The handler resolver, if present, will be called once for each proxy or dispatch instance that is created, and the handler chain returned by the resolver will be set on the instance.

**Parameters:**
**HandlerResolver** - The HandlerResolver to use for all subsequently created proxy/dispatch objects.

**See Also:**
- [HandlerResolver](#)

---

**getExecutor**

```java
public Executor getExecutor()
```

Returns the executor for this service instance. The executor is used for all asynchronous invocations that require callbacks.

**Returns:**
- The `java.util.concurrent.Executor` to be used to invoke a callback.

**See Also:**
- [Executor](#)

---

**setExecutor**

```java
public void setExecutor(Executor executor)
```

Sets the executor for this service instance. The executor is used for all asynchronous invocations that require callbacks.

**Parameters:**
- `executor` - The `java.util.concurrent.Executor` to be used to invoke a callback.

**Throws:**
- [SecurityException](#) - If the instance does not support setting an executor for security reasons (e.g. the necessary permissions are missing).

**See Also:**
- [Executor](#)
Create a Service instance. The specified WSDL document location and service qualified name must uniquely identify a wsdl:service element.

**Parameters:**
- `wsdlDocumentLocation` - URL for the WSDL document location for the service
- `serviceName` - QName for the service

**Throws:**
- `WebServiceException` - If any error in creation of the specified service
subject to license terms.

PS:

Enum Constant Detail

MESSAGE
public static final Service.Mode MESSAGE

PAYLOAD
public static final Service.Mode PAYLOAD

Method Detail

final public static Service.Mode[] values()
public static final Service.Mode[] values()

    Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

    for(Service.Mode c : Service.Mode.values())
        System.out.println(c);

    Returns:
    an array containing the constants of this enum type, in the order they're declared

public static Service.Mode valueOf(String name)

valueOf

public static Service.Mode valueOf(String name)

    Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

    Parameters:
    name - the name of the enum constant to be returned.

    Returns:
    the enum constant with the specified name

    Throws:
    IllegalArgumentException - if this enum type has no constant with the specified name

javax.xml.registry.infomodel Interface ServiceBinding

All Superinterfaces:
   ExtensibleObject, RegistryObject, URIValidator

public interface ServiceBinding
extends RegistryObject, URIValidator

Implements: RegistryObject, URIValidator

ServiceBinding RegistryObject Service ServiceBinding
SpecificationLink UDDI BindingTemplate

See also      javax.xml.registry.infomodel.Concept

ServiceBinding instances are RegistryObjects that represent technical
information on a specific way to access a specific interface offered by a
Service instance. A ServiceBinding may have a set of SpecificationLink
instances. Maps to a BindingTemplate in UDDI.

public String getAccessURI() throws JAXRException
URI NULL

0

    return URI

Throws JAXRException: JAXR

getAccessURI

String getAccessURI() throws JAXRException

    Gets the URI that gives access to the service via this binding. Default is a NULL String.

    Capability Level: 0

    Returns: the URI that gives access to the service via this binding

    Throws: JAXRException - If the JAXR provider encounters an internal error

public void setAccessURI(String uri) throws JAXRException
    URI accessURI targetBinding null
targetBinding accessURI JAXR
InvalidRequestException
setAccessURI

```java
void setAccessURI(String uri)
    throws JAXRException
```

Sets the URI that gives access to the service via this binding. The accessURI is mutually exclusive from targetBinding. JAXR Provider must throw an InvalidRequestException if an accessURI is set when there is already a non-null targetBinding defined.

**Capability Level: 0**

**Parameters:**
- **uri** - the URI that gives access to the service via this binding

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

---

```java
public ServiceBinding getTargetBinding() throws JAXRException
    ServiceBinding
```

```
return ServiceBinding
    throws JAXRException: JAXR
```

**getTargetBinding**

```java
ServiceBinding getTargetBinding()
```
Throws: 
   JAXRException - If the JAXR provider encounters an internal error

public void setTargetBinding(ServiceBinding binding) 
throws JAXRException
  ServiceBinding targetBinding accessURI null
  accessURI targetBinding JAXR
  InvalidRequestException

sets the next ServiceBinding in case there is a redirection. The targetBinding is mutually exclusive from the accessURI. JAXR Provider must throw an InvalidRequestException if a targetBinding is set when there is already a non-null accessURI defined.

Capability Level: 0
Parameters:
binding - the target ServiceBinding to which this object is redirected to

Throws:
JAXRException - If the JAXR provider encounters an internal error

public Service getService() throws JAXRException

0

return Service
Throws JAXRException: JAXR

getService

Service getService() throws JAXRException

Gets the parent service for which this is a binding.

Capability Level: 0

Returns:
the parent Service object

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void addSpecificationLink(SpecificationLink specificationLink) throws JAXRException
SpecificationLink

0
addSpecificationLink

void addSpecificationLink(SpecificationLink specificationLink)
throws JAXRException

Adds a child SpecificationLink.

Capability Level: 0

Parameters:
  specificationLink - the SpecificationLink being added

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public void addSpecificationLinks(java.util.Collection&lt;E&gt; specificationLinks) throws JAXRException
SpecificationLink Collection

0

addSpecificationLinks

void addSpecificationLinks(Collection specificationLinks)
throws JAXRException

Adds a Collection of SpecificationLink children.

Capability Level: 0
Parameters:
   specificationLinks - the Collection of SpecificationLinks being added

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public void removeSpecificationLink(SpecificationLink specificationLink) throws JAXRException

removeSpecificationLink

void removeSpecificationLink(SpecificationLink specificationLink) throws JAXRException

Removes a child SpecificationLink.

Capability Level: 0

Parameters:
   specificationLink - the SpecificationLink being removed

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public void removeSpecificationLinks(java.util.Collection<E> specificationLinks) throws JAXRException

removeSpecificationLinks
removeSpecificationLinks

void removeSpecificationLinks(Collection specificationLinks)
throws JAXRException

Removes a Collection of children SpecificationLinks.

**Capability Level: 0**

**Parameters:**

- specificationLinks - the Collection of SpecificationLinks being removed

**Throws:**

- JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getSpecificationLinks()
throws JAXRException
SpecificationLink

return SpecificationLink Collection
null

Throws

JAXRException: JAXR

javax.xml.ws.spi  Class ServiceDelegate

java.lang.Object
   javax.xml.ws.spi.ServiceDelegate

public abstract class ServiceDelegate
   extends Object

Service JAX-WS

Service javax.xml.ws.Provider#createServiceDelegate
Service since JAX-WS 2.0
See also javax.xml.ws.Service, javax.xml.ws.spi.Provider

Service delegates are used internally by Service objects to allow pluggability of JAX-WS implementations.

Every Service object has its own delegate, created using the javax.xml.ws.Provider#createServiceDelegate method. A Service object delegates all of its instance methods to its delegate.

Since:
   JAX-WS 2.0

Methods inherited from class java.lang.Object: `clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait`
### Constructor Detail

**protected ServiceDelegate()**

**ServiceDelegate**

**protected ServiceDelegate()**

### Method Detail

**getPort**

```java
public abstract <T> T getPort(QName portName, Class<T> serviceEndpointInterface)
```

The `getPort` method returns a stub. A service client uses this stub to invoke operations on the target service endpoint. The `serviceEndpointInterface` specifies the service endpoint interface that is supported by the created dynamic proxy or stub instance.

**Parameters:**
- `portName` - Qualified name of the service endpoint in the WSDL service description
- `serviceEndpointInterface` - Service endpoint interface supported by the dynamic proxy or stub instance

**Returns:**
Object Proxy instance that supports the specified service endpoint interface

**Throws:**
- `WebServiceException` - This exception is thrown in the following cases:
  - If there is an error in creation of the proxy
  - If there is any missing WSDL metadata as required by this method
getPort

public abstract <T> T getPort(Class<T> serviceEndpointInterface)

The getPort method returns a stub. The parameter serviceEndpointInterface specifies the service endpoint interface that is supported by the returned proxy. In the implementation of this method, the JAX-WS runtime system takes the responsibility of selecting a protocol binding (and a port) and configuring the proxy accordingly. The returned proxy should not be reconfigured by the client.

Parameters:
   serviceEndpointInterface - Service endpoint interface

Returns:
   Object instance that supports the specified service endpoint interface

Throws:
   WebServiceException -
   • If there is an error during creation of the proxy
   • If there is any missing WSDL metadata as required by this method
   • Optionally, if an illegal serviceEndpointInterface is specified
addPort

public abstract void addPort(QName portName,
        String bindingId,
        String endpointAddress)

Creates a new port for the service. Ports created in this way contain no WSDL port type information and can only be used for creating Dispatch instances.

Parameters:
    portName - Qualified name for the target service endpoint
    bindingId - A URI identifier of a binding.
    endpointAddress - Address of the target service endpoint as a URI

Throws:
    WebServiceException - If any error in the creation of the port

See Also:
    SOAPBinding.SOAP11HTTP_BINDING,
    SOAPBinding.SOAP12HTTP_BINDING,
    HTTPBinding.HTTP_BINDING

createDispatch

public abstract <T> Dispatch<T> createDispatch(QName portName,
        Class<T> type,
        Service.Mode mode)

Creates a Dispatch instance for use with objects of the users choosing.
Parameters:
portName - Qualified name for the target service endpoint
type - The class of object used to messages or message payloads. Implementations are required to support javax.xml.transform.Source and javax.xml.soap.SOAPMessage.
mode - Controls whether the created dispatch instance is message or payload oriented, i.e. whether the user will work with complete protocol messages or message payloads. E.g. when using the SOAP protocol, this parameter controls whether the user will work with SOAP messages or the contents of a SOAP body. Mode must be MESSAGE when type is SOAPMessage.

Returns:
Dispatch instance

Throws:
WebServiceException - If any error in the creation of the Dispatch object

See Also:
Source, SOAPMessage

abstract public Dispatch createDispatch(javax.xml.namespace.QName portName, JAXBContext context, Service.Mode mode)

JAXB Dispatch
portName Dispatch
context JAXB
mode SOAP SOAP SOAP

return dispatch
Throws ServiceException: Dispatch
See also javax.xml.bind.JAXBContext

createDispatch

public abstract Dispatch<Object> createDispatch(QName portName, JAXBContext context,
Creates a Dispatch instance for use with JAXB generated objects.

**Parameters:**
- `portName` - Qualified name for the target service endpoint
- `context` - The JAXB context used to marshall and unmarshall messages or message payloads.
- `mode` - Controls whether the created dispatch instance is message or payload oriented, i.e. whether the user will work with complete protocol messages or message payloads. E.g. when using the SOAP protocol, this parameter controls whether the user will work with SOAP messages or the contents of a SOAP body.

**Returns:**
- Dispatch instance

**Throws:**
- `ServiceException` - If any error in the creation of the Dispatch object

**See Also:**
- `JAXBContext`

```java
abstract public javax.xml.namespace.QName getServiceName()
```

```java
return
```

**getServiceName**

```java
public abstract QName getServiceName()
```

Gets the name of this service.

**Returns:**
- Qualified name of this service
abstract public java.util.Iterator<E> getPorts()

    Iterator QName
    return javax.xml.namespace.QName java.util.Iterator
    Throws WebServiceException: Service WSDL

getPorts

public abstract Iterator<QName> getPorts()

    Returns an Iterator for the list of QName of service endpoints grouped by this service

Returns:
    Returns java.util.Iterator with elements of type javax.xml.namespace.QName

Throws:
    WebServiceException - If this Service class does not have access to the required WSDL metadata

abstract public java.net.URL getWSDLDocumentLocation()

WSDL

    return WSDL URL

getWSDLDocumentLocation

public abstract URL getWSDLDocumentLocation()

    Gets the location of the WSDL document for this Service.

Returns:
    URL for the location of the WSDL document for this service

abstract public HandlerResolver getHandlerResolver()
getHandlerResolver

public abstract HandlerResolver getHandlerResolver()

Returns the configured handler resolver.

Returns:
   HandlerResolver The HandlerResolver being used by this Service instance, or null if there isn’t one.

Note:
   HandlerResolvers are not thread safe. They should be thread safe or be created on a thread pool.

abstract public void setHandlerResolver(HandlerResolver handlerResolver)

Sets the HandlerResolver for this Service instance.

The handler resolver, if present, will be called once for each proxy or dispatch instance that is created, and the handler chain returned by the resolver will be set on the instance.

Parameters:
   handlerResolver - The HandlerResolver to use for all subsequently created proxy/dispatch objects.

See Also:
   javax.xml.ws.handler.HandlerResolver
abstract public java.util.concurrent.Executor getExecutor()

Service

return java.util.concurrent.Executor

See also java.util.concurrent.Executor

getExecutor

public abstract Executor getExecutor()

Returns the executor for this Service instance. The executor is used for all asynchronous invocations that require callbacks.

Returns:
The java.util.concurrent.Executor to be used to invoke a callback.

See Also:
Executor

abstract public void setExecutor(java.util.concurrent.Executor executor)

Service

executor java.util.concurrent.Executor

Throws SecurityException:

See also java.util.concurrent.Executor

setExecutor

public abstract void setExecutor(Executor executor)

Sets the executor for this Service instance. The executor is used for all asynchronous invocations that require callbacks.
Parameters:
executor - The java.util.concurrent.Executor to be used to invoke a callback.

Throws:
SecurityException - If the instance does not support setting an executor for security reasons (e.g. the necessary permissions are missing).

See Also:
Executor

message  
getMessage

ServiceException

public ServiceException(String message)  

Constructs a new exception with the specified detail message. The cause is not initialized.

Parameters:
message - The detail message which is later retrieved using the getMessage method

public ServiceException(String message, Throwable cause)  
cause

message  
getMessage
cause  
getCause

ServiceException

public ServiceException(String message, Throwable cause)  

Constructs a new exception with the specified detail message and cause.

Parameters:
message - The detail message which is later retrieved using the getMessage method
cause - The cause which is saved for the later retrieval throw by the getCause method
public ServiceException(Throwable cause)

JAXRPCException cause

(cause
:cause.toString() cause

cause cause getCause null cause

ServiceException

public ServiceException(Throwable cause)

    Constructs a new exception with the specified cause and a detail message of (cause==null ? null : cause.toString()) (which typically contains the class and detail message of cause).

