Throws UnsupportedOperationException:
setPayload

void setPayload(Source payload)

Sets the message payload

Parameters:
    payload - message payload

Throws:
    WebServiceException - If any error during the setting of the payload in this message
    UnsupportedOperationException - If this operation is not supported

public Object getPayload(JAXBContext context)

JAXB

context JAXBContext
return null

Throws 
    WebServiceException: JAXBContext
    WebServiceException cause JAXBException

getPayload

Object getPayload(JAXBContext context)

Gets the message payload as a JAXB object. Note that there is no connection between the returned object and the message payload, changes to the payload require calling setPayload.

Parameters:
    context - The JAXBContext that should be used to unmarshall the message payload

Returns:
    The contained message payload; returns null if no payload is present in this message

Throws:
    WebServiceException - If an error occurs when using a supplied
JAXBContext to unmarshall the payload. The cause of the WebServiceException is the original JAXBException.

```java
public void setPayload(Object payload, JAXBContext context)
```

**payload**

**context**

JAXBContext

**Throws**

UnsupportedOperationException:

**Throws**

WebServiceException: JAXBContext

WebServiceException cause JAXBException

---

**setPayload**

```java
void setPayload(Object payload,
JAXBContext context)
```

Sets the message payload

**Parameters:**

- payload - message payload
- context - The JAXBContext that should be used to marshall the payload

**Throws:**

- UnsupportedOperationException - If this operation is not supported
- WebServiceException - If an error occurs when using the supplied JAXBContext to marshall the payload. The cause of the WebServiceException is the original JAXBException.

Throws ConverterException: NullPointerException
Throws NullPointerException: NullPointerException context

getAsObject

public Object getAsObject(FacesContext context, UIComponent component, String value)

Description copied from interface: Converter

Convert the specified string value, which is associated with the specified UIComponent, into a model data object that is appropriate for being stored during the Apply Request Values phase of the request processing lifecycle.

Specified by:
getAsObject in interface Converter

Parameters:
context - FacesContext for the request being processed
component - UIComponent with which this model object value is associated
value - String value to be converted (may be null)

Returns:
null if the value to convert is null, otherwise the result of the conversion

Throws:
ConverterException - if conversion cannot be successfully
public String getAsString(FacesContext context, UIComponent component, Object value)

Throws ConverterException: NullPointerException

Throws NullPointerException: context component null

Description copied from interface: Converter

Convert the specified model object value, which is associated with the specified UIComponent, into a String that is suitable for being included in the response generated during the Render Response phase of the request processing lifecycle.

Specified by:
getAsString in interface Converter

Parameters:
context - FacesContext for the request being processed
component - UIComponent with which this model object value is associated
value - Model object value to be converted (may be null)

Returns:
a zero-length String if value is null, otherwise the result of the conversion

Throws:
ConverterException - if conversion cannot be successfully performed
NullPointerException - if context or component is null

javax.faces.validator Class LongRangeValidator

java.lang.Object
   ↓ java.lang.Number
      ↓ javax.faces.validator.LongRangeValidator

All Implemented Interfaces:
   javax.faces.validator.Validator, javax.faces.validator.StateHolder

public class LongRangeValidator
extends java.lang.Object
implements javax.faces.validator.Validator, javax.faces.validator.StateHolder

Implements: javax.faces.validator.Validator, javax.faces.validator.StateHolder

LongRangeValidator extends Validator

- null
- long String TYPE_MESSAGE_ID
- Validator maximum minimum
  #NOT_IN_RANGE_MESSAGE_ID  ValidatorException
- Validator maximum MAXIMUM_MESSAGE_ID
  ValidatorException
- Validator minimum MINIMUM_MESSAGE_ID
  ValidatorException

ValidatorException ID javax.faces.Number Converter
Locale

LongRangeValidator is a Validator that checks the value of the corresponding component against specified minimum and maximum values. The following algorithm is implemented:

- If the passed value is null, exit immediately.
- If the current component value is not a floating point type, or a String
that is convertible to long, throw a `ValidatorException` containing a `TYPE_MESSAGE_ID` message.

- If both a `maximum` and `minimum` property has been configured on this `Validator`, check the component value against both limits. If the component value is not within this specified range, throw a `ValidatorException` containing a `NOT_IN_RANGE_MESSAGE_ID` message.
- If a `maximum` property has been configured on this `Validator`, check the component value against this limit. If the component value is greater than the specified maximum, throw a `ValidatorException` containing a `MAXIMUM_MESSAGE_ID` message.
- If a `minimum` property has been configured on this `Validator`, check the component value against this limit. If the component value is less than the specified minimum, throw a `ValidatorException` containing a `MINIMUM_MESSAGE_ID` message.

For all of the above cases that cause a `ValidatorException` to be thrown, if there are parameters to the message that match up with validator parameters, the values of these parameters must be converted using the `Converter` registered in the application under the converter id `javax.faces.Number`. This allows the values to be localized according to the current `Locale`.

</tbody>
</table>
Set the maximum value to be enforced by this Validator.

```java
void setMinimum(long minimum)
```

Set the minimum value to be enforced by this Validator.

```java
void setTransient(boolean transientValue)
```

Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

```java
void validate(FacesContext context, UIComponent component, Object value)
```

Perform the correctness checks implemented by this Validator against the specified UIComponent.

### Methods inherited from class java.lang.Object

class java.lang.Object

- `clone`, `finalize`, `getClass`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
maximum value check fails. The message format string for this message may optionally include the following placeholders:

- `{0}` replaced by the configured maximum value.
- `{1}` replaced by a String whose value is the label of the input component that produced this message.

See Also:
Constant Field Values

---

MINIMUM_MESSAGE_ID

public static final String MINIMUM_MESSAGE_ID

The message identifier of the FacesMessage to be created if the minimum value check fails. The message format string for this message may optionally include the following placeholders:

- `{0}` replaced by the configured minimum value.
- `{1}` replaced by a String whose value is the label of the input component that produced this message.

See Also:
Constant Field Values

---

NOT_IN_RANGE_MESSAGE_ID

public static final String NOT_IN_RANGE_MESSAGE_ID

The message identifier of the FacesMessage to be created if the maximum or minimum value check fails, and both the maximum and minimum values for this validator have been set. The message format string for this message may optionally include the following placeholders:
- `{0}` replaced by the configured minimum value.
- `{1}` replaced by the configured maximum value.
- `{2}` replaced by a `String` whose value is the label of the input component that produced this message.

**See Also:**
- [Constant Field Values](#)

### TYPE_MESSAGE_ID

```java
public static final String TYPE_MESSAGE_ID
```

The message identifier of the `FacesMessage` to be created if the current value of this component is not of the correct type. The message format string for this message may optionally include a `{0}` placeholder that will be replaced by a `String` whose value is the label of the input component that produced this message.

**See Also:**
- [Constant Field Values](#)

### Constructor Detail

**public LongRangeValidator()

Validator**

### LongRangeValidator

**public LongRangeValidator()

Construct a `Validator` with no preconfigured limits.**
public LongRangeValidator(long maximum)

Validator

maximum

LongRangeValidator

public LongRangeValidator(long maximum)

Construct a Validator with the specified preconfigured limit.

Parameters:
maximum - Maximum value to allow

public LongRangeValidator(long maximum, long minimum)

Validator

maximum
minimum

LongRangeValidator

public LongRangeValidator(long maximum, long minimum)

Construct a Validator with the specified preconfigured limits.

Parameters:
maximum - Maximum value to allow
minimum - Minimum value to allow

Method Detail
public long getMaximum()

    Validator

getMaximum

public long getMaximum()

    Return the maximum value to be enforced by this Validator.

public void setMaximum(long maximum)

    Validator

    maximum

setMaximum

public void setMaximum(long maximum)

    Set the maximum value to be enforced by this Validator.

    Parameters:
    maximum - The new maximum value

public long getMinimum()

    Validator

getMinimum
public long getMinimum()

Return the minimum value to be enforced by this Validator.

public void setMinimum(long minimum)

Validator

minimum

setMinimum

public void setMinimum(long minimum)

Set the minimum value to be enforced by this Validator.

Parameters:
minimum - The new minimum value

public void validate(FacesContext context, UIComponent component, Object value) throws ValidatorException

Throws

NullPointerException: NullPointerEception context
cOMPONENT null

ThOws ValidatorException: NullPointerEception

validate

public void validate(FacesContext context, UIComponent component, Object value)

throws ValidatorException

Description copied from interface: Validator

Perform the correctness checks implemented by this Validator
against the specified UICOMPONENT. If any violations are found, a ValidatorException will be thrown containing the FacesMessage describing the failure.

**Specified by:**

`validate` in interface `Validator`

**Parameters:**

- `context` - FacesContext for the request we are processing
- `component` - UICOMPONENT we are checking for correctness
- `value` - the value to validate

**Throws:**

- `NullPointerException` - if context or component is null
- `ValidatorException` - if validation fails

---

**public boolean equals(Object otherObj)**

**equals**

**public boolean equals(Object otherObj)**

**Overrides:**

`equals` in class `Object`

---

**public int hashCode()**

**hashCode**

**public int hashCode()**

**Overrides:**

`hashCode` in class `Object`

---

**public Object saveState(FacesContext context)**
saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

   Object state = component.saveState(facesContext);

component should be the same as before executing it.

The return from this method must be Serializable

Specified by:
   saveState in interface StateHolder

public void restoreState(FacesContext context, Object state)

restoreState

public void restoreState(FacesContext context, Object state)
Description copied from interface: **StateHolder**

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.

Specified by:  
`restoreState` in interface `StateHolder`

---

**public boolean isTransient()**

`isTransient`

**public boolean isTransient()**

Description copied from interface: **StateHolder**

If true, the Object implementing this interface must not participate in state saving or restoring.

Specified by:  
`isTransient` in interface `StateHolder`

---

**public void setTransient(boolean transientValue)**

`setTransient`

**public void setTransient(boolean transientValue)**

Description copied from interface: **StateHolder**
Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

**Specified by:**

`setTransient` in interface `StateHolder`

**Parameters:**

`transientValue` - boolean pass `true` if this Object will participate in state saving or restoring, otherwise pass `false`.

javax.activation  Class MailcapCommandMap

java.lang.Object
   └ javax.activation.CommandMap
      └ javax.activation.MailcapCommandMap

public class MailcapCommandMap
extends CommandMap

Extends: CommandMap

MailcapCommandMap CommandMap mailcap (1524) CommandMap MailcapCommandMap

mailcap

MailcapCommandMap mailcap MailcapCommandMap mailcap

1. MailcapCommandMap
2. .mailcap
3. <java.home>/lib/mailcap
4. META-INF/mailcap
5. META-INF/mailcap.default activation.jar

mailcap

mailcap mailcap (RFC 1524, A User Agent Configuration Mechanism For Multimedia Mail Format Information) MIME MIME MailcapCommandMap mailcap Java MIME

mailcap MailcapCommandMap x-j
MailcapCommandMap name \
x-java-<name> name content-handler
MailcapCommandMap DataContentHandler JavaBean
   x-java-view=com.foo.ViewBean
MailcapCommandMap extends the CommandMap abstract class. It implements a CommandMap whose configuration is based on mailcap files ([RFC 1524](https://www.rfc-editor.org/info/rfc1524)). The MailcapCommandMap can be configured both programmatically and via configuration files.

**Mailcap file search order:**

The MailcapCommandMap looks in various places in the user's system for mailcap file entries. When requests are made to search for commands in the MailcapCommandMap, it searches mailcap files in the following order:

1. Programatically added entries to the MailcapCommandMap instance.
2. The file `.mailcap` in the user's home directory.
3. The file `<java.home>/lib/mailcap`.
4. The file or resources named META-INF/mailcap.
5. The file or resource named META-INF/mailcap.default (usually found only in the activation.jar file).

**Mailcap file format:**
Mailcap files must conform to the mailcap file specification (RFC 1524, *A User Agent Configuration Mechanism For Multimedia Mail Format Information*). The file format consists of entries corresponding to particular MIME types. In general, the specification specifies applications for clients to use when they themselves cannot operate on the specified MIME type. The MailcapCommandMap extends this specification by using a parameter mechanism in mailcap files that allows JavaBeans(tm) components to be specified as corresponding to particular commands for a MIME type.

When a mailcap file is parsed, the MailcapCommandMap recognizes certain parameter signatures, specifically those parameter names that begin with x-java-. The MailcapCommandMap uses this signature to find command entries for inclusion into its registries. Parameter names with the form x-java-<name> are read by the MailcapCommandMap as identifying a command with the name name. When the name is content-handler the MailcapCommandMap recognizes the class signified by this parameter as a DataContentHandler. All other commands are handled generically regardless of command name. The command implementation is specified by a fully qualified class name of a JavaBean(tm) component. For example; a command for viewing some data can be specified as: x-java-view=com.foo.ViewBean.

When the command name is fallback-entry, the value of the command may be true or false. An entry for a MIME type that includes a parameter of x-java-fallback-entry=true defines fallback commands for that MIME type that will only be used if no non-fallback entry can be found. For example, an entry of the form text/*; x-java-fallback-entry=true; x-java-view=com.sun.TextViewer specifies a view command to be used for any text MIME type. This view command would only be used if a non-fallback view command for the MIME type could not be found.

MailcapCommandMap aware mailcap files have the following general form:

```
# Comments begin with a '#' and continue to the end of the line.
mime type; ; <parameter list>
# Where a parameter list consists of one or more parameters,
# where parameters look like: x-java-view=com.sun.TextViewer
# and a parameter list looks like:
```

# Note that mailcap entries that do not contain 'x-java' parameters and comply to RFC 1524 are simply ignored:
image/gif; /usr/dt/bin/sdtimage %s

Constructor Detail

public MailcapCommandMap()

MailcapCommandMap

public MailcapCommandMap()

    The default Constructor.

public MailcapCommandMap(String fileName) throws java.io.IOException

    mailcap

    fileName

    mailcap

    Throws

    java.io.IOException:
MailcapCommandMap

public MailcapCommandMap(String fileName)
throws IOException

    Constructor that allows the caller to specify the path of a mailcap file.

    Parameters:
    fileName - The name of the mailcap file to open

    Throws:
    IOException - if the file can't be accessed

public MailcapCommandMap(java.io.InputStream is)

    Constructor that allows the caller to specify an InputStream containing a mailcap file.

    Parameters:
    is - InputStream of the mailcap file to open

Method Detail

public CommandInfo[] getPreferredCommands(String mimeType)

    MIME MailcapCommandMap
    n
    mailcap

    MailcapCommandMap mailmap
    mimeType MIME
public CommandInfo[] getPreferredCommands(String mimeType)

Get the preferred command list for a MIME Type. The MailcapCommandMap searches the mailcap files as described above under Mailcap file search order.

The result of the search is a proper subset of available commands in all mailcap files known to this instance of MailcapCommandMap. The first entry for a particular command is considered the preferred command.

Specified by:  
getPreferredCommands in class CommandMap

Parameters:  
mimeType - the MIME type

Returns:  
the CommandInfo objects representing the preferred commands.

public CommandInfo[] getAllCommands(String mimeType)

Get all the available commands in all mailcap files known to this instance of MailcapCommandMap for this MIME type.
Specified by:
getAllCommands in class CommandMap

Parameters:
mimeType - the MIME type

Returns:
the CommandInfo objects representing all the commands.

public CommandInfo getCommand(String mimeType, String cmdName)

MIME mimeType
     cmdName
     MIME
     cmdName
     return

public void addMailcap(String mail_cap)

mailcap
    mail_cap mailcap
**addMailcap**

```java
public void addMailcap(String mail_cap)
```

Add entries to the registry. Programatically added entries are searched before other entries.

The string that is passed in should be in mailcap format.

**Parameters:**
- `mail_cap` - a correctly formatted mailcap string

---

**createDataContentHandler**

```java
public DataContentHandler createDataContentHandler(String mimeType)
```

MIME `DataContentHandler`

<table>
<thead>
<tr>
<th><code>mimeType</code></th>
<th>MIME</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>return</td>
</tr>
<tr>
<td></td>
<td>DataContentHandler</td>
</tr>
</tbody>
</table>

**createDataContentHandler**

```java
public DataContentHandler createDataContentHandler(String mimeType)
```

Return the DataContentHandler for the specified MIME type.

**Specified by:**
- `createDataContentHandler` in class `CommandMap`

**Parameters:**
- `mimeType` - the MIME type

**Returns:**
- the DataContentHandler

---

**getMimeTypes**

```java
public String[] getMimeTypes()
```

MIME
getMimeTypes

public String[] getMimeTypes()

Get all the MIME types known to this command map.

Overrides:
    getMimeTypes in class CommandMap

Returns:
    array of MIME types as strings

Since:
    JAF 1.1

getNativeCommands

public String[] getNativeCommands(String mimeType)

Get the native commands for the given MIME type. Returns an array of strings where each string is an entire mailcap file entry. The application will need to parse the entry to extract the actual command as well as any attributes it needs. See RFC 1524 for details of the mailcap entry syntax. Only mailcap entries that specify a view command for the specified MIME type are returned.

Returns:
    array of native command entries

since JavaMail 1.2 en

Formats and parses date specification based on the draft-ietf-drums-msg-fmt-08 dated January 26, 2000. This is a followup spec to RFC822.

This class does not take pattern strings. It always formats the date based on the specification below.
3.3 Date and Time Specification

Date and time occur in several header fields of a message. This section specifies the syntax for a full date and time specification. Though folding whitespace is permitted throughout the date-time specification, it is recommended that only a single space be used where FWS is required and no space be used where FWS is optional in the date-time specification; some older implementations may not interpret other occurrences of folding whitespace correctly.

date-time = [ day-of-week , ] date FWS time [CFWS]
day-of-week = ([FWS] day-name) / obs-day-of-week
day-name = "Mon" / "Tue" / "Wed" / "Thu" / "Fri" / "Sat" / "Sun"
date = day month year
year = 4*DIGIT / obs-year
month = (FWS month-name FWS) / obs-month
day = ([FWS] 1*2DIGIT) / obs-day
time = time-of-day FWS zone
time-of-day = hour : minute [ : second ]
hour = 2DIGIT / obs-hour
minute = 2DIGIT / obs-minute
second = 2DIGIT / obs-second
zone = ("+" / "-" ) 4DIGIT) / obs-zone

The day is the numeric day of the month. The year is any numeric year in
the common era.

The time-of-day specifies the number of hours, minutes, and optionally seconds since midnight of the date indicated.

The date and time-of-day SHOULD express local time.

The zone specifies the offset from Coordinated Universal Time (UTC, formerly referred to as "Greenwich Mean Time") that the date and time-of-day represent. The "+" or "-" indicates whether the time-of-day is ahead of or behind Universal Time. The first two digits indicate the number of hours difference from Universal Time, and the last two digits indicate the number of minutes difference from Universal Time. (Hence, +hhmm means +(hh * 60 + mm) minutes, and -hhmm means -(hh * 60 + mm) minutes). The form "+0000" SHOULD be used to indicate a time zone at Universal Time. Though "-0000" also indicates Universal Time, it is used to indicate that the time was generated on a system that may be in a local time zone other than Universal Time.

A date-time specification MUST be semantically valid. That is, the day-of-the-week (if included) MUST be the day implied by the date, the numeric day-of-month MUST be between 1 and the number of days allowed for the specified month (in the specified year), the time-of-day MUST be in the range 00:00:00 through 23:59:60 (the number of seconds allowing for a leap second; see [STD-12]), and the zone MUST be within the range -9959 through +9959.

XAResource JTA

LocalTransaction

version 0.5

See also
javax.resource.spi.ManagedConnectionFactory,
javax.transaction.xa.XAResource,
javax.resource.spi.LocalTransaction

ManagedConnection instance represents a physical connection to the underlying EIS.

A ManagedConnection instance provides access to a pair of interfaces: javax.transaction.xa.XAResource and javax.resource.spi.LocalTransaction.

XAResource interface is used by the transaction manager to associate and dissociate a transaction with the underlying EIS resource manager instance and to perform two-phase commit protocol. The ManagedConnection interface is not directly used by the transaction manager. More details on the XAResource interface are described in the JTA specification.

The LocalTransaction interface is used by the application server to manage local transactions.
Method Summary

</tbody>
</table>
void
Removes an already registered connection event listener from the ManagedConnection instance.

void setLogWriter(PrintWriter out)
Sets the log writer for this ManagedConnection instance.

**Method Detail**

**public Object getConnection(javax.security.auth.Subject subject, ConnectionRequestInfo cxRequestInfo) throws ResourceException**

ManagedConnection Subject ConnectionRequest

subject JAAS

cxRequestInfo ConnectionRequestInfo

return Object CCIManagedConnection

javax.resource.cci.Connection

Throws ResourceException:

Throws ResourceAdapterInternalException:

Throws SecurityException:

Throws CommException: EIS

Throws EISSystemException: EIS EIS

ManagedConnection

getConnection

**Object getConnection(Subject subject, ConnectionRequestInfo cxRequestInfo) throws ResourceException**

Creates a new connection handle for the underlying physical connection represented by the ManagedConnection instance. This
connection handle is used by the application code to refer to the underlying physical connection. This connection handle is associated with its ManagedConnection instance in a resource adapter implementation specific way.

The ManagedConnection uses the Subject and additional ConnectionRequest Info (which is specific to resource adapter and opaque to application server) to set the state of the physical connection.

**Parameters:**
- `subject` - security context as JAAS subject
- `cxRequestInfo` - ConnectionRequestInfo instance

**Returns:**
- generic Object instance representing the connection handle. For CCI, the connection handle created by a ManagedConnection instance is of the type `javax.resource.cci.Connection`.

**Throws:**
- `ResourceException` - generic exception if operation fails
- `ResourceAdapterInternalException` - resource adapter internal error condition
- `SecurityException` - security related error condition
- `CommException` - failed communication with EIS instance
- `EISSystemException` - internal error condition in EIS instance - used if EIS instance is involved in setting state of ManagedConnection

```java
public void destroy() throws ResourceException

ManagedConnection.destroy
ManagedConnection

Throws ResourceException:

Throws IllegalStateException: 
```

destroy
void destroy() throws ResourceException

Destroys the physical connection to the underlying resource manager.

To manage the size of the connection pool, an application server can explicitly call ManagedConnection.destroy to destroy a physical connection. A resource adapter should destroy all allocated system resources for this ManagedConnection instance when the method destroy is called.

Throws:
  ResourceException - generic exception if operation failed
  IllegalStateException - illegal state for destroying connection

public void cleanup() throws ResourceException

ManagedConnection

ManagedConnection.cleanup ManagedConnection
ManagedConnection ManagedConnection cleanup

ManagedConnection ManagedConnectionManagedConnection.cleanup

ManagedConnection.cleanup

ManagedConnection cleanup

Throws ResourceException:
Throws ResourceAdapterInternalException:
Throws IllegalStateException: localtransaction

cleanup
void cleanup() throws ResourceException

Application server calls this method to force any cleanup on the ManagedConnection instance.

The method ManagedConnection.cleanup initiates a cleanup of the any client-specific state as maintained by a ManagedConnection instance. The cleanup should invalidate all connection handles that had been created using this ManagedConnection instance. Any attempt by an application component to use the connection handle after cleanup of the underlying ManagedConnection should result in an exception.

The cleanup of ManagedConnection is always driven by an application server. An application server should not invoke ManagedConnection.cleanup when there is an uncompleted transaction (associated with a ManagedConnection instance) in progress.

The invocation of ManagedConnection.cleanup method on an already cleaned-up connection should not throw an exception.

The cleanup of ManagedConnection instance resets its client specific state and prepares the connection to be put back in to a connection pool. The cleanup method should not cause resource adapter to close the physical pipe and reclaim system resources associated with the physical connection.

Throws:

- ResourceException - generic exception if operation fails
- ResourceAdapterInternalException - resource adapter internal error condition
- IllegalStateException - Illegal state for calling connection cleanup. Example - if a localtransaction is in progress that doesn't allow connection cleanup

public void associateConnection(Object connection)
throws ResourceException
ManagedConnection ManagedConnection
associateConnection

associateConnection ManagedConnection ManagedConnection

connection

Throws ResourceException: ManagedConnection
Throws IllegalStateException:
Throws ResourceAdapterInternalException:

associateConnection

void associateConnection(Object connection)
throws ResourceException

Used by the container to change the association of an application-level connection handle with a ManagedConnection instance. The container should find the right ManagedConnection instance and call the associateConnection method.

The resource adapter is required to implement the associateConnection method. The method implementation for a ManagedConnection should dissociate the connection handle (passed as a parameter) from its currently associated ManagedConnection and associate the new connection handle with itself.

Parameters:
connection - Application-level connection handle

Throws:
ResourceException - Failed to associate the connection handle with this ManagedConnection instance
IllegalStateException - Illegal state for invoking this method
ResourceAdapterInternalException - Resource adapter internal error condition
public void addConnectionEventListener(ConnectionEventListener listener)
ManagedConnection

ConnectionEventListener ManagedConnection

listener ConnectionEventListener

addConnectionEventListener

void addConnectionEventListener(ConnectionEventListener listener)

Adds a connection event listener to the ManagedConnection instance.

The registered ConnectionEventListener instances are notified of connection close and error events, also of local transaction related events on the Managed Connection.

Parameters:
listener - a new ConnectionEventListener to be registered

public void removeConnectionEventListener(ConnectionEventListener listener)
ManagedConnection

removeConnectionEventListener

void removeConnectionEventListener(ConnectionEventListener listener)
Removes an already registered connection event listener from the ManagedConnection instance.

**Parameters:**

- **listener** - already registered connection event listener to be removed

---

```java
public XAResource getXAResource() throws ResourceException
```

javax.transaction.xa.XAresource JTA

ManagedConnection XAResource

```java
return XAResource
```

**Throws:**

- ResourceException
- NotSupportedException
- ResourceAdapterInternalException

---

**getXAResource**

```java
XAResource getXAResource() throws ResourceException
```

Returns an javax.transaction.xa.XAresource instance. An application server enlists this XAResource instance with the Transaction Manager if the ManagedConnection instance is being used in a JTA transaction that is being coordinated by the Transaction Manager.

**Returns:**

- XAResource instance

**Throws:**

- ResourceException - generic exception if operation fails
- NotSupportedException - if the operation is not supported
- ResourceAdapterInternalException - resource adapter internal error condition
public **LocalTransaction** getLocalTransaction() throws **ResourceException**

`javax.resource.spi.LocalTransaction` LocalTransaction RM

return LocalTransaction

**Throws**: ResourceException:

**Throws**: NotSupportedException:

**Throws**: ResourceAdapterInternalException:

---

**getLocalTransaction**

**LocalTransaction** getLocalTransaction()

throws **ResourceException**

Returns an `javax.resource.spi.LocalTransaction` instance. The LocalTransaction interface is used by the container to manage local transactions for a RM instance.

**Returns**: LocalTransaction instance

**Throws**: **ResourceException** - generic exception if operation fails

NotSupportedException - if the operation is not supported

ResourceAdapterInternalException - resource adapter internal error condition

---

public **ManagedConnectionMetaData** getMetaData() throws **ResourceException**

**EIS ManagedConnectionMetaData**

ManagedConenction EIS

return ManagedConnectionMetaData

**Throws**: ResourceException:

**Throws**: NotSupportedException:

**Throws**: NotSupportedIOException:
getMetaData

ManagedConnectionMetaData getMetaData() throws ResourceException

Gets the metadata information for this connection's underlying EIS resource manager instance. The ManagedConnectionMetaData interface provides information about the underlying EIS instance associated with the ManagedConnection instance.

Returns:
ManagedConnectionMetaData instance

Throws:
ResourceException - generic exception if operation fails
NotSupportedException - if the operation is not supported

public void setLogWriter(java.io.PrintWriter out) throws ResourceException

ManagedConnection writer

writer ManagedConnection
ManagedConnection

ManagedConnection ManagedConnectionFactory
writer setLogWriter ManagedConnection
writer/

out

Throws ResourceException:

Throws ResourceAdapterInternalException:

setLogWriter
void setLogWriter(PrintWriter out)
throws ResourceException

Sets the log writer for this ManagedConnection instance.

The log writer is a character output stream to which all logging and tracing messages for this ManagedConnection instance will be printed. Application Server manages the association of output stream with the ManagedConnection instance based on the connection pooling requirements.

When a ManagedConnection object is initially created, the default log writer associated with this instance is obtained from the ManagedConnectionFactory. An application server can set a log writer specific to this ManagedConnection to log/trace this instance using setLogWriter method.

Parameters:
   out - Character Output stream to be associated

Throws:
   ResourceException - generic exception if operation fails
   ResourceAdapterInternalException - resource adapter related error condition

public java.io.PrintWriter getLogWriter() throws
ResourceException

ManagedConnection writer

ManagedConnection writer
ConnectionManager ManagedConnection

ManagedConnection writer
ManagedConnectionFactory writer

return ManagedConnection

Throws ResourceException:
getLogWriter

`PrintWriter getLogWriter()` throws `ResourceException`

Gets the log writer for this ManagedConnection instance.

The log writer is a character output stream to which all logging and tracing messages for this ManagedConnection instance will be printed. ConnectionManager manages the association of output stream with the ManagedConnection instance based on the connection pooling requirements.

The Log writer associated with a ManagedConnection instance can be one set as default from the ManagedConnectionFactory (that created this connection) or one set specifically for this instance by the application server.

**Returns:**
Character output stream associated with this Managed-Connection instance

**Throws:**
`ResourceException` - generic exception if operation fails
javax.resource.spi

**Interface ManagedConnectionFactory**

**All Superinterfaces:**

[Serializable]

```java
public interface ManagedConnectionFactory
extends Serializable

Implements: java.io.Serializable
```

**ManagedConnectionFactory ManagedConnection EIS**

ManagedConnectionFactory ManagedConnectionFactory

JavaBean

```java
version 0.6
See also javax.resource.spi.ManagedConnection
```

ManagedConnectionFactory instance is a factory of both ManagedConnection and EIS-specific connection factory instances. This interface supports connection pooling by providing methods for matching and creation of ManagedConnection instance. A ManagedConnectionFactory instance is required to be a JavaBean.

**Version:**

0.6

### Method Detail

```java
public Object createConnectionFactory(ConnectionManager cxManager) throws ResourceException {
    Connection Factory Connection Factory
    return EIS ConnectionManager
    javax.resource.cci.ConnectionFactory
   Throws ResourceException:
```
createConnectionFactory

**Object** createConnectionFactory(**ConnectionManager** cxManager) throws **ResourceException**

Creates a Connection Factory instance. The Connection Factory instance gets initialized with the passed ConnectionManager. In the managed scenario, ConnectionManager is provided by the application server.

**Parameters:**

- **cxManager** - ConnectionManager to be associated with created EIS connection factory instance

**Returns:**

- EIS-specific Connection Factory instance or javax.resource.cci.ConnectionFactory instance

**Throws:**

- **ResourceException** - Generic exception
- **ResourceAdapterInternalException** - Resource adapter related error condition

---

```java
class ConnectionFactory
```

```java
public Object createConnectionFactory() throws ResourceException
```

**Connection Factory Connection Factory ConnectionManager**

```java
return EIS Connection Factory
javax.resource.cci.ConnectionFactory
```

**Throws**

- **ResourceException:**

**Throws**

- **ResourceAdapterInternalException:**

createConnectionFactory

**Object** createConnectionFactory()
Throws: ResourceException - Generic exception
        ResourceAdapterInternalException - Resource adapter related error condition

public ManagedConnection createManagedConnection(javax.security.auth.Subject subject, ConnectionRequestInfo cxRequestInfo) throws ResourceException

ManagedConnectionFactory subject
ConnectionRequestInfo cxRequestInfo ResourceAdapter

Throws: ResourceException:
        SecurityException:
        ResourceAllocationException:
        ResourceAdapterInternalException:
        EISSystemException: EIS

return ManagedConnection

createManagedConnection

ManagedConnection createManagedConnection(Subject subject,
Creates a new physical connection to the underlying EIS resource manager.

ManagedConnectionFactory uses the security information (passed as Subject) and additional ConnectionRequestInfo (which is specific to ResourceAdapter and opaque to application server) to create this new connection.

**Parameters:**
- `subject` - Caller's security information
- `cxRequestInfo` - Additional resource adapter specific connection request information

**Returns:**
- ManagedConnection instance

**Throws:**
- `ResourceException` - generic exception
- `SecurityException` - security related error
- `ResourceAllocationException` - failed to allocate system resources for connection request
- `ResourceAdapterInternalException` - resource adapter related error condition
- `EISSystemException` - internal error condition in EIS instance

```java
public ManagedConnection matchManagedConnections(java.util.Set<E> connectionSet, javax.security.auth.Subject subject, ConnectionRequestInfo cxRequestInfo) throws ResourceException
```

```
ManagedConnectionFactory Subject ConnectionRequestInfo Connector
ManagedConnection
```
return ManagedConnection null

matchManagedConnections

ManagedConnection matchManagedConnections(Set connectionSet, Subject subject, ConnectionRequestInfo cxRequestInfo) throws ResourceException

Returns a matched connection from the candidate set of connections.

ManagedConnectionFactory uses the security info (as in Subject) and information provided through ConnectionRequestInfo and additional Resource Adapter specific criteria to do matching. Note that criteria used for matching is specific to a resource adapter and is not prescribed by the Connector specification.

This method returns a ManagedConnection instance that is the best match for handling the connection allocation request.

Parameters:
- connectionSet - candidate connection set
- subject - caller's security information
- cxRequestInfo - additional resource adapter specific connection request information

Returns:
ManagedConnection if resource adapter finds an acceptable match otherwise null

Throws:
ResourceException - generic exception
**SecurityException** - security related error

**ResourceAdapterInternalException** - resource adapter related error condition

**NotSupportedException** - if operation is not supported

---

```java
public void setLogWriter(java.io.PrintWriter out) throws ResourceException
ManagedConnectionFactory writer

writer ManagedConnectionFactory

ApplicationServer ManagedConnectionFactory
ManagedConnectionFactory writer null writer
ManagedConnectionFactory ManagedConnectionFactory

ManagedConnectionFactory ManagedConnection """"
writer ApplicationServer ManagedConnectionFactory.setLogWriter
ManagedConnection
　　out PrintWriter
　　Thrown ResourceException:
　　Thrown ResourceAdapterInternalException:

setLogWriter

void setLogWriter(PrintWriter out)
　　throws ResourceException

Set the log writer for this ManagedConnectionFactory instance.

The log writer is a character output stream to which all logging and tracing messages for this ManagedConnectionFactory instance will be printed.

ApplicationServer manages the association of output stream with the ManagedConnectionFactory. When a ManagedConnectionFactory object is created the log writer is initially null, in other words, logging is disabled.
```
Once a log writer is associated with a ManagedConnectionFactory, logging and tracing for ManagedConnectionFactory instance is enabled.

The ManagedConnection instances created by ManagedConnectionFactory "inherits" the log writer, which can be overridden by ApplicationServer using ManagedConnection.setLogWriter to set ManagedConnection specific logging and tracing.

**Parameters:**
- `out` - PrintWriter - an out stream for error logging and tracing

**Throws:**
- `ResourceException` - generic exception
- `ResourceAdapterInternalException` - resource adapter related error condition

```java
public java.io.PrintWriter getLogWriter() throws ResourceException

ManagedConnectionFactory writer

ApplicationServer ManagedConnectionFactory writer null

return PrintWriter

Throws ResourceException:
```

**getLogWriter**

`PrintWriter getLogWriter()`

`throws ResourceException`

Get the log writer for this ManagedConnectionFactory instance.

The log writer is a character output stream to which all logging and tracing messages for this ManagedConnectionFactory instance will
be printed

ApplicationServer manages the association of output stream with the ManagedConnectionFactory. When a ManagedConnectionFactory object is created the log writer is initially null, in other words, logging is disabled.

**Returns:**
- PrintWriter

**Thows:**
- ResourceException - generic exception

```java
public int hashCode()
{
    return ManagedConnectionFactory
}
```

**hashCode**

```java
int hashCode()
{
    Returns the hash code for the ManagedConnectionFactory

    ** Overrides:**
    - hashCode in class Object

    ** Returns:**
    hash code for the ManagedConnectionFactory
}
```

```java
public boolean equals(Object other)
{
    return true
}
```

**equals**
boolean equals(Object other)

Check if this ManagedConnectionFactory is equal to another ManagedConnectionFactory.

Overrides:
   equals in class Object

Returns:
   true if two instances are equal
javax.resource.spi Interface ManagedConnectionMetaData

public interface ManagedConnectionMetaData

ManagedConnectionMetaData ManagedConnection EIS

ManagedConnection.getMetaData ManagedConnectionMetaData

version 0.8
See also javax.resource.spi.ManagedConnection

The ManagedConnectionMetaData interface provides information about the underlying EIS instance associated with a ManagedConnection instance. An application server uses this information to get runtime information about a connected EIS instance.

The method ManagedConnection.getMetaData returns a ManagedConnectionMetaData instance.

Version:
0.8

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getEISProductName()</td>
<td>Returns Product name of the underlying EIS instance</td>
</tr>
</tbody>
</table>
String `getEISProductName()`

Returns product name of the underlying EIS instance connected through the ManagedConnection.

```
public String getEISProductName() throws ResourceException
```

```
ManagedConnection EIS
```

```
return EIS
```

### getEISProductName

**Returns:**

Product name of the EIS instance.

**Throws:**

ResourceException

---

Int `getMaxConnections()`

Returns maximum limit on number of active concurrent connections that an EIS instance can support across client processes.

```
int getMaxConnections()
```

**Returns:**

Maximum limit on number of active concurrent connections.

---

String `getUserName()`

Returns name of the user associated with the ManagedConnection instance.

```
String getUserName()
```

**Returns:**

Name of the user associated with the ManagedConnection instance.

---

Method Detail

```
public String getEISProductVersion() throws ResourceException
```

```
ManagedConnection EIS
```

```
return EIS
```

**getEISProductVersion**

**Returns:**

Product version of the underlying EIS instance connected through the ManagedConnection.

**Throws:**

ResourceException
**ResourceException**

**ManagedConnection EIS**

```
ManagedConnectionManagedConnection
```

getEISProductVersion

```java
String getEISProductVersion()
```

returns `ResourceException`

Returns product version of the underlying EIS instance connected through the ManagedConnection.

**Returns:**
Product version of the EIS instance

**Throws:**
`ResourceException`

--

**public int getMaxConnections() throws ResourceException**

```
public int getMaxConnections()
```

returns `0`

```
return 0
```

getMaxConnections

```java
int getMaxConnections()
```

returns `ResourceException`

Returns maximum limit on number of active concurrent connections that an EIS instance can support across client processes. If an EIS instance does not know about (or does not have) any such limit, it returns a 0.

**Returns:**
Maximum limit for number of active concurrent connections

**Throws:**
`ResourceException`
public String getUserName() throws ResourceException
ManagedConnection EIS

return

getUserName

String getUserName()
throws ResourceException

Returns name of the user associated with the ManagedConnection instance. The name corresponds to the resource principal under whose whose security context, a connection to the EIS instance has been established.

Returns:
name of the user

Throws:
ResourceException

### Methods inherited from interface `javax.ejb.EJBOBJECT`

- `getEJBHome`, `getHandle`, `getPrimaryKey`, `isIdentical`, `remove`

### Method Detail

```java
public java.util.Set<E>
queryNames(javax.management.ObjectName name,
javax.management.QueryExp query) throws
java.rmi.RemoteException
MEJB
```
J2EEObjectNames

```java
public ObjectName queryNames(ObjectName name, QueryExp query)
throws RemoteException
```

The `queryNames` method gets the names of managed objects controlled by the MEJB. This method enables any of the following to be obtained: The names of all managed objects, the names of a set of managed objects specified by pattern matching on the `ObjectName`, a specific managed object name (equivalent to testing whether a managed object is registered). When the object name is null or no domain and key properties are specified, all objects are selected. It returns the set of J2EEObjectNames for the managed objects selected.

**Parameters:**
- `name` - The object name pattern identifying the managed objects to be retrieved. If null or no domain and key properties are specified, all the managed objects registered will be retrieved.

**Returns:**
- A set containing the ObjectNames for the managed objects selected. If no managed object satisfies the query, an empty set is returned.

**Throws:**
- `RemoteException` - A communication exception occurred during the execution of a remote method call

---

public boolean isRegistered(javax.management.ObjectName name) throws java.rmi.RemoteException

MEJB
isRegistered

boolean isRegistered(ObjectName name) throws RemoteException

Checks whether a managed object, identified by its object name, is already registered with the MEJB.

Parameters:
   name - The object name of the managed object to be checked.

Returns:
   True if the managed object is already registered in the MEJB, false otherwise.

Throws:
   RemoteException - A communication exception occurred during the execution of a remote method call

public Integer getMBeanCount() throws java.rmi.RemoteException

MEJB

Throws java.rmi.RemoteException:

getMBeanCount

Integer getMBeanCount() throws RemoteException

   Returns the number of managed objects registered in the MEJB.

   Throws:
      RemoteException - A communication exception occurred during
public javax.management.MBeanInfo
getMBeanInfo(javax.management.ObjectName name)
throws javax.management.IntrospectionException,
javax.management.InstanceNotFoundException,
javax.management.ReflectionException,
java.rmi.RemoteException

name
return MBeanInfo
Throws javax.management.IntrospectionException: introspection
Throws javax.management.InstanceNotFoundException:
Throws javax.management.ReflectionException:
Throws java.rmi.RemoteException:

getMBeanInfo
MBeanInfo getMBeanInfo(ObjectName name)
throws IntrospectionException,
InstanceNotFoundException,
ReflectionException,
RemoteException

This method discovers the attributes and operations that a managed object exposes for management.

Parameters:
name - The name of the managed object to analyze

Returns:
An instance of MBeanInfo allowing the retrieval of all attributes and operations of this managed object.

Throws:
IntrospectionException - An exception occurs during introspection.
**InstanceNotFoundException** - The managed object specified is not found.
**ReflectionException** - An exception occurred when trying to perform reflection on a managed object
**RemoteException** - A communication exception occurred during the execution of a remote method call

---

```java
public Object getAttribute(javax.management.ObjectName name, String attribute) throws
java.management.MBeanException, java.management.AttributeNotFoundException,
java.management.InstanceNotFoundException, java.management.ReflectionException,
java.rmi.RemoteException

    name
    attribute String
    return

Throws javax.management.AttributeNotFoundException:
Throws javax.management.MBeanException:
Throws javax.management.InstanceNotFoundException: MEJB
    java.management.ReflectionException: Dynamic MBean
        getAttribute
    java.rmi.RemoteException:
```

**getAttribute**

```java
Object getAttribute(ObjectName name, String attribute) throws
MBeanException,
AttributeNotFoundException, InstanceNotFoundException, ReflectionException,
RemoteException
```

Gets the value of a specific attribute of a named managed object.
The managed object is identified by its object name.

**Parameters:**

- `name` - The object name of the managed object from which the attribute is to be retrieved.
- `attribute` - A String specifying the name of the attribute to be retrieved.

**Returns:**

The value of the retrieved attribute.

**Throws:**

- `AttributeNotFoundException` - The attribute specified is not accessible in the managed object.
- `MBeanException` - Wraps an exception thrown by the managed object's getter.
- `InstanceNotFoundException` - The managed object specified is not registered in the MEJB.
- `ReflectionException` - An exception occurred when trying to invoke the `getAttribute` method of a Dynamic MBean.
- `RemoteException` - A communication exception occurred during the execution of a remote method call.

```java

name
attributes
return

Throws  javax.management.InstanceNotFoundException: MEJB

Throws  javax.management.ReflectionException: Dynamic MBean

Throws  java.rmi.RemoteException:
```
getAttributes

AttributeList getAttributes(ObjectName name, String[] attributes)
throws InstanceNotFoundException,
ReflectionException,
RemoteException

Enables the values of several attributes of a named managed object. The managed object is identified by its object name.

Parameters:
  name - The object name of the managed object from which the attributes are retrieved.
  attributes - A list of the attributes to be retrieved.

Returns:
  The list of the retrieved attributes.

Throws:
  InstanceNotFoundException - The managed object specified is not registered in the MEJB.
  ReflectionException - An exception occurred when trying to invoke the getAttributes method of a Dynamic MBean.
  RemoteException - A communication exception occurred during the execution of a remote method call

public void setAttribute(javax.management.ObjectName name, javax.management.Attribute attribute) throws
javax.management.InstanceNotFoundException,
javax.management.AttributeNotFoundException,
javax.management.InvalidAttributeValueException,
javax.management.MBeanException,
javax.management.ReflectionException,
java.rmi.RemoteException

  name
setAttribute

void setAttribute(ObjectName name, Attribute attribute)
throws InstanceNotFoundException, AttributeNotFoundException, InvalidAttributeValueException, MBeanException, ReflectionException, RemoteException

Sets the value of a specific attribute of a named managed object. The managed object is identified by its object name.

Parameters:

name - The name of the managed object within which the attribute is to be set.
attribute - The identification of the attribute to be set and the value it is to be set to.

Throws:

InstanceNotFoundException - The managed object specified is not registered in the MEJB.
AttributeNotFoundException - The attribute specified is not accessible in the managed object.
InvalidAttributeValueException - The value specified for the attribute is not valid.
MBeanException - Wraps an exception thrown by the managed object's setter.
ReflectionException - An exception occurred when trying to invoke the setAttribute method of a Dynamic MBean.
RemoteException - A communication exception occurred during the execution of a remote method call

```java

name
attributes
return
Throws javax.management.InstanceNotFoundException: MEJB
Throwsjavax.management.ReflectionException: Dynamic MBean
Throws java.rmi.RemoteException:

setAttributes

AttributeList setAttributes(ObjectName name, AttributeList attributes) throws InstanceNotFoundException, ReflectionException, RemoteException

Sets the values of several attributes of a named managed object. The managed object is identified by its object name.

Parameters:
name - The object name of the managed object within which the attributes are to be set.
attributes - A list of attributes: The identification of the attributes to be set and the values they are to be set to.

Returns:
```
The list of attributes that were set, with their new values.

**Throws:**
- `InstanceNotFoundException` - The managed object specified is not registered in the MEJB.
- `ReflectionException` - An exception occurred when trying to invoke the `setAttributes` method of a Dynamic MBean.
- `RemoteException` - A communication exception occurred during the execution of a remote method call.

```java
public Object invoke(javax.management.ObjectName name, String operationName, Object[] params, String[] signature) throws
java.management.InstanceNotFoundException, java.management.MBeanException, java.management.ReflectionException, java.rmi.RemoteException
```

```
name
operationName
params
signature
return
```

**Throws**
- `javax.management.InstanceNotFoundException`: MEJB
- `javax.management.MBeanException`: 
- `javax.management.ReflectionException`: `java.lang.Exception`
- `java.rmi.RemoteException`: 

**invoke**

```java
Object invoke(ObjectName name, String operationName, Object[] params, String[] signature)
```
Invokes an operation on a managed object.

Parameters:
- **name** - The object name of the managed object on which the method is to be invoked.
- **operationName** - The name of the operation to be invoked.
- **params** - An array containing the parameters to be set when the operation is invoked.
- **signature** - An array containing the signature of the operation.

The class objects will be loaded using the same class loader as the one used for loading the managed object on which the operation was invoked.

Returns:
The object returned by the operation, which represents the result of invoking the operation on the managed object specified.

Throws:
- **InstanceNotFoundException** - The managed object specified is not registered in the MEJB.
- **MBeanException** - Wraps an exception thrown by the managed object's invoked method.
- **ReflectionException** - Wraps a `java.lang.Exception` thrown while trying to invoke the method.
- **RemoteException** - A communication exception occurred during the execution of a remote method call.

```java
public String getDefaultDomain() throws java.rmi.RemoteException,
                             MEJB

    Throws java.rmi.RemoteException:
```

```
getDefaultDomain
```
String getDefaultDomain() throws RemoteException

Returns the default domain name of this MEJB.

Throws:
   RemoteException - A communication exception occurred during the execution of a remote method call

public ListenerRegistration getListenerRegistry() throws java.rmi.RemoteException
MEJB

   return javax.management.j2ee.ListenerRegistration

Throws java.rmi.RemoteException:

getListenerRegistry

ListenerRegistration getListenerRegistry() throws RemoteException

Returns the listener registry implementation for this MEJB. The listener registry implements the methods that enable clients to add and remove event notification listeners managed objects

Returns:
   An implementation of javax.management.j2ee.ListenerRegistration

Throws:
   RemoteException - A communication exception occurred during the execution of a remote method call

    joinColumns=
        @JoinColumn(name="CUST_ID", referencedColumnName="ID"),
    inverseJoinColumns=
        @JoinColumn(name="PHONE_ID", referencedColumnName="ID")
)
public Set getPhones() { return phones; }

PhoneNumberClass
@ManyToMany(mappedBy="phones")
public Set getCustomers() { return customers; }

since Java Persistence 1.0

Defines a many-valued association with many-to-many multiplicity. If the Collection is defined using generics to specify the element type, the associated target entity class does not need to be specified; otherwise it must be specified.

Every many-to-many association has two sides, the owning side and the non-owning, or inverse, side. The join table is specified on the owning side. If the association is bidirectional, either side may be designated as the owning side.

The same annotation elements for the OneToMany annotation apply to the ManyToMany annotation.

Example 1:
In Customer class:

@ManyToMany
@JoinTable(name="CUST_PHONES")
public Set getPhones() { return phones; }

In PhoneNumber class:

@ManyToMany(mappedBy="phones")
public Set getCustomers() { return customers; }

Example 2:
In Customer class:

```java
@ManyToMany(targetEntity=com.acme.PhoneNumber.class)
public Set getPhones() { return phones; }
```

In PhoneNumber class:

```java
@ManyToMany(targetEntity=com.acme.Customer.class, mappedBy="phones")
public Set getCustomers() { return customers; }
```

Example 3:

In Customer class:

```java
@ManyToMany
@JoinTable(name="CUST_PHONE",
    joinColumns=
        @JoinColumn(name="CUST_ID", referencedColumnName="ID"),
    inverseJoinColumns=
        @JoinColumn(name="PHONE_ID", referencedColumnName="ID")
)
public Set getPhones() { return phones; }
```

In PhoneNumber class:

```java
@ManyToMany(mappedBy="phones")
public Set getCustomers() { return customers; }
```

Since:
Java Persistence 1.0

</table>
abstract public Class<T> targetEntity()
Java generic Collection
generic Collection
targetEntity

public abstract Class targetEntity

(Optional) The entity class that is the target of the association. Optional only if the collection property is defined using Java generics. Must be specified otherwise.

Defaults to the parameterized type of the collection when defined using generics.

Default:
void.class

abstract public CascadeType[] cascade()
(Optional) The operations that must be cascaded to the target of the association.

Defaults to no operations being cascaded.

Default:

```java
{}
```

---

**abstract public FetchType fetch()**

**fetch**

```java
public abstract FetchType fetch()
```

(Optional) Whether the association should be lazily loaded or must be eagerly fetched. The **EAGER** strategy is a requirement on the persistenceprovider runtime that the associatedentities must be eagerly fetched. The **LAZY** strategy is a hint to the persistence provider runtime.

Default:

```java
LAZY
```

---

**abstract public String mappedBy()**

**mappedBy**

```java
public abstract String mappedBy()
```

The field that owns the relationship. Required unless the relationship is unidirectional.

Default:

PS:
javax.persistence  Annotation Type ManyToOne

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface ManyToOne

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

@ManyToOne(optional=false)
@JoinColumn(name="CUST_ID", nullable=false, updatable=false)
public Customer getCustomer() { return customer; }

since Java Persistence 1.0

This annotation defines a single-valued association to another entity class that has many-to-one multiplicity. It is not normally necessary to specify the target entity explicitly since it can usually be inferred from the type of the object being referenced.

Example:

@ManyToOne(optional=false)
@JoinColumn(name="CUST_ID", nullable=false, updatable=false)
public Customer getCustomer() { return customer; }

Since: Java Persistence 1.0

  ↓  javax.el.ELResolver  
  ↓  javax.el.MapELResolver

public class MapELResolver

extends ELResolver

**Extends:** ELResolver

java.util.Map

java.util.Map  base

 #isReadOnly  true#setValue  PropertyNotWritableException

ELResolver  CompositeELResolver  ELResolver

Javadoc

**since**  JSP 2.1

**See**  javax.el.CompositeELResolver, javax.el.ELResolver, java.util.Map

**also**  java.util.Map

Defines property resolution behavior on instances of Map.

This resolver handles base objects of type java.util.Map. It accepts any object as a property and uses that object as a key in the map. The resulting value is the value in the map that is associated with that key.

This resolver can be constructed in read-only mode, which means that isReadOnly will always return true and setValue(javax.el.ELContext, java.lang.Object, java.lang.Object, java.lang.Object) will always throw PropertyNotWritableException.

ELResolvers are combined together using CompositeELResolver, to
define rich semantics for evaluating an expression. See the javadocs for \texttt{ELResolver} for details.

\textbf{Since:}  
JSP 2.1

Constructor Detail

public MapELResolver()
/

MapELResolver

public MapELResolver()

Creates a new read/write MapELResolver.
public MapELResolver(boolean isReadOnly)

MapELResolver

public MapELResolver(boolean isReadOnly)

Creates a new MapELResolver whose read-only status is determined by the given parameter.

Parameters:
isReadOnly - true if this resolver cannot modify maps; false otherwise.

Method Detail

public Class<T> getType(ELContext context, Object base, Object property)

base

base Map ELContext propertyResolved true
true

base Map Object.class Map

context
base Map base
property

return ELContext propertyResolved true

Throws NullPointerException: context null

Throws ELEException: cause
**getType**

```java
public Class<?> getType(ELContext context, Object base, Object property)
```

If the base object is a map, returns the most general acceptable type for a value in this map.

If the base is a `Map`, the `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver, before returning. If this property is not `true` after this method is called, the caller should ignore the return value.

Assuming the base is a `Map`, this method will always return `Object.class`. This is because `Maps` accept any object as the value for a given key.

**Specified by:**
- `getType` in class `ELResolver`

**Parameters:**
- `context` - The context of this evaluation.
- `base` - The map to analyze. Only bases of type `Map` are handled by this resolver.
- `property` - The key to return the acceptable type for. Ignored by this resolver.

**Returns:**
- If the `propertyResolved` property of `ELContext` was set to `true`, then the most general acceptable type; otherwise undefined.

**Throws:**
- `NullPointerException` - if context is null
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

```java
public Object getValue(ELContext context, Object base, Object property)
```

```java
base property null
```
getValue

public Object getValue(ELContext context, Object base, Object property)

If the base object is a map, returns the value associated with the given key, as specified by the property argument. If the key was not found, null is returned.

If the base is a Map, the propertyResolved property of the ELContext object must be set to true by this resolver, before returning. If this property is not true after this method is called, the caller should ignore the return value.

Just as in Map.get(java.lang.Object), just because null is returned doesn’t mean there is no mapping for the key; it’s also possible that the Map explicitly maps the key to null.

Specified by:
getValue in class ELResolver

Parameters:
context - The context of this evaluation.
base - The map to be analyzed. Only bases of type Map are
handled by this resolver.

property - The key whose associated value is to be returned.

Returns:
If the propertyResolved property of ELContext was set to true, then the value associated with the given key or null if the key was not found. Otherwise, undefined.

Throws:

ClassCastException - if the key is of an inappropriate type for this map (optionally thrown by the underlying Map).

NullPointerException - if context is null, or if the key is null and this map does not permit null keys (the latter is optionally thrown by the underlying Map).

ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

public void setValue(ELContext context, Object base, Object property, Object val)

Base                Map            ELContext    propertyResolved    true

PropertyNotWritableException

java.util.Collections#unmodifiableMap              Map

PropertyNotWritableException Collection API

Map base

collection

base

property

val

Throws ClassCastException:

Throws NullPointerException: null null null

Throws IllegalArgumentException:
Throws: `ELException`: cause

Throws: `PropertyNotWritableException`:

**setValue**

```java
public void setValue(ELContext context,
                     Object base,
                     Object property,
                     Object val)
```

If the base object is a map, attempts to set the value associated with the given key, as specified by the `property` argument.

If the base is a `Map`, the `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver, before returning. If this property is not `true` after this method is called, the caller can safely assume no value was set.

If this resolver was constructed in read-only mode, this method will always throw `PropertyNotWritableException`.

If a `Map` was created using `Collections.unmodifiableMap(java.util.Map)`, this method must throw `PropertyNotWritableException`. Unfortunately, there is no Collections API method to detect this. However, an implementation can create a prototype unmodifiable `Map` and query its runtime type to see if it matches the runtime type of the base object as a workaround.

**Specified by:**

`setValue` in class `ELResolver`

**Parameters:**

- `context` - The context of this evaluation.
- `base` - The map to be modified. Only bases of type `Map` are handled by this resolver.
- `property` - The key with which the specified value is to be associated.
- `val` - The value to be associated with the specified key.

**Throws:**
**ClassCastException** - if the class of the specified key or value prevents it from being stored in this map.

**NullPointerException** - if context is null, or if this map does not permit null keys or values, and the specified key or value is null.

**IllegalArgumentException** - if some aspect of this key or value prevents it from being stored in this map.

**ELException** - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

**PropertyNotWritableException** - if this resolver was constructed in read-only mode, or if the put operation is not supported by the underlying map.

```java
public boolean isReadOnly(ELContext context, Object base, Object property) {
    return context == null;
}
```

Throws **NullPointerException**: context null

Throws **ELException**: cause
public boolean isReadOnly(ELContext context, Object base, Object property)

If the base object is a map, returns whether a call to setValue(javax.el.ELContext, java.lang.Object, java.lang.Object, java.lang.Object) will always fail.

If the base is a Map, the propertyResolved property of the ELContext object must be set to true by this resolver, before returning. If this property is not true after this method is called, the caller should ignore the return value.

If this resolver was constructed in read-only mode, this method will always return true.

If a Map was created using Collections.unmodifiableMap(java.util.Map), this method must return true. Unfortunately, there is no Collections API method to detect this. However, an implementation can create a prototype unmodifiable Map and query its runtime type to see if it matches the runtime type of the base object as a workaround.

Specified by:
isReadOnly in class ELResolver

Parameters:
context - The context of this evaluation.
base - The map to analyze. Only bases of type Map are handled by this resolver.
property - The key to return the read-only status for. Ignored by this resolver.

Returns:
If the propertyResolved property of ELContext was set to true, then true if calling the setValue method will always fail or false if it is possible that such a call may succeed; otherwise undefined.

Throws:
NullPointerException - if context is null
**ELException** - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

```java
public java.util.Iterator<E>
getFeatureDescriptors(ELContext context, Object base)
```

```java
Iterator 0 java.beans.FeatureDescriptor info
Map
```

- displayName - toString null "null"
- name – displayName
- shortDescription –
- expert - false
- hidden - false
- preferred - true

```java
FeatureDescriptor
```

- **ELResolver#TYPE** - getClass() null null
- **ELResolver#RESOLVABLE_AT_DESIGN_TIME** - true

```java
context
base
return 0
```

```java
getFeatureDescriptors
```

```java
public Iterator<FeatureDescriptor> getFeatureDescriptors(ELContext context, Object base)
```

If the base object is a map, returns an Iterator containing the set of
keys available in the Map. Otherwise, returns null.

The Iterator returned must contain zero or more instances of FeatureDescriptor. Each info object contains information about a key in the Map, and is initialized as follows:

- displayName - The return value of calling the toString method on this key, or "null" if the key is null.
- name - Same as displayName property.
- shortDescription - Empty string
- expert - false
- hidden - false
- preferred - true

In addition, the following named attributes must be set in the returned FeatureDescriptors:
- ELResolver.TYPE - The return value of calling the getClass() method on this key, or null if the key is null.
- ELResolver.RESOLVABLE_AT_DESIGN_TIME - true

Specified by:
getFeatureDescriptors in class ELResolver

Parameters:
context - The context of this evaluation.
base - The map whose keys are to be iterated over. Only bases of type Map are handled by this resolver.

Returns:
An Iterator containing zero or more (possibly infinitely more) FeatureDescriptor objects, each representing a key in this map, or null if the base object is not a map.

See Also:
FeatureDescriptor

public Class<T> getCommonPropertyType(ELContext context, Object base)
base       property       null
base       Map       Object.class       Map
getCommonPropertyType

```java
public Class<?>
getCommonPropertyType(ELContext context, Object base)
```

If the base object is a map, returns the most general type that this resolver accepts for the property argument. Otherwise, returns null.

Assuming the base is a Map, this method will always return Object.class. This is because Maps accept any object as a key.

Specified by:
- getCommonPropertyType in class ELResolver

Parameters:
- **context** - The context of this evaluation.
- **base** - The map to analyze. Only bases of type Map are handled by this resolver.

Returns:
- null if base is not a Map; otherwise Object.class.
javax.persistence  Annotation Type MapKey

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface MapKey

**Implements:** Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

```java
import java.util.Map

@Entity
public class Department {
    // ...
    @OneToMany(mappedBy="department")
    @MapKey(name="empId")
    public Map getEmployees() {...}
    // ...
}

@Entity
public class Employee {
    // ...
    @Id Integer getEmpid() {...}
    @ManyToOne
    @JoinColumn(name="dept_id")
    public Department getDepartment() {...}
    // ...
}
```

2

```java
@Entity
public class Department {
    // ...
    @OneToMany(mappedBy="department")
    @MapKey(name="empPK")
    public Map getEmployees() {...}
```

Is used to specify the map key for associations of type `Map`.

If a persistent field or property other than the primary key is used as a
map key then it is expected to have a uniqueness constraint associated
with it.

Example 1:

```java
@Entity
public class Department {
    ...
    @OneToMany(mappedBy="department")
    @MapKey(name="empId")
    public Map getEmployees() { ... }
    ...
}

@Entity
public class Employee {
    ...
    @Id Integer getEmpid() { ... }
    @ManyToOne
    @JoinColumn(name="dept_id")
    public Department getDepartment() { ... }
}```
Example 2:

@Entity
class Department {
...
    @OneToMany(mappedBy="department")
    @MapKey(name="empPK")
    public Map getEmployees() { ... }
...
}

@Entity
class Employee {
    @EmbeddedId
    public EmployeePK getEmpPK() { ... }
    ...
    @ManyToOne
    @JoinColumn(name="dept_id")
    public Department getDepartment() { ... }
...
}

@Embeddable
class EmployeePK {
    String name;
    Date bday;
}

Since:
Java Persistence 1.0

### Optional Element Summary

| **String** name | The name of the persistent field or property of the associated entity that is used as the map key. |

abstract public String name()
public abstract String name

The name of the persistent field or property of the associated entity that is used as the map key. If the name element is not specified, the primary key of the associated entity is used as the map key. If the primary key is a composite primary key and is mapped as IdClass, an instance of the primary key class is used as the key.

</tr>
</tbody>
</table>

null null | valueOf(String) | char | String | null |
char | NullPointerException |
A `MapMessage` object is used to send a set of name-value pairs. The names are `String` objects, and the values are primitive data types in the Java programming language. The names must have a value that is not null, and not an empty string. The entries can be accessed sequentially or randomly by name. The order of the entries is undefined. `MapMessage` inherits from the `Message` interface and adds a message body that contains a Map.

The primitive types can be read or written explicitly using methods for each type. They may also be read or written generically as objects. For instance, a call to `MapMessage.setInt("foo", 6)` is equivalent to `MapMessage setObject("foo", new Integer(6))`. Both forms are provided, because the explicit form is convenient for static programming, and the object form is needed when types are not known at compile time.

When a client receives a `MapMessage`, it is in read-only mode. If a client attempts to write to the message at this point, a `MessageNotWriteableException` is thrown. If `clearBody` is called, the message can now be both read from and written to.

`MapMessage` objects support the following conversion table. The marked cases must be supported. The unmarked cases must throw a `JMSException`. The `String`-to-primitive conversions may throw a runtime exception if the primitive's `valueOf()` method does not accept it as a valid `String` representation of the primitive.

A value written as the row type can be read as the column type.

<table>
<thead>
<tr>
<th></th>
<th>boolean byte short char int long float double String byte</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>true</code></td>
<td>X</td>
<td></td>
</tr>
<tr>
<td><code>false</code></td>
<td>X</td>
<td>X</td>
</tr>
</tbody>
</table>
Attempting to read a null value as a primitive type must be treated as calling the primitive's corresponding `valueOf(String)` conversion method with a null value. Since `char` does not support a `String` conversion, attempting to read a null value as a `char` must throw a `NullPointerException`.

Methods inherited from interface javax.jms.Message

public boolean getBoolean(String name) throws JMSException

boolean

name

return

Throws JMSException: JMS

getBoolean

boolean getBoolean(String name)

throws JMSException

Returns the boolean value with the specified name.

Parameters:

name - the name of the boolean

Returns:

the boolean value with the specified name

Throws:

JMSException - if the JMS provider fails to read the message due to some internal error.

MessageFormatException - if this type conversion is invalid.

public byte getByte(String name) throws JMSException

byte

name

return

Throws JMSException: JMS

Throws MessageFormatException:
getBytes

byte getByte(String name) throws JMSException

Returns the byte value with the specified name.

Parameters:
  name - the name of the byte

Returns:
  the byte value with the specified name

Throws:
  JMSException - if the JMS provider fails to read the message due to some internal error.
  MessageFormatException - if this type conversion is invalid.

public short getShort(String name) throws JMSException

short getShort(String name) throws JMSException: JMS

Throws
  JMSException: JMS
  MessageFormatException: MessageFormatException:

goingShort

short getShort(String name) throws JMSException

Returns the short value with the specified name.

Parameters:
  name - the name of the short

Returns:
  the short value with the specified name

Throws:
  JMSException - if the JMS provider fails to read the message due to some internal error.
public char getChar(String name) throws IOException

Unicode

name
return

Throws IOException: JMS

Throws MessageFormatException:

getChar

char getChar(String name)
throws IOException

Returns the Unicode character value with the specified name.

Parameters:
name - the name of the Unicode character

Returns:
the Unicode character value with the specified name

Throws:
IOException - if the JMS provider fails to read the message due to some internal error.
MessageFormatException - if this type conversion is invalid.

public int getInt(String name) throws IOException

int

name
return

Throws IOException: JMS

Throws MessageFormatException:

getInt
int getInt(String name) throws JMSException

Returns the int value with the specified name.

Parameters:
   name - the name of the int

Returns:
   the int value with the specified name

Throws:
   JMSException - if the JMS provider fails to read the message due to some internal error.
   MessageFormatException - if this type conversion is invalid.

gelong getLong(String name) throws JMSException

long getLong(String name) throws JMSException

public long getLong(String name) throws JMSException
long

name
return
long
long

Throws
   JMSException: JMS
   MessageFormatException:

getLong

long getLong(String name) throws JMSException

Returns the long value with the specified name.

Parameters:
   name - the name of the long

Returns:
   the long value with the specified name

Throws:
   JMSException - if the JMS provider fails to read the message due to some internal error.
   MessageFormatException - if this type conversion is invalid.
public float getFloat(String name) throws JMSException

float

name float
return float

Throws JMSException: JMS

Throws MessageFormatException:

getFloat

float getFloat(String name)

throws JMSException

Returns the float value with the specified name.

Parameters:
name - the name of the float

Returns:
the float value with the specified name

Throws:
JMSException - if the JMS provider fails to read the message due to some internal error.
MessageFormatException - if this type conversion is invalid.

__________________________________________________________________________

gpublic double getDouble(String name) throws JMSException

double

double

name double
return double

Throws JMSException: JMS

Throws MessageFormatException:

gDouble

double getDouble(String name)
public String getString(String name) throws JMSException

Parameters:
    name - the name of the String

Returns:
    the String value with the specified name; if there is no item by 
    this name, a null value is returned

Throws:
    JMSException - if the JMS provider fails to read the message due 
    to some internal error.
    MessageFormatException - if this type conversion is invalid.
public byte[] getBytes(String name) throws JMSException

byte[] getBytes(String name)
    throws JMSException

Returns the byte array value with the specified name.

Parameters:
    name - the name of the byte array

Returns:
    a copy of the byte array value with the specified name; if there is
    no item by this name, a null value is returned.

Throws:
    JMSException - if the JMS provider fails to read the message due
to some internal error.
    MessageFormatException - if this type conversion is invalid.

public Object getObject(String name) throws JMSException

Object getObject(String name)
    throws JMSException

Java “Java ”
setObject settype
Map

byte byte[] Byte[]
    name Java
return Java
Throws JMSException: JMS
**getObject**

```java
Object getObject(String name)
```

throws `JMSException`

Returns the value of the object with the specified name.

This method can be used to return, in objectified format, an object in the Java programming language ("Java object") that had been stored in the Map with the equivalent `setObject` method call, or its equivalent primitive `settype` method.

Note that byte values are returned as `byte[]`, not `Byte[]`.

**Parameters:**
- `name` - the name of the Java object

**Returns:**
- a copy of the Java object value with the specified name, in objectified format (for example, if the object was set as an `int`, an `Integer` is returned); if there is no item by this name, a null value is returned

**Throws:**
- `JMSException` - if the JMS provider fails to read the message due to some internal error.

---

**public java.util.Enumeration<E> getMapNames() throws JMSException**

```java
MapMessage return Enumeration MapMessage
```

Throws `JMSException` - JMS

---

**getMapNames**

```java
Enumeration getMapNames()
```

throws `JMSException`
Returns an Enumeration of all the names in the MapMessage object.

**Returns:**
an enumeration of all the names in this MapMessage

**Throws:**
- `JMSException` - if the JMS provider fails to read the message due to some internal error.

---

```java
public void setBoolean(String name, boolean value) throws JMSException

setBoolean

void setBoolean(String name, boolean value)
throws JMSException

Sets a boolean value with the specified name into the Map.

**Parameters:**
- name - the name of the boolean
- value - the boolean value to set in the Map

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageNotWriteableException` - if the message is in read-only mode.
```
public void setByte(String name, byte value) throws JMSException

   Sets a byte value with the specified name into the Map.

   Parameters:
   name - the name of the byte
   value - the byte value to set in the Map

   Throws:
   JMSException - if the JMS provider fails to write the message due to some internal error.
   IllegalArgumentException - if the name is null or if the name is an empty string.
   MessageNotWriteableException - if the message is in read-only mode.

public void setShort(String name, short value) throws JMSException

   Sets a short value with the specified name into the Map.

   Parameters:
   name - the name of the short
   value - the short value to set in the Map

   Throws:
   JMSException - if the JMS provider fails to write the message due to some internal error.
   IllegalArgumentException - if the name is null or if the name is an empty string.
   MessageNotWriteableException - if the message is in read-only mode.
Throws  

**setMessageNotWriteableException**:  

**setShort**

```java
void setShort(String name, short value)
    throws JMSException
```

Sets a short value with the specified name into the Map.

**Parameters:**
- `name` - the name of the short value
- `value` - the short value to set in the Map

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageNotWriteableException` - if the message is in read-only mode.

---

**public void setChar(String name, char value) throws JMSException**

**Unicode Map**

<table>
<thead>
<tr>
<th>name</th>
<th>Unicode Map Unicode</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td></td>
</tr>
</tbody>
</table>

**Throws**
- `JMSException`: JMS
- `IllegalArgumentException`: null
- `MessageNotWriteableException`:  

**setChar**

```java
void setChar(String name, char value)
    throws JMSException
```
Sets a Unicode character value with the specified name into the Map.

Parameters:
- **name** - the name of the Unicode character
- **value** - the Unicode character value to set in the Map

Throws:
- **JMSException** - if the JMS provider fails to write the message due to some internal error.
- **IllegalArgumentException** - if the name is null or if the name is an empty string.
- **MessageNotWriteableException** - if the message is in read-only mode.

```java
public void setInt(String name, int value) throws JMSException
```

Sets an **int** value with the specified name into the Map.

Parameters:
- **name** - the name of the **int**
- **value** - the **int** value to set in the Map

Throws:
- **JMSException** - if the JMS provider fails to write the message due
public void setLong(String name, long value) throws JMSException

Sets a long value with the specified name into the Map.

Parameters:
name - the name of the long
value - the long value to set in the Map

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
IllegalArgumentException - if the name is null or if the name is an empty string.
MessageNotWriteableException - if the message is in read-only mode.

public void setFloat(String name, float value) throws
JMSException

float Map

name float
value Map float

Throws JMSException: JMS
Throws IllegalArgumentException: null
Throws MessageNotWriteableException:

setFloat

void setFloat(String name, float value) throws JMSException

Sets a float value with the specified name into the Map.

Parameters:
name - the name of the float
value - the float value to set in the Map

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
IllegalArgumentException - if the name is null or if the name is an empty string.
MessageNotWriteableException - if the message is in read-only mode.

public void setDouble(String name, double value) throws JMSException

double Map

name double
value Map double

Throws JMSException: JMS
Throws IllegalArgumentException: null
Throws MessageNotWriteableException:
**setDouble**

```java
void setDouble(String name, 
    double value) 
    throws JMSException
```

Sets a double value with the specified name into the Map.

**Parameters:**
- name - the name of the double
- value - the double value to set in the Map

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageNotWriteableException` - if the message is in read-only mode.

---

**public void setString(String name, String value) throws JMSException**

```
    String Map
    name String
    value Map String
```

**Throws**
- `JMSException`: JMS
- `IllegalArgumentException`: null
- `MessageNotWriteableException`

**setString**

```java
void setString(String name, 
    String value) 
    throws JMSException
```

Sets a string value with the specified name into the Map.
Parameters:
- **name** - the name of the String
- **value** - the String value to set in the Map

Throws:
- **JMSException** - if the JMS provider fails to write the message due to some internal error.
- **IllegalArgumentException** - if the name is null or if the name is an empty string.
- **MessageNotWriteableException** - if the message is in read-only mode.

```java
public void setBytes(String name, byte[] value) throws JMSException
```

**Description:**
Sets a byte array value with the specified name into the Map.

**Parameters:**
- **name** - the name of the byte array
- **value** - the byte array value to set in the Map; the array is copied so that the value for **name** will not be altered by future modifications

**Throws:**
- **JMSException** - if the JMS provider fails to write the message due to some internal error.
**NullPointerException** - if the name is null, or if the name is an empty string.

**MessageNotWriteableException** - if the message is in read-only mode.

```java
public void setBytes(String name, byte[] value, int offset, int length) throws JMSException
```

Sets a portion of the byte array value with the specified name into the Map.

**Parameters:**
- `name` - the name of the byte array
- `value` - the byte array value to set in the Map
- `offset` - the initial offset within the byte array
- `length` - the number of bytes to use

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is
public void setObject(String name, Object value) throws JMSException

Map

<table>
<thead>
<tr>
<th>Integer</th>
<th>Double</th>
<th>Long</th>
<th>String</th>
<th>byte</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td></td>
<td></td>
<td>Java</td>
<td></td>
</tr>
<tr>
<td>value</td>
<td></td>
<td></td>
<td>Map</td>
<td>Java</td>
</tr>
</tbody>
</table>

Throws: 

- JMSException: JMS
- IllegalArgumentException: null
- MessageFormatException:
- MessageNotWriteableException:

setObject

void setObject(String name, Object value) throws JMSException

Sets an object value with the specified name into the Map.

This method works only for the objectified primitive object types (Integer, Double, Long ...), String objects, and byte arrays.

**Parameters:**

- name - the name of the Java object
- value - the Java object value to set in the Map

**Throws:**

- JMSException - if the JMS provider fails to write the message due to some internal error.
- IllegalArgumentException - if the name is null or if the name is an empty string.
MessageFormatException - if the object is invalid.
MessageNotWriteableException - if the message is in read-only mode.

```java
public boolean itemExists(String name) throws JMSException
```

Returns true if the item exists

**Parameters:**
- `name` - the name of the item to test

**Returns:**
- true if the item exists

**Throws:**
- `JMSException` - if the JMS provider fails to determine if the item exists due to some internal error.
PS:
javax.resource.cci Interface MappedRecord

All Superinterfaces:
   Cloneable, Map, Record, Serializable

public interface MappedRecord
extends Record, Map, Serializable

Implements: Record, java.util.Map<K, V>, java.io.Serializable

javax.resource.cci.MappedRecord MappedRecord
java.util.Map

version 0.8

The interface javax.resource.cci.MappedRecord is used for key-value map based representation of record elements. The MappedRecord interface extends both Record and java.util.Map interfaces.

Version:
   0.8
Author:
   Rahul Sharma

javax.persistence Annotation Type MappedSuperclass

@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface MappedSuperclass

Implements: Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)

MappedSuperclass

AttributeOverride
AssociationOverride XML

@MappedSuperclass
public class Employee {

    @Id protected Integer empId;
    @Version protected Integer version;
    @ManyToOne @JoinColumn(name="ADDR")
    protected Address address;

    public Integer getEmpId() { ... }
    public void setEmpId(Integer id) { ... }
    public Address getAddress() { ... }
    public void setAddress(Address addr) { ... }
}

// Default table is FTEMPLOYEE table
@Entity
public class FTEmployee extends Employee {

    // Inherited empId field mapped to FTEMPLOYEE.EMPID
    // Inherited version field mapped to FTEMPLOYEE.VERSION
    // Inherited address field mapped to FTEMPLOYEE.ADDR fk

    // Defaults to FTEMPLOYEE.SALARY

    protected Integer salary;
public FTEmployee() {}

public Integer getSalary() { ... }
public void setSalary(Integer salary) { ... }

@Entity @Table(name="PT_EMP")
@AssociationOverride(name="address",
joinColumns=@JoinColumn(name="ADDR_ID"))
public class PartTimeEmployee extends Employee {

    // Inherited empId field mapped to PT_EMP.EMPID
    // Inherited version field mapped to PT_EMP.VERSION
    // address field mapping overridden to PT_EMP.ADDR_ID fk
    @Column(name="WAGE")
    protected Float hourlyWage;

    public PartTimeEmployee() {}

    public Float getHourlyWage() { ... }
    public void setHourlyWage(Float wage) { ... }
}

Example: Non-entity superclass

public class Cart {

    // This state is transient
    Integer operationCount;

    public Cart() { operationCount = 0; }
    public Integer getOperationCount() { return operationCount;
    public void incrementOperationCount() { operationCount++;
}

@Entity
public class ShoppingCart extends Cart {

    Collection items = new Vector();

    public ShoppingCart() { super(); }

    ...

Designates a class whose mapping information is applied to the entities that inherit from it. A mapped superclass has no separate table defined for it.

A class designated with the `@MappedSuperclass` annotation can be mapped in the same way as an entity except that the mappings will apply only to its subclasses since no table exists for the mapped superclass itself. When applied to the subclasses the inherited mappings will apply in the context of the subclass tables. Mapping information may be overridden in such subclasses by using the `@AttributeOverride` and `@AssociationOverride` annotations or corresponding XML elements.

Example: Concrete class as a mapped superclass

```java
@MappedSuperclass
public class Employee {

    @Id protected Integer empId;
    @Version protected Integer version;
    @ManyToOne @JoinColumn(name="ADDR")
    protected Address address;

    public Integer getEmpId() { ... }
    public void setEmpId(Integer id) { ... }
    public Address getAddress() { ... }
    public void setAddress(Address addr) { ... }
}
```

// Default table is FTEMPLOYEE table
```java
@Entity
public class FTEmployee extends Employee {

    // Inherited empId field mapped to FTEMPLOYEE.EMPID
```
// Inherited version field mapped to FTEMPLOYEE.VERSION
// Inherited address field mapped to FTEMPLOYEE.ADDR fk

// Defaults to FTEMPLOYEE.SALARY
protected Integer salary;

public FTEmployee() {}
Collection items = new Vector();

public ShoppingCart() { super(); }

...

@OneToMany
public Collection getItems() { return items; }
public void addItem(Item item) {
  items.add(item);
  incrementOperationCount();
}

PS:
javax.xml.bind  **Class MarshalException**

```java
class MarshalException extends JAXBException
```

**Extends:** Throwable > Exception > JAXBException

All Implemented Interfaces:
- Serializable

This exception indicates that an error has occurred while performing a marshal operation that the provider is unable to recover from.

The `ValidationEventHandler` can cause this exception to be thrown during the marshal operations. See `ValidationEventHandler.handleEvent(ValidationEvent)`.

Since: JAXB1.0

public MarshalException(String message)  
MarshalException errorCode  linkedException  null  

message

MarshalAsException

public MarshalException(String message)

Construct a MarshalException with the specified detail message. The errorCode and linkedException will default to null.

Parameters:
message - a description of the exception

public MarshalException(String message, String errorCode)

errorCode MarshalException linkedException null  

message  
errorCode

MarshalAsException

public MarshalException(String message, String errorCode)

Construct a MarshalException with the specified detail message and
vendor specific errorCode. The linkedException will default to null.

Parameters:
message - a description of the exception
errorCode - a string specifying the vendor specific error code

public MarshalException(Throwables exception)
linkedException MarshalException errorCode
null

exception

MarshalException

public MarshalException(Throwables exception)

Construct a MarshalException with a linkedException. The detail message and vendor specific errorCode will default to null.

Parameters:
exception - the linked exception

public MarshalException(String message, Throwables exception)
linkedException MarshalException errorCode
null

message

exception

MarshalException

public MarshalException(String message, Throwables exception)

Construct a MarshalException with the specified detail message and
linkedException. The errorCode will default to null.

Parameters:
message - a description of the exception
exception - the linked exception

public MarshalException(String message, String errorCode, Throwable exception)

errorCode linkedException MarshalException
  message
code
exception

MarshalException

public MarshalException(String message, String errorCode, Throwable exception)

Construct a MarshalException with the specified detail message, vendor specific errorCode, and linkedException.

Parameters:
message - a description of the exception
errorCode - a string specifying the vendor specific error code
exception - the linked exception

void afterMarshal(Marshaller, Object parent);

/

Listener setListener(Listener)

"""

The **Marshaller** class is responsible for governing the process of serializing Java content trees back into XML data. It provides the basic marshalling methods:

**Assume the following setup code for all following code fragments:**

```java
JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
Unmarshaller u = jc.createUnmarshaller();
Object element = u.unmarshal( new File( "foo.xml" ) );
Marshaller m = jc.createMarshaller();
```

**Marshalling to a File:**

```java
OutputStream os = new FileOutputStream( "nosferatu.xml" );
m.marshal( element, os );
```

**Marshalling to a SAX ContentHandler:**

```java
// assume MyContentHandler instanceof ContentHandler
m.marshal( element, new MyContentHandler() );
```

**Marshalling to a DOM Node:**

```java
DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
dbf.setNamespaceAware(true);
DocumentBuilder db = dbf.newDocumentBuilder();
Document doc = db.newDocument();

m.marshal( element, doc );
```

**Marshalling to a java.io.OutputStream:**

```java
m.marshal( element, System.out );
```

**Marshalling to a java.io.Writer:**

```java
```

---

*Note: The above code snippets are simplified examples for illustration purposes and may require additional setup or configuration in a real-world application.*
m.marshal( element, new PrintWriter( System.out ) );

Marshalling to a javax.xml.transform.SAXResult:

// assume MyContentHandler instanceof ContentHandler
SAXResult result = new SAXResult( new MyContentHandler() );
m.marshal( element, result );

Marshalling to a javax.xml.transform.DOMResult:

DOMResult result = new DOMResult();
m.marshal( element, result );

Marshalling to a javax.xml.transform.StreamResult:

StreamResult result = new StreamResult( System.out );
m.marshal( element, result );

Marshalling to a javax.xml.stream.XMLStreamWriter:

XMLStreamWriter xmlStreamWriter =
    XMLOutputFactory.newInstance().createXMLStreamWriter( .
m.marshal( element, xmlStreamWriter );

Marshalling to a javax.xml.stream.XMLEventWriter:

XMLEventWriter xmlEventWriter =
    XMLOutputFactory.newInstance().createXMLEventWriter( ..
m.marshal( element, xmlEventWriter );

Marshalling content tree rooted by a JAXB element

The first parameter of the overloaded
Marshaller.marshal(java.lang.Object, ...) methods must be a
JAXB element as computed by
JAXBIntrospector.isElement(java.lang.Object); otherwise, a Marshaller.marshal method must throw a MarshalException. There exist two mechanisms to enable marshalling an instance that is not a JAXB element. One method is to wrap the instance as a value of a JAXBElememt, and pass the wrapper element as the first parameter to a Marshaller.marshal method. For java to schema binding, it is also possible to simply annotate the instance's class with @XmlRootElement.

Encoding

By default, the Marshaller will use UTF-8 encoding when generating XML data to a java.io.OutputStream, or a java.io.Writer. Use the setProperty API to change the output encoding used during these marshal operations. Client applications are expected to supply a valid character encoding name as defined in the W3C XML 1.0 Recommendation and supported by your Java Platform.

Validation and Well-Formedness

Client applications are not required to validate the Java content tree prior to calling any of the marshal API's. Furthermore, there is no requirement that the Java content tree be valid with respect to its original schema in order to marshal it back into XML data. Different JAXB Providers will support marshalling invalid Java content trees at varying levels, however all JAXB Providers must be able to marshal a valid content tree back to XML data. A JAXB Provider must throw a MarshalException when it is unable to complete the marshal operation due to invalid content. Some JAXB Providers will fully allow marshalling invalid content, others will fail on the first validation error.

Even when schema validation is not explicitly enabled for the marshal operation, it is possible that certain types of validation events will be detected during the operation. Validation events will be reported to the registered event handler. If the client application has not registered an event handler prior to invoking one of the marshal API's, then events will be delivered to a default event handler which will terminate the marshal operation after encountering the first error.
or fatal error. Note that for JAXB 2.0 and later versions, DefaultValidationEventHandler is no longer used.

Supported Properties

All JAXB Providers are required to support the following set of properties. Some providers may support additional properties.

jaxb.encoding - value must be a java.lang.String
  The output encoding to use when marshalling the XML data. The Marshaller will use "UTF-8" by default if this property is not specified.

jaxb.formatted.output - value must be a java.lang.Boolean
  This property controls whether or not the Marshaller will format the resulting XML data with line breaks and indentation. A true value for this property indicates human readable indented xml data, while a false value indicates unformatted xml data. The Marshaller will default to false (unformatted) if this property is not specified.

jaxb.schemaLocation - value must be a java.lang.String
  This property allows the client application to specify an xsi:schemaLocation attribute in the generated XML data. The format of the schemaLocation attribute value is discussed in an easy to understand, non-normative form in Section 5.6 of the W3C XML Schema Part 0: Primer and specified in Section 2.6 of the W3C XML Schema Part 1: Structures.

jaxb.noNamespaceSchemaLocation - value must be a java.lang.String
  This property allows the client application to specify an xsi:noNamespaceSchemaLocation attribute in the generated XML data. The format of the schemaLocation attribute value is discussed in an easy to understand, non-normative form in Section 5.6 of the W3C XML Schema Part 0: Primer and specified in Section 2.6 of the W3C XML Schema Part 1: Structures.

jaxb.fragment - value must be a java.lang.Boolean
  This property determines whether or not document level events will be generated by the Marshaller. If the property is not specified, the default is false. This property has different implications depending on which marshal api you are using -
when this property is set to true:

- **marshal(Object,ContentHandler)** - the Marshaller won't invoke `ContentHandler.startDocument()` and `ContentHandler.endDocument()`.
- **marshal(Object,Node)** - the property has no effect on this API.
- **marshal(Object,OutputStream)** - the Marshaller won't generate an xml declaration.
- **marshal(Object,Writer)** - the Marshaller won't generate an xml declaration.
- **marshal(Object,Result)** - depends on the kind of Result object, see semantics for Node, ContentHandler, and Stream APIs
- **marshal(Object,XMLStreamWriter)** - the Marshaller will not generate `XMLStreamConstants.START_DOCUMENT` and `XMLStreamConstants.END_DOCUMENT` events.
- **marshal(Object,XMLStreamWriter)** - the Marshaller will not generate `XMLStreamConstants.START_DOCUMENT` and `XMLStreamConstants.END_DOCUMENT` events.

**Marshal Event Callbacks**

"The Marshaller provides two styles of callback mechanisms that allow application specific processing during key points in the unmarshalling process. In 'class defined' event callbacks, application specific code placed in JAXB mapped classes is triggered during marshalling. 'External listeners' allow for centralized processing of marshal events in one callback method rather than by type event callbacks.

Class defined event callback methods allow any JAXB mapped class to specify its own specific callback methods by defining methods with the following method signatures:

```java
// Invoked by Marshaller after it has created an instance of boolean beforeMarshal(Marshaller, Object parent);

// Invoked by Marshaller after it has marshalled all properties void afterMmarshal(Marshaller, Object parent);
```
The class defined event callback methods should be used when the callback method requires access to non-public methods and/or fields of the class.

The external listener callback mechanism enables the registration of a `Marshaller.Listener` instance with a `setListener(Listener)` method. The external listener receives all callback events, allowing for more centralized processing than per class defined callback methods.

The 'class defined' and external listener event callback methods are independent of each other, both can be called for one event. The invocation ordering when both listener callback methods exist is defined in `Marshaller.Listener.beforeMarshal(Object)` and `Marshaller.Listener.afterMarshal(Object)`.

An event callback method throwing an exception terminates the current marshal process.

Method Summary

getAdapter(Class<A> type)

- Gets the adapter associated with the specified type.

AttachmentMarshaller getAttachmentMarshaller()

- Return the current event handler or the default event handler if one hasn't been set.

ValidationEventHandler getEventHandler()

- Return Marshaller.Listener registered with this Marshaller.

getNode(Object contentTree)

- Get a DOM tree view of the content tree(Optional).

getProperty(String name)

- Get the particular property in the underlying implementation of Marshaller.
Get the JAXP 1.3 Schema object being used to perform marshal-time validation.

```java
void marshal(Object jaxbElement, ContentHandler handler)
```

Marshal the content tree rooted at jaxbElement into SAX2 events.

```java
void marshal(Object jaxbElement, Node node)
```

Marshal the content tree rooted at jaxbElement into a DOM tree.

```java
void marshal(Object jaxbElement, OutputStream os)
```

Marshal the content tree rooted at jaxbElement into an output stream.

```java
void marshal(Object jaxbElement, Result result)
```

Marshal the content tree rooted at jaxbElement into the specified javax.xml.transform.Result.

```java
void marshal(Object jaxbElement, Writer writer)
```

Marshal the content tree rooted at jaxbElement into a Writer.

```java
void marshal(Object jaxbElement, XMLEventWriter writer)
```

Marshal the content tree rooted at jaxbElement into an XMLEventWriter.

```java
void marshal(Object jaxbElement, XMLStreamWriter writer)
```

Marshal the content tree rooted at jaxbElement into a XMLStreamWriter.

```java
<A extends XmlAdapter>
void setAdapter(Class<A> type, A adapter)
```

Associates a configured instance of XmlAdapter with this marshaller.

```java
void setAdapter(XmlAdapter adapter)
```

Associates a configured instance of XmlAdapter with this marshaller.

```java
void setAttachmentMarshaller(AttachmentMarshaller am)
```

Associate a context that enables binary data within an XML document to be transmitted as XML-binary optimized attachment.

```java
void setEventHandler(ValidationEventHandler handler)
```

Allow an application to register a validation event handler.

```java
void setListener(Marshaller.Listener listener)
```

Register marshal event callback Marshaller.Listener with this Marshaller.

```java
void setProperty(String name, Object value)
```

Set the particular property in the underlying implementation of Marshaller.

```java
void setSchema(Schema schema)
```

Specify the JAXP 1.3 Schema object that should be used to validate subsequent marshal operations against.
Field Detail

JAXB_ENCODING

static final String JAXB_ENCODING

The name of the property used to specify the output encoding in the marshalled XML data.

See Also:
Constant Field Values

JAXB_FORMATTED_OUTPUT

static final String JAXB_FORMATTED_OUTPUT

The name of the property used to specify whether or not the marshalled XML data is formatted with linefeeds and indentation.

See Also:
Constant Field Values

JAXB_SCHEMA_LOCATION

static final String JAXB_SCHEMA_LOCATION

The name of the property used to specify the xsi:schemaLocation attribute value to place in the marshalled XML output.

See Also:
Constant Field Values
JAXB_NO_NAMESPACE_SCHEMA_LOCATION

static final String JAXB_NO_NAMESPACE_SCHEMA_LOCATION

The name of the property used to specify the xsi:noNamespaceSchemaLocation attribute value to place in the marshalled XML output.

See Also:
Constant Field Values

JAXB_FRAGMENT

static final String JAXB_FRAGMENT

The name of the property used to specify whether or not the marshaller will generate document level events (ie calling startDocument or endDocument).

Constant Field Values

Method Detail

public void marshal(Object jaxbElement, javax.xml.transform.Result result) throws JAXBException

jaxbElement javax.xml.transform.Result

JAXB
javax.xml.transform.dom.DOMResultjavax.xml.transform.sax.SAXResult
javax.xml.transform.stream.StreamResult Result
marshal

```java
public void marshal(Object jaxbElement, java.io.OutputStream os) throws JAXBException
```

**Parameters:**
- `jaxbElement` - The root of content tree to be marshalled.
- `result` - XML will be sent to this Result

**Throws:**
- `JAXBException` - If any unexpected problem occurs during the marshalling.
- `MarshalException` - If the `ValidationEventHandler` returns false from its `handleEvent` method or the `Marshaller` is unable to marshal `obj` (or any object reachable from `obj`). See [Marshalling a JAXB element](https://docs.oracle.com/javase/8/docs/api/javax/xml/bind/Marshaller.html#marshal-javax.xml.bind.Element;javax.xml.transform.Result;). See [Marshalling a JAXB element](https://docs.oracle.com/javase/8/docs/api/javax/xml/bind/Marshaller.html#marshal-javax.xml.bind.Element;javax.xml.transform.Result;).
- `IllegalArgumentException` - If any of the method parameters are null

This method marshall the content tree rooted at `jaxbElement` into the specified `javax.xml.transform.Result`. All JAXB Providers must at least support `DOMResult`, `SAXResult`, and `StreamResult`. It can support other derived classes of `Result` as well.
void marshal(Object jaxbElement, OutputStream os)
    throws JAXBException

Marshal the content tree rooted at jaxbElement into an output stream.

Parameters:
  jaxbElement - The root of content tree to be marshalled.
  os - XML will be added to this stream.

Throws:
  JAXBException - If any unexpected problem occurs during the marshalling.
  MarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Marshaller is unable to marshal obj (or any object reachable from obj). See Marshalling a JAXB element.
  IllegalArgument Exception - If any of the method parameters are null
public void marshal(Object jaxbElement, org.xml.sax.ContentHandler handler) throws JAXBException

jaxbElement  SAX2

handler  XML  SAX2

Throws  JAXBException:

MarshalException:  ValidationEventHandler

Throws  handleEvent  false  Marshaller  obj  obj  .  JAXB

Throws  IllegalArgumentException:  null
marshal

void marshal(Object jaxbElement, ContentHandler handler) throws JAXBException

Marshal the content tree rooted at jaxbElement into SAX2 events.

Parameters:
  jaxbElement - The root of content tree to be marshalled.
  handler - XML will be sent to this handler as SAX2 events.

Throws:
  JAXBException - If any unexpected problem occurs during the marshalling.
  MarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Marshaller is unable to marshal obj (or any object reachable from obj). See Marshalling a JAXB element.
  IllegalArgumentException - If any of the method parameters are null

domain

public void marshal(Object jaxbElement, org.w3c.dom.Node node) throws JAXBException
  jaxbElement DOM
  node org.w3c.dom.Documentorg.w3c.dom.DocumentFragment
  org.w3c.dom.Element Node

Throws
  JAXBException:
  MarshalException: ValidationEventHandler

Throws
  handleEvent false Marshaller jaxbElement

Throws
  IllegalArgumentException: null
marshal

```java
void marshal(Object jaxbElement,
             Node node)
  throws JAXBException
```

Marshal the content tree rooted at jaxbElement into a DOM tree.

**Parameters:**
- `jaxbElement` - The content tree to be marshalled.
- `node` - DOM nodes will be added as children of this node. This parameter must be a Node that accepts children (Document, DocumentFragment, or Element)

**Throws:**
- `JAXBException` - If any unexpected problem occurs during the marshalling.
- `MarshalException` - If the ValidationEventHandler returns false from its handleEvent method or the Marshaller is unable to marshal jaxbElement (or any object reachable from jaxbElement). See Marshalling a JAXB element.
- `IllegalArgumentException` - If any of the method parameters are null

```java
public void marshal(Object jaxbElement, XMLStreamWriter writer) throws JAXBException
```

```java
jaxbElement javax.xml.stream.XMLStreamWriter
jaxbElement
writer XML
```

**Throws**
- `JAXBException`
- `MarshalException`: ValidationEventHandler
- `IllegalArgumentException`: null

since JAXB 2.0
void marshal(Object jaxbElement,
             XMLStreamWriter writer)
throws JAXBException

Marshal the content tree rooted at jaxbElement into a
XMLStreamWriter.

Parameters:
  jaxbElement - The content tree to be marshalled.
  writer - XML will be sent to this writer.

Throws:
  JAXBException - If any unexpected problem occurs during the
  marshalling.
  MarshalException - If the ValidationEventHandler returns false
  from its handleEvent method or the Marshaller is unable to
  marshal obj (or any object reachable from obj). See Marshalling
  a JAXB element.
  IllegalArgumentException - If any of the method parameters are
  null

Since:
  JAXB 2.0

public void marshal(Object jaxbElement, XMLEventWriter
writer) throws JAXBException

jaxbElement   : javax.xml.stream.XMLEventWriter
jaxbElement   : jaxbElement
writer        : XML

Throws
  JAXBException:
  MarshalException: ValidationEventHandler

Throws
  handleEvent false Marshaller obj obj .
  JAXB

Throws
  IllegalArgumentException: null

since
  JAXB 2.0

marshal
void marshal(Object jaxbElement, XMLEventWriter writer) throws JAXBException

Marshal the content tree rooted at jaxbElement into a XMLEventWriter.

Parameters:
jaxbElement - The content tree rooted at jaxbElement to be marshalled.
writer - XML will be sent to this writer.

Throws:
JAXBException - If any unexpected problem occurs during the marshalling.
MarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Marshaller is unable to marshal obj (or any object reachable from obj). See Marshalling a JAXB element.
IllegalArgumentException - If any of the method parameters are null

Since:
JAXB 2.0

public org.w3c.dom.Node getNode(Object contentTree) throws JAXBException

DOM DOM
org.w3c.dom.Node DOM
contentTree XML JAXB Java
return contentTree DOM

Throws UnsupportedOperationException: JAXB DOM
Throws IllegalArgumentException: null
Throws JAXBException:

getNode

Node getNode(Object contentTree)
Get a DOM tree view of the content tree(Optional). If the returned DOM tree is updated, these changes are also visible in the content tree. Use `marshal(Object, org.w3c.dom.Node)` to force a deep copy of the content tree to a DOM representation.

**Parameters:**
- `contentTree` - JAXB Java representation of XML content

**Returns:**
- the DOM tree view of the content tree

**Throws:**
- `UnsupportedOperationException` - If the JAXB provider implementation does not support a DOM view of the content tree
- `IllegalArgumentException` - If any of the method parameters are null
- `JAXBException` - If any unexpected problem occurs

---

```java
def setProperty(String name, Object value) throws PropertyException
```

**Thrown by:**
- `JAXB PropertyException`

**Throws:**
- `PropertyException`: 
- `IllegalArgumentException`: name null

---

Set the particular property in the underlying implementation of the `Marshaller`. This method can only be used to set one of the standard JAXB defined properties above or a provider specific property. Attempting to set an undefined property will result in an
PropertyException being thrown. See Supported Properties.

Parameters:
- `name` - the name of the property to be set. This value can either be specified using one of the constant fields or a user supplied string.
- `value` - the value of the property to be set

Throws:
- `PropertyException` - when there is an error processing the given property or value
- `IllegalArgumentException` - If the name parameter is null

```java
public Object getProperty(String name) throws PropertyException
```

Get the particular property in the underlying implementation of Marshaller. This method can only be used to get one of the standard JAXB defined properties above or a provider specific property. Attempting to get an undefined property will result in a PropertyException being thrown. See Supported Properties.

Parameters:
- `name` - the name of the property to retrieve

Returns:
- the value of the requested property

Throws:
public void setEventHandler(ValidationEventHandler handler) throws JAXBException

API JAXB marshal

null Marshaller

handler

Throws JAXBException:

setEventHandler

void setEventHandler(ValidationEventHandler handler) throws JAXBException

Allow an application to register a validation event handler.

The validation event handler will be called by the JAXB Provider if any validation errors are encountered during calls to any of the marshal API's. If the client application does not register a validation event handler before invoking one of the marshal methods, then validation events will be handled by the default event handler which will terminate the marshal operation after the first error or fatal error is encountered.

Calling this method with a null parameter will cause the Marshaller to revert back to the default default event handler.

Parameters:

handler - the validation event handler

Throws:
public ValidationEventHandler getEventHandler() throws JAXBException

return ValidationEventHandler

Throws JAXBException: 

getEventHandler

ValidationEventHandler getEventHandler() throws JAXBException

Return the current event handler or the default event handler if one hasn't been set.

Returns: 
the current ValidationEventHandler or the default event handler if it hasn't been set

Throws: 
JAXBException - if an error was encountered while getting the current event handler

public void setAdapter("XmlAdapter adapter)

Xm1Adapter marshaller

setAdapter(adapter.getClass(),adapter)

Throws IllegalArgumentException: adapter null

Throws UnsupportedOperationException: JAXB 1.0 since JAXB 2.0

See also setAdapter(Class,XmlAdapter)
setAdapter
void setAdapter(XmlAdapter adapter)

Associates a configured instance of XmlAdapter with this marshaller.

This is a convenience method that invokes
setAdapter(adapter.getClass(), adapter);

Throws:
IllegalArgumentException - if the adapter parameter is null.
UnsupportedOperationException - if invoked against a JAXB 1.0 implementation.

Since:
JAXB 2.0

See Also:
setAdapter(Class, XmlAdapter)

setAdapter
<A extends XmlAdapter> void setAdapter(Class<A> type,
A adapter)

Associates a configured instance of XmlAdapter with this marshaller.

Every marshaller internally maintains a Map<Class, XmlAdapter>,
which it uses for marshalling classes whose fields/methods are
annotated with XmlJavaTypeAdapter.

This method allows applications to use a configured instance of
XmlAdapter. When an instance of an adapter is not given, a
marshaller will create one by invoking its default constructor.

Parameters:
type - The type of the adapter. The specified instance will be used when XmlJavaTypeAdapter.value() refers to this type.
adapter - The instance of the adapter to be used. If null, it will
un-register the current adapter set for this type.

**Throws:**
- `IllegalArgumentException` - if the type parameter is null.
- `UnsupportedOperationException` - if invoked agains a JAXB 1.0 implementation.

**Since:**
JAXB 2.0

---

**getAdapter**

```java
<A extends XmlAdapter> A getAdapter(Class<A> type)
```

Gets the adapter associated with the specified type. This is the reverse operation of the method.

**Throws:**
- `IllegalArgumentException` - if the type parameter is null.
- `UnsupportedOperationException` - if invoked agains a JAXB 1.0 implementation.

**Since:**
JAXB 2.0

---

**public void setAttachmentMarshaller(AttachmentMarshaller am)**

**XML XML xml id URI (cid) XML**

**Throws**
IllegalStateException:

---

**setAttachmentMarshaller**

```java
void setAttachmentMarshaller(AttachmentMarshaller am)
```
Associate a context that enables binary data within an XML document to be transmitted as XML-binary optimized attachment. The attachment is referenced from the XML document content model by content-id URIs(cid) references stored within the xml document.

**Throws:**

*IllegalStateException* - if attempt to concurrently call this method during a marshal operation.

```java
public AttachmentMarshaller getAttachmentMarshaller()
```

**getAttachmentMarshaller**

```java
AttachmentMarshaller getAttachmentMarshaller()
```

```java
public void setSchema(javax.xml.validation.Schema schema)
```

**setSchema**

```java
void setSchema(Schema schema)
```

Specify the JAXP 1.3 Schema object that should be used to validate
subsequent marshal operations against. Passing null into this method will disable validation.

This method allows the caller to validate the marshalled XML as it's marshalled.

Initially this property is set to null.

Parameters:

- `schema` - Schema object to validate marshal operations against or null to disable validation

Throws:

- `UnsupportedOperationException` - could be thrown if this method is invoked on an Marshaller created from a JAXBContext referencing JAXB 1.0 mapped classes

Since:

JAXB2.0

---

```java
public javax.xml.validation.Schema getSchema()
```

JAXP 1.3

```java
getSchema()
```

Get the JAXP 1.3 `Schema` object being used to perform marshal-time validation. If there is no Schema set on the marshaller, then this method will return null indicating that marshal-time validation will not be performed.

Returns:
the Schema object being used to perform marshal-time validation or null if not present.

Throws:

UnsupportedOperationException - could be thrown if this method is invoked on an Marshaller created from a JAXBContext referencing JAXB 1.0 mapped classes

Since:
JAXB2.0

public void setListener(Marshaller.Listener listener)

Marshaller Listener Listener Listener Listener
listener null Listener

setListener

void setListener(Marshaller.Listener listener)

Register marshal event callback Marshaller.Listener with this Marshaller.

There is only one Listener per Marshaller. Setting a Listener replaces the previous set Listener. One can unregister current Listener by setting listener to null.

Parameters:

listener - an instance of a class that implements Marshaller.Listener

Since:
JAXB2.0
public Marshaller.Listener getListener()

getterListener

Marshaller.Listener getListener()

Return Marshaller.Listener registered with this Marshaller.

Returns:
 registered Marshaller.Listener or null if no Listener is registered with this Marshaller.

Since:
JAXB2.0

**Marshal Event Callback**

**since**  JAXB2.0

**See also**  ```setListener(Listener), getListener()```  

Register an instance of an implementation of this class with a **Marshall** to externally listen for marshal events.

This class enables pre and post processing of each marshalled object. The event callbacks are called when marshalling from an instance that maps to an xml element or complex type definition. The event callbacks are not called when marshalling from an instance of a Java datatype that represents a simple type definition.

External listener is one of two different mechanisms for defining marshal event callbacks. See **Marshal Event Callbacks** for an overview.

**Since:**
JAXB2.0

## Constructor Detail

public Marshaller.Listener()
Method Detail

public void beforeMarshal(Object source)

beforeMarshal

public void before Marshal( Object source )

Callback method invoked before marshalling from source to XML.

This method is invoked just before marshalling process starts to marshal source. Note that if the class of source defines its own beforeMarshal method, the class specific callback method is invoked just before this method is invoked.

Parameters:

source - instance of JAXB mapped class prior to marshalling from it.

public void afterMarshal(Object source)

afterMarshal

public void after Marshal( Object source )

source XML

source source afterMarshal

source source JAXB
public void afterMarshal(Object source)

Callback method invoked after marshalling source to XML.

This method is invoked after source and all its descendants have been marshalled. Note that if the class of source defines its own afterMarshal method, the class specific callback method is invoked just before this method is invoked.

Parameters:

source - instance of JAXB mapped class after marshalling it.

The Message interface is the root interface of all JMS messages. It defines the message header and the acknowledge method used for all messages.

Most message-oriented middleware (MOM) products treat messages as lightweight entities that consist of a header and a payload. The header contains fields used for message routing and identification; the payload contains the application data being sent.
Within this general form, the definition of a message varies significantly across products. It would be quite difficult for the JMS API to support all of these message models.

With this in mind, the JMS message model has the following goals:

- Provide a single, unified message API
- Provide an API suitable for creating messages that match the format used by provider-native messaging applications
- Support the development of heterogeneous applications that span operating systems, machine architectures, and computer languages
- Support messages containing objects in the Java programming language ("Java objects")
- Support messages containing Extensible Markup Language (XML) pages

JMS messages are composed of the following parts:

- Header - All messages support the same set of header fields. Header fields contain values used by both clients and providers to identify and route messages.
- Properties - Each message contains a built-in facility for supporting application-defined property values. Properties provide an efficient mechanism for supporting application-defined message filtering.
- Body - The JMS API defines several types of message body, which cover the majority of messaging styles currently in use.

**Message Bodies**

The JMS API defines five types of message body:

- **Stream** - A StreamMessage object's message body contains a stream of primitive values in the Java programming language ("Java primitives"). It is filled and read sequentially.
- **Map** - A MapMessage object's message body contains a set of name-value pairs, where names are String objects, and values are Java primitives. The entries can be accessed sequentially or
randomly by name. The order of the entries is undefined.

- **Text** - A `TextMessage` object's message body contains a `java.lang.String` object. This message type can be used to transport plain-text messages, and XML messages.
- **Object** - An `ObjectMessage` object's message body contains a `Serializable` Java object.
- **Bytes** - A `BytesMessage` object's message body contains a stream of uninterpreted bytes. This message type is for literally encoding a body to match an existing message format. In many cases, it is possible to use one of the other body types, which are easier to use. Although the JMS API allows the use of message properties with byte messages, they are typically not used, since the inclusion of properties may affect the format.

### Message Headers

The `JMSCorrelationID` header field is used for linking one message with another. It typically links a reply message with its requesting message.

`JMSCorrelationID` can hold a provider-specific message ID, an application-specific `String` object, or a provider-native `byte[]` value.

### Message Properties

A `Message` object contains a built-in facility for supporting application-defined property values. In effect, this provides a mechanism for adding application-specific header fields to a message.

Properties allow an application, via message selectors, to have a JMS provider select, or filter, messages on its behalf using application-specific criteria.

Property names must obey the rules for a message selector identifier. Property names must not be null, and must not be empty strings. If a property name is set and it is either null or an empty string, an `IllegalArgumentException` must be thrown.

Property values can be `boolean`, `byte`, `short`, `int`, `long`, `float`, `double`,
and String.

Property values are set prior to sending a message. When a client receives a message, its properties are in read-only mode. If a client attempts to set properties at this point, a MessageNotAllowedWriteableException is thrown. If clearProperties is called, the properties can now be both read from and written to. Note that header fields are distinct from properties. Header fields are never in read-only mode.

A property value may duplicate a value in a message's body, or it may not. Although JMS does not define a policy for what should or should not be made a property, application developers should note that JMS providers will likely handle data in a message's body more efficiently than data in a message's properties. For best performance, applications should use message properties only when they need to customize a message's header. The primary reason for doing this is to support customized message selection.

Message properties support the following conversion table. The marked cases must be supported. The unmarked cases must throw a JMSException. The String-to-primitive conversions may throw a runtime exception if the primitive's valueOf method does not accept the String as a valid representation of the primitive.

A value written as the row type can be read as the column type.

</tr>
</tbody>
</table>

In addition to the type-specific set/get methods for properties, JMS provides the setObjectProperty and getObjectProperty methods.
These support the same set of property types using the objectified primitive values. Their purpose is to allow the decision of property type to be made at execution time rather than at compile time. They support the same property value conversions.

The `setObjectProperty` method accepts values of class `Boolean`, `Byte`, `Short`, `Integer`, `Long`, `Float`, `Double`, and `String`. An attempt to use any other class must throw a `JMSException`.

The `getObjectProperty` method only returns values of class `Boolean`, `Byte`, `Short`, `Integer`, `Long`, `Float`, `Double`, and `String`.

The order of property values is not defined. To iterate through a message's property values, use `getPropertyNames` to retrieve a property name enumeration and then use the various property get methods to retrieve their values.

A message's properties are deleted by the `clearProperties` method. This leaves the message with an empty set of properties.

Getting a property value for a name which has not been set returns a null value. Only the `getStringProperty` and `getObjectProperty` methods can return a null value. Attempting to read a null value as a primitive type must be treated as calling the primitive's corresponding `valueOf(String)` conversion method with a null value.

The JMS API reserves the `JMSX` property name prefix for JMS defined properties. The full set of these properties is defined in the Java Message Service specification. New JMS defined properties may be added in later versions of the JMS API. Support for these properties is optional. The `String[] ConnectionMetaData.getJMSXPropertyNames` method returns the names of the JMSX properties supported by a connection.

JMSX properties may be referenced in message selectors whether or not they are supported by a connection. If they are not present in a message, they are treated like any other absent property.

JMSX properties defined in the specification as "set by provider on send" are available to both the producer and the consumers of the
message. JMSX properties defined in the specification as "set by provider on receive" are available only to the consumers.

JMSXGroupID and JMSXGroupSeq are standard properties that clients should use if they want to group messages. All providers must support them. Unless specifically noted, the values and semantics of the JMSX properties are undefined.

The JMS API reserves the JMS_vendor_name property name prefix for provider-specific properties. Each provider defines its own value for vendor_name. This is the mechanism a JMS provider uses to make its special per-message services available to a JMS client.

The purpose of provider-specific properties is to provide special features needed to integrate JMS clients with provider-native clients in a single JMS application. They should not be used for messaging between JMS clients.

Provider Implementations of JMS Message Interfaces

The JMS API provides a set of message interfaces that define the JMS message model. It does not provide implementations of these interfaces.

Each JMS provider supplies a set of message factories with its Session object for creating instances of messages. This allows a provider to use message implementations tailored to its specific needs.

A provider must be prepared to accept message implementations that are not its own. They may not be handled as efficiently as its own implementation; however, they must be handled.

Note the following exception case when a provider is handling a foreign message implementation. If the foreign message implementation contains a JMSReplyTo header field that is set to a foreign destination implementation, the provider is not required to handle or preserve the value of this header field.
Message Selectors

A JMS message selector allows a client to specify, by header field references and property references, the messages it is interested in. Only messages whose header and property values match the selector are delivered. What it means for a message not to be delivered depends on the MessageConsumer being used (see QueueReceiver and TopicSubscriber).

Message selectors cannot reference message body values.

A message selector matches a message if the selector evaluates to true when the message's header field values and property values are substituted for their corresponding identifiers in the selector.

A message selector is a String whose syntax is based on a subset of the SQL92 conditional expression syntax. If the value of a message selector is an empty string, the value is treated as a null and indicates that there is no message selector for the message consumer.

The order of evaluation of a message selector is from left to right within precedence level. Parentheses can be used to change this order.

Predefined selector literals and operator names are shown here in uppercase; however, they are case insensitive.

A selector can contain:

- Literals:
  - A string literal is enclosed in single quotes, with a single quote represented by doubled single quote; for example, 'literal' and 'literal''s'. Like string literals in the Java programming language, these use the Unicode character encoding.
  - An exact numeric literal is a numeric value without a decimal point, such as 57, -957, and +62; numbers in the range of long are supported. Exact numeric literals use the
integer literal syntax of the Java programming language.
- An approximate numeric literal is a numeric value in scientific notation, such as 7E3 and -57.9E2, or a numeric value with a decimal, such as 7., -95.7, and +6.2; numbers in the range of double are supported. Approximate literals use the floating-point literal syntax of the Java programming language.
- The boolean literals true and false.

Identifiers:
- An identifier is an unlimited-length sequence of letters and digits, the first of which must be a letter. A letter is any character for which the method Character.isJavaLetter returns true. This includes '_.' and '$'. A letter or digit is any character for which the method Character.isJavaLetterOrDigit returns true.
- Identifiers cannot be the names NULL, TRUE, and FALSE.
- Identifiers cannot be NOT, AND, OR, BETWEEN, LIKE, IN, IS, OR ESCAPE.
- Identifiers are either header field references or property references. The type of a property value in a message selector corresponds to the type used to set the property. If a property that does not exist in a message is referenced, its value is NULL.
- The conversions that apply to the get methods for properties do not apply when a property is used in a message selector expression. For example, suppose you set a property as a string value, as in the following:

```
myMessage.setStringProperty("NumberOfOrders", "2");
```

The following expression in a message selector would evaluate to false, because a string cannot be used in an arithmetic expression:

"NumberOfOrders > 1"

- Identifiers are case-sensitive.
- Message header field references are restricted to JMSDeliveryMode, JMSPriority, JMSMessageID, JMSTimestamp, JMSCorrelationID, and JMSType. JMSMessageID,
JMSCorrelationID, and JMSType values may be null and if so are treated as a NULL value.

- Any name beginning with 'JMSX' is a JMS defined property name.
- Any name beginning with 'JMS_' is a provider-specific property name.
- Any name that does not begin with 'JMS' is an application-specific property name.

White space is the same as that defined for the Java programming language: space, horizontal tab, form feed, and line terminator.

- Expressions:
  - A selector is a conditional expression; a selector that evaluates to true matches; a selector that evaluates to false or unknown does not match.
  - Arithmetic expressions are composed of themselves, arithmetic operations, identifiers (whose value is treated as a numeric literal), and numeric literals.
  - Conditional expressions are composed of themselves, comparison operations, and logical operations.
- Standard bracketing () for ordering expression evaluation is supported.
- Logical operators in precedence order: NOT, AND, OR
- Comparison operators: =, >, >=, <, <=, (not equal)
  - Only like type values can be compared. One exception is that it is valid to compare exact numeric values and approximate numeric values; the type conversion required is defined by the rules of numeric promotion in the Java programming language. If the comparison of non-like type values is attempted, the value of the operation is false. If either of the type values evaluates to NULL, the value of the expression is unknown.
  - String and boolean comparison is restricted to = and !=. Two strings are equal if and only if they contain the same sequence of characters.
- Arithmetic operators in precedence order:
  - +, - (unary)
  - *, / (multiplication and division)
  - +, - (addition and subtraction)
- Arithmetic operations must use numeric promotion in the Java programming language.

- `arithmetic-expr1 [NOT] BETWEEN arithmetic-expr2 AND arithmetic-expr3` (comparison operator)
  - "age BETWEEN 15 AND 19" is equivalent to "age >= 15 AND age <= 19"
  - "age NOT BETWEEN 15 AND 19" is equivalent to "age < 15 OR age > 19"

- `identifier [NOT] IN (string-literal1, string-literal2,...)` (comparison operator where `identifier` has a String or NULL value)
  - "Country IN ('UK', 'US', 'France')" is true for 'UK' and false for 'Peru'; it is equivalent to the expression "(Country = 'UK') OR (Country = 'US') OR (Country = 'France')"
  - "Country NOT IN ('UK', 'US', 'France')" is false for 'UK' and true for 'Peru'; it is equivalent to the expression "NOT ((Country = 'UK') OR (Country = 'US') OR (Country = 'France'))"
  - If `identifier` of an IN or NOT IN operation is NULL, the value of the operation is unknown.

- `identifier [NOT] LIKE pattern-value [ESCAPE escape-character]` (comparison operator, where `identifier` has a String value; `pattern-value` is a string literal where '_' stands for any single character; '%' stands for any sequence of characters, including the empty sequence; and all other characters stand for themselves. The optional `escape-character` is a single-character string literal whose character is used to escape the special meaning of the '_' and '%' in `pattern-value`.)
  - "phone LIKE '12%3'" is true for '123' or '12993' and false for '1234'
  - "word LIKE 'l_se'" is true for 'lose' and false for 'loose'
  - "underscored LIKE '_%' ESCAPE '\'" is true for '_foo' and false for 'bar'
  - "phone NOT LIKE '12%3'" is false for '123' or '12993' and true for '1234'
  - If `identifier` of a LIKE or NOT LIKE operation is NULL, the value of the operation is unknown.

- `identifier IS NULL` (comparison operator that tests for a null header field value or a missing property value)
- "prop_name IS NULL"
- identifier IS NOT NULL (comparison operator that tests for the existence of a non-null header field value or a property value)
- "prop_name IS NOT NULL"

JMS providers are required to verify the syntactic correctness of a message selector at the time it is presented. A method that provides a syntactically incorrect selector must result in a JMSException. JMS providers may also optionally provide some semantic checking at the time the selector is presented. Not all semantic checking can be performed at the time a message selector is presented, because property types are not known.

The following message selector selects messages with a message type of car and color of blue and weight greater than 2500 pounds:

"JMSType = 'car' AND color = 'blue' AND weight > 2500"

Null Values

As noted above, property values may be NULL. The evaluation of selector expressions containing NULL values is defined by SQL92 NULL semantics. A brief description of these semantics is provided here.

SQL treats a NULL value as unknown. Comparison or arithmetic with an unknown value always yields an unknown value.

The IS NULL and IS NOT NULL operators convert an unknown value into the respective TRUE and FALSE values.

The boolean operators use three-valued logic as defined by the following tables:

**The definition of the AND operator**

<table>
<thead>
<tr>
<th></th>
<th>AND</th>
<th>T</th>
<th>F</th>
<th>U</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>T</td>
<td>T</td>
<td>F</td>
<td>U</td>
</tr>
</tbody>
</table>
The definition of the **OR** operator

<table>
<thead>
<tr>
<th>OR</th>
<th>T</th>
<th>F</th>
<th>U</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>T</td>
<td>T</td>
<td>T</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>F</td>
<td>U</td>
</tr>
<tr>
<td>U</td>
<td>T</td>
<td>U</td>
<td>U</td>
</tr>
</tbody>
</table>

The definition of the **NOT** operator

<table>
<thead>
<tr>
<th>NOT</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
</tr>
<tr>
<td>F</td>
</tr>
<tr>
<td>T</td>
</tr>
<tr>
<td>U</td>
</tr>
</tbody>
</table>

Special Notes

When used in a message selector, the JMSDeliveryMode header field is treated as having the values 'PERSISTENT' and 'NON_PERSISTENT'.

Date and time values should use the standard long millisecond value. When a date or time literal is included in a message selector, it should be an integer literal for a millisecond value. The standard way to produce millisecond values is to use java.util.Calendar.

Although SQL supports fixed decimal comparison and arithmetic, JMS message selectors do not. This is the reason for restricting exact numeric literals to those without a decimal (and the addition of numerics with a decimal as an alternate representation for approximate numeric values).
SQL comments are not supported.

**Field Detail**

**DEFAULT_DELIVERY_MODE**

```java
static final int DEFAULT_DELIVERY_MODE
```

The message producer's default delivery mode is PERSISTENT.

**See Also:**

[DeliveryMode.PERSISTENT, Constant Field Values](#)

**DEFAULT_PRIORITY**

```java
static final int DEFAULT_PRIORITY
```

The message producer's default priority is 4.

**See Also:**

[Constant Field Values](#)

**DEFAULT_TIME_TO_LIVE**

```java
static final long DEFAULT_TIME_TO_LIVE
```
The message producer's default time to live is unlimited; the message never expires.

Constant Field Values

### Method Detail

```java
public String getJMSMessageID() throws JMSException

ID

JMSMessageID

JMSMessageID send publish

JMSMessageID String

JMSMessageID 'ID:' ID

ID ID JMS
MessageProducer.setDisableMessageID JMS
JMS ID null ID

return ID

Throws JMSException: JMS ID

See setJMSMessageID(String),
also setDisableMessageID(boolean)
```

**getJMSMessageID**

```java
String getJMSMessageID() throws JMSException

Gets the message ID.
```
The JMSMessageID header field contains a value that uniquely identifies each message sent by a provider.

When a message is sent, JMSMessageID can be ignored. When the send or publish method returns, it contains a provider-assigned value.

A JMSMessageID is a String value that should function as a unique key for identifying messages in a historical repository. The exact scope of uniqueness is provider-defined. It should at least cover all messages for a specific installation of a provider, where an installation is some connected set of message routers.

All JMSMessageID values must start with the prefix 'ID:'. Uniqueness of message ID values across different providers is not required.

Since message IDs take some effort to create and increase a message's size, some JMS providers may be able to optimize message overhead if they are given a hint that the message ID is not used by an application. By calling the MessageProducer.setDisableMessageID method, a JMS client enables this potential optimization for all messages sent by that message producer. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.

Returns:
  the message ID

Throws:
  JMSException - if the JMS provider fails to get the message ID due to some internal error.

See Also:
  setJMSMessageID(String),
  MessageProducer.setDisableMessageID(boolean)

public void setJMSMessageID(String id) throws
**setJMSMessageID**

```java
void setJMSMessageID(String id)
```

Sets the message ID.

JMS providers set this field when a message is sent. This method can be used to change the value for a message that has been received.

**Parameters:**

- `id` - the ID of the message

**Throws:**

- `JMSException` - if the JMS provider fails to set the message ID due to some internal error.

**See Also:**

- `getJMSMessageID()`

---

**public long getJMSTimestamp() throws JMSException**
getJMSTimestamp

long getJMSTimestamp() throws JMSException

Gets the message timestamp.

The JMSTimestamp header field contains the time a message was handed off to a provider to be sent. It is not the time the message was actually transmitted, because the actual send may occur later due to transactions or other client-side queueing of messages.

When a message is sent, JMSTimestamp is ignored. When the send or publish method returns, it contains a time value somewhere in the interval between the call and the return. The value is in the format of a normal millis time value in the Java programming language.

Since timestamps take some effort to create and increase a message's size, some JMS providers may be able to optimize message overhead if they are given a hint that the timestamp is not used by an application. By calling the MessageProducer.setDisableMessageTimestamp method, a JMS client enables this potential optimization for all messages sent by that message producer. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint, the timestamp must be set to its normal value.
public void setJMSTimestamp(long timestamp)
throws JMSException

Sets the message timestamp.

JMS providers set this field when a message is sent. This method can be used to change the value for a message that has been received.

Parameters:

timestamp - the timestamp for this message

Throws:

JMSException - if the JMS provider fails to set the timestamp due to some internal error.

See Also:

getJMSTimestamp()
public byte[] getJMSCorrelationIDAsBytes() throws JMSException
byte ID

JMSCorrelationID byte[]
return byte ID
Throws JMSException: JMS ID
See setJMSCorrelationID(String), getJMSCorrelationID(),
also setJMSCorrelationIDAsBytes(byte[])

getJMSCorrelationIDAsBytes

byte[] getJMSCorrelationIDAsBytes() throws JMSException

Gets the correlation ID as an array of bytes for the message.

The use of a byte[] value for JMSCorrelationID is non-portable.

Returns: the correlation ID of a message as an array of bytes
Throws: JMSException - if the JMS provider fails to get the correlation ID due to some internal error.
See Also: setJMSCorrelationID(String), getJMSCorrelationID(),
setJMSCorrelationIDAsBytes(byte[])

public void setJMSCorrelationIDAsBytes(byte[] correlationID) throws JMSException
byte ID
setJMSCorrelationIDAsBytes

void setJMSCorrelationIDAsBytes(byte[] correlationID) throws JMSException

Sets the correlation ID as an array of bytes for the message.

The array is copied before the method returns, so future modifications to the array will not alter this message header.

If a provider supports the native concept of correlation ID, a JMS client may need to assign specific JMSCorrelationID values to match those expected by native messaging clients. JMS providers without native correlation ID values are not required to support this method and its corresponding get method; their implementation may throw a java.lang.UnsupportedOperationException.

The use of a byte[] value for JMSCorrelationID is non-portable.

Parameters:
- correlationID - the correlation ID value as an array of bytes

Throws:
- JMSException - if the JMS provider fails to set the
setJMSCorrelationID

void setJMSCorrelationID(String correlationID)
Sets the correlation ID for the message.

A client can use the JMSCorrelationID header field to link one message with another. A typical use is to link a response message with its request message.

JMSCorrelationID can hold one of the following:

- A provider-specific message ID
- An application-specific String
- A provider-native byte[] value

Since each message sent by a JMS provider is assigned a message ID value, it is convenient to link messages via message ID. All message ID values must start with the 'ID:' prefix.

In some cases, an application (made up of several clients) needs to use an application-specific value for linking messages. For instance, an application may use JMSCorrelationID to hold a value referencing some external information. Application-specified values must not start with the 'ID:' prefix; this is reserved for provider-generated message ID values.

If a provider supports the native concept of correlation ID, a JMS client may need to assign specific JMSCorrelationID values to match those expected by clients that do not use the JMS API. A byte[] value is used for this purpose. JMS providers without native correlation ID values are not required to support byte[] values. The use of a byte[] value for JMSCorrelationID is non-portable.

**Parameters:**

- correlationID - the message ID of a message being referred to

**Throws:**

JMSException - if the JMS provider fails to set the
correlation ID due to some internal error.

See Also:
getJMSCorrelationID(), getJMSCorrelationIDAsBytes(), setJMSCorrelationIDAsBytes(byte[])

public String getJMSCorrelationID() throws JMException

ID

String ID

return String ID

Throws JMSException: JMS ID

See also setJMSCorrelationID(String), getJMSCorrelationIDAsBytes(), setJMSCorrelationIDAsBytes(byte[])

getJMSCorrelationID

String getJMSCorrelationID() throws JMSException

Gets the correlation ID for the message.

This method is used to return correlation ID values that are either provider-specific message IDs or application-specific String values.

Returns:
the correlation ID of a message as a String

Throws:
JMException - if the JMS provider fails to get the correlation ID due to some internal error.

See Also:
setJMSCorrelationID(String), getJMSCorrelationIDAsBytes(), setJMSCorrelationIDAsBytes(byte[])
public **Destination** getJMSReplyTo() throws **JMSException**

    Destination
    return
    Throws **JMSException**: JMS
    See also **setJMSReplyTo(Destination)**

getJMSReplyTo

**Destination** getJMSReplyTo() throws **JMSException**

    Gets the **destination** object to which a reply to this message should be sent.

    **Returns**: Destination to which to send a response to this message

    **Throws**: **JMSException** - if the JMS provider fails to get the JMSReplyTo destination due to some internal error.

    **See Also**: **setJMSReplyTo(Destination)**

-------------------

public void setJMSReplyTo(**Destination** replyTo) throws **JMSException**

    Destination
    JMSReplyTo **null** Queue Topic
    **null** JMSReplyTo

    JMSReplyTo

    **JMSCorrelationID**
    **replyTo** Destination
Throws  

See also

getJMSReplyTo()

setJMSReplyTo

void setJMSReplyTo(Destination replyTo)

sets the Destination object to which a reply to this message should be sent.

The JMSReplyTo header field contains the destination where a reply to the current message should be sent. If it is null, no reply is expected. The destination may be either a Queue object or a Topic object.

Messages sent with a null JMSReplyTo value may be a notification of some event, or they may just be some data the sender thinks is of interest.

Messages with a JMSReplyTo value typically expect a response. A response is optional; it is up to the client to decide. These messages are called requests. A message sent in response to a request is called a reply.

In some cases a client may wish to match a request it sent earlier with a reply it has just received. The client can use the JMSCorrelationID header field for this purpose.

Parameters:

replyTo - Destination to which to send a response to this message

Throws:

JMSException - if the JMS provider fails to set the JMSReplyTo destination due to some internal error.

See Also:

getJMSReplyTo()
public Destination getJMSDestination() throws JMSException

  Destination

JMSDestination

  send    publish

  JMSDestination
  return

  Throws   JMSException: JMS
  See also    setJMSDestination(Destination)

getJMSDestination

  Destination getJMSDestination()    throws JMSException

  Gets the Destination object for this message.

  The JMSDestination header field contains the destination to which the message is being sent.

  When a message is sent, this field is ignored. After completion of the send or publish method, the field holds the destination specified by the method.

  When a message is received, its JMSDestination value must be equivalent to the value assigned when it was sent.

  Returns: the destination of this message

  Throws:   JMSException - if the JMS provider fails to get the destination due to some internal error.

  See Also: setJMSDestination(Destination)
public void setJMSDestination(Destination destination) throws JMSException

Sets the Destination object for this message.

JMS providers set this field when a message is sent. This method can be used to change the value for a message that has been received.

Parameters:
- destination - the destination for this message

Throws:
- JMSException - if the JMS provider fails to set the destination due to some internal error.

See Also:
- getJMSDestination()

public int getJMSDeliveryMode() throws JMSException

DeliveryMode

return

Throws JMSException: JMS

See also setJMSDeliveryMode(int), javax.jms.DeliveryMode
getJMSDeliveryMode

```java
int getJMSDeliveryMode() throws JMSException
```

Gets the DeliveryMode value specified for this message.

**Returns:**
the delivery mode for this message

**Throws:**
JMSException - if the JMS provider fails to get the delivery mode due to some internal error.

**See Also:**
setJMSDeliveryMode(int), javax.jms.DeliveryMode

---

public void setJMSDeliveryMode(int deliveryMode)
throws JMSException

JMS

```java
deliveryMode
```

**Throws**
JMSException: JMS

**See also**
getJMSDeliveryMode(), javax.jms.DeliveryMode

---

setJMSDeliveryMode

```java
void setJMSDeliveryMode(int deliveryMode) throws JMSException
```

Sets the DeliveryMode value for this message.

JMS providers set this field when a message is sent. This method can be used to change the value for a message that has been received.
Parameters:
- deliveryMode - the delivery mode for this message

Throws:
- JMSException - if the JMS provider fails to set the delivery mode due to some internal error.

See Also:
- getJMSDeliveryMode(), DeliveryMode

public boolean getJMSRedelivered() throws JMSException

JMSRedelivered

    return true

Throws
- JMSException: JMS

See also
- setJMSRedelivered(boolean)

getJMSRedelivered

boolean getJMSRedelivered() throws JMSException

Gets an indication of whether this message is being redelivered.

If a client receives a message with the JMSRedelivered field set, it is likely, but not guaranteed, that this message was delivered earlier but that its receipt was not acknowledged at that time.

Returns:
- true if this message is being redelivered

Throws:
- JMSException - if the JMS provider fails to get the redelivered state due to some internal error.

See Also:
setJMSRedelivered( boolean )

public void setJMSRedelivered( boolean redelivered ) throws JMSException

  redelivered
  Throws JMSException: JMS
  See also getJMSRedelivered()

setJMSRedelivered

void setJMSRedelivered( boolean redelivered )
  throws JMSException

  Specifies whether this message is being redelivered.

  This field is set at the time the message is delivered. This method can be used to change the value for a message that has been received.

Parameters:
  redelivered - an indication of whether this message is being redelivered

Throws:
  JMSException - if the JMS provider fails to set the redelivered state due to some internal error.

See Also:
  getJMSRedelivered()

public String getJMSType() throws JMSException

  return
  Throws JMSException: JMS
getJMSType

`String getJMSType()`

Throws: `JMSException` - if the JMS provider fails to get the message type due to some internal error.

See Also: `setJMSType(String)`

public void setJMSType(String type) throws `JMSException`

setJMSType
void setJMSType(String type) throws JMSException

Sets the message type.

Some JMS providers use a message repository that contains the definitions of messages sent by applications. The JMSType header field may reference a message's definition in the provider's repository.

The JMS API does not define a standard message definition repository, nor does it define a naming policy for the definitions it contains.

Some messaging systems require that a message type definition for each application message be created and that each message specify its type. In order to work with such JMS providers, JMS clients should assign a value to JMSType, whether the application makes use of it or not. This ensures that the field is properly set for those providers that require it.

To ensure portability, JMS clients should use symbolic values for JMSType that can be configured at installation time to the values defined in the current provider's message repository. If string literals are used, they may not be valid type names for some JMS providers.

Parameters:
  type - the message type

Throws:
  JMSException - if the JMS provider fails to set the message type due to some internal error.

See Also:
  getJMSType()

public long getJMSExpiration() throws JMSException
JMSExpiration

send	publish

JMSExpiration

GMT

0

JMSAPI

getJMSExpiration

long getJMSExpiration()

return GMT

Throws JMSException: JMS

See also setJMSExpiration(long)

getJMSExpiration

long getJMSExpiration()

Throws JMSException

Gets the message's expiration value.

When a message is sent, the JMSExpiration header field is left unassigned. After completion of the send or publish method, it holds the expiration time of the message. This is the sum of the time-to-live value specified by the client and the GMT at the time of the send or publish.

If the time-to-live is specified as zero, JMSExpiration is set to zero to indicate that the message does not expire.

When a message's expiration time is reached, a provider should discard it. The JMS API does not define any form of notification of message expiration.

Clients should not receive messages that have expired; however, the JMS API does not guarantee that this will not happen.

Returns:
the time the message expires, which is the sum of the
time-to-live value specified by the client and the GMT
at the time of the send

Throws:

JMSException - if the JMS provider fails to get the
message expiration due to some internal error.

See Also:

setJMSExpiration(long)

public void setJMSExpiration(long expiration)
throws JMSException

JMS

expiration

Throws JMSException: JMS

See also getJMSExpiration()

setJMSExpiration

void setJMSExpiration(long expiration)
throws JMSException

Sets the message's expiration value.

JMS providers set this field when a message is sent. This
method can be used to change the value for a message
that has been received.

Parameters:

expiration - the message's expiration time

Throws:

JMSException - if the JMS provider fails to set the
message expiration due to some internal error.

See Also:

getJMSExpiration()
public int getJMSPriority() throws JMSException

JMS API 10 0 9 0-4 5-9

JMS API

    return

    Throws JMSException: JMS

    See also setJMSPriority(int)

getJMSPriority

int getJMSPriority() throws JMSException

Gets the message priority level.

The JMS API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. In addition, clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority.

The JMS API does not require that a provider strictly implement priority ordering of messages; however, it should do its best to deliver expedited messages ahead of normal messages.

Returns:
the default message priority

Throws:
JMSException - if the JMS provider fails to get the message priority due to some internal error.

See Also:
setJMSPriority(int)
public void setJMSPriority(int priority) throws JMSException

JMS

    priority

Throws JMSException: JMS
See also getJMSPriority()

setJMSPriority

void setJMSPriority(int priority)
    throws JMSException

Sets the priority level for this message.

JMS providers set this field when a message is sent. This method can be used to change the value for a message that has been received.

Parameters:
    priority - the priority of this message

Throws:
    JMSException - if the JMS provider fails to set the message priority due to some internal error.

See Also:
    getJMSPriority()

public void clearProperties() throws JMSException

Throws JMSException: JMS
clearProperties

void clearProperties() throws JMSException

Clears a message's properties.

The message's header fields and body are not cleared.

Throws:

  JMSException - if the JMS provider fails to clear the message properties due to some internal error.

public boolean propertyExists(String name) throws JMSException

  name
  return true

  Throws JMSException: JMS

propertyExists

boolean propertyExists(String name) throws JMSException

Indicates whether a property value exists.

Parameters:

  name - the name of the property to test

Returns:

  true if the property exists

Throws:

  JMSException - if the JMS provider fails to determine if the property exists due to some internal error.

public boolean getBooleanProperty(String name) throws JMSException
boolean

getBooleanProperty

boolean getBooleanProperty(String name)
throws JMSException

Returns the value of the boolean property with the specified name.

Parameters:
name - the name of the boolean property

Returns:
the boolean property value for the specified name

Throws:
JMSException - if the JMS provider fails to get the property value due to some internal error.
MessageFormatException - if this type conversion is invalid.

public byte getByteProperty(String name) throws JMSException

getByteProperty

byte getByteProperty(String name)
throws **JMSException**

Returns the value of the *byte* property with the specified name.

**Parameters:**
name - the name of the *byte* property

**Returns:**
the *byte* property value for the specified name

**Throws:**
**JMSException** - if the JMS provider fails to get the property value due to some internal error.
**MessageFormatException** - if this type conversion is invalid.

### public short getShortProperty(String name) throws **JMSException**

```
short getShortProperty(String name)
```

short

*name*

short

*return*

short

**Throws**
**JMSException**: JMS

**Throws**
**MessageFormatException**: 

### getShortProperty

```
short getShortProperty(String name)
```

short

*getShortProperty*(String *name*)

throws **JMSException**

Returns the value of the *short* property with the specified name.

**Parameters:**
name - the name of the *short* property

**Returns:**
the *short* property value for the specified name

**Throws:**
**JMSException** - if the JMS provider fails to get the
public int getIntProperty(String name) throws JMSException

int

name int
return int

Throws: JMSException: JMS
Throws: MessageFormatException: 

getIntProperty

int getIntProperty(String name) throws JMSException

Returns the value of the int property with the specified name.

Parameters:
name - the name of the int property

Returns:
the int property value for the specified name

Throws:
JMSException - if the JMS provider fails to get the property value due to some internal error.
MessageFormatException - if this type conversion is invalid.

public long getLongProperty(String name) throws JMSException

long

name long
return long
Throws: JMSException: JMS
Throws: MessageFormatException:

getLongProperty

long getLongProperty(String name) throws JMSException

Returns the value of the long property with the specified name.

Parameters:
name - the name of the long property

Returns:
the long property value for the specified name

Throws:
JMSException - if the JMS provider fails to get the property value due to some internal error.
MessageFormatException - if this type conversion is invalid.

public float getFloatProperty(String name) throws JMSException

float

name float
return float

Throws: JMSException: JMS
Throws: MessageFormatException:

getFloatProperty

float getFloatProperty(String name) throws JMSException

Returns the value of the float property with the specified name.
public double getDoubleProperty(String name) throws JMSException

Parameters:
name - the name of the double property

Returns:
the double property value for the specified name

Throws:
JMSException - if the JMS provider fails to get the property value due to some internal error.
MessageFormatException - if this type conversion is invalid.

getDoubleProperty

double getDoubleProperty(String name) throws JMSException

Parameters:
name - the name of the double property

Returns:
the double property value for the specified name

Throws:
JMSException - if the JMS provider fails to get the property value due to some internal error.
MessageFormatException - if this type conversion is invalid.
public String getStringProperty(String name) throws JMSException

    String
    name
    return

Throws: JMSException: JMS

getStringProperty

String getStringProperty(String name) throws JMSException

    String
    name
    return

Returns the value of the String property with the specified name.

Parameters:
    name - the name of the String property

Returns:
    the String property value for the specified name; if there is no property by this name, a null value is returned

Throws:
    JMSException - if the JMS provider fails to get the property value due to some internal error.
    MessageFormatException - if this type conversion is invalid.

public Object getObjectProperty(String name) throws JMSException

Java

    setObjectProperty
    name
    return

Throws: JMSException: JMS
**getObjectProperty**

```java
Object getObjectProperty(String name) throws JMSException
```

Returns the value of the Java object property with the specified name.

This method can be used to return, in objectified format, an object that has been stored as a property in the message with the equivalent `setObjectProperty` method call, or its equivalent primitive `setProperty` method.

**Parameters:**

- name - the name of the Java object property

**Returns:**

- the Java object property value with the specified name, in objectified format (for example, if the property was set as an `int`, an `Integer` is returned); if there is no property by this name, a null value is returned

**Throws:**

- `JMSException` - if the JMS provider fails to get the property value due to some internal error.

---

```java
public java.util.Enumeration<E> getPropertyNames() throws JMSException
```

**JMS**

```java
return
```

**Throws**

- `JMSException`: JMS

---

**getPropertyNames**
**Enumeration** `getPropertyNames()`

```java
public Enumeration getPropertyNames() throws JMSException {
    // Implementation...
    return null; // Example return value
}
```

Returns an `Enumeration` of all the property names.

Note that JMS standard header fields are not considered properties and are not returned in this enumeration.

**Returns:**
- an `Enumeration` of all the names of property values

**Throws:**
- `JMSException` - if the JMS provider fails to get the property names due to some internal error.

---

**public void setBooleanProperty(String name, boolean value)**

```java
public void setBooleanProperty(String name, boolean value) throws JMSException {
    // Implementation...
}
```

Sets a boolean property value with the specified name into the message.

**Parameters:**
- `name` - the name of the boolean property
- `value` - the boolean property value to set

**Throws:**
- `JMSException` - if the JMS provider fails to set the property due to some internal error.
IllegalArgumentException - if the name is null or if the name is an empty string.
MessageNotWriteableException - if properties are read-only

public void setByteProperty(String name, byte value) throws JMSException
  byte
  name	byte
  value	byte
  Throws JMSException: JMS
  Throws IllegalArgumentException: null
  Throws MessageNotWriteableException:

setByteProperty

void setByteProperty(String name, byte value)
  throws JMSException

Sets a byte property value with the specified name into the message.

Parameters:
  name - the name of the byte property
  value - the byte property value to set

Throws:
  JMSException - if the JMS provider fails to set the property due to some internal error.
  IllegalArgumentException - if the name is null or if the name is an empty string.
  MessageNotWriteableException - if properties are read-only

public void setShortProperty(String name, short value) throws JMSException
**setShortProperty**

```java
void setShortProperty(String name, short value)
throws JMSException
```

Sets a short property value with the specified name into the message.

**Parameters:**
- `name` - the name of the short property
- `value` - the short property value to set

**Throws:**
- `JMSException` - if the JMS provider fails to set the property due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageNotWriteableException` - if properties are read-only

---

**public void setIntProperty(String name, int value)**

```java
int
```

```java
void setIntProperty(String name, int value)
throws JMSException
```

Throws `JMSException`: JMS

Throws `IllegalArgumentException`: null

Throws `MessageNotWriteableException`: null
**setIntProperty**

```java
void setIntProperty(String name, int value)
    throws JMSException
```

Sets an `int` property value with the specified name into the message.

**Parameters:**
- `name` - the name of the `int` property
- `value` - the `int` property value to set

**Throws:**
- `JMSException` - if the JMS provider fails to set the property due to some internal error.
- `IllegalArgumentException` - if the name is `null` or if the name is an empty string.
- `MessageNotWriteableException` - if properties are read-only

---

**public void setLongProperty(String name, long value) throws JMSException**

```java
long name
long value
```

**Throws**
- `JMSException`: JMS
- `IllegalArgumentException`: `null`
- `MessageNotWriteableException`: 

---

**setLongProperty**

```java
void setLongProperty(String name, long value)
    throws JMSException
```

Sets a `long` property value with the specified name into the message.
public void setFloatProperty(String name, float value) throws JMSException

    float
    name  float
    value  float

    Throws  JMSException: JMS
    Throws  IllegalArgumentException: null
    Throws  MessageNotWriteableException:
public void setDoubleProperty(String name, double value) throws JMSException

Sets a double property value with the specified name into the message.

Parameters:
name - the name of the double property
double value - the double property value to set

Throws:
JMSException - if the JMS provider fails to set the property due to some internal error.
IllegalArgumentException - if the name is null or if the name is an empty string.
MessageNotWriteableException - if properties are read-only

public void setStringProperty(String name, String value) throws JMSException

String value
String
setStringProperty

```java
void setStringProperty(String name,
                       String value)
throws JMSException
```

Sets a string property value with the specified name into the message.

**Parameters:**
- `name` - the name of the string property
- `value` - the string property value to set

**Throws:**
- `JMSException` - if the JMS provider fails to set the property due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageNotWriteableException` - if properties are read-only
setObjectProperty

```java
void setObjectProperty(String name, Object value)
throws JMSException
```

Sets a Java object property value with the specified name into the message.

Note that this method works only for the objectified primitive object types (Integer, Double, Long ...) and String objects.

**Parameters:**
- `name` - the name of the Java object property
- `value` - the Java object property value to set

**Throws:**
- `JMSException` - if the JMS provider fails to set the property due to some internal error.
- `IllegalArgumentException` - if the name is null or if the name is an empty string.
- `MessageFormatException` - if the object is invalid
- `MessageNotWriteableException` - if properties are read-only

---

public void acknowledge() throws JMSException

```java
JMS acknowledge
```

**Throws** `JMSException`: JMS
acknowledge

void acknowledge() throws JMSException

Acknowledges all consumed messages of the session of this consumed message.

All consumed JMS messages support the acknowledge method for use when a client has specified that its JMS session's consumed messages are to be explicitly acknowledged. By invoking acknowledge on a consumed message, a client acknowledges all messages consumed by the session that the message was delivered to.

Calls to acknowledge are ignored for both transacted sessions and sessions specified to use implicit acknowledgement modes.

A client may individually acknowledge each message as it is consumed, or it may choose to acknowledge messages as an application-defined group (which is done by calling acknowledge on the last received message of the group, thereby acknowledging all messages consumed by the session.)

Messages that have been received but not acknowledged may be redelivered.

Throws:

  JMSException - if the JMS provider fails to acknowledge the messages due to some internal error.
  IllegalStateException - if this method is called on a closed session.

See Also:
public void clearBody() throws JMSException

Throws JMSException: JMS

clearBody

void clearBody()
throws JMSException

Clears out the message body. Clearing a message's body does not clear its header values or property entries.

If this message body was read-only, calling this method leaves the message body in the same state as an empty body in a newly created message.

Throws:

JMSException - if the JMS provider fails to clear the message body due to some internal error.

javax.mail  **Class Message**

**java.lang.Object**
  - javax.mail.Message

**All Implemented Interfaces:**
  - Part

**Direct Known Subclasses:**
  - MimeMessage

```java
public abstract class Message
    extends Object
    implements Part
```

**Implements:** Part

**Inner classes:** Message.RecipientType

**Extended by:** MimeMessage

This class models an email message. This is an abstract class. Subclasses provide actual implementations.

**See also**  
javax.mail.Part
Message implements the Part interface. Message contains a set of attributes and a "content". Messages within a folder also have a set of flags that describe its state within the folder.

Message defines some new attributes in addition to those defined in the Part interface. These attributes specify meta-data for the message - i.e., addressing and descriptive information about the message.

Message objects are obtained either from a Folder or by constructing a new Message object of the appropriate subclass. Messages that have been received are normally retrieved from a folder named "INBOX".

A Message object obtained from a folder is just a lightweight reference to the actual message. The Message is 'lazily' filled up (on demand) when each item is requested from the message. Note that certain folder implementations may return Message objects that are pre-filled with certain user-specified items. To send a message, an appropriate subclass of Message (e.g., MimeMessage) is instantiated, the attributes and content are filled in, and the message is sent using the Transport.send method.

Folder

getFolder()
Get the folder from which this message was obtained.

abstract Address[]

getFrom()
Returns the "From" attribute.

int getMessageNumber()
Get the Message number for this Message.

abstract Date

getReceivedDate()
Get the date this message was received.

abstract Address[]

getRecipients(Message.RecipientType type)
Get all the recipient addresses of the given type.

Address[]

getReplyTo()
Get the addresses to which replies should be directed.

abstract Date

getSentDate()
Get the date this message was sent.

abstract String

getSubject()
Get the subject of this message.

boolean isExpunged()
Checks whether this message is expunged.

boolean isSet(Flags.Flag flag)
Check whether the flag specified in the flag argument is set in this message.

boolean match(SearchTerm term)
Apply the specified Search criterion to this message.

abstract Message

reply(boolean replyToAll)
Get a new Message suitable for a reply to this message.

abstract void

saveChanges()
Save any changes made to this message into the message-store when the containing folder is closed, if the message is contained in a folder.

protected void

setExpunged(boolean expunged)
Sets the expunged flag for this Message.

void setFlag(Flags.Flag flag, boolean set)
Set the specified flag on this message to the specified value.

void setFlags(Flags flag, boolean set)
<table>

Field Detail
msgnum

protected int msgnum

   The number of this message within its folder, or zero if the message was not retrieved from a folder.

-------------------------------------------------------

expunged

protected boolean expunged

   True if this message has been expunged.

-------------------------------------------------------

folder

protected Folder folder

   The containing folder, if this message is obtained from a folder

-------------------------------------------------------

session

protected Session session

   The Session object for this Message

-------------------------------------------------------

**Constructor Detail**

protected Message()
**Message**

```java
protected Message()
```

No-arg version of the constructor.

---

**Message**

```java
protected Message(Folder folder, int msgnum)
```

Folder  Folder

    folder
    msgnum

Constructor that takes a Folder and a message number. Used by Folder implementations.

**Parameters:**

- `folder` - containing folder
- `msgnum` - this message's sequence number within this folder

---

**Message**

```java
protected Message(Session session)
```

Session  Message

    session
    Session

---

**Message**

```java
protected Message(Session session)
```
Constructor that takes a Session. Used for client created Message objects.

**Parameters:**

session - A Session object

**Method Detail**

```java
abstract public Address[] getFrom() throws MessagingException

"From" "From"
```

Returns the "From" attribute. The "From" attribute contains the identity of the person(s) who wished this message to be sent.

In certain implementations, this may be different from the entity that actually sent the message.

This method returns `null` if this attribute is not present in this message. Returns an empty array if this attribute is present, but contains no addresses.

**Returns:**

array of Address objects
abstract public void setFrom() throws MessagingException
Message "From" "mail.user"
"user.name"

Throws

Throws MessagingException: 
Throws IllegalWriteException: 
Throws IllegalStateException: READ_ONLY 

setFrom

public abstract void setFrom()

throws MessagingException

Set the "From" attribute in this Message. The value of this attribute is obtained from the property "mail.user". If this property is absent, the system property "user.name" is used.

Throws:

MessagingException
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ ONLY folder.

abstract public void setFrom(Address address) throws MessagingException
Message "From"

address

Throws MessagingException:

Throws IllegalWriteException:

Throws IllegalStateException: READ_ONLY
setFrom

public abstract void setFrom(Address address) throws MessagingException

Set the "From" attribute in this Message.

Parameters:
address - the sender

Throws:
MessagingException
IllegalArgumentException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.

abstract public void addFrom(Address[] addresses) throws MessagingException
"From"

addresses

Throws

IllegalWriteException:

IllegalStateException: READ_ONLY

MessagingException:

addFrom

public abstract void addFrom(Address[] addresses) throws MessagingException

Add these addresses to the existing "From" attribute

Parameters:
addresses - the senders

Throws:

IllegalArgumentException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a
abstract public Address[] getRecipients(Message.RecipientType type) throws MessagingException

null

type
return Address

Throws MessagingException:

See also

getRecipients

public abstract Address[] getRecipients(Message.RecipientType type) throws MessagingException

Get all the recipient addresses of the given type.

This method returns null if no recipients of the given type are present in this message. It may return an empty array if the header is present, but contains no addresses.

Parameters:

type - the recipient type

Returns:

array of Address objects

Throws: MessagingException

See Also:

Message.RecipientType.TO, Message.RecipientType.CC, Message.RecipientType.BCC
public Address[] getAllRecipients() throws MessagingException

getRecipients TOCC BCC

public Address[] getAllRecipients()

throws MessagingException

null

return Address

Throws MessagingException:

See also TO, CC, BCC, getRecipients

getAllRecipients

Get all the recipient addresses for the message. The default implementation extracts the TO, CC, and BCC recipients using the getRecipients method.

This method returns null if none of the recipient headers are present in this message. It may return an empty array if any recipient header is present, but contains no addresses.

Returns:
array of Address objects

Throws:
MessagingException

See Also:
Message.RecipientType.TO, Message.RecipientType.CC,
Message.RecipientType.BCC,
getRecipients(javax.mail.Message.RecipientType)

abstract public void setRecipients(Message.RecipientType type, Address[] addresses) throws MessagingException

addresses

type
addresses

Throws MessagingException:
 Throws IllegalArgumentException:
 Throws IllegalStateException: READ_ONLY

setRecipients

public abstract void setRecipients(Message.RecipientType type, Address[] addresses) throws MessagingException

Set the recipient addresses. All addresses of the specified type are replaced by the addresses parameter.

Parameters:
 type - the recipient type
 addresses - the addresses

Throws:
 MessagingException
 IllegalArgumentException - if the underlying implementation does not support modification of existing values
 IllegalStateException - if this message is obtained from a READ_ONLY folder.

public void setRecipient(Message.RecipientType type, Address address) throws MessagingException

setRecipients
 type
 address

Throws MessagingException:
 Throws IllegalArgumentException:
 Throws IllegalStateException:
**setRecipient**

```java
public void setRecipient(Message.RecipientType type, Address address)
        throws MessagingException
```

Set the recipient address. All addresses of the specified type are replaced by the address parameter.

The default implementation uses the `setRecipients` method.

**Parameters:**
- `type` - the recipient type
- `address` - the address

**Throws:**
- `MessagingException`
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values

---

**abstract public void addRecipients**

```java
abstract public void addRecipients(Message.RecipientType type, Address[] addresses) throws MessagingException
```

**Parameters:**
- `type` - the recipient type
- `addresses` - the recipient addresses

**Throws:**
- `MessagingException`
- `IllegalWriteException`
- `IllegalStateException`: `READ_ONLY`

---

**addRecipients**

```java
public abstract void addRecipients(Message.RecipientType type, Address[] addresses)
        throws MessagingException
```

Add these recipient addresses to the existing ones of the given type.

**Parameters:**
public void addRecipient(Message.RecipientType type, Address address) throws MessagingException

Add this recipient address to the existing ones of the given type.

The default implementation uses the addRecipients method.

Parameters:

type - the recipient type
address - the address

Throws:

MessageException
IllegalWriteException - if the underlying implementation does not support modification of existing values

IllegalStateException - if this message is obtained from a READ_ONLY folder.
public Address[] getReplyTo() throws MessagingException

getFrom

null

return

Throws MessagingException: getFrom

See also getFrom

getReplyTo

public Address[] getReplyTo()

throws MessagingException

Get the addresses to which replies should be directed. This will usually be the sender of the message, but some messages may direct replies to a different address.

The default implementation simply calls the getFrom method.

This method returns null if the corresponding header is not present. Returns an empty array if the header is present, but contains no addresses.

Returns:

addresses to which replies should be directed

Throws:

MessagingException

See Also:

getFrom()

public void setReplyTo(Address[] addresses) throws MessagingException

MessagingException
MethodNotSupportedException

addresses

Throws MessagingException:

Throws IllegalWriteException:

Throws IllegalStateException: READ_ONLY

Throws MethodNotSupportedException:

**setReplyTo**

public void setReplyTo(Address[] addresses) throws MessagingException

Set the addresses to which replies should be directed. (Normally only a single address will be specified.) Not all message types allow this to be specified separately from the sender of the message.

The default implementation provided here just throws the MethodNotSupportedException.

**Parameters:**
- addresses - addresses to which replies should be directed

**Throws:**
- MessagingException
- IllegalWriteException - if the underlying implementation does not support modification of existing values
- IllegalStateException - if this message is obtained from a READ_ONLY folder.
- MethodNotSupportedException - if the underlying implementation does not support setting this attribute

abstract public String getSubject() throws MessagingException
getSubject

public abstract String getSubject() throws MessagingException

Get the subject of this message.

Returns:
the subject

Throws:
MessagingException

abstract public void setSubject(String subject) throws MessagingException

subject

Throws MessagingException:
Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY

setSubject

public abstract void setSubject(String subject) throws MessagingException

Set the subject of this message.

Parameters:
subject - the subject

Throws:
MessagingException
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.

abstract public java.util.Date getSentDate() throws MessagingException

    return

    Throws MessagingException:

getSentDate

public abstract Date getSentDate() throws MessagingException

    Get the date this message was sent.

    Returns: the date this message was sent

    Throws: MessagingException

abstract public void setSentDate(java.util.Date date) throws MessagingException

    date

    Throws MessagingException:
    Throws IllegalArgumentException:
    Throws IllegalStateException: READ_ONLY

setSentDate

public abstract void setSentDate(Date date) throws MessagingException
Set the sent date of this message.

**Parameters:**
- `date` - the sent date of this message

**Throws:**
- `MessagingException`
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this message is obtained from a `READ_ONLY` folder.

```java
abstract public java.util.Date getReceivedDate() throws MessagingException

return

getReceivedDate

public abstract Date getReceivedDate() throws MessagingException

Get the date this message was received.

**Returns:**
- the date this message was received

**Throws:**
- `MessagingException`

```java
abstract public Flags getFlags() throws MessagingException

Flags

Flags

setF1
```
getFlags

```java
public abstract Flags getFlags() throws MessagingException {
    return new Flags();
}
```

Returns a Flags object containing the flags for this message.

Modifying any of the flags in this returned Flags object will not affect the flags of this message. Use `setFlags()` to do that.

Returns:
- Flags object containing the flags for this message

Throws:
- MessagingException

See Also:
- Flags, `setFlags(javax.mail.Flags, boolean)`

---

public boolean isSet(Flags.Flag flag) throws MessagingException

```java
getFlags

flag

return

Throws
- MessagingException:

See also
- javax.mail.Flags.Flag, ANSWERED, DELETED, DRAFT, FLAGGED, RECENT, SEEN

isSet
```
public boolean isset(Flags.Flag flag)
    throws MessagingException

Check whether the flag specified in the flag argument is set in this
message.

The default implementation uses getFlags.

Parameters:
    flag - the flag

Returns:
    value of the specified flag for this message

Throws:
    MessagingException

See Also:
    Flags.Flag, Flags.Flag.ANSWERED, Flags.Flag.DELETED,
    Flags.Flag.DRAFT, Flags.Flag.FLAGGED, Flags.Flag.RECENT,
    Flags.Flag.SEEN

abstract public void setFlags(Flags flag, boolean set)
    throws MessagingException

Flags

Message MessageChangedListener
MessageChangedEvent

flag                Flag
set

Throws
    MessagingException:
    IllegalWriteException:
    IllegalStateException: READ_ONLY

See also
    javax.mail.event.MessageChangedEvent

setFlags

public abstract void setFlags(Flags flag,
    boolean set)
throws MessagingException

Set the specified flags on this message to the specified value. Note that any flags in this message that are not specified in the given Flags object are unaffected.

This will result in a MessageChangedEvent being delivered to any MessageChangedListener registered on this Message's containing folder.

Parameters:
flag - Flags object containing the flags to be set
set - the value to be set

Throws:
MessagingException
IllegalWriteException - if the underlying implementation does not support modification of existing values.
IllegalStateException - if this message is obtained from a READ_ONLY folder.

See Also:
MessageChangedEvent
setFlag

public void setFlag(Flags.Flag flag, boolean set)
        throws MessagingException

Set the specified flag on this message to the specified value. This will result in a MessageChangedEvent being delivered to any MessageChangedListener registered on this Message's containing folder.

The default implementation uses the setFlags method.

Parameters:
   flag - Flags.Flag object containing the flag to be set
   set - the value to be set

Throws:
   MessagingException
   IllegalWriteException - if the underlying implementation does not support modification of existing values.
   IllegalStateException - if this message is obtained from a READ_ONLY folder.

See Also:
   MessageChangedEvent

public int getMessageNumber()
        Message Message Message Folder
Message Folder Message

    1 0

    return

gMessageNumber

public int getMessageNumber()
Get the Message number for this Message. A Message object's message number is the relative position of this Message in its Folder. Note that the message number for a particular Message can change during a session if other messages in the Folder are deleted and expunged.

Valid message numbers start at 1. Messages that do not belong to any folder (like newly composed or derived messages) have 0 as their message number.

**Returns:**
the message number

---

```java
protected void setMessageNumber(int msgnum)
Message Message

setMessageNumber
protected void setMessageNumber(int msgnum)

Set the Message number for this Message. This method is invoked only by the implementation classes.

---

```java
public Folder getFolder()
null

getFolder
public Folder getFolder()

Get the folder from which this message was obtained. If this is a new message or nested message, this method returns null.
public boolean isExpunged()

getMessageNumber()  Message

Folder  expunge()  Message  Folder
Message  "expunged"  isExpunged()  true
Folder  expunge()  Folder

expunge()

See also  expunge

isExpunged

public boolean isExpunged()

Checks whether this message is expunged. All other methods except getMessageNumber() are invalid on an expunged Message object.

Messages that are expunged due to an explicit expunge() request on the containing Folder are removed from the Folder immediately. Messages that are externally expunged by another source are marked "expunged" and return true for the isExpunged() method, but they are not removed from the Folder until an explicit expunge() is done on the Folder.

See the description of expunge() for more details on expunge handling.

See Also:
  Folder.expunge()
protected void setExpunged(boolean expunged)
Message expunged
expunged
expunged

setExpunged

protected void setExpunged(boolean expunged)

Sets the expunged flag for this Message. This method is to be used only by the implementation classes.

Parameters:
expunged - the expunged flag

abstract public Message reply(boolean replyToAll) throws MessagingException
Message Message

replyToAll Message
getReplyTo

"Subject" "Re:" "Re:"

replyToAll
return Message
Throws MessagingException:

reply

public abstract Message reply(boolean replyToAll)
throws MessagingException

Get a new Message suitable for a reply to this message. The new
Message will have its attributes and headers set up appropriately. Note that this new message object will be empty, that is, it will **not** have a "content". These will have to be suitably filled in by the client.

If `replyToAll` is set, the new Message will be addressed to all recipients of this message. Otherwise, the reply will be addressed to only the sender of this message (using the value of the `getReplyTo` method).

The "Subject" field is filled in with the original subject prefixed with "Re:" (unless it already starts with "Re:").

The reply message will use the same session as this message.

**Parameters:**
- `replyToAll` - reply should be sent to all recipients of this message  

**Returns:**
- the reply Message

**Throws:**
- `MessagingException`

```java
abstract public void saveChanges() throws MessagingException
```

**saveChanges**

**saveChanges** **Folder**

**READ ONLY** **saveChanges**

**Throws**
- `MessagingException`:
- `IllegalStateException`: **READ ONLY**
- `IllegalWriteException`:

```java
saveChanges
```

**saveChanges**

```java
public abstract void saveChanges()
```
Save any changes made to this message into the message-store when the containing folder is closed, if the message is contained in a folder. (Some implementations may save the changes immediately.) Update any header fields to be consistent with the changed message contents. If any part of a message's headers or contents are changed, saveChanges must be called to ensure that those changes are permanent. If saveChanges is not called, any such modifications may or may not be saved, depending on the message store and folder implementation.

Messages obtained from folders opened READ_ONLY should not be modified and saveChanges should not be called on such messages.

Throws:
- MessagingException
- IllegalStateException - if this message is obtained from a READ_ONLY folder.
- IllegalWriteException - if the underlying implementation does not support modification of existing values.

public boolean match(SearchTerm term) throws MessagingException

Apply the specified Search criterion to this message.
Parameters:
  term - the Search criterion

Returns:
  true if the Message matches this search criterion, false otherwise.

Throws:
  MessagingException

See Also:
  searchTerm
javax.mail Class Message.RecipientType

java.lang.Object
   javax.mail.Message.RecipientType

All Implemented Interfaces:
   Serializable

Direct Known Subclasses:
   MimeMessage.RecipientType

Enclosing class:
   Message

This inner class defines the types of recipients allowed by the Message class. The currently defined types are TO, CC and BCC. Note that this class only has a protected constructor, thereby restricting new Recipient types to either this class or subclasses. This effectively implements an
enumeration of the allowed Recipient types. The following code sample shows how to use this class to obtain the "TO" recipients from a message.

```java
Message msg = folder.getMessages(1);
Address[] a = m.getRecipients(Message.RecipientType.TO);
```

See Also:
- `Message.getRecipients(javax.mail.Message.RecipientType)`, `Message.setRecipients(javax.mail.Message.RecipientType, javax.mail.Address[])`, `Message.addRecipients(javax.mail.Message.RecipientType, javax.mail.Address[])`, Serialized Form

## Field Summary

<table>
<thead>
<tr>
<th>Static Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>Message.RecipientType.BCC</code></td>
<td>The &quot;Bcc&quot; (blind carbon copy) recipients.</td>

</tr>
<tr>
<td><code>Message.RecipientType.TO</code></td>
<td>The &quot;To&quot; (primary) recipients.</td>
</tr>
</tbody>
</table>

**protected string type**

The type of recipient, usually the name of a corresponding Internet standard header.

## Constructor Summary

**protected Message.RecipientType(String type)**

Constructor for use by subclasses.

## Method Summary

**protected Object readResolve()**

When deserializing a RecipientType, we need to make sure to return only one of the known static final instances
defined in this class.

Methods inherited from class java.lang. Object

clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait

Field Detail

TO

public static final Message.RecipientType TO

The "To" (primary) recipients.

CC

public static final Message.RecipientType CC

The "Cc" (carbon copy) recipients.

BCC

public static final Message.RecipientType BCC

The "Bcc" (blind carbon copy) recipients.
type

protected String type

The type of recipient, usually the name of a corresponding Internet standard header.

### Constructor Detail

protected Message.RecipientType(String type)

### Message.RecipientType

protected Message.RecipientType(String type)

Constructor for use by subclasses.

### Method Detail

protected Object readResolve() throws java.io.ObjectStreamException

RecipientType

**readResolve**

protected Object readResolve()

throws ObjectStreamException

When deserializing a RecipientType, we need to make sure to return only one of the known static final instances defined in this class. Subclasses must implement their own readResolve method that
checks for their known instances before calling this super method.

**Throws:**

ObjectStreamException

---

**public String toString()**

**toString**

public String toString()

**Overrides:**

toString in class Object

public interface MessageAware
```

Implemented by: MimePartDataSource

DataSources DataContentHandler

since JavaMail 1.1

See javax.mail.MessageContext, javax.activation.DataSource,
also javax.activation.DataContentHandler

An interface optionally implemented by DataSources to supply information to a DataContentHandler about the message context in which the data content object is operating.

Since:  
JavaMail 1.1

See Also:  
MessageContext, DataSource, DataContentHandler

### Method Summary

### Constructor Summary

**MessageChangedEvent**(Object source, int type, Message msg)
- Constructor.

### Method Summary

- **dispatch**(Object listener)
  - Invokes the appropriate MessageChangedListener method.

- **getMessage**()
  - Return the changed Message.

- **getMessageChangeType**()
  - Return the type of this event.

### Methods inherited from class java.util.EventObject

- getSource, toString

### Methods inherited from class java.lang.Object

- clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait

### Field Detail

**FLAGS_CHANGED**

- public static final int **FLAGS_CHANGED**
The message's flags changed.

See Also:
   Constant Field Values

---

ENVELOPE_CHANGED

public static final int ENVELOPE_CHANGED

   The message's envelope (headers, but not body) changed.

See Also:
   Constant Field Values

---

type

protected int type

   The event type.

---

msg

protected transient Message msg

   The message that changed.

---

source
type
msg

MessageChangedEvent

public MessageChangedEvent(Object source,
                          int type,
                          Message msg)

Constructor.

Parameters:
  source - The folder that owns the message
  type - The change type
  msg - The changed message

Method Detail

public int getMessageChangeType()

  return

getMessageChangeType

public int getMessageChangeType()

  Return the type of this event.

Returns:
  type
public Message getMessage()

    return

getMessage

public Message getMessage()

    Return the changed Message.

    Returns: the message

dispatch

public void dispatch(Object listener)
MessageChangedListener

dispatch

public void dispatch(Object listener)

    Invokes the appropriate MessageChangedListener method.

    Specified by:
    dispatch in class MailEvent
PS:

MessageChangedEvent.FLAGS_CHANGED, MessageChangedEvent.ENVELOPE_CHANGED
javax.jms Interface MessageConsumer

All Known Subinterfaces:
   QueueReceiver, TopicSubscriber

public interface MessageConsumer

Implemented by: QueueReceiver, TopicSubscriber

MessageConsumer Destination - MessageConsumer

MessageConsumer

receive receive

MessageListener MessageListener onMessage

MessageListener

version 1.0 - 13 March 1998 en

See javax.jms.QueueReceiver, javax.jms.TopicSubscriber, javax.jms.Session

A client uses a MessageConsumer object to receive messages from a destination. A MessageConsumer object is created by passing a Destination object to a message-consumer creation method supplied by a session.

MessageConsumer is the parent interface for all message consumers.

A message consumer can be created with a message selector. A message selector allows the client to restrict the messages delivered to the message consumer to those that match the selector.
A client may either synchronously receive a message consumer's messages or have the consumer asynchronously deliver them as they arrive.

For synchronous receipt, a client can request the next message from a message consumer using one of its `receive` methods. There are several variations of `receive` that allow a client to poll or wait for the next message.

For asynchronous delivery, a client can register a `MessageListener` object with a message consumer. As messages arrive at the message consumer, it delivers them by calling the `MessageListener`'s `onMessage` method.

It is a client programming error for a `MessageListener` to throw an exception.

**Version:**
1.0 - 13 March 1998

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>void close()</code></td>
<td>Closes the message consumer.</td>
</tr>
<tr>
<td><code>MessageListener getMessageListener()</code></td>
<td>Gets the message consumer's <code>MessageListener</code>.</td>
</tr>
<tr>
<td><code>String getMessageSelector()</code></td>
<td>Gets this message consumer's message selector expression.</td>
</tr>
<tr>
<td><code>Message receive()</code></td>
<td>Receives the next message produced for this message consumer.</td>
</tr>
<tr>
<td><code>receive(long timeout)</code></td>
<td></td>
</tr>
</tbody>
</table>
**Message**

Receives the next message that arrives within the specified timeout interval.

**receiveNoWait()**

Receives the next message if one is immediately available.

**setMessageListener(MessageListener listener)**

Sets the message consumer's MessageListener.

---

**Method Detail**

**public String getMessageSelector() throws JMSException**

```
return null
```

Throws: **JMSException**: JMS

---

**getMessagingSelector**

```
String getMessageSelector() throws JMSException
```

Gets this message consumer's message selector expression.

**Returns:**

- this message consumer's message selector, or null if no message selector exists for the message consumer (that is, if the message selector was not set or was set to null or the empty string)

**Throws:**

- **JMSException** - if the JMS provider fails to get the message selector due to some internal error.

---

**public MessageListener getMessageListener() throws JMSException**
getMessageListener

MessageListener getMessageListener()

throws JMSException

 Gets the message consumer's MessageListener.

 Returns:
the listener for the message consumer, or null if no listener is set

 Throws:
JMSException - if the JMS provider fails to get the message listener due to some internal error.

 See Also:
setMessageListener(javax.jms.MessageListener)

public void setMessageListener(MessageListener listener)

throws JMSException

 Sets the message consumer's MessageListener.

 Returns:
null

 Throws:
JMSException: JMS

 See also:
getMessageListener
void setMessageListener(MessageListener listener) throws JMSEception

Sets the message consumer's MessageListener.

Setting the message listener to null is the equivalent of unsetting the message listener for the message consumer.

The effect of calling MessageConsumer.setMessageListener While messages are being consumed by an existing listener or the consumer is being used to consume messages synchronously is undefined.

Parameters:
  listener - the listener to which the messages are to be delivered

Throws:
  JMSEception - if the JMS provider fails to set the message listener due to some internal error.

See Also:
  getMessageListener()

public Message receive() throws JMSEception

receive
  return null

Throws JMSEception: JMS

receive

Message receive() throws JMSEception
Receives the next message produced for this message consumer.

This call blocks indefinitely until a message is produced or until this message consumer is closed.

If this `receive` is done within a transaction, the consumer retains the message until the transaction commits.

**Returns:**
the next message produced for this message consumer, or null if this message consumer is concurrently closed

**Throws:**
`JMSException` - if the JMS provider fails to receive the next message due to some internal error.

```java
public Message receive(long timeout) throws JMSException
```

```
    timeout 0
    return null
```

`timeout` of zero never expires, and the call blocks indefinitely.

Receives the next message that arrives within the specified timeout interval.

This call blocks until a message arrives, the timeout expires, or this message consumer is closed. A `timeout` of zero never expires, and the call blocks indefinitely.
Parameters:
- timeout - the timeout value (in milliseconds)

Returns:
- the next message produced for this message consumer, or null if the timeout expires or this message consumer is concurrently closed

Throws:
- JMSException - if the JMS provider fails to receive the next message due to some internal error.

public Message receiveNoWait() throws JMSException

return null

Throws JMSException: JMS

receiveNoWait

Message receiveNoWait()
throws JMSException

Receives the next message if one is immediately available.

Returns:
- the next message produced for this message consumer, or null if one is not available

Throws:
- JMSException - if the JMS provider fails to receive the next message due to some internal error.

public void close() throws JMSException

Java MessageConsumer

receive receive null
Throws  JMSException: JMS

close

void close() throws JMSException

Closes the message consumer.

Since a provider may allocate some resources on behalf of a MessageConsumer outside the Java virtual machine, clients should close them when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

This call blocks until a receive or message listener in progress has completed. A blocked message consumer receive call returns null when this message consumer is closed.

Throws:
  JMSException - if the JMS provider fails to close the consumer due to some internal error.

javax.mail Class MessageContext

javax.lang.Object
   ^javax.mail.MessageContext

public class MessageContext
extends Object

Message MessageAware getMessageContext Me
MessageAware DataSources DataContentHandler

since JavaMail 1.1

See javax.mail.MessageAware, javax.activation.DataSource,
also javax.activation.DataContentHandler

The context in which a piece of Message content is contained. A
MessageContext object is returned by the getMessageContext method of the
MessageAware interface. MessageAware is typically implemented by
DataSources to allow a DataContentHandler to pass on information about
the context in which a data content object is operating.

Since: JavaMail 1.1
See Also: MessageAware, DataSource, DataContentHandler

Method Summary

<table>
<thead>
<tr>
<th>boolean containsProperty(String name)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Returns true if the MessageContext contains a property with the specified name.</td>
</tr>
</tbody>
</table>
**getProperty** (String name)

Gets the value of a specific property from the MessageContext

**getPropertyNames**()

Returns an Iterator view of the names of the properties in this MessageContext

**removeProperty** (String name)

Removes a property (name-value pair) from the MessageContext

**setProperty** (String name, Object value)

Sets the name and value of a property associated with the MessageContext.

### Method Detail

**public void setProperty(String name, Object value)**

<table>
<thead>
<tr>
<th>MessageContext</th>
<th>MessageContext</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>MessageContext</td>
</tr>
<tr>
<td>value</td>
<td></td>
</tr>
</tbody>
</table>

Throws

- IllegalArgumentException:
- UnsupportedOperationException:

**setProperty**

void **setProperty**(String name, Object value)

Sets the name and value of a property associated with the MessageContext. If the MessageContext contains a value of the same property, the old value is replaced.

**Parameters:**

- name - Name of the property associated with the MessageContext
- value - Value of the property

**Throws:**
**IllegalArgumentException** - If some aspect of the property is prevents it from being stored in the context

**UnsupportedOperationException** - If this method is not supported.

---

```java
public Object getProperty(String name)
```

**MessageContext**

```java
    name
    return
    Throws IllegalArgumentException:
```  

**getProperty**

```java
Object getProperty(String name)
```

Gets the value of a specific property from the `MessageContext`

**Parameters:**

```java
    name - Name of the property whose value is to be retrieved
```  

**Returns:**

```java
    Value of the property
```  

**Throws:**

```java
    IllegalArgumentException - if an illegal property name is specified
```  

---

```java
public void removeProperty(String name)
```

**MessageContext**

```java
    name
    Throws IllegalArgumentException:
```  

**removeProperty**

```java
void removeProperty(String name)
```

Removes a property (name-value pair) from the `MessageContext`
public boolean containsProperty(String name)
    MessageContext true
    name
    return MessageContext true false

containsProperty

boolean containsProperty(String name)
    Returns true if the MessageContext contains a property with the specified name.

Parameters:
    name - Name of the property whose presence is to be tested

Returns:
    Returns true if the MessageContext contains the property; otherwise false

public java.util.Iterator<E> getPropertyNames()
    MessageContext Iterator
    return Iterator

getPropertyNames

Iterator getPropertyNames()
    Returns an Iterator view of the names of the properties in this
MessageContext

Returns:
Iterator for the property names

Constant Field Values

OUTBOUND_MESSAGE_ATTACHMENTS

static final String OUTBOUND_MESSAGE_ATTACHMENTS

Standard property: Map of attachments to a message for the outbound message, key is the MIME Content-ID, value is a DataHandler.

Type: java.util.Map

See Also:
Constant Field Values

WSDL_DESCRIPTION
static final String WSDL_DESCRIPTION

Type: org.xml.sax.InputSource

See Also:
Constant Field Values

WSDL_SERVICE

static final String WSDL_SERVICE

Standard property: name of WSDL service.

Type: javax.xml.namespace.QName

See Also:
Constant Field Values

WSDL_PORT

static final String WSDL_PORT

Standard property: name of WSDL port.

Type: javax.xml.namespace.QName

See Also:
Constant Field Values
WSDL_INTERFACE

static final String WSDL_INTERFACE

Standard property: name of wsdl interface (2.0) or port type (1.1).

Type: javax.xml.namespace.QName

See Also:
   Constant Field Values

--------------------------------------------------------

WSDL_OPERATION

static final String WSDL_OPERATION

Standard property: name of WSDL operation.

Type: javax.xml.namespace.QName

See Also:
   Constant Field Values

--------------------------------------------------------

HTTP_RESPONSE_CODE

static final String HTTP_RESPONSE_CODE

Standard property: HTTP response status code.

Type: java.lang.Integer

See Also:
   Constant Field Values

--------------------------------------------------------
HTTP_REQUEST_HEADERS

static final String HTTP_REQUEST_HEADERS

Standard property: HTTP request headers.

Type: java.util.Map

See Also: Constant Field Values

HTTP_RESPONSE_HEADERS

static final String HTTP_RESPONSE_HEADERS

Standard property: HTTP response headers.

Type: java.util.Map

See Also: Constant Field Values

HTTP_REQUEST_METHOD

static final String HTTP_REQUEST_METHOD

Standard property: HTTP request method.

Type: java.lang.String

See Also: Constant Field Values
SERVLET_REQUEST

static final String SERVLET_REQUEST

    Standard property: servlet request object.

    Type: javax.servlet.http.HttpServletRequest

See Also:
    Constant Field Values

SERVLET_RESPONSE

static final String SERVLET_RESPONSE

    Standard property: servlet response object.

    Type: javax.servlet.http.HttpServletResponse

See Also:
    Constant Field Values

SERVLET_CONTEXT

static final String SERVLET_CONTEXT

    Standard property: servlet context object.

    Type: javax.servlet.ServletContext

See Also:
Constant Field Values

QUERY_STRING

static final String QUERY_STRING

Standard property: Query string for request.
Type: String

See Also:
Constant Field Values

PATH_INFO

static final String PATH_INFO

Standard property: Request Path Info
Type: String

See Also:
Constant Field Values

Method Detail

setScope

void setScope(String name, MessageContext.Scope scope)
Sets the scope of a property.

**Parameters:**
- `name` - Name of the property associated with the `MessageContext` scope
- `scope` - Desired scope of the property

**Throws:**
- `IllegalArgumentException` - if an illegal property name is specified

---

getScope

`MessageContext.Scope getScope(String name)`

Gets the scope of a property.

**Parameters:**
- `name` - Name of the property

**Returns:**
- Scope of the property

**Throws:**
- `IllegalArgumentException` - if a non-existant property name is specified

---

**Method Detail**

final public static MessageContext.Scope[] values()
values

public static final MessageContext.Scope[] values()

    Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

    for(MessageContext.Scope c : MessageContext.Scope.values())
        System.out.println(c);

    Returns:
    an array containing the constants of this enum type, in the order they're declared

public static MessageContext.Scope.valueOf(String name)

valueOf

public static MessageContext.Scope.valueOf(String name)

    Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

Parameters:
    name - the name of the enum constant to be returned.

Returns:
    the enum constant with the specified name

Throws:
    IllegalArgumentException - if this enum type has no constant with the specified name

Implements: MessageCountListener

MessageCount

The adapter which receives MessageCount events. The methods in this class are empty; this class is provided as a convenience for easily creating listeners by extending this class and overriding only the methods of interest.

Author:
   John Mani

Constructor Detail

public MessageCountAdapter()

MessageCountAdapter

public MessageCountAdapter()

Method Detail

public void messagesAdded(MessageCountEvent e)

messagesAdded

public void messagesAdded(MessageCountEvent e)

Description copied from interface: MessageCountListener
Invoked when messages are added into a folder.

Specified by:
messagesAdded in interface MessageCountListener

public void messagesRemoved(MessageCountEvent e)
public void messagesRemoved(MessageCountEvent e)

Description copied from interface: MessageCountListener
Invoked when messages are removed (expunged) from a folder.

Specified by:
messagesRemoved in interface MessageCountListener
javax.mail.event  **Class MessageCountEvent**

**java.lang.Object**  
  ↳ **java.util.EventObject**  
    ↳ **javax.mail.event.MailEvent**  
      ↳ **javax.mail.event.MessageCountEvent**

**All Implemented Interfaces:**  
  **Serializable**

```java
public class MessageCountEvent
  extends MailEvent

**Extends:** java.util.EventObject > MailEvent
```

MessageCountEvent IMAP MessageCountEvent  
RFC 2060  
getMessageCount  
isConnected  ""

This class notifies changes in the number of messages in a folder.

Note that some folder types may only deliver MessageCountEvents at certain times or after certain operations. IMAP in particular will only notify the client of MessageCountEvents when a client issues a new command. Refer to RFC 2060 [http://www.ietf.org/rfc/rfc2060.txt](http://www.ietf.org/rfc/rfc2060.txt) for details. A client may want "poll" the folder by occasionally calling the `getMessageCount` or `isConnected` methods to solicit any such notifications.

Field Detail

**ADDED**

public static final int **ADDED**

The messages were added to their folder

**See Also:**

Constant Field Values

**REMOVED**

public static final int **REMOVED**

The messages were removed from their folder

**See Also:**

Constant Field Values
protected int type

    The event type.

protected boolean removed

    If true, this event is the result of an explicit expunge by this client, and the messages in this folder have been renumbered to account for this. If false, this event is the result of an expunge by external sources.

protected transient Message[] msgs

    The messages.

Constructor Detail

public MessageCountEvent(Folder folder, int type, boolean removed, Message[]msgs)

    folder
    type
    removed       true false
    msgs          /
MessageCountEvent

public MessageCountEvent(Folder folder, int type, boolean removed, Message[] msgs)

Constructor.

Parameters:
folder - The containing folder
type - The event type
removed - If true, this event is the result of an explicit expunge by this client, and the messages in this folder have been renumbered to account for this. If false, this event is the result of an expunge by external sources.
msgs - The messages added/removed

Method Detail

public int getType()

    return

getype

public int getType()

    Return the type of this event.

    Returns:
    type

class public boolean isRemoved()

    true
**isRemoved**

```java
public boolean isRemoved()
```

Indicates whether this event is the result of an explicit expunge by this client, or due to an expunge from external sources. If `true`, this event is due to an explicit expunge and hence all remaining messages in this folder have been renumbered. If `false`, this event is due to an external expunge.

Note that this method is valid only if the type of this event is `REMOVED`.

---

**getMessages**

```java
public Message[] getMessages()
```

Return the array of messages added or removed.

---

**dispatch**

```java
public void dispatch(Object listener)
```

Dispatch

**MessageCountListener**

---

**dispatch**
public void dispatch(Object listener)

Invokes the appropriate MessageCountListener method.

Specified by: dispatch in class MailEvent
java.mail.event Interface MessageCountListener

**abstract public ActivationConfigProperty[] activationConfig()**

```java
public abstract ActivationConfigProperty[] activationConfig
```

Activation config properties.

**Default:**
```
{}
```
abstract public String mappedName()
Bean JNDI

mappedName

public abstract String mappedName

A product specific name (e.g. global JNDI name of a queue) that this message-driven bean should be mapped to. Application servers are not required to support any particular form or type of mapped name, nor the ability to use mapped names. The mapped name is product-dependent and often installation-dependent. No use of a mapped name is portable.

</tr>
<tr>
<td>throws EJBException</td>
</tr>
</tbody>
</table>
Bean

`ctx` MessageDrivenContext

Throws **EJBException**: 

**setMessageDrivenContext**

```java
void setMessageDrivenContext(MessageDrivenContext ctx)
throws EJBException
```

Set the associated message-driven context. The container calls this
text after the instance creation.

The enterprise Bean instance should store the reference to the context object in an instance variable.

This method is called with no transaction context.

**Parameters:**

- `ctx` - A MessageDrivenContext interface for the instance.

**Throws:**

- **EJBException** - Thrown by the method to indicate a failure caused by a system-level error.

---

**public void ejbRemove() throws EJBException**

```java
Throws EJBException:
```
**ejbRemove**

```java
void ejbRemove() throws EJBException
```

A container invokes this method before it ends the life of the message-driven object. This happens when a container decides to terminate the message-driven object.

This method is called with no transaction context.

**Throws:**

- **EJBException** - Thrown by the method to indicate a failure caused by a system-level error.

PS:
public interface MessageEndpoint

version 1.0

This defines a contract for a message endpoint. This is implemented by an application server.

**Version:**
1.0

**Author:**
Ram Jeyaraman

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>void afterDelivery()</td>
</tr>
<tr>
<td>This is called by a resource adapter after a message is delivered.</td>
</tr>
<tr>
<td>void beforeDelivery(Method method)</td>
</tr>
<tr>
<td>This is called by a resource adapter before a message is delivered.</td>
</tr>
<tr>
<td>void release()</td>
</tr>
<tr>
<td>This method may be called by the resource adapter to indicate that it no longer needs a proxy endpoint instance.</td>
</tr>
</tbody>
</table>

**Method Detail**

public void beforeDelivery(Method method) throws
NoSuchMethodException, ResourceException

method
Throws NoSuchMethodException:
Throws ResourceException:
Throws ApplicationServerInternalException:
Throws IllegalStateException:
Throws UnavailableException:

beforeDelivery

void beforeDelivery(Method method)
throws NoSuchMethodException,
ResourceException

This is called by a resource adapter before a message is delivered.

Parameters:
method - description of a target method. This information about the intended target method allows an application server to decide whether to start a transaction during this method call, depending on the transaction preferences of the target method. The processing (by the application server) of the actual message delivery method call on the endpoint must be independent of the class loader associated with this descriptive method object.

Throws:
NoSuchMethodException - indicates that the specified method does not exist on the target endpoint.
ResourceException - generic exception.
ApplicationServerInternalException - indicates an error condition in the application server.
IllegalStateException - indicates that the endpoint is in an illegal state for the method invocation. For example, this occurs when beforeDelivery and afterDelivery method calls are not paired.
public void afterDelivery() throws ResourceException

<table>
<thead>
<tr>
<th>Throws</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResourceException:</td>
</tr>
<tr>
<td>ApplicationServerInternalException:</td>
</tr>
<tr>
<td>IllegalStateException: beforeDelivery afterDelivery</td>
</tr>
<tr>
<td>UnavailableException:</td>
</tr>
</tbody>
</table>

This is called by a resource adapter after a message is delivered.

Throws:

- ResourceException - generic exception.
- ApplicationServerInternalException - indicates an error condition in the application server.
- IllegalStateException - indicates that the endpoint is in an illegal state for the method invocation. For example, this occurs when beforeDelivery and afterDelivery method calls are not paired.
- UnavailableException - indicates that the endpoint is not available.

public void release()
void release() 

This method may be called by the resource adapter to indicate that it no longer needs a proxy endpoint instance. This hint may be used by the application server for endpoint pooling decisions.
javax.resource.spi.endpoint Interface MessageEndpointFactory

public interface MessageEndpointFactory

version 1.0

This serves as a factory for creating message endpoints.

Version: 1.0
Author: Ram Jeyaraman

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>createEndpoint(XAResource xaResource)</code></td>
</tr>
<tr>
<td><code>isDeliveryTransacted(Method method)</code></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>public <code>MessageEndpoint createEndpoint(XAResource xaResource)</code> throws <code>UnavailableException</code></td>
</tr>
</tbody>
</table>
createEndpoint

**MessageEndpoint** createEndpoint(XAResource xaResource)

Throws UnavailableException:

This is used to create a message endpoint. The message endpoint is expected to implement the correct message listener type.

**Parameters:**
- xaResource - an optional XAResource instance used to get transaction notifications when the message delivery is transacted.

**Returns:**
- a message endpoint instance.

**Throws:**
- UnavailableException - indicates a transient failure in creating a message endpoint. Subsequent attempts to create a message endpoint might succeed.

public boolean isDeliveryTransacted(Method method)

Throws NoSuchMethodException:

**Method**

Returns true

isDeliveryTransacted

boolean isDeliveryTransacted(Method method)

Throws NoSuchMethodException:
This is used to find out whether message deliveries to a target method on a message listener interface that is implemented by a message endpoint will be transacted or not. The message endpoint may indicate its transacted delivery preferences (at a per method level) through its deployment descriptor. The message delivery preferences must not change during the lifetime of a message endpoint.

**Parameters:**
- **method**: description of a target method. This information about the intended target method allows an application server to find out whether the target method call will be transacted or not.

**Returns:**
- true, if message endpoint requires transacted message delivery.

**Throws:**
- **NoSuchMethodException** - indicates that the specified method does not exist on the target endpoint.
javax.jms Class MessageEOFException

java.lang.Object
   \u2192 java.lang.Throwable
      \u2192 java.lang.Exception
         \u2192 javax.jms.JMSException
            \u2192 javax.jms.MessageEOFException

All Implemented Interfaces:
   Serializable

public class MessageEOFException extends JMSException

Extends: Throwable > Exception > JMSException

StreamMessage  BytesMessage
version  26 August 1998

This exception must be thrown when an unexpected end of stream has been reached when a StreamMessage or BytesMessage is being read.

Version:
   26 August 1998

Author:
   Rahul Sharma

See Also:
   Serialized Form

Constructor Summary

MessageEOFException(String reason)
   Constructs a MessageEOFException with the specified reason.
MessageEOFException(String reason, String errorCode)

Constructs a MessageEOFException with the specified reason and error code.

Method Summary

Methods inherited from class javax.jms.JMSException
getErrorCode, getLinkedException, setLinkedException

Methods inherited from class java.lang.Throwable
fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, initCause, printStackTrace, printStackTrace, printStackTrace, setStackTrace, toString

public MessageEOFException(String reason, String errorCode)

MessageEOFException

reason

errorCode

MessageEOFException

public MessageEOFException(String reason, String errorCode)

Constructs a MessageEOFException with the specified reason and error code.
public MessageEOFException(String reason)

MessageEOFException

public MessageEOFException(String reason)

Constructs a MessageEOFException with the specified reason. The error code defaults to null.

Parameters:
reason - a description of the exception
javax.xml.soap  **Class MessageFactory**

```java
java.lang.Object
  ^ javax.xml.soap.MessageFactory
public abstract class MessageFactory
  extends Object
```

A **factory for creating SOAPMessage objects.**

A SAAJ client can create a `MessageFactory` object using the method

```java
MessageFactory mf = MessageFactory.newInstance();
MessageFactory mf12 = MessageFactory.newInstance(SOAPConstants.SOAP_...
```

- `SOAPPart`
- `SOAPEnvelope`
- `SOAPBody`
- `SOAPHeader`

```java
MessageFactory.createMessage()
MessageFactory.createMessage(MimeHeaders, java.io.InputStream) --
InputStream   MimeHeaders
```

```java
MessageFactory
  newInstance
  MessageFactory
```
newInstance, as shown in the following lines of code.