    Parameters:
    cause - The cause which is saved for the later retrieval throw by the getCause method. (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

Method Detail

public Throwable getLinkedCause()

    Gets the Linked cause

    Returns:
    The cause of this Exception or null if the cause is nonexistent or unknown
javax.xml.rpc Class ServiceFactory

java.lang.Object
   \ javax.xml.rpc.ServiceFactory

public abstract class ServiceFactory
extends Object

javax.xml.rpc.ServiceFactory javax.xml.rpc.Service
J2SE Service Service

ServiceFactory SERVICEFACTORY_PROPERTY
   version 1.1
   See also javax.xml.rpc.Service

The javax.xml.rpc.ServiceFactory is an abstract class that provides a factory for the creation of instances of the type javax.xml.rpc.Service. This abstract class follows the abstract static factory design pattern. This enables a J2SE based client to create a Service instance in a portable manner without using the constructor of the Service implementation class.

The ServiceFactory implementation class is set using the system property SERVICEFACTORY_PROPERTY.

Version: 1.1
Author: Rahul Sharma, Roberto Chinnici

Field Detail

SERVICEFACTORYPROPERTY

public static final String SERVICEFACTORY_PROPERTY

A constant representing the property used to lookup the name of a ServiceFactory implementation class.

See Also:
Constant Field Values

Constructor Detail

protected ServiceFactory()

ServiceFactory

protected ServiceFactory()

Method Detail

public static ServiceFactory newInstance() throws ServiceException

ServiceFactory
javax.xml.rpc.ServiceFactory

newInstance

public static ServiceFactory newInstance() throws ServiceException

Gets an instance of the ServiceFactory

Only one copy of a factory exists and is returned to the application each time this method is called.

The implementation class to be used can be overridden by setting the javax.xml.rpc.ServiceFactory system property.

Throws: ServiceException

abstract public Service createService(java.net.URL wsdlDocumentLocation, javax.xml.namespace.QName serviceName) throws ServiceException

Create a Service instance.

Parameters:
wsdlDocumentLocation - URL for the WSDL document location for the service
serviceName - QName for the service

Throws:
ServiceException - If any error in creation of the specified service

abstract public Service createService(javax.xml.namespace.QName serviceName) throws ServiceException

Service

serviceName - QName

Throws
ServiceException:

createService

public abstract Service createService(QName serviceName) throws ServiceException

Create a Service instance.

Parameters:
serviceName - QName for the service

Throws:
ServiceException - If any error in creation of the specified service

abstract public Service loadService(Class<T> serviceInterface) throws ServiceException

serviceInterface

Throws
ServiceException:
**loadService**

```java
public abstract Service loadService(Class serviceInterface)
    throws ServiceException
```

Create an instance of the generated service implementation class for a given service interface, if available.

**Parameters:**
- `serviceInterface` - Service interface

**Throws:**
- `ServiceException` - If there is any error while creating the specified service, including the case where a generated service implementation class cannot be located

```java
abstract public Service loadService(java.net.URL wsdlDocumentLocation, Class<T> serviceInterface, java.util.Properties properties)
    throws ServiceException
```

**ServiceException**
- `wsdlDocumentLocation` - WSDL URL
- `serviceInterface`
- `properties`

**Throws**
- `ServiceException`:

**loadService**

```java
public abstract Service loadService(URL wsdlDocumentLocation, Class serviceInterface, Properties properties)
    throws ServiceException
```

Create an instance of the generated service implementation class for a given service interface, if available. An implementation may use the provided `wsdlDocumentLocation` and `properties` to help locate the generated implementation class. If no such class is present, a `ServiceException` will be thrown.
Parameters:

- `wsdlDocumentLocation` - URL for the WSDL document location for the service or null
- `serviceInterface` - Service interface
- `properties` - A set of implementation-specific properties to help locate the generated service implementation class

Throws:

- `ServiceException` - If there is any error while creating the specified service, including the case where a generated service implementation class cannot be located

abstract public `Service` `loadService`(java.net.URL `wsdlDocumentLocation`, javax.xml.namespace.QName `serviceName`, java.util.Properties `properties`) throws `ServiceException`

Create an instance of the generated service implementation class for a given service, if available. The service is uniquely identified by the `wsdlDocumentLocation` and `serviceName` arguments. An implementation may use the provided `properties` to help locate the generated implementation class. If no such class is present, a `ServiceException` will be thrown.
**Parameters:**

- `wsdlDocumentLocation` - URL for the WSDL document location for the service or null
- `serviceName` - Qualified name for the service
- `properties` - A set of implementation-specific properties to help locate the generated service implementation class

**Throws:**

- `ServiceException` - If there is any error while creating the specified service, including the case where a generated service implementation class cannot be located
public interface ServiceLifecycle

void destroy()
JAX-RPC runtime system ends the lifecycle of a service endpoint instance by invoking the destroy method.

void init(Object context)
Used for initialization of a service endpoint.

public void init(Object context) throws ServiceException
JAX-RPC
The init method implementation should typecast the context parameter to an appropriate Java type. For service endpoints deployed on a servlet container based JAX-RPC runtime system, the context parameter is of the Java type `javax.xml.rpc.server.ServletEndpointContext`. The `ServletEndpointContext` provides an endpoint context maintained by the underlying servlet container based JAX-RPC runtime system.

**Parameters:**
- `context` - Endpoint context for a JAX-RPC service endpoint

**Throws:**
- `ServiceException` - If any error in initialization of the service endpoint; or if any illegal context has been provided in the init
public void destroy()
JAX-RPC destroy destroy

destroy

void destroy()

JAX-RPC runtime system ends the lifecycle of a service endpoint instance by invoking the destroy method. The service endpoint releases its resources in the implementation of the destroy method.

PS:
**javax.servlet Interface Servlet**

**All Known Subinterfaces:**
- [HttpJspPage](#), [JspPage](#)

**All Known Implementing Classes:**
- [FacesServlet](#), [GenericServlet](#), [HttpServlet](#)

```java
public interface Servlet

Implemented by: FacesServlet, GenericServlet, JspPage
```

A servlet is a small Java program that runs within a Web server. Servlets receive and respond to requests from Web clients, usually across HTTP, the HyperText Transfer Protocol.
To implement this interface, you can write a generic servlet that extends javax.servlet.GenericServlet or an HTTP servlet that extends javax.servlet.http.HttpServlet.

This interface defines methods to initialize a servlet, to service requests, and to remove a servlet from the server. These are known as life-cycle methods and are called in the following sequence:

1. The servlet is constructed, then initialized with the init method.
2. Any calls from clients to the service method are handled.
3. The servlet is taken out of service, then destroyed with the destroy method, then garbage collected and finalized.

In addition to the life-cycle methods, this interface provides the `getServletConfig` method, which the servlet can use to get any startup information, and the `getServletInfo` method, which allows the servlet to return basic information about itself, such as author, version, and copyright.

**Author:** Various

**See Also:** GenericServlet, HttpServlet

---

### Method Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><code>destroy()</code></td>
<td>Called by the servlet container to indicate to a servlet that the servlet is being taken out of service.</td>
</tr>
<tr>
<td></td>
<td><code>getServletConfig()</code></td>
<td>Returns a <code>ServletConfig</code> object, which contains initialization and startup parameters for this servlet.</td>
</tr>
<tr>
<td></td>

<td><code>init(ServletConfig config)</code></td>
<td>Called by the servlet container to indicate to a servlet</td>
</tr>
</tbody>
</table>
that the servlet is being placed into service.

```java
public void init(ServletConfig config) throws ServletException
```

Called by the servlet container to indicate to a servlet that the servlet is being placed into service.

The servlet container calls the `init` method exactly once after instantiating the servlet. The `init` method must complete successfully before the servlet can receive any requests.
The servlet container cannot place the servlet into service if the init method

1. Throws a ServletException
2. Does not return within a time period defined by the Web server

Parameters:
   config - a ServletConfig object containing the servlet's configuration and initialization parameters

Throws:
   ServletException - if an exception has occurred that interferes with the servlet's normal operation

See Also:
   UnavailableException, getServletConfig()

---

public <strong>ServletConfig</strong> getServletConfig()

Returns a ServletConfig object, which contains initialization and startup parameters for this servlet. The ServletConfig object returned is the one passed to the init method.

Implementations of this interface are responsible for storing the ServletConfig object so that this method can return it. The GenericServlet class, which implements this interface, already does this.
Returns:
the ServletConfig object that initializes this servlet

See Also:
init(javax.servlet.ServletConfig)

```java
public void service(ServletRequest req, ServletResponse res) throws ServletException, java.io.IOException

servlet  init()

servlet

servlet  servlet  Java
the Java tutorial on multi-threaded programming

req ServletRequest
res servlet

Throws ServletException: servlet

Throws java.io.IOException:

service

void service(ServletRequest req,
ServletResponse res)
throws ServletException,
IOException

Called by the servlet container to allow the servlet to respond to a request.

This method is only called after the servlet's init() method has completed successfully.

The status code of the response always should be set for a servlet that throws or sends an error.
Servlets typically run inside multithreaded servlet containers that can handle multiple requests concurrently. Developers must be aware to synchronize access to any shared resources such as files, network connections, and as well as the servlet's class and instance variables. More information on multithreaded programming in Java is available in the Java tutorial on multi-threaded programming.

**Parameters:**
- req - the ServletRequest object that contains the client's request
- res - the ServletResponse object that contains the servlet's response

**Throws:**
- ServletException - if an exception occurs that interferes with the servlet's normal operation
- IOException - if an input or output exception occurs

```java
public String getServletInfo()
{HtmlXML
    return servlet String
}
```

**getServletInfo**

```java
String getServletInfo()

    Returns information about the servlet, such as author, version, and copyright.

    The string that this method returns should be plain text and not markup of any kind (such as HTML, XML, etc.).

    **Returns:**
    a String containing servlet information
```
public void destroy()

Called by the servlet container to indicate to a servlet that the servlet is being taken out of service. This method is only called once all threads within the servlet's service method have exited or after a timeout period has passed. After the servlet container calls this method, it will not call the service method again on this servlet.

This method gives the servlet an opportunity to clean up any resources that are being held (for example, memory, file handles, threads) and make sure that any persistent state is synchronized with the servlet's current state in memory.
javax.servlet Interface ServletConfig

All Known Implementing Classes: GenericServlet, HttpServlet

public interface ServletConfig

Implemented by: GenericServlet

A servlet configuration object used by a servlet container to pass information to a servlet during initialization.

Method Summary

<table>

Method Detail
public String getServletName()

getServletName

String getServletName()

Returns the name of this servlet instance. The name may be provided via server administration, assigned in the web application deployment descriptor, or for an unregistered (and thus unnamed) servlet instance it will be the servlet's class name.

Returns: the name of the servlet instance

---

public ServletContext getServletContext()

getServletContext

ServletContext getServletContext()

Returns a reference to the ServletContext in which the caller is executing.

Returns: a ServletContext object, used by the caller to interact with its servlet container

See Also: ServletContext
public String getInitParameter(String name)

    String null

    name null
    return String

getInitParameter

String getInitParameter(String name)

    Returns a String containing the value of the named initialization
    parameter, or null if the parameter does not exist.

Parameters:
    name - a String specifying the name of the initialization
    parameter

Returns:
    a String containing the value of the initialization parameter

public java.util.Enumeration<E> getInitParameterNames()

    Enumeration servlet servlet
    Enumeration return servlet String Enumeration

getInitParameterNames

Enumeration getInitParameterNames()

    Returns the names of the servlet's initialization parameters as an
    Enumeration of String objects, or an empty Enumeration if the servlet
    has no initialization parameters.

Returns:
    an Enumeration of String objects containing the names of the
    servlet's initialization parameters

PS :
javax.servlet Interface ServletContext

public interface ServletContext

servlet servlet MIME

Java "Web ""Web " servlet Collection servlet
URL /catalog .war

Web "distributed"

ServletContext ServletConfig ServletConfig servlet
Web servlet
See also getServletConfig, getServletContext

Defines a set of methods that a servlet uses to communicate with its servlet container, for example, to get the MIME type of a file, dispatch requests, or write to a log file.

There is one context per "web application" per Java Virtual Machine. (A "web application" is a collection of servlets and content installed under a specific subset of the server's URL namespace such as /catalog and possibly installed via a .war file.)

In the case of a web application marked "distributed" in its deployment descriptor, there will be one context instance for each virtual machine. In this situation, the context cannot be used as a location to share global information (because the information won't be truly global). Use an external resource like a database instead.

The ServletContext object is contained within the ServletConfig object, which the Web server provides the servlet when the servlet is initialized.

**Method Detail**

**public String getContextPath()**

Web

URI "/" "/" servlet ""

```
getContextPath() since Servlet 2.5
See also  getApplicationContext()
```

### getApplicationContext

```
String getApplicationContext()
```

Returns the context path of the web application.

The context path is the portion of the request URI that is used to select the context of the request. The context path always comes first in a request URI. The path starts with a "/" character but does
not end with a "/" character. For servlets in the default (root) context, this method returns "."

It is possible that a servlet container may match a context by more than one context path. In such cases the 
HttpServletRequest.getContextPath() will return the actual context path used by the request and it may differ from the path returned by this method. The context path returned by this method should be considered as the prime or preferred context path of the application.

Returns:
The context path of the web application, or "" for the default (root) context

Since:
Servlet 2.5

See Also:
HttpServletRequest.getContextPath()

public ServletContext getContext(String uripath)

URL ServletContext

servlet RequestDispatcher "/" Web

servlet URL null
uripath Web String
return URL ServletContext null
See also javax.servlet.RequestDispatcher

gectContext

ServletContext getContext(String uripath)

Returns a ServletContext object that corresponds to a specified URL on the server.
This method allows servlets to gain access to the context for various parts of the server, and as needed obtain RequestDispatcher objects from the context. The given path must be begin with "/", is interpreted relative to the server's document root and is matched against the context roots of other web applications hosted on this container.

In a security conscious environment, the servlet container may return null for a given URL.

**Parameters:**

- `uripath` - a `String` specifying the context path of another web application in the container.

**Returns:**

the `ServletContext` object that corresponds to the named URL, or null if either none exists or the container wishes to restrict this access.

**See Also:**

RequestDispatcher

```java
public int getMajorVersion()

servlet Java Servlet API Version 2.5 2

return 2
```

**getMajorVersion**

```java
int getMajorVersion()

    Returns the major version of the Java Servlet API that this servlet container supports. All implementations that comply with Version 2.5 must have this method return the integer 2.