```java
MessageFactory mf = MessageFactory.newInstance();
MessageFactory mf12 = MessageFactory.newInstance(SOAPConstants.SOAP_1_2_PROTOCOL);
```

All `MessageFactory` objects, regardless of how they are created, will produce `SOAPMessage` objects that have the following elements by default:

- A `SOAPPart` object
- A `SOAPEnvelope` object
- A `SOAPBody` object
- A `SOAPHeader` object

In some cases, specialized `MessageFactory` objects may be obtained that produce messages prepopulated with additional entries in the `SOAPHeader` object and the `SOAPBody` object. The content of a new `SOAPMessage` object depends on which of the two `MessageFactory` methods is used to create it.

- `createMessage()`
  This is the method clients would normally use to create a request message.
- `createMessage(MimeHeaders, java.io.InputStream)` -- message has content from the `InputStream` object and headers from the `MimeHeaders` object
  This method can be used internally by a service implementation to create a message that is a response to a request.

---

**Constructor Summary**

<table>
<thead>
<tr>
<th>MessageFactory()</th>
</tr>
</thead>
</table>

**Method Summary**

<table>
<thead>
<tr>
<th>createMessage()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Creates a new <code>SOAPMessage</code> object with the</td>
</tr>
<tr>
<td>abstract <code>SOAPMessage</code></td>
</tr>
</tbody>
</table>
SOAPPart, SOAPEnvelope, SOAPBody, and SOAPHeader objects.

Create Message

```java
createMessage(MimeHeaders headers, InputStream in)
```

Internalizes the contents of the given InputStream object into a new SOAPMessage object and returns the SOAPMessage object.

Message Factory

```java
newInstance()
```

Creates a new MessageFactory object that is an instance of the default implementation (SOAP 1.1). This method uses the following ordered lookup procedure to determine the MessageFactory implementation class to load: Use the javax.xml.soap.MessageFactory system property.

```java
newInstance(String protocol)
```

Creates a new MessageFactory object that is an instance of the specified implementation.

Methods inherited from class java.lang.Object

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Constructor Detail

```java
public MessageFactory()
```

MessageFactory

```java
public MessageFactory()
```

Method Detail

```java
public static MessageFactory newInstance() throws SOAPException
```
MessageFactory (SOAP 1.1)

- `javax.xml.soap.MessageFactory`
- JRE "lib/jaxm.properties" `java.util.Properties`

- Services API JAR Services API jar
  META-INF/services/javax.xml.soap.MessageFactory

- `SAAJMetaFactory MessageFactory`

  ```java
  return MessageFactory
  ```

  Throws `SOAPException: MessageFactory`

  See also `javax.xml.soap.SAAJMetaFactory`

`newInstance`

```java
public static MessageFactory newInstance() throws SOAPException
```

Creates a new `MessageFactory` object that is an instance of the default implementation (SOAP 1.1). This method uses the following ordered lookup procedure to determine the `MessageFactory` implementation class to load:

- Use the `javax.xml.soap.MessageFactory` system property.
- Use the properties file "lib/jaxm.properties" in the JRE directory. This configuration file is in standard `java.util.Properties` format and contains the fully qualified name of the implementation class with the key being the system property defined above.
- Use the Services API (as detailed in the JAR specification), if available, to determine the classname. The Services API will look for a classname in the file META-INF/services/javax.xml.soap.MessageFactory in jars available to the runtime.
- Use the `SAAJMetaFactory` instance to locate the `MessageFactory` implementation class.
Returns:
a new instance of a MessageFactory

Throws:
SOAPException - if there was an error in creating the default implementation of the MessageFactory.

See Also:
SAAJMetaFactory

---

```java
public static MessageFactory newInstance(String protocol)
throws SOAPException

MessageFactory SOAP 1.1  SOAP 1.2
createMessage MIME  SAAJMetaFactory
MessageFactory
return MessageFactory
protocol DYNAMIC_SOAP_PROTOCOLDEFAULT_
SOAP_1_1_PROTOCOL SOAP_1_2_PROTOCOL

Throws
SOAPException: MessageFactory
since SAAJ 1.3
See also javax.xml.soap.SAAJMetaFactory
```

**newInstance**

```java
public static MessageFactory newInstance(String protocol)
throws SOAPException

Creates a new MessageFactory object that is an instance of the specified implementation. May be a dynamic message factory, a SOAP 1.1 message factory, or a SOAP 1.2 message factory. A dynamic message factory creates messages based on the MIME headers specified as arguments to the createMessage method. This method uses the SAAJMetaFactory to locate the implementation class and create the MessageFactory instance.

Parameters:
protocol - a string constant representing the class of the
specified message factory implementation. May be either
DYNAMIC_SOAP_PROTOCOL, DEFAULT_SOAP_PROTOCOL (which is the
same as) SOAP_1_1_PROTOCOL, OR SOAP_1_2_PROTOCOL.

Returns:
a new instance of a MessageFactory

Throws:
SOAPException - if there was an error in creating the specified
implementation of MessageFactory.

Since:
SAAJ 1.3

See Also:
SAAJMetaFactory

abstract public SOAPMessage createMessage() throws
SOAPException

SOAPPart SOAPEnvelope SOAPBody SOAPHeader SOAPMessage

SOAPPart SOAP "" SOAPMessage
AttachmentPart XML AttachmentPart SOAPMessage

Throws
SOAPException: SOAP

Throws
UnsupportedOperationException: MessageFactory

DYNAMIC_SOAP_PROTOCOL

createMessage

public abstract SOAPMessage createMessage() throws SOAPException

Creates a new SOAPMessage object with the default SOAPPart,
SOAPEnvelope, SOAPBody, and SOAPHeader objects. Profile-specific
message factories can choose to prepopulate the SOAPMessage object
with profile-specific headers.
Content can be added to this message's SOAPPart object, and the message can be sent "as is" when a message containing only a SOAP part is sufficient. Otherwise, the SOAPMessage object needs to create one or more AttachmentPart objects and add them to itself. Any content that is not in XML format must be in an AttachmentPart object.

**Returns:**

- a new SOAPMessage object

**Throws:**

- SOAPException - if a SOAP error occurs
- UnsupportedOperationException - if the protocol of this MessageFactory instance IS DYNAMIC_SOAP_PROTOCOL

```java
abstract public SOAPMessage createMessage(MimeHeaders headers, java.io.InputStream in) throws java.io.IOException, SOAPException

InputStream SOAPMessage SOAPMessage
in
headers

return SOAPMessage InputStream

Throws java.io.IOException:

Throws SOAPException:

IllegalArgumentException: MessageFactory MIME

Throws headers SOAP_1_1_PROTOCOL SOAP_1_2_PROTOCOL

MessageFactory IllegalArgumentException

createMessage

public abstract SOAPMessage createMessage(MimeHeaders headers, InputStream in) throws IOException, SOAPException

Internalizes the contents of the given InputStream object into a new SOAPMessage object and returns the SOAPMessage object.
Parameters:

in - the InputStream object that contains the data for a message
headers - the transport-specific headers passed to the message
in a transport-independent fashion for creation of the message

Returns:

a new SOAPMessage object containing the data from the given
InputStream object

Throws:

IOException - if there is a problem in reading data from the input
stream
SOAPException - may be thrown if the message is invalid
IllegalArgumentException - if the MessageFactory requires one
or more MIME headers to be present in the headers parameter
and they are missing. MessageFactory implementations for
SOAP_1_1_PROTOCOL or SOAP_1_2_PROTOCOL must not throw
IllegalArgumentException for this reason.
javax.jms Class MessageFormatException

java.lang.Object
   ↳ java.lang.Throwable
      ↳ java.lang.Exception
         ↳ javax.jms.JMSException
            ↳ javax.jms.MessageFormatException

All Implemented Interfaces:
   Serializable

public class MessageFormatException
    extends JMSException

Extends: Throwable > Exception > JMSException

This exception must be thrown when a JMS client attempts to use a data type not supported by a message or attempts to read data in a message as the wrong type. It must also be thrown when equivalent type errors are made with message property values. For example, this exception must be thrown if StreamMessage.writeObject is given an unsupported class or if StreamMessage.readShort is used to read a boolean value. Note that the special case of a failure caused by an attempt to read improperly formatted string data as numeric values must throw the java.lang.NumberFormatException.

## Method Summary

Methods inherited from class `javax.jms.JMSException`:
- `getErrorCode`, `getLinkedException`, `setLinkedException`

Methods inherited from class `java.lang.Throwable`:
- `fillInStackTrace`, `getCause`, `getLocaleMessage`, `getMessage`, `getStackTrace`, `initCause`, `printStackTrace`, `printStackTrace`, `printStackTrace`, `setStackTrace`, `toString`

Methods inherited from class `java.lang.Object`:
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `wait`, `wait`, `wait`

## Constructor Detail

```java
public MessageFormatException(String reason, String errorCode)
```

`MessageFormatException`

`reason`

`errorCode`
MessageFormatException

public MessageFormatException(String reason, String errorCode)

Constructs a MessageFormatException with the specified reason and error code.

Parameters:
reason - a description of the exception
errorCode - a string specifying the vendor-specific error code

public MessageFormatException(String reason)
MessageFormatException null
reason

MessageFormatException

public MessageFormatException(String reason)

Constructs a MessageFormatException with the specified reason. The error code defaults to null.

Parameters:
reason - a description of the exception

RFC822 “MessageId” - Internet “-ID”“-ID”  
MessageId

MessageId  String

This term models the RFC822 "MessageId" - a message-id for Internet messages that is supposed to be unique per message. Clients can use this term to search a folder for a message given its MessageId.

The MessageId is represented as a String.

PS:
A `MessageListener` object is used to receive asynchronously delivered messages.

Each session must insure that it passes messages serially to the listener. This means that a listener assigned to one or more consumers of the same session can assume that the `onMessage` method is not called with the next message until the session has completed the last call.

PS:
javax.jms Interface MessageProducer

All Known Subinterfaces:
  QueueSender, TopicPublisher

public interface MessageProducer

Implemented by: QueueSender, TopicPublisher

  MessageProducer  Destination -  MessageProducer

  JMSReplyTo

GMT

JMS JMS API

version 1.1 - February 2, 2002

See also javax.jms.TopicPublisher, javax.jms.QueueSender, createProducer

A client uses a MessageProducer object to send messages to a destination. A MessageProducer object is created by passing a Destination object to a message-producer creation method supplied by a session.

MessageProducer is the parent interface for all message producers.

A client also has the option of creating a message producer without supplying a destination. In this case, a destination must be provided with every send operation. A typical use for this kind of message producer is to send replies to requests using the request's JMSReplyTo destination.
A client can specify a default delivery mode, priority, and time to live for messages sent by a message producer. It can also specify the delivery mode, priority, and time to live for an individual message.

A client can specify a time-to-live value in milliseconds for each message it sends. This value defines a message expiration time that is the sum of the message's time-to-live and the GMT when it is sent (for transacted sends, this is the time the client sends the message, not the time the transaction is committed).

A JMS provider should do its best to expire messages accurately; however, the JMS API does not define the accuracy provided.

</tbody>
</table>
public void setDisableMessageID(boolean value) throws JMSException

Sets whether message IDs are disabled.

Since message IDs take some effort to create and increase a message's size, some JMS providers may be able to optimize message overhead if they are given a hint that the message ID is not used by an application. By calling the setDisableMessageID method on this message producer, a JMS client enables this potential optimization for all messages sent by this message producer. If the JMS provider accepts this hint, these messages must have the message ID set to null; if the provider ignores the hint, the message ID must be set to its normal unique value.

Message IDs are enabled by default.

Parameters:
value - indicates if message IDs are disabled

Throws:
JMSException - if the JMS provider fails to set message ID to disabled due to some internal error.
public boolean getDisableMessageID() throws JMSException

    ID

    return ID

    Throws JMSException: JMS ID

getDisableMessageID

boolean getDisableMessageID() throws JMSException

    Gets an indication of whether message IDs are disabled.

    Returns:
    an indication of whether message IDs are disabled

    Throws:
    JMSException - if the JMS provider fails to determine if message IDs are disabled due to some internal error.

public void setDisableMessageTimestamp(boolean value) throws JMSException

    JMS setDisableMessageTimestamp JMS

    value

    Throws JMSException: JMS

setDisableMessageTimestamp

void setDisableMessageTimestamp(boolean value)
Sets whether message timestamps are disabled.

Since timestamps take some effort to create and increase a message's size, some JMS providers may be able to optimize message overhead if they are given a hint that the timestamp is not used by an application. By calling the `setDisableMessageTimestamp` method on this message producer, a JMS client enables this potential optimization for all messages sent by this message producer. If the JMS provider accepts this hint, these messages must have the timestamp set to zero; if the provider ignores the hint, the timestamp must be set to its normal value.

Message timestamps are enabled by default.

**Parameters:**

- `value` - indicates if message timestamps are disabled

**Throws:**

- `JMSException` - if the JMS provider fails to set timestamps to disabled due to some internal error.

```
public boolean getDisableMessageTimestamp() throws JMSException {
    return false;
}
```

**Throws:**

- `JMSException` - JMS

**getDisableMessageTimestamp**

```
boolean getDisableMessageTimestamp() throws JMSException {
    return false;
}
```

Gets an indication of whether message timestamps are disabled.

**Returns:**

- an indication of whether message timestamps are disabled
**Throws:**

`JMSException` - if the JMS provider fails to determine if timestamps are disabled due to some internal error.

---

**public void setDeliveryMode(int deliveryMode)** throws `JMSException`

**PERSISTENT**

| deliveryMode | DeliveryMode.NON_PERSISTENT | DeliveryMode.PERSISTENT |

**Throws**  
`JMSException`: JMS

**See also**

getDeliveryMode, NON_PERSISTENT, PERSISTENT, DEFAULT_DELIVERY_MODE

---

**setDeliveryMode**

```java
void setDeliveryMode(int deliveryMode)
```

void **setDeliveryMode**(int deliveryMode)  
throws `JMSException`

Sets the producer's default delivery mode.

Delivery mode is set to PERSISTENT by default.

**Parameters:**

deliveryMode - the message delivery mode for this message producer; legal values are DeliveryMode.NON_PERSISTENT and DeliveryMode.PERSISTENT

**Throws:**

`JMSException` - if the JMS provider fails to set the delivery mode due to some internal error.

**See Also:**

getDeliveryMode(), DeliveryMode.NON_PERSISTENT, DeliveryMode.PERSISTENT, Message.DEFAULT_DELIVERY_MODE
public int getDeliveryMode() throws JMSException

    return

    Throws JMSException: JMS

    See also setDeliveryMode

getDeliveryMode

int getDeliveryMode() throws JMSException

    Gets the producer's default delivery mode.

    Returns: the message delivery mode for this message producer

    Throws: JMSException - if the JMS provider fails to get the delivery mode due to some internal error.

    See Also: setDeliveryMode(int)

public void setPriority(int defaultPriority) throws JMSException

JMS API 10 0 9 0-4 5-9 4

defaultPriority 0 9

    Throws JMSException: JMS

    See also getPriority, DEFAULT_PRIORITY

setPriority

void setPriority(int defaultPriority)

    throws JMSException
Sets the producer's default priority.

The JMS API defines ten levels of priority value, with 0 as the lowest priority and 9 as the highest. Clients should consider priorities 0-4 as gradations of normal priority and priorities 5-9 as gradations of expedited priority. Priority is set to 4 by default.

**Parameters:**
- `defaultPriority` - the message priority for this message producer; must be a value between 0 and 9

**Throws:**
- `JMSException` - if the JMS provider fails to set the priority due to some internal error.

**See Also:**
- `getPriority()`, `Message.DEFAULT_PRIORITY`
public void setTimeToLive(long timeToLive) throws JMSException

0

timeToLive 0

Throws JMSException: JMS
See also getTimeToLive, DEFAULT_TIME_TO_LIVE

setTimeToLive

void setTimeToLive(long timeToLive)
throws JMSException

Sets the default length of time in milliseconds from its dispatch time that a produced message should be retained by the message system.

Time to live is set to zero by default.

Parameters:

timeToLive - the message time to live in milliseconds; zero is unlimited

Throws:

JMSException - if the JMS provider fails to set the time to live due to some internal error.

See Also:

getTimeToLive(), Message.DEFAULT_TIME_TO_LIVE

public long getTimeToLive() throws JMSException

return 0

Throws JMSException: JMS
See also setTimeToLive
**getTimeToLive**

```java
long getTimeToLive() throws JMSException
```

Gets the default length of time in milliseconds from its dispatch time that a produced message should be retained by the message system.

**Returns:**
the message time to live in milliseconds; zero is unlimited

**Throws:**
JMSException - if the JMS provider fails to get the time to live due to some internal error.

**See Also:**
setTimeToLive(long)

---

**public Destination getDestination() throws JMSException**

```java
MessageProducer return Destination/
```

**Throws**
JMSException: JMSMessageProducer

since 1.1

---

**getDestination**

```java
Destination getDestination() throws JMSException
```

Gets the destination associated with this MessageProducer.

**Returns:**
this producer's Destination/

**Throws:**
JMSException - if the JMS provider fails to get the destination for this MessageProducer due to some internal error.
public void close() throws JMSException

Java MessageProducer
Throws JMSException: JMS

close

void close()
throws JMSException

Closes the message producer.

Since a provider may allocate some resources on behalf of a MessageProducer outside the Java virtual machine, clients should close them when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

Throws:
JMSException - if the JMS provider fails to close the producer due to some internal error.

public void send(Message message) throws JMSException

MessageProducer
message
Throws JMSException: JMS
Throws MessageFormatException: MessageProducer
Throws InvalidDestinationException: MessageProducer
Throws UnsupportedOperationException: MessageProducer
since 1.1
See also createProducer, javax.jms.MessageProducer
send

void send(Message message)
    throws JMSException

Sends a message using the MessageProducer's default delivery mode, priority, and time to live.

Parameters:
message - the message to send

Throws:
    JMSException - if the JMS provider fails to send the message due to some internal error.
    MessageFormatException - if an invalid message is specified.
    InvalidDestinationException - if a client uses this method with a MessageProducer with an invalid destination.
    UnsupportedOperationException - if a client uses this method with a MessageProducer that did not specify a destination at creation time.

Since:
    1.1

See Also:
    Session.createProducer(javax.jms.Destination),
    MessageProducer

public void send(Message message, int deliveryMode, int priority, long timeToLive) throws JMSException

message
deliveryMode
priority
timeToLive

Throws
    JMSException: JMS
    MessageFormatException:
    InvalidDestinationException:
**send**

void `send(Message message, int deliveryMode, int priority, long timeToLive)`

throws `JMSException`

Sends a message to the destination, specifying delivery mode, priority, and time to live.

**Parameters:**
- `message` - the message to send
- `deliveryMode` - the delivery mode to use
- `priority` - the priority for this message
- `timeToLive` - the message's lifetime (in milliseconds)

**Throws:**
- `JMSException` - if the JMS provider fails to send the message due to some internal error.
- `MessageFormatException` - if an invalid message is specified.
- `InvalidDestinationException` - if a client uses this method with a `MessageProducer` with an invalid destination.
- `UnsupportedOperationException` - if a client uses this method with a `MessageProducer` that did not specify a destination at creation time.

**Since:**
1.1

**See Also:**
- `Session.createProducer(javax.jms.Destination)`

```
public void send(Destination destination, Message message) throws JMSException
```
send

void send(Destination destination, Message message) throws JMSException

Sends a message to a destination for an unidentified message producer. Uses the MessageProducer's default delivery mode, priority, and time to live.

Typically, a message producer is assigned a destination at creation time; however, the JMS API also supports unidentified message producers, which require that the destination be supplied every time a message is sent.

Parameters:
- destination - the destination to send this message to
- message - the message to send

Throws:
- JMSEception - if the JMS provider fails to send the message due to some internal error.
- MessageFormatException - if an invalid message is specified.
- InvalidDestinationException - if a client uses this method with
an invalid destination.

UnsupportedOperationException - if a client uses this method with a MessageProducer that specified a destination at creation time.

Since:
1.1

send

void send(Destination destination,
Message message,
int deliveryMode,
int priority,
long timeToLive)
throws JMSException
Sends a message to a destination for an unidentified message producer, specifying delivery mode, priority and time to live.

Typically, a message producer is assigned a destination at creation time; however, the JMS API also supports unidentified message producers, which require that the destination be supplied every time a message is sent.

**Parameters:**
- **destination** - the destination to send this message to
- **message** - the message to send
- **deliveryMode** - the delivery mode to use
- **priority** - the priority for this message
- **timeToLive** - the message's lifetime (in milliseconds)

**Throws:**
- **JMSException** - if the JMS provider fails to send the message due to some internal error.
- **MessageFormatException** - if an invalid message is specified.
- **InvalidDestinationException** - if a client uses this method with an invalid destination.

**Since:**
1.1

**See Also:**
- `Session.createProducer(javax.jms.Destination)`

Constructor Detail

public MessagingException()
MessagingException

MessagingException

public MessagingException()
    Constructs a MessagingException with no detail message.

public MessagingException(String s)
MessagingException
    s

MessagingException

public MessagingException(String s)
    Constructs a MessagingException with the specified detail message.

    Parameters:
    s - the detail message

public MessagingException(String s, Exception e)
Exception MessagingException
    s
    e
See also
    getNextException, getNextException, getCause

MessagingException
public MessagingException(String s, Exception e)

Constructs a MessagingException with the specified Exception and detail message. The specified exception is chained to this exception.

Parameters:
s - the detail message
e - the embedded exception

See Also:
getNextException(), setNextException(java.lang.Exception), getCause()

Method Detail

public Exception getNextException()

public Throwable getCause()
public Throwable getCause()

Overrides the getCause method of Throwable to return the next exception in the chain of nested exceptions.

Overrides: 

gCause in class Throwable

Returns: 

next Exception, null if none.

public boolean setNextException(Exception ex)

MessagingException

ex

return Exception true false

setNextException

public boolean setNextException(Exception ex)

Add an exception to the end of the chain. If the end is not a MessagingException, this exception cannot be added to the end.

Parameters:

ex - the new end of the Exception chain

Returns: 

true if this Exception was added, false otherwise.

public String toString()

toString

public String toString()
Override toString method to provide information on nested exceptions.

Overrides:

`toString` in class `Throwable`
javax.faces.el Class MethodBinding

java.lang.Object

| deprecated | javax.el.MethodExpression |

public abstract class MethodBinding
extends Object

MethodBinding is an object that can be used to call an arbitrary public method, on an instance that is acquired by evaluatng the leading portion of a method binding expression via a ValueBinding. An immutable MethodBinding for a particular method binding expression can be acquired by calling the createMethodBinding() method of the Application instance for this web application.

### MethodBinding

**public MethodBinding()**

**Deprecated.**

### Method Detail

```java
abstract public Object invoke(FacesContext context, Object[] params) throws EvaluationException, MethodNotFoundException
```

*FacesContext*
**invoke**

public abstract Object invoke(FacesContext context, Object[] params) throws EvaluationException, MethodNotFoundException, NullPointerException

Deprecated.

Return the return value (if any) resulting from a call to the method identified by this method binding expression, passing it the specified parameters, relative to the specified FacesContext.

**Parameters:**
- context - FacesContext for the current request
- params - Array of parameters to be passed to the called method, or null for no parameters

**Throws:**
- EvaluationException - if an exception is thrown by the called method (the thrown exception must be included as the cause property of this exception)
- MethodNotFoundException - if no suitable method can be found
- NullPointerException - if context is null

---

abstract public Class<T> getType(FacesContext context) throws MethodNotFoundException

Java

context - FacesContext

Throws - MethodNotFoundException:
Throws
NullPointerException: context null

**getExpressionString**

```java
public String getExpressionString()
```

**Deprecated.**

Return the (possibly null) expression String, with leading and trailing delimiters, from which this MethodBinding was built. The default implementation returns null.

PREV CLASS    NEXT CLASS
SUMMARY: NESTED | FIELD | CONSTR | METHOD |

FRAMES    NO FRAMES
DETAIL: FIELD | CONSTR | METHOD |
javax.el **Class MethodExpression**

`java.lang.Object`  
  `javax.el.Expression`  
  `javax.el.MethodExpression`

All Implemented Interfaces:  
`Serializable`

```java
public abstract class MethodExpression extends Expression

Extends: Expression

Expression

ExpressionFactory#createMethodExpression MethodExpression
  FunctionMapper ELContext

#MethodInfo #invoke ELContext ELResolver .
[] ELResolver#getValue base base null
PropertyNotFoundException property String
MethodExpression

Expression javadoc
since JSP 2.1
See `javax.el.ELResolver, javax.el.Expression`
also `javax.el.ExpressionFactory`
```

An Expression that refers to a method on an object.

The `ExpressionFactory#createMethodExpression(javax.el.ELContext, java.lang.String, java.lang.Class, java.lang.Class[])` method can be used to parse an expression string and return a concrete instance of `MethodExpression` that encapsulates the parsed expression. The
FunctionMapper is used at parse time, not evaluation time, so one is not needed to evaluate an expression using this class. However, the ELContext is needed at evaluation time.

The getMethodInfo(javax.el.ELContext) and invoke(javax.el.ELContext, java.lang.Object[]) methods will evaluate the expression each time they are called. The ELResolver in the ELContext is used to resolve the top-level variables and to determine the behavior of the . and [] operators. For any of the two methods, the ELResolver.getValue(javax.el.ELContext, java.lang.Object, java.lang.Object) method is used to resolve all properties up to but excluding the last one. This provides the base object on which the method appears. If the base object is null, a PropertyNotFoundException must be thrown. At the last resolution, the final property is then coerced to a String, which provides the name of the method to be found. A method matching the name and expected parameters provided at parse time is found and it is either queried or invoked (depending on the method called on this MethodExpression).

See the notes about comparison, serialization and immutability in the Expression javadocs.

Since:
JSP 2.1

    return MethodInfo

    Throws NullPointerException: context
    Throws PropertyNotFoundException:
    Throws MethodNotFoundException:
    Throws ELException: cause
getMethodInfo

public abstract MethodInfo getMethodInfo(ELContext context)

Evaluates the expression relative to the provided context, and returns information about the actual referenced method.

Parameters:
context - The context of this evaluation

Returns: 
an instance of MethodInfo containing information about the method the expression evaluated to.

Throws: 
NullPointerException - if context is null
PropertyNotFoundException - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.
MethodNotFoundException - if no suitable method can be found.
ELException - if an exception was thrown while performing property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

abstract public Object invoke(ELContext context, Object[] params)
String String
String expectedReturnType ELException EL
“1.18 ” String
true

context
params null
return void null
Throws NullPointerException: context null
Throws PropertyNotFoundException:
Throws MethodNotFoundException:
ELException: String MethodExpression
Throws expectedReturnType void String expectedReturnType
“1.18 ”
invoke

public abstract Object invoke(ELContext context, Object[] params)

If a String literal is specified as the expression, returns the String literal coerced to the expected return type of the method signature. An ELException is thrown if expectedReturnType is void or if the coercion of the String literal to the expectedReturnType yields an error (see Section "1.18 Type Conversion" of the EL specification). If not a String literal, evaluates the expression relative to the provided context, invokes the method that was found using the supplied parameters, and returns the result of the method invocation. Any parameters passed to this method is ignored if isLiteralText() is true.

Parameters:
- context - The context of this evaluation.
- params - The parameters to pass to the method, or null if no parameters.

Returns:
the result of the method invocation (null if the method has a void return type).

throws:
- NullPointerException - if context is null
- PropertyNotFoundException - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.
- MethodNotFoundException - if no suitable method can be found.
- ELException - if a String literal is specified and expectedReturnType of the MethodExpression is void or if the coercion of the String literal to the expectedReturnType yields an error (see Section "1.18 Type Conversion").
- ELException - if an exception was thrown while performing property or variable resolution. The thrown exception must be included as the cause property of this exception, if available. If
the exception thrown is an InvocationTargetException, extract its cause and pass it to the ELException constructor.

**Constructor Detail**

public MethodExpressionActionListener()

**MethodExpressionActionListener**

public MethodExpressionActionListener()

public MethodExpressionActionListener(MethodExpression methodExpression)

MethodExpression ValueChangeListener
MethodExpressionActionListener

public MethodExpressionActionListener(MethodExpression methodExpression)

Construct a ValueChangeListener that contains a MethodExpression.

Method Detail

public void processAction(ActionEvent actionEvent)
throws AbortProcessingException

Throws  
NullPointerException: NullPointerException
AbortProcessingException: NullPointerException  
JavaServer Face

processAction

public void processAction(ActionEvent actionEvent)
throws AbortProcessingException

Description copied from interface: ActionListener

Invoked when the action described by the specified ActionEvent occurs.

Specified by: processAction in interface ActionListener

Parameters:
actionEvent - The ActionEvent that has occurred

Throws:
NullPointeException
AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed
public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. **This method must not save the state of children and facets.** That is done via theStateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

```java
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be Serializable

**Specified by:**

saveState in interface StateHolder

public void restoreState(FacesContext context, Object state)

restoreState

public void restoreState(FacesContext context, Object state)
Description copied from interface: **StateHolder**

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.

**Specified by:**

`restoreState` in interface **StateHolder**

---

**public boolean isTransient()**

**isTransient**

**public boolean isTransient()**

Description copied from interface: **StateHolder**

If true, the Object implementing this interface must not participate in state saving or restoring.

**Specified by:**

`isTransient` in interface **StateHolder**

---

**public void setTransient(boolean newTransientValue)**

**setTransient**

**public void setTransient(boolean newTransientValue)**

Description copied from interface: **StateHolder**
Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

**Specified by:**

`setTransient` in interface `StateHolder`

**Parameters:**

`newTransientValue` - boolean pass `true` if this Object will participate in state saving or restoring, otherwise pass `false`.

### Constructor Detail

```java
public MethodExpressionValidator()
```

### MethodExpressionValidator

```java
public MethodExpressionValidator()
```
public MethodExpressionValidator
(MethodExpression methodExpression)

MethodExpressionValidator

public MethodExpressionValidator
(MethodExpression methodExpression)

Construct a Validator that contains a MethodExpression.

Method Detail

public void validate
(FacesContext context, UIComponent component, Object value)
throws ValidatorException

Throws
NullPointerException: NullPointe
context
component null

Throws
ValidatorException: NullPointerException

validate

public void validate
(FacesContext context, UIComponent component, Object value)
throws ValidatorException

Description copied from interface: Validator

Perform the correctness checks implemented by this Validator against the specified UIComponent. If any violations are found, a ValidatorException will be thrown containing the FacesMessage describing the failure.

Specified by:
validate in interface Validator
Parameters:
- `context` - FacesContext for the request we are processing
- `component` - UIComponent we are checking for correctness
- `value` - the value to validate

Throws:
- `NullPointerException` - if `context` or `component` is null
- `ValidatorException` - if validation fails

public `Object` `saveState(FacesContext` `context)`

Description copied from interface: `StateHolder`

Gets the state of the instance as a `Serializable` Object.

If the class that implements this interface has references to instances that implement `StateHolder` (such as a `UIComponent` with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext)` method on all those instances as well. **This method must not save the state of children and facets.** That is done via the `StateManager`

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be `Serializable`

**Specified by:**
- `saveState` in interface `StateHolder`
public void restoreState(FacesContext context, Object state)

**restoreState**

```java
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface:** StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

**Specified by:**

```
restoreState in interface StateHolder
```

---

public boolean isTransient()

**isTransient**

```java
public boolean isTransient()
```

**Description copied from interface:** StateHolder

If true, the Object implementing this interface must not participate in state saving or restoring.

**Specified by:**

```
isTransient in interface StateHolder
```
public void setTransient(boolean transientValue)

setTransient

public void setTransient(boolean transientValue)

Description copied from interface: StateHolder

Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

Specified by:

setTransient in interface StateHolder

Parameters:

transientValue - boolean pass true if this Object will participate in state saving or restoring, otherwise pass false.
javax.faces.event Class
MethodExpressionValueChangeListener

java.lang.Object
   | javax.faces.event.MethodExpressionValueChangeListener

All Implemented Interfaces:
   com.sun.faces.event.ActionListener,
   javax.faces.event.ValueChangeListener

public class MethodExpressionValueChangeListener
   extends Object
   implements ValueChangeListener, StateHolder

Implements: ValueChangeListener, StateHolder

MethodExpressionValueChangeListener is a ValueChangeListener that wraps a MethodExpression. When it receives a ValueChangeEvent, it executes a method on an object identified by the MethodExpression.

Constructor Summary

<table>
<thead>
<tr>
<th>Constructor</th>
</tr>
</thead>
<tbody>
<tr>
<td>MethodExpressionValueChangeListener()</td>
</tr>
<tr>
<td>MethodExpressionValueChangeListener(MethodExpression methodExpression)</td>
</tr>
</tbody>
</table>

   Construct a ValueChangeListener that contains a MethodExpression.

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>isTransient()</td>
</tr>
</tbody>
</table>

| boolean | If true, the Object implementing this interface must not participate in state saving or restoring. |
|-----------------------------------------------|
| void processValueChange(ValueChangeEvent valueChangeEvent) | Invoked when the value change described by the specified ValueChangeEvent occurs. |
| void restoreState(FacesContext context, Object state) | Perform any processing required to restore the state from the entries in the state Object. |
| Object saveState(FacesContext context) | Gets the state of the instance as a Serializable Object. |
| void setTransient(boolean newTransientValue) | Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring. |

```

**public MethodExpressionValueChangeListener()**

```
MethodExpressionValueChangeListener
```

**public MethodExpressionValueChangeListener(MethodExpression methodExpression)**

```
MethodExpression ValueChangeListener
```
MethodExpressionValueChangeListener

public MethodExpressionValueChangeListener(MethodExpression methodExpression)

Construct a ValueChangeListener that contains a MethodExpression.

Method Detail

public void processValueChange(ValueChangeEvent valueChangeEvent) throws AbortProcessingException

Throws

NullPointerException: NullPointerException

Throws

AbortProcessingException: NullPointerException JavaServer Face

processValueChange

public void processValueChange(ValueChangeEvent valueChangeEvent) throws AbortProcessingException

Description copied from interface: ValueChangeListener

Invoked when the value change described by the specified ValueChangeEvent occurs.

Specified by: ValueChangeListener

Parameters:

valueChangeEvent - The ValueChangeEvent that has occurred

Throws:

NullPointerException

AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed
public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. **This method must not save the state of children and facets.** That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

component should be the same as before executing it.

The return from this method must be Serializable

Specified by:

saveState in interface StateHolder

public void restoreState(FacesContext context, Object state)

restoreState

public void restoreState(FacesContext context, Object state)
Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by: 
restoreState in interface StateHolder

---

public boolean isTransient()

isTransient

public boolean isTransient()  

Description copied from interface: StateHolder

If true, the Object implementing this interface must not participate in state saving or restoring.

Specified by:  
isTransient in interface StateHolder

---

public void setTransient(boolean newTransientValue)

setTransient

public void setTransient(boolean newTransientValue)

Description copied from interface: StateHolder
Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

**Specified by:**
setTransient in interface StateHolder

**Parameters:**
newTransientValue - boolean pass true if this Object will participate in state saving or restoring, otherwise pass false.

Constructor Detail

MethodInfo

public MethodInfo(String name,
                   Class<? extends ?> returnType,
                   Class<? extends []> paramTypes)

Creates a new instance of MethodInfo with the given information.

Parameters:
- name - The name of the method
- returnType - The return type of the method
- paramTypes - The types of each of the method's parameters

Method Detail

public String getName()

    return

dgetName

public String getName()

Returns the name of the method

Returns:
the name of the method
public Class<T> getReturnType()
    
    return

getReturnType

public Class<?> getReturnType()

    Returns the return type of the method

    Returns:
        the return type of the method

public Class<T>[] getParamTypes()

    return

getParamTypes

public Class<?>[] getParamTypes()

    Returns the parameter types of the method

    Returns:
        the parameter types of the method
PS:

MethodNotFoundException

message
MethodNotFoundException

public MethodNotFoundException(String message)

    Creates a MethodNotFoundException with the provided detail message.

    Parameters:
    message - the detail message

public MethodNotFoundException(Throwable exception)

    MethodNotFoundException
    exception

MethodNotFoundException

public MethodNotFoundException(Throwable exception)

    Creates a MethodNotFoundException with the given root cause.

    Parameters:
    exception - the originating cause of this exception

public MethodNotFoundException(String pMessage, Throwable pRootCause)

    MethodNotFoundException
    pMessage
    pRootCause

MethodNotFoundException

public MethodNotFoundException(String pMessage,
(Throwable pRootCause)

Creates a MethodNotFoundException with the given detail message and root cause.

**Parameters:**

- `pMessage` - the detail message
- `pRootCause` - the originating cause of this exception
javax.faces.el Class MethodNotFoundException

MimeUtility  setHeader   addHeader   addHeaderLine MIME
SMTP 1000

See also
   javax.mail.Part, javax.mail.internet.MimePart,
   javax.mail.internet.MimeUtility

This class represents a MIME body part. It implements the BodyPart
abstract class and the MimePart interface. MimeBodyParts are contained in MimeMultipart objects.

MimeBodyPart uses the InternetHeaders class to parse and store the headers of that body part.

A note on RFC 822 and MIME headers

RFC 822 header fields must contain only US-ASCII characters. MIME allows non ASCII characters to be present in certain portions of certain headers, by encoding those characters. RFC 2047 specifies the rules for doing this. The MimeUtility class provided in this package can be used to achieve this. Callers of the setHeader, addHeader, and addHeaderLine methods are responsible for enforcing the MIME requirements for the specified headers. In addition, these header fields must be folded (wrapped) before being sent if they exceed the line length limitation for the transport (1000 bytes for SMTP). Received headers may have been folded. The application is responsible for folding and unfolding headers as appropriate.

protected InternetHeaders headers

The InternetHeaders object that stores all the headers of this body part.

Fields inherited from class javax.mail.BodyPart

parent

Fields inherited from interface javax.mail.Part

ATTACHMENT, INLINE

Constructor Summary

MimeBodyPart()

An empty MimeBodyPart object is created.

MimeBodyPart(InputStream is)

Constructs a MimeBodyPart by reading and parsing the data from the specified input stream.

MimeBodyPart(InternetHeaders headers, byte[] content)

Constructs a MimeBodyPart using the given header and content bytes.

Method Summary

void addHeader(String name, String value)

Add this value to the existing values for this header_name.

void addHeaderLine(String line)

Add a header line to this body part

void attachFile(File file)

Use the specified file to provide the data for this part.

void attachFile(String file)

Use the specified file to provide the data for this part.

Enumeration getAllHeaderLines()

Get all header lines as an Enumeration of Strings.
<table>

<td>Convenience method that sets the given String as this part's content, with a primary MIME type of &quot;text&quot; and the specified MIME subtype.</td>
</tr>
</tbody>
</table>
protected void updateHeaders()

Examine the content of this body part and update the appropriate MIME headers.

void writeTo(OutputStream os)

Output the body part as an RFC 822 format stream.

Methods inherited from class javax.mail.BodyPart
getParent

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Field Detail

dh

protected DataHandler dh

The DataHandler object representing this Part's content.

content

protected byte[] content

Byte array that holds the bytes of the content of this Part.

contentStream
protected InputStream contentStream

If the data for this body part was supplied by an InputStream that implements the SharedInputStream interface, contentStream is another such stream representing the content of this body part. In this case, content will be null.

Since:
JavaMail 1.2

headers

protected InternetHeaders headers

The InternetHeaders object that stores all the headers of this body part.

Constructor Detail

public MimeBodyPart()

An empty MimeBodyPart object is created. This body part maybe filled in by a client constructing a multipart message.

public MimeBodyPart(java.io.InputStream is) throws MessagingException

MimeBodyPart MIME
MimeBodyPart

public MimeBodyPart(InputStream is) throws MessagingException

Constructs a MimeBodyPart by reading and parsing the data from the specified input stream. The parser consumes data till the end of the given input stream. The input stream must start at the beginning of a valid MIME body part and must terminate at the end of that body part.

Note that the "boundary" string that delimits body parts must not be included in the input stream. The intention is that the MimeMultipart parser will extract each body part's bytes from a multipart stream and feed them into this constructor, without the delimiter strings.

Parameters:

is - the body part Input Stream

Throws:

MessagingException

public MimeBodyPart(InternetHeaders headers, byte[] content) throws MessagingException

---

MimeBodyPart
public MimeBodyPart(InternetHeaders headers, byte[] content)
throws MessagingException

Constructs a MimeBodyPart using the given header and content bytes.

Used by providers.

**Parameters:**
- headers - The header of this part
- content - bytes representing the body of this part.

**Throws:**
- MessagingException

### Method Detail

**public int getSize() throws MessagingException**
-1

```
content null      contentStream null      available
-1
return -1
```

**getSize**

public int getSize()
throws MessagingException

Return the size of the content of this body part in bytes. Return -1 if the size cannot be determined.

Note that this number may not be an exact measure of the content size and may or may not account for any transfer encoding of the
content.

This implementation returns the size of the content array (if not null),
or, if contentStream is not null, and the available method returns a
positive number, it returns that number as the size. Otherwise, it
returns -1.

Specified by:
getSize in interface Part

Returns:
size in bytes, or -1 if not known

Throws:
MessagingException

public int getLineCount() throws MessagingException
Part -1

-1
    return -1

getLineCount

public int getLineCount()
    throws MessagingException

Return the number of lines for the content of this Part. Return -1 if
this number cannot be determined.

Note that this number may not be an exact measure of the content
length and may or may not account for any transfer encoding of the
content.

This implementation returns -1.
public String getContentType() throws MessagingException

RFC 822 "Content-Type" null
"text/plain"

    getHeader(name)
    return Content-Type

getContentType

public String getContentType() throws MessagingException

Returns the value of the RFC 822 "Content-Type" header field. This represents the content type of this body part. This value must not be null. If this field is unavailable, "text/plain" should be returned.

This implementation uses getHeader(name) to obtain the requisite header field.

Specified by: getContentType in interface Part

Returns: Content-Type of this body part

Throws: MessagingException

See Also: DataHandler
public boolean isMimeType(String mimeType) throws MessagingException

Part MIME primaryType subType

"text/plain" "text/plain; charset=foobar"

true

mimeType subType '*' subtype

isMimeType

public boolean isMimeType(String mimeType) throws MessagingException

Is this Part of the specified MIME type? This method compares only the primaryType and subType. The parameters of the content types are ignored.

For example, this method will return true when comparing a Part of content type "text/plain" with "text/plain; charset=foobar".

If the subType of mimeType is the special character '*', then the subtype is ignored during the comparison.

Specified by:

isMimeType in interface Part

Throws:

MessagingException

public String getDisposition() throws MessagingException
"Content-Disposition" disposition disposition

Content-Disposition null
getDisposition

public String getDisposition()
    throws MessagingException

    Returns the value of the "Content-Disposition" header field. This represents the disposition of this part. The disposition describes how the part should be presented to the user.

    If the Content-Disposition field is unavailable, null is returned.

    This implementation uses getHeader(name) to obtain the requisite header field.

Specify by:
    getDisposition in interface Part

Returns:
    disposition of this part, or null if unknown

Throws:
    MessagingException

See Also:
    headers

public void setDisposition(String disposition) throws MessagingException
"Content-Disposition" disposition null
"Content-Disposition"

    Throws IllegalArgumentException:
    Throws IllegalStateException: READ_ONLY
public void setDisposition(String disposition) throws MessagingException

Set the "Content-Disposition" header field of this body part. If the disposition is null, any existing "Content-Disposition" header field is removed.

Specified by:
   setDisposition in interface Part

Parameters:
   disposition - disposition of this part

Throws:
   IllegalWriteException - if the underlying implementation does not support modification
   IllegalStateException - if this body part is obtained from a READ_ONLY folder.
   MessagingException

See Also:
   Part.ATTACHMENT, Part.INLINE,
   Part.setFileName(java.lang.String)

public String getEncoding() throws MessagingException
"Content-Transfer-Encoding"

   getHeader(name)
   See also headers

getcoding

public String getEncoding() throws MessagingException

Returns the content transfer encoding from the "Content-Transfer-Encoding" header field. Returns null if the header is unavailable or its value is absent.
This implementation uses `getHeader(name)` to obtain the requisite header field.

**Specified by:**
- `getEncoding` in interface `MimePart`

**Returns:**
- `content-transfer-encoding`

**Throws:**
- `MessagingException`

**See Also:**
- `headers`

```java
public String getContentID() throws MessagingException {
    return null;
}
```

### getContentID

**public String getContentID() throws MessagingException**

Returns the value of the "Content-ID" header field. Returns `null` if the field is unavailable or its value is absent.

This implementation uses `getHeader(name)` to obtain the requisite header field.

**Specified by:**
- `getContentID` in interface `MimePart`

**Returns:**
- `content-ID`

**Throws:**
- `MessagingException`
public void setContentID(String cid) throws MessagingException

"Content-ID" cid null "Content-ID"

Throws IllegalWriteException:

Throws IllegalStateException: READ_ONLY

Throws MessagingException:

since JavaMail 1.3

setContentID

public void setContentID(String cid) throws MessagingException

Set the "Content-ID" header field of this body part. If the cid parameter is null, any existing "Content-ID" is removed.

Throws:

IllegalWriteException - if the underlying implementation does not support modification

IllegalStateException - if this body part is obtained from a READ_ONLY folder.

MessagingException

Since:

JavaMail 1.3

public String getContentMD5() throws MessagingException

"Content-MD5"

getHeader(name)

getContentMD5

public String getContentMD5() throws MessagingException

null
Return the value of the "Content-MD5" header field. Returns null if this field is unavailable or its value is absent.

This implementation uses getHeader(name) to obtain the requisite header field.

Specified by:
getContentMD5 in interface MimePart

Returns:
content-MD5

Throws:
MessagingException

public void setContentMD5(String md5) throws MessagingException
"Content-MD5"

Throws: IllegalWriteException:
Throws IllegalStateException: READ_ONLY

setContentMD5

public void setContentMD5(String md5)

throws MessagingException

Set the "Content-MD5" header field of this body part.

Specified by:
setContentMD5 in interface MimePart

Parameters:
md5 - the MD5 value

Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this body part is obtained from a READ_ONLY folder.
MessagingException
public String[] getContentLanguage() throws MessagingException

MimePart  Content-Language  Content-Language  RFC 1766  null

getHeader(name)

getContentLanguage

public String[] getContentLanguage() throws MessagingException

Get the languages specified in the Content-Language header of this MimePart. The Content-Language header is defined by RFC 1766. Returns null if this header is not available or its value is absent.

This implementation uses getHeader(name) to obtain the requisite header field.

Specified by:

getContentLanguage in interface MimePart

Throws:

MessagingException

public void setContentLanguage(String[] languages) throws MessagingException

MimePart  Content-Language  Content-Language  RFC 1766

languages

setContentLanguage

public void setContentLanguage(String[] languages) throws MessagingException
Set the Content-Language header of this MimePart. The Content-Language header is defined by RFC 1766.

**Specified by:**
`setContentLanguage` in interface `MimePart`

**Parameters:**
- `languages` - array of language tags

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification
- `MessagingException`

```java
public String getDescription() throws MessagingException
"Content-Description" null

Content-Description RFC 2047 Unicode

    getHeader(name)
    return

getDescription

public String getDescription() throws MessagingException

    Returns the "Content-Description" header field of this body part. This typically associates some descriptive information with this part. Returns null if this field is unavailable or its value is absent.

    If the Content-Description field is encoded as per RFC 2047, it is decoded and converted into Unicode. If the decoding or conversion fails, the raw data is returned as is.

    This implementation uses `getHeader(name)` to obtain the requisite header field.
```
public void setDescription(String description) throws MessagingException

"Content-Description" description

"Content-Description"

description US-ASCII description US-ASCII

MessagingException MessagingException
UnsupportedEncodingException

Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:
UnsupportedEncodingException

setDescription

public void setDescription(String description) throws MessagingException

Set the "Content-Description" header field for this body part. If the description parameter is null, then any existing "Content-Description" fields are removed.

If the description contains non US-ASCII characters, it will be encoded using the platform's default charset. If the description
contains only US-ASCII characters, no encoding is done and it is used as is.

Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.

**Specified by:**

`setDescription` in interface `Part`  

**Parameters:**

- `description` - content description

**Throws:**

- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this body part is obtained from a READ_ONLY folder.  
- `MessagingException` - otherwise; an UnsupportedEncodingException may be included in the exception chain if the charset conversion fails.

```java
class MyClass {
    public void setDescription(String description, String charset) throws MessagingException {
        "Content-Description" description "Content-Description"
        description US-ASCII description US-ASCII
        MessagingException MessagingException UnsupportedEncodingException

        description
        charset
        throws IllegalWriteException:
        Throws IllegalStateException: READ_ONLY
        MessagingException:
    }
}
```
setDescription

public void setDescription(String description, String charset)
    throws MessagingException

Set the "Content-Description" header field for this body part. If the description parameter is null, then any existing "Content-Description" fields are removed.

If the description contains non US-ASCII characters, it will be encoded using the specified charset. If the description contains only US-ASCII characters, no encoding is done and it is used as is.

Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.

Parameters:
    description - Description
    charset - Charset for encoding

 Throws:
    IllegalWriteException - if the underlying implementation does not support modification
    IllegalStateException - if this body part is obtained from a READ_ONLY folder.
    MessagingException - otherwise; an UnsupportedEncodingException may be included in the exception chain if the charset conversion fails.

public String getFileName() throws MessagingException
getFileName

```java
public String getFileName() throws MessagingException {
    Get the filename associated with this body part.

    Returns the value of the "filename" parameter from the "Content-Disposition" header field of this body part. If its not available, returns the value of the "name" parameter from the "Content-Type" header field of this body part. Returns null if both are absent.

    If the mail.mime.encodefilename System property is set to true, the MimeUtility.decodeText method will be used to decode the filename. While such encoding is not supported by the MIME spec, many mailers use this technique to support non-ASCII characters in filenames. The default value of this property is false.

    Specified by: getFileName in interface Part

    Returns: filename

    Throws: MessagingException
```

public void setFileName(String filename) throws MessagingException
"Content-Disposition" "filename" "Content-Type" "name"

mail.mime.encodefilename true
MimeUtility.encodeText MIME ASCII
false

Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY

setFileName

public void setFileName(String filename)
    throws MessagingException

Set the filename associated with this body part, if possible.

Sets the "filename" parameter of the "Content-Disposition" header field of this body part. For compatibility with older mailers, the "name" parameter of the "Content-Type" header is also set.

If the mail.mime.encodefilename System property is set to true, the MimeUtility.encodeText method will be used to encode the filename. While such encoding is not supported by the MIME spec, many mailers use this technique to support non-ASCII characters in filenames. The default value of this property is false.

Specified by:
    setFileName in interface Part

Parameters:
    filename - Filename to associate with this part

Throws:
    IllegalWriteException - if the underlying implementation does not support modification
    IllegalStateException - if this body part is obtained from a
public java.io.InputStream getInputStream() throws java.io.IOException, MessagingException "content"

DataHandler getDataHandler().getInputStream();

return InputStream

Throws MessagingException:

Throws java.io.IOException: DataHandler

javax.activation.DataHandler

See also getContentStream, getInputStream

getInputStream

public InputStream getInputStream()

throws IOException, MessagingException

Return a decoded input stream for this body part's "content".

This implementation obtains the input stream from the DataHandler. That is, it invokes getDataHandler().getInputStream();

Specified by:

getInputStream in interface Part

Returns:

an InputStream

Throws:

MessagingException

IOException - this is typically thrown by the DataHandler. Refer to the documentation for javax.activation.DataHandler for more details.

See Also:
**protected java.io.InputStream getContentStream() throws MessagingException**

DataHandler Part

See also content, getContentStream

---

**getContentStream**

protected InputStream getContentStream() throws MessagingException

Produce the raw bytes of the content. This method is used when creating a DataHandler object for the content. Subclasses that can provide a separate input stream for just the Part content might want to override this method.

**Throws:** MessagingException

**See Also:**
content, MimeMessage.getContentStream()
**getRawInputStream**

```java
public InputStream getRawInputStream() throws MessagingException
```

Return an InputStream to the raw data with any Content-Transfer-Encoding intact. This method is useful if the "Content-Transfer-Encoding" header is incorrect or corrupt, which would prevent the getInputStream method or getContent method from returning the correct data. In such a case the application may use this method and attempt to decode the raw data itself.

This implementation simply calls the getContentStream method.

**Throws:**
- MessagingException

**Since:**
JavaMail 1.2

**See Also:**
- getInputStream(), getContentStream()

---

**getDataHandler()**

```java
public DataHandler getDataHandler() throws MessagingException
```

Return a DataHandler for this body part's content.

**getDataHandler**

```java
public DataHandler getDataHandler() throws MessagingException
```

**See also**
- getDataHandler
The implementation provided here works just like the implementation in MimeMessage.

**Specified by:**
*getDataHandler* in interface *Part*

**Returns:**
DataHandler for the content

**Throws:**
*MessagingException*

**See Also:**
*MimeMessage.getDataHandler()*

```java
public Object getContent() throws java.io.IOException, MessagingException,
   java.activation.DataHandler

Java text/plain  String "multipart"
Multipart  DataHandler

DataHandler getDataHandler().getContent()
Multipart  Message
return

Throws *MessagingException;*

Throws java.io.IOException:  DataHandler
   javax.activation.DataHandler
```

**getContent**

```java
public Object getContent() throws IOException, MessagingException
```

Return the content as a Java object. The type of the object returned is of course dependent on the content itself. For example, the native format of a text/plain content is usually a String object. The native format for a "multipart" content is always a Multipart subclass. For content types that are unknown to the DataHandler system, an input
stream is returned as the content.

This implementation obtains the content from the DataHandler. That is, it invokes `getDataHandler().getContent();` If the content is a Multipart or Message object and was created by parsing a stream, the object is cached and returned in subsequent calls so that modifications to the content will not be lost.

**Specified by:**

`getContent` in interface `Part`

**Returns:**

Object

**Throws:**

`MessagingException`

`IOException` - this is typically thrown by the DataHandler. Refer to the documentation for `javax.activation.DataHandler` for more details.

**See Also:**

`DataHandler.getContent()`

---

**public void setDataHandler(DataHandler dh) throws MessagingException**

**DataHandler**

`dh` DataHandler

**Throws**

`IllegalWriteException`:

**Throws**

`IllegalStateException`: `READ_ONLY`

**setDataHandler**

**public void setDataHandler(DataHandler dh) throws MessagingException**

This method provides the mechanism to set this body part's content. The given DataHandler object should wrap the actual content.

**Specified by:**

`setDataHandler` in interface `Part`
Parameters:
   dh - The DataHandler for the content

Throws:
   IllegalArgumentException - if the underlying implementation does not support modification
   IllegalStateException - if this body part is obtained from a READ_ONLY folder.
   MessagingException

public void setContent(Object o, String type) throws MessagingException

DataHandler DataContentHandler JavaMail
setContent(foobar, "application/x-foobar")

DataContentHandler Java Activation Framework

"application/x-foobar" DataContentHandler Java

A convenience method for setting this body part's content.

The content is wrapped in a DataHandler object. Note that a DataContentHandler class for the specified type should be available to the JavaMail implementation for this to work right. That is, to do setContent(foobar, "application/x-foobar"), a DataContentHandler for "application/x-foobar" should be installed.
Refer to the Java Activation Framework for more information.

Specified by:

`setContent` in interface `Part`

Parameters:

- `o` - the content object
- `type` - Mime type of the object

Throws:

- `IllegalArgumentException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this body part is obtained from a `READ_ONLY` folder.
- `MessagingException`  

```java
public void setText(String text) throws MessagingException
MIME "text/plain" String US-ASCII
"charset"

text

charset setText

text

Throws

See also

setText(String text, String charset)
```

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain". If the string contains non US-ASCII characters, it will be encoded using the platform's default charset. The charset is also used to set the "charset" parameter.
Note that there may be a performance penalty if `text` is large, since this method may have to scan all the characters to determine what charset to use.

If the charset is already known, use the `setText` method that takes the charset parameter.

**Specified by:**
- `setText` in interface `MimePart`

**Specified by:**
- `setText` in interface `Part`

**Parameters:**
- `text` - the text content to set

**Throws:**
- `MessagingException` - if an error occurs

**See Also:**
- `setText(String text, String charset)`

```
public void setText(String text, String charset) throws MessagingException
MIME "text/plain" String Unicode
"charset"

    text
    charset

Throws                MessagingException:

setText

public void setText(String text, String charset)
    throws MessagingException

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain" and the specified charset. The given Unicode string will be charset-encoded using the specified charset. The charset is also used to set the "charset" parameter.
public void setText(String text, String charset, String subtype) throws MessagingException

MIME "text" MIME String Unicode "charset"

Convenience method that sets the given String as this part's content, with a primary MIME type of "text" and the specified MIME subtype. The given Unicode string will be charset-encoded using the specified charset. The charset is also used to set the "charset" parameter.

Specified by:
	setText in interface MimePart

Parameters:

text - the text content to set
charset - the charset to use for the text
subtype - the MIME subtype to use (e.g., "html")
public void setContent(Multipart mp) throws MessagingException

Multipart

mp Message multipart
Throws IllegalArgumentException:
Throws IllegalStateException: READ_ONLY

setContent

public void setContent(Multipart mp)
throws MessagingException

This method sets the body part's content to a Multipart object.

Specified by:
setContent in interface Part

Parameters:
mp - The multipart object that is the Message's content

Throws:
IllegalArgumentException - if the underlying implementation does not support modification of existing values.
IllegalStateException - if this body part is obtained from a READ_ONLY folder.
MessagingException

public void attachFile(java.io.File file) throws java.io.IOException, MessagingException

file File

Throws java.io.IOException:
public void attachFile(String file)
throws java.io.IOException, MessagingException

Use the specified file to provide the data for this part. The file name is used as the file name for this part and the data in the file is used as the data for this part. The encoding will be chosen appropriately for the file data.

Parameters:

- file - the File object to attach

Throws:

- java.io.IOException - errors related to accessing the file
- MessagingException - message related errors

Since:
JavaMail 1.4
Use the specified file to provide the data for this part. The simple file name is used as the file name for this part and the data in the file is used as the data for this part. The encoding will be chosen appropriately for the file data.

**Parameters:**
- `file` - the name of the file to attach

**Throws:**
- `IOException` - errors related to accessing the file
- `MessagingException` - message related errors

**Since:**
JavaMail 1.4

```java
public void saveFile(java.io.File file) throws java.io.IOException, MessagingException
```

MIME

<table>
<thead>
<tr>
<th>file</th>
<th>File</th>
</tr>
</thead>
</table>

**Throws**

- `IOException`: errors related to accessing the file
- `MessagingException`: message related errors

**since**
JavaMail 1.4

Save the contents of this part in the specified file. The content is decoded and saved, without any of the MIME headers.

**Parameters:**
- `file` - the File object to write to

**Throws:**
- `IOException` - errors related to accessing the file
- `MessagingException` - message related errors

**Since:**
public void saveFile(String file) throws java.io.IOException, MessagingException

MIME

file

Throws java.io.IOException: 
Throws MessagingException: 
since JavaMail 1.4

saveFile

public void saveFile(String file) throws IOException, MessagingException

Save the contents of this part in the specified file. The content is decoded and saved, without any of the MIME headers.

Parameters:
file - the name of the file to write to

Throws:
IOException - errors related to accessing the file
MessagingException - message related errors

Since:
JavaMail 1.4

public void writeTo(java.io.OutputStream os) throws java.io.IOException, MessagingException
RFC 822

Throws MessagingException: 
Throws java.io.IOException: javax.activation
See also writeTo
**writeTo**

```java
public void writeTo(OutputStream os)
throws IOException, MessagingException
```

Output the body part as an RFC 822 format stream.

**Specified by:**
writeTo in interface Part

**Throws:**
MessagingException
IOException - if an error occurs writing to the stream or if an error is generated by the javax.activation layer.

**See Also:**
DataHandler.writeTo(java.io.OutputStream)

---

**public String[] getHeader(String name) throws MessagingException**

**header_name** US-ASCII RFC 2047

- **name**
- **return**

See also
javax.mail.internet.MimeUtility

**getHeader**

```java
public String[] getHeader(String name)
throws MessagingException
```

Get all the headers for this header_name. Note that certain headers may be encoded as per RFC 2047 if they contain non US-ASCII characters and these should be decoded.

**Specified by:**
getHeader in interface Part

**Parameters:**
name - name of header
public String getHeader(String name, String delimiter) throws MessagingException

String delimiter delimiter
  name
delimiter
return

Throws: MessagingException

getHeader

public String getHeader(String name, String delimiter) throws MessagingException

String delimiter delimiter
  name
delimiter
return

Throws: MessagingException

Get all the headers for this header name, returned as a single String, with headers separated by the delimiter. If the delimiter is null, only the first header is returned.

Specified by: getHeader in interface MimePart

Parameters:
  name - the name of this header
delimiter - delimiter between fields in returned string

Returns:
  the value fields for all headers with this name

Throws: MessagingException

public void setHeader(String name, String value) throws
setHeader

public void setHeader(String name, String value)
throws MessagingException

Set the value for this header_name. Replaces all existing header values with this new value. Note that RFC 822 headers must contain only US-ASCII characters, so a header that contains non US-ASCII characters must be encoded as per the rules of RFC 2047.

Specified by:  
setHeader in interface Part

Parameters:

name - header name
value - header value

Throws:

MessagingException
IllegalWriteException - if the underlying implementation does not support modification of existing values

See Also:
MimeUtility

public void addHeader(String name, String value) throws MessagingException

header_name RFC 822  US-ASCII  US-ASCII  RFC 2047

name
value
addHeader

public void addHeader(String name, String value) throws MessagingException

Add this value to the existing values for this header_name. Note that
RFC 822 headers must contain only US-ASCII characters, so a
header that contains non US-ASCII characters must be encoded as
per the rules of RFC 2047.

Specified by:
   addHeader in interface Part

Parameters:
   name - header name
   value - header value

Throws:
   MessagingException
   IllegalWriteException - if the underlying implementation does
   not support modification of existing values

See Also:
   MimeUtility

public void removeHeader(String name) throws MessagingException

removeHeader

public void removeHeader(String name) throws MessagingException

Remove all headers with this name.
public java.util.Enumeration<E> getAllHeaders() throws MessagingException

Header Message
getAllHeaders

public Enumeration getAllHeaders() throws MessagingException

Return all the headers from this Message as an Enumeration of Header objects.

Specified by:

getAllHeaders in interface Part

Returns:
enumeration of Header objects

Throws:

MessagingException

public java.util.Enumeration<E> getMatchingHeaders(String[] names) throws MessagingException

Header Message
getMatchingHeaders

Specified by:

getAllHeaders in interface Part

Returns:
enumeration of Header objects

Throws:

MessagingException
getMatchingHeaders

public Enumeration getMatchingHeaders(String[] names) throws MessagingException

Return matching headers from this Message as an Enumeration of Header objects.

Specified by:
getMatchingHeaders in interface Part

Returns:
enumeration of Header objects

Throws:
MessagingException

getNonMatchingHeaders

public java.util.Enumeration<E>
getNonMatchingHeaders(String[] names) throws MessagingException
Header Message

getNonMatchingHeaders

public Enumeration getNonMatchingHeaders(String[] names) throws MessagingException

Return non-matching headers from this Message as an Enumeration of Header objects.

Specified by:
getNonMatchingHeaders in interface Part

Returns:
enumeration of Header objects

Throws:
MessagingException

public void addHeaderLine(String line) throws
**MessagingException**

**addHeaderLine**

```java
public void addHeaderLine(String line)
throws MessagingException
```

Add a header line to this body part

**Specified by:**

addHeaderLine in interface MimePart

**Throws:**

IllegalWriteException - if the underlying implementation does not support modification

**MessagingException**

---

```java
public java.util.Enumeration<String> getAllHeaderLines()
throws MessagingException
```

Get all header lines as an Enumeration of Strings. A Header line is a raw RFC 822 header line, containing both the "name" and "value" field.

**Specified by:**

getAllHeaderLines in interface MimePart

**Throws:**

MessagingException
public java.util.Enumeration<E> getMatchingHeaderLines(String[] names) throws MessagingException
String Header RFC 822 "name" "value"

getMatchingHeaderLines

public Enumeration getMatchingHeaderLines(String[] names) throws MessagingException

Get matching header lines as an Enumeration of Strings. A Header line is a raw RFC 822 header line, containing both the "name" and "value" field.

Specified by:
getMatchingHeaderLines in interface MimePart

Throws:
MessagingException

public java.util.Enumeration<E> getNonMatchingHeaderLines(String[] names) throws MessagingException
String Header RFC 822 "name" "value"

getNonMatchingHeaderLines

public Enumeration getNonMatchingHeaderLines(String[] names) throws MessagingException

Get non-matching header lines as an Enumeration of Strings. A Header line is a raw RFC 822 header line, containing both the "name" and "value" field.
protected void updateHeaders() throws MessagingException

MIME

- Store
  Message.saveChanges

updateHeaders

protected void updateHeaders()
    throws MessagingException

Examine the content of this body part and update the appropriate MIME headers. Typical headers that get set here are Content-Type and Content-Transfer-Encoding. Headers might need to be updated in two cases:
- A message being crafted by a mail application will certainly need to activate this method at some point to fill up its internal headers.
- A message read in from a Store will have obtained all its headers from the store, and so doesn't need this. However, if this message is editable and if any edits have been made to either the content or message structure, we might need to resync our headers.
In both cases this method is typically called by the Message.saveChanges method.

Throws:
    MessagingException

### Constructor Detail

```java
public MimeHeaders()
```

Vector MimeHeaders
MimeHeaders

public MimeHeaders()

Constructs a default MimeHeaders object initialized with an empty Vector object.

Method Detail

public String[] getHeader(String name)

String

name

return String

See also

setHeader

g.getHeader

public String[] getHeader(String name)

Returns all of the values for the specified header as an array of String objects.

Parameters:

name - the name of the header for which values will be returned

Returns:

a String array with all of the values for the specified header

See Also:

setHeader(java.lang.String, java.lang.String)

g.getHeader

public void setHeader(String name, String value)

RFC822 US-ASCII

name String

value String
**setHeader**

public void **setHeader**(String name, String value)

Replaces the current value of the first header entry whose name matches the given name with the given value, adding a new header if no existing header name matches. This method also removes all matching headers after the first one.

Note that RFC822 headers can contain only US-ASCII characters.

**Parameters:**
- name - a String with the name of the header for which to search
- value - a String with the value that will replace the current value of the specified header

**Throws:**
- IllegalArgumentException - if there was a problem in the mime header name or the value being set

**See Also:**
- [getHeader](#)

---

**public void addHeader(String name, String value)**

MimeHeader MimeHeaders

RFC822 US-ASCII

- name String
- value String

**Throws**
- IllegalArgumentException: MIME
addHeader

public void addHeader(String name, String value)

Adds a MimeHeader object with the specified name and value to this MimeHeaders object's list of headers.

Note that RFC822 headers can contain only US-ASCII characters.

Parameters:
- name - a String with the name of the header to be added
- value - a String with the value of the header to be added

Throws:
- IllegalArgumentException - if there was a problem in the mime header name or value being added

removeHeader

public void removeHeader(String name)

Remove all MimeHeader objects whose name matches the given name.

Parameters:
- name - a String with the name of the header for which to search

removeAllHeaders

public void removeAllHeaders()

Remove all MimeHeader objects from the list.
removeAllHeaders

public void removeAllHeaders()

Removes all the header entries from this MimeHeaders object.

public java.util.Iterator<E> getAllHeaders()

MimeHeaders MimeHeader
return Iterator MimeHeaders MimeHeader

getAllHeaders

public Iterator getAllHeaders()

Returns all the MimeHeaders in this MimeHeaders object.

Returns:

an Iterator object over this MimeHeaders object's list of MimeHeader objects

getMatchingHeaders

public java.util.Iterator<E> getMatchingHeaders(String[] names)

MimeHeader

String
return Iterator MimeHeader

getMatchingHeaders

public Iterator getMatchingHeaders(String[] names)

Returns all the MimeHeader objects whose name matches a name in the given array of names.

Parameters:
getNonMatchingHeaders

public java.util.Iterator<E>
getNonMatchingHeaders(String[] names)

Returns:
an Iterator object over the MimeHeader objects whose name matches one of the names in the given list

Parameters:
 names - an array of String objects with the names for which to search

Returns:
an Iterator object over the MimeHeader objects whose name matches one of the names in the given list

Returns all of the MimeHeader objects whose name does not match a name in the given array of names.

Parameters:
 names - an array of String objects with the names for which to search

Returns:
an Iterator object over the MimeHeader objects whose name does not match one of the names in the given list

  javax.mail.Message, javax.mail.internet.MimePart,
  javax.mail.internet.InternetAddress
This class represents a MIME style email message. It implements the Message abstract class and the MimePart interface.

Clients wanting to create new MIME style messages will instantiate an empty MimeMessage object and then fill it with appropriate attributes and content.

Service providers that implement MIME compliant backend stores may want to subclass MimeMessage and override certain methods to provide specific implementations. The simplest case is probably a provider that generates a MIME style input stream and leaves the parsing of the stream to this class.

MimeMessage uses the InternetHeaders class to parse and store the top level RFC 822 headers of a message.

The mail.mime.address.strict session property controls the parsing of address headers. By default, strict parsing of address headers is done. If this property is set to "false", strict parsing is not done and many illegal addresses that sometimes occur in real messages are allowed. See the InternetAddress class for details.

---

A note on RFC 822 and MIME headers

RFC 822 header fields must contain only US-ASCII characters. MIME allows non ASCII characters to be present in certain portions of certain headers, by encoding those characters. RFC 2047 specifies the rules for doing this. The MimeUtility class provided in this package can be used to achieve this. Callers of the setHeader, addHeader, and addHeaderLine methods are responsible for enforcing the MIME requirements for the specified headers. In addition, these header fields must be folded (wrapped) before being sent if they exceed the line length limitation for the transport (1000 bytes for SMTP). Received headers may have been folded. The application is responsible for folding and unfolding headers as appropriate.

### Fields inherited from class `javax.mail.Message`  
expunged, folder, msgnum, session

### Fields inherited from interface `javax.mail.Part`  
ATTACHMENT, INLINE

### Constructor Summary

- **protected**  
  `MimeMessage(Folder folder, InputStream is, int msgnum)`  
  Constructs a MimeMessage by reading and parsing the data from the specified MIME InputStream.

- **protected**  
  `MimeMessage(Folder folder, int msgnum)`  
  Constructs an empty MimeMessage object with the given Folder and message number.

- **protected**  
  `MimeMessage(Folder folder, InternetHeaders headers, byte[] content, int msgnum)`  
  Constructs a MimeMessage from the given InternetHeaders object and content.

- **protected**  
  `MimeMessage(MimeMessage source)`  
  Constructs a new MimeMessage with content initialized from the source MimeMessage.

- **protected**  
  `MimeMessage(Session session)`  
  Default constructor.

- **protected**  
  `MimeMessage(Session session, InputStream is)`  
  Constructs a MimeMessage by reading and parsing the data from the specified MIME InputStream.

### Method Summary

- **void**  
  `addFrom(Address[] addresses)`  
  Add the specified addresses to the existing "From" field.

- **void**  
  `addHeader(String name, String value)`  
  Add this value to the existing values for this header_name.

### Enumeration of Header objects.

- **String getMessageID()**
  - Returns the value of the "Message-ID" header field.

- **Enumeration getNonMatchingHeaderLines(String[] names)**
  - Get non-matching header lines as an Enumeration of Strings.

- **Enumeration getNonMatchingHeaders(String[] names)**
  - Return non-matching headers from this Message as an Enumeration of Header objects.

- **InputStream getRawInputStream()**
  - Return an InputStream to the raw data with any Content-Transfer-Encoding intact.

- **Date getReceivedDate()**
  - Returns the Date on this message was received.

- **Address[] getRecipients(Message.RecipientType type)**
  - Returns the recepients specified by the type.

- **Address[] getReplyTo()**
  - Return the value of the RFC 822 "Reply-To" header field.

- **Address getSender()**
  - Returns the value of the RFC 822 "Sender" header field.

- **Date getSentDate()**
  - Returns the value of the RFC 822 "Date" field.

- **int getSize()**
  - Return the size of the content of this message in bytes.

- **String getSubject()**
  - Returns the value of the "Subject" header field.

- **boolean isMimeType(String mimeType)**
  - Is this Part of the specified MIME type?

- **boolean isSet(Flags.Flag flag)**
  - Check whether the flag specified in the flag argument is set in this message.

### Field Detail

<table>
<thead>
<tr>
<th>dh</th>
</tr>
</thead>
<tbody>
<tr>
<td>protected DataHandler dh</td>
</tr>
</tbody>
</table>

The DataHandler object representing this Message's content.
protected byte[] content

Byte array that holds the bytes of this Message's content.

contentStream

protected InputStream contentStream

If the data for this message was supplied by an InputStream that implements the SharedInputStream interface, contentStream is another such stream representing the content of this message. In this case, content will be null.

Since:
JavaMail 1.2

headers

protected InternetHeaders headers

The InternetHeaders object that stores the header of this message.

flags

protected Flags flags

The Flags for this message.
modified

protected boolean modified

A flag indicating whether the message has been modified. If the message has not been modified, any data in the content array is assumed to be valid and is used directly in the writeTo method. This flag is set to true when an empty message is created or when the saveChanges method is called.

Since:
JavaMail 1.2

saved

protected boolean saved

Does the saveChanges method need to be called on this message? This flag is set to false by the public constructor and set to true by the saveChanges method. The writeTo method checks this flag and calls the saveChanges method as necessary. This avoids the common mistake of forgetting to call the saveChanges method on a newly constructed message.

Since:
JavaMail 1.2

Constructor Detail

public MimeMessage(<Session session>)

headers InternetHeaders flag

modified true
MimeMessage

`public MimeMessage(Session session)`

Default constructor. An empty message object is created. The `headers` field is set to an empty `InternetHeaders` object. The `flags` field is set to an empty `Flags` object. The `modified` flag is set to `true`.

`public MimeMessage(Session session, java.io.InputStream is) throws MessagingException`

MIME InputStream MimeMessageInputStream

**MIME**

`session
is
Throws MessagingException:`

MimeMessage

`public MimeMessage(Session session, InputStream is) throws MessagingException`

Constructs a `MimeMessage` by reading and parsing the data from the specified MIME InputStream. The InputStream will be left positioned at the end of the data for the message. Note that the input stream parse is done within this constructor itself.

The input stream contains an entire MIME formatted message with headers and data.

**Parameters:**
session - Session object for this message
is - the message input stream

Throws:
MessagingException

public MimeMessage(MimeMessage source) throws MessagingException

source MimeMessage  MimeMessage

source

Throws
MessagingException:

since
JavaMail 1.2

MimeMessage

public MimeMessage(MimeMessage source)
throws MessagingException

Constructs a new MimeMessage with content initialized from the source MimeMessage. The new message is independent of the original.

Note: The current implementation is rather inefficient, copying the data more times than strictly necessary.

Parameters:
source - the message to copy content from

Throws:
MessagingException

Since:
JavaMail 1.2

protected MimeMessage(Folder folder, int msgnum)
Folder MimeMessage

MimeMessage

protected MimeMessage(Folder folder, int msgnum)

Constructs an empty MimeMessage object with the given Folder and message number.

This method is for providers subclassing MimeMessage.

protected MimeMessage(Folder folder, java.io.InputStream is, int msgnum) throws MessagingException
MIME InputStream MimeMessageInputStream

MimeMessage

folder

is

msgnum

Throws MessagingException:

MimeMessage

protected MimeMessage(Folder folder, InputStream is, int msgnum)

throws MessagingException

Constructs a MimeMessage by reading and parsing the data from
the specified MIME InputStream. The InputStream will be left positioned at the end of the data for the message. Note that the input stream parse is done within this constructor itself.

This method is for providers subclassing MimeMessage.

**Parameters:**
- folder - The containing folder.
- is - the message input stream
- msgnum - Message number of this message within its folder

**Throws:**
- MessagingException

```java
protected MimeMessage(Folder folder, InternetHeaders headers, byte[] content, int msgnum) throws MessagingException
```

**InternetHeaders MimeMessage**

```java
folder
headers
content
msgnum
```

**Throws**
- MessagingException

**MimeMessage**

```java
protected MimeMessage(Folder folder,
                       InternetHeaders headers,
                       byte[] content,
                       int msgnum)
throws MessagingException
```

Constructs a MimeMessage from the given InternetHeaders object and content. This method is for providers subclassing MimeMessage.

**Parameters:**
- folder - The containing folder.
- headers - The headers
content - The message content
msgnum - Message number of this message within its folder

Throws:
MessagingException

---

**Method Detail**

```java
protected void parse(java.io.InputStream is) throws MessagingException
```

**InputStream**

`is`  

Throws
MessagingException:

---

**parse**

```java
protected void parse(InputStream is) throws MessagingException
```

Parse the InputStream setting the headers and content fields appropriately. Also resets the modified flag.

This method is intended for use by subclasses that need to control when the InputStream is parsed.

**Parameters:**

is - The message input stream

**Throws:**
MessagingException

---

```java
public Address[] getFrom() throws MessagingException
```

RFC 822 "From" "Sender" "Sender"

null
getFrom

public Address[] getFrom() throws MessagingException

Returns the value of the RFC 822 "From" header fields. If this header field is absent, the "Sender" header field is used. If the "Sender" header field is also absent, null is returned.

This implementation uses the getHeader method to obtain the requisite header field.

Specified by:
    getFrom in class Message

Returns:
    Address object

Throws:
    MessagingException

See Also:
    headers

public void setFrom(Address address) throws MessagingException

RFC 822 "From" address

address

Throws
    IllegalArgumentException:
    Throws
    IllegalStateException: READ_ONLY
    Throws
    MessagingException:
setFrom

public void setFrom(Address address) throws MessagingException

Set the RFC 822 "From" header field. Any existing values are replaced with the given address. If address is null, this header is removed.

Specified by:
    setFrom in class Message

Parameters:
    address - the sender of this message

Throws:
    IllegalWriteException - if the underlying implementation does not support modification of existing values
    IllegalStateException - if this message is obtained from a READ_ONLY folder.
    MessagingException

public void setFrom() throws MessagingException

    InternetAddress.getLocalAddress RFC 822 "From"

    Throws IllegalWriteException:
    Throws IllegalStateException: READ_ONLY
    Throws MessagingException:

setFrom

public void setFrom() throws MessagingException

Set the RFC 822 "From" header field using the value of the InternetAddress.getLocalAddress method.

Specified by:
    setFrom in class Message

Throws:
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public void addFrom(Address[] addresses) throws MessagingException
"From" "From"
addresses
Throws IllegalWriteException:
Throws IllegalStateException:  READ_ONLY
Throws MessagingException:

addFrom

public void addFrom(Address[] addresses) throws MessagingException
Add the specified addresses to the existing "From" field. If the "From" field does not already exist, it is created.

Specified by:
addFrom in class Message
Parameters:
addresses - the senders of this message
Throws:
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public Address getSender() throws MessagingException
RFC 822 "Sender" "Sender"
getHeader

return Address

Throws MessagingException:

since JavaMail 1.3

See also headers

getSender

public Address getSender() throws MessagingException

    Returns the value of the RFC 822 "Sender" header field. If the "Sender" header field is absent, null is returned.

    This implementation uses the getHeader method to obtain the requisite header field.

    Returns:
    Address object

    Throws:
    MessagingException

    Since:
    JavaMail 1.3

    See Also:
    headers

public void setSender(Address address) throws MessagingException

RFC 822 "Sender" address

address

Throws IllegalArgumentException:

Throws IllegalStateException: READ_ONLY

Throws MessagingException:

since JavaMail 1.3
setSender

public void setSender(Address address) throws MessagingException

Set the RFC 822 "Sender" header field. Any existing values are replaced with the given address. If address is null, this header is removed.

Parameters:
address - the sender of this message

Throws:
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

Since:
JavaMail 1.3

public Address[] getRecipients(Message.RecipientType type) throws MessagingException

RFC 822

Message.RecipientType.TO "To"
Message.RecipientType.CC "Cc"
Message.RecipientType.BCC "Bcc"
MimeMessage.RecipientType.NEWSGROUPS "Newsgroups"

null

g.getHeader

return Address
getRecipients

public Address[] getRecipients(Message.RecipientType type) throws MessagingException

Returns the recipients specified by the type. The mapping between the type and the corresponding RFC 822 header is as follows:

- Message.RecipientType.TO
- Message.RecipientType.CC
- Message.RecipientType.BCC
- MimeMessage.RecipientType.NEWSGROUPS

Returns null if the header specified by the type is not found or if its value is empty.

This implementation uses the getHeader method to obtain the requisite header field.

Specified by: getRecipients in class Message

Parameters:
- type - Type of recipient

Returns:
- array of Address objects

Throws:
- MessagingException - if header could not be retrieved
- AddressException - if the header is misformatted

See Also:
- headers, Message.RecipientType.TO, Message.RecipientType.CC,
  Message.RecipientType.BCC,
  MimeMessage.RecipientType.NEWSGROUPS
public Address[] getAllRecipients() throws MessagingException

TOCCBCC  NEWSGROUPS

return Address

Throws MessagingException:

See also TO, CC, BCC, NEWSGROUPS

getAllRecipients

public Address[] getAllRecipients()

throws MessagingException

Get all the recipient addresses for the message. Extracts the TO, CC, BCC, and NEWSGROUPS recipients.

Overrides:

getAllRecipients in class Message

Returns:
array of Address objects

Throws:
MessagingException

See Also:
Message.RecipientType.TO, Message.RecipientType.CC,
Message.RecipientType.BCC,
MimeMessage.RecipientType.NEWSGROUPS

public void setRecipients(Message.RecipientType type, Address[] addresses) throws MessagingException

null

type

addresses

Throws IllegalArgumentException:

Throws IllegalStateException: READ_ONLY

Throws MessagingException:

See also getRecipients
### setRecipients

```java
public void setRecipients(Message.RecipientType type,
                        Address[] addresses)
    throws MessagingException
```

Set the specified recipient type to the given addresses. If the address parameter is `null`, the corresponding recipient field is removed.

**Specified by:**
- `setRecipients` in class `Message`

**Parameters:**
- `type` - Recipient type
- `addresses` - Addresses

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this message is obtained from a `READ_ONLY` folder.
- `MessagingException`

**See Also:**
- `getRecipients(javax.mail.Message.RecipientType)`

---

```java
public void setRecipients(Message.RecipientType type,
                        String addresses)
    throws MessagingException
```

**Throws**
- `AddressException`
- `IllegalWriteException`
- `IllegalStateException: READ_ONLY`

**See also**
- `getRecipients`
setRecipients

public void setRecipients(Message.RecipientType type,
                          String addresses)
                          throws MessagingException

Set the specified recipient type to the given addresses. If the address parameter is null, the corresponding recipient field is removed.

Parameters:

  type - Recipient type
  addresses - Addresses

Throws:

  AddressException - if the attempt to parse the addresses String fails
  IllegalWriteException - if the underlying implementation does not support modification of existing values
  IllegalStateException - if this message is obtained from a READ_ONLY folder.
  MessagingException

Since:

  JavaMail 1.2

See Also:

  getRecipients(javax.mail.Message.RecipientType)

public void addRecipients(Message.RecipientType type,
Address[] addresses) throws MessagingException

  type
  addresses

  Throws          IllegalWriteException:
  Throws  IllegalStateException:  READ_ONLY
  Throws  MessagingException:
addRecipients

public void addRecipients(Message.RecipientType type,
                          Address[] addresses)
                          throws MessagingException

Add the given addresses to the specified recipient type.

Specified by:
    addRecipients in class Message

Parameters:
    type - Recipient type
    addresses - Addresses

Throws:
    IllegalWriteException - if the underlying implementation does
    not support modification of existing values
    IllegalStateException - if this message is obtained from a
    READ_ONLY folder.
    MessagingException

public void addRecipients(Message.RecipientType type,
                          String addresses) throws MessagingException

      type
addresses

Throws             AddressException:
Throws             IllegalWriteException:
Throws             IllegalStateException: READ_ONLY
Throws             MessagingException:
since              JavaMail 1.2
Add the given addresses to the specified recipient type.

**Parameters:**
- `type` - Recipient type
- `addresses` - Addresses

**Throws:**
- `AddressException` - if the attempt to parse the addresses String fails
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this message is obtained from a READ_ONLY folder.
- `MessagingException`

**Since:**
JavaMail 1.2

```java
public Address[] getReplyTo() throws MessagingException
RFC 822 "Reply-To"
```

- **Throws**
  - `MessagingException`
- **See also**
  - headers

**getReplyTo**

```java
public Address[] getReplyTo()
```

Return the value of the RFC 822 "Reply-To" header field. If this header is unavailable or its value is absent, then the `getFrom` method is called and its value is returned. This implementation uses the `getHeader` method to obtain the requisite header field.

**Overrides:**
- `getReplyTo` in class `Message`

**Returns:**
- addresses to which replies should be directed

**Throws:**
public void setReplyTo(Address[] addresses) throws MessagingException
RFC 822 "Reply-To" null

<table>
<thead>
<tr>

</tbody>
</table>

setReplyTo

public void setReplyTo(Address[] addresses) throws MessagingException

Set the RFC 822 "Reply-To" header field. If the address parameter is null, this header is removed.

Overrides:
setReplyTo in class Message

Parameters:
addresses - addresses to which replies should be directed

Throws:
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

MethodNotSupportedException - if the underlying implementation does not support setting this attribute

public String getSubject() throws MessagingException
"Subject" subject null
subject  RFC 2047  Unicode

getHeader
return Subject
Throws MessagingException: en
See also headers

getSubject

public String getSubject() throws MessagingException

Returns the value of the "Subject" header field. Returns null if the
subject field is unavailable or its value is absent.

If the subject is encoded as per RFC 2047, it is decoded and
converted into Unicode. If the decoding or conversion fails, the raw
data is returned as is.

This implementation uses the getHeader method to obtain the
requisite header field.

Specified by: getSubject in class Message
Returns: Subject
Throws: MessagingException
See Also: headers

public void setSubject(String subject) throws MessagingException
"Subject" subject US-ASCII subject
US-ASCII subject null "Subject"
subject

MessagingException MessagingException

public void setSubject(String subject)
    throws MessagingException

Set the "Subject" header field. If the subject contains non US-ASCII characters, it will be encoded using the platform's default charset. If the subject contains only US-ASCII characters, no encoding is done and it is used as-is. If the subject is null, the existing "Subject" field is removed.

The application must ensure that the subject does not contain any line breaks.

Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.

Specified by:
    setSubject in class Message

Parameters:
subject - The subject

Throws:
    IllegalWriteException - if the underlying implementation does not support modification of existing values
    IllegalStateException - if this message is obtained from a
READ_ONLY folder.

MessagingException. - An UnsupportedEncodingException may be included in the exception chain if the charset conversion fails.

```
public void setSubject(String subject, String charset)
throws MessagingException
"Subject" subject US-ASCII subject
US-ASCII subject null "Subject"

subject

MessagingException MessagingException
UnsupportedEncodingException

subject Subject
charset

Throws IllegalArgumentException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException.: UnsupportedEncodingException
```

```
setSubject

public void setSubject(String subject, String charset)
throws MessagingException

Set the "Subject" header field. If the subject contains non US-ASCII characters, it will be encoded using the specified charset. If the subject contains only US-ASCII characters, no encoding is done and it is used as-is. If the subject is null, the existing "Subject" header field is removed.

The application must ensure that the subject does not contain any line breaks.
```
Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.

**Parameters:**
- subject - The subject
- charset - The charset

**Throws:**
- IllegalArgumentException - if the underlying implementation does not support modification of existing values
- IllegalStateException - if this message is obtained from a READ_ONLY folder.
- MessagingException. - An UnsupportedEncodingException may be included in the exception chain if the charset conversion fails.

```java
public java.util.Date getSentDate() throws MessagingException

RFC 822 "Date" null
```

```java
getHeader
return
```

**Throws**
- MessagingException:

### getSentDate

```java
public Date getSentDate()
throws MessagingException
```

Returns the value of the RFC 822 "Date" field. This is the date on which this message was sent. Returns null if this field is unavailable or its value is absent.

This implementation uses the `getHeader` method to obtain the
requisite header field.

Specified by:
getSentDate in class Message

Returns:
The sent Date

Throws:
MessagingException

public void setSentDate(java.util.Date d) throws MessagingException
RFC 822 "Date"

Throws
IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:

setSentDate

public void setSentDate(Date d)
throws MessagingException

Set the RFC 822 "Date" header field. This is the date on which the creator of the message indicates that the message is complete and ready for delivery. If the date parameter is null, the existing "Date" field is removed.

Specified by:
setSentDate in class Message

Parameters:
d - the sent date of this message

Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException
public java.util.Date getReceivedDate() throws MessagingException

RFC 822

    null
    return

    Throws

getReceivedDate

public Date getReceivedDate()
    throws MessagingException

    Returns the Date on this message was received. Returns null if this
date cannot be obtained.

    Note that RFC 822 does not define a field for the received date.
Hence only implementations that can provide this date need return a
valid value.

    This implementation returns null.

    Specified by:
    getReceivedDate in class Message

    Returns:
    the date this message was received

    Throws:
    MessagingException

public int getSize() throws MessagingException
-1
GetSize

public int getSize() throws MessagingException

Return the size of the content of this message in bytes. Return -1 if the size cannot be determined.

Note that this number may not be an exact measure of the content size and may or may not account for any transfer encoding of the content.

This implementation returns the size of the content array (if not null), or, if contentStream is not null, and the available method returns a positive number, it returns that number as the size. Otherwise, it returns -1.

Specified by:
getSize in interface Part

Returns:
size of content in bytes

Throws:
MessagingException
public int getLineCount() throws MessagingException

Return the number of lines for the content of this message. Return -1 if this number cannot be determined.

Note that this number may not be an exact measure of the content length and may or may not account for any transfer encoding of the content.

This implementation returns -1.

Specified by: getLineCount in interface Part

Returns: number of lines in the content.

Throws: MessagingException

public String getContentType() throws MessagingException

RFC 822 "Content-Type" null "text/plain"

getHeader

return

Throws: MessagingException

See also javax.activation.DataHandler
**getContentType**

```java
public String getContentType() throws MessagingException {
    return getHeader("Content-Type").getValue();
}
```

Returns the value of the RFC 822 "Content-Type" header field. This represents the content-type of the content of this message. This value must not be null. If this field is unavailable, "text/plain" should be returned.

This implementation uses the `getHeader` method to obtain the requisite header field.

**Specified by:**
`getContentType` in interface `Part`

**Returns:**
The `ContentType` of this part

**Throws:**
`MessagingException`

**See Also:**
`DataHandler`

---

**public boolean isMimeType(String mimeType) throws MessagingException**

```java
public boolean isMimeType(String mimeType) throws MessagingException {
    if (mimeType.equals("text/plain") || mimeType.equals("text/plain; charset=foobar") || mimeType.equals("*")) {
        return true;
    }
    return false;
}
```

**isMimeType**

```java
public boolean isMimeType(String mimeType) throws MessagingException {
    if (mimeType.equals("text/plain") || mimeType.equals("text/plain; charset=foobar") || mimeType.equals("*")) {
        return true;
    }
    return false;
}
```
Is this Part of the specified MIME type? This method compares **only** the primaryType and subType. The parameters of the content types are ignored.

For example, this method will return `true` when comparing a Part of content type "text/plain" with "text/plain; charset=foobar".

If the subType of mimeType is the special character "*", then the subtype is ignored during the comparison.

**Specified by:**

`isMimeType` in interface `Part`

**Throws:**

`MessagingException`

```
public String getDisposition() throws MessagingException

"Content-Disposition" disposition disposition
```

**Content-Disposition**

<table>
<thead>
<tr>
<th>getHeader</th>
<th>disposition null</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>null</td>
</tr>
</tbody>
</table>

**Throws**

`MessagingException`

```
getDisposition
```

Returns the value of the "Content-Disposition" header field. This represents the disposition of this part. The disposition describes how the part should be presented to the user.

If the Content-Disposition field is unavailable, `null` is returned.
This implementation uses the `getHeader` method to obtain the requisite header field.

**Specified by:**
getDisposition in interface Part

**Returns:**
disposition of this part, or null if unknown

**Throws:**
MessagingException

**See Also:**
Part.ATTACHMENT, Part.INLINE, Part.getFileName()

---

```java
public void setDisposition(String disposition) throws MessagingException

Message "Content-Disposition"
disposition
null "Content-Disposition"

Throws
IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:
```

**setDisposition**

```java
public void setDisposition(String disposition) throws MessagingException

Set the "Content-Disposition" header field of this Message. If disposition is null, any existing "Content-Disposition" header field is removed.

**Specified by:**
setDisposition in interface Part

**Parameters:**
disposition - disposition of this part

**Throws:**
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

See Also:
Part.ATTACHMENT, Part.INLINE,
Part.setFileName(java.lang.String)

public String getEncoding() throws MessagingException
"Content-Transfer-Encoding"

    getHeader
    return

Throws
MessagingException:

getEncoding

public String getEncoding() throws MessagingException

    Returns the content transfer encoding from the "Content-Transfer-Encoding" header field. Returns null if the header is unavailable or its value is absent.

    This implementation uses the getHeader method to obtain the requisite header field.

    Specified by:
getEncoding in interface MimePart

Returns:
content-transfer-encoding

Throws:
MessagingException

public String getContentID() throws MessagingException
"Content-ID"

null
**getHeader**

return ID

Throws MessagingException:

---

**getContentID**

public String getContentID() throws MessagingException

Returns the value of the "Content-ID" header field. Returns null if the field is unavailable or its value is absent.

This implementation uses the getHeader method to obtain the requisite header field.

**Specified by:**

getContentID in interface MimePart

**Returns:**

content-ID

**Throws:**

MessagingException

---

**public void setContentID(String cid) throws MessagingException**

**Message** "Content-ID" cid null "Content-ID"

**Throws**

IllegalWriteException:

Throws IllegalStateException: READ_ONLY

Throws MessagingException:

---

**setContentID**

public void setContentID(String cid) throws MessagingException

Throws MessagingException
Set the "Content-ID" header field of this Message. If the cid parameter is null, any existing "Content-ID" is removed.

Throws:
- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this message is obtained from a READ_ONLY folder.
- `MessagingException`

```java
public String getContentMD5() throws MessagingException {
    return MD5;
}
```

`getContentMD5`

Returns the value of the "Content-MD5" header field. Returns `null` if this field is unavailable or its value is absent.

This implementation uses the `getHeader` method to obtain the requisite header field.

Specified by:
- `getContentMD5` in interface `MimePart`

Returns: content-MD5

Throws: `MessagingException`
public void setContentMD5(String md5) throws MessagingException

Message "Content-MD5"

Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:

setContentMD5

public void setContentMD5(String md5)
throws MessagingException

Set the "Content-MD5" header field of this Message.

Specified by:
setContentMD5 in interface MimePart

Parameters:
md5 - the MD5 value

Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public String getDescription() throws MessagingException

Message "Content-Description" null

Content-Description RFC 2047 Unicode

getHeader
return
Throws MessagingException:
getDescription

public String getDescription() throws MessagingException

    Returns the "Content-Description" header field of this Message. This typically associates some descriptive information with this part. Returns null if this field is unavailable or its value is absent.

    If the Content-Description field is encoded as per RFC 2047, it is decoded and converted into Unicode. If the decoding or conversion fails, the raw data is returned as-is

    This implementation uses the getHeader method to obtain the requisite header field.

Specified by: getDescription in interface Part

Returns: content-description

Throws: MessagingException

public void setDescription(String description) throws MessagingException

    Message "Content-Description" description
    null "Content-Description"

    description US-ASCII description US-ASCII

    MessagingException MessagingException UnsupportedEncodingException

    description

    Throws IllegalWriteException:
setDescription

public void setDescription(String description) throws MessagingException

Set the "Content-Description" header field for this Message. If the description parameter is null, then any existing "Content-Description" fields are removed.

If the description contains non US-ASCII characters, it will be encoded using the platform's default charset. If the description contains only US-ASCII characters, no encoding is done and it is used as-is.

Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.

Specified by:
    setDescription in interface Part
Parameters:
    description - content-description
Throws:
    IllegalWriteException - if the underlying implementation does not support modification
    IllegalStateException - if this message is obtained from a READ_ONLY folder.
    MessagingException. - An UnsupportedEncodingException may be included in the exception chain if the charset conversion fails.
    MessagingException
public void setDescription(String description, String charset) throws MessagingException

Message "Content-Description" description null "Content-Description"

description US-ASCII description US-ASCII

MessagingException MessagingException UnsupportedEncodingException

Throws IllegalWriteException:

Throws IllegalStateException: READ_ONLY

Throws MessagingException:

Throws UnsupportedEncodingException

setDescription

public void setDescription(String description, String charset)

throws MessagingException

Set the "Content-Description" header field for this Message. If the description parameter is null, then any existing "Content-Description" fields are removed.

If the description contains non US-ASCII characters, it will be encoded using the specified charset. If the description contains only US-ASCII characters, no encoding is done and it is used as-is.

Note that if the charset encoding process fails, a MessagingException is thrown, and an UnsupportedEncodingException is included in the chain of nested exceptions within the MessagingException.
public String[] getContentLanguage() throws MessagingException

Message "Content-Language" Content-Language
RFC 1766 null

getHeader
return Content-Language
Throws MessagingException:

getContentTypeLanguage

public String[] getContentLanguage() throws MessagingException

Get the languages specified in the "Content-Language" header field of this message. The Content-Language header is defined by RFC 1766. Returns null if this field is unavailable or its value is absent.

This implementation uses the getHeader method to obtain the requisite header field.

Specified by:
getContentLanguage in interface MimePart
Returns:
value of content-language header.

Throws:
MessagingException

public void setContentLanguage(String[] languages)
throws MessagingException
MimePart "Content-Language" Content-Language
RFC 1766

languages

Throws
IllegalWriteException:
Throws
IllegalStateException: READ_ONLY
Throws
MessagingException:

setContentLanguage

public void setContentLanguage(String[] languages)
throws MessagingException

Set the "Content-Language" header of this MimePart. The Content-Language header is defined by RFC 1766.

Specified by:
setContentLanguage in interface MimePart

Parameters:
languages - array of language tags

Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public String getMessageID() throws MessagingException
"Message-ID" null
getMessageID

public String getMessageID() throws MessagingException

Returns the value of the "Message-ID" header field. Returns null if this field is unavailable or its value is absent.

The default implementation provided here uses the getHeader method to return the value of the "Message-ID" field.

Returns:
Message-ID

Throws:
MessagingException - if the retrieval of this field causes any exception.

Since:
JavaMail 1.1

See Also:
javax.mail.search.MessageIDTerm

public String getFileName() throws MessagingException

"Content-Disposition" "filename" BodyPart "Content-Type" "name"

mail.mime.encodefilename true
getFileName

public String getFileName() throws MessagingException

Get the filename associated with this Message.

Returns the value of the "filename" parameter from the "Content-Disposition" header field of this message. If it's not available, returns the value of the "name" parameter from the "Content-Type" header field of this BodyPart. Returns null if both are absent.

If the mail.mime.encodefilename System property is set to true, the MimeUtility.decodeText method will be used to decode the filename. While such encoding is not supported by the MIME spec, many mailers use this technique to support non-ASCII characters in filenames. The default value of this property is false.

Specified by:
getFileName in interface Part

Returns:
filename

Throws:
MessagingException

public void setFileName(String filename) throws MessagingException

Message "Content-Disposition" "filename"
mail.mime.encodefilename true
MimeUtility.encodeText MIME ASCII
false

Throws
IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:

setFileName

public void setFileName(String filename)
throws MessagingException

Set the filename associated with this part, if possible.

Sets the "filename" parameter of the "Content-Disposition" header field of this message.

If the mail.mime.encodefilename System property is set to true, the
MimeUtility.encodeText method will be used to encode the filename.
While such encoding is not supported by the MIME spec, many
mailers use this technique to support non-ASCII characters in
filenames. The default value of this property is false.

Specified by:
setFileName in interface Part

Parameters:
filename - Filename to associate with this part

Throws:
IllegalWriteException - if the underlying implementation does
not support modification
IllegalStateException - if this message is obtained from a
READ_ONLY folder.
MessagingException

public java.io.InputStream getInputStream() throws
java.io.IOException, MessagingException
Message "content"

DataHandler getDataHandler().getInputStream()
return InputStream
Throws MessagingException:
Throws java.io.IOException: DataHandler javax.activation.DataHandler
See also getContentStream, getInputStream

getInputStream

public InputStream getInputStream()
throws IOException, MessagingException

Return a decoded input stream for this Message's "content".

This implementation obtains the input stream from the DataHandler, that is, it invokes getDataHandler().getInputStream().

Specified by:
getInputStream in interface Part
Returns:
an InputStream
Throw:
MessagingException
IOException - this is typically thrown by the DataHandler. Refer to the documentation for javax.activation.DataHandler for more details.
See Also:
getContentStream(), DataHandler.getInputStream()

protected java.io.InputStream getContentStream() throws
MessagingException
DataHandler

getContentStream

protected InputStream getContentStream() throws MessagingException

Produce the raw bytes of the content. This method is used during parsing, to create a DataHandler object for the content. Subclasses that can provide a separate input stream for just the message content might want to override this method.

This implementation returns a SharedInputStream, if contentStream is not null. Otherwise, it returns a ByteArrayInputStream constructed out of the content byte array.

Throws:
   MessagingException
See Also:
   content
getRawInputStream

public InputStream getRawInputStream() throws MessagingException

Return an InputStream to the raw data with any Content-Transfer-Encoding intact. This method is useful if the "Content-Transfer-Encoding" header is incorrect or corrupt, which would prevent the getInputStream method or getContent method from returning the correct data. In such a case the application may use this method and attempt to decode the raw data itself.

This implementation simply calls the getContentStream method.

Throws:
   MessagingException

Since:
   JavaMail 1.2

See Also:
   getInputStream(), getContentStream()

public DataHandler getDataHandler() throws MessagingException

Message DataHandler

g getContentStream

dataHandler() {
   if (dh == null) {
      dh = new DataHandler(new MimePartDataSource(this));
   }
   return dh;
}
Throws **MessagingException**: 

**getDataHandler**

```java
class MimePartDataSource implements DataSource {
    public getInputStream() {
        return MimeUtility.decode(
            getContentStream(), getEncoding());
    }
    ....
}
```

```java
public DataHandler getDataHandler() throws MessagingException
```

Return a DataHandler for this Message's content.

The implementation provided here works as follows. Note the use of the `getContentStream` method to generate the byte stream for the content. Also note that any transfer-decoding is done automatically within this method.

```java
gDataHandler() {
    if (dh == null) {
        dh = new DataHandler(new MimePartDataSource(this));
    }
    return dh;
}
```

```java
class MimePartDataSource implements DataSource {
    public getInputStream() {
        return MimeUtility.decode(
            getContentStream(), getEncoding());
    }
    ....
}
```
Specified by:
getDatasHandler in interface Part

Returns:
DataHandler for the content

Throws:
MessagingException

public Object getContent() throws java.io.IOException, MessagingException,
java.io.IOException:
java.activation.DataHandler
javax.mail.Part, getContent

getContents

public Object getContent() throws IOException,
MessagingException

Return the content as a Java object. The type of this object is
dependent on the content itself. For example, the native format of a
"text/plain" content is usually a String object. The native format for a
"multipart" message is always a Multipart subclass. For content
types that are unknown to the DataHandler system, an input stream
is returned as the content.
This implementation obtains the content from the DataHandler, that is, it invokes `getDataHandler().getContent()`. If the content is a Multipart or Message object and was created by parsing a stream, the object is cached and returned in subsequent calls so that modifications to the content will not be lost.

**Specified by:**
`getContent` in interface `Part`

**Returns:**
Object

**Throws:**
`MessagingException`
`IOException` - this is typically thrown by the DataHandler. Refer to the documentation for `javax.activation.DataHandler` for more details.

**See Also:**
`Part`, `DataHandler.getContent()`

---

```java
public void setDataHandler(DataHandler dh) throws MessagingException
```

**DataHandler**

- `dh` DataHandler
- **Throws**
  - `IllegalWriteException`
  - `IllegalStateException`: `READ_ONLY`
  - `MessagingException`

**setDataHandler**

```java
public void setDataHandler(DataHandler dh)
```

This method provides the mechanism to set this part's content. The given DataHandler object should wrap the actual content.

**Specified by:**
`setDataHandler` in interface `Part`
Parameters:

dh - The DataHandler for the content.

Throws:

- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this message is obtained from a READONLY folder.
- `MessagingException`

```java
public void setContent(Object o, String type) throws MessagingException
```

**Message**

**DataHandler**  **DataContentHandler**

**JavaMail**  ```java
setContent(foobar, "application/x-foobar")
```

**"application/x-foobar"**  **DataContentHandler**  **Java Activation Framework**

```java
type
Mime
```

Throws:

- `IllegalWriteException`
- `IllegalStateException`: READONLY
- `MessagingException`

**setContent**

```java
public void setContent(Object o, String type)
throws MessagingException
```

**A convenience method for setting this Message's content.**

The content is wrapped in a DataHandler object. Note that a DataContentHandler class for the specified type should be available to the JavaMail implementation for this to work right. i.e., to do `setContent(foobar, "application/x-foobar")`, a
DataContentHandler for "application/x-foobar" should be installed. Refer to the Java Activation Framework for more information.

**Specified by:**
```
setContent in interface Part
```

**Parameters:**
- `o` - the content object
- `type` - Mime type of the object

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this message is obtained from a READ_ONLY folder.
- `MessagingException`

---

```java
public void setText(String text) throws MessagingException

MIME "text/plain" String string US-ASCII "charset"

text

charset

setText

Throws: MessagingException:

See also

setText(String text, String charset)
```

---

**setText**

```java
public void setText(String text)

throws MessagingException
```

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain". If the string contains non US-ASCII characters, it will be encoded using the platform's default charset.
The charset is also used to set the "charset" parameter.

Note that there may be a performance penalty if text is large, since this method may have to scan all the characters to determine what charset to use.

If the charset is already known, use the setText method that takes the charset parameter.

**Specified by:**
- `setText` in interface `MimePart`
- `setText` in interface `Part`

**Parameters:**
- `text` - the text content to set

**Throws:**
- `MessagingException` - if an error occurs

**See Also:**
- `setText(String text, String charset)`

```
public void setText(String text, String charset) throws MessagingException

MIME "text/plain" String Unicode "charset"

  text
  charset

Throws       MessagingException:
```

### setText

```
public void setText(String text, String charset) throws MessagingException

MIME "text/plain" String Unicode "charset"

  text
  charset

Throws       MessagingException:
```

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain" and the specified charset. The given Unicode string will be charset-encoded using the specified charset.
The charset is also used to set the "charset" parameter.

**Specified by:**
```
setText in interface MimePart
```

**Parameters:**
- `text` - the text content to set
- `charset` - the charset to use for the text

**Throws:**
```
MessagingException - if an error occurs
```

```java
public void setText(String text, String charset, String subtype)
throws MessagingException
```

MIME "text" MIME String Unicode "charset"
```
  text
  charset
  subtype MIME "html"
```

**Throws**
```
MessagingException:
```

```
since JavaMail 1.4
```
charset - the charset to use for the text
subtype - the MIME subtype to use (e.g., "html")

Throws:
MessagingException - if an error occurs

Since:
JavaMail 1.4

public void setContent(Multipart mp) throws MessagingException

Message Multipart

ToFile multipart

Throws
IllegalWriteException:

Throws
IllegalStateException: READ_ONLY

Throws
MessagingException:

setContent

public void setContent(Multipart mp) throws MessagingException

This method sets the Message's content to a Multipart object.

Specified by:
setContent in interface Part

Parameters:
mp - The multipart object that is the Message's content

Throws:
IllegalWriteException - if the underlying implementation does not support modification of existing values
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public Message reply(boolean replyToAll) throws MessagingException

Message
replyToAll Message getReplyTo

"Subject" "Re:" "Re:" "Message-Id"
"In-Reply-To" ANSWERED "References"
"References" "In-Reply-To" "Message-Id" RFC 2822

replyToAll

return Message

Throws MessagingException:

reply

public Message reply(boolean replyToAll)

throws MessagingException

Get a new Message suitable for a reply to this message. The new Message will have its attributes and headers set up appropriately. Note that this new message object will be empty, i.e., it will not have a "content". These will have to be suitably filled in by the client.

If replyToAll is set, the new Message will be addressed to all recipients of this message. Otherwise, the reply will be addressed to only the sender of this message (using the value of the getReplyTo method).

The "Subject" field is filled in with the original subject prefixed with "Re:" (unless it already starts with "Re:"). The "In-Reply-To" header is set in the new message if this message has a "Message-Id" header. The ANSWERED flag is set in this message. The current implementation also sets the "References" header in the new message to include the contents of the "References" header (or, if missing, the "In-Reply-To" header) in this message, plus the contents of the "Message-Id" header of this message, as described in RFC 2822.
Specified by:
    reply in class Message
Parameters:
    replyToAll - reply should be sent to all recipients of this message
Returns:
    the reply Message
Throws:
    MessagingException

public void writeTo(java.io.OutputStream os) throws java.io.IOException, MessagingException
RFC 822
FilterOutputStream FilterOutputStream MIME Internet CRLF

    writeTo(OutputStream, String[]) null
    Throws java.io.IOException: javax.activation
    Throws MessagingException: writeTo
See also

writeTo

public void writeTo(OutputStream os)
    throws IOException, MessagingException

Output the message as an RFC 822 format stream.

Note that, depending on how the messag was constructed, it may use a variety of line termination conventions. Generally the output should be sent through an appropriate FilterOutputStream that converts the line terminators to the desired form, either CRLF for MIME compatibility and for use in Internet protocols, or the local
platform's line terminator for storage in a local text file.

This implementation calls the `writeTo(OutputStream, String[])` method with a null ignore list.

**Specified by:**
- `writeTo` in interface `Part`

**Throws:**
- `IOException` - if an error occurs writing to the stream or if an error is generated by the `javax.activation` layer.
- `MessagingException`

**See Also:**
- `DataHandler.writeTo(java.io.OutputStream)`

---

```java
public void writeTo(java.io.OutputStream os, String[] ignoreList) throws java.io.IOException, javax.activation.MessagingException, MessagingException
```

Output the message as an RFC 822 format stream, without specified headers. If the `saved` flag is not set, the `saveChanges` method is called. If the `modified` flag is not set and the `content` array is not null, the `content` array is written directly, after writing the appropriate message headers.

**Throws:**
public String[] getHeader(String name) throws MessagingException

header_name US-ASCII RFC 2047

headers InternetHeaders

name return

Throws MessagingException:

See also javax.mail.internet.MimeUtility

getHeader

public String[] getHeader(String name)

throws MessagingException

Get all the headers for this header_name. Note that certain headers may be encoded as per RFC 2047 if they contain non US-ASCII characters and these should be decoded.

This implementation obtains the headers from the headers InternetHeaders object.

Specified by:
getHeader in interface Part

Parameters:
name - name of header

Returns:
array of headers

Throws:
MessagingException
public String getHeader(String name, String delimiter) throws MessagingException

String delimiter

name
delimiter

return

Throws MessagingException:

getHeader

public String getHeader(String name, String delimiter) throws MessagingException

Get all the headers for this header name, returned as a single String, with headers separated by the delimiter. If the delimiter is null, only the first header is returned.

Specified by: getHeader in interface MimePart

Parameters:
  name - the name of this header
delimiter - separator between values

Returns:
  the value fields for all headers with this name

Throws:
  MessagingException

public void setHeader(String name, String value) throws MessagingException

header_name RFC 822  US-ASCII
US-ASCII  RFC 2047
Throws IllegalArgumentException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:
See also javax.mail.internet.MimeUtility

**setHeader**

```java
public void setHeader(String name, String value)
  throws MessagingException
```

Set the value for this header_name. Replaces all existing header values with this new value. Note that RFC 822 headers must contain only US-ASCII characters, so a header that contains non US-ASCII characters must have been encoded by the caller as per the rules of RFC 2047.

**Specified by:**
setHeader in interface Part

**Parameters:**
- name - header name
- value - header value

**Throws:**
- IllegalArgumentException - if the underlying implementation does not support modification
- IllegalStateException - if this message is obtained from a READ_ONLY folder.
- MessagingException

**See Also:**
MimeUtility

---

```java
public void addHeader(String name, String value) throws MessagingException
```

header_name RFC 822 US-ASCII US-
**addHeader**

```java
class Part {

    public void addHeader(String name, String value) throws MessagingException {
        // Implementation
    }
}
```

Add this value to the existing values for this header name. Note that RFC 822 headers must contain only US-ASCII characters, so a header that contains non US-ASCII characters must have been encoded as per the rules of RFC 2047.

**Specified by:**
- `addHeader` in interface `Part`

**Parameters:**
- `name` - header name
- `value` - header value

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this message is obtained from a READ_ONLY folder.
- `MessagingException` - if this message is obtained from a READ_ONLY folder.

**See Also:**
- `javax.mail.internet.MimeUtility`

---

```java
class Part {

    public void removeHeader(String name) throws MessagingException {
        // Implementation
    }
}
```
Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:

removeHeader

public void removeHeader(String name)
throws MessagingException

Remove all headers with this name.

Specified by:
removeHeader in interface Part
Parameters:
name - the name of this header
Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

public java.utilEnumeration{} getAllHeaders() throws MessagingException
Header Message

US-ASCII RFC 2047

    headers InternetHeaders
    return
    Throws MessagingException:
    See also javax.mail.internet.MimeUtility

getAllHeaders
public Enumeration getAllHeaders() throws MessagingException

Return all the headers from this Message as an enumeration of Header objects.

Note that certain headers may be encoded as per RFC 2047 if they contain non US-ASCII characters and these should be decoded.

This implementation obtains the headers from the headers InternetHeaders object.

Specified by:
getAllHeaders in interface Part

Returns:
array of header objects

Throws:
MessagingException

See Also:
MimeUtility

---

public java.util Enumeration<E> getMatchingHeaders(String[] names) throws MessagingException

Return matching headers from this Message as an Enumeration of Header objects. This implementation obtains the headers from the headers InternetHeaders object.

Specified by:
getMatchingHeaders in interface Part

Returns:
enumeration of Header objects

Throws:
MessagingException

public java.util.Enumeration<E>
getNonMatchingHeaders(String[] names) throws MessagingException

Header Message

Throws
MessagingException

getNonMatchingHeaders

public Enumeration getNonMatchingHeaders(String[] names) throws MessagingException

Return non-matching headers from this Message as an Enumeration of Header objects. This implementation obtains the header from the headers InternetHeaders object.

Specified by:
getNonMatchingHeaders in interface Part

Returns:
enumeration of Header objects

Throws:
MessagingException

public void addHeaderLine(String line) throws MessagingException

RFC 822

Throws
IllegalWriteException:

Throws
IllegalStateException: READ_ONLY

Throws
MessagingException:
addHeaderLine

public void addHeaderLine(String line)
    throws MessagingException

Add a raw RFC 822 header-line.

Specified by: 
    addHeaderLine in interface MimePart

Throws:
    IllegalWriteException - if the underlying implementation does not support modification
    IllegalStateException - if this message is obtained from a READ_ONLY folder.
    MessagingException

public java.util.Enumeration&lt;E&gt; getAllHeaderLines()
throws MessagingException
String Header  RFC 822  "name"  "value"

Throws: 
    MessagingException: 

getAllHeaderLines

public Enumeration getAllHeaderLines()
    throws MessagingException

Get all header lines as an Enumeration of Strings. A Header line is a raw RFC 822 header-line, containing both the "name" and "value" field.

Specified by: 
    getAllHeaderLines in interface MimePart

Throws: 
    MessagingException
public java.util.Enumeration<E> getMatchingHeaderLines(String[] names) throws MessagingException
String Header  RFC 822  "name"  "value"

Throws  

MessagingException:

getMatchingHeaderLines

public Enumeration getMatchingHeaderLines(String[] names)
throws MessagingException

Get matching header lines as an Enumeration of Strings. A Header line is a raw RFC 822 header-line, containing both the "name" and "value" field.

Specified by:
    getMatchingHeaderLines in interface MimePart

Throws:
    MessagingException

public java.util.Enumeration<E> getNonMatchingHeaderLines(String[] names) throws MessagingException
String Header  RFC 822  "name"  "value"

Throws  

MessagingException:

getNonMatchingHeaderLines

public Enumeration getNonMatchingHeaderLines(String[] names)
throws MessagingException

Get non-matching header lines as an Enumeration of Strings. A
Header line is a raw RFC 822 header-line, containing both the "name" and "value" field.

**Specified by:**
getNonMatchingHeaderLines in interface MimePart

**Throws:**
MessagingException

```java
public Flags getFlags() throws MessagingException

Flags
```

**Flags Flags**

```java
return Flags
Throws MessagingException:
See also javax.mail.Flags
```

getFlags

```java
public Flags getFlags() throws MessagingException

Return a Flags object containing the flags for this message.

Note that a clone of the internal Flags object is returned, so modifying the returned Flags object will not affect the flags of this message.

**Specified by:**
getFlags in class Message

**Returns:**
Flags object containing the flags for this message

**Throws:**
MessagingException

**See Also:**
Flags
public boolean isSet(Flags.Flag flag) throws MessagingException

flag

flag

return

Throws: MessagingException:
See javax.mail.Flags.Flag, ANSWERED, DELETED, DRAFT,
also FLAGGED, RECENT, SEEN

isSet

public boolean isSet(Flags.Flag flag)
throws MessagingException

Check whether the flag specified in the flag argument is set in this message.

This implementation checks this message's internal flags object.

Overrides:
iset in class Message

Parameters:
flag - the flag

Returns:
value of the specified flag for this message

Throws: MessagingException

See Also:
Flags.Flag, Flags.Flag.ANSWERED, Flags.Flag.DELETED,
Flags.Flag.DRAFT, Flags.Flag.FLAGGED, Flags.Flag.RECENT,
Flags.Flag.SEEN

public void setFlags(Flags flag, boolean set) throws
MessagingException

flags

Throws IllegalWriteException:
Throws IllegalStateException: READ_ONLY
Throws MessagingException:

setFlags

public void setFlags(Flags flag, boolean set)
throws MessagingException

Set the flags for this message.

This implementation modifies the flags field.

Specified by:
setFlags in class Message

Parameters:
flag - Flags object containing the flags to be set
set - the value to be set

Throws:
IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this message is obtained from a READ_ONLY folder.
MessagingException

See Also:
MessageChangedEvent

public void saveChanges() throws MessagingException
saveChanges

**READ ONLY**  saveChanges

| modified | true | save | true | updateHeaders |

**Throws**

- `IllegalWriteException`
- `IllegalStateException`: READ_ONLY
- `MessagingException`:

**saveChanges**

```java
public void saveChanges()
    throws MessagingException
```

Updates the appropriate header fields of this message to be consistent with the message's contents. If this message is contained in a Folder, any changes made to this message are committed to the containing folder.

If any part of a message's headers or contents are changed, `saveChanges` must be called to ensure that those changes are permanent. Otherwise, any such modifications may or may not be saved, depending on the folder implementation.

Messages obtained from folders opened READ_ONLY should not be modified and saveChanges should not be called on such messages.

This method sets the modified flag to true, the save flag to true, and then calls the updateHeaders method.

**Specified by:**

`saveChanges` in class `Message`

**Throws:**

- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this message is obtained from a READ_ONLY folder.
protected void updateMessageID() throws MessagingException

**updateMessageID**

protected void updateMessageID()

throws MessagingException

Update the Message-ID header. This method is called by the updateHeaders and allows a subclass to override only the algorithm for choosing a Message-ID.

**Throws:**

- **MessagingException**

**Since:**

JavaMail 1.4

protected void updateHeaders() throws MessagingException

**updateHeaders**

protected void updateHeaders()

throws MessagingException

Throws **IllegalWriteException:**

Throws **IllegalStateException:** READ_ONLY

Throws **MessagingException:**

protected void updateHeaders()
Called by the `saveChanges` method to actually update the MIME headers. The implementation here sets the `Content-Transfer-Encoding` header (if needed and not already set), the `MIME-Version` header and the `Message-ID` header. Also, if the content of this message is a `MimeMultipart`, its `updateHeaders` method is called.

**Throws:**

- `IllegalArgumentException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this message is obtained from a `READ_ONLY` folder.
- `MessagingException`
is - the InputStream to read the headers from

**Throws:**
MessagingException

**Since:**
JavaMail 1.2

---

**protected** **MimeMessage** createMimeMessage**(Session session)** throws **MessagingException**

MimeMessage  MimeMessage
MimeMessage  Session  MimeMessage
session  Session
return  MimeMessage
since  JavaMail 1.4

**createMimeMessage**

**protected** **MimeMessage** createMimeMessage**(Session session)** throws **MessagingException**

Create and return a MimeMessage object. The reply method uses this method to create the MimeMessage object that it will return. Subclasses can override this method to return a subclass of MimeMessage. This implementation simply constructs and returns a MimeMessage object using the supplied Session.

**Parameters:**

session - the Session to use for the new message

**Returns:**

the new MimeMessage object

**Throws:**

MessagingException

**Since:**
JavaMail 1.4

NEWSGROUPS

public static final MimeMessage.RecipientType NEWSGROUPS

The "Newsgroup" (Usenet news) recipients.

Constructor Detail
protected MimeMessage.RecipientType(String type)

MimeMessage.RecipientType

protected MimeMessage.RecipientType(String type)

Method Detail

protected Object readResolve() throws java.io.ObjectStreamException

readResolve

protected Object readResolve() throws ObjectStreamException

Description copied from class: Message.RecipientType
When deserializing a RecipientType, we need to make sure to return only one of the known static final instances defined in this class. Subclasses must implement their own readResolve method that checks for their known instances before calling this super method.

Overrides:
readResolve in class Message.RecipientType

Throws:
ObjectStreamException

PS:
The MimeMultipart class is an implementation of the abstract Multipart class that uses MIME conventions for the multipart data.
A MimeMultipart is obtained from a MimePart whose primary type is "multipart" (by invoking the part's `getContentType()` method) or it can be created by a client as part of creating a new MimeMessage.

The default multipart subtype is "mixed". The other multipart subtypes, such as "alternative", "related", and so on, can be implemented as subclasses of MimeMultipart with additional methods to implement the additional semantics of that type of multipart content. The intent is that service providers, mail JavaBean writers and mail clients will write many such subclasses and their Command Beans, and will install them into the JavaBeans Activation Framework, so that any JavaMail implementation and its clients can transparently find and use these classes. Thus, a MIME multipart handler is treated just like any other type handler, thereby decoupling the process of providing multipart handlers from the JavaMail API. Lacking these additional MimeMultipart subclasses, all subtypes of MIME multipart data appear as MimeMultipart objects.

An application can directly construct a MIME multipart object of any subtype by using the `MimeMultipart(String subtype)` constructor. For example, to create a "multipart/alternative" object, use `new MimeMultipart("alternative")`.

The `mail.mime.multipart.ignoreMissingEndBoundary` property may be set to `false` to cause a MessagingException to be thrown if the multipart data does not end with the required end boundary line. If this property is set to `true` or not set, missing end boundaries are not considered an error and the final body part ends at the end of the data.

The `mail.mime.multipart.ignoreMissingBoundaryParameter` System property may be set to `false` to cause a MessagingException to be thrown if the Content-Type of the MimeMultipart does not include a `boundary` parameter. If this property is set to `true` or not set, the multipart parsing code will look for a line that looks like a boundary line and use that as the boundary separating the parts.

Field Detail

\verb|ds|

\texttt{protected DataSource ds}

The DataSource supplying our InputStream.

\verb|parsed|

\texttt{protected boolean parsed}

Have we parsed the data from our InputStream yet? Defaults to true; set to false when our constructor is given a DataSource with an InputStream that we need to parse.

Constructor Detail

\texttt{public MimeMultipart()}

\texttt{MimeMultipart "multipart/mixed" contentType "boundary"}

\texttt{MimeBodyParts}
MimeMultipart

public MimeMultipart()

Default constructor. An empty MimeMultipart object is created. Its content type is set to "multipart/mixed". A unique boundary string is generated and this string is setup as the "boundary" parameter for the contentType field.

MimeBodyParts may be added later.

public MimeMultipart(String subtype)
MimeMultipart

MimeBodyPart

public MimeMultipart(String subtype)

Construct a MimeMultipart object of the given subtype. A unique boundary string is generated and this string is setup as the "boundary" parameter for the contentType field.

MimeBodyParts may be added later.

public MimeMultipart(DataSource ds) throws MessagingException
DataSource MimeMultipart bodypart

DataSource MultipartDataSource MultipartDataSource

MultipartDataSource Multipart
MimeMultipart

public MimeMultipart(DataSource ds) throws MessagingException

Constructs a MimeMultipart object and its bodyparts from the given DataSource.

This constructor handles as a special case the situation where the given DataSource is a MultipartDataSource object. In this case, this method just invokes the superclass (i.e., Multipart) constructor that takes a MultipartDataSource object.

Otherwise, the DataSource is assumed to provide a MIME multipart byte stream. The parsed flag is set to false. When the data for the body parts are needed, the parser extracts the "boundary" parameter from the content type of this DataSource, skips the 'preamble' and reads bytes till the terminating boundary and creates MimeBodyParts for each part of the stream.

Parameters:
  ds - DataSource, can be a MultipartDataSource

Throws:
  MessagingException

Method Detail

public void setSubType(String subtype) throws MessagingException

MimeMultipart  multipart  "mixed"
**setSubType**

```java
public void setSubType(String subtype) throws MessagingException
```

Set the subtype. This method should be invoked only on a new MimeMultipart object created by the client. The default subtype of such a multipart object is "mixed".

**Parameters:**
- `subtype` - Subtype

**Throws:**
- `MessagingException`

**getCount**

```java
public int getCount() throws MessagingException
```

BodyPart

```java
return
```

Return the number of enclosed BodyPart objects.

**Overrides:**
- `getCount` in class `Multipart`

**Returns:**
- number of parts

**Throws:**
- `MessagingException`

**See Also:**
- `Multipart.parts`
public BodyPart getBodyPart(int index) throws MessagingException

Get the specified BodyPart. BodyParts are numbered starting at 0.

Overrides: 
getBodyPart in class Multipart

Parameters:
index - the index of the desired BodyPart

Returns:
the Part

Throws:
MessagingException - if no such BodyPart exists

public BodyPart getBodyPart(String CID) throws MessagingException

ContentID (CID) MimeBodyPart null

return

getBodyPart

public BodyPart getBodyPart(String CID) throws MessagingException
Get the MimeBodyPart referred to by the given ContentID (CID). Returns null if the part is not found.

**Parameters:**
- CID - the ContentID of the desired part

**Returns:**
- the Part

**Throws:**
- MessagingException

---

```java
public boolean removeBodyPart(BodyPart part) throws MessagingException, IllegalWriteException
```

**multipart**

```
part
return part true false
```

**Throws**:
- MessagingException: Part
- IllegalWriteException:

---

**removeBodyPart**

```java
public boolean removeBodyPart(BodyPart part) throws MessagingException
```

Remove the specified part from the multipart message. Shifts all the parts after the removed part down one.

**Overrides:**
- removeBodyPart in class Multipart

**Parameters:**
- part - The part to remove

**Returns:**
- true if part removed, false otherwise

**Throws:**
- MessagingException - if no such Part exists
- IllegalWriteException - if the underlying implementation does not support modification of existing values
public void removeBodyPart(int index) throws MessagingException

Remove the part at specified location (starting from 0). Shifts all the parts after the removed part down one.

Overrides:
removeBodyPart in class Multipart

Parameters:
index - Index of the part to remove

Throws:
MessagingException
IndexOutOfBoundsException - if the given index is out of range.
IllegalWriteException - if the underlying implementation does not support modification of existing values

public void addBodyPart(BodyPart part) throws MessagingException
Part multipartBodyPart Part

Throws:
MessagingException
IllegalWriteException:
addBodyPart

public void addBodyPart(BodyPart part) throws MessagingException

Adds a Part to the multipart. The BodyPart is appended to the list of existing Parts.

Overrides:
addBodyPart in class Multipart

Parameters:
part - The Part to be appended

Throws:
MessagingException
IllegalWriteException - if the underlying implementation does not support modification of existing values

public void addBodyPart(BodyPart part, int index) throws MessagingException

Adds a BodyPart at position index. If index is not the last one in the list, the subsequent parts are shifted up. If index is larger than the number of parts present, the BodyPart is appended to the end.

Overrides:
addBodyPart in class Multipart

**Parameters:**
- part - The BodyPart to be inserted
- index - Location where to insert the part

**Throws:**
- MessagingException
- IllegalWriteException - if the underlying implementation does not support modification of existing values

---

```java
public boolean isComplete() throws MessagingException {
    multipart true multipart multipart false
    "mail.mime.multipart.ignoremissingendboundary" false MessagingException
    return true
    since JavaMail 1.4
```

**isComplete**

Return true if the final boundary line for this multipart was seen.
When parsing multipart content, this class will (by default) terminate
parsing with no error if the end of input is reached before seeing
the final multipart boundary line. In such a case, this method will return
false. (If the System property
"mail.mime.multipart.ignoremissingendboundary" is set to false,
parsing such a message will instead throw a MessagingException.)

**Returns:**
- true if the final boundary line was seen

**Throws:**
- MessagingException

**Since:**
- JavaMail 1.4
public String getPreamble() throws MessagingException

multipart IMAP

return null

since JavaMail 1.4

getPreamble

public String getPreamble()

throws MessagingException

Get the preamble text, if any, that appears before the first body part of this multipart. Some protocols, such as IMAP, will not allow access to the preamble text.

Returns:
the preamble text, or null if no preamble

Throws:
MessagingException

Since:
JavaMail 1.4

public void setPreamble(String preamble) throws MessagingException

MIME

\[ \text{preamble} \]

since JavaMail 1.4

setPreamble

public void setPreamble(String preamble)

throws MessagingException

Set the preamble text to be included before the first body part.
Applications should generally not include any preamble text. In some cases it may be helpful to include preamble text with instructions for users of pre-MIME software. The preamble text should be complete lines, including newlines.

**Parameters:**
- preamble - the preamble text

**Throws:**
- MessagingException

**Since:**
- JavaMail 1.4

```java
protected void updateHeaders() throws MessagingException
BodyPart updateHeaders
MimeMultipart boundary

Multipart Message saveChanges Message
MimeMultipart

updateHeaders

protected void updateHeaders()
throws MessagingException

Update headers. The default implementation here just calls the updateHeaders method on each of its children BodyParts.

Note that the boundary parameter is already set up when a new and empty MimeMultipart object is created.

This method is called when the saveChanges method is invoked on the Message object containing this Multipart. This is typically done as part of the Message send process, however note that a client is free to call it any number of times. So if the header updating process
is expensive for a specific MimeMultipart subclass, then it might itself want to track whether its internal state actually did change, and do the header updating only if necessary.

**Throws:**
- `MessagingException`

---

```java
public void writeTo(java.io.OutputStream os) throws java.io.IOException, MessagingException
```

**Specified by:**
- `writeTo` in class `Multipart`

**Throws:**
- `IOException` - if an IO related exception occurs
- `MessagingException`

---

```java
protected void parse() throws MessagingException
```

**since** JavaMail 1.2

---

**parse**

```java
protected void parse()
```
Parse the InputStream from our DataSource, constructing the appropriate MimeBodyParts. The parsed flag is set to true, and if true on entry nothing is done. This method is called by all other methods that need data for the body parts, to make sure the data has been parsed.

**Throws:**

- MessagingException

**Since:**

JavaMail 1.2

---

```java
protected InternetHeaders createInternetHeaders(InputStream is) throws MessagingException

InputStream InternetHeaders
InternetHeaders InternetHeaders

is InputStream

Throws

MessagingException:

since JavaMail 1.2

```

---

**createInternetHeaders**

```java
protected InternetHeaders createInternetHeaders(InputStream is) throws MessagingException

Create and return an InternetHeaders object that loads the headers from the given InputStream. Subclasses can override this method to return a subclass of InternetHeaders, if necessary. This implementation simply constructs and returns an InternetHeaders object.

**Parameters:**

- is - the InputStream to read the headers from

**Throws:**

- MessagingException:
protected MimeBodyPart createMimeBodyPart(InternetHeaders headers, byte[] content) throws MessagingException

Create and return a MimeBodyPart object to represent a body part parsed from the InputStream. Subclasses can override this method to return a subclass of MimeBodyPart, if necessary. This implementation simply constructs and returns a MimeBodyPart object.

Parameters:
- headers - the headers for the body part
- content - the content of the body part

Throws:
- MessagingException

Since:
JavaMail 1.2
createMimeBodyPart(java.io.InputStream is) throws MessagingException

MimeBodyPart  InputStream
MimeBodyPart  MimeBodyPart

is  InputStream

Throws  MessagingException:

since  JavaMail 1.2

createMimeBodyPart

protected  MimeBodyPart  createMimeBodyPart(InputStream is)

throws  MessagingException

Create and return a MimeBodyPart object to represent a body part parsed from the InputStream. Subclasses can override this method to return a subclass of MimeBodyPart, if necessary. This implementation simply constructs and returns a MimeBodyPart object.

Parameters:

is - InputStream containing the body part

Throws:

MessagingException

Since:

JavaMail 1.2

   MimeBodyPart, MimeMessage, PreencodedMimeBodyPart

public interface MimePart
extends Part

Implements: Part
Implemented by: MimeBodyPart, MimeMessage

MimePart MIMERFC 2045Section 2.4
MimePart Part RFC822 MIME MimeMessage
MimeBodyPart

See also javax.mail.internet.MimeUtility, javax.mail.Part

The MimePart interface models an Entity as defined by MIME (RFC2045, Section 2.4).

MimePart extends the Part interface to add additional RFC822 and MIME specific semantics and attributes. It provides the base interface for the MimeMessage and MimeBodyPart classes
A note on RFC822 and MIME headers

RFC822 and MIME header fields **must** contain only US-ASCII characters. If a header contains non US-ASCII characters, it must be encoded as per the rules in RFC 2047. The MimeUtility class provided in this package can be used to achieve this. Callers of the `setHeader`, `addHeader`, and `addHeaderLine` methods are responsible for enforcing the MIME requirements for the specified headers. In addition, these header fields must be folded (wrapped) before being sent if they exceed the line length limitation for the transport (1000 bytes for SMTP). Received headers may have been folded. The application is responsible for folding and unfolding headers as appropriate.

- setHeader
- writeTo
public String getHeader(String name, String delimiter)
throws MessagingException

String delimiter delimiter

return

Throws MessagingException:

getHeader

String getHeader(String name, String delimiter)
throws MessagingException

Get the values of all header fields available for this header, returned as a single String, with the values separated by the delimiter. If the delimiter is null, only the first value is returned.

Parameters:
- name - the name of this header
- delimiter - delimiter between fields in returned string

Returns:
- the value fields for all headers with this name

Throws:
- MessagingException

public void addHeaderLine(String line) throws MessagingException

RFC822

Throws IllegalWriteException:

Throws IllegalStateException: Part READ_ONLY
addHeaderLine

```java
void addHeaderLine(String line) throws MessagingException
```

Add a raw RFC822 header-line.

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification
- `IllegalStateException` - if this Part is obtained from a `READ_ONLY` folder
- `MessagingException`

---

```java
public java.util.Enumeration<E> getAllHeaderLines() throws MessagingException
```

String Header RFC822 "name" "value"

---

getAllHeaderLines

```java
Enumeration getAllHeaderLines() throws MessagingException
```

Get all header lines as an Enumeration of Strings. A Header line is a raw RFC822 header-line, containing both the "name" and "value" field.

**Throws:**
- `MessagingException`

---

```java
public java.util.Enumeration<E> getMatchingHeaderLines(String[] names) throws MessagingException
```

String Header RFC822 "name" "value"
getMatchingHeaderLines

Enumeration getMatchingHeaderLines(String[] names)
throws MessagingException

Get matching header lines as an Enumeration of Strings. A Header line is a raw RFC822 header-line, containing both the "name" and "value" field.

Throws:
MessagingException

public java.utilEnumeration<E>
getNonMatchingHeaderLines(String[] names) throws MessagingException
String Header RFC822 "name" "value"

getNonMatchingHeaderLines

Enumeration getNonMatchingHeaderLines(String[] names)
throws MessagingException

Get non-matching header lines as an Enumeration of Strings. A Header line is a raw RFC822 header-line, containing both the "name" and "value" field.

Throws:
MessagingException

public String getEncoding() throws MessagingException
getEncoding

```java
String getEncoding() throws MessagingException
```

Get the transfer encoding of this part.

Returns:
content-transfer-encoding

Throws:
MessagingException

getContentTypeID

```java
public String getContentTypeID() throws MessagingException
Content-ID null
```

```java
return
```

getContentTypeMD5

```java
public String getContentTypeMD5() throws MessagingException
Content-MD5 null
```

```java
return
```

Get the transfer encoding of this part. Returns null if none present.

Returns:
content-ID

Throws:
MessagingException

Get the Content-ID of this part. Returns null if none present.

Returns:
content-ID

Throws:
MessagingException

Get the Content-MD5 of this part. Returns null if none present.

Returns:
content-MD5

Throws:
MessagingException
getContentMD5

String getContentMD5() throws MessagingException

Get the Content-MD5 digest of this part. Returns null if none present.

Returns: content-MD5
Throws: MessagingException

public void setContentMD5(String md5) throws MessagingException

Content-MD5

md5 MD5
Throws IllegalWriteException:
Throws IllegalStateException: Part READ_ONLY

setContentMD5

void setContentMD5(String md5) throws MessagingException

Set the Content-MD5 of this part.

Parameters: md5 - the MD5 value
Throws: IllegalWriteException - if the underlying implementation does not support modification
IllegalStateException - if this Part is obtained from a READ_ONLY folder
MessagingException
public String[] getContentLanguage() throws MessagingException

MimePart  Content-Language Content-Language
RFC 1766  null

getContentLanguage

String[] getContentLanguage() throws MessagingException

Get the language tags specified in the Content-Language header of this MimePart. The Content-Language header is defined by RFC 1766. Returns null if this header is not available.

Throws:
MessagingException

public void setContentLanguage(String[] languages) throws MessagingException

MimePart  Content-Language Content-Language
RFC 1766

languages

Throws
IllegalWriteException:
Throws  IllegalStateException: Part  READ_ONLY

setContentLanguage

void  setContentLanguage(String[] languages)
throws MessagingException

Set the Content-Language header of this MimePart. The Content-Language header is defined by RFC1766.

Parameters:
languages - array of language tags
Throws:

- **IllegalWriteException** - if the underlying implementation does not support modification
- **IllegalStateException** - if this Part is obtained from a READ_ONLY folder
- **MessagingException**

```java
public void setText(String text) throws MessagingException
    MIME "text/plain" String string US-ASCII "charset"

    text

    charset

    setText

    text

    Throws **MessagingException**: 
    See also **setText(String text, String charset)**
```

**setText**

```java
void setText(String text)
    throws MessagingException
```

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain". If the string contains non US-ASCII characters, it will be encoded using the platform's default charset. The charset is also used to set the "charset" parameter.

Note that there may be a performance penalty if `text` is large, since this method may have to scan all the characters to determine what charset to use.

If the charset is already known, use the `setText` method that takes the charset parameter.
public void setText(String text, String charset) throws MessagingException

MIME "text/plain" String Unicode "charset"

text
charset

Throws MessagingException:

Convenience method that sets the given String as this part's content, with a MIME type of "text/plain" and the specified charset. The given Unicode string will be charset-encoded using the specified charset. The charset is also used to set "charset" parameter.

Parameters:
  text - the text content to set
  charset - the charset to use for the text

Throws:
  MessagingException - if an error occurs

void setText(String text, String charset, String subtype)
throws MessagingException

Convenience method that sets the given String as this part's content, with a primary MIME type of "text" and the specified MIME subtype. The given Unicode string will be charset-encoded using the specified charset. The charset is also used to set the "charset" parameter.

Parameters:
  text - the text content to set
  charset - the charset to use for the text
  subtype - the MIME subtype to use (e.g., "html")

Throws:
  MessagingException - if an error occurs

Class MimePartDataSource

java.lang.Object
  \- javax.mail.internet.MimePartDataSource

All Implemented Interfaces:
  DataSource, MessageAware

public class MimePartDataSource
extends Object
implements DataSource, MessageAware

Implements: DataSource, MessageAware

MimePart DataSource

See javax.mail.internet.MimePart,
also javax.activation.DataSource

A utility class that implements a DataSource out of a MimePart. This class is primarily meant for service providers.

Author: John Mani

See Also: MimePart, DataSource

Field Summary

<table>

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`

### Field Detail

**part**

protected `MimePart` **part**

The MimePart that provides the data for this DataSource.

**Since:**

JavaMail 1.4

### Constructor Detail
public MimePartDataSource(MimePart part)  
MimePart  DataSource

MimePartDataSource

public MimePartDataSource(MimePart part)

Constructor, that constructs a DataSource from a MimePart.

Method Detail

public java.io.InputStream getInputStream() throws java.io.IOException  
MimePart

MimePart  Content-Transfer-Encoding

getContentStream()  Part  MimeUtility.decode()

return

See also  getContentStream, getContentStream, decode

getInputStream

public InputStream getInputStream() throws IOException

Returns an input stream from this MimePart.

This method applies the appropriate transfer-decoding, based on the Content-Transfer-Encoding attribute of this MimePart. Thus the returned input stream is a decoded stream of bytes.

This implementation obtains the raw content from the Part using the
getContentStream() method and decodes it using the MimeUtility.decode() method.

**Specified by:**
getInputStream in interface DataSource

**Returns:**
decoded input stream

**Throws:**
IOException

**See Also:**
MimeMessage.getContentStream(),
MimeBodyPart.getContentStream(),
MimeUtility.decode(java.io.InputStream, java.lang.String)

---

public java.io.OutputStream getOutputStream() throws java.io.IOException

DataSource

UnknownServiceException

getOutputStream

public OutputStream getOutputStream() throws IOException

DataSource method to return an output stream.

This implementation throws the UnknownServiceException.

**Specified by:**
getOutputStream in interface DataSource

**Returns:**
an OutputStream

**Throws:**
IOException
public String getContentType()

MimePart getContentType

getContentType

public String getContentType()

    Returns the content-type of this DataSource.
    
    This implementation just invokes the getContentType method on the MimePart.
    
    Specified by: getContentType in interface DataSource
    
    Returns: the MIME Type

public String getName()

DataSource

getName

public String getName()

    DataSource method to return a name.
    
    This implementation just returns an empty string.
    
    Specified by:
getName in interface DataSource

Returns:
the name of the object.

Public MessageContext getMessageContext()

MessageContext
since JavaMail 1.1

getMessageContext

Public MessageContext getMessageContext()

Return the MessageContext for the current part.

Specified by:
getMessageContext in interface MessageAware

Since:
JavaMail 1.1

Constructor Detail

public MimeType()

MimeType

public MimeType()
    Default constructor.

public MimeType(String rawdata) throws MimeTypeParseException
String MimeType
    rawdata MIME
**MimeType**

```java
public MimeType(String rawdata) throws MimeTypeParseException
```

Constructor that builds a MimeType from a String.

**Parameters:**
- rawdata - the MIME type string

**Throws:**
- MimeTypeParseException

```java
public MimeType(String primary, String sub) throws MimeTypeParseException
```

**MimeType**

```java
primary MIME
sub MIME
```

**Throws:**
- MimeTypeParseException

**MimeType**

```java
public MimeType(String primary, String sub) throws MimeTypeParseException
```

Constructor that builds a MimeType with the given primary and sub type but has an empty parameter list.

**Parameters:**
- primary - the primary MIME type
- sub - the MIME sub-type

**Throws:**
- MimeTypeParseException - if the primary type or subtype is not a valid token

---

**Method Detail**
public String getPrimaryType()

    return MIME

getPrimaryType

public  String  getPrimaryType()

    Retrieve the primary type of this object.

    Returns:
        the primary MIME type

public void setPrimaryType(String primary) throws String

    primary MIME

    Throws: MimeTypeParseException:

setPrimaryType

public void setPrimaryType(String primary)

    throws MimeTypeParseException

    Set the primary type for this object to the given String.

    Parameters:
        primary - the primary MIME type

    Throws:
        MimeTypeParseException - if the primary type is not a valid token

public String getSubType()
getSubType

public String getSubType()

Retrieve the subtype of this object.

Returns:
the MIME subtype

setSubType

public void setSubType(String sub) throws MimeTypeParseException

String

sub

MIME

Throws:
MimeTypeParseException:

setSubType

public void setSubType(String sub)
throws MimeTypeParseException

Set the subtype for this object to the given String.

Parameters:
sub - the MIME subtype

Throws:
MimeTypeParseException - if the subtype is not a valid token

getParameterList
getParameters

public MimeTypeInfoList getParameters()

Retrieve this object's parameter list.

Returns:
  a MimeTypeInfoList object representing the parameters

getParameter

public String getParameter(String name)

Retrieve the value associated with the given name, or null if there is no current association.

Parameters:
  name - the parameter name

Returns:
  the parameter's value

setParameter

public void setParameter(String name, String value)

setParameter
Set the value to be associated with the given name, replacing any previous association.

**Parameters:**
- *name* - the parameter name
- *value* - the parameter's value

---

```java
public void removeParameter(String name)
```

Remove any value associated with the given name.

**Parameters:**
- *name* - the parameter name

---

```java
public String toString()
```

Return the String representation of this object.

**Overrides:**
- `toString` in class `Object`
public String getBaseType()

String

    return MIME

getBaseType

gpublic String getBaseType()

    Return a String representation of this object without the parameter list.

    Returns:
    the MIME type and sub-type

match

public boolean match(MimeType type)

type
    return MimeType

match

public boolean match(MimeType type)

    Determine if the primary and sub type of this object is the same as what is in the given type.

    Parameters:
    type - the MimeType object to compare with

    Returns:
    true if they match

match

public boolean match(String rawdata) throws 
MimeTypeParseException
### rawdata

```
rawdata
  rawdata MIME
  return true
```

### match

```java
public boolean match(String rawdata)
  throws MimeTypeParseException
```

Determine if the primary and sub type of this object is the same as the content type described in rawdata.

**Parameters:**
- `rawdata` - the MIME type string to compare with

**Returns:**
- `true` if they match

**Throws:**
- `MimeTypeParseException`

### writeExternal

```java
public void writeExternal(java.io.ObjectOutput out) throws java.io.IOException
```

writeExternal  DataOutput  ObjectOutput  writeObject
```

**Throws**
- `java.io.IOException`: I/O

### writeExternal

```java
public void writeExternal(ObjectOutput out)
  throws IOException
```

The object implements the writeExternal method to save its contents by calling the methods of DataOutput for its primitive values or calling the writeObject method of ObjectOutput for objects, strings and arrays.
public void readExternal(java.io.ObjectInput in) throws java.io.IOException, ClassNotFoundException
readExternal DataInput readObject
readExternal writeExternal
in ObjectInput
Throws ClassNotFoundException:

The object implements the readExternal method to restore its contents by calling the methods of DataInput for primitive types and readObject for objects, strings and arrays. The readExternal method must read the values in the same sequence and with the same types as were written by writeExternal.

boolean isEmpty()  
Determine whether or not this list is empty.

protected void parse(String parameterList)  
A routine for parsing the parameter list out of a String.

void remove(String name)  
Remove any value associated with the given name.

void set(String name, String value)  
Set the value to be associated with the given name, replacing any previous association.

int size()  
Return the number of name-value pairs in this list.

String toString()  
Return a string representation of this object.

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait

Constructor Detail

public MimeTypeParameterList()

Default constructor.

public MimeTypeParameterList(String parameterList)

throws MimeTypeParseException

MimeTypeParameterList
**MimeTypeParameterList**

public MimeTypeParameterList(String parameterList) throws MimeTypeParseException

Constructs a new MimeTypeParameterList with the passed in data.

**Parameters:**
- parameterList - an RFC 2045, 2046 compliant parameter list.

**Throws:**
- MimeTypeParseException

### Method Detail

**protected void parse(String parameterList) throws MimeTypeParseException**

String

```
parameterList
```

A routine for parsing the parameter list out of a String.

**Parameters:**
- parameterList - an RFC 2045, 2046 compliant parameter list.

**Throws:**
- MimeTypeParseException

**public int size()**

-
```java
public int size()
{
    return
}
```

**size**

Return the number of name-value pairs in this list.

**Returns:**
the number of parameters

```java
public boolean isEmpty()
{
    return true
}
```

**isEmpty**

Determine whether or not this list is empty.

**Returns:**
true if there are no parameters

```java
public String get(String name)
{
    return
}
```

**get**

public **String** get(String name)
Retrieve the value associated with the given name, or null if there is no current association.

**Parameters:**
- name - the parameter name

**Returns:**
- the parameter's value

---

**public void set(String name, String value)**

**set**

```java
public void set(String name, String value)
```

Set the value to be associated with the given name, replacing any previous association.

**Parameters:**
- name - the parameter name
- value - the parameter's value

---

**public void remove(String name)**

**remove**

```java
public void remove(String name)
```

Remove any value associated with the given name.
Parameters:
name - the parameter name

public java.util.Enumeration<E> getNames()

    return

getNames

public Enumeration getNames()

    Retrieve an enumeration of all the names in this list.

    Returns:
    an enumeration of all parameter names

public String toString()

toString

public String toString()

    Return a string representation of this object.

    Overrides:
    toString in class Object
Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS:
javax.activation  **Class MimeTypeError ParseException**

java.lang.Object  
  ⊃ java.lang.Throwable  
    ⊃ java.lang.Exception  
      ⊃ javax.activation.MimeTypeParseException

**All Implemented Interfaces:**

Serializable

```java
public class MimeTypeError ParseException
    extends Exception
```

**Extends:** Throwable > Exception

MimeType

A class to encapsulate MimeType parsing related exceptions.

**See Also:**

Serialized Form

Constructor Detail

public MimeTypeErrorParseException()
MimeTypeErrorParseException

MimeTypeErrorParseException

public MimeTypeErrorParseException()

Constructs a MimeTypeErrorParseException with no specified detail message.

public MimeTypeErrorParseException(String s)
MimeTypeErrorParseException

s

MimeTypeErrorParseException

public MimeTypeErrorParseException(String s)

Constructs a MimeTypeErrorParseException with the specified detail message.

Parameters:
s - the detail message.
javax.activation  Class MimetypesFileTypeMap

java.lang.Object
   ▼ javax.activation.FileTypeMap
      ▼ javax.activation.MimetypesFileTypeMap

public class MimetypesFileTypeMap extends FileTypeMap

Extends: FileTypeMap

File Type Map

MIME

MimetypesFileTypeMap MIME MimetypesFileTypeMap
MIME MIME

1. MimetypesFileTypeMap
2. .mime.types
3. <$java.home>/lib/mime.types
4. META-INF/mime.types
5. META-INF/mimetypes.default activation.jar

MIME

# '#'
# <mime > <>
#
text/plain txt text TXT
# file.txt file.text file.TXT
# mime "text/plain"

This class extends FileTypeMap and provides data typing of files via their file extension. It uses the .mime.types format.

MIME types file search order:
The MimetypesFileTypeMap looks in various places in the user's system for MIME types file entries. When requests are made to search for MIME types in the MimetypesFileTypeMap, it searches MIME types files in the following order:

1. Programmatically added entries to the MimetypesFileTypeMap instance.
2. The file `.mime.types` in the user's home directory.
3. The file `<java.home>/lib/mime.types`.
4. The file or resources named META-INF/mime.types.
5. The file or resource named META-INF/mimetypes.default (usually found only in the activation.jar file).

**MIME types file format:**

```
# comments begin with a '#'
# the format is <mime type> <space separated file extensions>
# for example:
text/plain txt text TXT
# this would map file.txt, file.text, and file.TXT to
# the mime type "text/plain"
```

**Method Summary**

**addMimeTypes**

Prepend the MIME type values to the registry.

**getContentType**

Return the MIME type of the file object.

**getContentType**

Return the MIME type based on the specified file name.

Methods inherited from class `javax.activation.FileTypeMap`

- `getDefaultFileTypeMap`, `setDefaultFileTypeMap`

Methods inherited from class `java.lang.Object`

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`

**Constructor Detail**

```java
public MimetypesFileTypeMap()
```

**MimetypesFileTypeMap**

```java
public MimetypesFileTypeMap()
```

The default constructor.

```java
public MimetypesFileTypeMap(String mimeTypeFileName)
```

`mimeTypeFileName`
public MimetypesFileTypeMap(String mimeTypeFileName) throws IOException

Construct a MimetypesFileTypeMap with programmatic entries added from the named file.

Parameters:
  mimeTypeFileName - the file name

Throws:
  IOException

public MimetypesFileTypeMap(java.io.InputStream is)
InputStream MimetypesFileTypeMap

MimetypesFileTypeMap

public MimetypesFileTypeMap(InputStream is)

Construct a MimetypesFileTypeMap with programmatic entries added from the InputStream.

Parameters:
  is - the input stream to read from

Method Detail

public void addMimeTypes(String mime_types)

MIME

  mime_types .mime.

addMimeTypes

public void addMimeTypes(String mime_types)
Prepend the MIME type values to the registry.

**Parameters:**
- mime_types - A .mime.types formatted string of entries.

```java
public String getContentType(java.io.File f)

MIME
getContentType(f.getName())

f
return

getContentType
```

**getContentType**

```java
public String getContentType(File f)

getContentType(f.getName())

f
return

MIME
```

**Specified by:**
- `getContentType` in class `FileTypeMap`

**Parameters:**
- f - the file

**Returns:**
- the file's MIME type

```java
public String getContentType(String filename)

MIME
"application/octet-stream"

filename
return

MIME
```

**getContentType**

```java
public String getContentType(String filename)

MIME
"application/octet-stream"

filename
return

MIME
```
Return the MIME type based on the specified file name. The MIME type entries are searched as described above under MIME types file search order. If no entry is found, the type "application/octet-stream" is returned.

**Specified by:**
getContentType in class FileTypeMap

**Parameters:**
filename - the file name

**Returns:**
the file's MIME type

Unicode String

MIME

mail.mime.decodetext.strict MIME MIME
mail.mime.decodetext.strict "false" true

mail.mime.encodeeol.strict "text" MIME Content-Transfer-
This is a utility class that provides various MIME related functionality.

There are a set of methods to encode and decode MIME headers as per RFC 2047. A brief description on handling such headers is given below:

RFC 822 mail headers **must** contain only US-ASCII characters. Headers that contain non US-ASCII characters must be encoded so that they contain only US-ASCII characters. Basically, this process involves using either BASE64 or QP to encode certain characters. RFC 2047 describes this in detail.

In Java, Strings contain (16 bit) Unicode characters. ASCII is a subset of Unicode (and occupies the range 0 - 127). A String that contains only ASCII characters is already mail-safe. If the String contains non US-ASCII characters, it must be encoded. An additional complexity in this step is that since Unicode is not yet a widely used charset, one might want to first charset-encode the String into another charset and then do the transfer-encoding.

Note that to get the actual bytes of a mail-safe String (say, for sending over SMTP), one must do

```
byte[] bytes = string.getBytes("iso-8859-1");
```

The `setHeader` and `addHeader` methods on MimeMessage and MimeBodyPart assume that the given header values are Unicode strings that contain only US-ASCII characters. Hence the callers of those methods must insure that the values they pass do not contain non US-ASCII characters. The methods in this class help do this.
The `getHeader` family of methods on `MimeMessage` and `MimeBodyPart` return the raw header value. These might be encoded as per RFC 2047, and if so, must be decoded into Unicode Strings. The methods in this class help to do this.

Several System properties control strict conformance to the MIME spec. Note that these are not session properties but must be set globally as System properties.

The `mail.mime.decodetext.strict` property controls decoding of MIME encoded words. The MIME spec requires that encoded words start at the beginning of a whitespace separated word. Some mailers incorrectly include encoded words in the middle of a word. If the `mail.mime.decodetext.strict` System property is set to "false", an attempt will be made to decode these illegal encoded words. The default is true.

The `mail.mime.encodeeol.strict` property controls the choice of Content-Transfer-Encoding for MIME parts that are not of type "text". Often such parts will contain textual data for which an encoding that allows normal end of line conventions is appropriate. In rare cases, such a part will appear to contain entirely textual data, but will require an encoding that preserves CR and LF characters without change. If the `mail.mime.encodeeol.strict` System property is set to "true", such an encoding will be used when necessary. The default is false.

In addition, the `mail.mime.charset` System property can be used to specify the default MIME charset to use for encoded words and text parts that don't otherwise specify a charset. Normally, the default MIME charset is derived from the default Java charset, as specified in the `file.encoding` System property. Most applications will have no need to explicitly set the default MIME charset. In cases where the default MIME charset to be used for mail messages is different than the charset used for files stored on the system, this property should be set.

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
public static final int ALL

See Also:
Constant Field Values

Method Detail

public static String getEncoding(DataSource ds)

- "text" US-ASCII "7bit" US-ASCII "base64" US-ASCII "quoted-printable"
- "text" US-ASCII "7bit" US-ASCII "base64"

getEncoding

public static String getEncoding(DataSource ds)

Get the content-transfer-encoding that should be applied to the input stream of this datasource, to make it mailsafe.

The algorithm used here is:

- If the primary type of this datasource is "text" and if all the bytes in its input stream are US-ASCII, then the encoding is "7bit". If more than half of the bytes are non-US-ASCII, then the encoding is "base64". If less than half of the bytes are non-US-ASCII, then the encoding is "quoted-printable".
- If the primary type of this datasource is not "text", then if all the bytes of its input stream are US-ASCII, the encoding is "7bit". If
there is even one non-US-ASCII character, the encoding is "base64".

**Parameters:**
- ds - DataSource

**Returns:**
the encoding. This is either "7bit", "quoted-printable" or "base64"

---

```java
public static String getEncoding(DataHandler dh) {
    return getEncoding(DataSource) instanceof InputStream ?
        writeTo
    : MIME "text/plain" String
        InputStream DataHandler writeTo

    since JavaMail 1.2
}
```

---

### getEncoding

```java
public static String getEncoding(DataHandler dh) {
    Same as getEncoding(DataSource) except that instead of reading the data from an InputStream it uses the writeTo method to examine the data. This is more efficient in the common case of a DataHandler created with an object and a MIME type (for example, a "text/plain" String) because all the I/O is done in this thread. In the case requiring an InputStream the DataHandler uses a thread, a pair of pipe streams, and the writeTo method to produce the data.

Since: JavaMail 1.2
```

---

```java
public static java.io.InputStream decode(java.io.InputStream is, String encoding) throws MessagingException
```
**InputStream RFC 2045**

"base64" "quoted-printable" "7bit" "8bit" "binary" "uuencode"

```
is
encoding
return
```

**decode**

```java
public static InputStream decode(InputStream is, String encoding)
throws MessagingException
```

Decode the given input stream. The Input stream returned is the decoded input stream. All the encodings defined in RFC 2045 are supported here. They include "base64", "quoted-printable", "7bit", "8bit", and "binary". In addition, "uuencode" is also supported.

**Parameters:**
- `is` - input stream
- `encoding` - the encoding of the stream.

**Returns:**
- decoded input stream.

**Throws:**
- `MessagingException`

---

```java
public static java.io.OutputStream encode(java.io.OutputStream os, String encoding)
throws MessagingException
```

RFC 2045 "base64" "quoted-printable" "7bit" "8bit" "binary" "uuencode"

```
    os
    encoding
    return
```
encode

public static OutputStream encode(OutputStream os, String encoding) throws MessagingException

Wrap an encoder around the given output stream. All the encodings defined in RFC 2045 are supported here. They include "base64", "quoted-printable", "7bit", "8bit" and "binary". In addition, "uuencode" is also supported.

Parameters:
- os - output stream
- encoding - the encoding of the stream.

Returns:
output stream that applies the specified encoding.

Throws:
MessagingException

---

public static java.io.OutputStream encode(java.io.OutputStream os, String encoding, String filename) throws MessagingException

RFC 2045 "base64" "quoted-printable" "7bit" "8bit" "binary" "uuencode" filename "uuencode"

os
encoding
filename uuencode
return
since JavaMail 1.2

en

encode

public static OutputStream encode(OutputStream os, String encoding, String filename)
Wrap an encoder around the given output stream. All the encodings defined in RFC 2045 are supported here. They include "base64", "quoted-printable", "7bit", "8bit" and "binary". In addition, "uuencode" is also supported. The filename parameter is used with the "uuencode" encoding and is included in the encoded output.

**Parameters:**
- os - output stream
- encoding - the encoding of the stream.
- filename - name for the file being encoded (only used with uuencode)

**Returns:**
output stream that applies the specified encoding.

**Throws:**
- MessagingException

**Since:**
JavaMail 1.2

```java
public static String encodeText(String text) throws java.io.UnsupportedEncodingException
RFC 2047 RFC 822 "text"

""RFC 822

MimePart part = ... String rawvalue = "FooBar Mailer, Japanese version 1.1"
try {
// If we know for sure that rawvalue contains only US-ASCII characters, we can skip the encoding part
part.setHeader("X-mailer", MimeUtility.encodeText(rawvalue)
catch (UnsupportedEncodingException e) {
```
public static String encodeText(String text) throws UnsupportedEncodingException

Encode a RFC 822 "text" token into mail-safe form as per RFC 2047.

The given Unicode string is examined for non US-ASCII characters. If the string contains only US-ASCII characters, it is returned as-is. If the string contains non US-ASCII characters, it is first character-encoded using the platform's default charset, then transfer-encoded using either the B or Q encoding. The resulting bytes are then returned as a Unicode string containing only ASCII characters.

Note that this method should be used to encode only "unstructured" RFC 822 headers.

Example of usage:

MimePart part = ...
String rawvalue = "FooBar Mailer, Japanese version 1.1"
try {
    // If we know for sure that rawvalue contains only US-ASCII characters, we can skip the encoding part
    part.setHeader("X-mailer", MimeUtility.encodeText(rawvalue)
} catch (UnsupportedEncodingException e) {
    // encoding failure
} catch (MessagingException me) {
    // setHeader() failure
Parameters:
  text - Unicode string

Returns:
  Unicode string containing only US-ASCII characters

Throws:
  UnsupportedEncodingException - if the encoding fails

public static String encodeText(String text, String charset, String encoding) throws java.io.UnsupportedEncodingException

RFC 2047 RFC 822 "text"

""RFC 822
  text
  charset null
  encoding "B" "Q" null ASCII "Q" "B"
  return US-ASCII Unicode

encodeText

public static String encodeText(String text, String charset, String encoding) throws UnsupportedEncodingException

Encode a RFC 822 "text" token into mail-safe form as per RFC 2047.

The given Unicode string is examined for non US-ASCII characters. If the string contains only US-ASCII characters, it is returned as-is.
the string contains non US-ASCII characters, it is first character-encoded using the specified charset, then transfer-encoded using either the B or Q encoding. The resulting bytes are then returned as a Unicode string containing only ASCII characters.

Note that this method should be used to encode only "unstructured" RFC 822 headers.

**Parameters:**
- text - the header value
- charset - the charset. If this parameter is null, the platform's default chatset is used.
- encoding - the encoding to be used. Currently supported values are "B" and "Q". If this parameter is null, then the "Q" encoding is used if most of characters to be encoded are in the ASCII charset, otherwise "B" encoding is used.

**Returns:**
Unicode string containing only US-ASCII characters

**Throws:**
UnsupportedEncodingException

```java
public static String decodeText(String etext) throws java.io.UnsupportedEncodingException
```

""" RFC 822 "*text"

RFC 2047 6.1
UnsupportedEncodingException String RFC 2047

```java
MimePart part = ...
String rawvalue = null;
String value = null;
try {
if ((rawvalue = part.getHeader("X-mailer")[0]) != null) 
value = MimeUtility.decodeText(rawvalue);
} catch (UnsupportedEncodingException e) {
```
Don't care
value = rawvalue;
} catch (MessagingException me) { }

return value;

decodeText

public static String decodeText(String etext)
throws UnsupportedEncodingException

Decode "unstructured" headers, that is, headers that are defined as 'text' as per RFC 822.

The string is decoded using the algorithm specified in RFC 2047, Section 6.1. If the charset-conversion fails for any sequence, an UnsupportedEncodingException is thrown. If the String is not an RFC 2047 style encoded header, it is returned as-is.

Example of usage:

MimePart part = ... String rawvalue = null; String value = null; try {
if ((rawvalue = part.getHeader("X-mailer") [0]) != null)
  value = MimeUtility.decodeText(rawvalue);
} catch (UnsupportedEncodingException e) {
  // Don't care
  value = rawvalue;
} catch (MessagingException me) { }

return value;
public static String encodeWord(String word) throws java.io.UnsupportedEncodingException
RFC 2047 RFC 822 "word"

RFC 822 "phrases" InternetAddress 'phrase'

    word                        Unicode
    return                      US-ASCII Unicode
    Throws                      java.io.UnsupportedEncodingException:

encodeWord

public static String encodeWord(String word)
throws UnsupportedEncodingException

Encode a RFC 2047 "word" token into mail-safe form as per RFC 822.

The given Unicode string is examined for non US-ASCII characters. If the string contains only US-ASCII characters, it is returned as-is. If the string contains non US-ASCII characters, it is first character-encoded using the platform's default charset, then transfer-encoded using either the B or Q encoding. The resulting bytes are then returned as a Unicode string containing only ASCII characters.

This method is meant to be used when creating RFC 822 "phrases". The InternetAddress class, for example, uses this to encode it's
'phrase' component.

**Parameters:**
- **word** - Unicode string

**Returns:**
- Array of Unicode strings containing only US-ASCII characters.

**Throws:**
- `UnsupportedEncodingException` - if the encoding fails

```java
public static String encodeWord(String word, String charset, String encoding) throws java.io.UnsupportedEncodingException
RFC 2047 RFC 822 "word"

| word     | Unicode |
| charset  | MIME    |
| encoding | "B" "Q" null ASCII "Q" "B"
| return   | US-ASCII Unicode |

Throws: java.io.UnsupportedEncodingException:
```

**encodeWord**

```java
public static String encodeWord(String word, String charset, String encoding) throws UnsupportedEncodingException

Encode a RFC 822 "word" token into mail-safe form as per RFC 2047.

The given Unicode string is examined for non US-ASCII characters. If the string contains only US-ASCII characters, it is returned as-is. If
the string contains non US-ASCII characters, it is first character-encoded using the specified charset, then transfer-encoded using either the B or Q encoding. The resulting bytes are then returned as a Unicode string containing only ASCII characters.

**Parameters:**
- `word` - Unicode string
- `charset` - the MIME charset
- `encoding` - the encoding to be used. Currently supported values are "B" and "Q". If this parameter is null, then the "Q" encoding is used if most of characters to be encoded are in the ASCII charset, otherwise "B" encoding is used.

**Returns:**
- Unicode string containing only US-ASCII characters

**Throws:**
- `UnsupportedEncodingException` - if the encoding fails

```java
public static String decodeWord(String eword) throws 
ParseException, java.io.UnsupportedEncodingException
```

**eword**

**Throws**
- `ParseException`: RFC 2047 encoded-word
- `java.io.UnsupportedEncodingException`:

**decodeWord**

```java
public static String decodeWord(String eword) 
throws ParseException, 
UnsupportedEncodingException
```

The string is parsed using the rules in RFC 2047 for parsing an "encoded-word". If the parse fails, a `ParseException` is thrown.
Otherwise, it is transfer-decoded, and then charset-converted into Unicode. If the charset-conversion fails, an UnsupportedEncodingException is thrown.

**Parameters:**
- `eword` - the encoded value

**Throws:**
- `ParseException` - if the string is not an encoded-word as per RFC 2047.
- `UnsupportedEncodingException` - if the charset conversion failed.

```java
public static String quote(String word, String specials)
' specials'
```

**HeaderTokenizer** - MIME  RFC 822

**RFC 822**  **MIME**

```java
word
specials
return
See also  MIME, RFC822
```

**quote**

```java
public static String quote(String word, String specials)
```

A utility method to quote a word, if the word contains any characters from the specified 'specials' list.

The **HeaderTokenizer** class defines two special sets of delimiters - MIME and RFC 822.

This method is typically used during the generation of RFC 822 and MIME header fields.
public static String fold(int used, String s)

Fold a string at linear whitespace so that each line is no longer than 76 characters, if possible. If there are more than 76 non-whitespace characters consecutively, the string is folded at the first whitespace after that sequence. The parameter `used` indicates how many characters have been used in the current line; it is usually the length of the header name.

Note that line breaks in the string aren't escaped; they probably should be.

**Parameters:**
- `used` - characters used in line so far
- `s` - the string to fold

**Parameters:**
- `word` - word to be quoted
- `specials` - the set of special characters

**Returns:**
the possibly quoted word

**See Also:**
HeaderTokenizer.MIME, HeaderTokenizer.RFC822
public static String unfold(String s)

Unfold a folded header. Any line breaks that aren't escaped and are followed by whitespace are removed.

Parameters:
  s - the string to unfold

Returns:
  the unfolded string

Since:
  JavaMail 1.4
public static String javaCharset(String charset)

Convert a MIME charset name into a valid Java charset name.

**Parameters:**
- charset - the MIME charset name

**Returns:**
- the Java charset equivalent. If a suitable mapping is not available, the passed in charset is itself returned.

---

public static String mimeCharset(String charset)

Java MIME

**JDK 1.2**

<table>
<thead>
<tr>
<th>charset</th>
<th>JDK</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>MIME/IANA</td>
</tr>
<tr>
<td>since</td>

</tr>
</tbody>
</table>

mimeCharset

public static String mimeCharset(String charset)

Convert a java charset into its MIME charset name.

Note that a future version of JDK (post 1.2) might provide this functionality, in which case, we may deprecate this method then.

**Parameters:**
- charset - the JDK charset

**Returns:**
- the MIME/IANA equivalent. If a mapping is not possible, the passed in charset itself is returned.

**Since:**
- JavaMail 1.1
public static String getDefaultJavaCharset()

    return Java MIME

since JavaMail 1.1

getDefaultJavaCharset

public static String getDefaultJavaCharset()

Get the default charset corresponding to the system's current default locale. If the System property mail.mime.charset is set, a system charset corresponding to this MIME charset will be returned.

Returns:
the default charset of the system's default locale, as a Java charset. (NOT a MIME charset)

Since:
JavaMail 1.1

Field Detail

EAR
public static final ModuleType EAR

   The module is an EAR archive.

---

EJB

public static final ModuleType EJB

   The module is an Enterprise Java Bean archive.

---

CAR

public static final ModuleType CAR

   The module is an Client Application archive.

---

RAR

public static final ModuleType RAR

   The module is an Connector archive.

---

WAR

public static final ModuleType WAR

   The module is an Web Application archive.
Constructor Detail

protected ModuleType(int value)

value

ModuleType

protected ModuleType(int value)

Construct a new enumeration value with the given integer value.

Parameters:
value - Integer value.

Method Detail

public int getValue()

return

getValue

public int getValue()

Returns this enumeration value's integer value.

Returns:
the value

protected String[] getStringTable()
getStringTable

protected String[] getStringTable()

Returns the string table for class ModuleType

protected ModuleType[] getEnumValueTable()

ModuleType

gEnumValueTable

protected ModuleType[] getEnumValueTable()

Returns the enumeration value table for class ModuleType

gEnumValueTable

public String getModuleExtension()

getModuleExtension

public String getModuleExtension()

Return the file extension string for this enumeration.

gEnumValueTable

public static ModuleType getModuleType(int value)

value

gEnumValueTable

public static ModuleType getModuleType(int value)
Return an object of the specified value.

**Parameters:**
- value - a designator for the object.

```java
public String toString()

ModuleType

toString
```

```java
public String toString()

Return the string name of this ModuleType or the integer value if outside the bounds of the table

**Overrides:**
- toString in class Object
```

```java
protected int getOffset()

0 EnumSyntax  0

return
```

```java
getOffset

protected int getOffset()

Returns the lowest integer value used by this enumeration value's enumeration class.

The default implementation returns 0. If the enumeration class (a subclass of class EnumSyntax) uses integer values starting at other
than 0, override this method in the subclass.

**Returns:**
the offset of the lowest enumeration value.
javax.mail  Class Multipart

javax.lang.Object
  ↳ javax.mail.Multipart

Direct Known Subclasses:
  MimeMultipart

public abstract class Multipart
extends Object

Extended by: MimeMultipart

Multipart Multipart

Multipart  Multipart DataContentHandler  "multipart/signed"
  DataHandler  getContent()  Multipart

  Multipart MIME
"alternative""mixed""related""parallel""signed"

Multipart

  version  1.16, 07/05/04

Multipart is a container that holds multiple body parts. Multipart provides methods to retrieve and set its subparts.

Multipart also acts as the base class for the content object returned by most Multipart DataContentHandlers. For example, invoking getContent() on a DataHandler whose source is a "multipart/signed" data source may return an appropriate subclass of Multipart.

Some messaging systems provide different subtypes of Multiparts. For example, MIME specifies a set of subtypes that include "alternative", "mixed", "related", "parallel", "signed", etc.
Multipart is an abstract class. Subclasses provide actual implementations.

</tbody>
</table>
### Methods

- **getParent()**
  Return the Part that contains this Multipart object, or null if not known.

- **boolean removeBodyPart(BodyPart part)**
  Remove the specified part from the multipart message.

- **void removeBodyPart(int index)**
  Remove the part at specified location (starting from 0).

- **protected void setMultipartDataSource(MultipartDataSource mp)**
  Setup this Multipart object from the given MultipartDataSource.

- **void setParent(Part parent)**
  Set the parent of this Multipart to be the specified Part.

- **abstract void writeTo(OutputStream os)**
  Output an appropriately encoded bytestream to the given OutputStream.

### Methods inherited from class java.lang.Object

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

---

### Field Detail

- **parts**

  protected Vector parts

  Vector of BodyPart objects.

- **contentType**
protected `String` `contentType`

This field specifies the content-type of this multipart object. It defaults to "multipart/mixed".

---

parent

protected `Part` `parent`

The `Part` containing this `Multipart`, if known.

**Since:**
JavaMail 1.1

**Constructor Detail**

protected `Multipart()`
`Multipart`

Default constructor. An empty `Multipart` object is created.

**Method Detail**

protected `void` `setMultipartDataSource`(`MultipartDataSource` `mp`) throws `MessagingException`
`MultipartDataSource` `Multipart`
MultipartDataSource BodyPart Multipart
Multipart contentType MultipartDataSource

Multipart IMAP multipart Multipart

\( mp \)          Multipart

**setMultipartDataSource**

protected void setMultipartDataSource(MultipartDataSource mp) throws MessagingException

Set up this Multipart object from the given MultipartDataSource.

The method adds the MultipartDataSource's BodyPart objects into this Multipart. This Multipart's contentType is set to that of the MultipartDataSource.

This method is typically used in those cases where one has a multipart data source that has already been pre-parsed into the individual body parts (for example, an IMAP datasource), but needs to create an appropriate Multipart subclass that represents a specific multipart subtype.

**Parameters:**

- \( mp \) - Multipart datasource

**Throws:**

- MessagingException

---

**public String getContentType()**

Multipart

contentType

return

See also contentType
**getContentType**

```java
public String getContentType()
```

Return the content-type of this Multipart.

This implementation just returns the value of the `contentType` field.

**Returns:**
- `contentType`

**See Also:**
- `contentType`

---

**public int getCount() throws MessagingException**

**BodyPart**

```java
return
```

See also

**getCount**

```java
public int getCount()
```

Throws: `MessagingException`

Return the number of enclosed BodyPart objects.

**Returns:**
- number of parts

**Throws:**
- `MessagingException`

**See Also:**
- `parts`
public **BodyPart** getBodyPart(int index) throws **MessagingException**

**Part**

index	Part
return	Part
Throws	**IndexOutOfBoundsException**:
Throws	**MessagingException**:

---

getBodyPart

public **BodyPart** getBodyPart(int index) throws **MessagingException**

Get the specified Part. Parts are numbered starting at 0.

**Parameters:**

index - the index of the desired Part

**Returns:**

the Part

**Throws:**

**IndexOutOfBoundsException** - if the given index is out of range.
**MessagingException**

---

public boolean removeBodyPart(**BodyPart** part) throws **MessagingException**

**multipart**

part
return	part true false
Throws	**MessagingException**: Part
Throws	**IllegalWriteException**:

---

removeBodyPart

public boolean removeBodyPart(**BodyPart** part)
Remove the specified part from the multipart message. Shifts all the parts after the removed part down one.

**Parameters:**
- **part** - The part to remove

**Returns:**
- true if part removed, false otherwise

**Throws:**
- **MessagingException** - if no such Part exists
- **IllegalWriteException** - if the underlying implementation does not support modification of existing values

---

```java
public void removeBodyPart(int index) throws MessagingException
```

Remove the part at specified location (starting from 0). Shifts all the parts after the removed part down one.

**Parameters:**
- **index** - Index of the part to remove

**Throws:**
- **MessagingException**
- **IndexOutOfBoundsException**
- **IllegalWriteException**

---

```java
public void removeBodyPart(int index) throws MessagingException
```
public void addBodyPart(BodyPart part) throws MessagingException

Part multipartBodyPart Part

    part   Part
     Throws    MessagingException:
    Throws    IllegalWriteException:

addBodyPart

public void addBodyPart(BodyPart part)
    throws MessagingException

    Adds a Part to the multipart. The BodyPart is appended to the list of existing Parts.

Parameters:
    part - The Part to be appended

Throws:
    MessagingException
    IllegalWriteException - if the underlying implementation does not support modification of existing values

addBodyPart

public void addBodyPart(BodyPart part, int index) throws MessagingException

index BodyPart index
BodyPart

    part   BodyPart
    index
     Throws    MessagingException:
    Throws    IllegalWriteException:

addBodyPart
public void addBodyPart(BodyPart part, int index) throws MessagingException

Adds a BodyPart at position index. If index is not the last one in the list, the subsequent parts are shifted up. If index is larger than the number of parts present, the BodyPart is appended to the end.

Parameters:
  part - The BodyPart to be inserted
  index - Location where to insert the part

Throws:
  MessagingException
  IllegalWriteException - if the underlying implementation does not support modification of existing values

abstract public void writeTo(java.io.OutputStream os) throws java.io.IOException, MessagingException

OutputStream

Throws: java.io.IOException: IO
Throws: MessagingException:

writeTo

class public abstract void writeTo(OutputStream os) throws IOException, MessagingException

OutputStream

Throws: IOException - if an IO related exception occurs
  MessagingException:

Output an appropriately encoded bytestream to the given OutputStream. The implementation subclass decides the appropriate encoding algorithm to be used. The bytestream is typically used for sending.

Throws:
  IOException - if an IO related exception occurs
  MessagingException
public Part getParent()

Return the Part that contains this Multipart object, or null if not known.

Since:
JavaMail 1.1

public void setParent(Part parent)

Set the parent of this Multipart to be the specified Part. Normally called by the Message or BodyPart setContent(Multipart) method. parent may be null if the Multipart is being removed from its containing Part.

Since:
JavaMail 1.1

javax.mail Interface MultipartDataSource

All Superinterfaces:  
[DataSource](javax.activation.DataSource)

---

```java
public interface MultipartDataSource
    extends DataSource

Implements: DataSource

MultipartDataSource
    extends DataSource
    implements Datasources, BodyParts, 
    DataContentHandlers

MultipartDataSource

    multipart IMAP
    version 1.8, 07/05/04
    See also javax.activation.DataSource
```

MultipartDataSource is a DataSource that contains body parts. This allows "mail aware" DataContentHandlers to be implemented more efficiently by being aware of such Datasources and using the appropriate methods to access BodyParts.

Note that the data of a MultipartDataSource is also available as an input stream.

This interface will typically be implemented by providers that preparse multipart bodies, for example an IMAP provider.

**Version:**
1.8, 07/05/04

PS:
public interface Name

XML URI

<wombat:GetLastTradePrice xmlns:wombat="http://www.wombat.org/trader">

"xmlns" "XML namespace"

- getQualifiedName "prefix:LocalName" = "WOMBAT:GetLastTradePrice"
- getURI "http://www.wombat.org/trader"
- getLocalName "GetLastTracePrice"
- getPrefix "WOMBAT"

XML SOAP

Name SOAPEnvelope.createName URI Name Name

se SOAPEnvelope Name

Name name = se.createName("GetLastTradePrice", "WOMBAT", "http://www.wombat.org/trader");

element addChildElement(name);

See SOAPEnvelope.createName, SOAPFactory.createName

also
A representation of an XML name. This interface provides methods for getting the local and namespace-qualified names and also for getting the prefix associated with the namespace for the name. It is also possible to get the URI of the namespace.

The following is an example of a namespace declaration in an element.

```xml
<wombat:GetLastTradePrice xmlns:wombat="http://www.wombat.org/trader"

("xmlns" stands for "XML namespace").) The following shows what the methods in the Name interface will return.

- `getQualifiedName` will return "prefix:LocalName" = "WOMBAT:GetLastTradePrice"
- `getURI` will return "http://www.wombat.org/trader"
- `getLocalName` will return "GetLastTracePrice"
- `getPrefix` will return "WOMBAT"

XML namespaces are used to disambiguate SOAP identifiers from application-specific identifiers.

`Name` objects are created using the method `SOAPEnvelope.createName`, which has two versions. One method creates `Name` objects with a local name, a namespace prefix, and a namespace URI, and the second creates `Name` objects with just a local name. The following line of code, in which `se` is a `SOAPEnvelope` object, creates a new `Name` object with all three.

```java
Name name = se.createName("GetLastTradePrice", "WOMBAT", "http://www.wombat.org/trader");
```

The following line of code gives an example of how a `Name` object can be used. The variable `element` is a `SOAPElement` object. This code creates a new `SOAPElement` object with the given name and adds it to `element`.

```java
element.addChildElement(name);
```

The `Name` interface may be deprecated in a future release of SAAJ in favor of `javax.xml.namespace.QName`
See Also:  
SOAPEnvelope.createName, SOAPFactory.createName

### Method Summary

### Method Detail

```java
def getLocalName()
    Name XML
    return
```

**getLocalName**

```java
String getLocalName()
```

Gets the local name part of the XML name that this Name object represents.

**Returns:**

a string giving the local name
public String get Qualified Name()

    Name  XML
    return

getQualifiedName

String getQualified Name()

Gets the namespace-qualified name of the XML name that this Name object represents.

Returns:
the namespace-qualified name as a string

public String getPrefix()

Name  Name  XML
return

getPrefix

String getPrefix()

Returns the prefix that was specified when this Name object was initialized. This prefix is associated with the namespace for the XML name that this Name object represents.

Returns:
the prefix as a string

public String getURI()

Name  XML  URI
return  URI
getURI

String getURI()

Returns the URI of the namespace for the XML name that this Name object represents.

Returns:
the URI as a string
javax.persistence Annotation Type NamedNativeQueries

@Target(value=TYPE)

Java Persistence

Java Persistence

```java
@NamedQuery(
    name="findFirstWithMatchingName",
    query="SELECT c FROM Customer c WHERE c.name LIKE :custName"
)
```

@PersistenceContext
public EntityManager em;
...

customers = em.createNamedQuery("findFirstWithMatchingName")
    .setParameter("custName", "Smith")
    .getResultList();

since  Java Persistence 1.0  en

Is used to specify a named query in the Java Persistence query language, which is a static query expressed in metadata. Query names are scoped to the persistence unit.