    Returns:
    2
```

```java
public int getMinorVersion()
```
getMinorVersion

int getMinorVersion()

Returns the minor version of the Servlet API that this servlet container supports. All implementations that comply with Version 2.5 must have this method return the integer 5.

Returns:
5

public String getMimeType(String file)

Returns the MIME type of the specified file, or null if the MIME type is not known. The MIME type is determined by the configuration of the servlet container, and may be specified in a web application deployment descriptor. Common MIME types are "text/html" and "image/gif".

Parameters:
file - a String specifying the name of a file

Returns:
a String specifying the file's MIME type
public java.util.Set<E> getResourcePaths(String path)
  Web path '/' Web '/' Web

/welcome.html
/catalog/index.html
/catalog/products.html
/catalog/offers/books.html
/catalog/offers/music.html
/customer/login.jsp
/WEB-INF/web.xml
/WEB-INF/classes/com.acme.OrderServlet.class,

g得到ResourcePaths("/") {"/welcome.html", "/catalog/", "/customer/", "/WEB-INF/"}
  path /
  return Web null
  since Servlet 2.3

得到ResourcePaths

Set  get得到ResourcePaths(String path)

  Returns a directory-like listing of all the paths to resources within the
  web application whose longest sub-path matches the supplied path
  argument. Paths indicating subdirectory paths end with a '/'. The
  returned paths are all relative to the root of the web application and
  have a leading '/'. For example, for a web application containing

  /welcome.html
  /catalog/index.html
  /catalog/products.html
  /catalog/offers/books.html
Parameters:
  path - the partial path used to match the resources, which must start with a /

Returns:
a Set containing the directory listing, or null if there are no resources in the web application whose path begins with the supplied path.

Since:
Servlet 2.3

public java.net.URL getResource(String path) throws java.net.MalformedURLException
URL "/"

servlet servlet .war

servlet URL URLConnection
null

URL URL
.jsp JSP RequestDispatcher

java.lang.Class.getResource
  path String
getResource

```java
URL getResource(String path)
throws MalformedURLException
```

Returns a URL to the resource that is mapped to a specified path. The path must begin with a "/" and is interpreted as relative to the current context root.

This method allows the servlet container to make a resource available to servlets from any source. Resources can be located on a local or remote file system, in a database, or in a .war file.

The servlet container must implement the URL handlers and URLConnection objects that are necessary to access the resource.

This method returns `null` if no resource is mapped to the pathname.

Some containers may allow writing to the URL returned by this method using the methods of the URL class.

The resource content is returned directly, so be aware that requesting a .jsp page returns the JSP source code. Use a RequestDispatcher instead to include results of an execution.

This method has a different purpose than java.lang.Class.getResource, which looks up resources based on a class loader. This method does not use class loaders.

**Parameters:**
- `path` - a String specifying the path to the resource

**Returns:**
the resource located at the named path, or `null` if there is no resource at that path

**Throws:**
**MalformedURLException** - if the pathname is not given in the correct form

```java
public java.io.InputStream getResourceAsStream(String path)
    throws MalformedURLException {
    InputStream resourceAsStream = null;
    URL servletURL = null;
    try {
        servletURL = new URL(path);
        resourceAsStream = servletURL.openStream();
    } catch (MalformedURLException e) {
        // e.printStackTrace();
        throw new MalformedURLException(e.getMessage());
    } catch (IOException e) {
        // e.printStackTrace();
        throw new MalformedURLException(e.getMessage());
    }
    return resourceAsStream;
}
```

getAsResourceAsStream

`java.lang.Class.getResourceAsStream(String path)`

Returns the resource located at the named path as an `InputStream` object.

The data in the `InputStream` can be of any type or length. The path must be specified according to the rules given in `getResource`. This method returns `null` if no resource exists at the specified path.

Meta-information such as content length and content type that is available via `getResource` method is lost when using this method.

The servlet container must implement the URL handlers and `URLConnection` objects necessary to access the resource.
This method is different from java.lang.Class.getResourceAsStream, which uses a class loader. This method allows servlet containers to make a resource available to a servlet from any location, without using a class loader.

**Parameters:**
- path - a String specifying the path to the resource

**Returns:**
- the InputStream returned to the servlet, or null if no resource exists at the specified path

```java
public RequestDispatcher getRequestDispatcher(String path)
```

- Returns a `RequestDispatcher` object that acts as a wrapper for the resource located at the given path. A `RequestDispatcher` object can be used to forward a request to the resource or to include the resource in a response. The resource can be dynamic or static.

The pathname must begin with a "/" and is interpreted as relative to the current context root. Use `getContext` to obtain a
RequestDispatcher for resources in foreign contexts. This method returns null if the ServletContext cannot return a RequestDispatcher.

Parameters:
- path - a String specifying the pathname to the resource

Returns:
a RequestDispatcher object that acts as a wrapper for the resource at the specified path, or null if the ServletContext cannot return a RequestDispatcher

See Also:
- RequestDispatcher, getContext(java.lang.String)

```java
public RequestDispatcher getNamedDispatcher(String name)
```

Servlet JSP  Web servlet

```java
ServletContext name
RequestDispatcher servlet null
return servlet RequestDispatcher ServletContext
See also javax.servlet.RequestDispatcher, getContext, getServletName
```

getNamedDispatcher

```java
RequestDispatcher getNamedDispatcher(String name)
```

Returns a RequestDispatcher object that acts as a wrapper for the named servlet.

Servlets (and JSP pages also) may be given names via server administration or via a web application deployment descriptor. A
servlet instance can determine its name using
`ServletConfig.getServletName()`.

This method returns `null` if the `ServletContext` cannot return a
RequestDispatcher for any reason.

**Parameters:**
- `name` - A `String` specifying the name of a servlet to wrap

**Returns:**
- A `RequestDispatcher` object that acts as a wrapper for the named
  servlet, or `null` if the `ServletContext` cannot return a
  RequestDispatcher

**See Also:**
- `RequestDispatcher`, `getContext(java.lang.String)`,
  `ServletConfig.getServletName()`

```java
public Servlet getServlet(String name) throws ServletException
```

Java Servlet API 2.1

deprecated

```
ServletContext servlet null Java Servlet API
```

servletServletContext servlet

**getServlet**

```java
Servlet getServlet(String name)
```

throws `ServletException`

**Deprecated. As of Java Servlet API 2.1, with no direct replacement.**

This method was originally defined to retrieve a servlet from a
`ServletContext`. In this version, this method always returns `null` and
remains only to preserve binary compatibility. This method will be
permanently removed in a future version of the Java Servlet API.
In lieu of this method, servlets can share information using the ServletContext class and can perform shared business logic by invoking methods on common non-servlet classes.

**Throws:**

`ServletException`

**getServlets**

`Enumeration getServlets()`

**Deprecated. As of Java Servlet API 2.0, with no replacement.**

This method was originally defined to return an Enumeration of all the servlets known to this servlet context. In this version, this method always returns an empty enumeration and remains only to preserve binary compatibility. This method will be permanently removed in a future version of the Java Servlet API.

---

**public java.util Enumeration&lt;E&gt; getServletNames()**

Java Servlet API 2.1

*deprecated*  
servlet  
Enumeration  
Enumeration  
Java Servlet API

---

**getServletNames**

`Enumeration getServletNames()`
**Deprecated.** As of Java Servlet API 2.1, with no replacement.

This method was originally defined to return an `Enumeration` of all the servlet names known to this context. In this version, this method always returns an empty `Enumeration` and remains only to preserve binary compatibility. This method will be permanently removed in a future version of the Java Servlet API.

---

```java
public void log(String msg)
servelet  servlet  servlet

msg  String
```

### log

```java
void log(String msg)
```

Writes the specified message to a servlet log file, usually an event log. The name and type of the servlet log file is specific to the servlet container.

**Parameters:**

- `msg` - a `String` specifying the message to be written to the log file.

---

```java
public void log(Exception exception, String msg)
```

Java Servlet API 2.1  
#log(String message, Throwable throwable)

```java
deprecated
```

```java
servelet
```

### log

```java
void log(Exception exception, String msg)
```
**Deprecated.** As of Java Servlet API 2.1, use `log(String message, Throwable throwable)` instead.

This method was originally defined to write an exception's stack trace and an explanatory error message to the servlet log file.

```java
public void log(String message, Throwable throwable)

message
throwable

log

void log(String message,
 Throwable throwable)

Writes an explanatory message and a stack trace for a given Throwable exception to the servlet log file. The name and type of the servlet log file is specific to the servlet container, usually an event log.

**Parameters:**
message - a String that describes the error or exception
throwable - the Throwable error or exception
```

```java
public String getRealPath(String path)

"http://host/contextPath/index.html" contextPath

getRealPath

public String getRealPath(String path) String "http://host/contextPath/index.html" contextPath ServletContext

path return .war null

String null
```

```java
public String getRealPath(String path)

String "http://host/contextPath/index.html" contextPath ServletContext

getRealPath

public String getRealPath(String path) String "http://host/contextPath/index.html" contextPath ServletContext

path return .war null

String null
```
**getRealPath**

`String getRealPath(String path)`

Returns a `String` containing the real path for a given virtual path. For example, the path "/index.html" returns the absolute file path on the server's filesystem would be served by a request for "http://host/contextPath/index.html", where contextPath is the context path of this ServletContext..

The real path returned will be in a form appropriate to the computer and operating system on which the servlet container is running, including the proper path separators. This method returns `null` if the servlet container cannot translate the virtual path to a real path for any reason (such as when the content is being made available from a .war archive).

**Parameters:**
- `path` - a `String` specifying a virtual path

**Returns:**
- a `String` specifying the real path, or `null` if the translation cannot be performed

---

**public String getServerInfo()**

`servlet` servlet

`servername/versionnumber`JavaServer Web Development Kit

`JavaServer Web Dev Kit/1.0`

`servlet` JavaServer Web Dev Kit/1.0 (JDK 1.1.6; Windows NT 4.0 x86)

return servlet String

**getServerInfo**
**String getServerInfo()**

Returns the name and version of the servlet container on which the servlet is running.

The form of the returned string is `servername/versionnumber`. For example, the JavaServer Web Development Kit may return the string `JavaServer Web Dev Kit/1.0`.

The servlet container may return other optional information after the primary string in parentheses, for example, `JavaServer Web Dev Kit/1.0 (JDK 1.1.6; Windows NT 4.0 x86)`.

**Returns:**

- a String containing at least the servlet container name and version number

---

**public String getInitParameter(String name)**

```
String null
```

**“Web ” webmaster**

```
name servlet
return String
```

See also **getInitParameter**

---

**getInitParameter**

```
String getInitParameter(String name)
```

Returns a String containing the value of the named context-wide initialization parameter, or null if the parameter does not exist.

This method can make available configuration information useful to an entire "web application". For example, it can provide a webmaster's email address or the name of a system that holds critical data.
Parameters:
name - a String containing the name of the parameter whose value is requested

Returns:
a String containing at least the servlet container name and version number

See Also:
ServletConfig.getInitParameter(java.lang.String)

---

public java.util.Enumeration&lt;E&gt; getInitParameterNames()

String Enumeration Enumeration
return String Enumeration
See also getInitParameter

getInitParameterNames

Enumeration getInitParameterNames()

Returns the names of the context's initialization parameters as an Enumeration of String objects, or an empty Enumeration if the context has no initialization parameters.

Returns:
an Enumeration of String objects containing the names of the context's initialization parameters

See Also:
ServletConfig.getInitParameter(java.lang.String)

---

public Object getAttribute(String name)
servlet
getAttributeNames

java.lang.object Java Servlet API
java.*javax.* sun.*

name String
**getAttribute**

```java
Object getAttribute(String name)
```

Returns the servlet container attribute with the given name, or `null` if there is no attribute by that name. An attribute allows a servlet container to give the servlet additional information not already provided by this interface. See your server documentation for information about its attributes. A list of supported attributes can be retrieved using `getAttributeNames`.

The attribute is returned as a `java.lang.Object` or some subclass. Attribute names should follow the same convention as package names. The Java Servlet API specification reserves names matching `java.*`, `javax.*`, and `sun.*`.

**Parameters:**
- `name` - a `String` specifying the name of the attribute

**Returns:**
- an `Object` containing the value of the attribute, or `null` if no attribute exists matching the given name

**See Also:**
- `getAttributeNames()`

---

**public java.util.Enumeration<E> getAttributeNames()**

```java
Enumeration Enumeration #getAttributes
```

Returns an `Enumeration` containing the names of all attributes that are recognized by the container. The enumeration can be cast to `java.util.Enumeration` and used to retrieve the corresponding values using `getAttribute`. The order of the enumation is unspecified.

**See Also:**
- `getAttribute`
Enumeration getAttributeNames()

Returns an Enumeration containing the attribute names available within this servlet context. Use the getAttribute(java.lang.String) method with an attribute name to get the value of an attribute.

Returns:
an Enumeration of attribute names
See Also:
getAttribute(java.lang.String)

public void setAttribute(String name, Object object)

Binds an object to a given attribute name in this servlet context. If the name specified is already used for an attribute, this method will replace the attribute with the new to the new attribute.

If listeners are configured on the ServletContext the container notifies them accordingly.

If a null value is passed, the effect is the same as calling removeAttribute().
Attribute names should follow the same convention as package names. The Java Servlet API specification reserves names matching java.*, javax.*, and sun.*.

Parameters:
- name - a String specifying the name of the attribute
- object - an Object representing the attribute to be bound

```java
public void removeAttribute(String name)
```

Removes the attribute with the given name from the servlet context. After removal, subsequent calls to `getAttribute(java.lang.String)` to retrieve the attribute's value will return `null`.

If listeners are configured on the `ServletContext` the container notifies them accordingly.

Parameters:
- name - a String specifying the name of the attribute to be removed