The following is an example of the definition of a named query in the Java Persistence query language:

```java
@NamedQuery(
name="findAllCustomersWithName",
query="SELECT c FROM Customer c WHERE c.name LIKE :custName"
)

The following is an example of the use of a named query:

```java
@PersistenceContext
public EntityManager em;
...
customers = em.createNamedQuery("findAllCustomersWithName")
    .setParameter("custName", "Smith")
    .getResultList();
```

Since:
Java Persistence 1.0

SUMMARY: NESTED | FIELD | CONSTR | METHOD | DETAIL: FIELD | CONSTR | METHOD |
javax.faces.component  Interface NamingContainer

All Known Implementing Classes:
   HtmlDataTable, HtmlForm, UIData, UIForm, UINamingContainer

public interface NamingContainer

Implemented by: UIData, UIForm, UINamingContainer

NamingContainer  UICOMPONENT  UICOMPONENT#findComponent
UICOMPONENT#getClientId

NamingContainer is an interface that must be implemented by any
UICOMPONENT that wants to be a naming container. Naming containers
affect the behavior of the UICOMPONENT.findComponent(java.lang.String)
and UICOMPONENT.getClientId(javax.faces.context.FacesContext)
methods; see those methods for further information.

---

Field Summary

| SEPARATOR_CHAR | static char | The separator character used in component identifiers
to demarcate navigation to a child naming container. |

Field Detail

SEPARATOR_CHAR
static final char SEPARATOR_CHAR
The separator character used in component identifiers to demarcate navigation to a child naming container.

SUMMARY: NESTED | FIELD | Constructor | Method |
FRAMES  NO FRAMES
DETAIL: FIELD | Constructor | Method |
A **NavigationHandler** is passed the outcome string returned by an application action invoked for this application, and will use this (along with related state information) to choose the view to be displayed next.

A default implementation of **NavigationHandler** must be provided by the JSF implementation, which will be utilized unless **setNavigationHandler()** is called to establish a different one. This default instance will compare the view identifier of the current view, the specified action binding, and the specified outcome against any navigation rules provided in **faces-config.xml** file(s). If a navigation case matches, the current view will be changed by a call to **FacesContext.setViewRoot()**. Note that a null outcome value will never match any navigation rule, so it can be used as an indicator that the current view should be redisplayed.

Constructor Detail

public NavigationHandler()

NavigationHandler

public NavigationHandler()

Method Detail

abstract public void handleNavigation(FacesContext context, String fromAction, String outcome)

Throws

- NullPointerException: context null

Other methods:
- FacesContext
  - `context`
  - `fromAction`
  - `outcome`
handleNavigation

public abstract void handleNavigation(FacesContext context, String fromAction, String outcome)

Perform navigation processing based on the state information in the specified FacesContext, plus the outcome string returned by an executed application action.

Parameters:
  context - The FacesContext for the current request
  fromAction - The action binding expression that was evaluated to retrieve the specified outcome, or null if the outcome was acquired by some other means
  outcome - The logical outcome returned by a previous invoked application action (which may be null)

Throws:
  NullPointerException - if context is null

Field Detail

newsgroup

protected String newsgroup

host

protected String host

Constructor Detail

public NewsAddress()

NewsAddress

public NewsAddress()

    Default constructor.

public NewsAddress(String newsgroup)

    NewsAddress

    newsgroup

NewsAddress

public NewsAddress(String newsgroup)
Construct a NewsAddress with the given newsgroup.

**Parameters:**
- newsgroup - the newsgroup

```
public NewsAddress(String newsgroup, String host)
```

```
NewsAddress
```

Construct a NewsAddress with the given newsgroup and host.

**Parameters:**
- newsgroup - the newsgroup
- host - the host

---

**Method Detail**

```
public String getType()
```

```
NewsAddress "news"
```

**getType**

```
public String getType()
```

Return the type of this address. The type of a NewsAddress is "news".

**Specified by:**
public void setNewsgroup(String newsgroup)

    newsgroup

setNewsgroup

public void setNewsgroup(String newsgroup)

    Set the newsgroup.

    Parameters:
    newsgroup - the newsgroup

public String getNewsgroup()

    return

getNewsgroup

public String getNewsgroup()

    Get the newsgroup.

    Returns:
    newsgroup

public void setHost(String host)
public void setHost(String host)

Set the host.

Parameters:
  host - the host

public String getHost()

return

public String toString()

RFC 1036

return

public String toString()
Convert this address into a RFC 1036 address.

**Specified by:**
`toString` in class `Address`

**Returns:**
newsgroup

---

**public boolean equals(Object a)**

equals

code: public boolean equals(Object a)

The equality operator.

**Specified by:**
equals in class `Address`

**Parameters:**
a - Address object

---

**public int hashCode()**

hashCode

code: public int hashCode()

Compute a hash code for the address.

**Overrides:**
hashCode in class `Object`
public static String toString(Address[] addresses)
NewsAddress US-ASCII

dates

Throws  ClassCastException, RuntimeException

return

toString

public static String toString(Address[] addresses)

Convert the given array of NewsAddress objects into a comma separated sequence of address strings. The resulting string contains only US-ASCII characters, and hence is mail-safe.

Parameters:
  addresses - array of NewsAddress objects

Returns:
  comma separated address strings

Throws:
  ClassCastException, - if any address object in the given array is not a NewsAddress objects. Note that this is a RuntimeException.

public static NewsAddress[] parse(String newsgroups)
throws AddressException

NewsAddress

newsgroups

return

Throws AddressException:

parse

public static NewsAddress[] parse(String newsgroups)
throws AddressException

Parse the given comma separated sequence of newsgroup into NewsAddress objects.

**Parameters:**

newsgroups - comma separated newsgroup string

**Returns:**

array of NewsAddress objects

**Throws:**

AddressException - if the parse failed

PS :
public interface Node
extends Node

Implements: org.w3c.dom.Node
Implemented by: SOAPElement, SOAPPart, Text

XML DOM Node

A representation of a node (element) in an XML document. This interface extends the standard DOM Node interface with methods for getting and setting the value of a node, for getting and setting the parent of a node, and for removing a node.

Field Summary

<table>
<thead>
<tr>
<th>Fields inherited from interface org.w3c.dom.Node</th>
</tr>
</thead>
<tbody>
<tr>
<td>ATTRIBUTE_NODE, CDATA_SECTION_NODE, COMMENT_NODE, DOCUMENT_FRAGMENT_NODE, DOCUMENT_NODE, DOCUMENT_POSITION_CONTAINED_BY, DOCUMENT_POSITION_CONTAINS, DOCUMENT_POSITION_DISCONNECTED, DOCUMENT_POSITION_FOLLOWING, DOCUMENT_POSITION_IMPLEMENTATION_SPECIFIC, DOCUMENT_POSITION_PRECEDING, DOCUMENT_TYPE_NODE, ELEMENT_NODE, ENTITY_NODE, ENTITY_REFERENCE_NODE, NOTATION_NODE, PROCESSING_INSTRUCTION_NODE, TEXT_NODE</td>
</tr>
</tbody>
</table>
## Method Summary

<tr>
<td><code>void recycleNode()</code></td>
<td>Notifies the implementation that this Node object is no longer being used by the application and that the implementation is free to reuse this object for nodes that may be created later.</td>
</tr>
<tr>
<td><code>void setParentElement(SOAPElement parent)</code></td>
<td>Sets the parent of this Node object to the given SOAPElement object.</td>
</tr>
<tr>
<td><code>void setValue(String value)</code></td>
<td>If this is a Text node then this method will set its value, otherwise it sets the value of the immediate (Text) child of this node.</td>
</tr>
</tbody>
</table>

## Methods inherited from interface org.w3c.dom.Node

appendChild, cloneNode, compareDocumentPosition, getAttributes, getBaseURI, getChildNodes, getFeature, getFirstChild, getLastChild, getLocalName, getNamespaceURI, getNextSibling, getNodeName, getNodeType, getNodeValue, getOwnerDocument, getParentNode, getPrefix, getPreviousSibling, getTextContent, getUserData, hasAttributes, hasChildNodes, insertBefore, isDefaultNamespace, isEqualNode, isSameNode, isSupported, lookupNamespaceURI, lookupPrefix, normalize, removeChild, replaceChild, setNodeValue, setPrefix, setTextContent, setUserData

## Method Detail
public String getValue()

String getValue()

Returns the value of this node if this is a Text node or the value of the immediate child of this node otherwise. If there is an immediate child of this Node that it is a Text node then it's value will be returned. If there is more than one Text node then the value of the first Text Node will be returned. Otherwise null is returned.

Returns:

- a String with the text of this node if this is a Text node or the text contained by the first immediate child of this Node object that is a Text object if such a child exists; null otherwise.

public void setValue(String value)

void setValue(String value)

If this is a Text node then this method will set its value, otherwise it sets the value of the immediate (Text) child of this node. The value of the immediate child of this node can be set only if, there is one child node and that node is a Text node, or if there are no children in which case a child Text node will be created.
Throws:

[IllegalStateException](#) - if the node is not a [Text](#) node and either has more than one child node or has a child node that is not a Text node.

Since:

SAAJ 1.2

---

**public void setParentElement(**[SOAPElement](#) parent)**

throws [SOAPException](#)

Sets the parent of this Node object to the given SOAPElement object.

**Parameters:**

parent - the SOAPElement object to be set as the parent of this Node object

**Throws:**

[SOAPException](#) - if there is a problem in setting the parent to the given element

**See Also:**

getParentElement()
**getParentElement**

`SOAPElement getParentElement()`

Returns the parent element of this `Node` object. This method can throw an `UnsupportedOperationException` if the tree is not kept in memory.

**Returns:**
the `SOAPElement` object that is the parent of this `Node` object or `null` if this `Node` object is root

**Throws:**
`UnsupportedOperationException` - if the whole tree is not kept in memory

**See Also:**
`setParentElement(javax.xml.soap.SOAPElement)`

---

**public void detachNode()**

`Node`

**detachNode**

`void detachNode()`

Removes this `Node` object from the tree.

---

**public void recycleNode()**

`Node`

`recycleNode` `detachNode`
recycleNode

void recycleNode()

Notifies the implementation that this Node object is no longer being used by the application and that the implementation is free to reuse this object for nodes that may be created later.

Calling the method recycleNode implies that the method detachNode has been called previously.

Method Detail

public String unmarshal(String text)

" "CR LF

unmarshal

public String unmarshal(String text)
Removes leading and trailing whitespaces of the string given as the parameter, then replace any tab, CR, and LF by a whitespace character ".

**Specified by:**

`unmarshal` in class `XmlAdapter<String, String>`

**Parameters:**

- `text` - The value to be converted. Can be null.

---

```java
public String marshal(String s)
```

`marshal`

```java
public String marshal(String s)
```

No-op. Just return the same string given as the parameter.

**Specified by:**

`marshal` in class `XmlAdapter<String, String>`

**Parameters:**

- `s` - The value to be converted. Can be null.

---

```java
protected static boolean isWhiteSpaceExceptSpace(char ch)
```

`isWhiteSpaceExceptSpace`

```java
protected static boolean isWhiteSpaceExceptSpace(char ch)
```

Returns true if the specified char is a white space character but not 0x20.

javax.xml.stream.events Interface NotationDeclaration

All Superinterfaces:
   XMLEvent, XMLStreamConstants

public interface NotationDeclaration
extends XMLEvent

Implements: XMLEvent

   publicId   systemId   null
            version     1.0

An interface for handling Notation Declarations Receive notification of a notation declaration event. It is up to the application to record the notation for later reference, At least one of publicId and systemId must be non-null. There is no guarantee that the notation declaration will be reported before any unparsed entities that use it.

Version:
   1.0

NotIdentifiableEventImpl
NotIdentifiableEventImpl

public NotIdentifiableEventImpl(int _severity, String _message, ValidationEventLocator _locator, Throwable _linkedException)

Create a new NotIdentifiableEventImpl.

Parameters:

_severity - The severity value for this event. Must be one of ValidationEvent.WARNING, ValidationEvent.ERROR, or ValidationEvent.FATAL_ERROR

_message - The text message for this event - may be null.

_locator - The locator object for this event - may be null.

_linkedException - An optional linked exception that may provide additional information about the event - may be null.

Throws:

IllegalArgumentException - if an illegal severity field is supplied
PS:
**Class** NotSupportedException

---

```
javax.resource
java.lang.Object
   ↘ java.lang.Throwable
      ↘ java.lang.Exception
         ↘ javax.resource.ResourceException
            ↘ javax.resource.NotSupportedException
```

**All Implemented Interfaces:**

* Serializable

---

```
public class NotSupportedException
extends ResourceException
```

**Extends:** Throwable > Exception > ResourceException

---

<table>
<thead>
<tr>
<th>NotSupportedException</th>
<th>NO_TRANSACTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>ManagedConnection</td>
<td>getXAResource</td>
</tr>
<tr>
<td></td>
<td>version</td>
</tr>
</tbody>
</table>

---

A `NotSupportedException` is thrown to indicate that callee (resource adapter or application server for system contracts) cannot execute an operation because the operation is not a supported feature. For example, if the transaction support level for a resource adapter is `NO_TRANSACTION`, an invocation of `getXAResource` method on a `ManagedConnection` object should throw a `NotSupportedException` exception.

### Methods inherited from class `java.lang.Object`
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `wait`, `wait`, `wait`

## Constructor Detail

```java
public NotSupportedException()
```

Constructs a new instance with null as its detail message.
null

NotSupportedException

public RuntimeException()

Constructs a new instance with null as its detail message.

public RuntimeException(String message)

message

NotSupportedException

public RuntimeException(String message)

message

Constructs a new instance with the specified detail message.

Parameters:

message - the detail message.

public RuntimeException(Throwable cause)

cause throwable

cause

NotSupportedException

public RuntimeException(Throwable cause)

cause

Constructs a new throwable with the specified cause.

Parameters:

cause - a chained exception of type Throwable.
public NotSupportedException(String message, Throwable cause)
        cause throwable
        message
        cause
        Throwable

NotSupportedException

public NotSupportedException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public NotSupportedException(String message, String errorCode)
        Throwable
        message
        errorCode

NotSupportedException

public NotSupportedException(String message, String errorCode)

Constructs a new throwable with the specified detail message and error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.
javax.transaction Class NotSupportedException

java.lang.Object
  └ java.lang.Throwable
      └ java.lang.Exception
           └ javax.transaction.NotSupportedException

All Implemented Interfaces:
  Serializable

public class NotSupportedException
  extends Exception

Extends: Throwable > Exception

NotSupportedException Transaction Manager

NotSupportedException exception indicates that the request cannot be executed because the operation is not a supported feature. For example, because nested transactions are not supported, the Transaction Manager throws this exception when a calling thread that is already associated with a transaction attempts to start a new transaction. (A nested transaction occurs when a thread is already associated with one transaction and attempts to start a second transaction.)

## Methods inherited from class java.lang.Object

- clone, finalize, getClass, notify, notifyAll, toString, wait, wait

## Field Detail

protected `SearchTerm` term

The search term to negate.

## Constructor Detail

public `NotTerm(SearchTerm t)`
public SearchTerm getTerm()

getTerm

public SearchTerm getTerm()

    Return the term to negate.

public boolean match(Message msg)

match

public boolean match(Message msg)

    Description copied from class: SearchTerm
    This method applies a specific match criterion to the given message and returns the result.

    Specified by:
        match in class SearchTerm
    Parameters:
        msg - The match criterion is applied on this message
    Returns:
        true, if the match succeeds, false if the match fails

public boolean equals(Object obj)

equals
public boolean equals(Object obj)

Equality comparison.

**Overrides:**

equals in class Object

---

public int hashCode()

hashCode

hashCode

public int hashCode()

Compute a hashCode for this object.

**Overrides:**

hashCode in class Object

- maxIntegerDigits
- minFractionDigits
- minIntegerDigits
- currency
- currencyCode
- currencySymbol
- currencyCode  JDK 1.4JVM
- currencySymbol

**Converter** implementation for `java.lang.Number` values.

The `getAsObject()` method parses a String into an `java.lang.Double` or `java.lang.Long`, according to the following algorithm:

- If the specified String is null, return a `null`. Otherwise, trim leading and trailing whitespace before proceeding.
- If the specified String - after trimming - has a zero length, return `null`.
- If the `locale` property is not null, use that `Locale` for managing parsing. Otherwise, use the `Locale` from the `UIViewRoot`.
- If a pattern has been specified, its syntax must conform the rules specified by `java.text.DecimalFormat`. Such a pattern will be used to parse, and the `type` property will be ignored.
- If a pattern has not been specified, parsing will be based on the `type` property, which expects a currency, a number, or a percent. The parse pattern for currencies, numbers, and percentages is determined by calling the `getCurrencyInstance()`, `getNumberInstance()`, or `getPercentInstance()` method of the `java.text.NumberFormat` class, passing in the selected `Locale`.
- If the `integerOnly` property has been set to true, only the integer portion of the String will be parsed. See the JavaDocs for the `setParseIntegerOnly()` method of the `java.text.NumberFormat` class for more information.

The `getAsString()` method expects a value of type `java.lang.Number` (or a subclass), and creates a formatted String according to the following algorithm:
If the specified value is null, return a zero-length String.
If the specified value is a String, return it unmodified.
If the locale property is not null, use that Locale for managing formatting. Otherwise, use the Locale from the FacesContext.
If a pattern has been specified, its syntax must conform the rules specified by java.text.DecimalFormat. Such a pattern will be used to format, and the type property (along with related formatting options described in the next paragraph) will be ignored.
If a pattern has not been specified, formatting will be based on the type property, which formats the value as a currency, a number, or a percent. The format pattern for currencies, numbers, and percentages is determined by calling the percentages is determined by calling the getCurrencyInstance(), getNumberInstance(), or getPercentInstance() method of the java.text.NumberFormat class, passing in the selected Locale. In addition, the following properties will be applied to the format pattern, if specified:
  - If the groupingUsed property is true, the setGroupingUsed(true) method on the corresponding NumberFormat instance will be called.
  - The minimum and maximum number of digits in the integer and fractional portions of the result will be configured based on any values set for the maxFractionDigits, maxIntegerDigits, minFractionDigits, and minIntegerDigits properties.
  - If the type is set to currency, it is also possible to configure the currency symbol to be used, using either the currencyCode or currencySymbol properties. If both are set, the value for currencyCode takes precedence on a JDK 1.4 (or later) JVM; otherwise, the value for currencySymbol takes precedence.

    public NumberConverter()
NumberConverter

class NumberConverter

Method Detail

public String getCurrencyCode()

type currency getAsString() ISO 4217 Locale

getCurrencyCode

public String getCurrencyCode()

Return the ISO 4217 currency code used by getAsString() with a type of currency. If not set, the value used will be based on the formatting Locale.

public void setCurrencyCode(String currencyCode)

type currency getAsString() ISO 4217

currencyCode

setCurrencyCode

public void setCurrencyCode(String currencyCode)

Set the ISO 4217 currency code used by getAsString() with a type of currency.

Parameters:
getCurrencySymbol

public String getCurrencySymbol()

    type currency getAsString() Locale

getCurrencySymbol

public String getCurrencySymbol()

    Return the currency symbol used by getAsString() with a type of currency. If not set, the value used will be based on the formatting Locale.

setCurrencySymbol

public void setCurrencySymbol(String currencySymbol)

    type currency getAsString()

                currencySymbol

setCurrencySymbol

public void setCurrencySymbol(String currencySymbol)

    Set the currency symbol used by getAsString() with a type of currency.

    Parameters:
                currencySymbol - The new currency symbol

public boolean isGroupingUsed()
isGroupingUsed

public boolean isGroupingUsed()

Return true if getAsString should include grouping separators if necessary. If not modified, the default value is true.

public void setGroupingUsed(boolean groupingUsed)

gAsString()

  groupingUsed

setGroupingUsed

public void setGroupingUsed(boolean groupingUsed)

  Set the flag indicating whether getAsString() should include grouping separators if necessary.

  Parameters:
    groupingUsed - The new grouping used flag

public boolean isIntegerOnly()

  getAsObject() true false

isIntegerOnly
public boolean isIntegerOnly()

    Return true if only the integer portion of the given value should be returned from getAsObject(). If not modified, the default value is false.

public void setIntegerOnly(boolean integerOnly)

    getAsObject() true

    integerOnly integer-only

setIntegerOnly

public void setIntegerOnly(boolean integerOnly)

    Set to true if only the integer portion of the given value should be returned from getAsObject().

    Parameters:
        integerOnly - The new integer-only flag

public int getMaxFractionDigits()

    getAsString()

getMaxFractionDigits

public int getMaxFractionDigits()

    Return the maximum number of digits getAsString() should render in the fraction portion of the result.
public void setMaxFractionDigits(int maxFractionDigits)

    getMaxString()

    maxFractionDigits

setMaxFractionDigits

public void setMaxFractionDigits(int maxFractionDigits)

    Set the maximum number of digits getMaxString() should render in the fraction portion of the result. If not set, the number of digits depends on the value being converted.

    Parameters:
    maxFractionDigits - The new limit

public int getMaxIntegerDigits()

    getMaxString()

getMaxIntegerDigits

public int getMaxIntegerDigits()

    Return the maximum number of digits getMaxString() should render in the integer portion of the result.

public void setMaxIntegerDigits(int maxIntegerDigits)

    getMaxString()

    maxIntegerDigits
setMaxIntegerDigits

public void setMaxIntegerDigits(int maxIntegerDigits)

Set the maximum number of digits getAsString() should render in the integer portion of the result. If not set, the number of digits depends on the value being converted.

Parameters:
maxIntegerDigits - The new limit

public int getMinFractionDigits()

getAsString()

getMinFractionDigits

public int getMinFractionDigits()  

Return the minimum number of digits getAsString() should render in the fraction portion of the result.

public void setMinFractionDigits(int minFractionDigits)

getAsString()

   minFractionDigits

setMinFractionDigits

public void setMinFractionDigits(int minFractionDigits)
Set the minimum number of digits `getAsString()` should render in the fraction portion of the result. If not set, the number of digits depends on the value being converted.

**Parameters:**

- `minFractionDigits` - The new limit

---

### public int getMinIntegerDigits()

`getAsString()`

---

#### getMinIntegerDigits

**public int getMinIntegerDigits()**

Return the minimum number of digits `getAsString()` should render in the integer portion of the result.

---

### public void setMinIntegerDigits(int minIntegerDigits)

`getAsString()`

#### setMinIntegerDigits

**public void setMinIntegerDigits(int minIntegerDigits)**

Set the minimum number of digits `getAsString()` should render in the integer portion of the result. If not set, the number of digits depends on the value being converted.

**Parameters:**
public java.util.Locale getLocale()

Locale null javax.faces.component.UIViewRoot Locale

getLocale

public Locale getLocale()

Return the Locale to be used when parsing numbers. If this value is null, the Locale stored in the UIViewRoot for the current request will be utilized.

public void setLocale(java.util.Locale locale)

Locale null javax.faces.component.UIViewRoot Locale

locale Locale null

setLocale

public void setLocale(Locale locale)

Set the Locale to be used when parsing numbers. If set to null, the Locale stored in the UIViewRoot for the current request will be utilized.

Parameters:
locale - The new Locale (or null)

public String getPattern()
**getPattern**

public String getPattern()

    Return the format pattern to be used when formatting and parsing numbers.

---

**public void setPattern(String pattern)**

    java.text.DecimalFormat getAsObject()
    getAsString() ConverterException

    pattern

**setPattern**

public void setPattern(String pattern)

    Set the format pattern to be used when formatting and parsing numbers. Valid values are those supported by java.text.DecimalFormat. An invalid value will cause a ConverterException when getAsObject() or getAsString() is called.

    Parameters:
    pattern - The new format pattern

---

**public String getType()**

    number
**getType**

public `String` `getType()`

Return the number type to be used when formatting and parsing numbers. If not modified, the default type is `number`.

**public void setType(String type)**

currenycurrency number percent getAsObject() getAsString()

`ConverterException`

`type`

**setType**

public void `setType(String type)`

Set the number type to be used when formatting and parsing numbers. Valid values are `currency`, `number`, or `percent`. An invalid value will cause a `ConverterException` when `getAsObject()` or `getAsString()` is called.

**Parameters:**

- `type` - The new number style

**public Object getAsObject(FacesContext context, UIComponent component, String value)**

Throws `ConverterException`: `NullPointerException`

Throws `NullPointerException`: `NullPointerException` context

`component null`

**getAsObject**
public Object getAsObject(FacesContext context, 
    UIComponent component, 
    String value)

Description copied from interface: Converter

Convert the specified string value, which is associated with the specified UIComponent, into a model data object that is appropriate for being stored during the Apply Request Values phase of the request processing lifecycle.

Specified by: 
    getAsObject in interface Converter

Parameters:
    context - FacesContext for the request being processed
    component - UIComponent with which this model object value is associated
    value - String value to be converted (may be null)

Returns:
    null if the value to convert is null, otherwise the result of the conversion

Throws:
    ConverterException - if conversion cannot be successfully performed
    NullPointerException - if context or component is null

public String getAsString(FacesContext context, 
    UIComponent component, Object value)

Throws ConverterException: NullPointeException

Throws NullPointeException: null

getAsString

public String getAsString(FacesContext context, 
    UIComponent component, Object value)
Description copied from interface: Converter

Convert the specified model object value, which is associated with the specified UIComponent, into a String that is suitable for being included in the response generated during the Render Response phase of the request processing lifecycle.

Specified by:
getAsString in interface Converter

Parameters:
context - FacesContext for the request being processed
component - UIComponent with which this model object value is associated
value - Model object value to be converted (may be null)

Returns:
a zero-length String if value is null, otherwise the result of the conversion

Throws:
ConverterException - if conversion cannot be successfully performed
NullPointerException - if context Or component is null

public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the
state of children and facets. That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

Object state = component.saveState(facesContext);

component should be the same as before executing it.

The return from this method must be Serializable

Specified by: saveState in interface StateHolder

public void restoreState(FacesContext context, Object state)

restoreState

public void restoreState(FacesContext context,
Object state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by: restoreState in interface StateHolder
public boolean isTransient()

isTransient

public boolean isTransient()

Description copied from interface: StateHolder

If true, the Object implementing this interface must not participate in state saving or restoring.

Specified by:
    isTransient in interface StateHolder

public void setTransient(boolean transientFlag)

setTransient

public void setTransient(boolean transientFlag)

Description copied from interface: StateHolder

Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

Specified by:
    setTransient in interface StateHolder

Parameters:
    transientFlag - boolean pass true if this Object will participate in state saving or restoring, otherwise pass false.

PS:
javax.jms Interface ObjectMessage

All Superinterfaces: Message

public interface ObjectMessage

extends Message

Implements: Message

ObjectMessage implements Java "Java" Message
Serializable Java

Java JDK 1.2 Collection

ObjectMessage Message Not Writeable Exception clearBody

version 1.0 - 6 August 1998

See also en
createObjectMessage(), createObjectMessage(Serializable),

An ObjectMessage object is used to send a message that contains a serializable object in the Java programming language ("Java object"). It inherits from the Message interface and adds a body containing a single reference to an object. Only Serializable Java objects can be used.

If a collection of Java objects must be sent, one of the Collection classes provided since JDK 1.2 can be used.

When a client receives an ObjectMessage, it is in read-only mode. If a client attempts to write to the message at this point, a
MessageNotWriteableException is thrown. If clearBody is called, the message can now be both read from and written to.

Version:
1.0 - 6 August 1998

DEFAULT_DELIVERY_MODE, DEFAULT_PRIORITY, DEFAULT_TIME_TO_LIVE

Method Summary

getObject() Gets the serializable object containing this message's data.

setObject(Serializable object) Sets the serializable object containing this message's data.

Methods inherited from interface javax.jms.Message

acknowledge, clearBody, clearProperties, getBooleanProperty, getByteProperty, getDoubleProperty, setFloatProperty, getIntProperty, getJMSCorrelationID, getJMSCorrelationIDAsBytes, getJMSDeliveryMode, getJMSDestination, getJMSExpiration, getJMSMessageID, getJMSPriority, getJMSRedelivered, getJMSReplyTo, getJMSTimestamp, getJMSType, getLongProperty, setObjectProperty, getPropertyNames, getShortProperty, getStringProperty, propertyExists, setBooleanProperty, setByteProperty, setDoubleProperty, setFloatProperty, setIntProperty, setJMSCorrelationID, setJMSCorrelationIDAsBytes, setJMSDeliveryMode, setJMSDestination, setJMSExpiration,
public void setObject(java.io.Serializable object) throws JMSException

    setObject()

object

Throws JMSException: JMS
Throws MessageFormatException: 
Throws MessageNotWriteableException:

setObject

void setObject(Serializable object)
    throws JMSException

Sets the serializable object containing this message's data. It is important to note that an objectMessage contains a snapshot of the object at the time setObject() is called; subsequent modifications of the object will have no effect on the ObjectMessage body.

Parameters:
    object - the message's data

Throws:
    JMSException - if the JMS provider fails to set the object due to some internal error.
    MessageFormatException - if object serialization fails.
    MessageNotWriteableException - if the message is in read-only mode.
public java.io.Serializable getObject() throws JMSException
null

return

Throws JMSException: JMS
Throws MessageFormatException:

getObject

Serializable getObject()
throws JMSException

Gets the serializable object containing this message's data. The default value is null.

Returns: the serializable object containing this message's data

Throws: JMSException - if the JMS provider fails to get the object due to some internal error.
MessageFormatException - if object deserialization fails.

`ObjectNotFoundException`

```java

Constructs an ObjectNotFoundException with no detail message.
```
public ObjectNotFoundException(String message)

Constructs an ObjectNotFoundException with the specified detail message.
javax.persistence  **Annotation Type OneToMany**

```java
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface OneToMany

**Implements:** Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

Collection  generic
1  generic
Customer
   @OneToMany(cascade=ALL, mappedBy="customer")
   public Set getOrders() { return orders; }
Order
   @ManyToOne
   @JoinColumn(name="CUST_ID", nullable=false)
   public Customer getCustomer() { return customer; }
2  generic
Customer
   @OneToMany(targetEntity=com.acme.Order.class, cascade=ALL,
     mappedBy="customer")
   public Set getOrders() { return orders; }
Order
   @ManyToOne
   @JoinColumn(name="CUST_ID", nullable=false)
   public Customer getCustomer() { return customer; }
```

since  Java Persistence 1.0  en
Defines a many-valued association with one-to-many multiplicity.

If the collection is defined using generics to specify the element type, the associated target entity type need not be specified; otherwise the target entity class must be specified.

Example 1: One-to-Many association using generics

In Customer class:

```java
@OneToMany(cascade=ALL, mappedBy="customer")
public Set getOrders() { return orders; }
```

In Order class:

```java
@ManyToOne
@JoinColumn(name="CUST_ID", nullable=false)
public Customer getCustomer() { return customer; }
```

Example 2: One-to-Many association without using generics

In Customer class:

```java
@OneToMany(targetEntity=com.acme.Order.class, cascade=ALL,
    mappedBy="customer")
public Set getOrders() { return orders; }
```

In Order class:

```java
@ManyToOne
@JoinColumn(name="CUST_ID", nullable=false)
public Customer getCustomer() { return customer; }
```

Since:
Java Persistence 1.0

---

</tbody>
</table>

abstract public Class<T> targetEntity()
Java generic Collection
generic Collection
targetEntity

public abstract Class targetEntity

(Optional) The entity class that is the target of the association. Optional only if the collection property is defined using Java generics. Must be specified otherwise.

Defaults to the parameterized type of the collection when defined using generics.

Default:
void.class

abstract public CascadeType[] cascade()
**cascade**

public abstract CascadeType[] cascade

(Optional) The operations that must be cascaded to the target of the association.

Defaults to no operations being cascaded.

Default:

{}  

---

**abstract public FetchType fetch()**

public abstract FetchType fetch

EAGER     LAZY

**fetch**

public abstract FetchType fetch

(Optional) Whether the association should be lazily loaded or must be eagerly fetched. The EAGER strategy is a requirement on the persistence provider runtime that the associated entities must be eagerly fetched. The LAZY strategy is a hint to the persistence provider runtime.

Default:

LAZY  

---

**abstract public String mappedBy()**

**mappedBy**
public abstract String mappedBy

The field that owns the relationship. Required unless the relationship is unidirectional.

Default: ""
javax.persistence Annotation Type OneToOne

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface OneToOne

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

1

Customer

    @OneToOne(optional=false)
    @JoinColumn(
        name="CUSTREC_ID", unique=true, nullable=false, updatable=false
    )
    public CustomerRecord getCustomerRecord() { return customerRecord; }

CustomerRecord

    @OneToOne(optional=false, mappedBy="customerRecord")
    public Customer getCustomer() { return customer; }

2

Employee

    @Entity
    public class Employee {
        @Id Integer id;

        @OneToOne @PrimaryKeyJoinColumn
        EmployeeInfo info;
        ...
    }

EmployeeInfo

    @Entity
    public class EmployeeInfo {
        @Id Integer id;
        ...
    }
This annotation defines a single-valued association to another entity that has one-to-one multiplicity. It is not normally necessary to specify the associated target entity explicitly since it can usually be inferred from the type of the object being referenced.

Example 1: One-to-one association that maps a foreign key column

On Customer class:

```java
@OneToOne(optional=false)
@JoinColumn(
    name="CUSTREC_ID", unique=true, nullable=false, updatable=false
)
public CustomerRecord getCustomerRecord() { return customerRecord; }
```

On CustomerRecord class:

```java
@OneToOne(optional=false, mappedBy="customerRecord")
public Customer getCustomer() { return customer; }
```

Example 2: One-to-one association that assumes both the source a

On Employee class:

```java
@Entity
public class Employee {
    @Id Integer id;

    @OneToOne @PrimaryKeyJoinColumn
    EmployeeInfo info;

    ...
}
```

On EmployeeInfo class:

```java
@Entity
public class EmployeeInfo {
    @Id Integer id;

    ...
}
```

OptimisticLockException entity

OptimisticLockException

public OptimisticLockException(Object entity)

Constructs a new OptimisticLockException exception with the specified entity.
public OptimisticLockException(String message, Throwable cause, Object entity)

Constructs a new OptimisticLockException exception with the specified detail message, cause, and entity.

Parameters:
message - the detail message.
cause - the cause.
entity - the entity.

Method Detail

public Object getEntity()

return

gEntity

public Object getEntity()
Returns the entity that caused this exception.

**Returns:**
the entity.
javax.persistence  Annotation Type OrderBy

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface OrderBy

**Implements:** Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

Collection

value orderby_list

orderby_list::= orderby_item [,orderby_item] *
orderby_item::= property_or_field_name [ASC | DESC]

    ASC    DESC    ASC

@Entity public class Course {
    ...
    @ManyToMany
    @OrderBy("lastname ASC")
    public List getStudents() {...};
    ...
}

@Entity public class Student {
    ...
    @ManyToMany(mappedBy="students")
    @OrderBy // PK is assumed
    public List getCourses() {...};
    ...
}
This annotation specifies the ordering of the elements of a collection valued association at the point when the association is retrieved.

The syntax of the value ordering element is an orderby_list, as follows:

```
orderby_list ::= orderby_item [,orderby_item] *
orderby_item ::= property_or_field_name [ASC | DESC]
```

If ASC or DESC is not specified, ASC (ascending order) is assumed.

If the ordering element is not specified, ordering by the primary key of the associated entity is assumed.

The property or field name must correspond to that of a persistent property or field of the associated class. The properties or fields used in the ordering must correspond to columns for which comparison operators are supported.

Example:

```java
@Entity
public class Course {
  ...
  @ManyToMany
  @OrderBy("lastname ASC")
  public List getStudents() {...};
  ...
}

@Entity
public class Student {
  ...
  @ManyToMany(mappedBy="students")
  @OrderBy // PK is assumed
  public List getCourses() {...};
  ...
}
```

**Since:**
Java Persistence 1.0
An orderby_list, specified as follows:

```
orderby_list ::= orderby_item [,orderby_item] *
orderby_item ::= property_or_field_name [ASC | DESC]
```

If ASC or DESC is not specified, ASC (ascending order) is assumed.

If the ordering element is not specified, ordering by the primary key of the associated entity is assumed.

PS :
javax.xml.registry.infomodel Interface Organization

All Superinterfaces:
   ExtensibleObject, RegistryObject

public interface Organization
extends RegistryObject

Implements: RegistryObject

Organization  Submitting Organization Organization
Organization Organization

See also  javax.xml.registry.infomodel.Service

Organization instances provide information on organizations such as a Submitting Organization. Each Organization instance may have a reference to a parent Organization. In addition it may have a contact attribute defining the primary contact within the organization. An Organization also has an address attribute.

**Method Detail**

```java
public PostalAddress getPostalAddress() throws
```
JAXRException
Organization

1

return Organization PostalAddress
Throws JAXRException: JAXR
supplierCardinality directed
link associates
aggregationByValue

getPostalAddress

PostalAddress getPostalAddress()
throws JAXRException

Gets the Address for this Organization.

Capability Level: 1

Returns:
the PostalAddress for this Organization

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setPostalAddress(PostalAddress address)
throws JAXRException
Organization

address Organization PostalAddress
Throws JAXRException: JAXR
**setPostalAddress**

```java
void setPostalAddress(PostalAddress address)
                throws JAXRException
```

Sets the address for this Organization.

**Capability Level: 1**

**Parameters:**
- `address` - the `PostalAddress` for this Organization

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public User getPrimaryContact() throws JAXRException**

```java
Organization Organization User
Organization getUsers
```

```java
return Organization Organization User null
Throws JAXRException: JAXR
```

**supplierCardinality**
- `directed` 1

**link**
- `aggregationByValue primaryContact` en
- `associates` en

**getPrimaryContact**

```java
User getPrimaryContact()
                throws JAXRException
```
Gets the primary Contact for this Organization. The primary contact is one of the Users of the Organization, as returned by the getUsers call on an Organization instance.

**Capability Level: 0**

**Returns:**
the User that is the primary Contact for this Organization. Must not be null

**Throws:**
*JAXRException* - If the JAXR provider encounters an internal error

---

```java
public void setPrimaryContact(User primaryContact) throws JAXRException
Organization User Collection Collection
User Collection User Collection User
Collection User

0

primaryContact Organization User

Throws JAXRException: JAXR

setPrimaryContact

void setPrimaryContact(User primaryContact) throws JAXRException
```

Sets the primary contact for this Organization. If the primary contact is not in the existing Collection of User instances for this object then it must be added to that Collection. If the primary contact is already in the existing Collection of User instances for this object, then it should not be added to the Users collection as a duplicate entry. In either case, the primary contact is a distinguished User instance within the Collection of User instances for this Object.
Capability Level: 0

Parameters:
   primaryContact - the User that is the primary Contact for this Organization

Throws:
   JAXRException - If the JAXR provider encounters an internal error

```java
public void addUser(User user) throws JAXRException

User

user

Throws
   JAXRException: JAXR
```

**addUser**

```java
void addUser(User user)
   throws JAXRException

Adds a User.

Capability Level: 0

Parameters:
   user - the User being added to this object

Throws:
   JAXRException - If the JAXR provider encounters an internal error
```

```java
public void addUsers(java.util.Collection<E> users) throws JAXRException

User  Collection
```
0

users  User Collection
Throws     JAXRException: JAXR

addUsers

void addUsers(Collection users) throws JAXRException

Adds a Collection of Users.

Capability Level: 0

Parameters:
users - the Collection of Users being added to this object

Throws:
JAXRException - If the JAXR provider encounters an internal error

0

User

Throws     JAXRException: JAXR

removeUser

void removeUser(User user) throws JAXRException

Removes a User.
public void removeUsers(java.util.Collection<E> users) throws JAXRException

Remove a Collection of Users.

Capability Level: 0

Parameters:
users - the Collection of Users being removed from this object

Throws:
JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getUsers() throws JAXRException

Organization User Collection
getUsers

```java
Collection getUsers() throws JAXRException
```

Gets the Collection of Users affiliated with this Organization. One of these users is designated as the primary contact.

**Capability Level: 0**

**Returns:**
Collection of User instances. The Collection may be empty but not null.

**Throws:**

JAXRException - If the JAXR provider encounters an internal error

**See Also:**
User

public java.util.Collection<E> getTelephoneNumbers(String phoneType) throws JAXRException
```java
User phoneType null telephoneNumber
```
getTelephoneNumbers

```java
Collection getTelephoneNumbers(String phoneType)
throws JAXRException
```

Gets the telephone numbers for this User that match the specified telephone number type. If phoneType is null return all telephoneNumbers.

**Capability Level:** 0

**Parameters:**
- `phoneType` - a String that specifies the type of phone numbers desired

**Returns:**
- Collection of TelephoneNumber instances. The Collection may be empty but not null.

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

**See Also:**
- `TelephoneNumber`

```
public void setTelephoneNumbers(java.util.Collection<E> phoneNumbers) throws JAXRException
```
**setTelephoneNumbers**

```java
void setTelephoneNumbers(Collection phoneNumbers)
throws JAXRException
```

Sets the various telephone numbers for this user.

**Capability Level:** 0

**Parameters:**
- `phoneNumbers` - the TelephoneNumbers being set for this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

**public void addService(Service service) throws JAXRException**

```java
service
Throws JAXRException: JAXR
```

**addService**

```java
void addService(Service service)
throws JAXRException
```
Adds a child Service.

**Capability Level:** 0

**Parameters:**
- `service` - the Service being added to this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

```java
public void addServices(java.util.Collection<E> services)
    throws JAXRException
```

**Service Collection**

**0**

- `services` - Service Collection
- **Throws**
  - `JAXRException`: JAXR

---

**addServices**

```java
void addServices(Collection services)
    throws JAXRException
```

Adds a Collection of Service children.

**Capability Level:** 0

**Parameters:**
- `services` - the Collection of Services being added to this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

```java
public void removeService(Service service) throws
```
**JAXRException**

**Service**

0

```java
service Service
```

Throws **JAXRException**: JAXR

**removeService**

```java
void removeService(Service service)
```

Removes a Service from this object.

Capability Level: 0

**Parameters:**

- service: the Service being removed from this object

**Throws:**

- **JAXRException**: If the JAXR provider encounters an internal error

```java
public void removeServices(java.util.Collection<E> services) throws JAXRException
```

Service Collection

0

```java
services Service Collection
```

Throws **JAXRException**: JAXR

**removeServices**
void removeServices(Collection services)
   throws JAXRException

   Removes a Collection of children Services from this object.

   **Capability Level:** 0

   **Parameters:**
   services - the Collection of Services being removed from this object

   **Throws:**
   JAXRException - If the JAXR provider encounters an internal error

---

public java.util.Collection<E> getServices() throws JAXRException

Service

0

getServices

Collection getServices() throws JAXRException

Gets all children Services.

**Capability Level:** 0
Returns:
Collection of Service instances. The Collection may be empty but not null.

Throws:
JAXRException - If the JAXR provider encounters an internal error

See Also:
Service

public void addChildOrganization(Organization organization) throws JAXRException

Adds a child Organization.

Capability Level: 1

Parameters:
organization - the child Organization being added

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void addChildOrganizations(java.util.Collection<E> organizations) throws JAXRException
Organization Collection

1

organizations Organization Collection
Throws JAXRException: JAXR

addChildOrganizations

void addChildOrganizations(Collection organizations)

throws JAXRException

Adds a Collection of Organization children.

Capability Level: 1

Parameters:
organizations - the Collection of child Organizations being added

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void removeChildOrganization(Organization organization) throws JAXRException

Organization

1

organization Organization
Throws JAXRException: JAXR

removeChildOrganization

void removeChildOrganization(Organization organization)
Removes a child Organization.

**Capability Level: 1**

**Parameters:**
- `organization` - the child Organization being removed

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

```java
public void removeChildOrganizations(java.util.Collection<E> organizations) throws JAXRException
Organization Collection

1

organizations Organization Collection
Throws JAXRException: JAXR

removeChildOrganizations

void removeChildOrganizations(Collection organizations) throws JAXRException

Removes a Collection of children Organizations.

**Capability Level: 1**

**Parameters:**
- `organizations` - the Collection of child Organizations being removed

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error
public int getChildOrganizationCount() throws JAXRException

1

    return Organization
    Throws JAXRException: JAXR

getChildOrganizationCount

int getChildOrganizationCount() throws JAXRException

    Gets number of children.

    Capability Level: 1

    Returns:
    the number of children Organizations

    Throws:
    JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getChildOrganizations() throws JAXRException

Organization

1

    return Organization CollectionCollection null
    Throws JAXRException: JAXR
    See also javax.xml.registry.infomodel.Organization
**getChildOrganizations**

```java
Collection getChildOrganizations() throws JAXRException
```

Gets all immediate children Organizations.

**Capability Level: 1**

**Returns:**
Collection of Organization instances. The Collection may be empty but not null.

**Throws:**
 JAXRException - If the JAXR provider encounters an internal error

**See Also:**
Organization

---

**public java.util.Collection<E> getDescendantOrganizations() throws JAXRException**

**Organization**

1

```java
return Organization CollectionCollection null
```

**Throws**
 JAXRException: JAXR

**See also**
javax.xml.registry.infomodel.Organization

---

**getDescendantOrganizations**

```java
Collection getDescendantOrganizations() throws JAXRException
```

Gets all descendant Organizations.

**Capability Level: 1**
Returns:
Collection of Organization instances. The Collection may be empty but not null.

Throws:
JAXRException - If the JAXR provider encounters an internal error

See Also:
Organization

public Organization getParentOrganization() throws JAXRException

Organization

1
return Organization Organization null
Throws JAXRException: JAXR

getParentOrganization

Organization getParentOrganization() throws JAXRException

Gets the parent (container) organization.

Capability Level: 1

Returns:
the parent Organization or null if object has no parent Organization

Throws:
JAXRException - If the JAXR provider encounters an internal error

public Organization getRootOrganization() throws
JAXRException
Organization

1

    return Organization Organization null

Throws    JAXRException:  JAXR

getRootOrganization

Organization getRootOrganization() throws JAXRException

Gets the root organization.

Capability Level: 1

Returns: the root Organization or null if object has no parent Organization

Throws:    JAXRException - If the JAXR provider encounters an internal error

javax.mail.search  Class OrTerm

java.lang.Object
   javax.mail.search.SearchTerm
   javax.mail.search.OrTerm

All Implemented Interfaces:
   Serializable

public final class OrTerm
extends SearchTerm

Extends: SearchTerm

SearchTerm OR

This class implements the logical OR operator on individual SearchTerms.

Author:  Bill Shannon, John Mani

See Also:  Serialized Form

Field Summary

| protected searchTerm[] terms | The array of terms on which the OR operator should be applied. |

Constructor Summary

OrTerm(SearchTerm[] t)  Constructor that takes an array of SearchTerms.
**OrTerm**(SearchTerm t1, SearchTerm t2)

Constructor that takes two operands.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Signature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean</td>
<td>equals(Object obj)</td>
<td>Equality comparison.</td>
</tr>
<tr>
<td>SearchTerm[]</td>
<td>getTerms()</td>
<td>Return the search terms.</td>
</tr>

</table>

### Methods inherited from class java.lang.Object

clone, finalize, getClass, notify, notifyAll, toString, wait, wait

### Field Detail

```java
protected SearchTerm[] terms
```

The array of terms on which the OR operator should be applied.

### Constructor Detail

```java
public OrTerm(SearchTerm t1, SearchTerm t2)
```
OrTerm

public OrTerm(SearchTerm t1, SearchTerm t2)

Constructor that takes two operands.

Parameters:
  t1 - first term
  t2 - second term

public OrTerm(SearchTerm[] t)

SearchTerm

  t

OrTerm

public OrTerm(SearchTerm[] t)

Constructor that takes an array of SearchTerms.

Parameters:
  t - array of search terms

Method Detail

public SearchTerm[] getTerms()
Return the search terms.

```java
public boolean match(Message msg)
```

The OR operation.

The terms specified in the constructor are applied to the given object and the OR operator is applied to their results.

**Specified by:**
```
match in class searchTerm
```

**Parameters:**

- `msg`: The specified SearchTerms are applied to this Message and the OR operator is applied to their results.

**Returns:**

- true if the OR succeeds, otherwise false

```java
public boolean equals(Object obj)
```

```java
public boolean equals(Object obj)
```
Equality comparison.

Overrides:
  equals in class Object

public int hashCode()
hashCode

hashCode

public int hashCode()
  Compute a hashCode for this object.

Overrides:
  hashCode in class Object
javax.servlet.jsp  Class PageContext

java.lang.Object
  ▼ javax.servlet.jsp.JspContext
    ▼ javax.servlet.jsp.PageContext

public abstract class PageContext
extends JspContext

Extends: JspContext

PageContext  JspContext  Servlet  JSP
PageContext  JSP  pageContext
PageContext  JSP  PageContext  JSP
JspFactory.getPageContext()  JspFactory.releasePageContext()

JSP Page Implementation  PageContextJspFactory

PageContext /

  •  API
  •  API
  •  JspWriter
  •
  •
  •  errorpage

JSP  JSP

  initialize()  release()
JspWriter  pushBody()

JSP

getException() getPage() getRequest() getResponse() getSession() getServletContext()

forward() include() handlePageException()

PageContext extends JspContext to provide useful context information for when JSP technology is used in a Servlet environment.

A PageContext instance provides access to all the namespaces associated with a JSP page, provides access to several page attributes, as well as a layer above the implementation details. Implicit objects are added to the pageContext automatically.

The PageContext class is an abstract class, designed to be extended to provide implementation dependent implementations thereof, by conformant JSP engine runtime environments. A PageContext instance is obtained by a JSP implementation class by calling the JspFactory.getPageContext() method, and is released by calling JspFactory.releasePageContext().

An example of how PageContext, JspFactory, and other classes can be used within a JSP Page Implementation object is given elsewhere.

The PageContext provides a number of facilities to the page/component author and page implementor, including:

- a single API to manage the various scoped namespaces
- a number of convenience API's to access various public objects
- a mechanism to obtain the JspWriter for output
- a mechanism to manage session usage by the page
- a mechanism to expose page directive attributes to the scripting environment
- mechanisms to forward or include the current request to other active
components in the application

- a mechanism to handle errorpage exception processing

**Methods Intended for Container Generated Code**

Some methods are intended to be used by the code generated by the container, not by code written by JSP page authors, or JSP tag library authors.

The methods supporting **lifecycle** are `initialize()` and `release()`

The following methods enable the **management of nested** JspWriter streams to implement Tag Extensions: `pushBody()`

**Methods Intended for JSP authors**

The following methods provide **convenient access** to implicit objects: `getException()`, `getPage()`, `getRequest()`, `getResponse()`, `getSession()`, `getServletConfig()` and `getServletContext()`.

The following methods provide support for **forwarding, inclusion and error handling**: `forward()`, `include()`, and `handlePageException()`.

</tr>
</tbody>
</table>
## Methods

**abstract void include(String relativeUrlPath)**

Causes the resource specified to be processed as part of the current ServletRequest and ServletResponse being processed by the calling Thread.

**abstract void include(String relativeUrlPath, boolean flush)**

Causes the resource specified to be processed as part of the current ServletRequest and ServletResponse being processed by the calling Thread.

**abstract void initialize(Servlet servlet, ServletRequest request, ServletResponse response, String errorPageURL, boolean needsSession, int bufferSize, boolean autoFlush)**

The initialize method is called to initialize an uninitialized PageContext so that it may be used by a JSP Implementation class to service an incoming request and response within its `_jspService()` method.

**BodyContent pushBody()**

Return a new BodyContent object, save the current "out" JspWriter, and update the value of the "out" attribute in the page scope attribute namespace of the PageContext.

**abstract void release()**

This method shall "reset" the internal state of a PageContext, releasing all internal references, and preparing the PageContext for potential reuse by a later invocation of initialize().

Field Detail

PAGE_SCOPE

public static final int PAGE_SCOPE

Page scope: (this is the default) the named reference remains available in this PageContext until the return from the current Servlet.service() invocation.

See Also:
Constant Field Values

REQUEST_SCOPE

public static final int REQUEST_SCOPE

Request scope: the named reference remains available from the ServletRequest associated with the Servlet until the current request is completed.

See Also:
Constant Field Values

SESSION_SCOPE

public static final int SESSION_SCOPE

Session scope (only valid if this page participates in a session): the named reference remains available from the HttpSession (if any) associated with the Servlet until the HttpSession is invalidated.
APPLICATION_SCOPE

public static final int APPLICATION_SCOPE

Application scope: named reference remains available in the ServletContext until it is reclaimed.

See Also: Constant Field Values

PAGE

public static final String PAGE

Name used to store the Servlet in this PageContext's nametables.

See Also: Constant Field Values

PAGECONTEXT

public static final String PAGECONTEXT

Name used to store this PageContext in it's own name table.

See Also: Constant Field Values
REQUEST

public static final String REQUEST

Name used to store ServletRequest in PageContext name table.

See Also:  
Constant Field Values

RESPONSE

public static final String RESPONSE

Name used to store ServletResponse in PageContext name table.

See Also:  
Constant Field Values

CONFIG

public static final String CONFIG

Name used to store ServletConfig in PageContext name table.

See Also:  
Constant Field Values

SESSION
public static final String SESSION

Name used to store HttpSession in PageContext name table.

See Also:
Constant Field Values

OUT

public static final String OUT

Name used to store current JspWriter in PageContext name table.

See Also:
Constant Field Values

APPLICATION

public static final String APPLICATION

Name used to store ServletContext in PageContext name table.

See Also:
Constant Field Values

EXCEPTION

public static final String EXCEPTION

Name used to store uncaught exception in ServletRequest attribute list and PageContext name table.

*Constant Field Values*

## Constructor Detail

```java
public PageContext()
```

**PageContext**

```java
public PageContext()
```

Sole constructor. (For invocation by subclass constructors, typically implicit.)

## Method Detail

```java
abstract public void initialize(Servlet servlet,
ServletRequest request, ServletResponse response, String errorPageURL,
boolean needsSession, int bufferSize,
boolean autoFlush) throws java.io.IOException,
IllegalStateException, IllegalArgumentException
```

initialize PageContext JSP _jspService()

JspFactory.getPageContext()

JspWriter "out"

```java

<table>
<thead>
<tr>
<th>servlet</th>
<th>PageContext</th>
<th>Servlet</th>
</tr>
</thead>
<tbody>
<tr>
<td>request</td>
<td></td>
<td>Servlet</td>
</tr>
<tr>
<td>response</td>
<td></td>
<td>Servlet</td>
</tr>
<tr>
<td>errorPageURL</td>
<td>errorpage</td>
<td>null</td>
</tr>
</tbody>
</table>
```
initialize

public abstract void initialize(Servlet servlet,
ServletRequest request,
ServletResponse response,
String errorPageURL,
boolean needsSession,
int bufferSize,
boolean autoFlush)
throws IOException,
IllegalStateException,
IllegalArgumentException

The initialize method is called to initialize an uninitialized PageContext so that it may be used by a JSP Implementation class to service an incoming request and response within it's _jspService() method.

This method is typically called from JspFactory.getPageContext() in order to initialize state.

This method is required to create an initial JspWriter, and associate the "out" name in page scope with this newly created object.

This method should not be used by page or tag library authors.

Parameters:

&bullet; servlet - The Servlet that is associated with this PageContext
&bullet; request - The currently pending request for this Servlet
&bullet; response - The currently pending response for this Servlet
&bullet; errorPageURL - The value of the errorpage attribute from the page directive or null
needsSession - The value of the session attribute from the page
directive
bufferSize - The value of the buffer attribute from the page
directive
autoFlush - The value of the autoflush attribute from the page
directive

**Throws:**

- `IOException` - during creation of JspWriter
- `IllegalStateException` - if out not correctly initialized
- `IllegalArgumentException` - If one of the given parameters is invalid

---

**abstract public void release()**

```java
"""PageContext initialize() PageContext

JspFactory.releasePageContext()"
```

---

**release**

**public abstract void release()**

This method shall "reset" the internal state of a PageContext,
releasing all internal references, and preparing the PageContext for
potential reuse by a later invocation of `initialize()`. This method is
typically called from `JspFactory.releasePageContext()`.

Subclasses shall envelope this method.

This method should not be used by page or tag library authors.
abstract public HttpSession getSession()
HttpSession
    return PageContext HttpSession null

getSession

public abstract HttpSession getSession()

    The current value of the session object (an HttpSession).

    Returns:
        the HttpSession for this PageContext or null

abstract public Object getPage()
Servlet javax.servlet.Servlet
    return PageContext

ggetPage

public abstract Object getPage()

    The current value of the page object (In a Servlet environment, this is an instance of javax.servlet.Servlet).

    Returns:
        the Page implementation class instance associated with this PageContext

abstract public ServletRequest getRequest()
ServletRequest
    return PageContext ServletRequest
**getRequest**

```java
public abstract ServletRequest getRequest()
```

The current value of the request object (a ServletRequest).

**Returns:**
The ServletRequest for this PageContext

---

**getResponse**

```java
abstract public ServletResponse getResponse()
```

```java
ServletResponse return PageContext ServletResponse
```

---

**getException**

```java
abstract public Exception getException()
```

```java
Exception return errorpage PageContext
```

---

**getException**

```java
public abstract Exception getException()
```

The current value of the exception object (an Exception).

**Returns:**
any exception passed to this as an errorpage
abstract public ServletConfig getServletConfig()
ServletConfig return PageContext ServletConfig

getServletConfig

public abstract ServletConfig getServletConfig()

The ServletConfig instance.

Returns:
the ServletConfig for this PageContext

abstract public ServletContext getServletContext()
ServletContext return PageContext ServletContext

getServletContext

public abstract ServletContext getServletContext()

The ServletContext instance.

Returns:
the ServletContext for this PageContext

abstract public void forward(String relativeUrlPath) throws ServletException, java.io.IOException

HttpServletRequest  HttpServletResponse ""

relativeUrlPath  "/" URL JSP ServletException
forward

public abstract void forward(String relativeUrlPath)
throws ServletException, IOException

This method is used to re-direct, or "forward" the current ServletRequest and ServletResponse to another active component in the application.

If the relativeUrlPath begins with a "/" then the URL specified is calculated relative to the DOCROOT of the ServletContext for this JSP. If the path does not begin with a "/" then the URL specified is calculated relative to the URL of the request that was mapped to the calling JSP.

It is only valid to call this method from a Thread executing within a _jspService(...) method of a JSP.

Once this method has been called successfully, it is illegal for the calling Thread to attempt to modify the ServletResponse object. Any such attempt to do so, shall result in undefined behavior. Typically, callers immediately return from _jspService(...) after calling this method.

Parameters:
relativeUrlPath - specifies the relative URL path to the target resource as described above

Throws:
- `IllegalStateException` - if `ServletResponse` is not in a state where a forward can be performed
- `ServletException` - if the page that was forwarded to throws a `ServletException`
- `IOException` - if an I/O error occurred while forwarding

```java
abstract public void include(String relativeUrlPath) throws ServletException, java.io.IOException
```

Thread ServletRequest ServletResponse
ServletResponse

```java
include  JSP  JspWriter "out"
```

```java
relativeUrlPath  "/"  URL  JSP  ServletContext
DOCROOT  "/"  URL  JSP  URL
```

```java
JSP  _jspService(...)  Thread
```

```java
relativeUrlPath  URL
Throws  ServletException:  ServletException
Throws  java.io.IOException:  I/O
```

```java
include
```

```java
public abstract void include(String relativeUrlPath) throws ServletException,
IOException
```

Causes the resource specified to be processed as part of the current ServletRequest and ServletResponse being processed by the calling Thread. The output of the target resources processing of the request
is written directly to the ServletResponse output stream.

The current JspWriter "out" for this JSP is flushed as a side-effect of this call, prior to processing the include.

If the `relativeUrlPath` begins with a "/" then the URL specified is calculated relative to the DOCROOT of the ServletContext for this JSP. If the path does not begin with a "/" then the URL specified is calculated relative to the URL of the request that was mapped to the calling JSP.

It is only valid to call this method from a Thread executing within a `_jspService(...)` method of a JSP.

**Parameters:**
- `relativeUrlPath` - specifies the relative URL path to the target resource to be included

**Throws:**
- `ServletException` - if the page that was forwarded to throws a ServletException
- `IOException` - if an I/O error occurred while forwarding

```java
abstract public void include(String relativeUrlPath, boolean flush) throws ServletException, java.io.IOException
```

Thread ServletRequest ServletResponse
getOut() JspWriter

flush true include JSP JspWriter
"out" JspWriter "out"

```java
relativeUrlPath "/" URL JSP ServletContext
DOCROOT "/" URL JSP URL
```

JSP _jspService(...) Thread

```java
relativeUrlPath URL
```
**include**

```java
public abstract void include(String relativeUrlPath,
                              boolean flush)
    throws ServletException,
            IOException
```

Causes the resource specified to be processed as part of the current ServletRequest and ServletResponse being processed by the calling Thread. The output of the target resources processing of the request is written directly to the current JspWriter returned by a call to `getOut()`.

If flush is true, The current JspWriter "out" for this JSP is flushed as a side-effect of this call, prior to processing the include. Otherwise, the JspWriter "out" is not flushed.

If the `relativeUrlPath` begins with a "/" then the URL specified is calculated relative to the DOCROOT of the ServletContext for this JSP. If the path does not begin with a "/" then the URL specified is calculated relative to the URL of the request that was mapped to the calling JSP.

It is only valid to call this method from a Thread executing within a `_jspService(...)` method of a JSP.

**Parameters:**
- `relativeUrlPath` - specifies the relative URL path to the target resource to be included
- `flush` - True if the JspWriter is to be flushed before the include, or false if not.

**Throws:**
- `ServletException` - if the page that was forwarded to throws a ServletException
IOException - if an I/O error occurred while forwarding

Since:
    JSP 2.0

abstract public void handlePageException(Exception e)
throws ServletException, java.io.IOException

JSP """"

servlet

JSP  ServletResponse

PageContext.handlePageException(Throwable)

Throws ServletException:
Throws java.io.IOException: I/O
Throws NullPointerException: null
See also handlePageException(Throwable)

handlePageException

public abstract void handlePageException(Exception e)
throws ServletException, IOException

This method is intended to process an unhandled 'page' level exception by forwarding the exception to the specified error page for this JSP. If forwarding is not possible (for example because the response has already been committed), an implementation dependent mechanism should be used to invoke the error page (e.g. "including" the error page instead).

If no error page is defined in the page, the exception should be rethrown so that the standard servlet error handling takes over.
A JSP implementation class shall typically clean up any local state prior to invoking this and will return immediately thereafter. It is illegal to generate any output to the client, or to modify any ServletResponse state after invoking this call.

This method is kept for backwards compatibility reasons. Newly generated code should use PageContext.handlePageException(Throwable).

**Parameters:**
- e - the exception to be handled

**Throws:**
- ServletException - if an error occurs while invoking the error page
- IOException - if an I/O error occurred while invoking the error page
- NullPointerException - if the exception is null

**See Also:**
handlePageException(Throwable)

```java
abstract public void handlePageException(Throwable t)
throws ServletException, java.io.IOException

JSP """

servlet

JSP ""

JSP  ServletResponse

<table>
<thead>
<tr>
<th>t</th>
<th>throwable</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>ServletException:</td>
</tr>
<tr>
<td>Throws</td>
<td>java.io.IOException: I/O</td>
</tr>
<tr>
<td>Throws</td>
<td>NullPointerException: null</td>
</tr>
<tr>
<td>See also</td>
<td>handlePageException(Exception)</td>
</tr>
</tbody>
</table>
```
public abstract void handlePageException(Throwable t) throws ServletException, IOException

This method is intended to process an unhandled 'page' level exception by forwarding the exception to the specified error page for this JSP. If forwarding is not possible (for example because the response has already been committed), an implementation dependent mechanism should be used to invoke the error page (e.g. "including" the error page instead).

If no error page is defined in the page, the exception should be rethrown so that the standard servlet error handling takes over.

This method is intended to process an unhandled "page" level exception by redirecting the exception to either the specified error page for this JSP, or if none was specified, to perform some implementation dependent action.

A JSP implementation class shall typically clean up any local state prior to invoking this and will return immediately thereafter. It is illegal to generate any output to the client, or to modify any ServletResponse state after invoking this call.

Parameters:
   t - the throwable to be handled

Throws:
   ServletException - if an error occurs while invoking the error page
   IOException - if an I/O error occurred while invoking the error page
   NullPointerException - if the exception is null

See Also:
   handlePageException(Exception)
public BodyContent pushBody()
BodyContent "out" JspWriter PageContext "out"

    return BodyContent

pushBody

public BodyContent pushBody()

    Return a new BodyContent object, save the current "out" JspWriter, and update the value of the "out" attribute in the page scope attribute namespace of the PageContext.

    Returns:
    the new BodyContent

public ErrorData getErrorData()

    return ErrorData Servlet isErrorPage "true"
    since 2.0

getErrorData

public ErrorData getErrorData()

    Provides convenient access to error information.

    Returns:
    an ErrorData instance containing information about the error, as obtained from the request attributes, as per the Servlet specification. If this is not an error page (that is, if the isErrorPage attribute of the page directive is not set to "true"), the information is meaningless.

    Since:
public abstract class PageData extends Object

JSP JSP XML

JSP TagLibraryValidator

Translation-time information on a JSP page. The information corresponds to the XML view of the JSP page.

Objects of this type are generated by the JSP translator, e.g. when being passed to a TagLibraryValidator instance.

PS :
This class holds MIME parameters (attribute-value pairs). The `mail.mime.encodeparameters` and `mail.mime.decodeparameters` System properties control whether encoded parameters, as specified by RFC 2231, are supported. By default, such encoded parameters are not supported.

Also, in the current implementation, setting the System property `mail.mime.decodeparameters.strict` to "true" will cause a `ParseException` to be thrown for errors detected while decoding encoded parameters. By default, if any decoding errors occur, the original (undecoded) string is used.

public ParameterList()

**ParameterList**

public ParameterList()

   No-arg Constructor.

---

public ParameterList(String s) throws ParseException

Constructor that takes a parameter-list string. The String is parsed and the parameters are collected and stored internally. A ParseException is thrown if the parse fails. Note that an empty parameter-list string is valid and will be parsed into an empty ParameterList.

**Parameters:**

   s - the parameter-list string.

**Throws:**

ParseException - if the parse fails.

---

**Method Detail**

public int size()
size

public int size()

    Return the number of parameters in this list.

    Returns:
    number of parameters.

get

public String get(String name)

    name
    return

    get

public void set(String name, String value)

    name
    value
public void set(String name, String value)

Set a parameter. If this parameter already exists, it is replaced by this new value.

Parameters:
  name - name of the parameter.
  value - value of the parameter.

public void set(String name, String value, String charset)

RFC 2231

  name
  value
  charset

since JavaMail 1.4

Set a parameter. If this parameter already exists, it is replaced by this new value. If the mail.mime.encodeparameters System property is true, and the parameter value is non-ASCII, it will be encoded with the specified charset, as specified by RFC 2231.

Parameters:
  name - name of the parameter.
  value - value of the parameter.
public void remove(String name)
ParameterList

remove

public void remove(String name)

Removes the specified parameter from this ParameterList. This method does nothing if the parameter is not present.

Parameters:
name - name of the parameter.

public java.util.Enumeration<E> getNames()

return

getNames

public Enumeration getNames()

Return an enumeration of the names of all parameters in this list.

Returns:
Enumeration of all parameter names in this list.
**toString**

```java
public String toString()
```

Convert this ParameterList into a MIME String. If this is an empty list, an empty string is returned.

**Overrides:**
toString in class Object

**Returns:**
String

---

```java
public String toString(int used)
```

**ParameterList** MIME String

```
used
  return
```

**toString**

```java
public String toString(int used)
```

Convert this ParameterList into a MIME String. If this is an empty list, an empty string is returned. The 'used' parameter specifies the number of character positions already taken up in the field into which the resulting parameter list is to be inserted. It's used to determine where to fold the resulting parameter list.

**Parameters:**
used - number of character positions already used, in the field into which the parameter list is to be inserted.

**Returns:**
String

**Constructor Detail**

```java
public ParseConversionEventImpl(int _severity, String _message, ValidationEventLocator _locator)
```

**ParseConversionEventImpl**

- `_severity` - The severity value for this event. Must be one of ValidationEvent.WARNING, ValidationEvent.ERROR, or ValidationEvent.FATAL_ERROR
- `_message` - The text message for this event - may be null.
- `_locator` - The locator object for this event - may be null.

**Throws:**

IllegallegalArgumentException - if an illegal severity field is supplied

```java
public ParseConversionEventImpl(int _severity, String _message, ValidationEventLocator _locator, Throwable _linkedException)
```
ParseConversionEventImpl

public ParseConversionEventImpl(int _severity, 
String _message, 
ValidationEventLocator _locator, 
Throwable _linkedException)

Create a new ParseConversionEventImpl.

Parameters:

_severity - The severity value for this event. Must be one of ValidationEvent.WARNING, ValidationEvent.ERROR, or ValidationEvent.FATAL_ERROR
_message - The text message for this event - may be null.
_locator - The locator object for this event - may be null.
_linkedException - An optional linked exception that may provide additional information about the event - may be null.

Throws:

IllegalArgumentException - if an illegal severity field is supplied

javax.mail Interface Part

All Known Subinterfaces: 
   MimePart

All Known Implementing Classes: 
   BodyPart, Message, MimeBodyPart, MimeMessage, PreencodedMimeBodyPart

public interface Part

Implemented by: BodyPart, Message, MimePart

Part Message BodyPart

Part "Content"

JavaMail API Part Mail Mail Part -
String

"content" getContentType() MIME

Part "content"

- DataHandler - getDataHandler() Part "content"
javax.activation.DataHandler DataHandler
- - getInputStream()
- Java - getContent() Java "content"
"multipart" Part Multipart "multipart" Part
getContentType() Multipart

Part writeTo() Part

Message BodyPart Part MIME Part
The Part interface is the common base interface for Messages and BodyParts.

Part consists of a set of attributes and a "Content".

**Attributes:**

The JavaMail API defines a set of standard Part attributes that are considered to be common to most existing Mail systems. These attributes have their own setter and getter methods. Mail systems may support other Part attributes as well, these are represented as name-value pairs where both the name and value are Strings.

**Content:**

The data type of the "content" is returned by the `getContentType()` method. The MIME typing system is used to name data types.

The "content" of a Part is available in various formats:

- As a DataHandler - using the `getDataHandler()` method. The "content" of a Part is also available through a `javax.activation.DataHandler` object. The DataHandler object allows clients to discover the operations available on the content, and to instantiate the appropriate component to perform those operations.
- As an input stream - using the `getInputStream()` method. Any mail-specific encodings are decoded before this stream is returned.
- As a Java object - using the `getContent()` method. This method returns the "content" as a Java object. The returned object is of course dependent on the content itself. In particular, a "multipart" Part's content is always a Multipart or subclass thereof. That is, `getContent()` on a "multipart" type Part will always return a Multipart (or subclass) object.

Part provides the `writeTo()` method that streams out its bytestream in
mail-safe form suitable for transmission. This bytestream is typically an aggregation of the Part attributes and its content's bytestream.

Message and BodyPart implement the Part interface. Note that in MIME parlance, Part models an Entity (RFC 2045, Section 2.4).

- Get all the headers for this header name.

**InputStream**

**getInputStream()**
- Return an input stream for this part's "content".

**int**

**getLineCount()**
- Return the number of lines in the content of this part.

**Enumeration**

**getMatchingHeaders(String[] header_names)**
- Return matching headers from this part as an Enumeration of Header objects.

**Enumeration**

**getNonMatchingHeaders(String[] header_names)**
- Return non-matching headers from this envelope as an Enumeration of Header objects.

**int**

**getSize()**
- Return the size of the content of this part in bytes.

**boolean**

**isMimeType(String mimeType)**
- Is this Part of the specified MIME type?

**void**

**removeHeader(String header_name)**
- Remove all headers with this name.

**void**

**setContent(Multipart mp)**
- This method sets the given Multipart object as this message's content.

**void**

**setContent(Object obj, String type)**
- A convenience method for setting this part's content.

**void**

**setDataHandler(DataHandler dh)**
- This method provides the mechanism to set this part's content.

**void**

**setDescription(String description)**
- Set a description String for this part.

**void**

**setDisposition(String disposition)**
- Set the disposition of this part.

**void**

**setFileName(String filename)**
- Set the filename associated with this part, if possible.

**void**

**setHeader(String header_name, String header_value)**
- Set the value for this header_name.
setText(String text)
A convenience method that sets the given String as this part's content with a MIME type of "text/plain".

writeTo(OutputStream os)
Output a bytestream for this Part.

Field Detail

ATTACHMENT
static final String ATTACHMENT
This part should be presented as an attachment.

See Also:
getDisposition(), setDisposition(java.lang.String), Constant Field Values

INLINE
static final String INLINE
This part should be presented inline.

See Also:
getDisposition(), setDisposition(java.lang.String), Constant Field Values

Method Detail
public int getSize() throws MessagingException
-1

    return
    Throws

getSize

int getSize()
throws MessagingException

    Return the size of the content of this part in bytes. Return -1 if the size cannot be determined.

    Note that the size may not be an exact measure of the content size and may or may not account for any transfer encoding of the content. The size is appropriate for display in a user interface to give the user a rough idea of the size of this part.

    Returns:
    size of content in bytes
    Throws:
    MessagingException

public int getLineCount() throws MessagingException
-1

    return
    Throws

getLineCount

int getLineCount()
throws MessagingException
Return the number of lines in the content of this part. Return -1 if the number cannot be determined. Note that this number may not be an exact measure of the content length and may or may not account for any transfer encoding of the content.

**Returns:**
- number of lines in the content.

**Throws:**
- MessagingException

---

```java
public String getContentType() throws MessagingException {
    return ContentType;
}
```

MIME Content-type

```
return
Throws
See also
```

**getContentType**

```java
String getContentType() throws MessagingException {
    return Content-Type;
}
```

Returns the Content-Type of the content of this part. Returns null if the Content-Type could not be determined.

The MIME typing system is used to name Content-types.

**Returns:**
- The ContentType of this part

**Throws:**
- MessagingException

**See Also:**
- javax.activation.DataHandler
public boolean isMimeType(String mimeType) throws MessagingException

Part MIME  primaryType  subType

"text/plain"  "text/plain; charset=foobar"

true

mimeType  subType  '*'  subtype

isMimeType

boolean isMimeType(String mimeType)

throws MessagingException

Is this Part of the specified MIME type? This method compares only the primaryType and subType. The parameters of the content types are ignored.

For example, this method will return true when comparing a Part of content type "text/plain" with "text/plain; charset=foobar".

If the subType of mimeType is the special character '*', then the subtype is ignored during the comparison.

Throws:
   MessagingException

public String getDisposition() throws MessagingException
disposition
disposition  RFC 2183

String disp = part.getDisposition();
if (disp == null || disp.equalsIgnoreCase(Part.ATTACHMENT))
    // treat as attachment if not first part

    return  disposition null
getDisposition

String getDisposition() throws MessagingException

Return the disposition of this part. The disposition describes how the part should be presented to the user. (See RFC 2183.) The return value should be considered without regard to case. For example:

```java
String disp = part.getDisposition();
if (disp == null || disp.equalsIgnoreCase(Part.ATTACHMENT))
   // treat as attachment if not first part
```

Returns:
- disposition of this part, or null if unknown

Throws:
- MessagingException

See Also:
- ATTACHMENT, INLINE, getFileName()

public void setDisposition(String disposition) throws MessagingException

disposition

Throws
- MessagingException
- IllegalWriteException:
- IllegalStateException: Part READONLY

See also
- ATTACHMENT, INLINE, setFileName

setDisposition

void setDisposition(String disposition)
Set the disposition of this part.

**Parameters:**
- disposition - disposition of this part

**Throws:**
- MessagingException
- IllegalWriteException - if the underlying implementation does not support modification of this header
- IllegalStateException - if this Part is obtained from a READ_ONLY folder

**See Also:**
- ATTACHMENT, INLINE, setFileName(java.lang.String)

---

```java
public String getDescription() throws MessagingException {
    return null;
}
```

**Description**

Return a description String for this part. This typically associates some descriptive information with this part. Returns null if none is available.

**Returns:**
- description of this part

**Throws:**
- MessagingException

---

```java
public void setDescription(String description) throws MessagingException {
}
```

**Description**

Set the disposition of this part.

**Parameters:**
- disposition - disposition of this part

**Throws:**
- MessagingException
- IllegalWriteException - if the underlying implementation does not support modification of this header
- IllegalStateException - if this Part is obtained from a READ_ONLY folder

**See Also:**
- ATTACHMENT, INLINE, setFileName(java.lang.String)
String

description

Throws MessagingException:

Throws IllegalArgumentException:

Throws IllegalStateException: Part READ_ONLY

setDescription

void setDescription(String description) throws MessagingException

Set a description String for this part. This typically associates some descriptive information with this part.

Parameters:

description - description of this part

Throws:

MessagingException

IllegalArgumentException - if the underlying implementation does not support modification of this header

IllegalStateException - if this Part is obtained from a READ_ONLY folder

public String getFileName() throws MessagingException

return

getFileName

String getFileName() throws MessagingException

Get the filename associated with this part, if possible. Useful if this part represents an "attachment" that was loaded from a file. The filename will usually be a simple name, not including directory
setFileName

void setFileName(String filename) throws MessagingException

""

filename

Throws IllegalWriteException:

Throws IllegalStateException: Part READ_ONLY

Parameters:
filename - Filename to associate with this part

Throws:

IllegalWriteException - if the underlying implementation does not support modification of this header
IllegalStateException - if this Part is obtained from a READ_ONLY folder
MessagingException

getInputStream

public java.io.InputStream getInputStream() throws java.io.IOException, MessagingException
public DataHandler getDataHandler() throws MessagingException

DataHandler

return InputStream

Throws java.io.IOException: DataHandler
javax.activation.DataHandler

Throws MessagingException:

See also getDataHandler, getInputStream

getInputStream

InputStream getInputStream()

throws IOException, MessagingException

Return an input stream for this part's "content". Any mail-specific transfer encodings will be decoded before the input stream is provided.

This is typically a convenience method that just invokes the DataHandler's getInputStream() method.

Returns:
an InputStream

Throws:
IOException - this is typically thrown by the DataHandler. Refer to the documentation for javax.activation.DataHandler for more details.
MessagingException

See Also:
getDataHandler(), DataHandler.getInputStream()
**getDataHandler**

```java
DataHandler getDataHandler() throws MessagingException
```

Return a DataHandler for the content within this part. The DataHandler allows clients to operate on as well as retrieve the content.

**Returns:**
- DataHandler for the content

**Throws:**
- MessagingException

---

**public Object getContent() throws java.io.IOException, MessagingException**

Java "text/plain" String "multipart"
Multipart DataHandler

```java
DataHandler getContent() throws MessagingException:
```

**Throws:**
- java.io.IOException: DataHandler
- javax.activation.DataHandler

See also
- getContent

---

**getContent**

```java
Object getContent()
```
Return the content as a Java object. The type of the returned object is of course dependent on the content itself. For example, the object returned for "text/plain" content is usually a String object. The object returned for a "multipart" content is always a Multipart subclass. For content-types that are unknown to the DataHandler system, an input stream is returned as the content.

This is a convenience method that just invokes the DataHandler's getContent() method

**Returns:**
Object

**Throws:**
- MessagingException
- IOException - this is typically thrown by the DataHandler. Refer to the documentation for javax.activation.DataHandler for more details.

**See Also:**
DataHandler.getContent()
DataHandler wraps around the actual content.

**Parameters:**

`dh` - The DataHandler for the content.

**Throws:**

- `MessagingException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this Part is obtained from a READ_ONLY folder

```java
public void setContent(Object obj, String type) throws MessagingException
    DataHandler
```

**DataContentHandler JavaMail**

```java
setContent("foobar", "application/x-foobar") "application/x-foobar" DataContentHandler Java Activation Framework
```

<table>
<thead>
<tr>
<th><code>obj</code></th>
<th>Java</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>type</code></td>
<td>MIME</td>
</tr>
</tbody>
</table>

**Throws**

- `IllegalWriteException`: 
- `IllegalStateException`: Part READ_ONLY

## setContent

```java
void setContent(Object obj,
                String type)
    throws MessagingException
```

A convenience method for setting this part's content. The part internally wraps the content in a DataHandler.

Note that a DataContentHandler class for the specified type should be available to the JavaMail implementation for this to work right.
i.e., to do `setContent(foobar, "application/x-foobar"),` a DataContentHandler for "application/x-foobar" should be installed. Refer to the Java Activation Framework for more information.

**Parameters:**
- `obj` - A java object.
- `type` - MIME type of this object.

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this Part is obtained from a `READ_ONLY` folder
- `MessagingException`

```java
public void setText(String text) throws MessagingException
MIME "text/plain" String
    text Message
Throws    IllegalWriteException:
Throws    IllegalStateException: Part `READ_ONLY`
```

A convenience method that sets the given String as this part's content with a MIME type of "text/plain".

**Parameters:**
- `text` - The text that is the Message's content.

**Throws:**
- `IllegalWriteException` - if the underlying implementation does not support modification of existing values
- `IllegalStateException` - if this Part is obtained from a `READ_ONLY` folder
- `MessagingException`
public void setContent(Multipart mp) throws MessagingException

Multipart

Throw: IllegalWriteException:

Thrown: IllegalStateException: Part READ_ONLY

**setContent**

void setContent(Multipart mp)

throws MessagingException

This method sets the given Multipart object as this message's content.

**Parameters:**

mp - The multipart object that is the Message's content

**Throws:**

IllegalWriteException - if the underlying implementation does not support modification of existing values

IllegalStateException - if this Part is obtained from a READ_ONLY folder

**Part**

Thrown: java.io.IOException: javax.activation

Thrown: MessagingException:

See also: writeTo
**writeTo**

```java
void writeTo(OutputStream os)
    throws IOException, MessagingException
```

Output a bytestream for this Part. This bytestream is typically an aggregation of the Part attributes and an appropriately encoded bytestream from its 'content'.

Classes that implement the Part interface decide on the appropriate encoding algorithm to be used.

The bytestream is typically used for sending.

**Throws:**

- `IOException` - if an error occurs writing to the stream or if an error is generated by the `javax.activation` layer.
- `MessagingException` - if an error occurs fetching the data to be written

**See Also:**

`DataHandler.writeTo(java.io.OutputStream)`

---

**public String[] getHeader(String header_name) throws MessagingException**

```java
null
```

```java
return
```  

**Throws**

`MessagingException`

---

**getHeader**

```java
String[] getHeader(String header_name)
    throws MessagingException
```
Get all the headers for this header name. Returns null if no headers for this header name are available.

Parameters:
- header_name - the name of this header

Returns:
- the value fields for all headers with this name

Throws:
- MessagingException

public void setHeader(String header_name, String header_value) throws MessagingException

header_name
- header_name
- header_value

Throws
- MessagingException:

Throws
- IllegalWriteException:

Throws
- IllegalStateException: Part READ_ONLY

setHeader

void setHeader(String header_name, String header_value) throws MessagingException

Set the value for this header_name. Replaces all existing header values with this new value.

Parameters:
- header_name - the name of this header
- header_value - the value for this header

Throws:
- MessagingException
- IllegalWriteException - if the underlying implementation does not support modification of existing values
- IllegalStateException - if this Part is obtained from a READ_ONLY folder
public void addHeader(String header_name, String header_value) throws MessagingException

header_name
  header_name
  header_value

Throws MessagingException:
Throws IllegalWriteException:
Throws IllegalStateException: Part READ_ONLY

addHeader

void addHeader(String header_name,
               String header_value)
throws MessagingException

Add this value to the existing values for this header_name.

Parameters:
  header_name - the name of this header
  header_value - the value for this header

Throws:
  MessagingException
  IllegalWriteException - if the underlying implementation does not support modification of existing values
  IllegalStateException - if this Part is obtained from a READ_ONLY folder

public void removeHeader(String header_name) throws MessagingException

header_name

Throws MessagingException:
Throws IllegalWriteException:
Throws IllegalStateException: Part READ_ONLY
removeHeader

void removeHeader(String header_name)
    throws MessagingException

Remove all headers with this name.

Parameters:
    header_name - the name of this header

Throws:
    MessagingException
    IllegalWriteException - if the underlying implementation does not support modification of existing values
    IllegalStateException - if this Part is obtained from a READ_ONLY folder

public java.utilEnumeration getHeaders() throws MessagingException

Header

return

Throws
    MessagingException:

getAllHeaders

Enumeration getHeaders()
    throws MessagingException

Return all the headers from this part as an Enumeration of Header objects.

Returns:
    enumeration of Header objects

Throws:
    MessagingException
public java.util.Enumeration<E> getMatchingHeaders(String[] header_names) throws MessagingException

Header

<table>
<thead>
<tr>
<th>return</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Throws: MessagingException

getMatchingHeaders

Enumeration getMatchingHeaders(String[] header_names) throws MessagingException

Returns:

- enumeration of Header objects

Throws:

- MessagingException

public java.util.Enumeration<E> getNonMatchingHeaders(String[] header_names) throws MessagingException

Header

<table>
<thead>
<tr>
<th>return</th>
<th>Header</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Throws: MessagingException

getNonMatchingHeaders

Enumeration getNonMatchingHeaders(String[] header_names) throws MessagingException

Returns:

Return non-matching headers from this envelope as an Enumeration of Header objects.
Returns:
   enumeration of Header objects

Throws:
   MessagingException
class PasswordAuthentication
extends Object

PasswordAuthentication Authenticator

version 1.6, 05/04/07
See java.net.PasswordAuthentication,
also javax.mail.Authenticator, getPasswordAuthentication()

The class PasswordAuthentication is a data holder that is used by Authenticator. It is simply a repository for a user name and a password.

Version:
1.6, 05/04/07
Author:
Bill Foote
See Also:
PasswordAuthentication, Authenticator, Authenticator.getPasswordAuthentication()

<td>Sets the target ManagedConnectionFactory instance for which the user name and password has been set by the application server.</td>
</tr>
</tbody>
</table>

## Constructor Detail

```java
public PasswordCredential(String userName, char[] password)
```
PasswordCredential

public PasswordCredential(String userName, char[] password)

Creates a new PasswordCredential object from the given user name and password.

Note that the given user password is cloned before it is stored in the new PasswordCredential object.

Parameters:

- userName - the user name
- password - the user's password

Method Detail

public String getUserName()

return

getUserName

public String getUserName()

Returns the user name.

Returns:

the user name

public char[] getPassword()
getPassword

public char[] getPassword()

    Returns the user password.

    Note that this method returns a reference to the password. It is the
caller's responsibility to zero out the password information after it is
no longer needed.

    Returns:
    the password

public ManagedConnectionFactory getManagedConnectionFactory()
ManagedConnectionFactory EIS
return ManagedConnectionFactory

getManagedConnectionFactory

public ManagedConnectionFactory getManagedConnectionFactory()()

    Gets the target ManagedConnectionFactory for which the user name
and password has been set by the application server. A
ManagedConnection- Factory uses this field to find out whether
PasswordCredential should be used by it for sign-on to the target
EIS instance.

Returns:
ManagedConnectionFactory instance for which user name and password have been specified

```
public void setManagedConnectionFactory(ManagedConnectionFactory mcf)
```

`setManagedConnectionFactory` sets the target ManagedConnectionFactory instance for which the user name and password have been set by the application server.

**Parameters:**
- `mcf` - ManagedConnectionFactory instance for which user name and password have been specified

```
public boolean equals(Object other)
```

`equals` compares this PasswordCredential with the specified object for
equality. The two PasswordCredential instances are the same if they are equal in username and password.

Overrides:

equals in class Object

Parameters:

other - Object to which PasswordCredential is to be compared

Returns:

true if and if the specified object is a PasswordCredential whose username and password are equal to this instance.

public int hashCode()
PasswordCredential

return PasswordCredential

hashCode

public int hashCode()

Returns the hash code for this PasswordCredential

Overrides:

hashCode in class Object

Returns:

hash code for this PasswordCredential
PS:
javax.annotation.security Annotation Type PermitAll

@Documented
@Retention(value=RUNTIME)
@Target(value={TYPE, METHOD})
public @interface PermitAll

Implements: Annotation
@Documented
@Retention(value=RUNTIME)
@Target(value={TYPE, METHOD})

"" RolesAllowed PermitAll
RolesAllowed

\[since\] 1.0
\[See\] javax.annotation.security.RolesAllowed,
\[also\] javax.annotation.security.DenyAll

Specifies that all security roles are allowed to invoke the specified method(s) i.e that the specified method(s) are "unchecked". It can be specified on a class or on methods. Specifying it on the class means that it applies to all methods of the class. If specified at the method level, it only affects that method. If the RolesAllowed is specified at the class level and this annotation is applied at the method level, the PermitAll annotation overrides the RolesAllowed for the specified method.

providers

protected static final Set<PersistenceProvider> providers

### Constructor Detail

public Persistence()
```java
public Persistence()

---

**Method Detail**

```java
public static EntityManagerFactory createEntityManagerFactory(String persistenceUnitName)

 EntityManagerFactory persistenceUnitName
 return

createEntityManagerFactory
```

Create and return an EntityManagerFactory for the named persistence unit.

**Parameters:**
- `persistenceUnitName` - The name of the persistence unit

**Returns:**
The factory that creates EntityManagers configured according to the specified persistence unit

```java
public static EntityManagerFactory createEntityManagerFactory(String persistenceUnitName,
java.util.Map<K, V> properties)

 EntityManagerFactory persistenceUnitName
 properties
 return

createEntityManagerFactory
```

createEntityManagerFactory

public static EntityManagerFactory createEntityManagerFactory(String persistenceUnitName, Map<String, String> properties)

Create and return an EntityManagerFactory for the named persistence unit using the given properties.

**Parameters:**
- persistenceUnitName - The name of the persistence unit
- properties - Additional properties to use when creating the factory. The values of these properties override any values that may have been configured elsewhere.

**Returns:**
The factory that creates EntityManagers configured according to the specified persistence unit.
javax.persistence Annotation Type PersistenceContext

@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface PersistenceContext

Implements: Annotation
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)

EntityManager

since Java Persistence 1.0

Expresses a dependency on an EntityManager persistence context.

Since:

## Enum Constant Detail

### TRANSACTION

```java
public static final PersistenceContextType TRANSACTION
```

Transaction-scoped persistence context

### EXTENDED

```java
public static final PersistenceContextType EXTENDED
```

Extended persistence context

## Method Detail
final public static PersistenceContextType[] values()

values

public static final PersistenceContextType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(PersistenceContextType c : PersistenceContextType.values())
    System.out.println(c);
```

Returns:
- an array containing the constants of this enum type, in the order they're declared

public static PersistenceContextType valueOf(String name)

valueOf

public static PersistenceContextType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

Parameters:
- name - the name of the enum constant to be returned.

Returns:
- the enum constant with the specified name

Throws:
- IllegalArgumentException - if this enum type has no constant with the specified name

PS :
javax.persistence  Class PersistenceException

java.lang.Object  
  └ java.lang.Throwable  
    └ java.lang.Exception  
      └ java.lang.RuntimeException  
        └ javax.persistence.PersistenceException

All Implemented Interfaces:
  Serializable

Direct Known Subclasses:
  EntityExistsException, EntityNotFoundException, NonUniqueResultException, NoResultException, OptimisticLockException, RollbackException, TransactionRequiredException

public class PersistenceException
  extends RuntimeException

Extends: Throwable > Exception > RuntimeException
Extended by: EntityExistsException, EntityNotFoundException, NonUniqueResultException, NoResultException, OptimisticLockException, RollbackException, TransactionRequiredException

PersistenceException NoResultException
NonUniqueResultException

since  Java Persistence 1.0

Thrown by the persistence provider when a problem occurs. All instances of PersistenceException except for instances of NoResultException and NonUniqueResultException will cause the current transaction, if one is active, to be marked for rollback.

Since:
Java Persistence 1.0

</tr>
</tbody>
</table>
PersistenceException

public PersistenceException()

    Constructs a new PersistenceException exception with null as its detail message.

------------------------------------------------------------------------

public PersistenceException(String message)

    PersistenceException
    message

PersistenceException

public PersistenceException(String message)

    Constructs a new PersistenceException exception with the specified detail message.

    Parameters:
    message - the detail message.

------------------------------------------------------------------------

public PersistenceException(String message, Throwable cause)

    PersistenceException
    message
    cause

PersistenceException

public PersistenceException(String message,
Constructs a new PersistenciaException exception with the specified detail message and cause.

Parameters:
message - the detail message.
cause - the cause.

public PersistenceException(Throwable cause)

PersistenciaException

public PersistenceException(Throwable cause)

Constructs a new PersistenceException exception with the specified cause.

Parameters:
cause - the cause.

(javax.persistence) Annotation Type PersistenceProperty

@Target(value={})
@Retention(value=RUNTIME)
public @interface PersistenceProperty

Implements: Annotation
@Target(value={})
@Retention(value=RUNTIME)

since Java Persistence 1.0

Describes a single container or persistence provider property.

Vendor specific properties may be included in the set of properties, and are passed to the persistence provider by the container when the entity manager is created. Properties that are not recognized by a vendor will be ignored.

Since:
Java Persistence 1.0

public interface PersistenceProvider

Interface implemented by a persistence provider. The implementation of this interface that is to be used for a given EntityManager is specified in persistence.xml file in the persistence archive. This interface is invoked by the Container when it needs to create an EntityManagerFactory, or by the Persistence class when running outside the Container.

Since:
Java Persistence 1.0

<table>
<thead>
<tr>
<th>Method Summary</th>

</tr>
</tbody>
</table>

Method Detail

public EntityManagerFactory
createEntityManagerFactory(String emName, java.util.Map<K, V> map)

javax.persistence.EntityManagerFactory Persistence

text

createEntityManagerFactory

EntityManagerFactory createEntityManagerFactory(String emName, Map map)

Called by Persistence class when an EntityManagerFactory is to be created.

Parameters:
emName - The name of the persistence unit
map - A Map of properties for use by the persistence provider. These properties may be used to override the values of the corresponding elements in the persistence.xml file or specify values for properties not specified in the persistence.xml.

Returns:
EntityManagerFactory for the persistence unit, or null if the provider is not the right provider

public EntityManagerFactory createContainerEntityManagerFactory(PersistenceUnitInfo info, java.util.Map<K, V> map)

javax.persistence.EntityManagerFactory

EntityManagerFactory

null

EntityManagerFactory
createContainerEntityManagerFactory

EntityManagerFactory createContainerEntityManagerFactory(PersistenceUnitInfo info, Map map)

Called by the container when an EntityManagerFactory is to be created.

Parameters:
  info - Metadata for use by the persistence provider
  map - A Map of integration-level properties for use by the persistence provider. Can be null if there is no integration-level property.

Returns:
  EntityManagerFactory for the persistence unit specified by the metadata

javax.persistence  **Annotation Type PersistenceUnit**

```java
@Target({TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface PersistenceUnit
```

**Implements:** Annotation
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)

Expresses a dependency on an [EntityManagerFactory](https://docs.oracle.com/javase/8/docs/api/javax/persistence/EntityManagerFactory.html).

**Since:**
Java Persistence 1.0

---

## Optional Element Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>name</th>
<th>The name by which the entity manager factory is to be accessed in the environment referencing context, and is not needed when dependency injection is used.</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>unitName</td>
<td>The name of the persistence unit as defined in the persistence.xml file.</td>
</tr>
</tbody>
</table>

```java
abstract public String name()
```

name
public abstract String name

The name by which the entity manager factory is to be accessed in the environment referencing context, and is not needed when dependency injection is used.

Default: 

abstract public String unitName()
persistence.xml  JNDI

unitName

public abstract String unitName

The name of the persistence unit as defined in the persistence.xml file. If specified, the persistence unit for the entity manager factory that is accessible in JNDI must have the same name.

Default: 

Submit a bug or feature

<td>PersistenceUnitTransactionType.getTransactionType()</td>
<td>Returns the transaction type of the entity managers created by the EntityManagerFactory.</td>
</tr>
</tbody>
</table>
**public String getPersistenceUnitName()**

`persistence.xml`
```
    return persistence.xml
```

**getPersistenceUnitName**

`String getPersistenceUnitName()`

Returns the name of the persistence unit. Corresponds to the name attribute in the persistence.xml file.

**Returns:**

The name of the persistence unit. Corresponds to the name attribute in the persistence.xml file.

---

**public String getPersistenceProviderClassName()**

`persistence.xml <provider>`
```
    return persistence.xml <provider>
```

**getPersistenceProviderClassName**

`String getPersistenceProviderClassName()`

Returns the fully qualified name of the persistence provider implementation class. Corresponds to the `<provider>` element in the persistence.xml file.

**Returns:**

The fully qualified name of the persistence provider implementation class. Corresponds to the `<provider>` element in the persistence.xml file.
public PersistenceUnitTransactionType getTransactionType()

EntityManagerFactory persistence.xml
    return EntityManagerFactory persistence.xml

getTransactionType

PersistenceUnitTransactionType getTransactionType()

Returns the transaction type of the entity managers created by the EntityManagerFactory. The transaction type corresponds to the transaction-type attribute in the persistence.xml file.

Returns:
    The transaction type of the entity managers created by the EntityManagerFactory. The transaction type corresponds to the transaction-type attribute in the persistence.xml file.

public javax.sql.DataSource getJtaDataSource()
JTA persistence.xml <jta-data-source>

    return JTA persistence.xml <jta-data-source>

getJtaDataSource

DataSource getJtaDataSource()

Returns the JTA-enabled data source to be used by the persistence provider. The data source corresponds to the <jta-data-source> element in the persistence.xml file or is provided at deployment or by the container.

Returns:
    the JTA-enabled data source to be used by the persistence provider. The data source corresponds to the <jta-data-source>
element in the persistence.xml file or is provided at deployment or by the container.

public javax.sql.DataSource getNonJtaDataSource()
JTA persistence.xml <non-jta-data-source>

return JTA persistence.xml <non-jta-data-source>

getNonJtaDataSource

Returns the non-JTA-enabled data source to be used by the persistence provider for accessing data outside a JTA transaction. The data source corresponds to the named <non-jta-data-source> element in the persistence.xml file or provided at deployment or by the container.

Returns:
The non-JTA-enabled data source to be used by the persistence provider for accessing data outside a JTA transaction. The data source corresponds to the named <non-jta-data-source> element in the persistence.xml file or provided at deployment or by the container.

public java.util.List<E> getMappingFileNames()
XML orm.xml persistence.xml <mapping-file>

return XML orm.xml persistence.xml <mapping-file>

getMappingFileNames
List<String> getMappingFileNames()

Returns the list of mapping file names that the persistence provider must load to determine the mappings for the entity classes. The mapping files must be in the standard XML mapping format, be uniquely named and be resource-loadable from the application classpath. This list will not include the orm.xml file if one was specified. Each mapping file name corresponds to a <mapping-file> element in the persistence.xml file.

Returns:
The list of mapping file names that the persistence provider must load to determine the mappings for the entity classes. The mapping files must be in the standard XML mapping format, be uniquely named and be resource-loadable from the application classpath. This list will not include the orm.xml file if one was specified. Each mapping file name corresponds to a <mapping-file> element in the persistence.xml file.

public java.util.List<E> getJarFileUrls()

Returns a list of URLs for the jar files or exploded jar file directories that the persistence provider must examine for managed classes of the persistence unit. Each URL corresponds to a named element in the persistence.xml file. A URL will either be a file: URL referring to a jar file or referring to a directory that contains an exploded jar file, or some other URL from which an InputStream in jar format can be obtained.
Returns:
a list of URL objects referring to jar files or directories.

```java
public java.net.URL getPersistenceUnitRootUrl()
    jar URL WEB-INF/classes URL
    jar jar file:URL jar InputStream URL
    return jar URL
```

**getPersistenceUnitRootUrl**

```java
URL getPersistenceUnitRootUrl()
```

Returns the URL for the jar file or directory that is the root of the persistence unit. (If the persistence unit is rooted in the WEB-INF/classes directory, this will be the URL of that directory.) The URL will either be a file: URL referring to a jar file or referring to a directory that contains an exploded jar file, or some other URL from which an InputStream in jar format can be obtained.

**Returns:**
a URL referring to a jar file or directory.

```java
public java.util.List<E> getManagedClassNames()
persistence.xml <class>
    return persistence.xml <class>
```

**getManagedClassNames**

```java
List<String> getManagedClassNames()
```

Returns the list of the names of the classes that the persistence provider must add it to its set of managed classes. Each name corresponds to a named <class> element in the persistence.xml file.
Returns:
The list of the names of the classes that the persistence provider must add it to its set of managed classes. Each name corresponds to a named <class> element in the persistence.xml file.

public boolean excludeUnlistedClasses()
persistence.xml  <exclude-unlisted-classes>
  return  persistence.xml  <exclude-unlisted-classes>

excludeUnlistedClasses

boolean excludeUnlistedClasses()

  Returns whether classes in the root of the persistence unit that have not been explicitly listed are to be included in the set of managed classes. This value corresponds to the <exclude-unlisted-classes> element in the persistence.xml file.

  Returns:
  Whether classes in the root of the persistence unit that have not been explicitly listed are to be included in the set of managed classes. This value corresponds to the <exclude-unlisted-classes> element in the persistence.xml file.

public java.util.Properties getProperties()
persistence.xml  <property>
  return  persistence.xml  <property>

getProperties

Properties getProperties()

  Returns properties object. Each property corresponds to a
<property> element in the persistence.xml file

**Returns:**
Properties object. Each property corresponds to a <property> element in the persistence.xml file

---

```java
public ClassLoader getClassLoader()
```

**ClassLoader getClassLoader()**

Returns ClassLoader that the provider may use to load any classes, resources, or open URLs.

**Returns:**
ClassLoader that the provider may use to load any classes, resources, or open URLs.

---

```java
public void addTransformer(ClassTransformer transformer)
```

**PersistenceUnitInfo#getClassLoader**

**PersistenceUnitInfo#getNewTempClassLoader**

**addTransformer**

```java
void addTransformer(ClassTransformer transformer)
```

Add a transformer supplied by the provider that will be called for every new class definition or class redefinition that gets loaded by the loader returned by the `getClassLoader()` method. The transformer has no effect on the result returned by the
getNewTempClassLoader() method. Classes are only transformed once within the same classloading scope, regardless of how many persistence units they may be a part of.

**Parameters:**

transformer - A provider-supplied transformer that the Container invokes at class-(re)definition time

```java
public ClassLoader getNewTempClassLoader()
```

URL ClassLoader

PersistenceUnitInfo#getClassLoader
PersistenceProvider#createContainerEntityManagerFactory(ClassLoader

```java
return ClassLoader
```

getNewTempClassLoader

ClassLoader getNewTempClassLoader()

```
ClassLoader
```

Return a new instance of a ClassLoader that the provider may use to temporarily load any classes, resources, or open URLs. The scope and classpath of this loader is exactly the same as that of the loader returned by getClassLoader(). None of the classes loaded by this class loader will be visible to application components. The provider may only use this ClassLoader within the scope of the PersistenceProvider.createContainerEntityManagerFactory(javax.persistence.spi.PersistenceUnitInfo, java.util.Map) call.

**Returns:**

Temporary ClassLoader with same visibility as current loader

Enum Constant Detail

JTA
public static final PersistenceUnitTransactionType JTA

   JTA entity manager

RESOURCE_LOCAL
public static final PersistenceUnitTransactionType RESOURCE_LOCAL

   resource-local entity manager

Method Detail
### values

```java
public static final PersistenceUnitTransactionType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(PersistenceUnitTransactionType c : PersistenceUnitTransactionType.values())
    System.out.println(c);
```

**Returns:**
- an array containing the constants of this enum type, in the order they're declared

### valueOf

```java
public static PersistenceUnitTransactionType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**
- name - the name of the enum constant to be returned.

**Returns:**
- the enum constant with the specified name

**Throws:**
- `IllegalArgumentException` - if this enum type has no constant
with the specified name

Method Detail

public String getLastName() throws JAXRException

Returns: the person's last name
Throws: JAXRException - If the JAXR provider encounters an internal error

public void setLastName(String lastName) throws JAXRException

Throws: JAXRException: JAXR
setLastName

void setLastName(String lastName) throws JAXRException

Sets the last name (surname) for this Person.

Capability Level: 1

Parameters:
    lastName - the person's last name

Throws:
    JAXRException - If the JAXR provider encounters an internal error

public String getFirstName() throws JAXRException

Person

1

return

Throws JAXRException: JAXR

gFirstName

String getFirstName() throws JAXRException

 Gets the first name for this Person. Default is an empty String.

Capability Level: 1

Returns:
    the person's first name

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setFirstName(String firstName) throws JAXRException
Person

1

firstName

Throws JAXRException: JAXR

setFirstName

void setFirstName(String firstName)
throws JAXRException

Sets the first name for this Person.

Capability Level: 1

Parameters:
firstName - the person's first name

Throws:
JAXRException - If the JAXR provider encounters an internal error

public String getMiddleName() throws JAXRException
Person

1

return

Throws JAXRException: JAXR
getMiddleName

String getMiddleName() throws JAXRException

Gets the middle name for this Person. Default is an empty String.

Capability Level: 1

Returns:
the person's middle name

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setMiddleName(String middleName) throws JAXRException
Person

1

middleName

Throws JAXRException: JAXR

setMiddleName

void setMiddleName(String middleName) throws JAXRException

Sets the middle name for this Person.

Capability Level: 1

Parameters:
middleName - the person's middle name
Throws: *JAXRException* - If the JAXR provider encounters an internal error

```java
public String getFullName() throws JAXRException
Person
```

```java
0
```

```java
return
Throws JAXRException: JAXR
```

**getFullName**

```java
String getFullName() throws JAXRException
```

Gets the fully formatted name for this person. Default is an empty `String`.

**Capability Level: 0**

**Returns:**
the person's full name

**Throws:**
*JAXRException* - If the JAXR provider encounters an internal error

```java
public void setFullName(String fullName) throws JAXRException
Person
```

```java
0
```

```java
fullName
```
setFullName

```java
void setFullName(String fullName)
    throws JAXRException
```

Sets the fully formatted name for this person.

**Capability Level: 0**

**Parameters:**
- `fullName` - the person's full name

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

  - `context`  
  - `phasId`  
  - `lifecycle`  

  **Throws**  
  - `NullPointerException`: `context` `phasId` `Lifecycle` `null`

**PhaseEvent**

```java
public PhaseEvent(FacesContext context,
```
Construct a new event object from the specified parameters. The specified Lifecycle will be the source of this event.

**Parameters:**
- context - FacesContext for the current request
- phaseId - Identifier of the current request processing lifecycle phase
- lifecycle - Lifecycle instance

**Throws:**
- NullPointerException - if context OR phaseId OR Lifecycle is null

### Method Detail

**public FacesContext getFacesContext()**

Return the FacesContext for the request being processed.

**public PhaseId getPhaseId()**

**public PhaseId getPhaseId()**
Return the `PhaseId` representing the current request processing lifecycle phase.
javax.faces.event Class PhaseId

java.lang.Object
   javax.faces.event.PhaseId

All Implemented Interfaces:
   Comparable

public class PhaseId
   extends Object
   implements Comparable

Implements: Comparable<T>

FacesEvent getPhaseId()

Typesafe enumeration of the legal values that may be returned by the getPhaseId() method of the FacesEvent interface.

<table>

</tr>
</tbody>
</table>

**Method Summary**

| int compareTo(Object other) | Compare this PhaseId instance to the specified one. |
| int getOrdinal() | Return the ordinal value of this PhaseId instance. |
| String toString() | Return a String representation of this PhaseId instance. |

**Methods inherited from class java.lang.Object**

close, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait

**Field Detail**
ANY_PHASE

`public static final PhaseId ANY_PHASE`

Identifier that indicates an interest in events, no matter which request processing phase is being performed.

---

RESTORE_VIEW

`public static final PhaseId RESTORE_VIEW`

Identifier that indicates an interest in events queued for the Restore View phase of the request processing lifecycle.

---

APPLY_REQUEST_VALUES

`public static final PhaseId APPLY_REQUEST_VALUES`

Identifier that indicates an interest in events queued for the Apply Request Values phase of the request processing lifecycle.

---

PROCESS_VALIDATIONS

`public static final PhaseId PROCESS_VALIDATIONS`

Identifier that indicates an interest in events queued for the Process Validations phase of the request processing lifecycle.
**UPDATE_MODEL_VALUES**

```java
public static final PhaseId UPDATE_MODEL_VALUES
```

Identifier that indicates an interest in events queued for the *Update Model Values* phase of the request processing lifecycle.

---

**INVOKE_APPLICATION**

```java
public static final PhaseId INVOKE_APPLICATION
```

Identifier that indicates an interest in events queued for the *Invoke Application* phase of the request processing lifecycle.

---

**RENDER_RESPONSE**

```java
public static final PhaseId RENDER_RESPONSE
```

Identifier for the *Render Response* phase of the request processing lifecycle.

---

**VALUES**

```java
public static final List<PhaseId> VALUES
```

List of valid *PhaseId* instances, in ascending order of their ordinal value.
public int compareTo(Object other)

    PhaseId 0

    other

compareTo

public int compareTo(Object other)

    Compare this PhaseId instance to the specified one. Returns a negative integer, zero, or a positive integer if this object is less than, equal to, or greater than the specified object.

    Specified by: compareTo in interface Comparable

    Parameters:
    other - The other object to be compared to

public int getOrdinal()

    PhaseId

getOrdinal

public int getOrdinal()

    Return the ordinal value of this PhaseId instance.

gpublic String toString()
toString

public String toString()

Return a String representation of this PhaseId instance.

Overrides:
toString in class Object

javax.faces.event Interface PhaseListener

All Superinterfaces: 
EventListerner, Serializable

public interface PhaseListener
extends EventListener, Serializable

Implements: java.util.EventListerner, java.io.Serializable

An interface implemented by objects that wish to be notified at the beginning and ending of processing for each standard phase of the request processing lifecycle.

<table>

| Method Detail |
public void afterPhase(PhaseEvent event)

""

afterPhase

void afterPhase(PhaseEvent event)

Handle a notification that the processing for a particular phase has just been completed.

public void beforePhase(PhaseEvent event)

""

beforePhase

void beforePhase(PhaseEvent event)

Handle a notification that the processing for a particular phase of the request processing lifecycle is about to begin.

public PhaseId getPhaseId()

PhaseEvent PhaseId
PhaseId.ANY_PHASE

getPhaseId
PhaseId getPhaseId()

Return the identifier of the request processing phase during which this listener is interested in processing PhaseEvent events. Legal values are the singleton instances defined by the PhaseId class, including PhaseId.ANY_PHASE to indicate an interest in being notified for all standard phases.

refresh PolicyConfiguration PolicyConfigurationFactory
getPolicyConfiguration inService
The methods of this interface are used by containers to create policy statements in a Policy provider. An object that implements the PolicyConfiguration interface provides the policy statement configuration interface for a corresponding policy context within the corresponding Policy provider.

The life cycle of a policy context is defined by three states; "open", "inService", and "deleted". A policy context is in one of these three states.

A policy context in the "open" state is in the process of being configured, and may be operated on by any of the methods of the PolicyConfiguration interface. A policy context in the "open" state must not be assimilated at Policy.refresh into the policy statements used by the Policy provider in performing its access decisions. In order for the policy statements of a policy context to be assimilated by the associated provider, the policy context must be in the "inService" state. A policy context in the "open" state is transitioned to the "inService" state by calling the commit method.

A policy context in the "inService" state is available for assimilation into the policy statements being used to perform access decisions by the associated Policy provider. Providers assimilate policy contexts containing policy statements when the refresh method of the provider is called. When a provider's refresh method is called, it must assimilate only those policy contexts whose state is "inService" and it must ensure that the policy statements put into service for each policy context are only those defined in the context at the time of the call to refresh. A policy context in the "inService" state is not available for additional configuration and may be returned to the "open" state by calling the getPolicyConfiguration method of the PolicyConfigurationFactory.

A policy context in the "deleted" state is neither available for configuration, nor is it available for assimilation into the Provider. A policy
context whose state is "deleted" may be reclaimed for subsequent processing by calling the getPolicyConfiguration method of the associated PolicyConfigurationFactory. A "deleted" policy context is transitioned to the "open" state when it it returned as a result of a call to getPolicyConfiguration.

The following table captures the correspondence between the policy context life cycle and the methods of the PolicyConfiguration interface. The rightmost 3 columns of the table correspond to the PolicyConfiguration state identified at the head of the column. The values in the cells of these columns indicate the next state resulting from a call to the method identified in the leftmost column of the corresponding row, or that calling the method is unsupported in the state represented by the column (in which case the state will remain unchanged).

<table>

</tbody>
</table>

For a provider implementation to be compatible with multi-threaded environments, it may be necessary to synchronize the refresh method of the provider with the methods of its PolicyConfiguration interface and with the getPolicyConfiguration and inService methods of its PolicyConfigurationFactory.

void Creates a relationship between this configuration and another such that they share the same principal-to-role mappings.

void removeExcludedPolicy()
Used to remove any excluded policy statements from this PolicyConfiguration.

void removeRole(String roleName)
Used to remove a role and all its permissions from this PolicyConfiguration.

void removeUncheckedPolicy()
Used to remove any unchecked policy statements from this PolicyConfiguration.

Method Detail

public String getContextID() throws PolicyContextException

    return

    Throws
    SecurityException: "setPolicy" SecurityPermission
    AccessControlContext

    Throws
    PolicyContextException: getContextID

getContextID

String getContextID()
    throws PolicyContextException

This method returns this object's policy context identifier.

Returns:
    this object's policy context identifier.

Throws:
SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.

PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the getBuildContextID method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

```java
public void addToRole(String roleName, java.security.PermissionCollection permissions) throws PolicyContextException
PolicyConfiguration Role PolicyConfiguration

Policy ""

roleName
permissions CollectionCollection Collection Collection

Throws SecurityException: "setPolicy" SecurityPermission
AccessControlContext

Throws UnsupportedOperationException: PolicyConfiguration
"deleted" "inService"

Throws PolicyContextException: addToRole
PolicyContextException
```

addToRole

```java
void addToRole(String roleName,
PermissionCollection permissions)
throws PolicyContextException

Used to add permissions to a named role in this PolicyConfiguration. If the named Role does not exist in the PolicyConfiguration, it is created as a result of the call to this function.
```
It is the job of the Policy provider to ensure that all the permissions added to a role are granted to principals "mapped to the role".

**Parameters:**
- **roleName** - the name of the Role to which the permissions are to be added.
- **permissions** - the collection of permissions to be added to the role. The collection may be either a homogenous or heterogenous collection.

**Throws:**
- **SecurityException** - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- **UnsupportedOperationException** - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.
- **PolicyConfigurationException** - if the implementation throws a checked exception that has not been accounted for by the addToRole method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyConfigurationException.

```java
public void addToRole(String roleName, java.security.Permission permission) throws PolicyConfigurationException
    PolicyConfiguration Role PolicyConfiguration
```

Policy ""

- **roleName**
- **permission**

**Throws**
- SecurityException: "setPolicy" SecurityPermission

- UnsupportedOperationException: PolicyConfigurationException
  - "deleted" "inService"
Throws  

PolicyContextException: addToRole

```java
public void addToUncheckedPolicy(java.security.PermissionCollection
```

**addToRole**

```java
void addToRole(String roleName, Permission permission)
```

Throws  

SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.

UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.

PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the addToRole method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

Parameters:

- **roleName** - the name of the Role to which the permission is to be added.

- **permission** - the permission to be added to the role.

addToExcludedPolicy

void addToExcludedPolicy(Permission permission)
throws PolicyContextException

Used to add a single excluded policy statement to this PolicyConfiguration.

Parameters:
permission - the permission to be added to the excluded policy statements.

Throws:
SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.
PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the addToExcludedPolicy method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.
public void removeRole(String roleName) throws PolicyConfigurationException
PolicyConfiguration

removeRole
void removeRole(String roleName)
throws PolicyConfigurationException

Used to remove a role and all its permissions from this PolicyConfiguration.

Parameters:
roleName - the name of the Role to remove from this PolicyConfiguration.

Throws:
SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.
PolicyConfigurationException - if the implementation throws a checked exception that has not been accounted for by the removeRole method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyConfigurationException.
public void removeUncheckedPolicy() throws PolicyConfigurationException

PolicyConfiguration

Throws SecurityException: "setPolicy" SecurityPermission AccessControlContext

Throws UnsupportedOperationException: PolicyConfiguration "deleted" "inService"

Throws PolicyConfigurationException: removeUncheckedPolicy

PolicyConfigurationException

removeUncheckedPolicy

void removeUncheckedPolicy() throws PolicyConfigurationException

Used to remove any unchecked policy statements from this PolicyConfiguration.

Throws:

SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.

UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.

PolicyConfigurationException - if the implementation throws a checked exception that has not been accounted for by the removeUncheckedPolicy method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyConfigurationException.

public void removeExcludedPolicy() throws PolicyConfigurationException

PolicyConfiguration

Throws SecurityException: "setPolicy" SecurityPermission AccessControlContext

Throws UnsupportedOperation exception: PolicyConfiguration
removeExcludedPolicy

void removeExcludedPolicy() throws PolicyContextException

Used to remove any excluded policy statements from this PolicyConfiguration.

Throws:
- SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.
- PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the removeExcludedPolicy method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

public void linkConfiguration(PolicyConfiguration link) throws PolicyContextException

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration Collection

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration

PolicyConfiguration PolicyConfiguration
linkConfiguration

void linkConfiguration(PolicyConfiguration link)
throws PolicyContextException

Creates a relationship between this configuration and another such that they share the same principal-to-role mappings. PolicyConfigurations are linked to apply a common principal-to-role mapping to multiple separately manageable PolicyConfigurations, as is required when an application is composed of multiple modules.

Note that the policy statements which comprise a role, or comprise the excluded or unchecked policy collections in a PolicyConfiguration are unaffected by the configuration being linked to another.

Parameters:
link - a reference to a different PolicyConfiguration than this PolicyConfiguration.

The relationship formed by this method is symetric, transitive and idempotent. If the argument PolicyConfiguration does not have a different Policy context identifier than this PolicyConfiguration no relationship is formed, and an exception, as described below, is thrown.

Throws:
SecurityException - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
UnsupportedOperationException - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" or "inService" when this method is called.

IllegalArgumentException - if called with an argument PolicyConfiguration whose Policy context is equivalent to that of this PolicyConfiguration.

PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the linkConfiguration method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

```java
public void delete() throws PolicyContextException
PolicyConfiguration PolicyConfiguration
deletegetContextID inService
UnsupportedOperationException
```

Throws

SecurityException: "setPolicy" SecurityPermission
AccessControlContext

Throws PolicyContextException: delete PolicyContextException

delete

void delete()
throws PolicyContextException

Causes all policy statements to be deleted from this PolicyConfiguration and sets its internal state such that calling any method, other than delete, getContextID, or inService on the PolicyConfiguration will be rejected and cause an UnsupportedOperationException to be thrown.

This operation has no affect on any linked PolicyConfigurations other
than removing any links involving the deleted PolicyConfiguration.

**Throws:**
- **SecurityException** - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- **PolicyContextException** - if the implementation throws a checked exception that has not been accounted for by the delete method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

```java
public void commit() throws PolicyContextException
PolicyConfiguration "inService" "inService"
Policy.refresh PolicyConfiguration
getPolicyConfiguration "inService" "open"

"inService" PolicyConfiguration commit
deletegetContextID inService
UnsupportedOperationException

Throws
- SecurityException: "setPolicy" SecurityPermission
  AccessControlContext
- UnsupportedOperationException: PolicyConfiguration
  "deleted"
- PolicyContextException: commit
  PolicyContextException
```

`commit`

```java
void commit()
    throws PolicyContextException
```

This method is used to set to "inService" the state of the policy context whose interface is this PolicyConfiguration Object. Only those policy contexts whose state is "inService" will be included in
the policy contexts processed by the Policy.refresh method. A policy context whose state is "inService" may be returned to the "open" state by calling the getPolicyConfiguration method of the PolicyConfiguration factory with the policy context identifier of the policy context.

When the state of a policy context is "inService", calling any method other than commit, delete, getApplicationContext, or inService on its PolicyConfiguration Object will cause an UnsupportedOperationException to be thrown.

Throws:

- **SecurityException** - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- **UnsupportedOperationException** - if the state of the policy context whose interface is this PolicyConfiguration Object is "deleted" when this method is called.
- **PolicyContextException** - if the implementation throws a checked exception that has not been accounted for by the commit method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

```java
public boolean inService() throws PolicyContextException

PolicyConfiguration "inService"

return "inService" true false

Throws SecurityException: "setPolicy" SecurityPermission
AccessControlContext

Throws PolicyContextException: inService
PolicyContextException
```

This method is used to determine if the policy context whose
interface is this PolicyConfiguration Object is in the "inService" state.

**Returns:**
true if the state of the associated policy context is "inService";
false otherwise.

**Throws:**
- `SecurityException` - if called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- `PolicyContextException` - if the implementation throws a checked exception that has not been accounted for by the inService method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.
public abstract class PolicyConfigurationFactory extends Object

finder PolicyConfigurationFactory PolicyConfiguration Policy Provider

See also java.security.Permission, javax.security.jacc.PolicyConfiguration, javax.security.jacc.PolicyConfigurationException

Abstract factory and finder class for obtaining the instance of the class that implements the PolicyConfigurationFactory of a provider. The factory will be used to instantiate PolicyConfiguration objects that will be used by the deployment tools of the container to create and manage policy contexts within the Policy Provider.

Implementation classes must have a public no argument constructor that may be used to create an operational instance of the factory implementation class.

### Constructor Detail

**public PolicyConfigurationFactory()**

**PolicyConfigurationFactory**

**public PolicyConfigurationFactory()**
public static PolicyConfigurationFactory getPolicyConfigurationFactory() throws ClassNotFoundException, PolicyContextException

javax.security.jacc.PolicyConfigurationFactory.provider

return PolicyConfigurationFactory

Throws: SecurityException: "setPolicy" SecurityPermission

AccessControlContext

Throws: ClassNotFoundException:

PolicyContextException: getPolicyConfigurationFactory
PolicyContextException

getPolicyConfigurationFactory

public static PolicyConfigurationFactory getPolicyConfigurationFactory() throws ClassNotFoundException, PolicyContextException

This static method uses a system property to find and instantiate (via a public constructor) a provider specific factory implementation class. The name of the provider specific factory implementation class is obtained from the value of the system property,

javax.security.jacc.PolicyConfigurationFactory.provider.

Returns: the singleton instance of the provider specific PolicyConfigurationFactory implementation class.

Throws: SecurityException - when called by an AccessControlContext
that has not been granted the "setPolicy" SecurityPermission.  

`ClassNotFoundException` - when the class named by the system property could not be found including because the value of the system property has not been set. 

`PolicyContextException` - if the implementation throws a checked exception that has not been accounted for by the getPolicyConfigurationFactory method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException

```
abstract public PolicyConfiguration getPolicyConfiguration(String contextID, boolean remove) 
throws PolicyContextException
PolicyConfiguration PolicyConfiguration

PolicyConfiguration "deleted"
"inService" "open"  PolicyConfiguration

PolicyConfiguration PolicyConfiguration

PolicyConfiguration

contextID PolicyConfiguration null
remove boolean PolicyConfiguration true false
return Policy PolicyConfiguration
Throws SecurityException: "setPolicy" SecurityPermission
AccessControlContext
Throws PolicyContextException: getPolicyConfiguration
PolicyContextException

g etPolicyConfiguration
```
This method is used to obtain an instance of the provider specific class that implements the PolicyConfiguration interface that corresponds to the identified policy context within the provider. The methods of the PolicyConfiguration interface are used to define the policy statements of the identified policy context.

If at the time of the call, the identified policy context does not exist in the provider, then the policy context will be created in the provider and the Object that implements the context's PolicyConfiguration Interface will be returned. If the state of the identified context is "deleted" or "inService" it will be transitioned to the "open" state as a result of the call. The states in the lifecycle of a policy context are defined by the PolicyConfiguration interface.

For a given value of policy context identifier, this method must always return the same instance of PolicyConfiguration and there must be at most one actual instance of a PolicyConfiguration with a given policy context identifier (during a process context).

To preserve the invariant that there be at most one PolicyConfiguration object for a given policy context, it may be necessary for this method to be thread safe.

**Parameters:**

- contextID - A String identifying the policy context whose PolicyConfiguration interface is to be returned. The value passed to this parameter must not be null.

- remove - A boolean value that establishes whether or not the policy statements of an existing policy context are to be removed before its PolicyConfiguration object is returned. If the value passed to this parameter is true, the policy statements of an existing policy context will be removed. If the value is false, they will not be removed.

**Returns:**

an Object that implements the PolicyConfiguration Interface
matched to the Policy provider and corresponding to the identified policy context.

**Throws:**

- [*SecurityException*](#) - when called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.
- [*PolicyContextException*](#) - if the implementation throws a checked exception that has not been accounted for by the getPolicyConfiguration method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.

```java
abstract public boolean inService(String contextID) throws PolicyContextException
Policy "inService"

  contextID
  return "inService" true false
  Throws SecurityException: "setPolicy" SecurityPermission
          AccessControlContext
  Throws PolicyContextException: inService
          PolicyContextException

inService

public abstract boolean inService(String contextID)
  throws PolicyContextException

This method determines if the identified policy context exists with state "inService" in the Policy provider associated with the factory.

**Parameters:**

- contextID - A string identifying a policy context

**Returns:**

true if the identified policy context exists within the provider and its state is "inService", false otherwise.
Throws:

`SecurityException` - when called by an AccessControlContext that has not been granted the "setPolicy" SecurityPermission.

`PolicyContextException` - if the implementation throws a checked exception that has not been accounted for by the inService method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException.
This utility class is used by containers to communicate policy context identifiers and other policy relevant context to Policy providers. Policy providers use the policy context identifier to select the subset of policy to apply in access decisions.

The value of a policy context identifier is a String and each thread has an independently established policy context identifier. A container will establish the thread-scoped value of a policy context identifier by calling the static setContextID method. The value of a thread-scoped policy
context identifier is available (to Policy) by calling the static `getContextID` method.

This class is also used by Policy providers to request additional thread-scoped policy relevant context objects from the calling container. Containers register container-specific `PolicyContext` handlers using the static `registerHandler` method. Handler registration is scoped to the class, such that the same handler registrations are active in all thread contexts. Containers may use the static method `setHandlerData` to establish a thread-scoped parameter that will be passed to handlers when they are activated by Policy providers. The static `getContext` method is used to activate a handler and obtain the corresponding context object.

The static accessor functions provided by this class allow per-thread policy context values to be established and communicated independent of a common reference to a particular `PolicyContext` instance.

The `PolicyContext` class may encapsulate static `ThreadLocal` instance variables to represent the policy context identifier and handler data values.

The Application server must bundle or install the `PolicyContext` class, and the containers of the application server must prevent the methods of the `PolicyContext` class from being called from calling contexts that are not authorized to call these methods. With the exception of the `getContextID` and `GetHandlerKeys` methods, containers must restrict and afford access to the methods of the `PolicyContext` class to calling contexts trusted by the container to perform container access decisions. The `PolicyContext` class may satisfy this requirement (on behalf of its container) by rejecting calls made from an `AccessControlContext` that has not been granted the "setPolicy" SecurityPermission, and by ensuring that Policy providers used to perform container access decisions are granted the "setPolicy" permission.

## Methods inherited from class java.lang.Object
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
public static void setContextID(String contextID)

contextID String PolicyContext null

Throws SecurityException: AccessControlContext

setContextID

Authorization protected method used to modify the value of the policy context identifier associated with the thread on which this method is called.

Parameters:
contextID - a String that represents the value of the policy context identifier to be assigned to the PolicyContext for the calling thread. The value null is a legitimate value for this parameter.

Throws:
SecurityException - if the calling AccessControlContext is not authorized by the container to call this method.

public static String getContextID()

return String null setContext null

Throws SecurityException: AccessControlContext

getContextID

This static method returns the value of the policy context identifier associated with the thread on which the accessor is called.
Returns:
The String (or null) policy context identifier established for the thread. This method must return the default policy context identifier, null, if the policy context identifier of the thread has not been set via setContext to another value.

Throws:
SecurityException - if the calling AccessControlContext is not authorized by the container to call this method. Containers may choose to authorize calls to this method by any AccessControlContext.

```java
public static void setHandlerData(Object data)
PolicyContext
data Policy null
```

Throws  SecurityException:  AccessControlContext

setHandlerData

Authorization protected method that may be used to associate a thread-scoped handler data object with the PolicyContext. The handler data object will be made available to handlers, where it can serve to supply or bind the handler to invocation scoped state within the container.

Parameters:

data - a container-specific object that will be associated with the calling thread and passed to any handler activated by a Policy provider (on the thread). The value null is a legitimate value for this parameter, and is the value that will be used in the activation of handlers if the setHandlerData has not been called on the thread.

Throws:
SecurityException - if the calling AccessControlContext is not authorized by the container to call this method.
public static void registerHandler(String key, PolicyContextHandler handler, boolean replace) throws PolicyContextException

Authorization protected method used to register a container specific PolicyContext handler. A handler may be registered to handle multiple keys, but at any time, at most one handler may be registered for a key.

Parameters:
- key - a (case-sensitive) String that identifies the context object handled by the handler. The value of this parameter must not be null.
- handler - an object that implements the PolicyContextHandler interface. The value of this parameter must not be null.
- replace - this boolean value defines the behavior of this method if, when it is called, a PolicyContextHandler has already been registered to handle the same key. In that case, and if the value of this argument is true, the existing handler is replaced with the argument handler. If the value of this parameter is false the
existing registration is preserved and an exception is thrown.

**Throws:**
- `IllegalArgumentException` - if the value of either of the handler or key arguments is null, or the value of the replace argument is false and a handler with the same key as the argument handler is already registered.
- `SecurityException` - if the calling AccessControlContext is not authorized by the container to call this method.
- `PolicyContextException` - if an operation by this method on the argument PolicyContextHandler causes it to throw a checked exception that is not accounted for in the signature of this method.

---

### public static java.util.Set<E> getHandlerKeys()

**return**

```
Set E String PolicyContext
```

**Throws**

```
SecurityException: AccessControlContext
AccessControlContext
```

### getHandlerKeys

This method may be used to obtain the keys that identify the container specific context handlers registered by the container.

**Returns:**

A Set, the elements of which, are the String key values that identify the handlers that have been registered and therefore may be activated on the PolicyContext.

**Throws:**

```
SecurityException - if the calling AccessControlContext is not authorized by the container to call this method. Containers may choose to authorize calls to this method by any AccessControlContext.
```
public static Object getContext(String key) throws PolicyContextException

Policy PolicyContextHandler

key String PolicyContextHandler null

return null

Throws IllegalArgumentException: PolicyContextHandler

Throws SecurityException: AccessControlContext

Throws PolicyContextException: PolicyContextHandler

getContext

public static Object getContext(String key)

throws PolicyContextException

This method may be used by a Policy provider to activate the PolicyContextHandler registered to the context object key and cause it to return the corresponding policy context object from the container. When this method activates a handler, it passes to the handler the context object key and the handler data associated with the calling thread.

Parameters:

key - a String that identifies the PolicyContextHandler to activate and the context object to be acquired from the handler. The value of this parameter must not be null.

Returns:

the container and handler specific object containing the desired context. A null value is returned if the corresponding handler has been registered, and the value of the corresponding context is null.

Throws:

IllegalArgumentException - if a PolicyContextHandler has not been registered for the key or the registered handler no longer supports the key.

SecurityException - if the calling AccessControlContext is not authorized by the container to call this method.

PolicyContextException - if an operation by this method on the
identified PolicyContextHandler causes it to throw a checked exception that is not accounted for in the signature of this method.

public PolicyContextException()
PolicyContextException
null

PolicyContextException

public PolicyContextException()

Constructs a new PolicyContextException with null as its detail message, describing the cause of the exception.

public PolicyContextException(String msg)
PolicyContextException

    msg
String

PolicyContextException

public PolicyContextException(String msg)

Constructs a new PolicyContextException with the specified detail message.

Parameters:
    msg -- a String containing a detail message describing the cause of the exception.

public PolicyContextException(String msg, Throwable cause)
PolicyContextException

    msg
String
    cause  "" Throwable null

PolicyContextException
public PolicyContextException(String msg, Throwable cause)

Constructs a new PolicyContextException with the specified detail message and cause. The cause will be encapsulated in the constructed exception.

Parameters:
- msg -- a String containing a detail message describing the cause of the exception.
- cause -- the Throwable that is "causing" this exception to be constructed. A null value is permitted, and the value passed through this parameter may subsequently be retrieved by calling getCause() on the constructed exception.

public PolicyContextException(Throwable cause)

cause PolicyContextException

cause "" Throwable null
getcause

PolicyContextException

public PolicyContextException(Throwable cause)

Constructs a new PolicyContextException with the specified cause. The cause will be encapsulated in the constructed exception.

Parameters:
- cause -- the Throwable that is "causing" this exception to be constructed. A null value is permitted, and the value passed through this parameter may subsequently be retrieved by calling getCause() on the constructed exception.

PS:
public interface PolicyContextHandler

This interface defines the methods that must be implemented by handlers that are to be registered and activated by the PolicyContext class. The PolicyContext class provides methods for containers to register and activate container-specific PolicyContext handlers. Policy providers use the PolicyContext class to activate handlers to obtain (from the container) additional policy relevant context to apply in their access decisions. All handlers registered and activated via the PolicyContext class must implement the PolicyContextHandler interface.

</tr>
<tr>
<td><strong>String</strong></td>
</tr>
<tr>
<td><strong>supports</strong>(String key)</td>
</tr>
</tbody>
</table>
This public method returns a boolean result indicating whether or not the handler supports the context object identified by the (case-sensitive) key value.

**Method Detail**

```java
public boolean supports(String key) throws PolicyContextException

**Parameters:**
key - a String value identifying a context object that could be supported by the handler. The value of this parameter must not be null.

**Returns:**
a boolean indicating whether or not the context object corresponding to the argument key is handled by the handler.

**Throws:**
PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown exception.
```
public String[] getKeys() throws PolicyContextException
null
    return String 0 null
Throws PolicyContextException: PolicyContextException

getKeys

String[] getKeys()
    throws PolicyContextException

This public method returns the keys identifying the context objects supported by the handler. The value of each key supported by a handler must be a non-null String value.

Returns:
    an array containing String values identifying the context objects supported by the handler. The array must not contain duplicate key values. In the unlikely case that the Handler supports no keys, the handler must return a zero length array. The value null must never be returned by this method.

Throws:
    PolicyContextException - if the implementation throws a checked exception that has not been accounted for by the method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown PolicyContextException

public Object getContext(String key, Object data) throws PolicyContextException

PolicyContext getRuleContext()

PolicyContext
PolicyContext
getContext

```java
Object getContext(String key,
                   Object data)
throws PolicyContextException
```

This public method is used by the PolicyContext class to activate the handler and obtain from it the context object identified by the (case-sensitive) key. In addition to the key, the handler will be activated with the handler data value associated within the PolicyContext class with the thread on which the call to this method is made.

Note that the policy context identifier associated with a thread is available to the handler by calling PolicyContext.getContextID().

**Parameters:**
- `key` - a String that identifies the context object to be returned by the handler. The value of this parameter must not be null.
- `data` - the handler data object associated with the thread on which the call to this method has been made. Note that the value passed through this parameter may be null.

**Returns:**
- The container and handler specific object containing the desired context. A null value may be returned if the value of the corresponding context is null.

**Throws:**
- `PolicyContextException` - if the implementation throws a checked exception that has not been accounted for by the method signature. The exception thrown by the implementation class will be encapsulated (during construction) in the thrown `PolicyContextException`

**Method Detail**

public String getStreet() throws `JAXRException`
getStreet

```java
String getStreet() throws JAXRException
```

Returns the street name. Default is an empty String.

**Capability Level:** 0

**Returns:**
- the street name

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

```java
public void setStreet(String street) throws JAXRException
```

Sets the street name.
public String getStreetNumber() throws JAXRException

    Returns the street number. Default is an empty String.

    Capability Level: 0

    Parameters:
            street - the street name
    Throws:
        JAXRException - If the JAXR provider encounters an internal error

public void setStreetNumber(String streetNumber) throws JAXRException

**setStreetNumber**

```java
void setStreetNumber(String streetNumber)
throws JAXRException
```

Sets the street number.

**Capability Level: 0**

**Parameters:**
- `streetNumber` - the street number

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public String getCity() throws JAXRException**

```java
String getCity()
throws JAXRException
```

Returns the city. Default is an empty String.
public void setCity(String city) throws JAXRException

Sets the city.

Parameters:  
city - the city

Throws:  
JAXRException - If the JAXR provider encounters an internal error

public String getStateOrProvince() throws JAXRException

0
return

Throws

JAXRException: JAXR

getStateOrProvince

String getStateOrProvince() throws JAXRException

Returns the state or province. Default is an empty String.

Capability Level: 0

Returns:
the state or province

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setStateOrProvince(String stateOrProvince) throws JAXRException

0

stateOrProvince

Throws

JAXRException: JAXR

setStateOrProvince

void setStateOrProvince(String stateOrProvince) throws JAXRException

Sets the state or province.

Capability Level: 0
Parameters:
  stateOrProvince - the state or province

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public String getPostalCode() throws JAXRException

0

    return US

Throws:
  JAXRException: JAXR

getPostalCode

String getPostalCode() throws JAXRException

    Returns the postal or zip code. Default is an empty String.

    Capability Level: 0

    Returns:
    the postal code (e.g. US zip code)

    Throws:
    JAXRException - If the JAXR provider encounters an internal error

public void setPostalCode(String postalCode) throws JAXRException

0
**postalCode**

**US**

**Throws**

**JAXRException**

JAXR

### setPostalCode

**void** setPostalCode(String postalCode)

*Throws* **JAXRException**

Sets the postal or zip code.

**Capability Level: 0**

**Parameters:**

*postalCode* - the postal code (e.g. US zip code)

**Throws:**

**JAXRException** - If the JAXR provider encounters an internal error

---

**public String getCountry() throws JAXRException**

**0**

**return**

**Throws** **JAXRException**

JAXR

### getCountry

**String** getCountry()

*throws* **JAXRException**

Returns the country. Default is an empty String.

**Capability Level: 0**

**Returns:**
public void setCountry(String country) throws JAXRException

Sets the country.

Capability Level: 0

Parameters:
  country - the country

Throws:  
  JAXRException - If the JAXR provider encounters an internal error

public String getType() throws JAXRException

String "headquarters"

return PostalAddress "Home" "Office"
Throws

JAXRException: JAXR

get Type

String getType()

throws JAXRException

Returns the type of address (for example, "headquarters") as a String.

Capability Level: 0

Returns:
the type for this PostalAddress. This is an arbitrary String (e.g. "Home", "Office")

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setType(String type) throws JAXRException

String "headquarters"

0

type PostalAddress "Home""Office"

Throws JAXRException: JAXR

set Type

void setType(String type)

throws JAXRException

Sets the type of address (for example, "headquarters") as a String.

Capability Level: 0
Parameters:
  type - the type for this PostalAddress. This is an arbitrary String (e.g. "Home", "Office")

Throws:
  JAXRException - If the JAXR provider encounters an internal error

---

public void setPostalScheme(ClassificationScheme scheme) throws JAXRException
PostalAddress

setPostalScheme

void setPostalScheme(ClassificationScheme scheme)
throws JAXRException

Sets a user-defined postal scheme for codifying the attributes of PostalAddress.

Capability Level: 0

Parameters:
  scheme - the user defined postal scheme.

Throws:
  JAXRException - If the JAXR provider encounters an internal error

---

public ClassificationScheme getPostalScheme() throws JAXRException
PostalAddress
RegistryService#getDefaultPostalScheme()

0

return

Throws

JAXRException: JAXR

See also
getDefaultPostalScheme()

getPostalScheme

ClassificationScheme getPostalScheme() throws JAXRException

Returns a user-defined postal scheme for codifying the attributes of PostalAddress. If none is defined for this object, then must return the default value returned by RegistryService# getDefaultPostalScheme()

Capability Level: 0

Returns:

the user defined postal scheme.

Throws:

JAXRException - If the JAXR provider encounters an internal error

See Also:

RegistryService.getDefaultPostalScheme()
The `PostConstruct` annotation is used on a method that needs to be executed after dependency injection is done to perform any initialization. This method MUST be invoked before the class is put into service. This annotation MUST be supported on all classes that support dependency injection. The method annotated with `PostConstruct` MUST be invoked even if the class does not request any resources to be injected. Only one method can be annotated with this annotation. The method on which the `PostConstruct` annotation is applied MUST fulfill all of the following criteria:

- The method MUST NOT have any parameters except in the case of EJB interceptors in which case it takes an `InvocationContext` object as defined by the EJB specification.
- The return type of the method MUST be `void`.
- The method MUST NOT throw a checked exception.
- The method on which `PostConstruct` is applied MAY be public, protected, package private or private.
- The method MUST NOT be static except for the application client.
- The method MAY be final.
- If the method throws an unchecked exception the class MUST NOT be put
into service except in the case of EJBs where the EJB can handle exceptions and even recover from them.

javax.annotation  Annotation Type PreDestroy

@Documented
@Retention(value=RUNTIME)
@Target(value=METHOD)
public @interface PreDestroy

Implements: Annotation
@Documented
@Retention(value=RUNTIME)
@Target(value=METHOD)

PreDestroy  PreDestroy  Java EE 5
PostConstruct  PreDestroy  EJB (interceptor)
EJB  InvocationContext  void PreDestroy  public
protectedpackage private  private static final EJB

since  1.0

See  javax.annotation.PostConstruct,
also  javax.annotation.Resource

The PreDestroy annotation is used on methods as a callback notification
to signal that the instance is in the process of being removed by the
container. The method annotated with PreDestroy is typically used to
release resources that it has been holding. This annotation MUST be
supported by all container managed objects that support PostConstruct
except the application client container in Java EE 5. The method on
which the PreDestroy annotation is applied MUST fulfill all of the
following criteria - - The method MUST NOT have any parameters except
in the case of EJB interceptors in which case it takes an
InvocationContext object as defined by the EJB specification. - The return
type of the method MUST be void. - The method MUST NOT throw a
checked exception. - The method on which PreDestroy is applied MAY
be public, protected, package private or private. - The method MUST
NOT be static. - The method MAY be final. - If the method throws an
unchecked exception it is ignored except in the case of EJBs where the
EJB can handle exceptions.

Class PreencodedMimeBodyPart

extends MimeBodyPart

Extends: BodyPart > MimeBodyPart

A MimeBodyPart that handles data that has already been encoded. This class is useful when constructing a message and attaching data that has already been encoded (for example, using base64 encoding). The data may have been encoded by the application, or may have been stored in a file or database in encoded form. The encoding is supplied when this object is created. The data is attached to this object in the usual fashion, by using the setText, setContent, or setDataHandler methods.

Since: JavaMail 1.4

Constructor Detail

public PreencodedMimeBodyPart(String encoding)
PreencodedMimeBodyPart MIME Content-Transfer-Encoding

PreencodedMimeBodyPart

public PreencodedMimeBodyPart(String encoding)

Create a PreencodedMimeBodyPart that assumes the data is encoded using the specified encoding. The encoding must be a MIME supported Content-Transfer-Encoding.

Method Detail

public String getEncoding() throws MessagingException

getEncoding

public String getEncoding()
throws MessagingException
Returns the content transfer encoding specified when this object was created.

**Specified by:**
`getEncoding` in interface `MimePart`

**Overrides:**
`getEncoding` in class `MimeBodyPart`

**Returns:**
content-transfer-encoding

**Throws:**
`MessagingException`

**See Also:**
`MimeBodyPart.headers`

---

```java
public void writeTo(java.io.OutputStream os) throws java.io.IOException, MessagingException
RFC 822
```

**Throws**
`MessagingException`

**Throws**
`java.io.IOException`: `javax.activation`

**See also**
`writeTo`

---

**writeTo**

```java
public void writeTo(OutputStream os)
```

**Throws**
`IOException`, `MessagingException`

Output the body part as an RFC 822 format stream.

**Specified by:**
`writeTo` in interface `Part`

**Overrides:**
`writeTo` in class `MimeBodyPart`

**Throws:**
`MessagingException`  
`IOException`: if an error occurs writing to the stream or if an error is generated by the `javax.activation` layer.
protected void updateHeaders() throws MessagingException

Content-Transfer-Encoding

updateHeaders

protected void updateHeaders()
    throws MessagingException

Force the Content-Transfer-Encoding header to use the encoding that was specified when this object was created.

Overrides:
    updateHeaders in class MimeBodyPart

Throws:
    MessagingException

Java Persistence 1.0
javax.persistence  Annotation Type
PrimaryKeyJoinColumn

@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface PrimaryKeyJoinColumn

Implements: Annotation
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)

JOINED   SecondaryTable   OneToOne

JOINED   PrimaryKeyJoinColumn

Customer  ValuedCustomer

@Entity
@Table(name="CUST")
@Inheritance(strategy=JOINED)
@DiscriminatorValue("CUST")
public class Customer { ... }

@Entity
@Table(name="VCUST")
@DiscriminatorValue("VCUST")
@PrimaryKeyJoinColumn(name="CUST_ID")
public class ValuedCustomer extends Customer { ... }

since  Java Persistence 1.0

This annotation specifies a primary key column that is used as a foreign key to join to another table.

It is used to join the primary table of an entity subclass in the JOINED mapping strategy to the primary table of its superclass; it is used within a
SecondaryTable annotation to join a secondary table to a primary table; and it may be used in a OneToOne mapping in which the primary key of the referencing entity is used as a foreign key to the referenced entity.

If no PrimaryKeyJoinColumn annotation is specified for a subclass in the JOINED mapping strategy, the foreign key columns are assumed to have the same names as the primary key columns of the primary table of the superclass.

Example: Customer and ValuedCustomer subclass

```java
@Entity
@Table(name="CUST")
@Inheritance(strategy=JOINED)
@DiscriminatorValue("CUST")
public class Customer {
    ...
}

@Entity
@Table(name="VCUST")
@DiscriminatorValue("VCUST")
@PrimaryKeyJoinColumn(name="CUST_ID")
public class ValuedCustomer extends Customer {
    ...
}
```

Since:
Java Persistence 1.0

### Optional Element Summary

<table>
<thead>
<tr>
<th>String</th>
<th>columnDefinition</th>
<th>(Optional) The SQL fragment that is used when generating the DDL for the column.</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>name</td>
<td>The name of the primary key column of the current table.</td>
</tr>
<tr>
<td>String</td>
<td>referencedColumnName</td>
<td>(Optional) The name of the primary key column of the table being joined to.</td>
</tr>
</tbody>
</table>

abstract public String name()
name

public abstract String name

The name of the primary key column of the current table.

Defaults to the same name as the primary key column of the primary table of the superclass (JOINED mapping strategy); the same name as the primary key column of the primary table (SecondaryTable mapping); or the same name as the primary key column for the table for the referencing entity (OneToOne mapping)

Default: ""

abstract public String referencedColumnName()

referencedColumnName

public abstract String referencedColumnName

(Optional) The name of the primary key column of the table being joined to.

Defaults to the same name as the primary key column of the primary table of the superclass (JOINED mapping strategy); the same name
as the primary key column of the primary table (SecondaryTable mapping); or the same name as the primary key column for the table for the referencing entity (OneToOne mapping)

Default:

```java
abstract public String columnDefinition()
DDL  SQL

OneToOne
```

```
sql

columnDefinition

public abstract String columnDefinition

(Optional) The SQL fragment that is used when generating the DDL for the column. This should not be specified for a OneToOne primary key association.

Defaults to the generated SQL to create a column of the inferred type.

Default:

```java
""
```
PS:
**javax.persistence**

**Annotation Type**

**PrimaryKeyJoinColumn**

```java
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface PrimaryKeyJoinColumn
```

**Implements:** Annotation

```java
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
```

**PrimaryCustomerJoinColumn**

```java
@Entity
@Table(name="VCUST")
@DiscriminatorValue("VCUST")
@PrimaryKeyJoinColumn(
    @PrimaryKeyJoinColumn(name="CUST_ID",
        referencedColumnName="ID"),
    @PrimaryKeyJoinColumn(name="CUST_TYPE",
        referencedColumnName="TYPE")
)
public class ValuedCustomer extends Customer {
    ...
}
```

**since** Java Persistence 1.0

This annotation groups `PrimaryKeyJoinColumn` annotations. It is used to map composite foreign keys.

**Example 1: ValuedCustomer subclass**

```java
@Entity
@Table(name="VCUST")
@DiscriminatorValue("VCUST")
@PrimaryKeyJoinColumn(
    @PrimaryKeyJoinColumn(name="CUST_ID",
        referencedColumnName="ID"),
    @PrimaryKeyJoinColumn(name="CUST_TYPE",
        referencedColumnName="TYPE")
)
public class ValuedCustomer extends Customer { ... }

Since:
Java Persistence 1.0

| The data section of the processing instruction |
### Method Detail

#### public String getTarget()

    return PI null

**getTarget**

String getTarget()

The target section of the processing instruction

**Returns:**

the String value of the PI or null

#### public String getData()

    return PI null

**getData**

String getData()
The data section of the processing instruction

**Returns:**
the String value of the PI's data or null
javax.enterprise.deploy.spi.status  Class ProgressEvent

java.lang.Object
   \ java.util.EventObject
      \ javax.enterprise.deploy.spi.status.ProgressEvent

All Implemented Interfaces:
   Serializable

public class ProgressEvent
   extends EventObject

   Extends: java.util.EventObject

   See also  javax.enterprise.deploy.spi.status.ProgressListener,
   javax.enterprise.deploy.spi.status.ProgressObject

An event which indicates that a deployment status change has occurred.

See Also:
   ProgressListener, ProgressObject, Serialized Form

Field Summary

<table>
<thead>
<tr>
<th>Fields inherited from class java.util.EventObject</th>
</tr>
</thead>
<tbody>
<tr>
<td>source</td>
</tr>
</tbody>
</table>

Constructor Summary

ProgressEvent(Object source, TargetModuleID targetModuleID, DeploymentStatus sCode)

Creates a new object representing a deployment progress event.
Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeploymentStatus</td>
<td>getDeploymentStatus()</td>
</tr>
<tr>
<td>TargetModuleID</td>
<td>getTargetModuleID()</td>
</tr>
</tbody>
</table>

- **DeploymentStatus**
  - getDeploymentStatus() — Retrieve the status information.

- **TargetModuleID**
  - getTargetModuleID() — Retrieve the TargetModuleID for this event

Methods inherited from class java.util.EventObject:
- getSource, toString

Methods inherited from class java.lang.Object:
- clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait

Constructor Detail

```java
public ProgressEvent(Object source, TargetModuleID targetModuleID, DeploymentStatus sCode)
```

- `source` - Event
- `sCode` - ProgressEvent

**ProgressEvent**

```java
public ProgressEvent(Object source, TargetModuleID targetModuleID, DeploymentStatus sCode)
```

Creates a new object representing a deployment progress event.

**Parameters:**
- `source` - the object on which the Event initially occurred.
- `sCode` - the object containing the status information.
public TargetModuleID getTargetModuleID()
TargetModuleID

    return TargetModuleID

getTargetModuleID

public TargetModuleID getTargetModuleID()

    Retrieve the TargetModuleID for this event

    Returns:
        the object containing the TargetModuleID

gDeploymentStatus

public DeploymentStatus getDeploymentStatus()

    return

gDeploymentStatus

public DeploymentStatus getDeploymentStatus()

    Retrieve the status information.

    Returns:
        the object containing the status information.
Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS :
javax.enterprise.deploy.spi.status  

**Interface ProgressListener**

*All Superinterfaces:*  
*EventListener*

```java
public interface ProgressListener extends EventListener

Implements: java.util.EventListener
```

The listener interface for receiving deployment progress events.

### Method Summary

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>handleProgressEvent</code></td>
<td>Invoked when a deployment progress event occurs.</td>
</tr>
</tbody>
</table>

### Method Detail

```java
public void handleProgressEvent(ProgressEvent event)
```

`event`

**handleProgressEvent**

```java
void handleProgressEvent(ProgressEvent event)
```

Invoked when a deployment progress event occurs.
Parameters:

event - the progress status event.

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS:
javax.enterprise.deploy.spi.status  Interface ProgressObject

public interface ProgressObject

ProgressObject

cancel  isCancelSupported  cancel

The ProgressObject interface tracks and reports the progress of the deployment activities, distribute, start, stop, undeploy.

This class has an optional cancel method. The support of the cancel function can be tested by the isCancelSupported method.

The ProgressObject structure allows the user the option of polling for status or to provide a callback.

---

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>addProgressListener(ProgressListener pol)</code></td>
<td>Add a listener to receive Progress events on deployment actions.</td>
</tr>
<tr>
<td><code>cancel()</code></td>
<td>(optional) A cancel request on an in-process operation stops all further processing of the operation and returns the environment to its original state before the operation was executed.</td>

<tr>
<td>isStopSupported()</td>
<td>Tests whether the vendor supports a stop operation for deployment activities.</td>
</tr>
<tr>
<td>removeProgressListener(ProgressListener pol)</td>
<td>Remove a ProgressObject listener.</td>
</tr>
<tr>
<td>stop()</td>
<td>(optional) A stop request on an in-process operation allows the operation on the current TargetModuleID to run to completion but does not process any of the remaining unprocessed TargetModuleID objects.</td>
</tr>
</tbody>
</table>

### Method Detail

```java
public DeploymentStatus getDeploymentStatus()
```

Returns:

getDeploymentStatus

```java
DeploymentStatus getDeploymentStatus()
```

Retrieve the status of this activity.

**Returns:**
An object containing the status information.

```java
public TargetModuleID[] getResultTargetModuleIDs()
DeploymentManager TargetModuleID
return TargetModuleID
```

### getResultTargetModuleIDs

```java
TargetModuleID[] getResultTargetModuleIDs()
```

Retrieve the list of TargetModuleIDs successfully processed or created by the associated DeploymentManager operation.

**Returns:**
- a list of TargetModuleIDs.

```java
public ClientConfiguration getClientConfiguration(TargetModuleID id)
TargetModuleID ClientConfiguration
return TargetModuleID ClientConfiguration null
```

### getClientConfiguration

```java
ClientConfiguration getClientConfiguration(TargetModuleID id)
```

Return the ClientConfiguration object associated with the TargetModuleID.

**Returns:**
- ClientConfiguration for a given TargetModuleID or null if none exists.

```java
public boolean isCancelSupported()
```
isCancelSupported

boolean isCancelSupported()

Tests whether the vendor supports a cancel operation for deployment activities.

Returns:
true if canceling an activity is supported by this platform.

public void cancel() throws OperationUnsupportedException

void cancel() throws OperationUnsupportedException

(optional) A cancel request on an in-process operation stops all further processing of the operation and returns the environment to its original state before the operation was executed. An operation that has run to completion cannot be cancelled.

Throws:
OperationUnsupportedException - this optional command is not supported by this implementation.

public boolean isStopSupported()
**isStopSupported**

boolean isStopSupported()

Tests whether the vendor supports a stop operation for deployment activities.

**Returns:**

true if canceling an activity is supported by this platform.

---

**public void stop() throws OperationUnsupportedException**

**TargetModuleID**  **TargetModuleID**

**getResultTargetModuleIDs**  **TargetModuleID**

**Throws**  **OperationUnsupportedException**:

(stop) A stop request on an in-process operation allows the operation on the current TargetModuleID to run to completion but does not process any of the remaining unprocessed TargetModuleID objects. The processed TargetModuleIDs must be returned by the method getResultTargetModuleIDs.

**Throws:**

**OperationUnsupportedException** - this optional command is not supported by this implementation.

---

**public void addProgressListener(ProgressListener pol)**

Progress
addProgressListener

void addProgressListener(ProgressListener pol)

Add a listener to receive Progress events on deployment actions.

Parameters:
   pol - the listener to receive events

See Also:
   ProgressEvent

public void removeProgressListener(ProgressListener pol)

Remove a ProgressObject listener.

Parameters:
   pol - the listener being removed

- `getCause`, `getErrorCode`, `getLinkedException`, `printStackTrace`, `printStackTrace`, `printStackTrace`, `setLinkedException`, `toString`

Methods inherited from class `java.lang.Throwable`
- `fillInStackTrace`, `getLocalizedMessage`, `getMessage`, `getStackTrace`, `initCause`, `setStackTrace`

Methods inherited from class `java.lang.Object`
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `wait`, `wait`, `wait`
## Constructor Detail

```java
public PropertyException(String message)
PropertyExceptionerrorCode  linkedException
null
    message
```

### PropertyException

```java
public PropertyException(String message)
    Construct a PropertyException with the specified detail message. The errorCode and linkedException will default to null.

Parameters:
    message - a description of the exception
```

```java
public PropertyException(String message, String errorCode)
PropertyExceptionerrorCode  linkedException
null
    message
    errorCode
```

### PropertyException

```java
public PropertyException(String message, String errorCode)
    Construct a PropertyException with the specified detail message and vendor specific errorCode. The linkedException will default to null.

Parameters:
```
message - a description of the exception
errorCode - a string specifying the vendor specific error code

public PropertyException(Throwable exception)
linkedException  PropertyException errorCode
null

exception

PropertyException

public PropertyException(Throwable exception)

Construct a PropertyException with a linkedException. The detail message and vendor specific errorCode will default to null.

Parameters:
exception - the linked exception

PropertyException

public PropertyException(String message, Throwable exception)
linkedException  PropertyException errorCode
null

message
exception

PropertyException

public PropertyException(String message, Throwable exception)

Construct a PropertyException with the specified detail message and linkedException. The errorCode will default to null.

Parameters:
message - a description of the exception
exception - the linked exception

public PropertyException(String message, String errorCode, Throwable exception)
errorCode linkedException PropertyException
message
errorCode
exception

PropertyException

public PropertyException(String name, Object value)
value.toString() PropertyException
name
value

PropertyException

public PropertyException(String name, Object value)
Construct a PropertyException whose message field is set based on the name of the property and value.toString().

**Parameters:**
- name - the name of the property related to this exception
- value - the value of the property related to this exception

javax.el Class PropertyNotFoundException

java.lang.Object
  ▼ java.lang.Throwable
     ▼ java.lang.Exception
          ▼ java.lang.RuntimeException
               ▼ javax.el.ELException
                    ▼ javax.el.PropertyNotFoundException

All Implemented Interfaces:
    Serializable

public class PropertyNotFoundException

extends ELException

Extends: Throwable > Exception > RuntimeException > ELException

    ValueExpression    MethodExpression

JavaBean

    since                JSP 2.1

Thrown when a property could not be found while evaluating a
ValueExpression or MethodExpression.

For example, this could be triggered by an index out of bounds while
setting an array value, or by an unreadable property while getting the
value of a JavaBeans property.

Since:
    JSP 2.1

```

```java
public PropertyNotFoundException()
```

```java
public PropertyNotFoundException()
```

```java
public PropertyNotFoundException()
```

```java
public PropertyNotFoundException()
```
Creates a PropertyNotFoundException with no detail message.

```java
public PropertyNotFoundException(String message)

    PropertyNotFoundException
    message

PropertyNotFoundException

public PropertyNotFoundException(String message)

    Creates a PropertyNotFoundException with the provided detail message.

    Parameters:
    message - the detail message

PropertyNotFoundException

public PropertyNotFoundException(Throwable exception)

    PropertyNotFoundException
    exception

PropertyNotFoundException

public PropertyNotFoundException(Throwable exception)

    Creates a PropertyNotFoundException with the given root cause.

    Parameters:
    exception - the originating cause of this exception

PropertyNotFoundException

public PropertyNotFoundException(String pMessage, Throwable pRootCause)

    PropertyNotFoundException
public PropertyNotFoundException(String pMessage, Throwable pRootCause)

Creates a PropertyNotFoundException with the given detail message and root cause.

Parameters:
  pMessage - the detail message
  pRootCause - the originating cause of this exception

</tbody>
</table>

### Method Summary

Methods inherited from class `java.lang.Throwable`:
- `fillInStackTrace`, `getCause`, `getLocaleMessage`, `getMessage`, `getStackTrace`, `initCause`, `printStackTrace`, `printStackTrace`, `printStackTrace`, `setStackTrace`, `toString`

Methods inherited from class `java.lang.Object`:
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `wait`, `wait`, `wait`

### Constructor Detail

```java
public PropertyNotWritableException()
```

```java
PropertyNotWritableException
```

```java
public PropertyNotWritableException()
```
Creates a PropertyNotWritableException with no detail message.

```java
public PropertyNotWritableException(String pMessage)
```

**PropertyNotWritableException**

```java
public PropertyNotWritableException(String pMessage)
```

Creates a PropertyNotWritableException with the provided detail message.

**Parameters:**

- `pMessage` - the detail message

```
public PropertyNotWritableException(Throwable exception)
```

**PropertyNotWritableException**

```java
public PropertyNotWritableException(Throwable exception)
```

Creates a PropertyNotWritableException with the given root cause.

**Parameters:**

- `exception` - the originating cause of this exception

```
public PropertyNotWritableException(String pMessage, Throwable pRootCause)
```

**PropertyNotWritableException**
PropertyNotWritableException

public PropertyNotWritableException(String pMessage, Throwable pRootCause)

Creates a PropertyNotWritableException with the given detail message and root cause.

Parameters:
  pMessage - the detail message
  pRootCause - the originating cause of this exception

PS:
**Class PropertyResolver**

```java
import java.lang.Object;
import javax.faces.el.PropertyResolver;
```

**Deprecated. This has been replaced by ELResolver.**

**PropertyResolver** represents a pluggable mechanism for accessing a "property" of an underlying Java object instance. Different **PropertyResolver** implementations can support property resolution on instances of different Java classes (such as introspection-based access to properties of a JavaBeans component, or `get()` and `put()` calls on a `java.util.Map` instance).

All implementations must respect the rules for JavaBeans component, `java.util.Map`, `java.util.List` and array instances defined for each method but are allowed to add custom semantics for other types.

## Constructor Detail

public PropertyResolver()
PropertyResolver

public PropertyResolver()

    Deprecated.

Method Detail

abstract public Object getValue(Object base, Object property) throws EvaluationException, PropertyNotFoundException

base

Bean base String base Map

    base
    property
    return

    throws EvaluationException:

    throws PropertyNotFoundException: Bean base

getValue

public abstract Object getValue(Object base, Object property) throws EvaluationException, PropertyNotFoundException

    Deprecated.

    Return the value of the specified property from the specified base object.

    For a bean base object, the property is coerced to a String and used as the property name. For all other base object types (e.g., a Map),
the property is used without any coercing.

**Parameters:**
- base - The base object whose property value is to be returned
- property - The property to be returned

**Returns:**
- The property value, or null if base or property is null, or if the property doesn't exist and the base object is a Map instance

**Throws:**
- `EvaluationException` - if an exception is thrown while getting the property value (the thrown exception must be included as the cause property of this exception)
- `PropertyNotFoundException` - if the specified property for a bean base object does not exist or is not readable

```java
abstract public Object getValue(Object base, int index)
throws EvaluationException, PropertyNotFoundException
```

```java
base

    base
index
return

    base null base null
```

**Throws**

- `EvaluationException`:  
- `PropertyNotFoundException`:  

```java
getValue
```

```java
public abstract Object getValue(Object base,
int index)
throws EvaluationException,
PropertyNotFoundException
```

**Deprecated.**

Return the value at the specified index of the specified base object.
Parameters:
- base - The base object whose property value is to be returned
- index - The index of the value to return

Returns:
- The property value, or null if base is null, or if the index is out of bounds for the base object

Throws:
- EvaluationException - if an exception is thrown while getting the property value (the thrown exception must be included as the cause property of this exception)
- PropertyNotFoundException - if the index is out of bounds or if base is null

abstract public void setValue(Object base, Object property, Object value) throws EvaluationException, PropertyNotFoundException

base

Bean base String base Map

Throws EvaluationException:

Throws PropertyNotFoundException: Bean base
null

setValue

public abstract void setValue(Object base, Object property, Object value)
throws EvaluationException, PropertyNotFoundException
Deprecated.

Set the specified value of the specified property on the specified base object.

For a bean base object, the property is coerced to a `String` and used as the property name. For all other base object types (e.g., a Map), the property is used without any coercing.

**Parameters:**
- `base` - The base object whose property value is to be set
- `property` - The property to be set
- `value` - The value of the property to be set

**Throws:**
- `EvaluationException` - if an exception is thrown while setting the property value (the thrown exception must be included as the cause property of this exception)
- `PropertyNotFoundException` - if the specified bean base object property does not exist or is not writeable, or if `base` or `name` is `null`

```java
abstract public void setValue(Object base, int index, Object value) throws EvaluationException, PropertyNotFoundException

base

base

index

value

Throws EvaluationException:

Throws PropertyNotFoundException: base null

setValue

public abstract void setValue(Object base,

```
Set the value at the specified index of the specified base object.

**Parameters:**
- `base` - The base object whose property value is to be set
- `index` - The index of the value to set
- `value` - The value to be set

**Throws:**
- `EvaluationException` - if an exception is thrown while setting the property value (the thrown exception must be included as the cause property of this exception)
- `PropertyNotFoundException` - if the index is out of bounds or if `base` is null

```java
abstract public boolean isReadOnly(Object base, Object property) throws EvaluationException, PropertyNotFoundException
```

```java
Bean base String base Map

  base base
  property
  return base true false

  Throws EvaluationException:
  property
  base

  Throws PropertyNotFoundException: Bean base
  property null
```

`isReadOnly`
public abstract boolean isReadOnly(Object base, Object property)
throws EvaluationException, PropertyNotFoundException

Deprecated.

Checks if the specified property is read-only.

For a bean base object, the property is coerced to a String and used as the property name. For all other base object types (e.g., a Map), the property is used without any coercing.

Parameters:
- base - The base object whose property is to be analyzed
- property - The property to be analyzed

Returns:
- true if the specified property of the specified base object is known to be immutable; otherwise false

Throws:
- EvaluationException - if an exception is thrown while testing the property (the thrown exception must be included as the cause property of this exception)
- PropertyNotFoundException - if the specified bean base object property does not exist or if base or property is null

abstract public boolean isReadOnly(Object base, int index)
throws EvaluationException, PropertyNotFoundException

base
index
return base

base

true
false

base
null

base
null
isReadOnly

public abstract boolean isReadOnly(Object base, int index) throws EvaluationException, PropertyNotFoundException

Deprecated.

Checks if the specified index is read-only.

Parameters:
  base - The base object whose property is to be analyzed
  index - The index of the value whose type is to be returned

Returns:
  true if the value at the specified index of the specified base object is known to be immutable; otherwise, false

Throws:
  EvaluationException - if an exception is thrown while testing the property (the thrown exception must be included as the cause property of this exception)
  PropertyNotFoundException - if the index is out of bounds or if base is null

abstract public Class<T> getType(Object base, Object property) throws EvaluationException, PropertyNotFoundException

java.lang.Class null

Bean base       String base Map
base
property
return java.lang.Class base null
Throws EvaluationException:
Throws PropertyNotFoundException: Bean base property null
getType

public abstract Class getType(Object base, Object property) throws EvaluationException, PropertyNotFoundException

Deprecated.

Return the java.lang.Class representing the type of the specified property. An instance of any Object of that type may be set as the value of that property, as long as the property is not read-only. The actual value of the property, if non-null, is guaranteed to be an instance of this type, or an instance of a subclass of this type. This method is also useful for discovering the type of Objects that may be set as the value of the property.

For a bean base object, the property is coerced to a String and used as the property name. For all other base object types (e.g., a Map), the property is used without any coercing.

Parameters:
  base - The base object whose property is to be analyzed
  property - The property to be analyzed

Returns:
  the java.lang.Class representing the type of the specified property of the specified base object, if it can be determined; otherwise null

Throws:
  EvaluationException - if an exception is thrown while testing the property (the thrown exception must be included as the cause property of this exception)
  PropertyNotFoundException - if the specified bean base object property does not exist or if base or property is null
Throws `EvaluationException`, `PropertyNotFoundException`

`java.lang.Class`

```
public abstract Class getType(Object base, int index)
throws EvaluationException,
PropertyNotFoundException
```

**Deprecated.**

Return the `java.lang.Class` representing the type of the specified index.

**Parameters:**
- `base` - The base object whose property is to be analyzed
- `index` - The index of the value whose type is to be returned

**Returns:**
- The `java.lang.Class` representing the type of value at the specified index of the specified base object, if it can be determined; otherwise null

**Throws:**
- `EvaluationException` - if an exception is thrown while testing the property (the thrown exception must be included as the cause property of this exception)
- `PropertyNotFoundException` - if the index is out of bounds or if `base` is null

Constructor Detail

class ProtocolException()
null cause
Throwable.initCause(java.lang Throwable)
**ProtocolException**

```java
public ProtocolException()
```

Constructs a new protocol exception with null as its detail message. The cause is not initialized, and may subsequently be initialized by a call to Throwable.initCause(java.lang.Throwable).

```java
public ProtocolException(String message)
cause Throwable.initCause(java.lang.Throwable)
```

```java
message Throwable.getMessage()
```

**ProtocolException**

```java
public ProtocolException(String message)
```

Constructs a new protocol exception with the specified detail message. The cause is not initialized, and may subsequently be initialized by a call to Throwable.initCause(java.lang.Throwable).

**Parameters:**

- `message` - the detail message. The detail message is saved for later retrieval by the Throwable.getMessage() method.

```java
public ProtocolException(String message, Throwable cause)
```

```java
message Throwable.getMessage()
cause cause Throwable.getCause() null
```

**ProtocolException**
public ProtocolException(String message, Throwable cause)

Constructs a new runtime exception with the specified detail message and cause. Note that the detail message associated with cause is not automatically incorporated in this runtime exception's detail message.

Parameters:
message - the detail message (which is saved for later retrieval by the Throwable.getMessage() method).
cause - the cause (which is saved for later retrieval by the Throwable.getCause() method). (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

public ProtocolException(Throwable cause)

cause (cause==null ? null :cause.toString())

cause

ProtocolException

public ProtocolException(Throwable cause)

Constructs a new runtime exception with the specified cause and a detail message of (cause==null ? null : cause.toString()) (which typically contains the class and detail message of cause). This constructor is useful for runtime exceptions that are little more than wrappers for other throwables.

Parameters:
cause - the cause (which is saved for later retrieval by the Throwable.getCause() method). (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

javax.mail Class Provider

java.lang.Object
  ↓ javax.mail.Provider

public class Provider
  extends Object

Inner classes: Provider.Type

Provider  javamail.providers  javamail.default.providers
Provider

  version  1.11, 07/05/04

The Provider is a class that describes a protocol implementation. The values typically come from the javamail.providers and javamail.default.providers resource files. An application may also create and register a Provider object to dynamically add support for a new provider.

Version: 1.11, 07/05/04
Author: Max Spivak, Bill Shannon

---

## Nested Class Summary

<table>
<thead>
<tr>
<th>static class</th>
<th>Provider.Type</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This inner class defines the Provider type.</td>
</tr>
</tbody>
</table>

## Constructor Summary

Provider(Provider.Type type, String protocol, String classname, String vendor, String version)
Create a new provider of the specified type for the specified protocol.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getClassName()</code></td>
<td>Returns name of the class that implements the protocol</td>
</tr>
<tr>
<td><code>getProtocol()</code></td>
<td>Returns the protocol supported by this Provider</td>
</tr>
<tr>
<td><code>getType()</code></td>
<td>Returns the type of this Provider</td>
</tr>
<tr>
<td><code>getVendor()</code></td>
<td>Returns name of vendor associated with this implementation or null</td>
</tr>
<tr>
<td><code>getVersion()</code></td>
<td>Returns version of this implementation or null if no version</td>
</tr>
<tr>
<td><code>toString()</code></td>
<td>Overrides Object.toString()</td>
</tr>
</tbody>
</table>

### Constructor Detail

```java
public Provider(Provider.Type type, String protocol, String classname, String vendor, String version)
```

- `type` Type.STORE  Type.TRANSPORT
- `protocol`            
- `classname`            
- `vendor` null
public Provider(Provider.Type type,
        String protocol,
        String classname,
        String vendor,
        String version)

Create a new provider of the specified type for the specified protocol. The specified class implements the provider.

Parameters:
  type - Type.STORE or Type.TRANSPORT
  protocol - valid protocol for the type
  classname - class name that implements this protocol
  vendor - optional string identifying the vendor (may be null)
  version - optional implementation version string (may be null)

Since:
   JavaMail 1.4

Method Detail

public Provider.Type getType()

getType

public Provider.Type getType()

  Returns the type of this Provider

public String getProtocol()
Provider

definition

public String getProtocol()

    Returns the protocol supported by this Provider

PS:
javax.xml.ws  Interface Provider<T>

public interface Provider<T>

    Provider SEI
    ServiceMode Provider

since JAX-WS 2.0
See javax.xml.transform.Source,
also javax.xml.soap.SOAPMessage, javax.xml.ws.ServiceMode

Service endpoints may implement the Provider interface as a dynamic alternative to an SEI. Implementations are required to support Provider<Source> and Provider<SOAPMessage>. The ServiceMode annotation can be used to control whether the Provider instance will receive entire protocol messages or just message payloads.

Since: JAX-WS 2.0
See Also: Source, SOAPMessage, ServiceMode

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>invoke(T request)</td>
<td>Invokes an operation according to the contents of the request message.</td>
</tr>
</tbody>
</table>

### Method Detail
invoke

I invoke(I request)

Invokes an operation according to the contents of the request message.

Parameters:
request - The request message or message payload.

Returns:
The response message or message payload. May be null if there is no response.

Throws:
WebServiceException - if there is an error processing request. The cause of the WebServiceException may be set to a subclass of ProtocolException to control the protocol level representation of the exception.

Constant Field Values

Constructor Detail

Provider
protected Provider()

    Creates a new instance of Provider

## Method Detail

provider

public static Provider provider()

    Creates a new provider object.

    The algorithm used to locate the provider subclass to use consists of
    the following steps:

    - If a resource with the name of META-INF/services/javax.xml.ws.spi.Provider exists, then its first
      line, if present, is used as the UTF-8 encoded name of the
      implementation class.
    - If the $java.home/lib/jaxws.properties file exists and it is
      readable by the java.util.Properties.load(InputStream)
      method and it contains an entry whose key is
      javax.xml.ws.spi.Provider, then the value of that entry is used
      as the name of the implementation class.
    - If a system property with the name javax.xml.ws.spi.Provider
      is defined, then its value is used as the name of the
      implementation class.
    - Finally, a default implementation class name is used.

createServiceDelegate

public abstract ServiceDelegate createServiceDelegate(URL wsdlDocume

QName serviceN

class serviceC
Creates a service delegate object.

**Parameters:**

wsdlDocumentLocation - A URL pointing to the WSDL document for the service, or null if there isn't one.

serviceName - The qualified name of the service.

serviceClass - The service class, which must be either javax.xml.ws.Service or a subclass thereof.

**Returns:**

The newly created service delegate.

---

createEndpoint

```java
public abstract Endpoint createEndpoint(String bindingId, Object implementor)
```

Creates an endpoint object with the provided binding and implementation object.

**Parameters:**

bindingId - A URI specifying the desired binding (e.g. SOAP/HTTP)

implementor - A service implementation object to which incoming requests will be dispatched. The corresponding class must be annotated with all the necessary Web service annotations.

**Returns:**

The newly created endpoint.

---

createAndPublishEndpoint

```java
public abstract Endpoint createAndPublishEndpoint(String address, Object implementor)
```

Creates and publishes an endpoint object with the specified address
and implementation object.

**Parameters:**

address - A URI specifying the address and transport/protocol to use. A http: URI must result in the SOAP 1.1/HTTP binding being used. Implementations may support other URI schemes.

implementor - A service implementation object to which incoming requests will be dispatched. The corresponding class must be annotated with all the necessary Web service annotations.

**Returns:**

The newly created endpoint.
**javax.mail**  **Class Provider.Type**

import java.lang.Object
- javax.mail.Provider.Type

**Enclosing class:**
- Provider

### Method Detail

**public java.util.List&lt;E&gt; getResultList()**

SELECT List

```
return
```

Throws

- `IllegalStateException`: Java Persistence
- `IllegalStateException`: UPDATE
- `IllegalStateException`: DELETE

**getResultList**

```
List getResultList()
```

Execute a SELECT query and return the query results as a List.

**Returns:**

- a list of the results

**Throws:**
IllegalStateException - if called for a Java Persistence query language UPDATE or DELETE statement

public Object getSingleResult()

SELECT
return

Throws

NoResultException:
NonUniqueResultException:
IllegalStateException: Java Persistence UPDATE DELETE

getSingleResult

Object getSingleResult()

Execute a SELECT query that returns a single result.

Returns:
the result

Throws:

NoResultException - if there is no result
NonUniqueResultException - if more than one result
IllegalStateException - if called for a Java Persistence query language UPDATE or DELETE statement

public int executeUpdate()

return

Throws
IllegalStateException: Java Persistence SELECT
TransactionRequiredException:

executeUpdate
int executeUpdate()

Execute an update or delete statement.

**Returns:**
the number of entities updated or deleted

**Throws:**
- `IllegalStateException` - if called for a Java Persistence query language SELECT statement
- `TransactionRequiredException` - if there is no transaction

---

public `Query` setMaxResults(int maxResult)

```
maxResult
return
```

**Throws**
`IllegalArgumentException:`

---

`setMaxResults`

`Query` `setMaxResults`(int `maxResult`)

Set the maximum number of results to retrieve.

**Parameters:**
- `maxResult`

**Returns:**
the same query instance

**Throws:**
- `IllegalArgumentException` - if argument is negative

---

public `Query` setFirstResult(int startPosition)

```
startPosition 0
return
```

**Throws**
`IllegalArgumentException:`
setFirstResult

*Query setFirstResult*(int startPosition)

Set the position of the first result to retrieve.

**Parameters:**
- startPosition - the start position of the first result, numbered from 0

**Returns:**
- the same query instance

**Throws:**
- `IllegalArgumentException` - if argument is negative

---

public *Query setHint*(String hintName, Object value)

**hintName**
- value

**return**
- Throws: `IllegalArgumentException`

---

setHint

*Query setHint*(String hintName, Object value)

Set an implementation-specific hint. If the hint name is not recognized, it is silently ignored.

**Parameters:**
- hintName -
- value -

**Returns:**
- the same query instance
Throws:

*IllegalArgumentException* - if the second argument is not valid for the implementation

```java
public Query setParameter(String name, Object value)
```

- **name**
- **value**
- return
- **Throws**  IllegalArgument Exception:

**setParameter**

```java
Query setParameter(String name, Object value)
```

Bind an argument to a named parameter.

**Parameters:**
- name - the parameter name
- value -

**Returns:**
- the same query instance

**Throws:**

*IllegalArgumentException* - if parameter name does not correspond to parameter in query string or argument is of incorrect type

```java
public Query setParameter(String name, java.util.Date value, TemporalType temporalType)
```

- **name**
- **value**
- **temporalType**
setParameter

Query setParameter(String name, Date value, TemporalType temporalType)

Bind an instance of java.util.Date to a named parameter.

Parameters:
- name -
- value -
- temporalType -

Returns:
- the same query instance

Throws:
- IllegalArgumentException - if parameter name does not correspond to parameter in query string

public Query setParameter(String name, java.util.Calendar value, TemporalType temporalType)

java.util.Calendar
- name
- value
- temporalType

return

Throws IllegalArgumentException:
Bind an instance of java.util.Calendar to a named parameter.

**Parameters:**
- name - 
- value - 
- temporalType -

**Returns:**
the same query instance

**Throws:**
- **IllegalArgumentException** - if parameter name does not correspond to parameter in query string

---

```java
public Query setParameter(int position, Object value)
```

- **position**
- **value**
- **return**

**Throws**
- IllegalArgumentException:

---

**setParameter**

```java
Query setParameter(int position, Object value)
```

 Bind an argument to a positional parameter.

**Parameters:**
- position -
- value -

**Returns:**
the same query instance

**Throws:**
- **IllegalArgumentException** - if position does not correspond to positional parameter of query or argument is of incorrect type
public Query setParameter(int position, java.util.Date value, TemporalType temporalType)
java.util.Date
  position
  value
  temporalType
  return
  Throws IllegalArgumentException:

setParameter

Query setParameter(int position, Date value, TemporalType temporalType)
Bind an instance of java.util.Date to a positional parameter.

Parameters:
  position -
  value -
  temporalType -

Returns:
  the same query instance

Throws:
  IllegalArgumentException - if position does not correspond to positional parameter of query

public Query setParameter(int position, java.util.Calendar value, TemporalType temporalType)
java.util.Calendar
  position
  value
  temporalType
  return
  Throws IllegalArgumentException:
setParameter

```java
Query setParameter(int position,
    Calendar value,
    TemporalType temporalType)
```

Bind an instance of java.util.Calendar to a positional parameter.

**Parameters:**
- position -
- value -
- temporalType -

**Returns:**
the same query instance

**Throws:**
IllegalArgumentException - if position does not correspond to positional parameter of query

---

public Query setFlushMode(FlushModeType flushMode)

```java
flushMode
```

setFlushMode

```java
Query setFlushMode(FlushModeType flushMode)
```

Set the flush mode type to be used for the query execution. The flush mode type applies to the query regardless of the flush mode type in use for the entity manager.

**Parameters:**
- flushMode -

PS:
The Query interface encapsulates a query in a declarative query language. Currently a Query can be an SQL query or an ebXML Filter Query only. In future support for other query languages such as XQL query may be added. The query must conform to a fixed schema as defined by the JAXR specification.

ID RegistryObject

0

id RegistryObject Key ID

objectType LifeCycleManager

return OrganizationUser RegistryObject

Throws JAXRException: JAXR

getRegistryObject

RegistryObject getRegistryObject(String id, String objectType)

Throws JAXRException

Gets the RegistryObject specified by the Id and type of object.

Capability Level: 0

Parameters:

id - is the id of the Key for a RegistryObject.

objectType - is a constant definition from LifeCycleManager that specifies the type of object desired.

Returns:

the RegistryObject, returned as its concrete type (e.g. Organization, User etc.).

Throws:
public RegistryObject getRegistryObject(String id) throws JAXRException
ID RegistryObject

1

<table>
<thead>
<tr>
<th>id</th>
<th>ID</th>

</table>

Throws: JAXRException - If the JAXR provider encounters an internal error

getRegistryObject

RegistryObject getRegistryObject(String id) throws JAXRException

Gets the RegistryObject specified by the Id.

Capability Level: 1

Parameters:
- id - the id for the desired object

Returns:
- the RegistryObject, returned as its concrete type (e.g. Organization, User etc.).

Throws:
- JAXRException - If the JAXR provider encounters an internal error

public BulkResponse getRegistryObjects(java.util.Collection<E> objectKeys) throws JAXRException
RegistryObjectOrganizationUser

1

objectKeys | Key Collection
--- | ---
return | BulkResponse RegistryObjectOrganizationUser Collection
Throws | JAXRException: JAXR

getRegistryObjects

BulkResponse getRegistryObjects(Collection objectKeys) throws JAXRException

Gets the specified RegistryObjects. The objects are returned as their concrete type (e.g. Organization, User etc.).

Capability Level: 1

Parameters:
objectKeys - a Collection of Key objects for the desired objects

Returns:
BulkResponse containing a heterogeneous Collection of RegistryObjects (e.g. Organization, User etc.).

Throws:
JAXRException - If the JAXR provider encounters an internal error

public BulkResponse getRegistryObjects(java.util.Collection<E> objectKeys, String objectTypes) throws JAXRException
RegistryObjectOrganizationUser

0

objectKeys | Key Collection
getRegistryObjects

BulkResponse getRegistryObjects(Collection objectKeys, String objectTypes)
throws JAXRException

Gets the specified RegistryObjects. The objects are returned as their concrete type (e.g. Organization, User etc.).

Capability Level: 0

Parameters:
  objectKeys - a Collection of Key objects for the desired objects
  objectTypes - a Collection of String objects that allow filtering desired objects by their type

Returns:
  BulkResponse containing a heterogeneous Collection of RegistryObjects (e.g. Organization, User etc.).

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public BulkResponse getRegistryObjects() throws JAXRException

RegistryObjectOrganizationUser

0

return BulkResponse RegistryObjectOrganizationUser Collection
Throws JAXRException: JAXR
getRegistryObjects

**BulkResponse getRegistryObjects() throws JAXRException**

Gets the RegistryObjects owned by the caller. The objects are returned as their concrete type (e.g. Organization, User etc.).

**Capability Level: 0**

**Returns:**
- BulkResponse containing a heterogeneous Collection of RegistryObjects (e.g. Organization, User etc.).

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

```java
public BulkResponse getRegistryObjects(String objectType) throws JAXRException
RegistryObject RegistryObject
OrganizationUser

0

objectType  LifeCycleManager
return BulkResponse RegistryObjectOrganizationUser
Collection
Throws JAXRException: JAXR
See also ORGANIZATION
```

getRegistryObjects

**BulkResponse getRegistryObjects(String objectType) throws JAXRException**
Gets the RegistryObjects owned by the caller, that are of the specified type. The objects are returned as their concrete type (e.g. Organization, User etc.).

**Capability Level: 0**

**Parameters:**
- **objectType** - Is a constant that defines the type of object sought. See LifeCycleManager for constants for object types.

**Returns:**
BulkResponse containing a heterogeneous Collection of RegistryObjects (e.g. Organization, User etc.).

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

**See Also:**
LifeCycleManager.ORGANIZATION

```java
public RegistryService getRegistryService() throws JAXRException

RegistryService
0

return RegistryService

Throws JAXRException: JAXR

associates
<javax.xml.registry.RegistryService>

getRegistryService

RegistryService getRegistryService()

throws JAXRException

Returns the parent RegistryService that created this object.

**Capability Level: 0**
```
Returns:
the RegistryService created this object

Throws:
JAXRException - If the JAXR provider encounters an internal error
javax.jms Interface Queue

- Session.CreateProducer(Destination destination)

JMS API

version 1.1 February 2 - 2000

See also createConsumer(Destination), createProducer(Destination), createQueue(String), createQueue(String)

A Queue object encapsulates a provider-specific queue name. It is the way a client specifies the identity of a queue to JMS API methods. For those methods that use a Destination as a parameter, a Queue object used as an argument. For example, a queue can be used to create a MessageConsumer and a MessageProducer by calling:

- Session.CreateConsumer(Destination destination)
- Session.CreateProducer(Destination destination)
The actual length of time messages are held by a queue and the consequences of resource overflow are not defined by the JMS API.

Version:
1.1 February 2 - 2000

</thead>
<tbody>
<tr>
<td><strong>String getQueueName()</strong></td>
<td>Gets the name of this queue.</td>
</tr>
<tr>
<td><strong>String toString()</strong></td>
<td>Returns a string representation of this object.</td>
</tr>
</tbody>
</table>

---

### Method Detail

**public String getQueueName() throws JMSException**

```java
return
```

**Throws**

- JMSException
- Queue
- JMS

**getQueueName**

```java
String getQueueName() throws JMSException
```
Gets the name of this queue.

Clients that depend upon the name are not portable.

**Returns:**
the queue name

**Throws:**
JMSException - if the JMS provider implementation of `Queue` fails to return the queue name due to some internal error.

---

```java
public String toString()

    return toString()
```

toString

`String` `toString()`

Returns a string representation of this object.

**Overrides:**
toString in class `Object`

**Returns:**
the provider-specific identity values for this queue
javax.jms  Interface QueueBrowser

public interface QueueBrowser

QueueBrowser

getEnumeration  java.util.Enumeration

JMS API  JMS

Session  QueueSession  QueueBrowser

version  1.1 April 9, 2002

See  createBrowser, createBrowser,
also  javax.jms.QueueReceiver

A client uses a QueueBrowser object to look at messages on a queue without removing them.

The getEnumeration method returns a java.util.Enumeration that is used to scan the queue's messages. It may be an enumeration of the entire content of a queue, or it may contain only the messages matching a message selector.

Messages may be arriving and expiring while the scan is done. The JMS API does not require the content of an enumeration to be a static snapshot of queue content. Whether these changes are visible or not depends on the JMS provider.

A QueueBrowser can be created from either a Session or a QueueSession.

Version:
   1.1 April 9, 2002

Author:
   Mark Hapner, Rich Burridge, Kate Stout

<tr>
<td><code>String getMessageSelector()</code></td>
<td>Gets this queue browser's message selector expression.</td>
</tr>
<tr>
<td><code>Queue getQueue()</code></td>
<td>Gets the queue associated with this queue browser.</td>
</tr>
</tbody>
</table>

### Method Detail

```java
public Queue getQueue() throws JMSException {
    return ...
}
```

**Throws:**

- `JMSException`: JMS

**getQueue**

```java
Queue getQueue() throws JMSException {
    Gets the queue associated with this queue browser.
    
    **Returns:**
    
    the queue
```
Throws:

`JMSException` - if the JMS provider fails to get the queue associated with this browser due to some internal error.

```java
public String getMessageSelector() throws JMSException
{
    return null;
}
```

Throws

`JMSException`: JMS

`getMessageSelector`

```java
String getMessageSelector() throws JMSException;
```

Gets this queue browser's message selector expression.

Returns:

this queue browser's message selector, or null if no message selector exists for the message consumer (that is, if the message selector was not set or was set to null or the empty string)

Throws:

`JMSException` - if the JMS provider fails to get the message selector for this browser due to some internal error.

```java
public java.util Enumeration<E> getEnumeration() throws JMSException
{
    return null;
}
```

Throws

`JMSException`: JMS

`getEnumeration`

```java
Enumeration getEnumeration();
```
throws JMSException

Gets an enumeration for browsing the current queue messages in the order they would be received.

Returns:
an enumeration for browsing the messages

Throws:
   JMSException - if the JMS provider fails to get the enumeration for this browser due to some internal error.

public void close() throws JMSException

QueueBrowser

QueueBrowser Java

Throws JMSException: JMS

close

void close()
   throws JMSException

Closes the QueueBrowser.

Since a provider may allocate some resources on behalf of a QueueBrowser outside the Java virtual machine, clients should close them when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

Throws:
   JMSException - if the JMS provider fails to close this browser due to some internal error.

PS:
javax.jms Interface QueueConnection

All Superinterfaces:
  Connection

All Known Subinterfaces:
  XAQueueConnection

public interface QueueConnection
extends Connection

Implements: Connection
Implemented by: XAQueueConnection

QueueConnection	JMS	QueueConnection
QueueConnection	QueueSession	QueueSession
QueueConnection

QueueConnection / createDurableConnection
Connection	QueueConnection	IllegalStateException

version 1.1 - April 9, 2002
See javax.jms.Connection, javax.jms.ConnectionFactory,
also javax.jms.QueueConnectionFactory

A QueueConnection object is an active connection to a point-to-point JMS provider. A client uses a QueueConnection object to create one or more QueueSession objects for producing and consuming messages.

A QueueConnection can be used to create a QueueSession, from which specialized queue-related objects can be created. A more general, and recommended, approach is to use the Connection object.
The QueueConnection object should be used to support existing code that has already used it.

A QueueConnection cannot be used to create objects specific to the publish/subscribe domain. The createDurableConnectionConsumer method inherits from Connection, but must throw an IllegalStateException if used from QueueConnection.

Version:
   1.1 - April 9, 2002

Author:
   Mark Hapner, Rich Burridge, Kate Stout

---

### Method Detail

```java
public QueueSession createQueueSession(boolean transacted, int acknowledgeMode) throws JMSException
```
createQueueSession

QueueSession createQueueSession(boolean transacted, int acknowledgeMode) throws JMSException

Creates a QueueSession object.

Parameters:
- transacted - indicates whether the session is transacted
- acknowledgeMode - indicates whether the consumer or the client will acknowledge any messages it receives; ignored if the session is transacted. Legal values are Session.AUTO_ACKNOWLEDGE, Session.CLIENT_ACKNOWLEDGE, and Session.DUPS_OK_ACKNOWLEDGE.

Returns:
a newly created queue session

Throws:
- JMSException - if the QueueConnection object fails to create a session due to some internal error or lack of support for the specific transaction and acknowledgement mode.

See Also:
- Session.AUTO_ACKNOWLEDGE, Session.CLIENT_ACKNOWLEDGE, Session.DUPS_OK_ACKNOWLEDGE
createConnectionConsumer(Queue queue, String messageSelector, ServerSessionPool sessionPool, int maxMessages) throws JMSException

queue
messageSelector null
sessionPool
maxMessages
return

Throws JMSException: QueueConnection
messageSelector

Throws InvalidDestinationException:

Throws InvalidSelectorException:

See also javax.jms.ConnectionConsumer

createConnectionConsumer

ConnectionConsumer createConnectionConsumer(Queue queue,
String messageSelector,
ServerSessionPool sessionPool,
int maxMessages) throws JMSException

Creates a connection consumer for this connection (optional operation). This is an expert facility not used by regular JMS clients.

Parameters:
queue - the queue to access
messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
sessionPool - the server session pool to associate with this connection consumer
maxMessages - the maximum number of messages that can be assigned to a server session at one time

Returns:
the connection consumer

Throws:

JMSException - if the QueueConnection object fails to create a connection consumer due to some internal error or invalid arguments for sessionPool and messageSelector.

InvalidDestinationException - if an invalid queue is specified.

InvalidSelectorException - if the message selector is invalid.

<td>Creates a queue connection with the specified user identity.</td>
</tr>
</tbody>
</table>

Methods inherited from interface `javax.jms.ConnectionFactory`:
- `createConnection`
- `createConnection`

Method Detail

```java
public QueueConnection createQueueConnection() throws JMSException
```

```java
return Connection
```

Throws:
- `JMSException`: JMS
- `JMSSecurityException`: JMSSecurityException
Creates a queue connection with the default user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

Returns:
a newly created queue connection

Throws:

- JMSException - if the JMS provider fails to create the queue connection due to some internal error.
- JMSSecurityException - if client authentication fails due to an invalid user name or password.

```java
public QueueConnection createQueueConnection(String userName, String password) throws JMSException
```

**createQueueConnection**

**Parameters:**
- userName - the caller's user name
- password - the caller's password

**Returns:**
a newly created queue connection
Throws:

- **JMSException** - if the JMS provider fails to create the queue connection due to some internal error.
- **JMSSecurityException** - if client authentication fails due to an invalid user name or password.
public interface QueueReceiver

extends MessageConsumer

Implements: MessageConsumer

A client uses a QueueReceiver object to receive messages that have been delivered to a queue.

Although it is possible to have multiple QueueReceivers for the same queue, the JMS API does not define how messages are distributed between the QueueReceivers.

If a QueueReceiver specifies a message selector, the messages that are not selected remain on the queue. By definition, a message selector
allows a QueueReceiver to skip messages. This means that when the skipped messages are eventually read, the total ordering of the reads does not retain the partial order defined by each message producer. Only QueueReceiver instances without a message selector will read messages in message producer order.

Creating a MessageConsumer provides the same features as creating a QueueReceiver. A MessageConsumer object is recommended for creating new code. The QueueReceiver is provided to support existing code.

javax.jms Class QueueRequestor

javax.lang.Object
  ↓ javax.jms.QueueRequestor

public class QueueRequestor
extends Object

QueueRequestor
QueueRequestor QueueSession Queue TemporaryQueue request

/JMS

version 1.0 - 8 July 1998

See also javax.jms.TopicRequestor

The QueueRequestor helper class simplifies making service requests.

The QueueRequestor constructor is given a non-transacted QueueSession and a destination Queue. It creates a TemporaryQueue for the responses and provides a request method that sends the request message and waits for its reply.

This is a basic request/reply abstraction that should be sufficient for most uses. JMS providers and clients are free to create more sophisticated versions.

Version: 1.0 - 8 July 1998

Author: Mark Hapner, Rich Burridge

queue /

Throws JMSException: JMS
Throws InvalidDestinationException: QueueRequesto

QueueRequestor

public QueueRequestor(QueueSession session,
Constructor for the QueueRequestor class.

This implementation assumes the session parameter to be non-transacted, with a delivery mode of either AUTO_ACKNOWLEDGE or DUPS_OK_ACKNOWLEDGE.

Parameters:
- session: the QueueSession the queue belongs to
- queue: the queue to perform the request/reply call on

Throws:
- JMSException: if the JMS provider fails to create the QueueRequestor due to some internal error.
- InvalidDestinationException: if an invalid queue is specified.

### Method Detail

**public Message request(Message message) throws JMSException**

```java
JMSReplyTo message
return
```

Throws: JMSException: JMS

Sends a request and waits for a reply. The temporary queue is used for the JMSReplyTo destination, and only one reply per request is expected.

Parameters:
- message: the message to send
Returns:
the reply message

Throws:

- [JMSException](#) - if the JMS provider fails to complete the request due to some internal error.

---

public void close() throws [JMSException](#)

QueueRequestor

---

QueueRequestor Java

QueueRequestor QueueSession

Throws [JMSException](#): JMS

---

close

close

public void close()

Throws [JMSException](#)

Closes the QueueRequestor and its session.

Since a provider may allocate some resources on behalf of a QueueRequestor outside the Java virtual machine, clients should close them when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

Note that this method closes the QueueSession object passed to the QueueRequestor constructor.

Throws:

- [JMSException](#) - if the JMS provider fails to close the QueueRequestor due to some internal error.

JMSTimeStamp send
MessageProducer.setDisableMessageID
MessageProducer.setDisableMessageTimestamp send
JMSMessageID JMSTimeStamp

MessageProducer QueueSender MessageProducer

version 1.1 - February 2, 2002

See javax.jms.MessageProducer,
also createProducer(Destination), createSender(Queue)
A client uses a QueueSender object to send messages to a queue.

Normally, the queue is specified when a QueueSender is created. In this case, an attempt to use the send methods for an unidentified QueueSender will throw a java.lang.UnsupportedOperationException.

If the QueueSender is created with an unidentified Queue, an attempt to use the send methods that assume that the Queue has been identified will throw a java.lang.UnsupportedOperationException.

During the execution of its send method, a message must not be changed by other threads within the client. If the message is modified, the result of the send is undefined.

After sending a message, a client may retain and modify it without affecting the message that has been sent. The same message object may be sent multiple times.

The following message headers are set as part of sending a message: JMSDestination, JMSDeliveryMode, JMSExpiration, JMSPriority, JMSMessageID and JMSTimeStamp. When the message is sent, the values of these headers are ignored. After the completion of the send, the headers hold the values specified by the method sending the message. It is possible for the send method not to set JMSMessageID and JMSTimeStamp if the setting of these headers is explicitly disabled by the MessageProducer.setDisableMessageID or MessageProducer.setDisableMessageTimestamp method.

Creating a MessageProducer provides the same features as creating a QueueSender. A MessageProducer object is recommended when creating new code. The QueueSender is provided to support existing code.

## Method Detail

```java
public Queue getQueue() throws JMSException

    QueueSender

    return

    Throws  JMSException: JMS
```

**getQueue**

*Queue* `getQueue()`
throws JMSException

Gets the queue associated with this QueueSender.

**Returns:**
this sender's queue

**Throws:**
JMSException - if the JMS provider fails to get the queue for this QueueSender due to some internal error.

```java
public void send(Message message) throws JMSException
    QueueSender
message

Throws JMSException: JMS
Throws MessageFormatException: 
Throws InvalidDestinationException:
Throws UnsupportedOperationException:
See also getDeliveryMode(), getTimeToLive(), getPriority()
```

send

```java
void send(Message message)
    throws JMSException
```

Sends a message to the queue. Uses the QueueSender's default delivery mode, priority, and time to live.

**Specified by:**
send in interface MessageProducer

**Parameters:**
message - the message to send

**Throws:**
JMSException - if the JMS provider fails to send the message due to some internal error.
MessageFormatException - if an invalid message is specified.
InvalidDestinationException - if a client uses this method with a QueueSender with an invalid queue.
UnsupportedOperationException - if a client uses this method with a QueueSender that did not specify a queue at creation time.

Throws InvalidDestinationException: Queue
Throws UnsupportedOperationException:

send

void send(Message message,
    int deliveryMode,
    int priority,
    long timeToLive)
    throws JMSException

Sends a message to the queue, specifying delivery mode, priority, and time to live.

Specified by:
    send in interface MessageProducer

Parameters:
    message - the message to send
deliveryMode - the delivery mode to use
priority - the priority for this message
timeToLive - the message's lifetime (in milliseconds)
Throws:

- `JMSException` - if the JMS provider fails to send the message due to some internal error.
- `MessageFormatException` - if an invalid message is specified.
- `InvalidDestinationException` - if a client uses this method with a `QueueSender` with an invalid queue.
- `UnsupportedOperationException` - if a client uses this method with a `QueueSender` that did not specify a queue at creation time.

See Also:

- `Session.createProducer(javax.jms.Destination)`

```java
public void send(Queue queue, Message message) throws JMSException
```

Sends a message to a queue for an unidentified message producer. Uses the `QueueSender`'s default delivery mode, priority, and time to live.

Typically, a message producer is assigned a queue at creation time; however, the JMS API also supports unidentified message
producers, which require that the queue be supplied every time a message is sent.

**Parameters:**
- `queue` - the queue to send this message to
- `message` - the message to send

**Throws:**
- `JMSException` - if the JMS provider fails to send the message due to some internal error.
- `MessageFormatException` - if an invalid message is specified.
- `InvalidDestinationException` - if a client uses this method with an invalid queue.

**See Also:**
- `MessageProducer.getDeliveryMode()`,
- `MessageProducer.getTimeToLive()`,
- `MessageProducer.getPriority()`

```java
public void send(Queue queue, Message message, int deliveryMode, int priority, long timeToLive) throws JMSException
```

**JMS API**

```java
    queue
    message
    deliveryMode
    priority
    timeToLive
```

**Throws**
- `JMSException`: JMS
- `MessageFormatException`: JMS
- `InvalidDestinationException`: JMS

send
void send(Queue queue,
   Message message,
   int deliveryMode,
   int priority,
   long timeToLive)
   throws JMSEException

Sends a message to a queue for an unidentified message producer, specifying delivery mode, priority and time to live.

Typically, a message producer is assigned a queue at creation time; however, the JMS API also supports unidentified message producers, which require that the queue be supplied every time a message is sent.

Parameters:
   queue - the queue to send this message to
   message - the message to send
   deliveryMode - the delivery mode to use
   priority - the priority for this message
   timeToLive - the message's lifetime (in milliseconds)

Throws:
   JMSEException - if the JMS provider fails to send the message due to some internal error.
   MessageFormatException - if an invalid message is specified.
   InvalidDestinationException - if a client uses this method with an invalid queue.

  • createTemporaryTopic
  • createTopic
  • unsubscribe

version 1.1 - April 2, 2002
See javax.jms.Session, createQueueSession(boolean, int),
getQueueSession()
redelivered when a consumer next accesses the queue.

A QueueSession is used for creating Point-to-Point specific objects. In general, use the Session object. The QueueSession is used to support existing code. Using the Session object simplifies the programming model, and allows transactions to be used across the two messaging domains.

A QueueSession cannot be used to create objects specific to the publish/subscribe domain. The following methods inherit from Session, but must throw an IllegalStateException if they are used from QueueSession:

- createDurableSubscriber
- createTemporaryTopic
- createTopic
- unsubscribe

## Method Detail

```java
class Queue

public Queue createQueue(String queueName) throws JMSException
```

Queue
createQueue

**createQueue(String queueName)**

Throws **JMSException**

Creates a queue identity given a queue name.

This facility is provided for the rare cases where clients need to dynamically manipulate queue identity. It allows the creation of a queue identity with a provider-specific name. Clients that depend on this ability are not portable.

Note that this method is not for creating the physical queue. The physical creation of queues is an administrative task and is not to be initiated by the JMS API. The one exception is the creation of temporary queues, which is accomplished with the createTemporaryQueue method.

**Specified by:**
createQueue in interface Session

**Parameters:**

queueName - the name of this Queue

**Returns:**

a Queue with the given name

**Throws:**

**JMSException** - if the session fails to create a queue due to some internal error.

public **QueueReceiver** createReceiver(Queue queue)

throws **JMSException**
createReceiver

**QueueReceiver createReceiver(Queue queue)**

Throws **JMSException**: 
Throws **InvalidDestinationException**: 

Creates a **QueueReceiver** object to receive messages from the specified queue.

**Parameters:**
- **queue** - the Queue to access

**Throws:**
- **JMSException** - if the session fails to create a receiver due to some internal error.
- **InvalidDestinationException** - if an invalid queue is specified.