```java
public String getServletContextName()
```

Returns the name of the Web display-name. Since Servlet 2.3
getServletContextName

String getServletContextName()

Returns the name of this web application corresponding to this ServletContext as specified in the deployment descriptor for this web application by the display-name element.

Returns:
The name of the web application or null if no name has been declared in the deployment descriptor.

Since:
Servlet 2.3
public class ServletContextAttributeEvent

extends ServletContextEvent

Extends: java.util.EventObject > ServletContextEvent

Web servlet since v 2.3

See also javax.servlet.ServletContextAttributeListener

This is the event class for notifications about changes to the attributes of the servlet context of a web application.

Since:

v 2.3

public ServletContextAttributeEvent(*ServletContext source, String name, Object value*)

ServletContextAttributeEvent

ServletContextAttributeEvent
Construct a ServletContextAttributeEvent from the given context for the given attribute name and attribute value.

**Method Detail**

**public String getName()**

**getVersion**

public String getName()

Return the name of the attribute that changed on the ServletContext.

**public Object getValue()**

**getValue**

public Object getValue()

Returns the value of the attribute that has been added, removed, or replaced. If the attribute was added, this is the value of the attribute. If the attribute was removed, this is the value of the removed attribute. If the attribute was replaced, this is the old value of the attribute.
javax.servlet  Interface ServletContextAttributeListener

All Superinterfaces:
EventListener

public interface ServletContextAttributeListener
extends EventListener

Implements: java.util.EventListener

Web servlet Web
since v 2.3
See also javax.servlet.ServletContextAttributeEvent

Implementations of this interface receive notifications of changes to the attribute list on the servlet context of a web application. To receive notification events, the implementation class must be configured in the deployment descriptor for the web application.

Since:
v 2.3

void contextInitialized(ServletContextEvent sce)

Notification that the web application initialization process is starting. All ServletContextListeners are notified of context initialization before any filter or servlet in the web application is initialized.

public void contextDestroyed(ServletContextEvent sce)
servlet ServletContextListener servlet

calendarDestroyed

void contextDestroyed(ServletContextEvent sce)

Notification that the servlet context is about to be shut down. All servlets and filters have been destroy()ed before any ServletContextListeners are notified of context destruction.
PS:
javax.xml.rpc.server Interface ServletEndpointContext

public interface ServletEndpointContext

ServletEndpointContext servlet JAX-RPC servlet
JAX-RPC ServiceLifecycle.init context Java
javax.xml.rpc.server.ServletEndpointContext
	servlet
	servlet JAX-RPC ServletEndpointContext JAX-RPC

version 1.1

The ServletEndpointContext provides an endpoint context maintained by
the underlying servlet container based JAX-RPC runtime system. For
service endpoints deployed on a servlet container based JAX-RPC
runtime system, the context parameter in the ServiceLifecycle.init
method is required to be of the Java type
javax.xml.rpc.server.ServletEndpointContext.

A servlet container based JAX-RPC runtime system implements the
ServletEndpointContext interface. The JAX-RPC runtime system is
required to provide appropriate session, message context, servlet context
and user principal information per method invocation on the endpoint
class.

Version: 1.1
Author: Rahul Sharma, Roberto Chinnici

Method Summary

`getHttpSession()`
<table>
<thead>
<tr>
<th>HttpSession</th>
<th>The <code>getHttpSession</code> method returns the current HTTP session (as a <code>javax.servlet.http.HttpSession</code>).</th>
</tr>
</thead>
<tbody>
<tr>
<td>MessageContext</td>
<td>The method <code>getMessageContext</code> returns the MessageContext targeted for this endpoint instance.</td>
</tr>
<tr>
<td>ServletContext</td>
<td>The method <code>getServletContext</code> returns the ServletContext associated with the web application that contain this endpoint.</td>
</tr>
<tr>
<td>Principal</td>
<td>Returns a <code>java.security.Principal</code> instance that contains the name of the authenticated user for the current method invocation on the endpoint instance.</td>
</tr>
<tr>
<td>boolean</td>
<td><code>isUserInRole(String role)</code> Returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical &quot;role&quot;.</td>
</tr>
</tbody>
</table>

### Method Detail

```java
public MessageContext getMessageContext()
```

**Handler**

- `getMessageContext`  
- `MessageContext`  
- `HandlerChain`

**HandlerChain**

- `SOAP`

**return**

- `MessageContext`

**Throws**

- `NoSuchElementException`

**See also**

- `javax.xml.rpc.handler.MessageContext`,  
- `javax.xml.rpc.handler.HandlerChain`,  
- `javax.xml.rpc.handler.Handler`

**getMessageContext**

- `MessageContext`  
- `getMessageContext()`
The method `getMessageContext` returns the `MessageContext` targeted for this endpoint instance. This enables the service endpoint instance to access the `MessageContext` propagated by request `HandlerChain` (and its contained `Handler` instances) to the target endpoint instance and to share any SOAP message processing related context. The endpoint instance can access and manipulate the `MessageContext` and share the SOAP message processing related context with the response `HandlerChain`.

**Returns:**

- `MessageContext`; If there is no associated `MessageContext`, this method returns `null`.

**Throws:**

- `IllegalStateException` - if this method is invoked outside a remote method implementation by a service endpoint instance.

**See Also:**

- `MessageContext`, `HandlerChain`, `Handler`

```java
public java.security.Principal getUserPrincipal()
```

Returns a `java.security.Principal` instance that contains the name of the authenticated user for the current method invocation on the endpoint instance. This method returns `null` if there is no associated principal yet. The underlying JAX-RPC runtime system takes the responsibility of providing the appropriate authenticated principal for a remote method invocation on the service endpoint instance.

**Returns:**

- A `java.security.Principal` for the authenticated principal
associated with the current invocation on the servlet endpoint instance; Returns null if there no authenticated user associated with a method invocation.

See Also:
Principal

```java
public HttpSession getHttpSession()
```

The `getHttpSession` method returns the current HTTP session (as a `javax.servlet.http.HttpSession`). When invoked by the service endpoint within a remote method implementation, the `getHttpSession` returns the HTTP session associated currently with this method invocation. This method returns `null` if there is no HTTP session currently active and associated with this service endpoint. An endpoint class should not rely on an active HTTP session being always there; the underlying JAX-RPC runtime system is responsible for managing whether or not there is an active HTTP session.

The `getHttpSession` method throws `JAXRPCException` if invoked by an non HTTP bound endpoint.

**Returns:**
The HTTP session associated with the current invocation or
null if there is no active session.

**Throws:**
JAXRPCException - If this method invoked by any non-HTTP bound endpoint

**See Also:**
 HttpSession

```java
public ServletContext getServletContext()
```

The method `getServletContext` returns the `ServletContext` associated with the web application that contain this endpoint. According to the Servlet specification, There is one context per web application (installed as a WAR) per JVM. A servlet based service endpoint is deployed as part of a web application.

**Returns:**
ServletContext

**See Also:**
ServletContext

```java
public boolean isUserInRole(String role)
```

`role` String

`return` boolean

false
boolean isUserInRole(String role)

Returns a boolean indicating whether the authenticated user for the current method invocation on the endpoint instance is included in the specified logical "role".

Parameters:
role - a String specifying the name of the role

Returns:
a boolean indicating whether the authenticated user associated with the current method invocation belongs to a given role; false if the user has not been authenticated.
**javax.servlet**  
**Class ServletException**

java.lang.Object  
  ▼ java.lang.Throwable  
    ▼ java.lang.Exception  
      ▼ javax.servlet.ServletException

**All Implemented Interfaces:**  
Serializable

**Direct Known Subclasses:**  
UnavailableException

```
public class ServletException
    extends Exception

Extends: Throwable > Exception
Extended by: UnavailableException

servlet
```

Defines a general exception a servlet can throw when it encounters difficulty.

### Constructor Detail

**public ServletException()**

Constructs a new servlet exception.
public ServletException(String message)

message String

ServletException

Constructs a new servlet exception with the specified message. The message can be written to the server log and/or displayed for the user.

Parameters:
message - a String specifying the text of the exception message

public ServletException(String message, Throwable rootCause)

message String
rootCause servlet Throwable Servlet

ServletException

Constructs a new servlet exception when the servlet needs to throw an exception and include a message about the "root cause" exception that interfered with its normal operation, including a description message.

Parameters:
message - a String containing the text of the exception message
rootCause - the Throwable exception that interfered with the
public ServletException(Throwable rootCause)

server servlet “” servlet

Thrownables getLocalizedMessage ServletException

rootCause servlet Throwable servlet

ServletException

public ServletException(Throwable rootCause)

Constructs a new servlet exception when the servlet needs to throw an exception and include a message about the "root cause" exception that interfered with its normal operation. The exception's message is based on the localized message of the underlying exception.

This method calls the getLocalizedMessage method on the Throwable exception to get a localized exception message. When subclassing ServletException, this method can be overridden to create an exception message designed for a specific locale.

Parameters:

rootCause - the Throwable exception that interfered with the servlet's normal operation, making the servlet exception necessary

Method Detail

public Throwable getRootCause()
getRootCause

public Throwable getRootCause()

Returns the exception that caused this servlet exception.

**Returns:**
the Throwable that caused this servlet exception
javax.servlet  **Class ServletInputStream**

**java.lang.Object**
  └ java.io.InputStream

**All Implemented Interfaces:**
  Closeable

---

```java
public abstract class ServletInputStream extends InputStream

Extends: java.io.InputStream

readLine  HTTP POST
```

**ServletInputStream**  ServletRequest#getInputStream

-servlet  java.io.InputStream.read()

**See also**  javax.servlet.ServletRequest

---

Provides an input stream for reading binary data from a client request, including an efficient `readLine` method for reading data one line at a time. With some protocols, such as HTTP POST and PUT, a ServletInputStream object can be used to read data sent from the client.

A ServletInputStream object is normally retrieved via the ServletRequest.getInputStream() method.

This is an abstract class that a servlet container implements. Subclasses of this class must implement the `java.io.InputStream.read()` method.

## Constructor Detail

protected ServletInputStream()

ServletInputStream

protected ServletInputStream()

    Does nothing, because this is an abstract class.

## Method Detail
public int readLine(byte[] b, int off, int len) throws java.io.IOException

-1

$b$ byte
$off$ int
$len$ int
$return$ -1

Throws java.io.IOException:

readLine

public int readLine(byte[] b,
                     int off,
                     int len)
        throws IOException

Reads the input stream, one line at a time. Starting at an offset, reads bytes into an array, until it reads a certain number of bytes or reaches a newline character, which it reads into the array as well.

This method returns -1 if it reaches the end of the input stream before reading the maximum number of bytes.

Parameters:
   $b$ - an array of bytes into which data is read
   $off$ - an integer specifying the character at which this method begins reading
   $len$ - an integer specifying the maximum number of bytes to read

Returns:
   an integer specifying the actual number of bytes read, or -1 if the end of the stream is reached

Throws:
IOException - if an input or output exception has occurred

  Does nothing, because this is an abstract class.

Method Detail
public void print(String s) throws java.io.IOException

String - (CRLF)

    s

Throws java.io.IOException:

print

public void print(String s)
throws IOException

    Prints a String to the client, without a carriage return-line feed (CRLF) character at the end.

Parameters:
    s - the String to send to the client

    IOException - if an input or output exception occurred

public void print(boolean b) throws java.io.IOException

boolean - (CRLF)

    b

Throws java.io.IOException:

print

public void print(boolean b)
throws IOException

    Prints a boolean value to the client, with no carriage return-line feed (CRLF) character at the end.

Parameters:
    b - the boolean value to send to the client

    IOException - if an input or output exception occurred
public void print(char c) throws java.io.IOException
- (CRLF)
  c
  Throws java.io.IOException:

print

public void print(char c)  
throws IOException

  Writes a character to the client, with no carriage return-line feed (CRLF) at the end.

  Parameters:
  c - the character to send to the client

  Throws:
  IOException - if an input or output exception occurred

public void print(int i) throws java.io.IOException
int - (CRLF)
  i
  int
  Throws java.io.IOException:

print

public void print(int i)  
throws IOException

  Writes an int to the client, with no carriage return-line feed (CRLF) at the end.

  Parameters:
i - the int to send to the client

Throws:

IOException - if an input or output exception occurred

public void print(long l) throws java.io.IOException

long - (CRLF)

/                     long

Throws         java.io.IOException:

print

public void print(long l) throws IOException

Writes a long value to the client, with no carriage return-line feed (CRLF) at the end.

Parameters:

l - the long value to send to the client

Throws:

IOException - if an input or output exception occurred

public void print(float f) throws java.io.IOException

float - (CRLF)

/                     float

Throws         java.io.IOException:

print

public void print(float f) throws IOException

Writes a float value to the client, with no carriage return-line feed (CRLF) at the end.
Parameters:
f - the float value to send to the client

Throws:
IOException - if an input or output exception occurred

---

public void print(double d) throws java.io.IOException

double - (CRLF)

\[ d \]

Throws
java.io.IOException:

---

print

public void print(double d)
throws IOException

Writes a double value to the client, with no carriage return-line feed (CRLF) at the end.

Parameters:
d - the double value to send to the client

Throws:
IOException - if an input or output exception occurred

---

println

public void println() throws java.io.IOException
- (CRLF)

Throws
java.io.IOException:

---

println

public void println()
throws IOException

Writes a carriage return-line feed (CRLF) to the client.
Throws:  
[IOException] - if an input or output exception occurred

```java
public void println(String s) throws java.io.IOException
String - (CRLF)
    s                  String
    StringBuffer
Throws  java.io.IOException:
```

println

```java
public void println(String s) throws IOException
    String s
    String
    StringBuffer
```

Writes a String to the client, followed by a carriage return-line feed (CRLF).

**Parameters:**
- s - the String to write to the client

**Throws:**
- [IOException] - if an input or output exception occurred

```java
public void println(boolean b) throws java.io.IOException
boolean - (CRLF)
    b                  boolean
    boolean
```

println

```java
public void println(boolean b) throws IOException
    boolean b
    boolean
```

Writes a boolean value to the client, followed by a carriage return-line feed (CRLF).
public void println(char c) throws java.io.IOException - (CRLF)
    c
    Throws java.io.IOException:

println

public void println(char c)
    throws IOException

    Writes a character to the client, followed by a carriage return-line feed (CRLF).

Parameters:
    c - the character to write to the client

Throws:
    IOException - if an input or output exception occurred

public void println(int i) throws java.io.IOException
    int - (CRLF)
    i
    int
    Throws java.io.IOException:

println

public void println(int i)
    throws IOException

    Writes an int to the client, followed by a carriage return-line feed
(CRLF) character.

**Parameters:**
- `i` - the int to write to the client

**Throws:**
- [IOException](https://docs.oracle.com/javase/8/docs/api/java/io/IOException.html) - if an input or output exception occurred

```java
public void println(long l) throws java.io.IOException
long - (CRLF)

/          long
Throws     java.io.IOException:
```

**println**

```java
public void println(long l)
throws IOException

Writes a long value to the client, followed by a carriage return-line feed (CRLF).

**Parameters:**
- `l` - the long value to write to the client

**Throws:**
- [IOException](https://docs.oracle.com/javase/8/docs/api/java/io/IOException.html) - if an input or output exception occurred

```java
public void println(float f) throws java.io.IOException
float - (CRLF)

/          float
f
Throws     java.io.IOException:
```

**println**

```java
public void println(float f)
throws IOException
```
Writes a float value to the client, followed by a carriage return-line feed (CRLF).

**Parameters:**
- f - the float value to write to the client

**Throws:**
- [IOException](https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/io/IOException.html) - if an input or output exception occurred

```java
public void println(double d) throws java.io.IOException
```

**double** - (CRLF)

```java
double d
```

**Throws**
- java.io.IOException:

---

**println**

```java
public void println(double d)
```

Throws [IOException](https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/io/IOException.html)

Writes a double value to the client, followed by a carriage return-line feed (CRLF).

**Parameters:**
- d - the double value to write to the client

**Throws:**
- [IOException](https://docs.oracle.com/en/java/javase/11/docs/api/java.base/java/io/IOException.html) - if an input or output exception occurred

public interface ServletRequest

Implemented by: HttpServletRequest, ServletRequestWrapper

.servlet.servlet ServletRequest ServletRequest

javax.servlet.http.HttpServletRequest HTTP

See also  javax.servlet.http.HttpServletRequest

---

Defines an object to provide client request information to a servlet. The servlet container creates a ServletRequest object and passes it as an argument to the servlet's service method.

A ServletRequest object provides data including parameter name and values, attributes, and an input stream. Interfaces that extend ServletRequest can provide additional protocol-specific data (for example, HTTP data is provided by HttpServletRequest).

</table>

**Method Detail**

```java
public Object getAttribute(String name) {
    Object null
}
```

**servle HTTPS**

`javax.servlet.request.X509Certificate`  
`ServletRequest#setAttribute`  
`RequestDispatcher`
getAttribute

```
public java.util.Enumeration<E> getAttributeNames()
```

```java
Object getAttribute(String name)
```

Returns the value of the named attribute as an `Object`, or `null` if no attribute of the given name exists.

Attributes can be set two ways. The servlet container may set attributes to make available custom information about a request. For example, for requests made using HTTPS, the attribute `javax.servlet.request.X509Certificate` can be used to retrieve information on the certificate of the client. Attributes can also be set programatically using `setAttribute(java.lang.String, java.lang.Object)`. This allows information to be embedded into a request before a `RequestDispatcher` call.

Attribute names should follow the same conventions as package names. This specification reserves names matching `java.*`, `javax.*`, and `sun.*`.

**Parameters:**
- `name` - A `String` specifying the name of the attribute

**Returns:**
- An `Object` containing the value of the attribute, or `null` if the attribute does not exist
getAttributeNames

Enumeration getAttributeNames()

Returns an Enumeration containing the names of the attributes available to this request. This method returns an empty Enumeration if the request has no attributes available to it.

Returns:
   an Enumeration of strings containing the names of the request's attributes

public String getCharacterEncoding()

return String null

getCharacterEncoding

String getCharacterEncoding()

Returns the name of the character encoding used in the body of this request. This method returns null if the request does not specify a character encoding

Returns:
   a String containing the name of the character encoding, or null if the request does not specify a character encoding

public void setCharacterEncoding(String env) throws java.io.UnsupportedEncodingException
getReader()

env String

Throws java.io.UnsupportedEncodingException: ServletRequest
setCharacterEncoding

```java
void setCharacterEncoding(String env)
    throws UnsupportedEncodingException
```

Overrides the name of the character encoding used in the body of this request. This method must be called prior to reading request parameters or reading input using getReader(). Otherwise, it has no effect.

**Parameters:**
- `env` - String containing the name of the character encoding.

**Throws:**
- `UnsupportedEncodingException` - if this ServletRequest is still in a state where a character encoding may be set, but the specified encoding is invalid

---

public int getContentTypeLength()

```java
    -1 HTTP servlet CGI
    CONTENT_LENGTH
    return -1
```

**getContentLength**

```java
int getContentLength()
```

Returns the length, in bytes, of the request body and made available by the input stream, or -1 if the length is not known. For HTTP servlets, same as the value of the CGI variable CONTENT_LENGTH.

**Returns:**
- an integer containing the length of the request body or -1 if the length is not known
public String getContentType()

MIME CONTENT_TYPE
return MIME String null

getContentType

String getContentType()

Returns the MIME type of the body of the request, or null if the type is not known. For HTTP servlets, same as the value of the CGI variable CONTENT_TYPE.

Returns:
- a String containing the name of the MIME type of the request,
- or null if the type is not known

public ServletInputStream getInputStream() throws java.io.IOException

ServletInputStream getInputStream()

throws IOException

Retrieves the body of the request as binary data using a ServletInputStream. Either this method or getReader() may be called to read the body, not both.

Returns:
- a ServletInputStream object containing the body of the request
### getParameter(String name)

**public String getParameter(String name)**

*String* null HTTP servlet

- **Throws:**
  - `IllegalStateException` - if the `getReader()` method has already been called for this request
  - `IOException` - if an input or output exception occurred

<table>
<thead>
<tr>
<th>Method Call</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>#getParameterValues()</code></td>
<td>Get all parameters for a request.</td>
</tr>
</tbody>
</table>

**Http POST**

1. `#getInputStream`
2. `#getReader`

- `String name`
- `String return`
- `See also` `getParameterValues`

---

### getParameter

**String getParameter(String name)**

Returns the value of a request parameter as a `String`, or `null` if the parameter does not exist. Request parameters are extra information sent with the request. For HTTP servlets, parameters are contained in the query string or posted form data.

You should only use this method when you are sure the parameter has only one value. If the parameter might have more than one value, use `getParameterValues(java.lang.String)`.

If you use this method with a multivalued parameter, the value returned is equal to the first value in the array returned by `getParameterValues`.

If the parameter data was sent in the request body, such as occurs
with an HTTP POST request, then reading the body directly via `getInputStream()` or `getReader()` can interfere with the execution of this method.

**Parameters:**
- `name` - a `String` specifying the name of the parameter

**Returns:**
- a `String` representing the single value of the parameter

**See Also:**
- `getParameterValues(java.lang.String)`

```java
public java.util.Enumeration<String> getParameterNames()
```

**getParameterNames**

Returns an `Enumeration` of `String` objects containing the names of the parameters contained in this request. If the request has no parameters, the method returns an empty `Enumeration`.

**Returns:**
- an `Enumeration` of `String` objects, each `String` containing the name of a request parameter; or an empty `Enumeration` if the request has no parameters

```java
public String[] getParameterValues(String name)
```

**getParameterValues(String name)**

1

- `name` - a `String`

**See also:**
- `getParameter`
getParameterValues

String[] getParameterValues(String name)

Returns an array of String objects containing all of the values the given request parameter has, or null if the parameter does not exist.

If the parameter has a single value, the array has a length of 1.

Parameters:
    name - a String containing the name of the parameter whose value is requested

Returns:
    an array of String objects containing the parameter's values

See Also:
    getParameter(java.lang.String)

getParameterMap

public java.util.Map<K, V> getParameterMap()

java.util.Map HTTP servlet
    return java.util.Map String String

getParameterMap

Map getParameterMap()

Returns a java.util.Map of the parameters of this request. Request parameters are extra information sent with the request. For HTTP servlets, parameters are contained in the query string or posted form data.

Returns:
    an immutable java.util.Map containing parameter names as keys and parameter values as map values. The keys in the parameter map are of type String. The values in the parameter map are of type String array.
public String getProtocol()

String getProtocol()

Returns the name and version of the protocol the request uses in the form protocol/majorVersion.minorVersion, for example, HTTP/1.1. For HTTP servlets, the value returned is the same as the value of the CGI variable SERVER_PROTOCOL.

Returns:

a String containing the protocol name and version number

public String getScheme()

String getScheme()

Returns the name of the scheme used to make this request, for example, http, https, or ftp. Different schemes have different rules for constructing URLs, as noted in RFC 1738.

Returns:

a String containing the name of the scheme used to make this request
public String getServerName()

getServerName

String getServerName()

Returns the host name of the server to which the request was sent. It is the value of the part before ":" in the Host header value, if any, or the resolved server name, or the server IP address.

Returns:
- a String containing the name of the server

public int getServerPort()

getServerPort

int getServerPort()

Returns the port number to which the request was sent. It is the value of the part after ":" in the Host header value, if any, or the server port where the client connection was accepted on.

Returns:
- an integer specifying the port number

public java.io.BufferedReader getReader() throws java.io.IOException

BufferedReader getReader

#getInputStream
getReader

**BufferedReader getReader()**

Throws: `IOException`

Retrieves the body of the request as character data using a `BufferedReader`. The reader translates the character data according to the character encoding used on the body. Either this method or `getInputStream()` may be called to read the body, not both.

Returns:

- A `BufferedReader` containing the body of the request

Throws:

- `UnsupportedEncodingException` - if the character set encoding used is not supported and the text cannot be decoded
- `IllegalStateException` - if `getInputStream()` method has been called on this request
- `IOException` - if an input or output exception occurred

See Also:

- `getInputStream()`

---

```
public String getRemoteAddr()
```

Internet Protocol (IP)  HTTP servlet CGI

**REMOTE_ADDR**

```
return IP String
```

**getRemoteAddr**

```
String getRemoteAddr()
```
Returns the Internet Protocol (IP) address of the client or last proxy that sent the request. For HTTP servlets, same as the value of the CGI variable REMOTE_ADDR.

**Returns:**

a String containing the IP address of the client that sent the request

```java
public String getRemoteHost()
```

**IP HTTP servlet CGI**

return String

**getRemoteHost**

```java
String getRemoteHost()
```

Returns the fully qualified name of the client or the last proxy that sent the request. If the engine cannot or chooses not to resolve the hostname (to improve performance), this method returns the dotted-string form of the IP address. For HTTP servlets, same as the value of the CGI variable REMOTE_HOST.

**Returns:**

a String containing the fully qualified name of the client

```java
public void setAttribute(String name, Object o)
```

**RequestDispatcher**

```java
java.*javax.* com.sun.* Sun Microsystems
null #removeAttribute
RequestDispatcher Web servlet servlet
```

name String
setAttribute

void setAttribute(String name, Object o)

Stores an attribute in this request. Attributes are reset between requests. This method is most often used in conjunction with RequestDispatcher.

Attribute names should follow the same conventions as package names. Names beginning with java.*, javax.*, and com.sun.*, are reserved for use by Sun Microsystems.
If the object passed in is null, the effect is the same as calling removeAttribute(java.lang.String).
It is warned that when the request is dispatched from the servlet resides in a different web application by RequestDispatcher, the object set by this method may not be correctly retrieved in the caller servlet.

Parameters:

   name - a String specifying the name of the attribute
   o - the Object to be stored

public void removeAttribute(String name)

   java.*javax.*  com.sun.*  Sun Microsystems
   name  String

removeAttribute
void **removeAttribute**(*String* name)

Removes an attribute from this request. This method is not generally needed as attributes only persist as long as the request is being handled.

Attribute names should follow the same conventions as package names. Names beginning with java.*, javax.*, and com.sun.*, are reserved for use by Sun Microsystems.

**Parameters:**

name - a String specifying the name of the attribute to remove

---

**public java.util.Locale getLocale()**

Accept-Language

return

**getLocale**

**Locale getLocale()**

Returns the preferred **Locale** that the client will accept content in, based on the Accept-Language header. If the client request doesn't provide an Accept-Language header, this method returns the default locale for the server.

**Returns:**

the preferred **Locale** for the client

---

**public java.utilEnumeration**<E> **getLocales()**

**Locale Enumeration** Accept-Language

Accept-Language

return

**getLocales**

**Locale Enumeration**

return
getLocales

Enumeration getLocales()

Returns an Enumeration of Locale objects indicating, in decreasing order starting with the preferred locale, the locales that are acceptable to the client based on the Accept-Language header. If the client request doesn't provide an Accept-Language header, this method returns an Enumeration containing one Locale, the default locale for the server.

Returns:
    an Enumeration of preferred Locale objects for the client

public boolean isSecure()

boolean HTTPS

    return boolean

isSecure

boolean isSecure()

Returns a boolean indicating whether this request was made using a secure channel, such as HTTPS.

Returns:
    a boolean indicating if the request was made using a secure channel

google public RequestDispatcher getRequestDispatcher(String path)

RequestDispatcher RequestDispatcher

    RequestDispatcher

servlet "/" servlet
getRequestDispatcher

getRequestDispatcher(String path)

Returns a RequestDispatcher object that acts as a wrapper for the resource located at the given path. A RequestDispatcher object can be used to forward a request to the resource or to include the resource in a response. The resource can be dynamic or static.

The pathname specified may be relative, although it cannot extend outside the current servlet context. If the path begins with a "/" it is interpreted as relative to the current context root. This method returns null if the servlet container cannot return a RequestDispatcher.

The difference between this method and ServletContext.getRequestDispatcher(String) is that this method can take a relative path.

Parameters:
- path - a String specifying the pathname to the resource. If it is relative, it must be relative against the current servlet.

Returns:
- a RequestDispatcher object that acts as a wrapper for the resource at the specified path, or null if the servlet container cannot return a RequestDispatcher

See Also:
- RequestDispatcher
- ServletContext.getRequestDispatcher(String)
public String getRealPath(String path)

getRealPath

String getRealPath(String path)

Deprecated. As of Version 2.1 of the Java Servlet API, use ServletContext.getRealPath(java.lang.String) instead.

public int getRemotePort()

getRemotePort

int getRemotePort()

Returns the Internet Protocol (IP) source port of the client or last proxy that sent the request.

Returns:
an integer specifying the port number

Since:
2.4

public String getLocalName()

getLocalName

String getLocalName()

Internet Protocol (IP)

return IP String

since 2.4
getLocalName

public String getLocalName()

    Returns the host name of the Internet Protocol (IP) interface on which the request was received.

    Returns:  
        a String containing the host name of the IP on which the request was received.

    Since:  
        2.4

public String getLocalAddr()

    Returns the Internet Protocol (IP) address of the interface on which the request was received.

    Returns:  
        a String containing the IP address on which the request was received.

    Since:  
        2.4

public int getLocalPort()
void getLocalPort()

Returns the Internet Protocol (IP) port number of the interface on which the request was received.

Returns:

an integer specifying the port number

Since:

2.4
Class ServletRequestAttributeEvent

public class ServletRequestAttributeEvent
extends ServletRequestEvent

Extends: java.util.EventObject > ServletRequestEvent

Since: Servlet 2.4
See also: javax.servlet.ServletRequestAttributeListener

This is the event class for notifications of changes to the attributes of the servlet request in an application.