---

**public QueueReceiver createReceiver(Queue queue, String messageSelector)**

Throws **JMSException**

**QueueReceiver**

- **queue**
- **null**

**Throws:**
- **JMSException**: 
- **InvalidDestinationException**: 
- **InvalidSelectorException**: 

**createReceiver**

**QueueReceiver createReceiver(Queue queue, String messageSelector)**

Throws **JMSException**
Creates a QueueReceiver object to receive messages from the specified queue using a message selector.

**Parameters:**
- `queue` - the Queue to access
- `messageSelector` - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.

**Throws:**
- `JMSException` - if the session fails to create a receiver due to some internal error.
- `InvalidDestinationException` - if an invalid queue is specified.
- `InvalidSelectorException` - if the message selector is invalid.

```java
public QueueSender createSender(Queue queue) throws JMSException
{
  QueueSender queue
  Queue null
}

createSender
```

```java
QueueSender createSender(Queue queue) throws JMSException
{
  Creates a QueueSender object to send messages to the specified queue.

  **Parameters:**
  - `queue` - the Queue to access, or null if this is an unidentified producer

  **Throws:**
  - `JMSException` - if the session fails to create a sender due to some internal error.
```
InvalidDestinationException - if an invalid queue is specified.

**public QueueBrowser createBrowser(Queue queue) throws JMSException**

QueueBrowser

queue: Queue

Throws: JMSException:

Throws: InvalidDestinationException:

createBrowser

QueueBrowser createBrowser(Queue queue)

throws JMSException

Creates a QueueBrowser object to peek at the messages on the specified queue.

Specified by:
createBrowser in interface Session

Parameters:

queue - the Queue to access

Throws:

JMSException - if the session fails to create a browser due to some internal error.

InvalidDestinationException - if an invalid queue is specified.

**public QueueBrowser createBrowser(Queue queue, String messageSelector) throws JMSException**

QueueBrowser

queue: Queue

messageSelector: null

Throws: JMSException:

Throws: InvalidDestinationException:

Throws: InvalidSelectorException:
**createBrowser**

```
QueueBrowser createBrowser(Queue queue,
                           String messageSelector)
throws JMSException
```

Creates a `QueueBrowser` object to peek at the messages on the specified queue using a message selector.

**Specified by:**
`createBrowser` in interface `Session`

**Parameters:**
- `queue` - the Queue to access
- `messageSelector` - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.

**Throws:**
- `JMSException` - if the session fails to create a browser due to some internal error.
- `InvalidDestinationException` - if an invalid queue is specified.
- `InvalidSelectorException` - if the message selector is invalid.

**public TemporaryQueue createTemporaryQueue() throws JMSException**

```
TemporaryQueue createTemporaryQueue()
```

**Throws** `JMSException`: 

**createTemporaryQueue**

```
TemporaryQueue createTemporaryQueue()
throws JMSException
```

Creates a `TemporaryQueue` object. Its lifetime will be that of the
QueueConnection unless it is deleted earlier.

Specified by:

createTemporaryQueue in interface Session

Returns:

a temporary queue identity

Throws:

JMSException - if the session fails to create a temporary queue due to some internal error.
javax.mail  **Class Quota**

```java
java.lang.Object
   | javax.mail.Quota
```

public class **Quota** extends **Object**

**Inner classes:** **Quota.Resource**

(quotas root) Quota.Resource

RFC 2087

<table>
<thead>
<tr>
<th>since</th>
<th>JavaMail 1.4</th>
</tr>
</thead>
<tbody>
<tr>
<td>version</td>
<td>1.7, 07/05/04</td>
</tr>
</tbody>
</table>

This class represents a set of quotas for a given quota root. Each quota root has a set of resources, represented by the **Quota.Resource** class. Each resource has a name (for example, "STORAGE"), a current usage, and a usage limit. See RFC 2087.

**Since:** JavaMail 1.4
**Version:** 1.7, 07/05/04
**Author:** Bill Shannon

---

**Nested Class Summary**

<table>
<thead>
<tr>
<th>static class</th>
<th><strong>Quota.Resource</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>An individual resource in a quota root.</td>
</tr>
</tbody>
</table>

**Field Summary**
The name of the quota root.

The set of resources associated with this quota root.

**Constructor Summary**

```java
Quota(String quotaRoot)
```

Create a Quota object for the named quotaroot with no associated resources.

**Method Summary**

```java
void setResourceLimit(String name, long limit)
```

Set a resource limit for this quota root.

**Methods inherited from class java.lang.Object**

`clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait`

**Field Detail**

```java
public String quotaRoot
```

The name of the quota root.

```java
resources
```
public Quota.Resource[] resources

The set of resources associated with this quota root.

### Constructor Detail

```java
public Quota(String quotaRoot)
```

Create a Quota object for the named quotaroot with no associated resources.

**Parameters:**
- `quotaRoot` - the name of the quota root

### Method Detail

```java
public void setResourceLimit(String name, long limit)
```

Set a resource limit for this quota root.
Parameters:
  name - the name of the resource
  limit - the resource limit

Submit a bug or feature

PS:
javax.mail Class Quota.Resource

java.lang.Object
   \_ javax.mail.Quota.Resource

Enclosing class:
   Quota

public static class Quota.Resource
extends Object

Contained within: Quota

since JavaMail 1.4

An individual resource in a quota root.

Since:
   JavaMail 1.4

Field Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>long</td>
<td>limit</td>
<td>The usage limit for the resource.</td>
</tr>
<tr>
<td>String</td>
<td>name</td>
<td>The name of the resource.</td>
</tr>
<tr>
<td>long</td>
<td>usage</td>
<td>The current usage of the resource.</td>
</tr>
</tbody>
</table>

Constructor Summary

Quota.Resource(String name, long usage, long limit)
Construct a Resource object with the given name, usage, and limit.

Method Summary

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Field Detail

name

public String name

The name of the resource.

usage

public long usage

The current usage of the resource.

limit

public long limit

The usage limit for the resource.
public Quota.Resource(String name, long usage, long limit)

Construct a Resource object with the given name, usage, and limit.

Parameters:
- name - the resource name
- usage - the current usage of the resource
- limit - the usage limit for the resource
javax.mail Interface QuotaAwareStore

public interface QuotaAwareStore

Store 2087 getQuota setQuota IMAP QUOTA

since JavaMail 1.4 en

An interface implemented by Stores that support quotas. The getQuota and setQuota methods support the quota model defined by the IMAP QUOTA extension. Refer to RFC 2087 for more information.

Since:
JavaMail 1.4

Method Summary

<table>
<thead>
<tr>
<th>Quota[]</th>
<th>getQuota(String root)</th>
<th>Get the quotas for the named quota root.</th>
</tr>
</thead>
<tbody>
<tr>
<td>void</td>
<td>setQuota(Quota quota)</td>
<td>Set the quotas for the quota root specified in the quota argument.</td>
</tr>
</tbody>
</table>

Method Detail

public Quota[] getQuota(String root) throws MessagingException
getQuota

Quota[] getQuota(String root) throws MessagingException

Get the quotas for the named quota root. Quotas are controlled on the basis of a quota root, not (necessarily) a folder. The relationship between folders and quota roots depends on the server. Some servers might implement a single quota root for all folders owned by a user. Other servers might implement a separate quota root for each folder. A single folder can even have multiple quota roots, perhaps controlling quotas for different resources.

Parameters:
root - the name of the quota root

Returns:
array of Quota objects

Throws:
MessagingException - if the server doesn't support the QUOTA extension

public void setQuota(Quota quota) throws MessagingException

setQuota

void setQuota(Quota quota) throws MessagingException
Set the quotas for the quota root specified in the quota argument. Typically this will be one of the quota roots obtained from the getQuota method, but it need not be.

**Parameters:**
- `quota` - the quota to set

**Throws:**
- `MessagingException` - if the server doesn't support the QUOTA extension
javax.management.j2ee.statistics Interface RangeStatistic

All Superinterfaces:
Statistic

All Known Subinterfaces:
BoundedRangeStatistic

public interface RangeStatistic
extends Statistic

Implements: Statistic
Implemented by: BoundedRangeStatistic

Specifies standard measurements of the lowest and highest values an attribute has held as well as its current value.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>long getCurrent()</td>
<td>The current value of this attribute.</td>
</tr>
<tr>
<td>long getHighWaterMark()</td>
<td>The highest value this attribute has held since the beginning of the measurement.</td>
</tr>
<tr>
<td>long getLowWaterMark()</td>
<td>The lowest value this attribute has held since the beginning of the measurement.</td>
</tr>
</tbody>
</table>

Methods inherited from interface javax.management.j2ee.statistics.Statistic
getDescription, getLastSampleTime, getName, getStartTime, getUnit
public long getHighWaterMark()

getHighWaterMark

long getHighWaterMark()

The highest value this attribute has held since the beginning of the measurement.

public long getLowWaterMark()

getLowWaterMark

long getLowWaterMark()

The lowest value this attribute has held since the beginning of the measurement.

public long getCurrent()

getCurrent

long getCurrent()

The current value of this attribute.

## Constructor Detail

### public ReadOnlyFolderException(Folder folder)

**MessagingException**

- **folder**
  - Folder
- **since**
  - JavaMail 1.2

### public ReadOnlyFolderException(Folder folder)

**ReadOnlyFolderException**
Constructs a MessagingException with the specified folder.

**Parameters:**
- folder - the Folder

**Since:**
JavaMail 1.2

```java
public ReadOnlyFolderException(Folder folder, String message)
```

**MessagingException**

```java
public ReadOnlyFolderException(Folder folder, String message)
```

ReadonlyFolderException

```java
public ReadonlyFolderException(Folder folder, String message)
```

Constructs a MessagingException with the specified folder and the specified detail message.

**Parameters:**
- folder - the Folder
- message - the detailed error message

**Since:**
JavaMail 1.2

### Method Detail

```java
public Folder getFolder()
```

`Folder`

**Since:**
JavaMail 1.2
public Folder getFolder()

Returns the dead Folder object.

Since:
JavaMail 1.2
**javax.mail.search Class ReceivedDateTerm**

```

```
  comparison
  `date`
  Comparison
```

**ReceivedDateTerm**

```java
public ReceivedDateTerm(int comparison, `Date` `date`)
```

Constructor.
Parameters:
  comparison - the Comparison type
date - the date to be compared

### Method Detail

**public boolean match(Message msg)**

```java
    msg  Message
    return true false
```

**match**

public boolean match(Message msg)

The match method.

**Specified by:**

match in class SearchTerm

**Parameters:**

msg - the date comparator is applied to this Message's sent date

**Returns:**

true if the comparison succeeds, otherwise false

---

**public boolean equals(Object obj)**

**equals**

public boolean equals(Object obj)

Equality comparison.

**Overrides:**
equals in class DateTerm

public RecipientStringTerm(Message.RecipientType type, String pattern)

Constructor.

Parameters:
  type - the recipient type
  pattern - the address pattern to be compared.

public Message.RecipientType getRecipientType()

getRecipientType

public Message.RecipientType getRecipientType()

Return the type of recipient to match with.

public boolean match(Message msg)
match

public boolean match(Message msg)

Check whether the address specified in the constructor is a substring of the recipient address of this Message.

Specified by:
match in class searchTerm
Parameters:
msg - The comparison is applied to this Message's recipient address.
Returns:
true if the match succeeds, otherwise false.

equals

public boolean equals(Object obj)

Equals

public boolean equals(Object obj)

Equality comparison.

Overrides:
equals in class AddressStringTerm

hashCode

public int hashCode()

hashCode
public int hashCode()

Compute a hashCode for this object.

Overrides:
hashCode in class StringTerm

javax.resource.cci Interface Record

All Superinterfaces:
  Cloneable, Serializable

All Known Subinterfaces:
  IndexedRecord, MappedRecord, ResultSet

public interface Record
extends Cloneable, Serializable

Implements: Cloneable, java.io.Serializable
Implemented by: IndexedRecord, MappedRecord, ResultSet

javax.resource.cci.Record Interaction execute

Record

- MappedRecord- Collection
- IndexedRecord Collection
- JavaBean EIS ERP
- java.util.Map
- java.sql.ResultSet
- javax.resource.cci.ResultSet

MappedRecord IndexedRecord Record MappedRecord
IndexedRecord Java MappedRecord IndexedRecord
version 0.8
See also  javax.resource.cci.Interaction, java.sql.ResultSet

The javax.resource.cci.Record interface is the base interface for the representation of an input or output to the execute methods defined on an Interaction.

The Record interface can be extended to form a one of the following
representations:

- **MappedRecord**: A key-value pair based collection represents a record. This interface is based on the `java.util.Map`
- **IndexedRecord**: An ordered and indexed collection represents a record. This interface is based on the `java.util.List`.
- **JavaBean based representation of an EIS abstraction**: An example is a custom record generated to represent a purchase order in an ERP system.
- **javax.resource.cci.ResultSet**: This interface extends both `java.sql.ResultSet` and `javax.resource.cci.Record`. A ResultSet represents tabular data.

A MappedRecord or IndexedRecord can contain another Record. This means that MappedRecord and IndexedRecord can be used to create a hierarchical structure of any arbitrary depth. A basic Java type is used as the leaf element of a hierarchical structure represented by a MappedRecord or IndexedRecord.

**Version**: 0.8

**Author**: Rahul Sharma

**See Also**: Interaction, ResultSet

### Method Summary

<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>clone()</code></td>
<td>Creates and returns a copy of this object.</td>
</tr>
<tr>
<td><code>equals(Object other)</code></td>
<td>Check if this instance is equal to another Record.</td>
</tr>
<tr>
<td><code>getRecordName()</code></td>
<td>Gets the name of the Record.</td>
</tr>
<tr>
<td><code>getRecordShortDescription()</code></td>
<td>Gets a short description string for the Record.</td>
</tr>
<tr>
<td><code>hashCode()</code></td>
<td></td>
</tr>
</tbody>
</table>
Returns the hash code for the Record instance.

void setRecordName(String name)
Sets the name of the Record.

void setRecordShortDescription(String description)
Sets a short description string for the Record.

Method Detail

public String getRecordName()
Record
return
Record

getRecordName

String getRecordName()

Gets the name of the Record.

Returns:
String representing name of the Record

public void setRecordName(String name)
Record
name
Record

setRecordName

void setRecordName(String name)

Sets the name of the Record.

Parameters:
public void setRecordShortDescription(String description)

Sets a short description string for the Record. This property is used primarily by application development tools.

Parameters:

description - Description of the Record

public String getRecordShortDescription()

Gets a short description string for the Record. This property is used primarily by application development tools.

Returns:

String representing a short description of the Record

public boolean equals(Object other)

name - Name of the Record
equals

boolean equals(Object other)

Check if this instance is equal to another Record.

Overrides: equals in class Object

Returns: true if two instances are equal

public int hashCode()
Record

return

hashCode

int hashCode()

Returns the hash code for the Record instance.

Overrides: hashCode in class Object

Returns: hash code

public Object clone() throws CloneNotSupportedException
“”
return

Throws CloneNotSupportedException: Cloneable clone
**clone**

```java
Object clone()
    throws CloneNotSupportedException
```

Creates and returns a copy of this object. The precise meaning of "copy" may depend on the class of the object.

**Returns:**
a clone of this instance.

**Throws:**
- `CloneNotSupportedException` - If the object's class does not support the Cloneable interface. Subclasses that override the clone method can also throw this exception to indicate that an instance cannot be cloned.

</table>
public **MappedRecord** createMappedRecord(String recordName) throws **ResourceException**

**MappedRecord** RecordFactory

```java
recordName
return
```

<table>
<thead>
<tr>
<th>Throws</th>
</tr>
</thead>
<tbody>
<tr>
<td>•</td>
</tr>
</tbody>
</table>

**Throws** ```java
NotFoundException: MappedRecord
```

**createMappedRecord**

```java
MappedRecord createMappedRecord(String recordName)
throws ResourceException
```

Creates a MappedRecord. The method takes the name of the record that is to be created by the RecordFactory. The name of the record acts as a pointer to the meta information (stored in the metadata repository) for a specific record type.

**Parameters:**

- **recordName** - Name of the Record

**Returns:**

- MappedRecord

**Throws:**

- **ResourceException** - Failed to create a MappedRecord. Example error cases are:
  - Invalid specification of record name
  - Resource adapter internal error
  - Failed to access metadata repository
- **NotSupportedException** - Operation not supported

```java
public IndexedRecord createIndexedRecord(String
```

---
recordName) throws ResourceException
IndexedRecord
RecordFactory

createIndexedRecord

createIndexedRecord(String recordName) throws ResourceException

Creates a IndexedRecord. The method takes the name of the record that is to be created by the RecordFactory. The name of the record acts as a pointer to the meta information (stored in the metadata repository) for a specific record type.

Parameters:
recordName - Name of the Record

Returns:
IndexedRecord

Throws:
ResourceException - Failed to create an IndexedRecord.
Example error cases are:
- Invalid specification of record name
- Resource adapter internal error
- Failed to access metadata repository

NotSupportedException - Operation not supported

The Referenceable interface extends the javax.naming.Referenceable interface. It enables support for JNDI Reference mechanism for the registration of the connection factory in the JNDI name space. Note that the implementation and structure of Reference is specific to an application server.

The implementation class for a connection factory interface is required to implement both java.io.Serializable and javax.resource.Referenceable interfaces to support JNDI registration.

Version:
0.9

Author:
Rahul Sharma
### Method Summary

<table>
<thead>
<tr>
<th>void setReference(Reference reference)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sets the Reference instance.</td>
</tr>
</tbody>
</table>

### Method Detail

```java
public void setReference(javax.naming.Reference reference)
Reference getReference
javax.naming.Referenceable Reference
```

#### setReference

```java
void setReference(Reference reference)
```

Sets the Reference instance. This method is called by the deployment code to set the Reference that can be later returned by the getReference method (as defined in the javax.naming.Referenceable interface).

**Parameters:**

- reference - A Reference instance

**See Also:**

- `Referenceable.getReference()`
Submit a bug or feature

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS :

**javax.faces.el Class ReferenceSyntaxException**

```java
java.lang.Object
  └ java.lang.Throwable
      └ java.lang.Exception
          └ java.lang.RuntimeException
              └ javax.faces.FacesException
                  └ javax.faces.el.EvaluationException
                      └ javax.faces.el.ReferenceSyntaxException
```

**All Implemented Interfaces:**
- Serializable

---

**Deprecated.** *This has been replaced by ELException.*

**Extends:** Throwable > Exception > RuntimeException > FacesException > EvaluationException

```java
public class ReferenceSyntaxException
extends EvaluationException
```

An exception reporting a syntax error in a method binding expression or value binding expression.

**See Also:**
- Serialized Form

---

**Constructor Summary**

```java
ReferenceSyntaxException()
```

**Deprecated.** Construct a new exception with no detail message
or root cause.

ReferenceSyntaxException(String message)

    Deprecated. Construct a new exception with the specified detail message and no root cause.

ReferenceSyntaxException(String message, Throwable cause)

    Deprecated. Construct a new exception with the specified detail message and root cause.

ReferenceSyntaxException(Throwable cause)

    Deprecated. Construct a new exception with the specified root cause.

Constructor Detail

public ReferenceSyntaxException()
ReferenceSyntaxException

public ReferenceSyntaxException()

    Deprecated.

    Construct a new exception with no detail message or root cause.

public ReferenceSyntaxException(String message)

    message

ReferenceSyntaxException

public ReferenceSyntaxException(String message)

    Deprecated.

    Construct a new exception with the specified detail message and no root cause.

    Parameters:
    
    message - The detail message for this exception

public ReferenceSyntaxException(Throwables cause)

    (cause == null ? null : cause.toString())

    cause

ReferenceSyntaxException
public ReferenceSyntaxException(Throwable cause)

Depreciated.

Construct a new exception with the specified root cause. The detail message will be set to (cause == null ? null : cause.toString())

Parameters:
cause - The root cause for this exception

public ReferenceSyntaxException(String message, Throwable cause)

message
cause

ReferenceSyntaxException

public ReferenceSyntaxException(String message, Throwable cause)

Depreciated.

Construct a new exception with the specified detail message and root cause.

Parameters:
message - The detail message for this exception
cause - The root cause for this exception

javax.xml.registry.infomodel Interface RegistryEntry

All Superinterfaces:
   ExtensibleObject, RegistryObject, Versionable

All Known Subinterfaces:
   ClassificationScheme, ExtrinsicObject, RegistryPackage, Service

public interface RegistryEntry
   extends RegistryObject, Versionable

Implements: RegistryObject, Versionable
Implemented by: ClassificationScheme, ExtrinsicObject, RegistryPackage, Service

RegistryEntry RegistryObject

The RegistryEntry interface is a base interface for interfaces in the model that require additional metadata beyond what is provided by the RegistryObject interface. A few interfaces in the model represent high level (coarse grain) objects in the registry that require additional metadata such as version information and indication of the stability or volatility of the information.

Method Detail

public int getStatus() throws JAXRException
RegistryEntry

UnsupportedCapabilityException

See
return
Throws
JAXRException: JAXR

getStatus
public int getStability() throws JAXRException

Registry RegistryEntry

1

UnsupportedCapabilityException

Get the stability indicator for the RegistryEntry within the Registry. The stability indicator is provided by the submitter as an indication of the level of stability for the content.

Capability Level: 1
This method must throw UnsupportedCapabilityException in lower capability levels.
Returns:
the stability indicator as an integer enumeration

Throws:
   JAXRException - If the JAXR provider encounters an internal error

See Also:
   STABILITY_DYNAMIC

public void setStability(int stability) throws JAXRException
RegistryEntry

1

UnsupportedCapabilityException

stability

Throws
   JAXRException: JAXR

setStability

void setStability(int stability)
   throws JAXRException

Sets the stability indicator for the RegistryEntry.

Capability Level: 1
   This method must throw UnsupportedCapabilityException in lower capability levels.

Parameters:
   stability - the stability indicator

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public java.util.Date getExpiration() throws JAXRException
Registry RegistryEntry expirationDate
expirationDate STABILITY_DYNAMIC null

1

UnsupportedCapabilityException

return Date
Throws JAXRException: JAXR

getExpiration

Date getExpiration() throws JAXRException

Gets expirationDate attribute of the RegistryEntry within the Registry. This attribute defines a time limit upon the stability indication provided by the stability attribute. Once the expirationDate has been reached the stability attribute in effect becomes STABILITY_DYNAMIC implying that content can change at any time and in any manner. A null value implies that there is no expiration on stability attribute.

Capability Level: 1
This method must throw UnsupportedCapabilityException in lower capability levels.

Returns:
the expiration Date for the stability indicator

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setExpiration(java.util.Date expiration) throws JAXRException
expirationDate
setExpiration

void setExpiration(Date expiration)
  throws JAXRException

Sets the expirationDate.

Capability Level: 1

Parameters:
  expiration - the expiration Date for the stability indicator

Throws:
  JAXRException - If the JAXR provider encounters an internal error
javax.xml.registry Class RegistryException

java.lang.Object
    ↓ java.lang.Throwable
        ↓ java.lang.Exception
            ↓ javax.xml.registry.JAXRException
                ↓ javax.xml.registry.RegistryException

All Implemented Interfaces:
    Serializable, JAXRResponse

Direct Known Subclasses:
    DeleteException, FindException, SaveException

public class RegistryException
extends JAXRException

Extends: Throwable > Exception > JAXRException
Extended by: DeleteException, FindException, SaveException

JAXR Exception

This is the common base class for all Exceptions that are detected on the registry provider side rather than the JAXR client side.

**Constructor Detail**

**public RegistryException()**

Throws: JAXRException

Constructs a JAXRException object with no reason or embedded Throwable.

**public RegistryException(String reason)**

Constructs a JAXRException object with the given String as the reason for the exception being thrown.

**Parameters:**

- reason - a description of what caused the exception
public RegistryException(String reason, Throwable cause)

    JAXRException     String     Throwable

Throwable

    reason
    cause

JAXRException

public RegistryException(String reason, Throwable cause)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

Parameters:

    reason - a description of what caused the exception
    cause - a Throwable object that is to be embedded in this JAXRException object

---

public RegistryException(Throwable cause)

    Throwable     JAXRException

    cause     Exception     Throwable

RegistryException

public RegistryException(Throwable cause)

    Constructs a JAXRException object initialized with the given Throwable object.

Parameters:

    cause - the Throwable that caused this Exception
**Method Detail**

```java
class getErrorObjectKey()

public Key getErrorObjectKey() throws JAXRException

Key return
```

**getErrorObjectKey**

```java
public Key getErrorObjectKey() throws JAXRException

Gets the Key to the first object that encountered an error in the registry.

Returns:
the key to the first object in error

Throws:
JAXRException
```

```java
public void setErrorObjectKey(Key key) throws JAXRException

Key key
```

**setErrorObjectKey**

```java
public void setErrorObjectKey(Key key) throws JAXRException

Sets the Key to the first object that encountered an error in the registry.

Parameters:
key - the key to the first object in error
```
Throws:

`JAXRException`

addSlot, addSlots, getSlot, getSlots, removeSlot, removeSlots

---

**Method Detail**

public **Key** getKey() throws **JAXRException**  
ID (UUID)

0

    return **Key**  
    Throws **JAXRException**: JAXR
getKey

public Key getKey() throws JAXRException

Gets the key representing the universally unique ID (UUID) for this object.

**Capability Level:** 0

**Returns:**
the Key for this object

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

getDescription

public InternationalString getDescription() throws JAXRException

0

return null

**Throws:**
JAXRException: JAXR
the description for this object which must not be null

Throws:  
JAXRException - If the JAXR provider encounters an internal error

public void setDescription(InternationalString description) 
throws JAXRException

Sets the context independent textual description for this object.

Capability Level: 0

Parameters:  
description - the description for this object

Throws: 
JAXRException - If the JAXR provider encounters an internal error

public InternationalString getName() throws JAXRException

0
return null
Throws JAXRException: JAXR

getName

**InternationalString** getName()
throws JAXRException

Gets the user-friendly name of this object.

**Capability Level:** 0

**Returns:**
the name for this object which must not be null.

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

```java
public void setName(**InternationalString** name) throws JAXRException
```

Sets user-friendly name of object in repository.

**Capability Level:** 0
Parameters:
   name - the name for this object

Throws:
   JAXRException - If the JAXR provider encounters an internal error

```
public void setKey(Key key) throws JAXRException
ID (UUID)
```

```
key
```

Throws
   JAXRException: JAXR

setKey

```
void setKey(Key key)
throws JAXRException
```

Sets the key representing the universally unique ID (UUID) for this object.

**Capability Level: 0**

Parameters:
   key - the key for this object

Throws:
   JAXRException - If the JAXR provider encounters an internal error

```
public String toXML() throws JAXRException
Object XML API
UnsupportedCapabilityException
```

0
toXML

```java
String toXML() throws JAXRException
```

Returns a registry provider specific XML representation of this Object. This may be used as a last resort back door way to get to a provider specific information element that is not accessible via the API. Implementation may choose to throw a UnsupportedCapabilityException.

**Capability Level: 0**

**Returns:**
the String containing the XML representation for this object

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

---

```java
public void addClassification(Classification classification) throws JAXRException
```

Classification Classification classifiedObject

0

**classification**

**Throws**
JAXRException: JAXR

---

```java
void addClassification(Classification classification) throws JAXRException
```

addClassification
Adds specified Classification to this object. Silently replaces the classifiedObject in Classification with reference to this object.

**Capability Level:** 0

**Parameters:**
- classification - the Classification being added

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

```java
public void addClassifications(java.util.Collection<? extends Classification> classifications) throws JAXRException
```

**addClassifications**

```java
void addClassifications(Collection classifications) throws JAXRException
```

Adds specified Classifications to this object. Silently replaces the classifiedObject in Classifications with reference to this object.

**Capability Level:** 0

**Parameters:**
- classifications - the Collection of Classifications being added

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error
public void removeClassification(Classification classification) throws JAXRException

Removes specified Classification from this object.

Capability Level: 0

Parameters:

classification - the Classification being removed

Throws:

JAXRException - If the JAXR provider encounters an internal error

public void removeClassifications(java.util.Collection<E> classifications) throws JAXRException

Removes specified Classifications from this object.

Capability Level: 0

Parameters:

classifications - the Classifications being removed

Throws:

JAXRException - If the JAXR provider encounters an internal error
void removeClassifications(Collection classifications) throws JAXRException

Removes specified Classifications from this object.

**Capability Level: 0**

**Parameters:**
- classifications - the Collection of Classifications being removed

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

public void setClassifications(java.util.Collection<E> classifications) throws JAXRException

Classification Classification

0

classifications Classification Collection

**Throws**
- JAXRException: JAXR

**setClassifications**

void setClassifications(Collection classifications) throws JAXRException

Replaces all previous Classifications with specified Classifications.

**Capability Level: 0**

**Parameters:**
- classifications - the Collection of Classifications being set

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error
public java.util.Collection\<E\> getClassifications() throws JAXRException

Classification

0

return Classification Collection Collection null

Throws JAXRException: JAXR

link aggregationByValue

associates 

supplierCardinality 

label

See also javax.xml.registry.infomodel.Classification

gOfClassifications

Collection getClassifications() throws JAXRException

Gets the Classification instances that classify this object.

Capability Level: 0

Returns: Collection of Classification instances. The Collection may be empty but not null.

Throws: JAXRException - If the JAXR provider encounters an internal error

See Also: Classification

public java.util.Collection\<E\> getAuditTrail() throws
JAXRException
AuditableEvent Collection

1
UnsupportedCapabilityException

return AuditableEvent CollectionCollection null

Throws JAXRException: JAXR

link aggregationByValue

associates <{AuditableEvent}>

supplierCardinality 1..*

label auditTrail

See also javax.xml.registry.infomodel.AuditableEvent

getauditTrail

Collection getAuditTrail() throws JAXRException

Returns the complete audit trail of all requests that effected a state change in this object as an ordered Collection of AuditableEvent objects.

Capability Level: 1
This method must throw UnsupportedCapabilityException in lower capability levels.

Returns:
Collection of AuditableEvent instances. The Collection may be empty but not null.

Throws:
JBAXRException - If the JAXR provider encounters an internal error

See Also:
AuditableEvent
public void addAssociation(Association association) throws JAXRException

Adding specified Association to use this object as source. Silently replaces the sourceObject in Association with reference to this object.

Capability Level: 0

Parameters:

- association - the Association being added

Throws:

- JAXRException - If the JAXR provider encounters an internal error

public void addAssociations(java.util.Collection<E> associations) throws JAXRException

Adding specified Associations to use this object as source. Silently replaces the sourceObject in Association with reference to this object.

Capability Level: 0

Parameters:

- associations - the Collection of Associations being added

Throws:

- JAXRException - If the JAXR provider encounters an internal error
addAssociations

void addAssociations(Collection associations) throws JAXRException

Adds specified Associations to use this object as source. Silently replaces the sourceObject in Associations with reference to this object.

Capability Level: 0

Parameters:
associations - the Collection of Associations being added

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void removeAssociation(Association association) throws JAXRException

Association

void removeAssociation(Association association) throws JAXRException

Removes specified Association from this object.

Capability Level: 0
Parameters:
  association - the Association being removed

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public void removeAssociations(java.util.Collection<? extends Association> associations) throws JAXRException

Removes specified Associations from this object.

Capability Level: 0

Parameters:
  associations - the Collection of Associations being removed

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public void setAssociations(java.util.Collection<? extends Association> associations) throws JAXRException

This method sets the specified Associations to this object.

Capability Level: 0

Parameters:
  associations - the Collection of Associations being set

Throws:
  JAXRException - If the JAXR provider encounters an internal error
setAssociations

void setAssociations(Collection associations) throws JAXRException

Replaces all previous Associations from this object with specified Associations.

Capability Level: 0

Parameters:

associations - the Collection of Associations being set

Throws:

JAXRException - If the JAXR provider encounters an internal error

---

public java.util.Collection&lt;E&gt; getAssociations() throws JAXRException

Association

0

return Association CollectionCollection null

Throws JAXRException: JAXR

See also javax.xml.registry.infomodel.Association

getAssociations

Collection getAssociations() throws JAXRException

Gets all Associations where this object is source.
Capability Level: 0

Returns:
Collection of Association instances. The Collection may be empty but not null.

Throws:
JAXRException - If the JAXR provider encounters an internal error

See Also:
Association

```java
public java.util.Collection<E> getAssociatedObjects()
throws JAXRException

RegistryObject Collection

UnsupportedCapabilityException

return
RegistryObject Collection
null

Throws
JAXRException: JAXR
associationAsClass

clientCardinality

associates

undirected

label

See also
javax.xml.registry.infomodel.RegistryObject
```
this object.

**Capability Level: 1**
This method must throw UnsupportedCapabilityException in lower capability levels.

**Returns:**
Collection of RegistryObject instances. The Collection may be empty but not null.

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

**See Also:**
RegistryObject

---

```java
public void addExternalIdentifier(ExternalIdentifier externalIdentifier) throws JAXRException
    ExternalIdentifier registryObject

0

    externalIdentifier Externallldentifier
    Throws JAXRException: JAXR
```

**addExternalIdentifier**

```java
void addExternalIdentifier(ExternalIdentifier externalIdentifier)
    throws JAXRException
```

Adds specified ExternalIdentifier as an external identifier to this object. Silently replaces the registryObject in ExternalIdentifier with reference to this object.

**Capability Level: 0**

**Parameters:**
public void addExternalIdentifiers(java.util.Collection<E> externalIdentifiers) throws JAXRException

Parameters:

- **externalIdentifiers**: the Collection of ExternalIdentifiers being added

Throws:

- **JAXRException**: If the JAXR provider encounters an internal error

---

**addExternalIdentifiers**

void addExternalIdentifiers(Collection externalIdentifiers)

throws JAXRException

Adds specified ExternalIdentifiers as an external identifiers to this object. Silently replaces the registryObject in ExternalIdentifiers with reference to this object.

**Capability Level**: 0

**Parameters**: 

- **externalIdentifiers**: the Collection of ExternalIdentifiers being added

**Throws**: 

- **JAXRException**: If the JAXR provider encounters an internal error

---

public void removeExternalIdentifier(ExternalIdentifier externalIdentifier) throws JAXRException

**Throws**: 

- **JAXRException**: If the JAXR provider encounters an internal error

---

**public void addExternalIdentifiers(ExternalIdentifier being added**

**Throws**: 

- **JAXRException**: If the JAXR provider encounters an internal error
ExternalIdentifier

0

Throws

JAXRException: JAXR

removeExternalIdentifier

void removeExternalIdentifier(ExternalIdentifier externalIdentifier)
throws JAXRException

Removes specified ExternalIdentifier as an external identifier from this object.

Capability Level: 0

Parameters:

externalIdentifier - the ExternalIdentifier being removed

Throws:

JAXRException - If the JAXR provider encounters an internal error

public void removeExternalIdentifiers(java.util.Collection<E> externalIdentifiers) throws JAXRException

ExternalIdentifier

0

Throws

JAXRException: JAXR

removeExternalIdentifiers
void removeExternalIdentifiers(Collection externalIdentifiers) throws JAXRException

Removes specified ExternalIdentifiers as an external identifiers from this object.

**Capability Level:** 0

**Parameters:**
- externalIdentifiers - the Collection of ExternalIdentifiers being removed

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

public void setExternalIdentifiers(java.util.Collection\<E\> externalIdentifiers) throws JAXRException

ExternalIdentifier Collection

0

externalIdentifiers - ExternalIdentifier Collection

**Throws**
- JAXRException: JAXR

---

**setExternalIdentifiers**

void setExternalIdentifiers(Collection externalIdentifiers) throws JAXRException

Replaces all previous external identifiers with specified Collection of ExternalIdentifiers as an external identifier.

**Capability Level:** 0

**Parameters:**
- externalIdentifiers - the Collection of ExternalIdentifiers being set
Throws:

`JAXRException` - If the JAXR provider encounters an internal error

```java
public java.util.Collection<E> getExternalIdentifiers()
throws JAXRException
```

Returns the `ExternalIdentifier` instances that are external identifiers for this object.

**Capability Level:** 0

**Returns:**

Collection of `ExternalIdentifier` instances. The Collection may be empty but not null.

**Throws:**

`JAXRException` - If the JAXR provider encounters an internal error
public void addExternalLink(ExternalLink externalLink) throws JAXRException
ExternalLink

0

addExternalLink

void addExternalLink(ExternalLink externalLink)
   throws JAXRException

    Adds specified ExternalLink to this object.

    Capability Level: 0

    Parameters:
        externalLinks - the ExternalLink being added

    Throws:
        JAXRException - If the JAXR provider encounters an internal error

public void addExternalLinks(java.util.Collection<E> externalLinks) throws JAXRException
ExternalLink

0

addExternalLinks
addExternalLinks

void addExternalLinks(Collection externalLinks)
throws JAXRException

Adds specified ExternalLinks to this object.

Capability Level: 0

Parameters:
   externalLinks - the Collection of ExternalLinks being added

Throws:
   JAXRException - If the JAXR provider encounters an internal error

removeExternalLink

public void removeExternalLink(ExternalLink externalLink)
throws JAXRException

Removes specified ExternalLink from this object.

Capability Level: 0

Parameters:
public void removeExternalLinks(java.util.Collection\<E\> externalLinks) throws JAXRException

Removes specified ExternalLinks from this object.

Capability Level: 0

Parameters:
- externalLinks - the Collection of ExternalLinks being removed

Throws:
- JAXRException - If the JAXR provider encounters an internal error
setExternalLinks

void setExternalLinks(Collection externalLinks)

throws JAXRException

Replaces all previous ExternalLinks with specified ExternalLinks.

Capability Level: 0

Parameters:

externalLink - the Collection of ExternalLinks being set

Throws:

JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getExternalLinks() throws JAXRException

ExternalLink

javax.xml.registry.infomodel.ExternalLink
getExternalLinks

`Collection getExternalLinks()` throws `JAXRException`

Returns the ExternalLinks associated with this object.

**Capability Level: 0**

**Returns:**
Collection of ExternalLink instances. The Collection may be empty but not null.

**Throws:**
`JAXRException` - If the JAXR provider encounters an internal error

**See Also:**
`ExternalLink`

---

public `Concept getObjectType()` throws `JAXRException`

`RegistryObject`

1

`UnsupportedCapabilityException`

```
return ObjectType ClassificationScheme Concept
```  

**Throws:**
`JAXRException`: JAXR

---

getObjectType

`Concept getObjectType()` throws `JAXRException`

Gets the object type that best describes the RegistryObject.

**Capability Level: 1**
This method must throw UnsupportedCapabilityException in lower capability levels.

**Returns:**
the object type as a Concept within the pre-defined ClassificationScheme named ObjectType

**Throws:**
  - JAXRException - If the JAXR provider encounters an internal error

```java
public Organization getSubmittingOrganization() throws JAXRException
```

**getSubmittingOrganization**

**Returns:**
the Organization that submitted this object to the registry

**Throws:**
  - JAXRException - If the JAXR provider encounters an internal error

```java
public java.util.Collection<E> getRegistryPackages() throws JAXRException
```

Method Detail

public void addRegistryObject(RegistryObject registryObject) throws JAXRException
RegistryObject

1

registryObject RegistryObject
Throws JAXRException: JAXR

addRegistryObject

void addRegistryObject(RegistryObject registryObject) throws JAXRException

Adds a child RegistryObject as member.

Capability Level: 1

Parameters:
registryObject - the RegistryObject being added

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void addRegistryObjects(java.util.Collection<E> registryObjects) throws JAXRException
RegistryObject Collection
addRegistryObjects

void addRegistryObjects(Collection registryObjects)
throws JAXRException

Adds a Collection of RegistryObject children as members.

Capability Level: 1

Parameters:
registryObjects - the Collection of RegistryObjects being added

Throws:
JAXRException - If the JAXR provider encounters an internal error

removeRegistryObject

void removeRegistryObject(RegistryObject registryObject)
throws JAXRException

Removes a child RegistryObject from membership.
Capability Level: 1

Parameters:
   registryObject - the RegistryObject being removed

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public void removeRegistryObjects(java.util.Collection<E> registryObjects) throws JAXRException
RegistryObject Collection

removeRegistryObjects

void removeRegistryObjects(Collection registryObjects)
   throws JAXRException

Removes a Collection of children RegistryObjects from membership.

Capability Level: 1

Parameters:
   registryObjects - the Collection of RegistryObject being removed

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public java.util.Set<E> getRegistryObjects() throws JAXRException
return RegistryObject Set
Throws JAXRException: JAXR

getRegistryObjects

Set getRegistryObjects()
throws JAXRException

Gets the collection of member RegistryObjects of this RegistryPackage.

Capability Level: 1

Returns: the Set of RegistryObjects that are members of this object
Throws: JAXRException - If the JAXR provider encounters an internal error

**Method Detail**

```java
public CapabilityProfile getCapabilityProfile() throws JAXRException
JAXR CapabilityProfile

0

return JAXR CapabilityProfile

Throws JAXRException: JAXR

associates <{javax.xml.registry.CapabilityProfile}>

See also javax.xml.registry.LifeCycleManager
```

getCapabilityProfile

`CapabilityProfile getCapabilityProfile()` throws `JAXRException`

Returns the CapabilityProfile for the JAXR provider.

**Capability Level:** 0

**Returns:**

the CapabilityProfile for a JAXR provider
public **BusinessLifeCycleManager**

getBusinessLifeCycleManager() throws **JAXRException**

JAXR BusinessLifeCycleManager

0

```java
return BusinessLifeCycleManager
Throws JAXRException: JAXR
associates <javax.xml.registry.BusinessLifeCycleManager>
See also javax.xml.registry.LifeCycleManager
```

**getBusinessLifeCycleManager**

**BusinessLifeCycleManager** getBusinessLifeCycleManager() throws **JAXRException**

Returns the BusinessLifeCycleManager object implemented by the JAXR provider.

**Capability Level:** 0

**Returns:**
the BusinessLifeCycleManager

**Throws:**

**JAXRException** - If the JAXR provider encounters an internal error

**See Also:**
**LifeCycleManager**
public **BusinessQueryManager** getBusinessQueryManager() throws **JAXRException**

JAXR **BusinessQueryManager**

```java
return BusinessQueryManager
Throws JAXRException: JAXR
associates <{BusinessQueryManager}> directed
```

**getBusinessQueryManager**

```java
BusinessQueryManager getBusinessQueryManager() throws JAXRException

Returns the BusinessQueryManager object implemented by the JAXR provider.

**Capability Level: 0**

**Returns:**
the BusinessQueryManager

**Throws:**
JAXRException - If the JAXR provider encounters an internal error
```

public **DeclarativeQueryManager** getDeclarativeQueryManager() throws **JAXRException**, **UnsupportedCapabilityException**

JAXR **DeclarativeQueryManager**

```java
1
return DeclarativeQueryManager
```
**getDeclarativeQueryManager**

`DeclarativeQueryManager getDeclarativeQueryManager()` throws `JAXRException`

Returns the DeclarativeQueryManager object implemented by the JAXR provider.

**Capability Level: 1**

**Returns:**
the DeclarativeQueryManager

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error
- `UnsupportedCapabilityException`

```java
public BulkResponse getBulkResponse(String requestId) throws InvalidRequestException, JAXRException
    requestId BulkResponse requestId
BulkResponse requestId Bulkresponse
InvalidRequestException
```

**requestId** ID
**return** BulkResponse
**Throws** `InvalidRequestException`: requestId
**Throws** `JAXRException`: JAXR
getBulkResponse

BulkResponse getBulkResponse(String requestId) throws InvalidRequestException, JAXRException

Returns the BulkResponse associated with specified requestId. Once a client retrieves a BulkResponse for a particular requestId any subsequent calls to retrieve the Bulkresponse for the same requestId should result in an InvalidRequestException.

Capability Level: 0

Parameters:
requestId - the id for a previous asynchronous request

Returns:
The BulkResponse that contains the result for the specified request

Throws:
InvalidRequestException - if no responses exist for specified requestId
JAXRException - If the JAXR provider encounters an internal error

public ClassificationScheme getDefaultPostalScheme() throws JAXRException

PostalAddress

0

return ClassificationScheme

Throws JAXRException: JAXR

getDefaultPostalScheme

ClassificationScheme getDefaultPostalScheme() throws JAXRException
Gets the default user-defined postal scheme for codifying the attributes of PostalAddress.

**Capability Level: 0**

**Returns:**
the ClassificationScheme that is the default postal scheme

**Throws:**
  - `JAXRException` - If the JAXR provider encounters an internal error

```java
public String makeRegistrySpecificRequest(String request) throws JAXRException {
    String returnString = ...;
    return returnString;
}
```

**makeRegistrySpecificRequest**

`String makeRegistrySpecificRequest(String request) throws JAXRException` - Takes a String that is an XML request in a registry-specific format, sends the request to the registry, and returns a String that is the registry-specific XML response.

**Capability Level: 0**

**Parameters:**
request - the registry-specific request in a String representation

**Returns:**
the String that is the XML response in a registry-specific manner
Throws:

`JAXRException` - If the JAXR provider encounters an internal error
javax.ejb  Annotation Type Remote

```
@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface Remote
```

**Implements:** Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)

Bean value()

Declares the remote business interface(s) for a session bean. When used on an interface, designates that interface as a remote business interface. In this case, no value() is provided.

---

### Optional Element Summary

@Target(value=METHOD)
@Retention(value=RUNTIME)
public @interface Remove

**Implements:** Annotation
@Target(value=METHOD)
@Retention(value=RUNTIME)

Bean  Bean

Applied to a business method of a stateful session bean class. Indicates that the stateful session bean is to be removed by the container after completion of the method.

<table>
<thead>
<tr>
<th>Optional Element Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>boolean retainIfException</strong></td>
</tr>
</tbody>
</table>

**abstract public boolean retainIfException()**
true  Bean

**retainIfException**

public abstract boolean retainIfException

   If true, the stateful session bean will not be removed if an exception is thrown from the designated method.

**Default:**
false
javax.ejb  Class RemoveException

java.lang.Object
   ↓ java.lang.Throwable
      ↓ java.lang.Exception
         ↓ javax.ejb.RemoveException

All Implemented Interfaces:
   Serializable

public class RemoveException
   extends Exception

Extends: Throwable > Exception

Bean  EJB  EJB  RemoveException

The RemoveException exception is thrown at an attempt to remove an EJB object when the enterprise Bean or the container does not allow the EJB object to be removed.

PS : 
A `Renderer` converts the internal representation of `UIComponent`s into the output stream (or writer) associated with the response we are creating for a particular request. Each `Renderer` knows how to render one or more `UIComponent` types (or classes), and advertises a set of render-dependent attributes that it recognizes for each supported `UIComponent`.

Families of `Renderer`s are packaged as a `RenderKit`, and together support the rendering of all of the `UIComponent`s in a view associated with a `FacesContext`. Within the set of `Renderer`s for a particular `RenderKit`, each must be uniquely identified by the `rendererType` property.

Individual `Renderer` instances will be instantiated as requested during the rendering process, and will remain in existence for the remainder of the lifetime of a web application. Because each instance may be invoked from more than one request processing thread simultaneously, they MUST be programmed in a thread-safe manner.
### Constructor Summary

**Renderer()**

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
</table>
| **String** | `convertClientId(FacesContext context, String clientId)`  
Convert the component generated client id to a form suitable for transmission to the client. |
| **void** | `decode(FacesContext context, UIComponent component)`  
Decode any new state of the specified `UIComponent` from the request contained in the specified `FacesContext`, and store that state on the `UIComponent`. |
| **void** | `encodeBegin(FacesContext context, UIComponent component)`  
Render the beginning specified `UIComponent` to the output stream or writer associated with the response we are creating. |
| **void** | `encodeChildren(FacesContext context, UIComponent component)`  
Render the child components of this `UIComponent`, following the rules described for `encodeBegin()` to acquire the appropriate value to be rendered. |
| **void** | `encodeEnd(FacesContext context, UIComponent component)`  
Render the ending of the current state of the specified `UIComponent`, following the rules described for `encodeBegin()` to acquire the appropriate value to be rendered. |
| **Object** | `getConvertedValue(FacesContext context, UIComponent component, Object submittedValue)`  
Attempt to convert previously stored state information into an object of the type required for this component (optionally using the registered `Converter` for this component, if there is one). |
| **boolean** | `getRendersChildren()`  
Return a flag indicating whether this `Renderer` is responsible for rendering the children the component it is asked to render. |
Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Constructor Detail

public Renderer()

Renderer

public Renderer()

Method Detail

public void decode(FacesContext context, UIComponent component)

FacesContext UIComponent UIComponent

UIComponent queueEvent()

context component

Throws NullPointerException: context component null

decode

public void decode(FacesContext context, UIComponent component)

Decode any new state of the specified UIComponent from the request contained in the specified FacesContext, and store that state on the UIComponent.
During decoding, events may be enqueued for later processing (by event listeners that have registered an interest), by calling queueEvent() on the associated UIComponent.

**Parameters:**
- **context** - FacesContext for the request we are processing
- **component** - UIComponent to be decoded.

**Throws:**
- NullPointerException - if context or component is null

```java
public void encodeBegin(FacesContext context, UIComponent component) throws java.io.IOException

UIComponent writer getConvertedValue()
decode()

context FacesContext
component UIComponent

Throws java.io.IOException: /
Throws NullPointerException: context component null
```

**encodeBegin**

```java
public void encodeBegin(FacesContext context, UIComponent component)
throws IOException

Render the beginning specified UIComponent to the output stream or writer associated with the response we are creating. If the conversion attempted in a previous call to getConvertedValue() for this component failed, the state information saved during execution of decode() should be used to reproduce the incorrect input.

**Parameters:**
- **context** - FacesContext for the request we are processing
- **component** - UIComponent to be rendered
public void encodeChildren(FacesContext context, UICOMPONENT component) throws java.io.IOException

    UICOMPONENT encodeBegin() rendersChildren true

    context FacesContext
    component UICOMPONENT

    Throws java.io.IOException: /
    Throws NullPointerException: context component null

**encodeChildren**

public void encodeChildren(FacesContext context, UICOMPONENT component) throws IOException

Render the child components of this UICOMPONENT, following the rules described for encodeBegin() to acquire the appropriate value to be rendered. This method will only be called if the rendersChildren property of this component is true.

**Parameters:**

context - FacesContext for the response we are creating
component - UICOMPONENT whose children are to be rendered

**Throws:**

IOException - if an input/output error occurs while rendering
NullPointerException - if context or component is null

public void encodeEnd(FacesContext context, UICOMPONENT component) throws java.io.IOException
**encodeBegin()**

```
context
component
```

**Throws**
- `java.io.IOException: /`
- `NullPointerException: context component null`

**encodeEnd**

```
public void encodeEnd(FacesContext context, UIComponent component)
throws IOException
```

Render the ending of the current state of the specified `UIComponent`, following the rules described for `encodeBegin()` to acquire the appropriate value to be rendered.

**Parameters:**
- `context` - `FacesContext` for the response we are creating
- `component` - `UIComponent` to be rendered

**Throws:**
- `IOException` - if an input/output error occurs while rendering
- `NullPointerException` - if context Or component is null

```
public String convertClientId(FacesContext context, String clientId)
```

**ID**

```
clientId
```

**Throws**
- `NullPointerException: context clientId null`
**convertClientId**

```java
public String convertClientId(FacesContext context, String clientId)
```

Convert the component generated client id to a form suitable for transmission to the client.

The default implementation returns the argument `clientId` unchanged.

**Parameters:**
- `context` - `FacesContext` for the current request
- `clientId` - the client identifier to be converted to client a specific format.

**Throws:**
- `NullPointerException` - if `context` or `clientId` is null

---

**public boolean getRendersChildren()**

```java
Renderer false
```

**getRendersChildren**

```java
public boolean getRendersChildren()
```

Return a flag indicating whether this `Renderer` is responsible for rendering the children the component it is asked to render. The default implementation returns `false`.

---

**public Object getConvertedValue(FacesContext context, UIComponent component, Object submittedValue) throws ConverterException**
javax.faces.convert.Converter

ConverterException

context context
component component
submittedValue submittedValue

Throws ConverterException:
Throws NullPointerException:

getConvertedValue

public Object getConvertedValue(FacesContext context, UIComponent component, Object submittedValue)
throws ConverterException

Attempt to convert previously stored state information into an object of the type required for this component (optionally using the registered Converter for this component, if there is one). If conversion is successful, the new value should be returned from this method; if not, a ConverterException should be thrown.

Parameters:
context - FacesContext for the request we are processing
component - UIComponent to be decoded.
submittedValue - a value stored on the component during decode.

Throws:
ConverterException - if the submitted value cannot be converted successfully.
NullPointerException - if context or component is null

Factory

JavaServer Faces Web RenderKit RenderKitFactory
getRenderKit() RenderKit RenderKit
javax.faces.application.ViewHandler

RenderKit ResponseStateManager

RenderKit represents a collection of Renderer instances that, together, know how to render JavaServer Faces UICOMPONENT instances for a specific client. Typically, RenderKits are specialized for some combination of client device type, markup language, and/or user Locale. A RenderKit also acts as a Factory for associated Renderer instances, which perform the actual rendering process for each component.

A typical JavaServer Faces implementation will configure one or more RenderKit instances at web application startup. They are made available through calls to the getRenderKit() methods of RenderKitFactory. Because RenderKit instances are shared, they must be implemented in a thread-safe manner. Due to limitations in the current specification having multiple RenderKit instances at play in the same application requires a custom ViewHandler instance that is aware of how to deal with this case. This limitation will be lifted in a future version of the spec.
The RenderKit instance must also vend a ResponseStateManager instance, which is used in the process of saving and restoring tree structure and state.

family rendererType Renderer Renderer
Renderer Renderer

renderer

Throws

NullPointerException: family rendererType renderer null

addRenderer

public abstract void addRenderer(String family,
String rendererType,
Renderer renderer)

Register the specified Renderer instance, associated with the specified component family and rendererType, to the set of
Renderer s registered with this RenderKit, replacing any previously registered Renderer for this combination of identifiers.

Parameters:
- family - Component family of the Renderer to register
- rendererType - Renderer type of the Renderer to register
- renderer - Renderer instance we are registering

Throws:
- NullPointerException - if family or rendererType or renderer is null

abstract public Renderer getRenderer(String family, String rendererType)

family  rendererType  Renderer  null

family  Rendered  Renderer
rendererType  Rendered  Renderer

Throws  NullPointerException:  family  rendererType  null

getRenderer

public abstract Renderer getRenderer(String family, String rendererType)

Return the Renderer instance most recently registered for the specified component family and rendererType, if any; otherwise, return null.

Parameters:
- family - Component family of the requested Renderer instance
- rendererType - Renderer type of the requested Renderer instance

Throws:
- NullPointerException - if family or rendererType is null
abstract public **ResponseStateManager** getResponseStateManager()

**ResponseStateManager**

getResponseStateManager

public abstract **ResponseStateManager** getResponseStateManager()

Return an instance of **ResponseStateManager** to handle rendering technology specific state management decisions.

abstract public **ResponseWriter**

createResponseWriter(java.io.Writer writer, String contentTypeList, String characterEncoding)

**ResponseWriter**

```
javax.servlet.ServletResponse getCharacterEncoding()
```

writer **ResponseWriter** writer

```
"Accept (Accept header style)"
```

RenderKit **null** RenderKit "Accept"

```

```
Accept Accept
```

RFC 2616_14.1

```
"ISO-8859-1"
```

ResponseWriter **null** the IANA

characterEncoding

```
null
```

**ResponseWriter**

`Throws` **IllegalArgumentException**: contentTypeList

characterEncoding
createResponseWriter

public abstract ResponseWriter createResponseWriter(Writer writer, String contentTypeList, String characterEncoding)

Use the provided Writer to create a new ResponseWriter instance for the specified (optional) content type, and character encoding.

Implementors are advised to consult the getCharacterEncoding() method of class ServletResponse to get the required value for the characterEncoding for this method. Since the Writer for this response will already have been obtained (due to it ultimately being passed to this method), we know that the character encoding cannot change during the rendering of the response.

Parameters:
- writer - the Writer around which this ResponseWriter must be built.
- contentTypeList - an "Accept header style" list of content types for this response, or null if the RenderKit should choose the best fit. As of the current version, the values accepted by the Standard render-kit for this parameter include any valid "Accept header style" String that includes the String text/html, application/xhtml+xml, application/xml or text/xml. This may change in a future version. The RenderKit must support a value for this argument that comes straight from the Accept HTTP header, and therefore requires parsing according to the specification of the Accept header. Please see Section 14.1 of RFC 2616 for the specification of the Accept header.
- characterEncoding - such as "ISO-8859-1" for this ResponseWriter, or null if the RenderKit should choose the best fit. Please see the IANA for a list of character encodings.

Returns: a new ResponseWriter.

Throws:
- IllegalArgumentException - if no matching content type can be found in contentTypeList, no appropriate content type can be found with the implementation dependent best fit algorithm, or no matching character encoding can be found for the argument.
abstract public ResponseStream createResponseStream(java.io.OutputStream out)

OutputStream ResponseStream

createResponseStream

public abstract ResponseStream createResponseStream(OutputStream out)

Use the provided OutputStream to create a new ResponseStream instance.
**javax.faces.render** Class **RenderKitFactory**

**java.lang.Object**
   ∧ **javax.faces.render.RenderKitFactory**

```
public abstract class RenderKitFactory
extends Object
```

**RenderKitFactory**  
**RenderKit**  
**JavaServer Faces**  
**Web**  
**RenderKitFactory**

```
RenderKitFactory factory = (RenderKitFactory) FactoryFinder.getFactory(FactoryFinder.RENDER_KIT_FACTORY);
```

**RenderKitFactory** is a factory object that registers and returns **RenderKit** instances. Implementations of JavaServer Faces must provide at least a default implementation of **RenderKit**. Advanced implementations (or external third party libraries) may provide additional **RenderKit** implementations (keyed by render kit identifiers) for performing different types of rendering for the same components.

There must be one **RenderKitFactory** instance per web application that is utilizing JavaServer Faces. This instance can be acquired, in a portable manner, by calling:

```
RenderKitFactory factory = (RenderKitFactory) FactoryFinder.getFactory(FactoryFinder.RENDER_KIT_FACTORY);
```

---

**Field Summary**
<table>
<thead>
<tr>
<th>Field Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>HTML_BASIC_RENDER_KIT</strong></td>

</tbody>
</table>

The render kit identifier of the default `RenderKit` instance for this JavaServer Faces implementation.

### Constructor Summary

#### `RenderKitFactory()`

### Method Summary

#### `abstract void addRenderKit(String renderKitId, RenderKit renderKit)`

- Register the specified `RenderKit` instance, associated with the specified `renderKitId`, to be supported by this `RenderKitFactory`, replacing any previously registered `RenderKit` for this identifier.

#### `abstract RenderKit getRenderKit(FacesContext context, String renderKitId)`

- Return a `RenderKit` instance for the specified render kit identifier, possibly customized based on dynamic characteristics of the specified `FacesContext`, if non-null.

#### `abstract Iterator<String> getRenderKitIds()`

- Return an `Iterator` over the set of render kit identifiers registered with this factory.

*Methods inherited from class java.lang.Object*

- `clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait`
public static final String HTML_BASIC_RENDER_KIT

The render kit identifier of the default RenderKit instance for this JavaServer Faces implementation.

Constructor Detail

public RenderKitFactory()

Method Detail

abstract public void addRenderKit(String renderKitId, RenderKit renderKit)

void addRenderKit(String renderKitId, RenderKit renderKit)

Throws

NullPointerException: renderKitId null

addRenderKit

public abstract void addRenderKit(String renderKitId, RenderKit renderKit)

null

Register the specified RenderKit instance, associated with the
specified renderKitId, to be supported by this RenderKitFactory, replacing any previously registered RenderKit for this identifier.

Parameters:
- renderKitId - Identifier of the RenderKit to register
- renderKit - RenderKit instance that we are registering

Throws:
- NullPointerException - if renderKitId or renderKit is null

abstract public RenderKit getRenderKit(FacesContext context, String renderKitId)

Return a RenderKit instance for the specified render kit identifier, possibly customized based on dynamic characteristics of the specified FacesContext, if non-null. If there is no registered RenderKit for the specified identifier, return null. The set of available render kit identifiers is available via the getRenderKitIds() method.

Parameters:
- context - FacesContext for the request currently being processed, or null if none is available.
- renderKitId - Render kit identifier of the requested RenderKit instance
Throws:

- `IllegalArgumentException` - if no `RenderKit` instance can be returned for the specified identifier
- `NullPointerException` - if `renderKitId` is `null`

abstract public java.util.Iterator<E> getRenderKitIds()

```
Iterator RenderKitFactory.HTML_BASIC_RENDER_KIT
```

getRenderKitIds

code

class

public abstract Iterator<String> getRenderKitIds()

Return an `Iterator` over the set of render kit identifiers registered with this factory. This set must include the value specified by `RenderKitFactory.HTML_BASIC_RENDER_KIT`.

javax.servlet Interface RequestDispatcher

public interface RequestDispatcher

servletHTML  JSP servlet

servlet servlet RequestDispatcher

See also
getRequestDispatcher(java.lang.String),
getNamedDispatcher(java.lang.String),
getRequestDispatcher(java.lang.String)

Defines an object that receives requests from the client and sends them to any resource (such as a servlet, HTML file, or JSP file) on the server. The servlet container creates the RequestDispatcher object, which is used as a wrapper around a server resource located at a particular path or given by a particular name.

This interface is intended to wrap servlets, but a servlet container can create RequestDispatcher objects to wrap any type of resource.

Author:
Various

ServletContext.getRequestDispatcher(java.lang.String),
ServletContext.getNamedDispatcher(java.lang.String),
ServletRequest.getRequestDispatcher(java.lang.String)

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>forward</strong> (ServletRequest request, ServletResponse response)</td>
</tr>
<tr>
<td>Forwards a request from a servlet to another resource (servlet, JSP file, or HTML file) on the server.</td>
</tr>
</tbody>
</table>
**Method Detail**

```java
class MethodDetail {
    public void forward(ServletRequest request, ServletResponse response) throws ServletException, java.io.IOException {
        ServletRequestWrapper request = (ServletRequestWrapper) request;
        ServletResponseWrapper response = (ServletResponseWrapper) response;

        ServletRequest wrappedRequest = request.getWrappedRequest();
        ServletResponse wrappedResponse = response.getWrappedResponse();

        // method implementation...
    }
}
```

Forwards a request from a servlet to another resource (servlet, JSP file, or HTML file) on the server. This method allows one servlet to do...
preliminary processing of a request and another resource to
generate the response.

For a RequestDispatcher obtained via getRequestDispatcher(), the
ServletRequest object has its path elements and parameters
adjusted to match the path of the target resource.

forward should be called before the response has been committed to
the client (before response body output has been flushed). If the
response already has been committed, this method throws an
IllegalStateException. Uncommitted output in the response buffer is
automatically cleared before the forward.

The request and response parameters must be either the same
objects as were passed to the calling servlet's service method or be
subclasses of the ServletRequestWrapper or ServletResponseWrapper
classes that wrap them.

Parameters:
request - a ServletRequest object that represents the request
the client makes of the servlet
response - a ServletResponse object that represents the
response the servlet returns to the client

Throws:
ServletException - if the target resource throws this exception
IOException - if the target resource throws this exception
IllegalStateException - if the response was already committed

public void include(ServletRequest request,
ServletResponse response) throws ServletException,
java.io.IOException
servletJSP  HTML

ServletResponse  servlet

request  response  servlet service
ServletRequestWrapper  ServletResponseWrapper
include

void include(ServletRequest request,
              ServletResponse response)
  throws ServletException,
         IOException

Includes the content of a resource (servlet, JSP page, HTML file) in the response. In essence, this method enables programmatic server-side includes.

The ServletResponse object has its path elements and parameters remain unchanged from the caller's. The included servlet cannot change the response status code or set headers; any attempt to make a change is ignored.

The request and response parameters must be either the same objects as were passed to the calling servlet's service method or be subclasses of the ServletRequestWrapper or ServletResponseWrapper classes that wrap them.

Parameters:

request - a ServletRequest object that contains the client's request
response - a ServletResponse object that contains the servlet's response

Throws:

ServletException - if the included resource throws this exception
IOException - if the included resource throws this exception

@Retention(value=RUNTIME)  
@Documented

bean  WebMethod  localName  operationName  
targetNamespace  SEI

Java  className

   since  JAX-WS 2.0

See also  javax.jws.WebMethod

Usage:

Used to annotate methods in the Service Endpoint Interface with the request wrapper bean to be used at runtime. The default value of the localName is the operationName, as defined in WebMethod annotation and the targetNamespace is the target namespace of the SEI.

When starting from Java this annotation is used to resolve overloading conflicts in document literal mode. Only the className is required in this case.

Since:
   JAX-WS 2.0

PS :
javax.annotation  Annotation Type Resource

@Target(value={TYPE, FIELD, METHOD})
@Retention(value=RUNTIME)
public @interface Resource

Implements: Annotation
Inner classes: Resource.AuthenticationType
@Target(value={TYPE, FIELD, METHOD})
@Retention(value=RUNTIME)

Resource

Inherited private

The Resource annotation marks a resource that is needed by the application. This annotation may be applied to an application component class, or to fields or methods of the component class. When the annotation is applied to a field or method, the container will inject an instance of the requested resource into the application component when the component is initialized. If the annotation is applied to the component class, the annotation declares a resource that the application will look up at runtime.

Even though this annotation is not marked Inherited, deployment tools are required to examine all superclasses of any component class to discover all uses of this annotation in all superclasses. All such annotation instances specify resources that are needed by the application component. Note that this annotation may appear on private fields and methods of superclasses; the container is required to perform injection in these cases as well.

Optional Element Summary

[authentication]
<table>
<thead>
<tr>
<th><strong>Resource.AuthenticationType</strong></th>
<th>The authentication type to use for this resource.</th>
</tr>
</thead>

<td><strong>type</strong></td>
</tr>
<tr>
<td></td>
<td>The Java type of the resource.</td>
</tr>
</tbody>
</table>

```java
abstract public String name()

JNDI  JavaBean
```

**name**

```
public abstract String name
```

The JNDI name of the resource. For field annotations, the default is the field name. For method annotations, the default is the JavaBeans property name corresponding to the method. For class annotations, there is no default and this must be specified.

**Default:**

```
"
```

---

```java
abstract public Class<T> type()

Java  JavaBean
```
type

public abstract Class type

The Java type of the resource. For field annotations, the default is the type of the field. For method annotations, the default is the type of the JavaBeans property. For class annotations, there is no default and this must be specified.

Default:
java.lang.Object.class

abstract public Resource.AuthenticationType authentication()

authentication

public abstract Resource.AuthenticationType authentication

The authentication type to use for this resource. This may be specified for resources representing a connection factory of any supported type, and must not be specified for resources of other types.

Default:
CONTAINER

abstract public boolean shareable()

shareable
public abstract boolean shareable

    Indicates whether this resource can be shared between this component and other components. This may be specified for resources representing a connection factory of any supported type, and must not be specified for resources of other types.

    Default:
    true

abstract public String mappedName()

    A product specific name that this resource should be mapped to. The name of this resource, as defined by the name element or defaulted, is a name that is local to the application component using the resource. (It's a name in the JNDI java:comp/env namespace.) Many application servers provide a way to map these local names to names of resources known to the application server. This mapped name is often a global JNDI name, but may be a name of any form.

    Application servers are not required to support any particular form or type of mapped name, nor the ability to use mapped names. The mapped name is product-dependent and often installation-dependent. No use of a mapped name is portable.

    Default:
    ""
abstract public String description()

description

public abstract String description

Description of this resource. The description is expected to be in the default language of the system on which the application is deployed. The description can be presented to the Deployer to help in choosing the correct resource.

Default:

"""

Method Detail

final public static Resource.AuthenticationType[] values()
Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(Resource.AuthenticationType c : Resource.AuthenticationType.values())
    System.out.println(c);
```

**Returns:**

an array containing the constants of this enum type, in the order they're declared

---

```java
public static Resource.AuthenticationType valueOf(String name)
```

**valueOf**

```java
public static Resource.AuthenticationType valueOf(String name)
```

Returns the enum constant of this type with the specified name. The string must match *exactly* an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**

- `name` - the name of the enum constant to be returned.

**Returns:**

the enum constant with the specified name

**Throws:**

`IllegalArgumentException` - if this enum type has no constant with the specified name
to license terms.

PS:
javax.resource.spi  Interface ResourceAdapter

public interface ResourceAdapter

JavaBean

version 1.0

This represents a resource adapter instance and contains operations for lifecycle management and message endpoint setup. A concrete implementation of this interface is required to be a JavaBean.

Version: 1.0
Author: Ram Jeyaraman

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>endpointActivation(MessageEndpointFactory endpointFactory, ActivationSpec spec)</code></td>
<td>This is called during the activation of a message endpoint.</td>
</tr>
<tr>
<td><code>endpointDeactivation(MessageEndpointFactory endpointFactory, ActivationSpec spec)</code></td>
<td>This is called when a message endpoint is deactivated.</td>
</tr>
<tr>
<td><code>getXAResources(ActivationSpec[] specs)</code></td>
<td>This method is called by the application server during crash recovery.</td>
</tr>
<tr>
<td><code>start(BootstrapContext ctx)</code></td>
<td>This is called when a resource adapter instance is bootstrapped.</td>
</tr>
<tr>
<td><code>stop()</code></td>
<td>This is called when a resource adapter instance is undeployed or during application server shutdown.</td>
</tr>
</tbody>
</table>
public void start(BootstrapContext ctx) throws ResourceAdapterInternalException

ResourceAdapter JavaBean

ctx

Throws ResourceAdapterInternalException:

start

void start(BootstrapContext ctx)
    throws ResourceAdapterInternalException

This is called when a resource adapter instance is bootstrapped. This may be during resource adapter deployment or application server startup. This is a startup notification from the application server, and this method is called by an application server thread. The application server thread executes in an unspecified context.

During this method call a ResourceAdapter JavaBean is responsible for initializing the resource adapter instance. Any exception thrown during this method call causes the application server to abort the bootstrap procedure for this specific resource adapter instance.

Parameters:
    ctx - a bootstrap context containing references to useful facilities that could be used by a resource adapter instance.

Throws:
    ResourceAdapterInternalException - indicates bootstrap failure. The resource adapter instance is unusable and must be discarded.
public void stop()

ResourceAdapter JavaBean

stop

void stop()

This is called when a resource adapter instance is undeployed or during application server shutdown. This is a shutdown notification from the application server, and this method is called by an application server thread. The application server thread executes in an unspecified context.

During this method call, a ResourceAdapter JavaBean is responsible for performing an orderly shutdown of the resource adapter instance. Any exception thrown by this method call does not alter the processing of the application server shutdown or resource adapter undeployment that caused this method call. The application server may log the exception information for error reporting purposes.

public void endpointActivation(MessageEndpointFactory endpointFactory, ActivationSpec spec) throws ResourceException

endpointFactory
  spec
  Throws

spec
  JavaBean
  NotSupportedException:
endpointActivation

void endpointActivation(MessageEndpointFactory endpointFactory, 
    ActivationSpec spec) 
    throws ResourceException

This is called during the activation of a message endpoint. This causes the resource adapter instance to do the necessary setup (ie., setup message delivery for the message endpoint with a message provider). Note that message delivery to the message endpoint might start even before this method returns.

Endpoint activation is deemed successful only when this method completes successfully without throwing any exceptions.

Parameters:
    endpointFactory - a message endpoint factory instance.
    spec - an activation spec JavaBean instance.

Throws:
    NotSupportedException - indicates message endpoint activation rejection due to incorrect activation setup information.
    ResourceException

public void endpointDeactivation(MessageEndpointFactory endpointFactory, ActivationSpec spec)

endpointActivation

endpointFactory
    spec JavaBean

endpointDeactivation

void endpointDeactivation(MessageEndpointFactory endpointFactory, 
    ActivationSpec spec)
This is called when a message endpoint is deactivated. The instances passed as arguments to this method call should be identical to those passed in for the corresponding endpointActivation call. This causes the resource adapter to stop delivering messages to the message endpoint.

Any exception thrown by this method is ignored. After this method call, the endpoint is deemed inactive.

**Parameters:**
- endpointFactory - a message endpoint factory instance.
- spec - an activation spec JavaBean instance.

```java
public XAResource[] getXAResources(ActivationSpec[] specs) throws ResourceException
```

**Throws** ResourceException:

<table>
<thead>
<tr>
<th>XAResource null</th>
<th>XAResource</th>
</tr>
</thead>
<tbody>
<tr>
<td>specs</td>
<td>ActivationSpec JavaBean JavaBean</td>
</tr>
</tbody>
</table>

This method is called by the application server during crash recovery. This method takes in an array of ActivationSpec JavaBeans and returns an array of XAResource objects each of which represents a unique resource manager. The resource adapter may return null if it does not implement the XAResource interface. Otherwise, it must return an array of XAResource objects, each of which represents a unique resource manager that was used by the endpoint applications. The application server uses the XAResource objects to query each resource manager for a list of in-doubt
transactions. It then completes each pending transaction by sending the commit decision to the participating resource managers.

**Parameters:**

specs - an array of ActivationSpec JavaBeans each of which corresponds to an deployed endpoint application that was active prior to the system crash.

**Returns:**

an array of XAResource objects each of which represents a unique resource manager.

**Throws:**

ResourceException - generic exception if operation fails due to an error condition.

This interface specifies the methods to associate a ResourceAdapter object with other objects that implement this interface like ManagedConnectionFactory and ActivationSpec.

Version:
   1.0

Author:
   Ram Jeyaraman

### Method Summary

<table>
<thead>
<tr>
<th>ResourceAdapter</th>
<th>getRA()</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get the associated ResourceAdapter object.</td>
<td></td>
</tr>
</tbody>
</table>

| void | setRA(ResourceAdapter ra) |
| Associate this object with a ResourceAdapter object. |

### Method Detail
public ResourceAdapter getResourceAdapter()

ResourceAdapter

return ResourceAdapter

getResourceAdapter

ResourceAdapter getResourceAdapter()

Get the associated ResourceAdapter object.

Returns:

the associated ResourceAdapter object.

public void setResourceAdapter(ResourceAdapter ra)
throws ResourceException

ResourceAdapter

ra

ResourceAdapter

Throws ResourceException:

Throws ResourceAdapterInternalException:

Throws IllegalStateException:

setResourceAdapter

void setResourceAdapter(ResourceAdapter ra)
throws ResourceException

Associate this object with a ResourceAdapter object. Note, this method must be called exactly once. That is, the association must not change during the lifetime of this object.

Parameters:

ra - ResourceAdapter object to be associated with.

Throws:

ResourceException - generic exception.

ResourceAdapterInternalException - resource adapter related
error condition.

IllegalStateException - indicates that this object is in an illegal state for the method invocation. For example, this occurs when this method is called more than once on the same object.
Class

javax.resource.spi Class ResourceAdapterInternalException

java.lang.Object
  \  \ java.lang.Throwable
    \  \ java.lang.Exception
      \  \ javax.resource.ResourceException
        \  \ javax.resource.spi.ResourceAdapterInternalException

All Implemented Interfaces:
  Serializable

public class ResourceAdapterInternalException extends ResourceException

Extends: Throwable > Exception > ResourceException

ResourceAdapterInternalException

  • EIS
  • EIS
  •

version 1.0

A ResourceAdapterInternalException indicates any system-level error conditions related to a resource adapter. The common conditions indicated by this exception type are:

  • Invalid configuration for creation of a new physical connection. An example is invalid server name for a target EIS instance.
  • Failure to create a physical connection to a EIS instance due to communication protocol error or any resource adapter implementation specific error.
  • Error conditions internal to resource adapter implementation.

Method Summary

Methods inherited from class `javax.resource.ResourceException`
- `getErrorCode`, `getLinkedException`, `getMessage`, `setErrorCause`, `setLinkedException`

Methods inherited from class `java.lang.Throwable`
- `fillInStackTrace`, `getCause`, `getLocalizedMessage`, `getStackTrace`, `initCause`, `printStackTrace`, `printStackTrace`, `printStackTrace`, `setStackTrace`, `toString`

Methods inherited from class `java.lang.Object`
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, 
Constructor Detail

public ResourceAdapterInternalException()

null

ResourceAdapterInternalException

public ResourceAdapterInternalException()

Constructs a new instance with null as its detail message.

public ResourceAdapterInternalException(String message)

message

ResourceAdapterInternalException

public ResourceAdapterInternalException(String message)

Constructs a new instance with the specified detail message.

Parameters:
message - the detail message.

public ResourceAdapterInternalException(Throwable cause)

cause throwable

cause Throwable
ResourceAdapterInternalException

public ResourceAdapterInternalException(Throwable cause)

Constructs a new throwable with the specified cause.

**Parameters:**
- cause - a chained exception of type Throwable.

---

public ResourceAdapterInternalException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

**Parameters:**
- message - the detail message.
- cause - a chained exception of type Throwable.

---

public ResourceAdapterInternalException(String message, String errorCode)

Constructs a new throwable with the specified message and cause.

**Parameters:**
- message - the detail message.
- errorCode - the error code.
ResourceAdapterInternalException

public ResourceAdapterInternalException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

PS:
The interface `javax.resource.cci.ResourceAdapterMetaData` provides information about capabilities of a resource adapter implementation. Note that this interface does not provide information about an EIS instance that is connected through the resource adapter.

A CCI client uses a `ConnectionFactory.getMetaData` to get metadata information about the resource adapter. The `getMetaData` method does not require that an active connection to an EIS instance should have been established.

The `ResourceAdapterMetaData` can be extended to provide more information specific to a resource adapter implementation.

</tbody>
</table>
public String getAdapterVersion()

    return

getAdapterVersion

String getAdapterVersion()

    Gets the version of the resource adapter.

    Returns:
    String representing version of the resource adapter

public String getAdapterVendorName()

    return

getAdapterVendorName

String getAdapterVendorName()

    Gets the name of the vendor that has provided the resource adapter.

    Returns:
    String representing name of the vendor that has provided the resource adapter

public String getAdapterName()
getAdapterName

String getAdapterName()

Gets a tool displayable name of the resource adapter.

Returns:
String representing the name of the resource adapter

getAdapterShortDescription

String getAdapterShortDescription()

Gets a tool displayable short description of the resource adapter.

Returns:
String describing the resource adapter

getSpecVersion

String getSpecVersion()

Returns a string representation of the version of the connector
architecture specification that is supported by the resource adapter.

**Returns:**
String representing the supported version of the connector architecture

```
public String[] getInteractionSpecsSupported()
CCI InteractionSpec InteractionSpec
InteractionSpec CCI InteractionSpec 0

return CCI InteractionSpec
See alsojavax.resource.cci.InteractionSpec
```

getInteractionSpecsSupported

```
String[] getInteractionSpecsSupported()

Returns an array of fully-qualified names of InteractionSpec types supported by the CCI implementation for this resourceSpec adapter. Note that the fully-qualified class name is for the implementation class of an InteractionSpec. This method may be used by tools vendor to find information on the supported InteractionSpec types. The method should return an array of length 0 if the CCI implementation does not define specific InteractionSpec types.

**Returns:**
Array of fully-qualified class names of InteractionSpec classes supported by this resource adapter's CCI implementation

See Also:
InteractionSpec
```

generic supportsExecuteWithInputAndOutputRecord()

```
public boolean supportsExecuteWithInputAndOutputRecord()
```

supportsExecuteWithInputAndOutputRecord

boolean supportsExecuteWithInputAndOutputRecord()

Returns true if the implementation class for the Interaction interface implements public boolean execute(InteractionSpec ispec, Record input, Record output) method; otherwise the method returns false.

Returns:
boolean depending on method support

See Also:
Interaction
public boolean supportsLocalTransactionDemarcation()

    LocalTransaction LocalTransaction  EIS  true

        return  LocalTransaction  true false

See also  javax.resource.cci.LocalTransaction

supportsLocalTransactionDemarcation

boolean  supportsLocalTransactionDemarcation()

    Returns  true if the resource adapter implements the
    LocalTransaction interface and supports local transaction
    demarcation on the underlying EIS instance through the
    LocalTransaction interface.

    Returns:
    true if resource adapter supports resource manager local
    transaction demarcation through LocalTransaction interface;
    false otherwise

### Methods inherited from class java.lang.Object

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `wait`, `wait`, `wait`
public ResourceAllocationException(String reason, String errorCode)

Constructs a ResourceAllocationException with the specified reason and error code.

Parameters:
- reason - a description of the exception
- errorCode - a string specifying the vendor-specific error code

public ResourceAllocationException(String reason)

ResourceAllocationException null reason

ResourceAllocationException

public ResourceAllocationException(String reason)

Constructs a ResourceAllocationException with the specified reason. The error code defaults to null.

Parameters:
- reason - a description of the exception

All Implemented Interfaces:
  Serializable

public class ResourceAllocationException
  extends RuntimeException

Extends: Throwable > Exception > RuntimeException

ResourceAllocationException
  version 1.0

A ResourceAllocationException can be thrown by an application server or resource adapter to indicate any failure to allocate system resources (example: threads, physical connections). An example is error condition when an upper bound is reached on the maximum number of physical connections that can be managed by an application server specific connection pool.

ResourceAllocationException

public ResourceAllocationException()

    Constructs a new instance with null as its detail message.

-------------------

public ResourceAllocationException(String message)

    message

ResourceAllocationException

public ResourceAllocationException(String message)

    Constructs a new instance with the specified detail message.

    Parameters:
    message - the detail message.

-------------------

public ResourceAllocationException(Throwables acuse)

    cause Throwable

ResourceAllocationException

public ResourceAllocationException(Throwable cause)

    Constructs a new throwable with the specified cause.

    Parameters:
    cause - a chained exception of type Throwable.

-------------------

public ResourceAllocationException(String message,
ResourceAllocationException

public ResourceAllocationException(String message,
        Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public ResourceAllocationException(String message,
        String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

</tr>
<tr>
<td><strong>See also</strong></td>
</tr>
<tr>
<td>javax.el.CompositeELResolver, javax.el.ELResolver, java.util.ResourceBundle</td>
</tr>
</tbody>
</table>

**Defines property resolution behavior on instances of** **ResourceBundle.**

This resolver handles base objects of type java.util.ResourceBundle. It accepts any object as a property and coerces it to a java.lang.String for invoking **ResourceBundle.getObject(java.lang.String).**

This resolver is read only and will throw a **PropertyNotWritableException** if setValue is called.

**ELResolvers** are combined together using **CompositeELResolvers**, to define rich semantics for evaluating an expression. See the javadocs for
**ELResolver** for details.

Since: JSP 2.1

Constructor Detail

public ResourceBundleELResolver()

ResourceBundleELResolver

public ResourceBundleELResolver()

Method Detail

public Object getValue(ELContext context, Object base, Object property)

    base ResourceBundle String base
    ResourceBundle getObject Object
    base ResourceBundle ELContext propertyResolved true
    true

    context
    base ResourceBundle
    property String
    ELContext propertyResolved true null

    return null ResourceBundle String Object
**Throws**

NullPointerException: context null

**Throws** **ELException**: cause

---

**getValue**

```java
public Object getValue(ELContext context,
                      Object base,
                      Object property)
```

If the base object is an instance of ResourceBundle, the provided property will first be coerced to a String. The object returned by `getObject` on the base ResourceBundle will be returned.

If the base is ResourceBundle, the `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver, before returning. If this property is not `true` after this method is called, the caller should ignore the return value.

**Specified by:**

`getValue` in class **ELResolver**

**Parameters:**

- `context` - The context of this evaluation.
- `base` - The ResourceBundle to analyze.
- `property` - The name of the property to analyze. Will be coerced to a String.

**Returns:**

If the `propertyResolved` property of `ELContext` was set to `true`, then `null` if property is `null`; otherwise the object for the given key (property coerced to String) from the `ResourceBundle`. If no object for the given key can be found, then the String "??" + key + "??".

**Throws:**

- NullPointerException - if context is `null`
- ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.
public Class<T> getType(ELContext context, Object base, Object property)

Throws

If the base object is an instance of ResourceBundle, return null, since the resolver is read only.

If the base is ResourceBundle, the propertyResolved property of the ELContext object must be set to true by this resolver, before returning. If this property is not true after this method is called, the caller should ignore the return value.

Specified by:

g getType in class ELResolver

Parameters:

c context - The context of this evaluation.
b base - The ResourceBundle to analyze.
p property - The name of the property to analyze.

Returns:

If the propertyResolved property of ELContext was set to true, then null; otherwise undefined.

Throws:
public void setValue(ELContext context, Object base, Object property, Object value)

Throws

NullPointersException - if context is null

PropertyNotWritableException - Always thrown if base is an instance of ResourceBundle.

If the base object is a ResourceBundle, throw a

PropertyNotWritableException.

Specified by:

setValue in class ELResolver

Parameters:

class context - The context of this evaluation.

Object base - The ResourceBundle to be modified. Only bases that are of type ResourceBundle are handled.

Object property - The String property to use.

Object value - The value to be set.

Throws:

NullPointersException - if context is null.

PropertyNotWritableException - Always thrown if base is an instance of ResourceBundle.
public boolean isReadOnly(ELContext context, Object base, Object property)

<table>
<thead>
<tr>
<th>context</th>
<th>ResourceBundle</th>
<th>true</th>
</tr>
</thead>
<tbody>
<tr>
<td>base</td>
<td>ResourceBundle</td>
<td>base</td>
</tr>
<tr>
<td>property</td>
<td>String</td>
<td></td>
</tr>
<tr>
<td>return</td>
<td>ELContext</td>
<td>propertyResolved</td>
</tr>
</tbody>
</table>

Throws: NullPointerException: context null

isReadOnly

public boolean isReadOnly(ELContext context, Object base, Object property)

If the base object is not null and an instance of ResourceBundle, return true.

Specified by: isReadOnly in class ELResolver

Parameters:
- context - The context of this evaluation.
- base - The ResourceBundle to be modified. Only bases that are of type ResourceBundle are handled.
- property - The String property to use.

Returns:
- If the propertyResolved property of ELContext was set to true, then true; otherwise undefined.

Throws:
- NullPointerException - if context is null

public java.util.Iterator<E> getFeatureDescriptors(ELContext context, Object base)

<table>
<thead>
<tr>
<th>base</th>
<th>ResourceBundle</th>
<th>Iterator</th>
<th>Resource</th>
<th>null</th>
</tr>
</thead>
<tbody>
<tr>
<td>null</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
Iterator 0     java.beans.FeatureDescriptor  info

ResourceBundle

- displayName - String
- name – displayName
- shortDescription –
- expert - false
- hidden - false
- preferred - true

FeatureDescriptor

- ELResolver#TYPE - String.class
- ELResolver#RESOLVABLE_AT_DESIGN_TIME - true

class context
  base ResourceBundle base

return 0

FeatureDescriptor Iterator base
  ResourceBundle null

getFeatureDescriptors

public Iterator getFeatureDescriptors(ELContext context,
                                      Object base)

If the base object is a ResourceBundle, returns an Iterator
containing the set of keys available in the ResourceBundle.
Otherwise, returns null.

The Iterator returned must contain zero or more instances of
FeatureDescriptor. Each info object contains information about a key
in the ResourceBundle, and is initialized as follows:

- displayName - The string key
- name - Same as displayName property.
- shortDescription - Empty string
• expert - false
• hidden - false
• preferred - true

In addition, the following named attributes must be set in the returned FeatureDescriptorS:
• ELResolver.TYPE - String.class
• ELResolver.RESOLVABLE_AT_DESIGN_TIME - true

Specified by:
  getFeatureDescriptors in class ELResolver

Parameters:
  context - The context of this evaluation.
  base - The bundle whose keys are to be iterated over. Only bases of type ResourceBundle are handled by this resolver.

Returns:
  An Iterator containing zero or more (possibly infinitely more) FeatureDescriptor objects, each representing a key in this bundle, or null if the base object is not a ResourceBundle.

See Also:
  FeatureDescriptor

public Class<T> getCommonPropertyType(ELContext context, Object base)
  base ResourceBundle property null

  base ResourceBundle String.class
  context
  base ResourceBundle base
  return base ResourceBundle null String.class

getCommonPropertyType

public Class<? super Object> getCommonPropertyType(ELContext context, Object base)
If the base object is a ResourceBundle, returns the most general type that this resolver accepts for the property argument. Otherwise, returns null.

Assuming the base is a ResourceBundle, this method will always return String.class.

**Specified by:**

getCommonPropertyType in class ELResolver

**Parameters:**

context - The context of this evaluation.

base - The bundle to analyze. Only bases of type ResourceBundle are handled by this resolver.

**Returns:**

null if base is not a ResourceBundle; otherwise String.class.

Connector  ResourceException

- Java getMessage()
- 
- ResourceException J2SE  1.4

version  1.0
This is the root interface of the exception hierarchy defined for the Connector architecture. The ResourceException provides the following information:

- A resource adapter vendor specific string describing the error. This string is a standard Java exception message and is available through getMessage() method.
- resource adapter vendor specific error code.
- reference to another exception. Often a resource exception will be result of a lower level problem. If appropriate, this lower level exception can be linked to the ResourceException. Note, this has been deprecated in favor of J2SE release 1.4 exception chaining facility.

## Constructor Detail

```java
public ResourceException()
null
```
ResourceException

public ResourceException()

    Constructs a new instance with null as its detail message.

public ResourceException(String message)

    message

ResourceException

public ResourceException(String message)

    Constructs a new instance with the specified detail message.

    Parameters:
        message - the detail message.

ResourceException

public ResourceException(Throwable cause)

    cause  throwable

    cause

ResourceException

public ResourceException(Throwable cause)

    Constructs a new throwable with the specified cause.

    Parameters:
        cause - a chained exception of type Throwable.
public ResourceException(String message, Throwable cause)
cause throwable
    message
    cause

ResourceException

public ResourceException(String message, Throwable cause)

    Constructs a new throwable with the specified detail message and cause.

    Parameters:
    message - the detail message.
    cause - a chained exception of type Throwable.

public ResourceException(String message, String errorCode)
throwable
    message
    errorCode

ResourceException

public ResourceException(String message, String errorCode)

    Create a new throwable with the specified message and error code.

    Parameters:
    message - a description of the exception.
    errorCode - a string specifying the vendor specific error code.
public void setErrorCode(String errorCode)

    errorCode

setErrorCode

public void setErrorCode(String errorCode)

    Set the error code.

Parameters:
    errorCode - the error code.

public String getErrorCode()

    return

gGetErrorCode

public String getErrorCode()

    Get the error code.

Returns:
    the error code.

public Exception getLinkedException()

    return Exception null

deprecated

    J2SE 1.4 thrower throwable

    java.lang.Throwable getCause

    initCause
getLinkedExceptionHandler

```java
public Exception getLinkedExceptionHandler()
```

**Deprecated. J2SE release 1.4 supports a chained exception facility that allows any throwable to know about another throwable, if any, that caused it to get thrown.** Refer to `getCause` and `initCause` methods of the `java.lang.Throwable` class.

Get the exception linked to this ResourceException

**Returns:**
- linked Exception, null if none

---

setLinkedExceptionHandler

```java
public void setLinkedExceptionHandler(Exception ex)
```

**Exception ResourceException**

```java
ex Exception
```

**deprecated J2SE 1.4** throwable throwable

```java
java.lang.Throwable getCause initCause
```

Add a linked Exception to this ResourceException.

**Parameters:**
- ex - linked Exception
public String getMessage()

    return

getMessage

public String getMessage()

    Returns a detailed message string describing this exception.

    Overrides: getMessage in class Throwable

    Returns: 
        a detailed message string.
javax.annotation Annotation Type Resources

javax.resource.cci  **Class ResourceWarning**

`java.lang.Object`  
  ▼ `java.lang.Throwable`  
    ▼ `java.lang.Exception`  
      ▼ `javax.resource.ResourceException`  
        ▼ `javax.resource.cci.ResourceWarning`

All Implemented Interfaces:  
  `Serializable`

---

**public class** ResourceWarning  
**extends** ResourceException

**Extends:** Throwable > Exception > **ResourceException**

**ResourceWarning** EIS

**See also**  
getWarnings

A `ResourceWarning` provides information on warnings related to execution of an interaction with an EIS. Warnings are silently chained to the object whose method caused it to be reported.

**See Also:**  
`Interaction.getWarnings()`, **Serialized Form**

---

**Constructor Detail**

```java
public ResourceWarning()
null

ResourceWarning

public ResourceWarning()

    Constructs a new instance with null as its detail message.

public ResourceWarning(String message)

    message

ResourceWarning

public ResourceWarning(String message)

    Constructs a new instance with the specified detail message.