See Also:
ServletRequestAttributeListener, Serialized Form

Field Summary

Fields inherited from class java.util.EventObject
source
Constructor Summary

ServletResponseAttributeEvent (ServletContext sc, ServletRequest request, String name, Object value)

Construct a ServletRequestAttributeEvent giving the servlet context of this web application, the ServletRequest whose attributes are changing and the name and value of the attribute.

Constructor Detail

public ServletRequestAttributeEvent (ServletContext sc, ServletRequest request, String name, Object value)

Web servlet ServletRequest
ServletResponseAttributeEvent

sc ServletContext
ServletRequestAttributeEvent

public ServletRequestAttributeEvent(ServletContext sc, ServletRequest request, String name, Object value)

Construct a ServletRequestAttributeEvent giving the servlet context of this web application, the ServletRequest whose attributes are changing and the name and value of the attribute.

Parameters:
- `sc` - the ServletContext that is sending the event.
- `request` - the ServletRequest that is sending the event.
- `name` - the name of the request attribute.
- `value` - the value of the request attribute.

Method Detail

public String getName()

ServletRequest return

getName

public String getName()

Return the name of the attribute that changed on the ServletRequest.

Returns:
- the name of the changed request attribute
public Object getValue()

    return

getValue

public Object getValue()

    Returns the value of the attribute that has been added, removed or replaced. If the attribute was added, this is the value of the attribute. If the attribute was removed, this is the value of the removed attribute. If the attribute was replaced, this is the old value of the attribute.

    Returns:
    the value of the changed request attribute
javax.servlet Interface
ServletRequestAttributeListener

All Superinterfaces:
EventListener

public interface ServletRequestAttributeListener
extends EventListener

Implements: java.util.EventListener

ServletRequestAttributeListener Web Web servlet	servlet

since Servlet 2.4

A ServletRequestAttributeListener can be implemented by the developer interested in being notified of request attribute changes. Notifications will be generated while the request is within the scope of the web application in which the listener is registered. A request is defined as coming into scope when it is about to enter the first servlet or filter in each web application, as going out of scope when it exits the last servlet or the first filter in the chain.

Since:
Servlet 2.4

<table>
<thead>

<td>Notification that an existing attribute has been removed from</td>
</tr>
</tbody>
</table>
Method Detail

public void attributeAdded(ServletRequestAttributeEvent srae)
  servlet

attributeAdded

void attributeAdded(ServletRequestAttributeEvent srae)
  Notification that a new attribute was added to the servlet request. Called after the attribute is added.

public void attributeRemoved(ServletRequestAttributeEvent srae)
  servlet

attributeRemoved

void attributeRemoved(ServletRequestAttributeEvent srae)
  Notification that an existing attribute has been removed from the servlet request. Called after the attribute is removed.

public void attributeReplaced(ServletRequestAttributeEvent srae)
servlet

attributeReplaced

void attributeReplaced(ServletRequestAttributeEvent srae)

Notification that an attribute was replaced on the servlet request. Called after the attribute is replaced.
javax.servlet Class ServletRequestEvent

java.lang.Object
   java.util.EventObject
      javax.servlet.ServletRequestEvent

All Implemented Interfaces:
   Serializable

Direct Known Subclasses:
   ServletRequestAttributeEvent

public class ServletRequestEvent
   extends EventObject

Extends: java.util.EventObject
Extended by: ServletRequestAttributeEvent

ServletRequest Web ServletContext
   since Servlet 2.4
See also javax.servlet.ServletRequestListener

Events of this kind indicate lifecycle events for a ServletRequest. The source of the event is the ServletContext of this web application.

Since:
   Servlet 2.4
See Also:
   ServletRequestListener, Serialized Form

### Constructor Detail

```java
class ServletRequestEvent {
    public ServletRequestEvent(ServletContext `sc`, ServletRequest `request`)
        ServletContext `sc` Web ServletContext
        ServletRequest `request` ServletRequest
}
```

ServletRequestEvent
public ServletRequestEvent(ServletContext sc, ServletRequest request)

Construct a ServletRequestEvent for the given ServletContext and ServletRequest.

Parameters:
  sc - the ServletContext of the web application.
  request - theServletRequest that is sending the event.

Method Detail

public ServletRequest getServletRequest()
ServletRequest

getServletRequest

public ServletRequest getServletRequest()

Returns the ServletRequest that is changing.

public ServletContext getServletContext()
Web  ServletContext

getServletContext

public ServletContext getServletContext()

Returns the ServletContext of this web application.

Submit a bug or feature

PS:
javax.servlet Interface ServletRequestListener

All Superinterfaces: 
EventListener

public interface ServletRequestListener 

extendsEventListener

Implements: java.util.EventListener

ServletRequestListener Web Web servlet servlet

since Servlet 2.4

A ServletRequestListener can be implemented by the developer interested in being notified of requests coming in and out of scope in a web component. A request is defined as coming into scope when it is about to enter the first servlet or filter in each web application, as going out of scope when it exits the last servlet or the first filter in the chain.

Since: Servlet 2.4

Method Summary

javax.servlet

**Class ServletRequestWrapper**

java.lang.Object

└ javax.servlet.ServletRequestWrapper

### All Implemented Interfaces:

- ServletRequest

### Direct Known Subclasses:

- HttpServletRequestWrapper

---

```java
public class ServletRequestWrapper
extends Object
implements ServletRequest
```

**Implements:** ServletRequest  
**Extended by:** HttpServletRequestWrapper

ServletRequest  Servlet  Wrapper  Decorator

**since**  v 2.3

**See also**  javax.servlet.ServletRequest

Provides a convenient implementation of the ServletRequest interface that can be subclassed by developers wishing to adapt the request to a Servlet. This class implements the Wrapper or Decorator pattern. Methods default to calling through to the wrapped request object.

**Since:**

v 2.3

**See Also:**

ServletRequest
### Constructor Summary

**ServletRequestWrapper**(ServletRequest request)  
Creates a ServletRequest adaptor wrapping the given request object.

Constructor Detail

public ServletRequestWrapper(ServletRequest request)
ServletRequest

Throws
IllegalArgumentException: request null

ServletRequestWrapper

public ServletRequestWrapper(ServletRequest request)

Creates a ServletRequest adaptor wrapping the given request object.

Throws:
IllegalArgumentException - if the request is null

Method Detail

public ServletRequest getRequest()

getRequest

public ServletRequest getRequest()

getRequest

Return the wrapped request object.

public void setRequest(ServletRequest request)
**setRequest**

public void setRequest(ServletRequest request)

Sets the request object being wrapped.

**Throws:**

IllegalArgumentException - if the request is null.

---

**public Object getAttribute(String name)**

getAttribute(String name)

**getAttribute**

public Object getAttribute(String name)

The default behavior of this method is to call getAttribute(String name) on the wrapped request object.

**Specified by:**

getAttribute in interface ServletRequest

**Parameters:**

name - a String specifying the name of the attribute

**Returns:**

an Object containing the value of the attribute, or null if the attribute does not exist

---

**public java.util.Enumeration<E> getAttributeNames()**

getAttributeNames()
**getAttributeNames**

```java
public Enumeration getAttributeNames()
```

The default behavior of this method is to return `getAttributeNames()` on the wrapped request object.

**Specified by:**
`getAttributeNames` in interface `ServletRequest`

**Returns:**
an `Enumeration` of strings containing the names of the request's attributes

---

**public String getCharacterEncoding()**

```java
getCharacterEncoding()
```

**getCharacterEncoding**

```java
public String getCharacterEncoding()
```

The default behavior of this method is to return `getCharacterEncoding()` on the wrapped request object.

**Specified by:**
`getCharacterEncoding` in interface `ServletRequest`

**Returns:**
a `String` containing the name of the character encoding, or `null` if the request does not specify a character encoding

---

**public void setCharacterEncoding(String enc) throws java.io.UnsupportedEncodingException**

```java
setCharacterEncoding
```
public void setCharacterEncoding(String enc)
    throws UnsupportedEncodingException

    The default behavior of this method is to set the character encoding
    on the wrapped request object.

    Specified by:
        setCharacterEncoding in interface ServletRequest

    Parameters:
        enc - String containing the name of the character encoding.

    Throws:
        UnsupportedEncodingException - if this ServletRequest is still in a
        state where a character encoding may be set, but the specified
        encoding is invalid

public int getContentType()
getContentType()

gContentType

public int getContentType()

    The default behavior of this method is to return getContentType()
    on the wrapped request object.

    Specified by:
        getContentType in interface ServletRequest

    Returns:
        an integer containing the length of the request body or -1 if the
        length is not known

-------------------

public String getContentType()
getContentType()
getContentType

public String getContentType()

The default behavior of this method is to return getContentType() on the wrapped request object.

Specified by:
getContentType in interface ServletRequest

Returns:
a String containing the name of the MIME type of the request, or null if the type is not known

---

public ServletInputStream getInputStream() throws java.io.IOException

getInputStream()

getInputStream

public ServletInputStream getInputStream() throws IOException

The default behavior of this method is to return getInputStream() on the wrapped request object.

Specified by:
getInputStream in interface ServletRequest

Returns:
a ServletInputStream object containing the body of the request

Throws:
IOException - if an input or output exception occurred

---

public String getParameter(String name)

getParameter(String name)
getParameter

public String getParameter(String name)

The default behavior of this method is to return getParameter(String name) on the wrapped request object.

Specified by:

generateParameter in interface ServletRequest

Parameters:

name - a String specifying the name of the parameter

Returns:

a String representing the single value of the parameter

See Also:

ServletRequest.getParameterValues(java.lang.String)

generateParameterMap

public java.util.Map<K, V> getParameterMap()

getParameterMap()

generateParameterMap

public Map getParameterMap()

The default behavior of this method is to return getParameterMap() on the wrapped request object.

Specified by:

generateParameterMap in interface ServletRequest

Returns:

an immutable java.util.Map containing parameter names as keys and parameter values as map values. The keys in the parameter map are of type String. The values in the parameter map are of type String array.

generateParameterNames

public java.util Enumeration<E> getParameterNames()

getParameterNames()
**getParameterNames**

public Enumeration getParameterNames()

The default behavior of this method is to return getParameterNames() on the wrapped request object.

**Specified by:**
getParameterNames in interface ServletRequest

**Returns:**
- an Enumeration of String objects, each String containing the name of a request parameter; or an empty Enumeration if the request has no parameters

---

**public String[] getParameterValues(String name)**

**getParameterValues(String name)**

**getParameterValues**

public String[] getParameterValues(String name)

The default behavior of this method is to return getParameterValues(String name) on the wrapped request object.

**Specified by:**
getParameterValues in interface ServletRequest

**Parameters:**
- name - a String containing the name of the parameter whose value is requested

**Returns:**
- an array of String objects containing the parameter's values

**See Also:**
ServletRequest.getParameter(java.lang.String)
public String getProtocol()
getProtocol()

getProtocol

public String getProtocol()

The default behavior of this method is to return getProtocol() on the
wrapped request object.

Specified by:

getProtocol in interface ServletRequest

Returns:

a String containing the protocol name and version number

public String getScheme()
getScheme()

getScheme

public String getScheme()

The default behavior of this method is to return getScheme() on the
wrapped request object.

Specified by:

getScheme in interface ServletRequest

Returns:

a String containing the name of the scheme used to make this
request

public String getServerName()
getServerName()
getServerName

public String getServerName()

    The default behavior of this method is to return getServerName() on the wrapped request object.

Specified by:
    getServerName in interface ServletRequest

Returns:
    a String containing the name of the server

getServerPort

public int getServerPort()

getServerPort()

getServerPort

public int getServerPort()

    The default behavior of this method is to return getServerPort() on the wrapped request object.

Specified by:
    getServerPort in interface ServletRequest

Returns:
    an integer specifying the port number

getReader

public java.io.BufferedReader getReader() throws java.io.IOException

getReader()

getReader

public BufferedReader getReader()
The default behavior of this method is to return getReader() on the wrapped request object.

Specified by:  
getReader in interface ServletRequest

Returns:  
a BufferedReader containing the body of the request

Throws:  
IOException - if an input or output exception occurred

See Also:  
ServletRequest.getInputStream()
public String getRemoteHost()

The default behavior of this method is to return getRemoteHost() on the wrapped request object.

Specified by:
getRemoteHost in interface ServletRequest

Returns:
a String containing the fully qualified name of the client

------

public void setAttribute(String name, Object o)
setAttribute(String name, Object o)

setAttribute

public void setAttribute(String name, Object o)

The default behavior of this method is to return setAttribute(String name, Object o) on the wrapped request object.

Specified by:
setAttribute in interface ServletRequest

Parameters:
name - a String specifying the name of the attribute
o - the Object to be stored

------

public void removeAttribute(String name)
removeAttribute(String name)

removeAttribute

public void removeAttribute(String name)

The default behavior of this method is to call removeAttribute(String
name) on the wrapped request object.

**Specified by:**

removeAttribute in interface ServletRequest

**Parameters:**

name - a String specifying the name of the attribute to remove

---

```java
public java.util.Locale getLocale()
getLocale()

getLocale
```

**getLocale**

**getLocal**

```java
public Locale getLocale()
```

The default behavior of this method is to return getLocale() on the wrapped request object.

**Specified by:**

getLocale in interface ServletRequest

**Returns:**

the preferred Locale for the client

---

```java
public java.util Enumeration<E> getLocales()
getLocales()

getLocales
```

**getLocales**

**getLocales**

```java
public Enumeration getLocales()
```

The default behavior of this method is to return getLocales() on the wrapped request object.

**Specified by:**

getLocales in interface ServletRequest
Returns:
an Enumeration of preferred Locale objects for the client

public boolean isSecure()
isSecure()  

isSecure  

The default behavior of this method is to return isSecure() on the wrapped request object.

Specified by:
   isSecure in interface ServletRequest
Returns:
a boolean indicating if the request was made using a secure channel

public RequestDispatcher getRequestDispatcher(String path)
getRequestDispatcher(String path)  

getRequestDispatcher  

The default behavior of this method is to return getRequestDispatcher(String path) on the wrapped request object.

Specified by:
   getRequestDispatcher in interface ServletRequest
Parameters:
   path - a String specifying the pathname to the resource. If it is
relative, it must be relative against the current servlet.  

**Returns:**

A `RequestDispatcher` object that acts as a wrapper for the resource at the specified path, or `null` if the servlet container cannot return a `RequestDispatcher`.

See Also:

- `RequestDispatcher`
- `ServletContext.getRequestDispatcher(java.lang.String)`

---

```java
public String getRealPath(String path)
getRealPath(String path)
```

**getRealPath**

```java
public String getRealPath(String path)
```

The default behavior of this method is to return `getRealPath(String path)` on the wrapped request object.

Specified by:

- `getRealPath` in interface `ServletRequest`

---

```java
public int getRemotePort()
getRemotePort()
```

**getRemotePort**

```java
public int getRemotePort()
```

The default behavior of this method is to return `getRemotePort()` on the wrapped request object.

Specified by:
getRemotePort in interface ServletRequest

Returns:
an integer specifying the port number

Since:
2.4

public String getLocalName()
getLocalName()
since 2.4

getLocalName

public String getLocalName()

The default behavior of this method is to return getLocalName() on the wrapped request object.

Specified by:
getLocalName in interface ServletRequest

Returns:
a String containing the host name of the IP on which the request was received.

Since:
2.4

public String getLocalAddr()
getLocalAddr()
since 2.4

getLocalAddr

public String getLocalAddr()

The default behavior of this method is to return getLocalAddr() on
the wrapped request object.

**Specified by:**
getLocalAddr in interface ServletRequest

**Returns:**
a String containing the IP address on which the request was received.

**Since:**
2.4

---

```java
public int getLocalPort()
getLocalPort()
since 2.4
```

**getLocalPort**

public int getLocalPort()

The default behavior of this method is to return getLocalPort() on the wrapped request object.

**Specified by:**
getLocalPort in interface ServletRequest

**Returns:**
an integer specifying the port number

**Since:**
2.4

PS:
javax.servlet  Interface ServletResponse

All Known Subinterfaces:
  HttpServletResponse

All Known Implementing Classes:
  HttpServletResponseWrapper, ServletResponseWrapper

public interface ServletResponse

Implemented by: HttpServletResponse, ServletResponseWrapper

Servlet servlet ServletResponse servlet

MIME  #getOutputStream  ServletOutputStream
#getWriter  PrintWriter  multipart
ServletOutputStream

  #setCharacterEncoding  #setContentType  MIME  charset
#setLocale  charset  ISO-8859-1  setCharacterEncoding setContentType  setLocale  getWriter

MIME  Internet  RFC  RFC 2045  SMTP  HTTP  MIME

See also  javax.servlet.ServletOutputStream

Defines an object to assist a servlet in sending a response to the client. The servlet container creates a ServletResponse object and passes it as an argument to the servlet's service method.

To send binary data in a MIME body response, use the ServletOutputStream returned by getOutputStream(). To send character data, use the PrintWriter object returned by getWriter(). To mix binary and text data, for example, to create a multipart response, use a
ServletOutputStream and manage the character sections manually.

The charset for the MIME body response can be specified explicitly using the `setCharacterEncoding(java.lang.String)` and `setContentType(java.lang.String)` methods, or implicitly using the `setLocale(java.util.Locale)` method. Explicit specifications take precedence over implicit specifications. If no charset is specified, ISO-8859-1 will be used. The `setCharacterEncoding`, `setContentType`, or `setLocale` method must be called before `getWriter` and before committing the response for the character encoding to be used.

See the Internet RFCs such as RFC 2045 for more information on MIME. Protocols such as SMTP and HTTP define profiles of MIME, and those standards are still evolving.

</tbody>
</table>
public String getCharacterEncoding()
(MIME charset)

Returns the name of the character encoding (MIME charset) used for the body sent in this response. The character encoding may have been specified explicitly using the setCharacterEncoding(java.lang.String) or setContentType(java.lang.String) methods, or implicitly using the setLocale(java.util.Locale) method. Explicit specifications take precedence over implicit specifications. Calls made to these methods after getWriter has been called or after the response has been committed have no effect on the character encoding. If no character encoding has been specified, ISO-8859-1 is returned.

See RFC 2047 (http://www.ietf.org/rfc/rfc2047.txt) for more information about character encoding and MIME.

Returns:

a String specifying the name of the character encoding, for example, UTF-8

public String getContentType()
MIME

getCharacterEncoding()  getWriter()  charset
charset
return
since
String text/html; charset=UTF-8 null
2.4

getContentType

String getContentType()

Returns the content type used for the MIME body sent in this response. The content type proper must have been specified using setContentType(java.lang.String) before the response is committed. If no content type has been specified, this method returns null. If a content type has been specified, and a character encoding has been explicitly or implicitly specified as described in getCharacterEncoding() or getWriter() has been called, the charset parameter is included in the string returned. If no character encoding has been specified, the charset parameter is omitted.

Returns:

a String specifying the content type, for example, text/html; charset=UTF-8, or null

Since:

2.4

public ServletOutputStream getOutputStream() throws java.io.IOException

ServletOutputStream flush()

return ServletOutputStream

Throws

IllegalStateException: getWriter

Throws

java.io.IOException:
getOutputStream

`ServletOutputStream getOutputStream()`

Throws `IOException`

Returns a `ServletOutputStream` suitable for writing binary data in the response. The servlet container does not encode the binary data.

Calling `flush()` on the `ServletOutputStream` commits the response. Either this method or `getWriter()` may be called to write the body, not both.

Returns:
a `ServletOutputStream` for writing binary data

Throws:

- `IllegalStateException` - if the `getWriter` method has been called on this response
- `IOException` - if an input or output exception occurred

See Also:
- `getWriter()`

---

public java.io.PrintWriter `getWriter()` throws java.io.IOException

```
#get
getCharacterEncoding
ISO-8859-1
getOutputStream
ISO-8859-1

PrintWriter flush()
```

```
#getOutputStream
return PrintWriter
Throws UnsupportedEncodingException: getCharacterEncoding
Throws IllegalStateException: getOutputStream
```
Throws: java.io.IOException:
See also: getOutputStream, setCharacterEncoding

getWriter

`getWriter()`

Throws: IOException

`getWriter()`

Returns a PrintWriter object that can send character text to the client. The PrintWriter uses the character encoding returned by `getCharacterEncoding()`. If the response's character encoding has not been specified as described in `getCharacterEncoding` (i.e., the method just returns the default value ISO-8859-1), `getWriter` updates it to ISO-8859-1.

Calling flush() on the PrintWriter commits the response.

Either this method or `getOutputStream()` may be called to write the body, not both.

Returns:
a PrintWriter object that can return character data to the client

Throws:
UnsupportedEncodingException - if the character encoding returned by `getCharacterEncoding` cannot be used
`IllegalStateException` - if the `getOutputStream` method has already been called for this response object
`IOException` - if an input or output exception occurred

See Also:
`getOutputStream()`, `setCharacterEncoding(java.lang.String)`

---

public void setCharacterEncoding(String charset)
(MIME charset) UTF-8

`#setLocale` text/html String `#setContentType`

UTF-8 String text/html; charset=UTF-8 String
-setContentType

-getWriter

-servlet writer HTTP Content-Type
-servlet HTTP servlet writer

-setCharacterEncoding

-void setCharacterEncoding(String charset)

Sets the character encoding (MIME charset) of the response being sent to the client, for example, to UTF-8. If the character encoding has already been set by setContentType(java.lang.String) or setLocale(java.util.Locale), this method overrides it. Calling setContentType(java.lang.String) with the String of text/html and calling this method with the String of UTF-8 is equivalent with calling setContentType with the String of text/html; charset=UTF-8.

This method can be called repeatedly to change the character encoding. This method has no effect if it is called after getWriter has been called or after the response has been committed.

Containers must communicate the character encoding used for the servlet response’s writer to the client if the protocol provides a way for doing so. In the case of HTTP, the character encoding is communicated as part of the Content-Type header for text media types. Note that the character encoding cannot be communicated via HTTP headers if the servlet does not specify a content type; however, it is still used to encode text written via the servlet
response's writer.

**Parameters:**

- **charset** - a String specifying only the character set defined by IANA Character Sets
  
  (http://www.iana.org/assignments/character-sets)

**Since:**

2.4

**See Also:**

`#setLocale`

```java
public void setContentLength(int len)
```

**HTTP servlet**

**HTTP Content-Length**

| len | Content-Length |

**setContentLength**

```java
void setContentLength(int len)
```

Sets the length of the content body in the response. In HTTP servlets, this method sets the HTTP Content-Length header.

**Parameters:**

- **len** - an integer specifying the length of the content being returned to the client; sets the Content-Length header

---

```java
public void setContentType(String type)
```

**getWriter**

**servlet**

**writer**

**HTTP**

<table>
<thead>
<tr>
<th>type</th>
<th>MIME</th>
</tr>
</thead>
</table>

**Content-Type**

| String |

**See also**

`setLocale`, `setCharacterEncoding`, `getOutputStream`, `getWriter`
**setContentType**

*void setContentType(String type)*

Sets the content type of the response being sent to the client, if the response has not been committed yet. The given content type may include a character encoding specification, for example, `text/html;charset=UTF-8`. The response's character encoding is only set from the given content type if this method is called before `getWriter` is called.

This method may be called repeatedly to change content type and character encoding. This method has no effect if called after the response has been committed. It does not set the response's character encoding if it is called after `getWriter` has been called or after the response has been committed.

Containers must communicate the content type and the character encoding used for the servlet response's writer to the client if the protocol provides a way for doing so. In the case of HTTP, the `Content-Type` header is used.

**Parameters:**
- *type* - a `String` specifying the MIME type of the content

**See Also:**
- `setLocale(java.util.Locale)`, `setCharacterEncoding(java.lang.String), getOutputStream()`, `getWriter()`

---

**public void setSize(int size)**

*javax.servlet.*

**size**

*IllegalStateException*
Throws: IllegalArgumentException
See also: getBufferSize, flushBuffer, isCommitted, reset

**setBufferSize**

```java
void setBufferSize(int size)
```

Sets the preferred buffer size for the body of the response. The servlet container will use a buffer at least as large as the size requested. The actual buffer size used can be found using getBufferSize.

A larger buffer allows more content to be written before anything is actually sent, thus providing the servlet with more time to set appropriate status codes and headers. A smaller buffer decreases server memory load and allows the client to start receiving data more quickly.

This method must be called before any response body content is written; if content has been written or the response object has been committed, this method throws an IllegalArgumentException.

**Parameters:**
- `size` - the preferred buffer size

**Throws:**
- `IllegalArgumentException` - if this method is called after content has been written

**See Also:**
- `getBufferSize()`, `flushBuffer()`, `isCommitted()`, `reset()`

---

```java
public int getBufferSize()
```

```java
0
```

```java
return setBufferSize, flushBuffer, isCommitted, reset
```

See also: setBufferSize, flushBuffer, isCommitted, reset
**getBufferSize**

```java
int getBufferSize()
```

Returns the actual buffer size used for the response. If no buffering is used, this method returns 0.

**Returns:**
the actual buffer size used

**See Also:**
`setBufferSize(int), flushBuffer(), isCommitted(), reset()`

---

**public void flushBuffer() throws java.io.IOException**

See also `setBufferSize, getBufferSize, isCommitted, reset`

---

**flushBuffer**

```java
void flushBuffer() throws IOException
```

Forces any content in the buffer to be written to the client. A call to this method automatically commits the response, meaning the status code and headers will be written.

**Throws:**
`IOException`

**See Also:**
`setBufferSize(int), getBufferSize(), isCommitted(), reset()`

---

**public void resetBuffer()**

since 2.3

See also `setBufferSize, getBufferSize, isCommitted, reset`
resetBuffer

void resetBuffer()

Clears the content of the underlying buffer in the response without clearing headers or status code. If the response has been committed, this method throws an IllegalStateException.

Since:
2.3
See Also:
setBufferSize(int), getBufferSize(), isCommitted(), reset()

public boolean isCommitted()

boolean return

See also setBufferSize, getBufferSize, flushBuffer, reset

isCommitted

boolean isCommitted()

Returns a boolean indicating if the response has been committed. A committed response has already had its status code and headers written.

Returns:
  a boolean indicating if the response has been committed
See Also:
  setBufferSize(int), getBufferSize(), flushBuffer(), reset()

public void reset()

throws

IllegalStateException:

See also setBufferSize, getBufferSize, flushBuffer, isCommitted
reset

void reset()

Clears any data that exists in the buffer as well as the status code and headers. If the response has been committed, this method throws an IllegalStateException.

Throws:

- IllegalStateException - if the response has already been committed

See Also:

- setBufferSize(int), getBufferSize(), flushBuffer(), isCommitted()

public void setLocale(java.util.Locale loc)

getWriter locale-encoding-mapping-list

charset #setContentType
#setCharacterEncoding getWriter

servlet writer HTTP Content-Language
Content-Type servlet HTTP

servlet writer loc

See also getLocale, setContentType, setCharacterEncoding

setLocale

void setLocale(Locale loc)
Sets the locale of the response, if the response has not been committed yet. It also sets the response's character encoding appropriately for the locale, if the character encoding has not been explicitly set using `setContentType(java.lang.String)` or `setCharacterEncoding(java.lang.String)`, `getWriter` hasn't been called yet, and the response hasn't been committed yet. If the deployment descriptor contains a `locale-encoding-mapping-list` element, and that element provides a mapping for the given locale, that mapping is used. Otherwise, the mapping from locale to character encoding is container dependent.

This method may be called repeatedly to change locale and character encoding. The method has no effect if called after the response has been committed. It does not set the response's character encoding if it is called after `setContentType(java.lang.String)` has been called with a charset specification, after `setCharacterEncoding(java.lang.String)` has been called, after `getWriter` has been called, or after the response has been committed.

Containers must communicate the locale and the character encoding used for the servlet response's writer to the client if the protocol provides a way for doing so. In the case of HTTP, the locale is communicated via the `Content-Language` header, the character encoding as part of the `Content-Type` header for text media types. Note that the character encoding cannot be communicated via HTTP headers if the servlet does not specify a content type; however, it is still used to encode text written via the servlet response's writer.

**Parameters:**

- `loc` - the locale of the response

**See Also:**

`getLocale()`, `setContentType(java.lang.String)`,
`setCharacterEncoding(java.lang.String)`

```java
public java.util.Locale getLocale()
#setLocale

setLocale

See also

setLocale
```
getLocale

locale getLocale()

Returns the locale specified for this response using the
setLocale(java.util.Locale) method. Calls made to setLocale after
the response is committed have no effect. If no locale has been
specified, the container's default locale is returned.