    Parameters:
    message - the detail message.

public ResourceWarning(Throwable cause)

cause  throwable

ResourceWarning

public ResourceWarning(Throwable cause)
```
Constructs a new throwable with the specified cause.

**Parameters:**
- `cause` - a chained exception of type `Throwable`.

---

```java
public ResourceWarning(String message, Throwable cause)
```

**cause throwable**

- `message` - the detail message.
- `cause` - a chained exception of type `Throwable`.

---

```java
public ResourceWarning(String message, String errorCode)
```

**throwable**

- `message` - the detail message.
- `errorCode` - the error code.

---

```java
ResourceWarning
```

**Constructs a new throwable with the specified detail message and cause.**

**Parameters:**
- `message` - the detail message.
- `cause` - a chained exception of type `Throwable`.

---

```java
ResourceWarning
```

**Constructs a new throwable with the specified detail message and error code.**

**Parameters:**
- `message` - the detail message.
- `errorCode` - the error code.
Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

Method Detail

public ResourceWarning getLinkedWarning()

ResourceWarning
return ResourceWarning
null

getLinkedWarning

public ResourceWarning getLinkedWarning()

getLinkedWarning

getLinkedWarning

Public. J2SE release 1.4 supports a chained exception facility that allows any throwable to know about another throwable, if any, that caused it to get thrown. Refer to getCause and initCause methods of the java.lang.Throwable class.

Retrieves the warning chained to this ResourceWarning object.

Returns:
next ResourceWarning in the chain; null if none.

public void setLinkedWarning(ResourceWarning warning)

ResourceWarning

setLinkedWarning

setLinkedWarning

setLinkedWarning

Deprecated. J2SE release 1.4 supports a chained exception facility that allows any throwable to know about another throwable, if any, that caused it to get thrown. Refer to getCause and initCause methods of the java.lang.Throwable class.
setLinkedWarning

public void setLinkedWarning(ResourceWarning warning)

**Deprecated.** J2SE release 1.4 supports a chained exception facility that allows any throwable to know about another throwable, if any, that caused it to get thrown. Refer to `getCause` and `initCause` methods of the `java.lang.Throwable` class.

Adds an `ResourceWarning` object to the end of the chain.

**Parameters:**

- `warning` - `ResourceWarning` to be added to the chain.
javax.xml.ws Interface Response<T>

All Superinterfaces:
  Future<T>

public interface Response<T>
extends Future<T>

Implements: java.util.concurrent.Future<V>

Response

  get(...) cause RemoteException
  WebServiceException

since JAX-WS 2.0

The Response interface provides methods used to obtain the payload and context of a message sent in response to an operation invocation.

For asynchronous operation invocations it provides additional methods to check the status of the request. The get(...) methods may throw the standard set of exceptions and their cause may be a RemoteException or a WebServiceException that represents the error that occurred during the asynchronous method invocation.

Since:
  JAX-WS 2.0

public abstract class ResponseStateManager
extends Object

ResponseStateManager is the helper class to StateManager that knows the specific rendering technology being used to generate the response. It is a singleton abstract class, vended by the RenderKit. This class knows the mechanics of saving state, whether it be in hidden fields, session, or some combination of the two.

Field Summary

| static String | RENDER_KIT_ID_PARAM | The name of the request parameter used by the default implementation of ViewHandler.calculateRenderKitId(javax.faces.context.FacesContext) to derive a RenderKit ID. |
| static String | VIEW_STATE_PARAM | Implementations must use this value as the name and id of the client parameter in which to save the state between requests. |

Constructor Summary

ResponseStateManager()

public ResponseStateManager()
public void writeState(FacesContext context, Object state)
throws java.io.IOException

writeState

public void writeState(FacesContext context, Object state)
throws IOException

Throws:
IOException

public void writeState(FacesContext context, StateManager.SerializedView state) throws java.io.IOException

state ResponseWriter writer

javax.faces.application.StateManager.SerializedView

String HTTP

javax.faces.application.StateManager#STATE_SAVING_METHOD_CLI!

deprecated #writeState(javax.faces.context.FacesContext,javax.lang.Object)

context FacesContext

writeState

public void writeState(FacesContext context, StateManager.SerializedView state)
throws IOException

**Deprecated.** *This method has been replaced by* `writeState(javax.faces.context.FacesContext, java.lang.Object)`.* The default implementation of this method does nothing.*

Take the argument `state` and write it into the output using the current `ResponseWriter`, which must be correctly positioned already.

If the `StateManager.SerializedView` is to be written out to hidden fields, the implementation must take care to make all necessary character replacements to make the Strings suitable for inclusion as an HTTP request parameter.

If the state saving method for this application is `StateManager.STATE_SAVING_METHOD_CLIENT`, the implementation may encrypt the state to be saved to the client. We recommend that the state be unreadable by the client, and also be tamper evident. The reference implementation follows these recommendations.

**Parameters:**
- `context` - The `FacesContext` instance for the current request
- `state` - The serialized state information previously saved

**Throws:**
- IOException

```java
public Object getState(FacesContext context, String viewId)
```

**Object**

- `writeState(javax.faces.context.FacesContext, java.lang.Object)`
- `getTreeStructureToRestore`
- `getComponentStateToRestore`  
  - `ResponseStateManager`  
  - `getComponentStateToRestore`  
  - `SerializedView`

since 1.2
getState

public Object getState(FacesContext context, String viewId)

The implementation must inspect the current request and return an Object representing the tree structure and component state passed in to a previous invocation of writeState(FacesContext, java.lang.Object).

For backwards compatibility with existing ResponseStateManager implementations, the default implementation of this method calls getTreeStructureToRestore(javax.faces.context.FacesContext, java.lang.String) and getComponentStateToRestore(javax.faces.context.FacesContext) and creates and returns a two element Object array with element zero containing the structure property and element one containing the state property of the SerializedView.

Parameters:
context - The FacesContext instance for the current request
viewId - View identifier of the view to be restored

Returns:
the tree structure and component state Object passed in to writeState. If this is an initial request, this method returns null.

Since:
1.2

public Object getTreeStructureToRestore(FacesContext context, String viewId)

writeState() Object
getTreeStructureToRestore

```java
public Object getTreeStructureToRestore(FacesContext context, String viewId)
```

**Deprecated. This method has been replaced by**

The default implementation returns `null`.

The implementation must inspect the current request and return the tree structure Object passed to it on a previous invocation of `writeState()`.

**Parameters:**
- context - The `FacesContext` instance for the current request
- viewId - View identifier of the view to be restored

---

getComponentStateToRestore

```java
public Object getComponentStateToRestore(FacesContext context)
```

**Deprecated. This method has been replaced by**
The default implementation returns `null`.

The implementation must inspect the current request and return the component state object passed to it on a previous invocation of `writeState()`.

**Parameters:**

```java
public boolean isPostback(FacesContext context)
```

**postback true**

```java
javax.faces.application.ViewHandler#restoreView
javax.faces.application.ViewHandler#createView
ResponseStateManager postback true false
```

**HTML RenderKit**

```java
javax.faces.context.ExternalContext requestParameterMap #VIEW_STATE_PARAM true
```

**JSF 1.2**

```java
ResponseStateManager
javax.faces.context.ExternalContext requestParameterMap 0 true
```

since 1.2

**isPostback**

```java
public boolean isPostback(FacesContext context)
```

Return true if the current request is a postback. This method is leveraged from the `Restore View Phase` to determine if `ViewHandler.restoreView(javax.faces.context.FacesContext, java.lang.String)` or `ViewHandler.createView(javax.faces.context.FacesContext, java.lang.String)` should be called. The default implementation must return true if this `ResponseStateManager` instance wrote out
state on a previous request to which this request is a postback, false otherwise.

The implementation if this method for the Standard HTML RenderKit must consult the \texttt{ExternalContext}'s \texttt{requestParameterMap} and return \texttt{true} if and only if there is a key equal to the value of the symbolic constant \texttt{VIEW\_STATE\_PARAM}.

For backwards compatibility with implementations of \texttt{ResponseStateManager} prior to JSF 1.2, a default implementation is provided that consults the \texttt{ExternalContext}'s \texttt{requestParameterMap} and return \texttt{true} if its size is greater than 0.

\textbf{Since:} 1.2

  ▼ java.io.Writer
    ▼ javax.faces.context.ResponseWriter

All Implemented Interfaces:
  Closeable, Flushable, Appendable

Direct Known Subclasses:
  ResponseWriterWrapper

public abstract class ResponseWriter
  extends Writer

  Extends: java.io.Writer
  Extended by: ResponseWriterWrapper

ResponseWriter  java.io.Writer  write()
 HTML  XML

ResponseWriter is an abstract class describing an adapter to an underlying output mechanism for character-based output. In addition to the low-level write() methods inherited from java.io.Writer, this class provides utility methods that are useful in producing elements and attributes for markup languages like HTML and XML.

Methods inherited from class `java.lang.Object`:
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`

**Constructor Detail**

public `ResponseWriter()`
ResponseWriter

public ResponseWriter()

Method Detail

abstract public String getContentType()

ResponseWriter "text/html" "charset="

getContentType

public abstract String getContentType()

Return the content type (such as "text/html") for this ResponseWriter. Note: this must not include the "charset=" suffix.

abstract public String getCharacterEncoding()

ResponseWriter "ISO-8859-1" the IANA

getCharacterEncoding

public abstract String getCharacterEncoding()

Return the character encoding (such as "ISO-8859-1") for this ResponseWriter. Please see the IANA for a list of character encodings.
abstract public void flush() throws java.io.IOException

Writer  OutputStream  Writer  OutputStream
ResponseWriter

flush

public abstract void flush()
    throws IOException

Flush any output buffered by the output method to the underlying Writer or OutputStream. This method will not flush the underlying Writer or OutputStream; it simply clears any values buffered by this ResponseWriter.

Specified by:
    flush in interface Flushable
Specified by:
    flush in class Writer
Throws:
    IOException

abstract public void startDocument() throws java.io.IOException

throws java.io.IOException: /

startDocument

public abstract void startDocument()
    throws IOException
Write whatever text should begin a response.

**Throws:**
- IOException - if an input/output error occurs

---

```java
abstract public void endDocument() throws java.io.IOException
```

**startElement()**

**Throws**
- java.io.IOException: /

---

**endDocument**

```java
public abstract void endDocument() throws IOException
```

Write whatever text should end a response. If there is an open element that has been created by a call to `startElement()`, that element will be closed first.

**Throws:**
- IOException - if an input/output error occurs

---

```java
abstract public void startElement(String name, UIComponent component) throws java.io.IOError
```

```java
writeAttribute() writeURIAttribute() startElement()writeComment()writeText()endElement()endDocument()write() "">
```

- `name`
- `component`

**Throws**
- java.io.IOException: /
startElement

public abstract void startElement(String name, UIComponent component) throws IOException

Write the start of an element, up to and including the element name. Once this method has been called, clients can call the writeAttribute() or writeURIAttribute() methods to add attributes and corresponding values. The starting element will be closed (that is, the trailing '>' character added) on any subsequent call to startElement(), writeComment(), writeText(), endElement(), endDocument(), close(), flush(), or write().

Parameters:

- name - Name of the element to be started
- component - The UIComponent (if any) to which this element corresponds

Throws:

- IOException - if an input/output error occurs
- NullPointerException - if name is null

abstract public void endElement(String name) throws java.io.IOException

startElement()
public abstract void endElement(String name) throws IOException

Write the end of an element, after closing any open element created by a call to startElement(). Elements must be closed in the inverse order from which they were opened; it is an error to do otherwise.

Parameters:
   name - Name of the element to be ended

Throws:
   IOException - if an input/output error occurs
   NullPointerException - if name is null

abstract public void writeAttribute(String name, Object value, String property) throws java.io.IOException

String startElement()

   name
   value
   property
   UIComponent

Throws
   IllegalStateException:
   java.io.IOException: /
   NullPointerException: name null

writeAttribute

public abstract void writeAttribute(String name, Object value, String property) throws IOException

Write an attribute name and corresponding value, after converting that text to a String (if necessary), and after performing any escaping appropriate for the markup language being rendered. This method may only be called after a call to startElement(), and before the opened element has been closed.
Parameters:

- **name** - Attribute name to be added
- **value** - Attribute value to be added
- **property** - Name of the property or attribute (if any) of the UIComponent associated with the containing element, to which this generated attribute corresponds

Throws:

- **IllegalStateException** - if this method is called when there is no currently open element
- **IOException** - if an input/output error occurs
- **NullPointerException** - if name is null

abstract public void writeURIAttribute(String name, Object value, String property) throws java.io.IOException

String URI

```
startElement()
```

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
<th>property</th>
<th>Throws</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>IllegalStateException:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>java.io.IOException: /</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>NullPointerException: name null</td>
</tr>
</tbody>
</table>

writeURIAttribute

public abstract void writeURIAttribute(String name, Object value, String property) throws IOException

Write a URI attribute name and corresponding value, after converting that text to a String (if necessary), and after performing any encoding appropriate to the markup language being rendered. This method may only be called after a call to startElement(), and before the opened element has been closed.
Parameters:
  name - Attribute name to be added
  value - Attribute value to be added
  property - Name of the property or attribute (if any) of the UIComponent associated with the containing element, to which this generated attribute corresponds

Throws:
  IllegalStateException - if this method is called when there is no currently open element
  IOException - if an input/output error occurs
  NullPointerException - if name is null

abstract public void writeComment(Object comment)
throws java.io.IOException

String startElement()

comment

Throws java.io.IOException: /

Throws NullPointerException: comment null

writeComment

public abstract void writeComment(Object comment)
throws IOException

Write a comment containing the specified text, after converting that text to a String (if necessary), and after performing any escaping appropriate for the markup language being rendered. If there is an open element that has been created by a call to startElement(), that element will be closed first.

Parameters:
  comment - Text content of the comment

Throws:
  IOException - if an input/output error occurs
abstract public void writeText(Object text, String property)
throws java.io.IOException

Parameters:
  text - Text to be written
  property - Name of the property or attribute (if any) of the UIComponent associated with the containing element, to which this generated text corresponds

Throws:
  IOException - if an input/output error occurs
  NullPointerException - if text is null

public void writeText(Object text, UIComponent component, String property) throws java.io.IOException
String

```java
public void writeText(Object text, UIComponent component, String property)
```

Parameters:
- `text` - Text to be written
- `component` - The `UIComponent` (if any) to which this element corresponds
- `property` - Name of the property or attribute (if any) of the `UIComponent` associated with the containing element, to which
abstract public void writeText(char[] text, int off, int len) throws java.io.IOException

   writeText

   public abstract void writeText(char[] text,
       int off,
       int len)
   throws IOException

Write text from a character array, after any performing any escaping appropriate for the markup language being rendered. If there is an open element that has been created by a call to startElement(), that element will be closed first.

Parameters:
   text - Text to be written
   off - Starting offset (zero-relative)
   len - Number of characters to be written

Throws:
**IndexOutOfBoundsException** - if the calculated starting or ending position is outside the bounds of the character array

**IOException** - if an input/output error occurs

**NullPointerException** - if text is null

---

**abstract public ResponseWriter cloneWithWriter(java.io.Writer writer)**

**Parameters:**

- **writer** - The **Writer** that is the output destination

---

See also startElement(String, javax.faces.component.UIComponent)

startElement

public void startElement(String name, UIComponent component)
throws IOException

The default behavior of this method is to call
ResponseWriter.startElement(String, javax.faces.component.UIComponent) on the wrapped ResponseWriter
object.

Specified by:
**startElement** in class `ResponseWriter`

**Parameters:**
- `name` - Name of the element to be started
- `component` - The `UIComponent` (if any) to which this element corresponds

**Throws:**
- `IOException` - if an input/output error occurs

**Since:**
1.2

**See Also:**
- `ResponseWriter.startElement(String, javax.faces.component.UIComponent)`

```java
class ResponseWriter {
    public void endElement(String name) throws IOException {
        // The default behavior of this method is to call
        ResponseWriter.endElement(String) on the wrapped ResponseWriter object.
    }
}
```

**endElement**

```java
public void endElement(String name)
    throws IOException
```

**Specified by:**
- `endElement` in class `ResponseWriter`

**Parameters:**
- `name` - Name of the element to be ended

**Throws:**
- `IOException` - if an input/output error occurs

**Since:**
public void writeAttribute(String name, Object value, String property) throws java.io.IOException

Since: 1.2
See also: writeAttribute(String, Object, String)

writeAttribute

public void writeAttribute(String name,
Object value,
String property)
throws IOException

The default behavior of this method is to call ResponseWriter.writeAttribute(String, Object, String) on the wrapped ResponseWriter object.

Specified by:
writeAttribute in class ResponseWriter

Parameters:
name - Attribute name to be added
value - Attribute value to be added
property - Name of the property or attribute (if any) of the UICOMPONENT associated with the containing element, to which this generated attribute corresponds

Throws:
IOException - if an input/output error occurs

Since: 1.2
See Also:
ResponseWriter.writeAttribute(String, Object, String)
public void writeURIAttribute(String name, Object value, String property) throws IOException

Since 1.2
See also writeURIAttribute(String, Object, String)

writeURIAttribute

public void writeURIAttribute(String name, Object value, String property) throws IOException

The default behavior of this method is to call ResponseWriter.writeURIAttribute(String, Object, String) on the wrapped ResponseWriter object.

Specified by:
writeURIAttribute in class ResponseWriter

Parameters:
name - Attribute name to be added
value - Attribute value to be added
property - Name of the property or attribute (if any) of the UIComponent associated with the containing element, to which this generated attribute corresponds

Throws:
IOException - if an input/output error occurs

Since 1.2
See Also:
ResponseWriter.writeURIAttribute(String, Object, String)
public void writeComment(Object comment) throws IOException

ResponseWriter writeComment(Object)

since 1.2
See also writeComment(Object)

writeComment

public void writeComment(Object comment)
throws IOException

The default behavior of this method is to call
ResponseWriter.writeComment(Object) on the wrapped
ResponseWriter object.

Specified by:
writeComment in class ResponseWriter

Parameters:
comment - Text content of the comment

Throws:
IOException - if an input/output error occurs

Since:
1.2

See Also:
ResponseWriter.writeComment(Object)

public void writeText(Object text, String property) throws IOException

ResponseWriter writeText(Object, String)

since 1.2
See also writeText(Object, String)
writeText

public void writeText(Object text, String property)
throws IOException

The default behavior of this method is to call
ResponseWriter.writeText(Object, String) on the wrapped
ResponseWriter object.

Specified by:
   writeText in class ResponseWriter

Parameters:
   text - Text to be written
   property - Name of the property or attribute (if any) of the
   UIComponent associated with the containing element, to which
   this generated text corresponds

Throws:
   IOException - if an input/output error occurs

Since:
   1.2

See Also:
   ResponseWriter.writeText(Object, String)

public void writeText(Object text, UIComponent component, String property) throws java.io.IOException

ResponseWriter writeText(Object, UIComponent, String)

since
   1.2

See also
   writeText(Object, String)

writeText

public void writeText(Object text, UIComponent component, String property)
throws IOException

The default behavior of this method is to call
ResponseWriter.writeText(Object, UIComponent, String) on the
wrapped ResponseWriter object.

Overrides:
   writeText in class ResponseWriter

Parameters:
   text - Text to be written
   component - The UIComponent (if any) to which this element
               corresponds
   property - Name of the property or attribute (if any) of the
              UIComponent associated with the containing element, to which
              this generated text corresponds

Throws:
   IOException - if an input/output error occurs

Since: 1.2

See Also:
   ResponseWriter.writeText(Object, String)

public void writeText(char[] text, int off, int len) throws
java.io.IOException

   ResponseWriter   writeText(char[], int, int)

   since            1.2
   See also         writeText(char[], int, int)

writeText

public void writeText(char[] text, int off, int len)
   throws IOException
The default behavior of this method is to call `ResponseWriter.writeText(char[], int, int)` on the wrapped `ResponseWriter` object.

**Specified by:**
`writeText` in class `ResponseWriter`

**Parameters:**
- `text` - Text to be written
- `off` - Starting offset (zero-relative)
- `len` - Number of characters to be written

**Throws:**
- `IOException` - if an input/output error occurs

**Since:**
1.2

**See Also:**
`ResponseWriter.writeText(char[], int, int)`

```java
public ResponseWriter cloneWithWriter(java.io.Writer writer)
```

**ResponseWriter**  
`cloneWithWriter(java.io.Writer)`

- **since**
  1.2
- **See also**
  `cloneWithWriter(java.io.Writer)`

`cloneWithWriter`

```java
public ResponseWriter cloneWithWriter(Writer writer)
```

The default behavior of this method is to call `ResponseWriter.cloneWithWriter(java.io.Writer)` on the wrapped `ResponseWriter` object.

**Specified by:**
`cloneWithWriter` in class `ResponseWriter`

**Parameters:**
- `writer` - Writer to be used for writing
public void close() throws java.io.IOException

ResponseWriter close()

since 1.2
See also close()

close

public void close() throws IOException

The default behavior of this method is to call Writer.close() on the wrapped ResponseWriter object.

Specified by:
   close in interface Closeable
Specified by:
   close in class Writer
Throws:
   IOException
Since: 1.2
See Also:
   Writer.close()

public void write(char[] cbuf, int off, int len) throws java.io.IOException

ResponseWriter write(char[], int, int)
write

public void write(char[] cbuf,
        int off,
        int len)
    throws IOException

The default behavior of this method is to call Writer.write(char[],
        int, int) on the wrapped ResponseWriter object.

Specified by: write in class Writer

Throws: IOException

Since: 1.2

See Also: Writer.write(char[], int, int)
javax.faces.model Class ResultDataModel

java.lang.Object
   javax.faces.model.DataModel
   javax.faces.model.ResultDataModel

public class ResultDataModel
extends DataModel

Extends: DataModel

ResultDataModel is a convenience implementation of DataModel that wraps a JSTL Result object, typically representing the results of executing an SQL query via JSTL tags.

<table>
<thead>
<tr>
<th>Constructor Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultDataModel()</td>
</tr>
<tr>
<td>Construct a new ResultDataModel with no specified wrapped data.</td>

</thead>
<tbody>
<tr>
<td>int getRowCount()</td>
</tr>
<tr>
<td>If there is wrappedData available, return the length of the array returned by calling getRows() on the underlying Result.</td>
</tr>
<tr>
<td>SortedMap getRowData()</td>
</tr>
<tr>
<td>If row data is available, return the SortedMap array element</td>
</tr>
</tbody>
</table>
at the index specified by \texttt{rowIndex} of the array returned by calling \texttt{getRows()} on the underlying \texttt{Result}.

\begin{verbatim}

Object

getRowIndex()  
   Return the zero-relative index of the currently selected row.

getWrappedData()  
   Return the object representing the data wrapped by this \texttt{DataModel}, if any.

boolean isRowAvailable()  
   Return \texttt{true} if there is \texttt{wrappedData} available, and the current value of \texttt{rowIndex} is greater than or equal to zero, and less than the length of the array returned by calling \texttt{getRows()} on the underlying \texttt{Result}.

void setRowIndex(int rowIndex)  
   Set the zero-relative index of the currently selected row, or \texttt{-1} to indicate that we are not positioned on a row.

void setWrappedData(Object data)  
   Set the object representing the data collection wrapped by this \texttt{DataModel}.

Methods inherited from class \texttt{javax.faces.model.DataModel}
addDataModelListener, getDataModelListeners, removeDataModelListener

Methods inherited from class \texttt{java.lang.Object}
code, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

\end{verbatim}

Constructor Detail

public \texttt{ResultDataModel()}

\texttt{ResultDataModel}
ResultDataModel

public ResultDataModel()

    Construct a new ResultDataModel with no specified wrapped data.

public ResultDataModel(javax.servlet.jsp.jstl.sql.Result result)

    Result ResultDataModel

        result Result

ResultDataModel

public ResultDataModel(javax.servlet.jsp.jstl.sql.Result result)

    Construct a new ResultDataModel wrapping the specified Result.

Parameters:

    result - Result to be wrapped (if any)

Method Detail

public boolean isRowAvailable()

    wrappedData rowIndex 0 Result getRows()

    true false

    Throws FacesException:
isRowAvailable

public boolean isRowAvailable()

Return true if there is wrappedData available, and the current value of rowIndex is greater than or equal to zero, and less than the length of the array returned by calling getRows() on the underlying Result. Otherwise, return false.

Specified by: isRowAvailable in class DataModel
Throws: FacesException - if an error occurs getting the row availability

public int getRowCount()

wrappedData Result getRows() wrappedData -1

Throws FacesException:

getRowCount

public int getRowCount()

If there is wrappedData available, return the length of the array returned by calling getRows() on the underlying Result. If no wrappedData is available, return -1.

Specified by: getRowCount in class DataModel
Throws: FacesException - if an error occurs getting the row count

public Object getRowData()
```java
SortedMap getRowData() {
    if (row data is available, return the SortedMap array element at the
    index specified by rowIndex of the array returned by calling getRows()
    on the underlying Result. If no wrapped data is available, return
    null.

    Note that, if a non-null Map is returned by this method, it will contain
    the values of the columns for the current row, keyed by column
    name. Column name comparisons must be performed in a case-
    insensitive manner.

    Specified by:
        getRowData in class DataModel
    Throws:
        FacesException - if an error occurs getting the row data
        IllegalArgumentException - if now row data is available at the
        currently specified row index
}
```

```java
public int getRowIndex() {
    Throws FacesException: NullPointerException
}
```

```java
getRowIndex
```
Description copied from class: **DataModel**

Return the zero-relative index of the currently selected row. If we are not currently positioned on a row, or no wrappedData is available, return -1.

**Specified by:**

   getRowIndex in class **DataModel**

**Throws:**

   FacesException - if an error occurs getting the row index

---

**public void setRowIndex(int rowIndex)**

**Throws**

   FacesException: NullPointerException

   IllegalArgumentException: NullPointerException  

   IllegalArgumentException: rowIndex -1

**setRowIndex**

**public void setRowIndex(int rowIndex)**

Description copied from class: **DataModel**

Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row. It is possible to set the row index at a value for which the underlying data collection does not contain any row data. Therefore, callers may use the isRowAvailable() method to detect whether row data will be available for use by the getRowData() method.

If there is no wrappedData available when this method is called, the specified rowIndex is stored (and may be retrieved by a subsequent call to getRowData()), but no event is sent. Otherwise, if the currently selected row index is changed by this call, a DataModelEvent will be sent to the rowSelected() method of all registered DataModelListeners.

**Specified by:**
**setRowIndex** in class **DataModel**

**Parameters:**
- **rowIndex** - The new zero-relative index (must be non-negative)

**Throws:**
- **FacesException** - if an error occurs setting the row index
- **IllegalArgumentException** - if **rowIndex** is less than -1

---

**public Object getWrappedData()**

**getWrappedData**

**public Object getWrappedData()**

**Description copied from class: **DataModel**

Return the object representing the data wrapped by this **DataModel**, if any.

**Specified by:**
- **getWrappedData** in class **DataModel**

---

**public void setWrappedData(Object data)**

**Throws**
- ClassCastException: data null Result

**setWrappedData**

**public void setWrappedData(Object data)**

**Description copied from class: **DataModel**

Set the object representing the data collection wrapped by this **DataModel**. If the specified **data** is null, detach this **DataModel** from any previously wrapped data collection instead.

If **data** is non-null, the currently selected row index must be set to
zero, and a DataModelEvent must be sent to the rowSelected() method of all registered DataModelListener indicating that this row is now selected.

**Specified by:**

setWrappedData in class DataModel

**Parameters:**

data - Data collection to be wrapped, or null to detach from any previous data collection

**Throws:**

ClassCastException - if data is non-null and is not a Result
public interface ResultSet
extends Record, ResultSet

Implements: Record, java.sql.ResultSet

ResultSet Interaction  EIS CCI ResultSet  JDBC ResultSet

CCI ResultSet  Connectors 1.0  CCI
since 0.8
See also java.sql.ResultSet

A ResultSet represents tabular data that is retrieved from an EIS instance by the execution of an Interaction. The CCI ResultSet is based on the JDBC ResultSet.

Refer the CCI specification in Connectors 1.0 for detailed requirements on the implementation of a CCI ResultSet.

Since: 0.8
Author: Rahul Sharma

PS :
javax.faces.model Class ResultSetDataModel

java.lang.Object
   ↓ javax.faces.model.DataModel
      ↓ javax.faces.model.ResultSetDataModel

public class ResultSetDataModel

extends DataModel

Extends: DataModel

ResultSetDataModel is a convenience implementation of DataModel that wraps a ResultSet of Java objects. Note that the specified ResultSet MUST be scrollable. In addition, if input components (that will be updating model values) reference this object in value binding expressions, the specified ResultSet MUST be updatable.

Constructor Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ResultSetDataModel()</td>
<td>Construct a new ResultSetDataModel with no specified wrapped data.</td>
</tr>
<tr>
<td>ResultSetDataModel(ResultSet resultSet)</td>
<td>Construct a new ResultSetDataModel wrapping the specified ResultSet.</td>
</tr>
</tbody>
</table>

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>getRowCount()</td>
</tr>
</tbody>
</table>
Return -1, since ResultSet does not provide a standard way to determine the number of available rows without scrolling through the entire ResultSet, and this can be very expensive if the number of rows is large.

Object
getRowData()
If row data is available, return a Map representing the values of the columns for the row specified by rowIndex, keyed by the corresponding column names.

int
getRowIndex()
Return the zero-relative index of the currently selected row.

Object
getWrappedData()
Return the object representing the data wrapped by this DataModel, if any.

boolean
isRowAvailable()
Return true if there is wrappedData available, and the result of calling absolute() on the underlying ResultSet, passing the current value of rowIndex plus one (to account for the fact that ResultSet uses one-relative indexing), returns true.

void
setRowIndex(int rowIndex)
Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row.

void
setWrappedData(Object data)
Set the object representing the data collection wrapped by this DataModel.

Methods inherited from class javax.faces.model.DataModel
addDataModelListener, getDataModelListeners, removeDataModelListener

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Constructor Detail
public ResultSetDataModel()

        ResultSetDataModel

ResultSetDataModel

public ResultSetDataModel()

        Construct a new ResultSetDataModel with no specified wrapped data.

public ResultSetDataModel(java.sql.ResultSet resultSet)

        ResultSet         ResultSetDataModel

        resultSet         ResultSet

ResultSetDataModel

public ResultSetDataModel(ResultSet resultSet)

        Construct a new ResultSetDataModel wrapping the specified ResultSet.

        Parameters:
        resultSet - ResultSet to be wrapped (if any)

Method Detail

public boolean isRowAvailable()
**isRowAvailable**

```java
public boolean isRowAvailable()
```

Return `true` if there is wrappedData available, and the result of calling `absolute()` on the underlying `ResultSet`, passing the current value of `rowIndex` plus one (to account for the fact that `ResultSet` uses one-relative indexing), returns `true`. Otherwise, return `false`.

**Specified by:**

`isRowAvailable` in class `DataModel`

**Throws:**

`FacesException` - if an error occurs getting the row availability

---

**public int getRowCount()**

```java
-1  ResultSet  ResultSet
```

**Throws**

`FacesException`:

---

**getRowCount**

```java
public int getRowCount()
```

Return `-1`, since `ResultSet` does not provide a standard way to determine the number of available rows without scrolling through the entire `ResultSet`, and this can be very expensive if the number of rows is large.

**Specified by:**

`getRowCount` in class `DataModel`
Throws:

* FacesException - if an error occurs getting the row count

public Object getRowData()

    Map rowIndex null

null Map AbstractMap JavaDoc Map

• Map Comparator String.CASE_INSENSITIVE_ORDER

• UnsupportedOperationException clear() remove()
• entrySet() Set
  ◦ Set UnsupportedOperationException Set
    Iterator
  ◦ set value ResultSet
• keySet() Set UnsupportedOperationException Set
    Iterator
• containsKey() false put()
  InvalidArgumentException Map ResultSet
• values() Collection UnsupportedOperationException
    Collection Iterator

Throws       FacesException:
Throws       InvalidArgumentException:

getRowData

public Object getRowData()

If row data is available, return a Map representing the values of the columns for the row specified by rowIndex, keyed by the corresponding column names. If no wrapped data is available, return null.
If a non-null Map is returned, its behavior must correspond to the contract for a mutable Map as described in the JavaDocs for AbstractMap, with the following exceptions and specialized behavior:

- The Map, and any supporting objects it returns, must perform all column name comparisons in a case-insensitive manner. This case-insensitivity must be implemented using a case-insensitive Comparator, such as String.CASE_INSENSITIVE_ORDER.
- The following methods must throw UnsupportedOperationException: clear(), remove().
- The entrySet() method must return a Set that has the following behavior:
  - Throw UnsupportedOperationException for any attempt to add or remove entries from the Set, either directly or indirectly through an Iterator returned by the Set.
  - Updates to the value of an entry in this set must write through to the corresponding column value in the underlying ResultSet.
- The keySet() method must return a Set that throws UnsupportedOperationException on any attempt to add or remove keys, either directly or through an Iterator returned by the Set.
- The put() method must throw IllegalArgumentException if a key value for which containsKey() returns false is specified. However, if a key already present in the Map is specified, the specified value must write through to the corresponding column value in the underlying ResultSet.
- The values() method must return a Collection that throws UnsupportedOperationException on any attempt to add or remove values, either directly or through an Iterator returned by the Collection.

Specified by:
getRowData in class DataModel

Throws:
FacesException - if an error occurs getting the row data
IllegalArgumentException - if now row data is available at the currently specified row index
public int getRowIndex()

Throws  FacesException: NullPointerException

gRowIndex

public int getRowIndex()

Description copied from class: DataModel

Return the zero-relative index of the currently selected row. If we are not currently positioned on a row, or no wrappedData is available, return -1.

Specified by:
getRowIndex in class DataModel

Throws:
FacesException - if an error occurs getting the row index

public void setRowIndex(int rowIndex)

Throws  FacesException: NullPointerException

Throws  IllegalArgumentException: NullPointerException  
rowIndex -1

setRowIndex

public void setRowIndex(int rowIndex)

Description copied from class: DataModel

Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row. It is possible to set the row index at a value for which the underlying data collection does not contain any row data. Therefore, callers may use the isRowAvailable() method to detect whether row data will be available for use by the getRowData() method.
If there is no wrappedData available when this method is called, the specified rowIndex is stored (and may be retrieved by a subsequent call to getRowData()), but no event is sent. Otherwise, if the currently selected row index is changed by this call, a DataModelEvent will be sent to the rowSelected() method of all registered DataModelListener.

Specified by:
    setRowIndex in class DataModel

Parameters:
    rowIndex - The new zero-relative index (must be non-negative)

Throws:
    FacesException - if an error occurs setting the row index
    IllegalArgumentException - if rowIndex is less than -1

public Object getWrappedData()

getWrappedData

public Object getWrappedData()

    Description copied from class: DataModel

    Return the object representing the data wrapped by this DataModel, if any.

    Specified by:
    getWrappedData in class DataModel

public void setWrappedData(Object data)

    Throws ClassCastException: NullPointerException  

setWrappedData
public void setWrappedData(Object data)

**Description copied from class: DataModel**

Set the object representing the data collection wrapped by this DataModel. If the specified data is null, detach this DataModel from any previously wrapped data collection instead.

If data is non-null, the currently selected row index must be set to zero, and a DataModelEvent must be sent to the rowSelected() method of all registered DataModelListener indicating that this row is now selected.

**Specified by:**

setWrappedData in class DataModel

**Parameters:**

data - Data collection to be wrapped, or null to detach from any previous data collection

**Throws:**

ClassCastException - if data is not of the appropriate type for this DataModel implementation
The interface `javax.resource.cci.ResultSetInfo` provides information on the support provided for ResultSet by a connected EIS instance. A component calls the method `Connection.getResultInfo` to get the `ResultSetInfo` instance.

A CCI implementation is not required to support `javax.resource.cci.ResultSetInfo` interface. The implementation of this interface is provided only if the CCI supports the ResultSet facility.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>boolean deletesAreDetected(int type)</code></td>
<td></td>
</tr>
</tbody>
</table>
boolean insertsAreDetected(int type)
Indicates whether or not a visible row insert can be
detected by calling ResultSet.rowInserted.

boolean othersDeletesAreVisible(int type)
Indicates whether deletes made by others are visible.

boolean othersInsertsAreVisible(int type)
Indicates whether inserts made by others are visible.

boolean othersUpdatesAreVisible(int type)
Indicates whether updates made by others are visible.

boolean ownDeletesAreVisible(int type)

boolean ownInsertsAreVisible(int type)

boolean ownUpdatesAreVisible(int type)

boolean supportsResultSetType(int type)
Indicates whether or not a resource adapter supports a
type of ResultSet.

boolean supportsResultSetConcurrency(int type, int concurrency)
Indicates whether or not a resource adapter supports the
concurrency type in combination with the given ResultSet type/

boolean updatesAreDetected(int type)
Indicates whether or not a visible row update can be
detected by calling the method ResultSet.rowUpdated.

**Method Detail**

public boolean updatesAreDetected(int type) throws ResourceException

Resultset.rowUpdated

typtype Resultset.ResultSet.TYPE_XXX
return true false

Throws ResourceException:
updatesAreDetected

boolean updatesAreDetected(int type) throws ResourceException

Indicates whether or not a visible row update can be detected by calling the method ResultSet.rowUpdated.

Parameters:
- type - type of the ResultSet i.e. ResultSet.TYPE_XXX

Returns:
- true if changes are detected by the result set type; false otherwise

Throws:
- ResourceException - Failed to get the information

See Also:
- ResultSet.rowUpdated()
Parameters:
  type - type of the ResultSet i.e. ResultSet.TYPE_XXX

Returns:
  true if changes are detected by the result set type; false otherwise

Throws:
  ResourceException - Failed to get the information

See Also:
  ResultSet.rowInserted()

</tbody>
</table>

**supportsResultTypeConcurrency**

boolean **supportsResultTypeConcurrency**(int type, int concurrency) throws ResourceException

Indicates whether or not a resource adapter supports the concurrency type in combination with the given ResultSet type/

**Parameters:**
- `type` - type of the ResultSet i.e. ResultSet.TYPE_XXX
- `concurrency` - ResultSet concurrency type defined in java.sql.ResultSet

**Returns:**
- true if the specified combination supported; false otherwise

**Throws:**
- `ResourceException` - Failed to get the information
public boolean othersUpdatesAreVisible(int type) throws ResourceException

    type                ResultSet  ResultSet.TYPE_XXX
    return              ResultSet  true  false
    Throws               ResourceException:

othersUpdatesAreVisible

boolean othersUpdatesAreVisible(int type)
    throws ResourceException

    Indicates whether updates made by others are visible.

Parameters:
    type - type of the ResultSet i.e. ResultSet.TYPE_XXX

Returns:
    true if updates by others are visible for the ResultSet type; false otherwise

Throws:
    ResourceException - Failed to get the information

public boolean othersDeletesAreVisible(int type) throws ResourceException

    type                ResultSet  ResultSet.TYPE_XXX
    return              ResultSet  true  false
    Throws               ResourceException:

othersDeletesAreVisible

boolean othersDeletesAreVisible(int type)
    throws ResourceException

    Indicates whether deletes made by others are visible.
Parameters:
  type - type of the ResultSet i.e. ResultSet.TYPE_XXX

Returns:
  true if deletes by others are visible for the ResultSet type; false otherwise

Throws:
  ResourceException - Failed to get the information

public boolean othersInsertsAreVisible(int type) throws ResourceException

  type  ResultSet  ResultSet.TYPE_XXX
  return ResultSet  true  false

Throws
  ResourceException:

othersInsertsAreVisible

boolean othersInsertsAreVisible(int type)
  throws ResourceException

Indicates whether inserts made by others are visible.

Parameters:
  type - type of the ResultSet i.e. ResultSet.TYPE_XXX

Returns:
  true if inserts by others are visible for the ResultSet type; false otherwise

Throws:
  ResourceException - Failed to get the information

public boolean ownUpdatesAreVisible(int type) throws ResourceException

OthersInsertsAreVisible
ownUpdatesAreVisible

boolean ownUpdatesAreVisible(int type)
throws ResourceException

Throws:

javax.annotation.security Annotation Type RolesAllowed

@Documented
@Retention(value=RUNTIME)
@Target(value={TYPE, METHOD})
public @interface RolesAllowed

**Implements:** Annotation
@Documented
@Retention(value=RUNTIME)
@Target(value={TYPE, METHOD})

RolesAllowed

since 1.0

Specifies the list of roles permitted to access method(s) in an application. The value of the RolesAllowed annotation is a list of security role names. This annotation can be specified on a class or on method(s). Specifying it at a class level means that it applies to all the methods in the class. Specifying it on a method means that it is applicable to that method only. If applied at both the class and methods level, the method value overrides the class value if the two conflict.

Since:

1.0

          └ java.lang.RuntimeException
              └ javax.persistence.PersistenceException
                  └ javax.persistence.RollbackException

All Implemented Interfaces:
  Serializable

class RollbackException

  extends PersistenceException

  Extends: Throwable > Exception > RuntimeException > PersistenceException

EntityTransaction.commit() since Java Persistence 1.0

  See also commit()

Thrown by the persistence provider when the EntityTransaction.commit() fails.

Since:
  Java Persistence 1.0

See Also:
  EntityTransaction.commit(), Serialized Form

Constructor Summary

RollbackException()
  Constructs a new RollbackException exception with null as its detail message.
RollbackException(String message)
   Constructs a new RollbackException exception with the specified detail message.

RollbackException(String message, Throwable cause)
   Constructs a new RollbackException exception with the specified detail message and cause.

RollbackException(Throwable cause)
   Constructs a new RollbackException exception with the specified cause.

Method Summary

Methods inherited from class java.lang.Throwable
fillInStackTrace, getCause, getLocalizedMessage, getMessage, getStackTrace, initCause, printStackTrace, printStackTrace, printStackTrace, setStackTrace, toString

public RollbackException(String message)
RollbackException
message

RollbackException

public RollbackException(String message)

    Constructs a new RollbackException exception with the specified
detail message.

    Parameters:
    message - the detail message.

public RollbackException(String message, Throwable cause)
RollbackException
message
cause

RollbackException

public RollbackException(String message, Throwable cause)

    Constructs a new RollbackException exception with the specified
detail message and cause.

    Parameters:
    message - the detail message.
    cause - the cause.

public RollbackException(Throwables cause)
RollbackException
public RollbackException(Throwable cause)

Constructs a new RollbackException exception with the specified cause.

Parameters:
cause - the cause.
javax.transaction

Class RollbackException

java.lang.Object

**Class SAAJMetaFactory**

```java
java.lang.Object
  ^javax.xml.soap.SAAJMetaFactory
```

**public abstract class SAAJMetaFactory**

**extends Object**

SAAJ API SAAJ 1.3  
SAAJ 1.2  
SAAJMetaFactory

**SAAJMetaFactory  public**

```
    since SAAJ 1.3
```

The access point for the implementation classes of the factories defined in the SAAJ API. All of the `newInstance` methods defined on factories in SAAJ 1.3 defer to instances of this class to do the actual object creation. The implementations of `newInstance()` methods (in SOAPFactory and MessageFactory) that existed in SAAJ 1.2 have been updated to also delegate to the SAAJMetaFactory when the SAAJ 1.2 defined lookup fails to locate the Factory implementation class name.

SAAJMetaFactory is a service provider interface. There are no public methods on this class.

**Since:**

SAAJ 1.3

</tr>
</tbody>
</table>

Throws

since

SAAJ 1.3

SAAJResult

public SAAJResult()
    throws SOAPException

    Creates a SAAJResult that will present results in the form of a SAAJ tree that supports the default (SOAP 1.1) protocol.

This kind of SAAJResult is meant for use in situations where the results will be used as a parameter to a method that takes a parameter whose type, such as SOAPElement, is drawn from the SAAJ API. When used in a transformation, the results are populated into the SOAPPart of a SOAPMessage that is created internally. The SOAPPart returned by DOMResult.getNode() is not guaranteed to be well-formed.

Throws:

    SOAPException - if there is a problem creating a SOAPMessage

Since:

    SAAJ 1.3

public SAAJResult(String protocol) throws SOAPException
    SAAJResult SAAJ DYNAMIC_SOAP_PROTOCOL
UnsupportedException

SAAJResult | SOAPElement | SAAJ API |
------------|-------------|----------|
SOAPMessage | SOAPPart | getNode() |

protocol SAAJ SOAP
SAAJResult

public SAAJResult(String protocol)
throws SOAPException

Creates a SAAJResult that will present results in the form of a SAAJ tree that supports the specified protocol. The DYNAMIC_SOAP_PROTOCOL is ambiguous in this context and will cause this constructor to throw an UnsupportedOperationException.

This kind of SAAJResult is meant for use in situations where the results will be used as a parameter to a method that takes a parameter whose type, such as SOAPElement, is drawn from the SAAJ API. When used in a transformation the results are populated into the SOAPPart of a SOAPMessage that is created internally. The SOAPPart returned by DOMResult.getNode() is not guaranteed to be well-formed.

Parameters:
protocol - the name of the SOAP protocol that the resulting SAAJ tree should support

Throws:
SOAPException - if a SOAPMessage supporting the specified protocol cannot be created

Since:
SAAJ 1.3
SAAJResult

public SAAJResult(SOAPMessage message)

Creates a SAAJResult that will write the results into the SOAPPart of the supplied SOAPMessage. In the normal case these results will be written using DOM APIs and, as a result, the finished SOAPPart will not be guaranteed to be well-formed unless the data used to create it is also well formed. When used in a transformation the validity of the SOAPMessage after the transformation can be guaranteed only by means outside SAAJ specification.

Parameters:
message -- the message whose SOAPPart will be populated as a result of some transformation or marshalling operation

Since:
SAAJ 1.3

public SAAJResult(SOAPElememt rootNode)

Creates a SAAJResult that will write the results as a child node of the SOAPElememt specified. In the normal case these results will be written using DOM APIs and as a result may invalidate the structure of the SAAJ tree. This kind of SAAJResult should only be used when the validity of the incoming data can be guaranteed by means outside of
the SAAJ specification.

**Parameters:**
- `rootNode` - the root to which the results will be appended

**Since:**
SAAJ 1.3

---

### Method Detail

**public Node getResult()**

```java
default Node Tree
since SAAJ 1.3
```

**getResult**

**public Node getResult()**

**Returns:**
the resulting Tree that was created under the specified root Node.

**Since:**
SAAJ 1.3

public SaveException()
 Throwable JAXRException

SaveException
 public SaveException()

    Constructs a JAXRException object with no reason or embedded Throwable.

public SaveException(String reason)
 JAXRException String reason

SaveException
 public SaveException(String reason)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown.

    Parameters:
    reason - a description of what caused the exception

public SaveException(String reason, Throwable cause)
 JAXRException String Throwable

Throwables
   reason
   cause JAXRException Throwable
SaveException

public SaveException(String reason, Throwable cause)

Constructs a JAXRException object with the given string as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

Parameters:
reason - a description of what caused the exception
cause - a Throwable object that is to be embedded in this JAXRException object

public SaveException(Throwable cause)

(Throwable cause) Throwable JAXRException
cause Exception Throwable

SaveException

public SaveException(Throwable cause)

Constructs a JAXRException object initialized with the given Throwable object.

Parameters:
cause - the Throwable that caused this Exception

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>getRowCount()</strong></td>
<td>If there is wrapped data available, return 1.</td>
</tr>
<tr>
<td><strong>getRowData()</strong></td>
<td>If wrapped data is available, return the wrapped data instance.</td>
</tr>
<tr>
<td><strong>getIndex()</strong></td>
<td></td>
</tr>
</tbody>
</table>
Return the zero-relative index of the currently selected row.

**getWrappedData()**

Return the object representing the data wrapped by this DataModel, if any.

**isRowAvailable()**

Return true if there is wrappedData available, and the current value of rowIndex is zero.

**setRowIndex(int rowIndex)**

Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row.

**setWrappedData(Object data)**

Set the object representing the data collection wrapped by this DataModel.

**Methods inherited from class javax.faces.model.DataModel**

- addDataModelListener
- getDataModelListeners
- removeDataModelListener

**Methods inherited from class java.lang.Object**

- clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

**Constructor Detail**

**public ScalarDataModel()**

ScalarDataModel

**public ScalarDataModel()**
Construct a new ScalarDataModel with no specified wrapped data.

```java
public ScalarDataModel(Object scalar)

ScalarDataModel

scalar
```

ScalarDataModel

```java
public ScalarDataModel(Object scalar)

Construct a new ScalarDataModel wrapping the specified scalar object.

Parameters:
scalar - Scalar to be wrapped (if any)
```

**Method Detail**

```java
public boolean isRowAvailable()

wrappedData  rowIndex  0   true  false

Throws  FacesException:
```

isRowAvailable

```java
public boolean isRowAvailable()

Return true if there is wrappedData available, and the current value of rowIndex is zero. Otherwise, return false.

Specified by:
```
**isRowAvailable** in class **DataModel**

**Throws:**
- **FacesException** - if an error occurs getting the row availability

---

**public int getRowCount()**

wrappedData 1       wrappedData -1

**Throws**
- **FacesException**

**getRowCount**

**public int getRowCount()**

If there is wrappedData available, return 1. If no wrappedData is available, return -1.

**Specified by:**
- **getRowCount** in class **DataModel**

**Throws:**
- **FacesException** - if an error occurs getting the row count

---

**public Object getRowData()**

null

**Throws**
- **FacesException**
- **IllegalArgumentException**

**getRowData**

**public Object getRowData()**

If wrapped data is available, return the wrapped data instance.
Otherwise, return null.

Specified by:

getRowData in class DataModel

Throws:

FacesException - if an error occurs getting the row data
IllegalArgumentException - if now row data is available at the currently specified row index

public int getRowIndex()

Throws FacesException: NullPointerException

getRowIndex

public int getRowIndex()

Description copied from class: DataModel

Return the zero-relative index of the currently selected row. If we are not currently positioned on a row, or no wrappedData is available, return -1.

Specified by:

getRowIndex in class DataModel

Throws:

FacesException - if an error occurs getting the row index

public void setRowIndex(int rowIndex)

Throws FacesException: NullPointerException

Throws IllegalArgumentException: NullPointerException rowIndex -1

setRowIndex
public void setRowIndex(int rowIndex)

**Description copied from class:** [DataModel](#)

Set the zero-relative index of the currently selected row, or -1 to indicate that we are not positioned on a row. It is possible to set the row index at a value for which the underlying data collection does not contain any row data. Therefore, callers may use the `isRowAvailable()` method to detect whether row data will be available for use by the `getRowData()` method.

If there is no `wrappedData` available when this method is called, the specified `rowIndex` is stored (and may be retrieved by a subsequent call to `getRowData()`), but no event is sent. Otherwise, if the currently selected row index is changed by this call, a `DataModelEvent` will be sent to the `rowSelected()` method of all registered `DataModelListener`s.

**Specified by:**

`setRowIndex` in class [DataModel](#)

**Parameters:**

- `rowIndex` - The new zero-relative index (must be non-negative)

**Throws:**

- [FacesException](#) - if an error occurs setting the row index
- [IllegalArgumentException](#) - if `rowIndex` is less than -1

---

public Object getWrappedData()

**getWrappedData**

public Object getWrappedData()

**Description copied from class:** [DataModel](#)

Return the object representing the data wrapped by this [DataModel](#), if any.
public void setWrappedData(Object data)

Description copied from class: DataModel

Set the object representing the data collection wrapped by this DataModel. If the specified data is null, detach this DataModel from any previously wrapped data collection instead.

If data is non-null, the currently selected row index must be set to zero, and a DataModelEvent must be sent to the rowSelected() method of all registered DataModelListener indicating that this row is now selected.

Specified by:
setWrappedData in class DataModel

Parameters:
- data - Data collection to be wrapped, or null to detach from any previous data collection

Throws:
- ClassCastException - if data is not of the appropriate type for this DataModel implementation
Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS:
**javax.xml.bind Class SchemaOutputResolver**

**java.lang.Object**

- javax.xml.bind.SchemaOutputResolver

```java
public abstract class SchemaOutputResolver
    extends Object```

JAXB

Controls where a JAXB implementation puts the generates schema files.

An implementation of this abstract class has to be provided by the calling application to generate schemas.

This is a class, not an interface so as to allow future versions to evolve without breaking the compatibility.

**Author:**
Kohsuke Kawaguchi (kohsuke.kawaguchi@sun.com)

---

### Constructor Summary

**SchemaOutputResolver()**

---

### Method Summary

**createOutput(String namespaceUri, String suggestedFileName)**
Decides where the schema file (of the given namespace URI) will be written, and return it as a Result object.

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Constructor Detail

public SchemaOutputResolver()

SchemaOutputResolver

public SchemaOutputResolver()

Method Detail

abstract public javax.xml.transform.Result createOutput(String namespaceUri, String suggestedFileName) throws java.io.IOException

 URI

namespaceUri      URI null
suggestedFileName JAXB "schema1.xsd"

return  <xs:import>
<xs:import>

createOutput
public abstract Result createOutput(String namespaceUri, String suggestedFileName)
throws IOException

Decides where the schema file (of the given namespace URI) will be written, and return it as a Result object.

This method is called only once for any given namespace. IOW, all the components in one namespace is always written into the same schema document.

Parameters:
namespaceUri - The namespace URI that the schema declares. Can be the empty string, but never be null.
suggestedFileName - A JAXB implementation generates an unique file name (like "schema1.xsd") for the convenience of the callee. This name can be used for the file name of the schema, or the callee can just ignore this name and come up with its own name. This is just a hint.

Returns:
a Result object that encapsulates the actual destination of the schema. If the Result object has a system ID, it must be an absolute system ID. Those system IDs are relativized by the caller and used for <xs:import> statements. If the Result object does not have a system ID, a schema for the namespace URI is generated but it won’t be explicitly <xs:import>ed from other schemas. If null is returned, the schema generation for this namespace URI will be skipped.

Throws:
IOException

public class ScopedAttributeELResolver
extends ELResolver

Defines variable resolution behavior for scoped attributes.

This resolver handles all variable resolutions (where base is null. It searches PageContext.findAttribute() for a matching attribute. If not found, it will return null, or in the case of setValue it will create a new attribute in the page scope with the given name.

Since:
   JSP 2.1

Methods inherited from class `java.lang.Object`:
- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`
### Constructor Detail

**ScopedAttributeELResolver**

```java
public ScopedAttributeELResolver()
```

### Method Detail

**getValue**

```java
public Object getValue(ELContext context, Object base, Object property)
```

If the base object is `null`, searches the page, request, session and application scopes for an attribute with the given name and returns it, or `null` if no attribute exists with the current name.

The `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver before returning if base is `null`. If this property is not `true` after this method is called, the caller should ignore the return value.

**Specified by:**

`getValue` in class `ELResolver`

**Parameters:**

- `context` - The context of this evaluation.
- `base` - Only `null` is handled by this resolver. Other values will result in an immediate return.
- `property` - The name of the scoped attribute to resolve.

**Returns:**

- If the `propertyResolved` property of `ELContext` was set to `true`, then the scoped attribute; otherwise undefined.

**Throws:**

- `NullPointerException` - if context is `null`
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.
**getType**

```java
public Class<Object> getType(ELContext context, Object base, Object property)
```

If the base object is `null`, returns `Object.class` to indicate that any type is valid to set for a scoped attribute.

The `propertyResolved` property of the `ELContext` object must be set to `true` by this resolver before returning if base is `null`. If this property is not `true` after this method is called, the caller should ignore the return value.

Specified by:
`getType` in class `ELResolver`

Parameters:
- `context` - The context of this evaluation.
- `base` - Only `null` is handled by this resolver. Other values will result in an immediate return.
- `property` - The name of the scoped attribute to resolve.

Returns:
If the `propertyResolved` property of `ELContext` was set to `true`, then `Object.class`; otherwise undefined.

Throws:
- `NullPointerException` - if `context` is `null`
- `ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

**setValue**

```java
public void setValue(ELContext context, Object base, Object property, Object val)
```

If the base object is `null`, sets an existing scoped attribute to the
new value, or creates a new scoped attribute if one does not exist by this name.

If the provided attribute name matches the key of an attribute in page scope, request scope, session scope, or application scope, the corresponding attribute value will be replaced by the provided value. Otherwise, a new page scope attribute will be created with the given name and value.

The propertyResolved property of the ELContext object must be set to true by this resolver before returning if base is null. If this property is not true after this method is called, the caller should ignore the return value.

Specified by:
setValue in class ELResolver

Parameters:
context - The context of this evaluation.
base - Only null is handled by this resolver. Other values will result in an immediate return.
property - The name of the scoped attribute to set.
val - The value for the scoped attribute.

Throws:
NullPointerException - if context is null.
ELException - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

isReadOnly

public boolean isReadOnly(ELContext context, Object base, Object property)

If the base object is null, returns false to indicate that scoped attributes are never read-only.

The propertyResolved property of the ELContext object must be set to true by this resolver before returning if base is null. If this property
is not true after this method is called, the caller should ignore the return value.

**Specified by:**

`isReadOnly` in class `ELResolver`  

**Parameters:**

- `context` - The context of this evaluation.
- `base` - Only null is handled by this resolver. Other values will result in an immediate return.
- `property` - The name of the scoped attribute.

**Returns:**

If the `propertyResolved` property of `ELContext` was set to true, then false; otherwise undefined.

**Throws:**

`NullPointerException` - if `context` is null.
`ELException` - if an exception was thrown while performing the property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

---

### getFeatureDescriptors

```java
public Iterator<FeatureDescriptor> getFeatureDescriptors(ELContext context, Object base)
```

If the base object is `null`, returns an `Iterator` containing `FeatureDescriptor` objects with information about each scoped attribute resolved by this resolver. Otherwise, returns `null`.

The `Iterator` returned must contain one instance of `FeatureDescriptor` for each scoped attribute found in any scope. Each info object contains information about a single scoped attribute, and is initialized as follows:

- `displayName` - The name of the scoped attribute.
- `name` - Same as `displayName` property.
- `shortDescription` - A suitable description for the scoped attribute. Should include the attribute's current scope (page, request, session, application). Will vary by implementation.
In addition, the following named attributes must be set in the returned FeatureDescriptors:

- **ELResolver.TYPE** - The current runtime type of the scoped attribute.
- **ELResolver.RESOLVABLE_AT_DESIGN_TIME** - true.

**Specified by:**

*getFeatureDescriptors* in class *ELResolver*

**Parameters:**

- **context** - The context of this evaluation.
- **base** - Only null is handled by this resolver. Other values will result in a null return value.

**Returns:**

An Iterator containing one FeatureDescriptor object for each scoped attribute, or null if base is not null.

**See Also:**

*FeatureDescriptor*

---

**getCommonPropertyType**

```java
public Class<String> getCommonPropertyType(ELContext context, Object base)
```

If the base object is null, returns String.class. Otherwise, returns null.

**Specified by:**

*getCommonPropertyType* in class *ELResolver*

**Parameters:**

- **context** - The context of this evaluation.
- **base** - Only null is handled by this resolver. Other values will result in a null return value.

**Returns:**

null if base is not null; otherwise String.class.

javax.mail.search  Class SearchTerm

java.lang.Object  
   javax.mail.search.SearchTerm

All Implemented Interfaces:
   Serializable

Direct Known Subclasses:
   AddressTerm, AndTerm, ComparisonTerm, FlagTerm, NotTerm, OrTerm, StringTerm

public abstract class SearchTerm
extends Object
implements Serializable

Implements: java.io.Serializable
Extended by: AddressTerm, AndTerm, ComparisonTerm, FlagTerm, NotTerm, OrTerm, StringTerm

JavaMail API

      JDK 1.1    Message.RecipientType
Message.RecipientType  readReplace  JDK 1.2

Search criteria are expressed as a tree of search-terms, forming a parse-tree for the search expression.

Search-terms are represented by this class. This is an abstract class; subclasses implement specific match methods.
Search terms are serializable, which allows storing a search term between sessions. **Warning:** Serialized objects of this class may not be compatible with future JavaMail API releases. The current serialization support is appropriate for short term storage.

**Warning:** Search terms that include references to objects of type `Message.RecipientType` will not be deserialized correctly on JDK 1.1 systems. While these objects will be deserialized without throwing any exceptions, the resulting objects violate the `type-safe enum` contract of the `Message.RecipientType` class. Proper deserialization of these objects depends on support for the `readReplace` method, added in JDK 1.2.

---

### Constructor Detail

public `SearchTerm()`
abstract public boolean match(Message msg)

method applies a specific match criterion to the given message and returns the result.

Parameters:
msg - The match criterion is applied on this message

Returns:
true, it the match succeeds, false if the match fails
javax.persistence

Annotation Type SecondaryTable

@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface SecondaryTable

**Implements:** Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)

SecondaryTable

```java
@Target
@Retention
public @interface SecondaryTable
```

1

```java
@Entity
@Table(name="CUSTOMER")
@SecondaryTable(name="CUST_DETAIL",
    pkJoinColumns=@PrimaryKeyJoinColumn(name="CUST_ID"))
public class Customer { ... }
```

2

```java
@Entity
@Table(name="CUSTOMER")
@SecondaryTable(name="CUST_DETAIL",
    pkJoinColumns={
        @PrimaryKeyJoinColumn(name="CUST_ID"),
        @PrimaryKeyJoinColumn(name="CUST_TYPE")})
public class Customer { ... }
```

since Java Persistence 1.0

This annotation is used to specify a secondary table for the annotated entity class. Specifying one or more secondary tables indicates that the data for the entity class is stored across multiple tables.

If no `SecondaryTable` annotation is specified, it is assumed that all
persistent fields or properties of the entity are mapped to the primary table. If no primary key join columns are specified, the join columns are assumed to reference the primary key columns of the primary table, and have the same names and types as the referenced primary key columns of the primary table.

Example 1: Single secondary table with a single primary key column.

```java
@Entity
@Table(name="CUSTOMER")
@SecondaryTable(name="CUST_DETAIL",
    pkJoinColumns=@PrimaryKeyJoinColumn(name="CUST_ID"))
public class Customer {
    ...
}
```

Example 2: Single secondary table with multiple primary key columns.

```java
@Entity
@Table(name="CUSTOMER")
@SecondaryTable(name="CUST_DETAIL",
    pkJoinColumns={
        @PrimaryKeyJoinColumn(name="CUST_ID"),
        @PrimaryKeyJoinColumn(name="CUST_TYPE"))
    public class Customer {
        ...
    }
```

Since:
Java Persistence 1.0

**Element Detail**

**abstract public String name()**

**name**

```java
public abstract String name
```

(Required) The name of the table.

**abstract public String catalog()**

**catalog**

```java
public abstract String catalog
```

(Optional) The catalog of the table.

Defaults to the default catalog.

**Default:**

"""
abstract public String schema()

schema

public abstract String schema

(Optional) The schema of the table.

Defaults to the default schema for user.

Default: ""

abstract public PrimaryJoinColumn[] pkJoinColumns()

pkJoinColumns

public abstract PrimaryJoinColumn[] pkJoinColumns

(Optional) The columns that are used to join with the primary table.

Defaults to the column(s) of the same name(s) as the primary key column(s) in the primary table

Default:

{}
abstract public UniqueConstraint[] uniqueConstraints()

uniqueConstraints

public abstract UniqueConstraint[] uniqueConstraints

(Optional) Unique constraints that are to be placed on the table. These are typically only used if table generation is in effect. These constraints apply in addition to any constraints specified by the Column andJoinColumn annotations and constraints entailed by primary key mappings.

Defaults to no additional constraints.

Default:
{}

This annotation is used to specify multiple secondary tables for an entity.

Example 1: Multiple secondary tables assuming primary key column

    @Entity
@Table(name="EMPLOYEE")
@SecondaryTables(
    @SecondaryTable(name="EMP_DETAIL"),
    @SecondaryTable(name="EMP_HIST")
)
public class Employee { ... }

Example 2: Multiple secondary tables with differently named primary key columns.

@Entity
@Table(name="EMPLOYEE")
@SecondaryTables(
    @SecondaryTable(name="EMP_DETAIL",
        pkJoinColumns=@PrimaryKeyJoinColumn(name="EMPL_ID")),
    @SecondaryTable(name="EMP_HIST",
        pkJoinColumns=@PrimaryKeyJoinColumn(name="EMPLOYEE_ID"))
)
public class Employee { ... }

public class SecurityException

extends ResourceException

Extends: Throwable > Exception > ResourceException

SecurityException

  • Subject
  • EIS
  • EIS
  • EIS EIS
  • EIS

version 1.0

A SecurityException indicates error conditions related to the security contract between an application server and resource adapter. The common error conditions represented by this exception are:

  • Invalid security information (represented as a Subject instance) passed across the security contract - for example, credentials have expired or have invalid format.
  • Lack of support for a specific security mechanism in an EIS or resource adapter.
  • Failure to create a connection to an EIS because of failed
authentication or authorization.

- Failure to authenticate a resource principal to an EIS instance or failure to establish a secure association with an underlying EIS instance.
- Access control exception to indicate that a requested access to an EIS resource or a request to create a new connection is denied.

SecurityException

#### public SecurityException()

Constructs a new instance with null as its detail message.

#### public SecurityException(String message)

*message*

SecurityException

#### public SecurityException(String message)

Constructs a new instance with the specified detail message.

**Parameters:**

message - the detail message.
public SecurityException(Throwable cause)
    cause  throwable

SecurityException

public SecurityException(Throwable cause)
    Constructs a new throwable with the specified cause.
    Parameters:
    cause - a chained exception of type Throwable.

public SecurityException(String message, Throwable cause)
    cause  throwable

SecurityException

public SecurityException(String message, Throwable cause)
    Constructs a new throwable with the specified detail message and cause.
    Parameters:
    message - the detail message.
    cause - a chained exception of type Throwable.

public SecurityException(String message, String errorCode)
throwable

message

errorCode

SecurityException

public SecurityException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:

message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

**Constructor Detail**

**public SelectItem()**

Construct a SelectItem with no initialized property values.

**SelectItem**

**public SelectItem()**

Construct a SelectItem with no initialized property values.

**public SelectItem(Object value)**

SelectItem.label String description
null disabled false escape true
**SelectItem**

public `SelectItem(Object value)`

Construct a `SelectItem` with the specified value. The `label` property will be set to the value (converted to a String, if necessary), the `description` property will be set to null, the `disabled` property will be set to false, and the `escape` property will be set to true.

**Parameters:**

- `value` - Value to be delivered to the model if this item is selected by the user

---

public `SelectItem(Object value, String label)`

Construct a `SelectItem` with the specified value and label. The `description` property will be set to null, the `disabled` property will be set to false, and the `escape` property will be set to true.

**Parameters:**

- `value` - Value to be delivered to the model if this item is selected by the user
public SelectItem(Object value, String label, String description)

SelectItem disabled false escape true

value
label
description

SelectItem

public SelectItem(Object value, String label, String description)

Construct a SelectItem instance with the specified value, label and description. This disabled property will be set to false, and the escape property will be set to true.

Parameters:
value - Value to be delivered to the model if this item is selected by the user
label - Label to be rendered for this item in the response
description - Description of this item, for use in tools

public SelectItem(Object value, String label, String description, boolean disabled)

SelectItem escape true

value
label
description
SelectItem

public SelectItem(Object value, String label, String description, boolean disabled)

Construct a SelectItem instance with the specified property values. The escape property will be set to true.

Parameters:

value - Value to be delivered to the model if this item is selected by the user
label - Label to be rendered for this item in the response
description - Description of this item, for use in tools
disabled - Flag indicating that this option is disabled

class SelectItem

public SelectItem(Object value, String label, String description, boolean disabled, boolean escape)

SelectItem

 value
 label
 description
 disabled
 escape
 since 1.2

SelectItem

public SelectItem(Object value, String label, String description,
boolean disabled, boolean escape)

Construct a SelectItem instance with the specified property values.

**Parameters:**
- value - Value to be delivered to the model if this item is selected by the user
- label - Label to be rendered for this item in the response
- description - Description of this item, for use in tools
- disabled - Flag indicating that this option is disabled
- escape - Flag indicating that the text of this option should be escaped when rendered.

**Since:**
1.2

### Method Detail

**public String getDescription()**

**getDescription**

**public String getDescription()**

Return a description of this item, for use in development tools.

---

**public void setDescription(String description)**

*description*
**setDescription**

```java
public void setDescription(String description)
```

Set the description of this item, for use in development tools.

**Parameters:**
- `description` - The new description

**isDisabled**

```java
public boolean isDisabled()
```

true

**setDisabled**

```java
public void setDisabled(boolean disabled)
```

true

**disabled**

Set the disabled flag for this item, which should modify the rendered output to make this item unavailable for selection by the user if set to true.
true.

Parameters:
  disabled - The new disabled flag

public String getLabel()

getLabel

public String getLabel()

  Return the label of this item, to be rendered visibly for the user.

public void setLabel(String label)

setLabel

public void setLabel(String label)

  Set the label of this item, to be rendered visibly for the user.

  Parameters:
    label - The new label

public Object getValue()
**getValue**

public Object getValue()

    Return the value of this item, to be delivered to the model if this item is selected by the user.

---

**public void setValue(Object value)**

    value

**setValue**

public void setValue(Object value)

    Set the value of this item, to be delivered to the model if this item is selected by this user.

**Parameters:**

    value - The new value

---

**public boolean isEscape()**

    return escape

**isEscape**

public boolean isEscape()
Getter for property escape.

>Returns:

Value of property escape.

```
public void setEscape(boolean escape)
```

setEscape

public void setEscape(boolean escape)

Setter for property escape.

**Parameters:**

escape - New value of property escape.
javax.faces.model Class SelectItemGroup

java.lang.Object
   ↓ javax.faces.model.SelectItem
      ↓ javax.faces.model.SelectItemGroup

SelectItemGroup selectItems Renderer
<select> HTML Renderer <optgroup> HTML 4.01

SelectItemGroup is a subclass of SelectItem that identifies a set of options that will be made available as a subordinate "submenu" or "options list", depending upon the requirements of the UISelectMany or UISelectOne renderer that is actually used. In general, the value property of this instance will be ignored, and the label property of this instance will be used to label the submenu.

Although it is feasible to incorporate SelectItemGroup instances in the selectItems property of this instance (thereby creating a data structure suitable for cascading submenus), some renderers may place restrictions on the level of nesting they support. For example, HTML based renderers that create an <select> element will typically render this instance as an <optgroup> element, but the HTML 4.01 Specification disallows nested option groups.
Constructor Summary

**SelectItemGroup()**
Construct a SelectItemGroup with no initialized property values.

**SelectItemGroup(String label)**
Construct a SelectItemGroup with the specified label and no associated selectItems.

**SelectItemGroup(String label, String description, boolean disabled, SelectItem[] selectItems)**
Construct a SelectItemGroup with the specified properties.

Constructor Detail

```java
public SelectItemGroup()
```
public SelectItemGroup()

Construct a SelectItemGroup with no initialized property values.

public SelectItemGroup(String label)

selectItem SelectItemGroup value 0
String description null disabled false

label

Throws NullPointerException: label false

public SelectItemGroup(String label)

Construct a SelectItemGroup with the specified label and no associated selectItems. The value property will be set to a zero-length String, the description property will be set to null, and the disabled property will be set to false.

Parameters:
label - Label to be rendered for this group in the response

Throws:
NullPointerException - if label is false

public SelectItemGroup(String label, String description, boolean disabled, SelectItem[] selectItems)
Construct a `SelectItemGroup` with the specified properties. The value property will be set to a zero-length String.

**Parameters:**
- `label` - Label to be rendered for this group in the response
- `description` - Description of this group, for use in tools
- `disabled` - Flag indicating that this group is disabled
- `selectItems` - Array of `SelectItem` describing the items available in this group

**Throws:**
- `NullPointerException` - if `label` or `selectItems` is `false`
public SelectItem[] getSelectItems()

Return the set of subordinate SelectItem for this group.

public void setSelectItems(SelectItem[] selectItems)

Throws NullPointerException: selectItems null

setSelectItems

public void setSelectItems(SelectItem[] selectItems)

Set the set of subordinate SelectItem for this group.

Parameters:
selectItems - The new set of subordinate items

Throws:
NullPointerException - if selectItems is null

### Constructor Detail
SendFailedException

public SendFailedException()

Constructs a SendFailedException with no detail message.

public SendFailedException(String s)

Constructs a SendFailedException with the specified detail message.

Parameters:

s - the detail message

public SendFailedException(String s, Exception e)

See also
getNextException, setNextException
Constructs a SendFailedException with the specified string and the specified address objects.

Parameters:
- msg - the detail message
- ex - the embedded exception

See also:
- MessagingException.getNextException()
- MessagingException.setNextException(java.lang.Exception)
validSent - valid addresses to which message was sent
validUnsent - valid addresses to which message was not sent
invalid - the invalid addresses

### Method Detail

**public Address[] getValidSentAddresses()**

```
return null
```

**getValidSentAddresses**

**public Address[] getValidSentAddresses()**

> Return the addresses to which this message was sent successfully.

**Returns:**
Addresses to which the message was sent successfully or null

**public Address[] getValidUnsentAddresses()**

```
return null
```

**getValidUnsentAddresses**

**public Address[] getValidUnsentAddresses()**

> Return the addresses that are valid but to which this message was not sent.

**Returns:**
Addresses that are valid but to which the message was not sent successfully or null

public Address[] getInvalidAddresses()

    return null

getInvalidAddresses

public Address[] getInvalidAddresses()

    Return the addresses to which this message could not be sent.

    Returns:
    Addresses to which the message sending failed or null;

PS:
javax.persistence Annotation Type SequenceGenerator

@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface SequenceGenerator

Implements: Annotation
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)

GeneratedValue

@SequenceGenerator(name="EMP_SEQ", allocationSize=25)

since Java Persistence 1.0

This annotation defines a primary key generator that may be referenced by name when a generator element is specified for the GeneratedValue annotation. A sequence generator may be specified on the entity class or on the primary key field or property. The scope of the generator name is global to the persistence unit (across all generator types).

Example:

@SequenceGenerator(name="EMP_SEQ", allocationSize=25)

Since: Java Persistence 1.0

### Required Element Summary

<table>
<thead>
<tr>
<th></th>
<th>name</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Required</td>
</tr>
</tbody>
</table>
|   | A unique generator name that can be
referenced by one or more classes to be the generator for primary key values.

### Optional Element Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Element Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>int</td>
<td>allocationSize</td>
<td>(Optional) The amount to increment by when allocating sequence numbers from the sequence.</td>
</tr>
<tr>
<td>int</td>
<td>initialValue</td>
<td>(Optional) The value from which the sequence object is to start generating.</td>
</tr>
<tr>
<td>String</td>
<td>sequenceName</td>
<td>(Optional) The name of the database sequence object from which to obtain primary key values.</td>
</tr>
</tbody>
</table>

### Element Detail

abstract public String name()

**name**

public abstract String name

(Required) A unique generator name that can be referenced by one or more classes to be the generator for primary key values.

abstract public String sequenceName()
sequenceName

public abstract String sequenceName

(Optional) The name of the database sequence object from which to obtain primary key values.

Defaults to a provider-chosen value.

Default: ""

abstract public int initialValue()

initialValue

public abstract int initialValue

(Optional) The value from which the sequence object is to start generating.

Default: 1

abstract public int allocationSize()

allocationSize

public abstract int allocationSize

(Optional) The amount to increment by when allocating sequence numbers from the sequence.
Default:
50

**javax.jms Interface ServerSession**

public interface ServerSession

ServerSession JMS

ServerSession

- `getSession` - ServerSession JMS
- `start` - ServerSession JMS run

JMS ConnectionConsumer ServerSession
ConnectionConsumer ServerSessionPool ServerSession
ServerSession JMS JMS ServerSession

ServerSession ServerSession ServerSession start
start ServerSession run Session run
run ServerSession ServerSession ServerSessionPool

JMS API ConnectionConsumer Session
ConnectionConsumer Session JMS

**version** 1.0 - 9 March 1998

See [javax.jms.ServerSessionPool](#),
also [javax.jms.ConnectionConsumer](#)

A `ServerSession` object is an application server object that is used by a server to associate a thread with a JMS session (optional).

A `ServerSession` implements two methods:

- `getSession` - returns the `ServerSession`'s JMS session.
- `start` - starts the execution of the `ServerSession` thread and results in the execution of the JMS session's `run` method.
A `ConnectionConsumer` implemented by a JMS provider uses a `ServerSession` to process one or more messages that have arrived. It does this by getting a `ServerSession` from the `ConnectionConsumer`'s `ServerSessionPool`; getting the `ServerSession`'s JMS session; loading it with the messages; and then starting the `ServerSession`.

In most cases the `ServerSession` will register some object it provides as the `ServerSession`'s thread run object. The `ServerSession`'s start method will call the thread's `start` method, which will start the new thread, and from it, call the `run` method of the `ServerSession`'s run object. This object will do some housekeeping and then call the `Session`'s `run` method. When `run` returns, the `ServerSession`'s run object can return the `ServerSession` to the `ServerSessionPool`, and the cycle starts again.

Note that the JMS API does not architect how the `ConnectionConsumer` loads the `Session` with messages. Since both the `ConnectionConsumer` and `Session` are implemented by the same JMS provider, they can accomplish the load using a private mechanism.

**Version:**
1.0 - 9 March 1998

</tr>
</tbody>
</table>

---

### Method Detail
public **Session** getSession() throws **JMSException**

ServerSession Session Connection Session Session

ServerSession start

return

Throws **JMSException**: JMS

---

**getSession**

```java
public **Session** getSession()
```

throws **JMSException**

Return the ServerSession's Session. This must be a Session created by the same Connection that will be dispatching messages to it. The provider will assign one or more messages to the Session and then call `start` on the ServerSession.

Returns:
the server session's session

Throws:
**JMSException** - if the JMS provider fails to get the associated session for this ServerSession due to some internal error.

---

public void start() throws **JMSException**

Session run

Throws **JMSException**: JMS

---

**start**

```java
public void start()
```

throws **JMSException**

Cause the Session's `run` method to be called to process messages that were just assigned to it.

Throws:
**JMSException** - if the JMS provider fails to start the server session to process messages due to some internal error.

Submit a bug or feature

PS:
### Interface ServerSessionPool

```java
public interface ServerSessionPool
```

<table>
<thead>
<tr>
<th>ServerSessionPool</th>
<th>ConnectionConsumer</th>
<th>ServerSession</th>
</tr>
</thead>
<tbody>
<tr>
<td>getServerSession</td>
<td>JMS API</td>
<td>ServerSession</td>
</tr>
<tr>
<td></td>
<td>ServerSession</td>
<td>ServerSession</td>
</tr>
</tbody>
</table>

**Version:** 1.0 - 9 March 1998

**See also:** [javax.jms.ServerSession](en)

A `ServerSessionPool` object is an object implemented by an application server to provide a pool of `ServerSession` objects for processing the messages of a `ConnectionConsumer` (optional).

Its only method is `getServerSession`. The JMS API does not architect how the pool is implemented. It could be a static pool of `ServerSession` objects, or it could use a sophisticated algorithm to dynamically create `ServerSession` objects as needed.

If the `ServerSessionPool` is out of `ServerSession` objects, the `getServerSession` call may block. If a `ConnectionConsumer` is blocked, it cannot deliver new messages until a `ServerSession` is eventually returned.

**Version:** 1.0 - 9 March 1998

**Author:** Mark Hapner, Rich Burridge

**See Also:**
Method Summary

<table>
<thead>
<tr>
<th>ServerSession</th>
<th>getServerSession()</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return a server session from the pool.</td>
</tr>
</tbody>
</table>

Method Detail

```java
class ServerSession {
    public ServerSession getServerSession() throws JMSException {
        return ServerSession.getServerSession();
    }
}
```

`getServerSession`

Returns:

- a server session from the pool

Throws:

- `JMSException` - if an application server fails to return a `ServerSession` out of its server session pool.

Field Detail

protected Session session

The session from which this service was created.
protected URLName url

The URLName of this service.

protected boolean debug

Debug flag for this service. Set from the session's debug flag when this service is created.

## Constructor Detail

protected Service(Session session, URLName urlName)

- `session`: Session object for this service
- `urlName`: URLName object to be used for this service

Constructor.

## Method Detail
public void connect() throws MessagingException

A generic connect method that takes no parameters. Subclasses can implement the appropriate authentication schemes. Subclasses that need additional information might want to use some properties or might get it interactively using a popup window.

If the connection is successful, an "open" ConnectionEvent is delivered to any ConnectionListeners on this service.

Most clients should just call this method to connect to the service.

It is an error to connect to an already connected service.

The implementation provided here simply calls the following connect(String, String, String) method with nulls.

Throws:
public void connect(String host, String user, String password) throws MessagingException

ConnectionListener "open" Connec
Connect to the specified address. This method provides a simple authentication scheme that requires a username and password.

If the connection is successful, an "open" ConnectionEvent is delivered to any ConnectionListeners on this service.

It is an error to connect to an already connected service.

The implementation in the Service class will collect defaults for the host, user, and password from the session, from the URLName for this service, and from the supplied parameters and then call the protocolConnect method. If the protocolConnect method returns false, the user will be prompted for any missing information and the protocolConnect method will be called again. The subclass should override the protocolConnect method. The subclass should also implement the getURLName method, or use the implementation in this class.

On a successful connection, the setURLName method is called with a URLName that includes the information used to make the connection, including the password.

If the username passed in is null, a default value will be chosen as described above. If the password passed in is null and this is the first successful connection to this service, the user name and the password collected from the user will be saved as defaults for subsequent connection attempts to this same service when using other Service object instances (the connection information is typically always saved within a particular Service object instance). The password is saved using the Session method setPasswordAuthentication. If the password passed in is not null, it is not saved, on the assumption that the application is managing passwords explicitly.

**Parameters:**

host - the host to connect to
public void connect(String user, String password) throws MessagingException

null

user

password

Throws: AuthenticationFailedException - for authentication failures

Throws: MessagingException - for other failures

Throws: IllegalStateException - if the service is already connected

See Also: ConnectionEvent, Session.setPasswordAuthentication(javax.mail.URLName, javax.mail.PasswordAuthentication)

public void connect(String user, String password) throws MessagingException

null

user

password

Throws: AuthenticationFailedException:

Throws: MessagingException:

Throws: IllegalStateException:

since JavaMail 1.4

See also setPasswordAuthentication, connect(java.lang.String, java.lang.String, java.lang.String)

**connect**

public void connect(String user, String password) throws MessagingException

Connect to the current host using the specified username and password. This method is equivalent to calling the connect(host, user, password) method with null for the host name.

**Parameters:**

user - the user name
password - this user's password

**Throws:**
- `AuthenticationFailedException` - for authentication failures
- `MessagingException` - for other failures
- `IllegalStateException` - if the service is already connected

**Since:**
JavaMail 1.4

**See Also:**
- `ConnectionEvent`

- `connect(java.lang.String, java.lang.String, java.lang.String)`

---

```java
public void connect(String host, int port, String user, String password)
throws MessagingException
```

**connect(host, user, password)**

- `host`
- `port` -1
- `user`
- `password`

**Throws**
- `AuthenticationFailedException`
- `MessagingException`
- `IllegalStateException`

**See also**
- `javax.mail.event.ConnectionEvent`

---

```java
public void connect(String host, int port, String user, String password)
throws MessagingException
```

**connect**

- `String host`,
- `int port`,
- `String user`,
- `String password`

**throws** `MessagingException`

Similar to `connect(host, user, password)` except a specific port can be specified.
Parameters:
  host - the host to connect to
  port - the port to connect to (-1 means the default port)
  user - the user name
  password - this user's password

Throws:
  AuthenticationFailedException - for authentication failures
  MessagingException - for other failures
  IllegalStateException - if the service is already connected

           java.lang.String), ConnectionEvent

protected boolean protocolConnect(String host, int port,
String user, String password) throws MessagingException

null protocolConnect fals
false AuthenticationFailedException String

protocolConnect
  host
  port
  user
  password
  return

Throws AuthenticationFailedException:
Throws MessagingException:

protocolConnect

protected boolean protocolConnect(String host,
  int port,
  String user,
  String password)
The service implementation should override this method to perform the actual protocol-specific connection attempt. The default implementation of the `connect` method calls this method as needed.

The `protocolConnect` method should return `false` if a user name or password is required for authentication but the corresponding parameter is null; the `connect` method will prompt the user when needed to supply missing information. This method may also return `false` if authentication fails for the supplied user name or password. Alternatively, this method may throw an `AuthenticationFailedException` when authentication fails. This exception may include a String message with more detail about the failure.

The `protocolConnect` method should throw an exception to report failures not related to authentication, such as an invalid host name or port number, loss of a connection during the authentication process, unavailability of the server, etc.

**Parameters:**
- `host` - the name of the host to connect to
- `port` - the port to use (-1 means use default port)
- `user` - the name of the user to login as
- `password` - the user's password

**Returns:**
- true if connection successful, false if authentication failed

**Throws:**
- `AuthenticationFailedException` - for authentication failures
- `MessagingException` - for non-authentication failures

---

public boolean isConnected()
isConnected

public boolean isConnected()

Is this service currently connected?

This implementation uses a private boolean field to store the connection state. This method returns the value of that field.

Subclasses may want to override this method to verify that any connection to the message store is still alive.

**Returns:**
true if the service is connected, false if it is not connected

---

protected void setConnected(boolean connected)

connect  close

isConnected
connected  true false

setConnected

protected void setConnected(boolean connected)

Set the connection state of this service. The connection state will automatically be set by the service implementation during the connect and close methods. Subclasses will need to call this method to set the state if the service was automatically disconnected.

The implementation in this class merely sets the private field returned by the isConnected method.
Parameters:

- **connected**: true if the service is connected, false if it is not connected

---

public void close() throws **MessagingException**

ConnectionListener  close ConnectionEvent

Messaging FolderMessage

MessagingException

setConnected(false)  **connected**: false

ConnectionListener  close ConnectionEvent

finally  super.close()

Throws  **MessagingException**:  

See also  javax.mail.event.ConnectionEvent

---

**close**

public void **close()**

throws **MessagingException**

Close this service and terminate its connection. A close ConnectionEvent is delivered to any ConnectionListeners. Any Messaging components (Folders, Messages, etc.) belonging to this service are invalid after this service is closed. Note that the service is closed even if this method terminates abnormally by throwing a MessagingException.

This implementation uses setConnected(false) to set this service's connected state to false. It will then send a close ConnectionEvent to any registered ConnectionListeners. Subclasses overriding this method to do implementation specific cleanup should call this method as a last step to insure event notification, probably by including a call to super.close() in a finally clause.

Throws:
public URLName getURLName()

Return a URLName representing this service. The returned URLName does *not* include the password field.

Subclasses should only override this method if their URLName does not follow the standard format.

The implementation in the Service class returns (usually a copy of) the url field with the password and file information stripped out.

**Returns:**
the URLName representing this service

**See Also:**
URLName
### setURLName

```java
protected void setURLName(URLName url)
```

Set the URLName representing this service. Normally used to update the `url` field after a service has successfully connected.

Subclasses should only override this method if their URL does not follow the standard format. In particular, subclasses should override this method if their URL does not require all the possible fields supported by `URLName`; a new `URLName` should be constructed with any unneeded fields removed.

The implementation in the `Service` class simply sets the `url` field.

See Also:
- [URLName](javax.mail.URLName)

---

### public void addConnectionListener(ConnectionListener l)

#### Connection

```java
public void addConnectionListener(ConnectionListener l)
```

`ConnectionListener` is the interface that represents a connection listener. See also [javax.mail.event.ConnectionEvent](javax.mail.event.ConnectionEvent)

### addConnectionListener

```java
public void addConnectionListener(ConnectionListener l)
```
Add a listener for Connection events on this service.

The default implementation provided here adds this listener to an internal list of ConnectionListeners.

**Parameters:**
- `l` - the Listener for Connection events

**See Also:**
- [ConnectionEvent](#)

---

```java
public void removeConnectionListener(ConnectionListener l)
```

**Connection**

**ConnectionListener**

Remove a Connection event listener.

The default implementation provided here removes this listener from the internal list of ConnectionListeners.

**Parameters:**
- `l` - the listener

**See Also:**
- [addConnectionListener](#)

---

```java
protected void notifyConnectionListeners(int type)
```

**Connection**

**ConnectionListener**

Connection
ConnectionListener

**notifyConnectionListeners**

```java
protected void notifyConnectionListeners(int type)
```

Notify all ConnectionListeners. Service implementations are expected to use this method to broadcast connection events.

The provided default implementation queues the event into an internal event queue. An event dispatcher thread dequeues events from the queue and dispatches them to the registered ConnectionListeners. Note that the event dispatching occurs in a separate thread, thus avoiding potential deadlock problems.

**public String toString()**

```java
URLName toString() getURLName.toString() toString
```

**toString**

```java
public String toString()
```

Return getURLName.toString() if this service has a URLName, otherwise it will return the default toString.

**Overrides:**

`toString` in class `Object`

**protected void queueEvent(MailEvent event, java.util.Vector<E> vector)**
queueEvent

protected void queueEvent(MailEvent event, Vector vector)

Add the event and vector of listeners to the queue to be delivered.

protected void finalize() throws Throwable

finalize

protected void finalize() throws Throwable

Stop the event dispatcher thread so the queue can be garbage collected.

Overrides:
   finalize in class Object

Throws:
   Throwable
javax.xml.registry.infomodel Interface Service

All Superinterfaces:

getProvidingOrganization

    Organization getProvidingOrganization() throws JAXRException

    Gets the Organization that provides this service. Providing Organization may be null. The providing Organization may be different from the Submitting Organization as defined by RegistryObject#getSubmittingOrganization.

    Capability Level: 0

    Returns:
the Organization that provides this service

Throws:

JAXRException - If the JAXR provider encounters an internal error

See Also:

RegistryObject.getSubmittingOrganization()

public void setProvidingOrganization(Organization providingOrganization) throws JAXRException
Organization

0

providingOrganization

Throws

JAXRException: JAXR

setProvidingOrganization

void setProvidingOrganization(Organization providingOrganization)
throws JAXException

Sets the Organization that provides this service.

Capability Level: 0

Parameters:

providingOrganization - the Organization that provides this service

Throws:

JAXRException - If the JAXR provider encounters an internal error

public void addServiceBinding(ServiceBinding serviceBinding) throws JAXRException
ServiceBinding
addServiceBinding

void addServiceBinding(ServiceBinding serviceBinding)
    throws JAXRException

Adds a child ServiceBinding.

Capability Level: 0

Parameters:
    serviceBinding - the ServiceBinding being added

Throws:
    JAXRException - If the JAXR provider encounters an internal error

public void addServiceBindings(java.util.Collection<E> serviceBindings) throws JAXRException
ServiceBinding Collection

addServiceBindings

void addServiceBindings(Collection serviceBindings)
    throws JAXRException

Adds a Collection of ServiceBinding children.
public void removeServiceBinding(ServiceBinding serviceBinding) throws JAXRException

Removes a child ServiceBinding.

Capability Level: 0

Parameters:
    serviceBinding - the ServiceBinding being removed

Throws:
    JAXRException - If the JAXR provider encounters an internal error
**removeServiceBindings**

```java
void removeServiceBindings(Collection serviceBindings)
throws JAXRException
```

Removes a Collection of children ServiceBindings.

**Capability Level:** 0

**Parameters:**
- `serviceBindings` - the Collection of ServiceBindings being removed

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

**public java.util.Collection<E> getServiceBindings() throws JAXRException**

```java
ServiceBinding Collection
null
```

**Throws:**

</tr>
</tbody>
</table>
The getPort method returns either an instance of a generated stub implementation class or a dynamic proxy. A service client uses this dynamic proxy to invoke operations on the target service endpoint. The `serviceEndpointInterface` specifies the service endpoint interface that is supported by the created dynamic proxy or stub instance.

**Parameters:**
- `portName` - Qualified name of the service endpoint in the WSDL service description
- `serviceEndpointInterface` - Service endpoint interface supported by the dynamic proxy or stub instance

**Returns:**
java.rmi.Remote Stub instance or dynamic proxy that supports the specified service endpoint interface

**Throws:**
- `ServiceException` - This exception is thrown in the following cases:
  - If there is an error in creation of the dynamic proxy or stub instance
  - If there is any missing WSDL metadata as required by this method
  - Optionally, if an illegal `serviceEndpointInterface` or `portName` is specified

**See Also:**
- Proxy, InvocationHandler

---

`getPort`

```java
Remote getPort(Class serviceEndpointInterface)
        throws ServiceException
```

The `getPort` method returns either an instance of a generated stub implementation class or a dynamic proxy. The parameter
serviceEndpointInterface specifies the service endpoint interface that is supported by the returned stub or proxy. In the implementation of this method, the JAX-RPC runtime system takes the responsibility of selecting a protocol binding (and a port) and configuring the stub accordingly. The returned Stub instance should not be reconfigured by the client.

**Parameters:**
- serviceEndpointInterface - Service endpoint interface

**Returns:**
- Stub instance or dynamic proxy that supports the specified service endpoint interface

**Throws:**
- ServiceException -
  - If there is an error during creation of stub instance or dynamic proxy
  - If there is any missing WSDL metadata as required by this method
  - Optionally, if an illegal serviceEndpointInterface is specified

---

getCalls

**Call**[] get Calls(QName portName)

throws ServiceException

Gets an array of preconfigured call objects for invoking operations on the specified port. There is one call object per operation that can be invoked on the specified port. Each call object is pre-configured and does not need to be configured using the setter methods on call interface.

Each invocation of the get Calls method returns a new array of preconfigured call objects

This method requires the Service implementation class to have access to the WSDL related metadata.
createCall

```java
Call createCall(QName portName)
```

Throws: `ServiceException` - If any error in the creation of the call object

Parameters:
- `portName` - Qualified name for the target service endpoint

Returns: Call instance

createCall

```java
Call createCall(QName portName, QName operationName)
```

Throws: `ServiceException` - If any error in the creation of the call object

Parameters:
- `portName` - Qualified name for the target service endpoint
- `operationName` - Qualified Name of the operation for which this
call object is to be created.

**Returns:**
Call instance

**Throws:**
ServiceException - If any error in the creation of the call object

---

createCall

```java
Call createCall(QName portName,
String operationName)
throws ServiceException
```

Creates a call instance.

**Parameters:**
- portName - Qualified name for the target service endpoint
- operationName - Name of the operation for which this call object is to be created.

**Returns:**
Call instance

**Throws:**
ServiceException - If any error in the creation of the call object

---

createCall

```java
Call createCall()
throws ServiceException
```

Creates a call object not associated with specific operation or target service endpoint. This call object needs to be configured using the setter methods on the call interface.

**Returns:**
Call object
Throws:

ServiceException - If any error in the creation of the call object

---

getServiceName

QName getServiceName()

Gets the name of this service.

**Returns:**

Qualified name of this service

---

getPorts

Iterator getPorts() throws ServiceException

Returns an Iterator for the list of QNames of service endpoints grouped by this service

**Returns:**

Returns java.util.Iterator with elements of type javax.xml.namespace.QName

**Throws:**

ServiceException - If this Service class does not have access to the required WSDL metadata

---

getWSDLDocumentLocation

URL getWSDLDocumentLocation()
Gets the location of the WSDL document for this Service.

**Returns:**
URL for the location of the WSDL document for this service

---

**get TypeMappingRegistry**

TypeMappingRegistry getTypeMappingRegistry()

Gets the TypeMappingRegistry for this Service object. The returned TypeMappingRegistry instance is pre-configured to support the standard type mapping between XML and Java types as required by the JAX-RPC specification.

**Returns:**
The TypeMappingRegistry for this Service object.

**Throws:**
java.lang.UnsupportedOperationException - if the Service class does not support the configuration of TypeMappingRegistry.

---

**getHandlerRegistry**

HandlerRegistry getHandlerRegistry()

Returns the configured HandlerRegistry instance for this Service instance.

**Returns:**
HandlerRegistry

**Throws:**
java.lang.UnsupportedOperationException - if the Service class does not support the configuration of a HandlerRegistry.

PS:
javax.xml.ws  **Class Service**

**java.lang.Object**
  - **javax.xml.ws.Service**

```java
public class Service
extends Object

Implements: RegistryEntry
```

Service  Organization Web  RegistryObject Service  ServiceBinding  UDDI  BusinessService

**See also**  **javax.xml.registry.infomodel.ServiceBinding**

Service objects provide the client view of a Web service.

Service acts as a factory of the following:

- Proxies for a target service endpoint.
- Instances of `javax.xml.ws.Dispatch` for dynamic message-oriented invocation of a remote operation.

The ports available on a service can be enumerated using the `getPorts` method. Alternatively, you can pass a service endpoint interface to the `UnaryPort` method and let the runtime select a compatible port.

Handler chains for all the objects created by a `Service` can be set by means of a `HandlerResolver`.

An `Executor` may be set on the service in order to gain better control over the threads used to dispatch asynchronous callbacks. For instance, thread pooling with certain parameters can be enabled by creating a `ThreadPoolExecutor` and registering it with the service.

**Since:**
JAX-WS 2.0

| <T> | getPort(Class<T> serviceEndpointInterface) |
The `getPort` method returns a stub.

```java
public <T> T getPort(QName portName, Class<T> serviceEndpointInterface)
```

The `getPort` method returns a stub. A service client uses this stub to invoke operations on the target service endpoint. The `serviceEndpointInterface` specifies the service endpoint.
interface that is supported by the created dynamic proxy or stub instance.

**Parameters:**
- **portName** - Qualified name of the service endpoint in the WSDL service description
- **serviceEndpointInterface** - Service endpoint interface supported by the dynamic proxy or stub instance

**Returns:**
Object Proxy instance that supports the specified service endpoint interface

**Throws:**
- **WebServiceException** - This exception is thrown in the following cases:
  - If there is an error in creation of the proxy
  - If there is any missing WSDL metadata as required by this method
  - Optionally, if an illegal **serviceEndpointInterface** or **portName** is specified

**See Also:**
- [Proxy](#), [InvocationHandler](#)

---

getPort

public `<T>` T getPort(Class `<T>` serviceEndpointInterface)

The getPort method returns a stub. The parameter **serviceEndpointInterface** specifies the service endpoint interface that is supported by the returned proxy. In the implementation of this method, the JAX-WS runtime system takes the responsibility of selecting a protocol binding (and a port) and configuring the proxy accordingly. The returned proxy should not be reconfigured by the client.

**Parameters:**
- **serviceEndpointInterface** - Service endpoint interface

**Returns:**
Object instance that supports the specified service endpoint interface

**Throws:**

- `WebServiceException` -
  - If there is an error during creation of the proxy
  - If there is any missing WSDL metadata as required by this method
  - Optionally, if an illegal `serviceEndpointInterface` is specified

### addPort

```java
public void addPort(QName portName,
                     String bindingId,
                     String endpointAddress)
```

Creates a new port for the service. Ports created in this way contain no WSDL port type information and can only be used for creating `Dispatch` instances.

**Parameters:**
- `portName` - Qualified name for the target service endpoint
- `bindingId` - A `String` identifier of a binding.
- `endpointAddress` - Address of the target service endpoint as a `URI`

**Throws:**

- `WebServiceException` - If any error in the creation of the port

**See Also:**

- `SOAPBinding.SOAP11HTTP_BINDING`, `SOAPBinding.SOAP12HTTP_BINDING`, `HTTPBinding.HTTP_BINDING`

### createDispatch

```java
public <T> Dispatch<T> createDispatch(QName portName,
                                       Class<T> type,
                                       ...
```

Service.Mode (mode)

Creates a Dispatch instance for use with objects of the users choosing.

Parameters:
- portName - Qualified name for the target service endpoint
- type - The class of object used to messages or message payloads. Implementations are required to support javax.xml.transform.Source and javax.xml.soap.SOAPMessage.
- mode - Controls whether the created dispatch instance is message or payload oriented, i.e. whether the user will work with complete protocol messages or message payloads. E.g. when using the SOAP protocol, this parameter controls whether the user will work with SOAP messages or the contents of a SOAP body. Mode must be MESSAGE when type is SOAPMessage.

Returns:
- Dispatch instance

Throws:
- WebServiceException - If any error in the creation of the Dispatch object

See Also:
- Source, SOAPMessage

createDispatch

public Dispatch<Object> createDispatch(QName portName,
                                           JAXBContext context,
                                           Service.Mode mode)

Creates a Dispatch instance for use with JAXB generated objects.

Parameters:
- portName - Qualified name for the target service endpoint
- context - The JAXB context used to marshall and
unmarshall messages or message payloads.
mode - Controls whether the created dispatch instance is message or payload oriented, i.e. whether the user will work with complete protocol messages or message payloads. E.g. when using the SOAP protocol, this parameter controls whether the user will work with SOAP messages or the contents of a SOAP body.

**Returns:**
Dispatch instance

**Throws:**
ServiceException - If any error in the creation of the Dispatch object

**See Also:**
JAXBContext

---

**getServiceName**

public QName getServiceName()

Gets the name of this service.

**Returns:**
Qualified name of this service

---

**getPorts**

public Iterator<QName> getPorts()

Returns an Iterator for the list of QNames of service endpoints grouped by this service

**Returns:**
Returns java.util.Iterator with elements of type javax.xml.namespace.QName

**Throws:**
**WebServiceException** - If this Service class does not have access to the required WSDL metadata

---

**getWSDLDocumentLocation**

```java
public URL getWSDLDocumentLocation()
```

Gets the location of the WSDL document for this Service.

**Returns:**
URL for the location of the WSDL document for this service

---

**getHandlerResolver**

```java
public HandlerResolver getHandlerResolver()
```

Returns the configured handler resolver.

**Returns:**
HandlerResolver The HandlerResolver being used by this Service instance, or null if there isn't one.

---

**setHandlerResolver**

```java
public void setHandlerResolver(HandlerResolver handlerResolver)
```

Sets the HandlerResolver for this Service instance.