Class ServletResponseWrapper

javax.servlet
java.lang.Object
  ↓ javax.servlet.ServletResponseWrapper

All Implemented Interfaces:
  ServletResponse

Direct Known Subclasses:
  HttpServletResponseWrapper

public class ServletResponseWrapper
extends Object
implements ServletResponse

Implements: ServletResponse
Extended by: HttpServletResponseWrapper

ServletResponse  Servlet  Wrapper  Decorator

since  v 2.3  
See also  javax.servlet.ServletResponse

Provides a convenient implementation of the ServletResponse interface that can be subclassed by developers wishing to adapt the response from a Servlet. This class implements the Wrapper or Decorator pattern. Methods default to calling through to the wrapped response object.

Since:  
v 2.3
Author:

Constructor Detail

public ServletResponseWrapper(ServletResponse response)
ServletResponse

Throws IllegalArgumentException: response null

ServletResponseWrapper

public ServletResponseWrapper(ServletResponse response)

Creates a ServletResponse adaptor wrapping the given response object.

Throws: IllegalArgumentException - if the response is null.

Method Detail

public ServletResponse getResponse()

ServletResponse

getResponse

public ServletResponse getResponse()

Return the wrapped ServletResponse object.

public void setResponse(ServletResponse response)

Throws IllegalArgumentException: response null

setResponse

public void setResponse(ServletResponse response)

Sets the response being wrapped.
Throws:

**IllegalArgumentException** - if the response is null.

```java
public void setCharacterEncoding(String charset)
```

since 2.4

**setCharacterEncoding**

```java
public void setCharacterEncoding(String charset)
```

The default behavior of this method is to call `setCharacterEncoding(String charset)` on the wrapped response object.

**Specified by:**

`setCharacterEncoding` in interface `ServletResponse`

**Parameters:**

- `charset` - a String specifying only the character set defined by IANA Character Sets
  (http://www.iana.org/assignments/character-sets)

**Since:**

2.4

**See Also:**

`#setLocale`

---

```java
public String getCharacterEncoding()
```

```java
getCharacterEncoding()
```

**getCharacterEncoding**

```java
public String getCharacterEncoding()
```

The default behavior of this method is to return
getCharacterEncoding() on the wrapped response object.

Specified by:
- getCharacterEncoding in interface ServletResponse

Returns:
- a String specifying the name of the character encoding, for example, UTF-8

public ServletOutputStream getOutputStream() throws java.io.IOException

getOutputStream()

getOutputStream

public ServletOutputStream getOutputStream() throws IOException

The default behavior of this method is to return getOutputStream() on the wrapped response object.

Specified by:
- getOutputStream in interface ServletResponse

Returns:
- a ServletOutputStream for writing binary data

Throws:
- IOException - if an input or output exception occurred

See Also:
- ServletResponse.getWriter()

public java.io.PrintWriter getWriter() throws java.io.IOException

getWriter()
public PrintWriter getWriter() throws IOException

The default behavior of this method is to return getWriter() on the wrapped response object.

Specified by:
   getWriter in interface ServletResponse

Returns:
a PrintWriter object that can return character data to the client

Throws:
   IOException - if an input or output exception occurred

See Also:
   ServletResponse.getOutputStream(), ServletResponse.setCharacterEncoding(java.lang.String)

---

public void setContentLength(int len)

setContentLength

public void setContentLength(int len)

The default behavior of this method is to call setContentLength(int len) on the wrapped response object.

Specified by:
   setContentLength in interface ServletResponse

Parameters:
   len - an integer specifying the length of the content being returned to the client; sets the Content-Length header

---

public void setContentType(String type)

setContentType(String type)
**setContentType**

public void **setContentType**(String type)

The default behavior of this method is to call setContentType(String type) on the wrapped response object.

**Specified by:**
`setContentType` in interface `ServletResponse`

**Parameters:**
type - a `String` specifying the MIME type of the content

**See Also:**

---

**public String getContentType()**

`getContentType()`

since 2.4

---

**getContentType**

public `String` `getContentType()`

The default behavior of this method is to return getContentType() on the wrapped response object.

**Specified by:**
`getContentType` in interface `ServletResponse`

**Returns:**
a `String` specifying the content type, for example, `text/html; charset=UTF-8`, or null

**Since:**
2.4
public void setBufferSize(int size)
setBufferSize(int size)

setBufferSize

public void setBufferSize(int size)

The default behavior of this method is to call setBufferSize(int size) on the wrapped response object.

Specified by:

setBufferSize in interface ServletResponse

Parameters:

size - the preferred buffer size

See Also:

ServletResponse.getBufferSize(), ServletResponse.flushBuffer(), ServletResponse.isCommitted(), ServletResponse.reset()

---------------------------

generateBuffer(int size)

generateBuffer()

generateBuffer

public int generateBuffer(int size)

generateBuffer()

The default behavior of this method is to return generateBuffer(int size) on the wrapped response object.

Specified by:

generateBuffer in interface ServletResponse

Returns:

the actual buffer size used

See Also:

ServletResponse.generateBuffer(int), ServletResponse.flushBuffer(), ServletResponse.isCommitted()
public void flushBuffer() throws java.io.IOException
flushBuffer()

flushBuffer

public void flushBuffer()
throws IOException

The default behavior of this method is to call flushBuffer() on the wrapped response object.

Specified by:
flushBuffer in interface ServletResponse

Throws:
IOException

See Also:
ServletResponse.setBufferSize(int), ServletResponse.getBufferSize(), ServletResponse.isCommitted(), ServletResponse.reset()

public boolean isCommitted()

isCommitted()

isCommitted

public boolean isCommitted()

    The default behavior of this method is to return isCommitted() on the wrapped response object.

Specified by:
isCommitted in interface ServletResponse
Returns:
a boolean indicating if the response has been committed

See Also:
ServletResponse.setBufferSize(int),
ServletResponse.getBufferSize(),
ServletResponse.flushBuffer(), ServletResponse.reset()

public void reset()
    reset()

reset

public void reset()
    The default behavior of this method is to call reset() on the wrapped response object.

Specified by:
reset in interface ServletResponse

See Also:
ServletResponse.setBufferSize(int),
ServletResponse.getBufferSize(),
ServletResponse.flushBuffer(), ServletResponse.isCommitted()

public void resetBuffer()
    resetBuffer()

resetBuffer

public void resetBuffer()
    The default behavior of this method is to call resetBuffer() on the wrapped response object.
public void setLocale(java.util.Locale loc)
setLocale(Locale loc)

setLocale

public void setLocale(Locale loc)

The default behavior of this method is to call setLocale(Locale loc) on the wrapped response object.

Specified by: setLocale in interface ServletResponse

Parameters:
loc - the locale of the response

See Also:
ServletResponse.getLocale(),
ServletResponse.setContentType(java.lang.String),
ServletResponse.setCharacterEncoding(java.lang.String)

public java.util.Locale getLocale()
getLocale()

getLocale

public Locale getLocale()

The default behavior of this method is to return getLocale() on the
wrapped response object.

**Specified by:**
getLocale in interface ServletResponse

**See Also:**
ServletRequest.setLocale(java.util.Locale)

Implemented by: QueueSession, TopicSession, XASession

Session Java (JVM) JMS

•
•
• TemporaryTopics  TemporaryQueues
•
•
•
•
• QueueBrowsers

MessageConsumer  Session  MessageProducer

close
A `Session` object is a single-threaded context for producing and consuming messages. Although it may allocate provider resources outside the Java virtual machine (JVM), it is considered a lightweight JMS object.

A session serves several purposes:

- It is a factory for its message producers and consumers.
- It supplies provider-optimized message factories.
- It is a factory for `TemporaryTopics` and `TemporaryQueues`.
- It provides a way to create `Queue` or `Topic` objects for those clients that need to dynamically manipulate provider-specific destination names.
- It supports a single series of transactions that combine work spanning its producers and consumers into atomic units.
- It defines a serial order for the messages it consumes and the messages it produces.
- It retains messages it consumes until they have been acknowledged.
- It serializes execution of message listeners registered with its message consumers.
- It is a factory for QueueBrowsers.

A session can create and service multiple message producers and consumers.

One typical use is to have a thread block on a synchronous MessageConsumer until a message arrives. The thread may then use one or more of the Session's MessageProducerS.

If a client desires to have one thread produce messages while others consume them, the client should use a separate session for its producing thread.

Once a connection has been started, any session with one or more registered message listeners is dedicated to the thread of control that delivers messages to it. It is erroneous for client code to use this session or any of its constituent objects from another thread of control. The only exception to this rule is the use of the session or connection close method.

It should be easy for most clients to partition their work naturally into sessions. This model allows clients to start simply and incrementally add message processing complexity as their need for concurrency grows.

The close method is the only session method that can be called while some other session method is being executed in another thread.

A session may be specified as transacted. Each transacted session supports a single series of transactions. Each transaction groups a set of message sends and a set of message receives into an atomic unit of work. In effect, transactions organize a session's input message stream and output message stream into series of atomic units. When a transaction commits, its atomic unit of input is acknowledged and its associated atomic unit of output is sent. If a transaction rollback is done, the transaction's sent messages are destroyed and the session's input is automatically recovered.
The content of a transaction's input and output units is simply those messages that have been produced and consumed within the session's current transaction.

A transaction is completed using either its session's commit method or its session's rollback method. The completion of a session's current transaction automatically begins the next. The result is that a transacted session always has a current transaction within which its work is done.

The Java Transaction Service (JTS) or some other transaction monitor may be used to combine a session's transaction with transactions on other resources (databases, other JMS sessions, etc.). Since Java distributed transactions are controlled via the Java Transaction API (JTA), use of the session's commit and rollback methods in this context is prohibited.

The JMS API does not require support for JTA; however, it does define how a provider supplies this support.

Although it is also possible for a JMS client to handle distributed transactions directly, it is unlikely that many JMS clients will do this. Support for JTA in the JMS API is targeted at systems vendors who will be integrating the JMS API into their application server products.

**Field Detail**

<table>
<thead>
<tr>
<th>Field Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTO_ACKNOWLEDGE</td>
<td>static final int</td>
</tr>
</tbody>
</table>

With this acknowledgment mode, the session automatically
acknowledges a client's receipt of a message either when the session has successfully returned from a call to receive or when the message listener the session has called to process the message successfully returns.

See Also:
Constant Field Values

CLIENT_ACKNOWLEDGE

static final int CLIENT_ACKNOWLEDGE

With this acknowledgment mode, the client acknowledges a consumed message by calling the message's acknowledge method. Acknowledging a consumed message acknowledges all messages that the session has consumed.

When client acknowledgment mode is used, a client may build up a large number of unacknowledged messages while attempting to process them. A JMS provider should provide administrators with a way to limit client overrun so that clients are not driven to resource exhaustion and ensuing failure when some resource they are using is temporarily blocked.

See Also:
Message.acknowledge(), Constant Field Values

DUPS_OK_ACKNOWLEDGE

static final int DUPS_OK_ACKNOWLEDGE

This acknowledgment mode instructs the session to lazily acknowledge the delivery of messages. This is likely to result in the delivery of some duplicate messages if the JMS provider fails, so it
should only be used by consumers that can tolerate duplicate messages. Use of this mode can reduce session overhead by minimizing the work the session does to prevent duplicates.

See Also:
   Constant Field Values

SESSION_TRANSACTED

static final int SESSION_TRANSACTED

This value is returned from the method getAcknowledgeMode if the session is transacted. If a Session is transacted, the acknowledgement mode is ignored.

See Also:
   Constant Field Values

Method Detail

public BytesMessage createBytesMessage() throws JMSException

createBytesMessage

BytesMessage createBytesMessage() throws JMSException

Creates a BytesMessage object. A BytesMessage object is used to send a message containing a stream of uninterpreted bytes.

 Throws:
public MapMessage createMapMessage() throws JMSException

Throws: JMSException - if the JMS provider fails to create this message due to some internal error.

createMapMessage

public Message createMessage() throws JMSException

Throws: JMSException - if the JMS provider fails to create this message due to some internal error.

createMessage

Creates a Message object. The Message interface is the root interface of all JMS messages. A Message object holds all the standard
message header information. It can be sent when a message containing only header information is sufficient.

**Throws:**

- `JMSException` - if the JMS provider fails to create this message due to some internal error.

```java
public ObjectMessage createObjectMessage() throws JMSException
```

Creates an `ObjectMessage` object. An `ObjectMessage` object is used to send a message that contains a serializable Java object.

**Throws:**

- `JMSException` - if the JMS provider fails to create this message due to some internal error.

```java
ObjectMessage createObjectMessage(java.io.Serializable object) throws JMSException
```

```java
public ObjectMessage createObjectMessage(java.io.Serializable object) throws JMSException
```
ObjectMessage createObjectMessage(Serializable object) throws JMSException

Creates an initialized ObjectMessage object. An ObjectMessage object is used to send a message that contains a serializable Java object.

Parameters:
  object - the object to use to initialize this message

Throws:
  JMSException - if the JMS provider fails to create this message due to some internal error.

public StreamMessage createStreamMessage() throws JMSException

StreamMessage StreamMessage Java
  Throws JMSException: JMS

createStreamMessage

StreamMessage createStreamMessage() throws JMSException

Creates a StreamMessage object. A StreamMessage object is used to send a self-defining stream of primitive values in the Java programming language.

Throws:
  JMSException - if the JMS provider fails to create this message due to some internal error.

public TextMessage createTextMessage() throws JMSException

TextMessage TextMessage String
  Throws JMSException: JMS
createTextMessage

TextMessage createTextMessage() throws JMSException

Creates a TextMessage object. A TextMessage object is used to send a message containing a String object.

Throws:
   JMSException - if the JMS provider fails to create this message due to some internal error.

public TextMessage createTextMessage(String text) throws JMSException

TextMessage createTextMessage(String text)

Throws JMSException: JMS

createTextMessage

TextMessage createTextMessage(String text) throws JMSException

Creates an initialized TextMessage object. A TextMessage object is used to send a message containing a String.

Parameters:
   text - the string used to initialize this message

Throws:
   JMSException - if the JMS provider fails to create this message due to some internal error.

public boolean getTransacted() throws JMSException

return true
getTransacted

boolean getTransacted() throws JMSException

Indicates whether the session is in transacted mode.

Returns:
true if the session is in transacted mode

Throws:
JMSException - if the JMS provider fails to return the transaction mode due to some internal error.

public int getAcknowledgeMode() throws JMSException

return SESSION_TRANSACTED

Throws JMSException: JMS

since 1.1

See also createSession

getAcknowledgeMode

int getAcknowledgeMode() throws JMSException

Returns the acknowledgement mode of the session. The acknowledgement mode is set at the time that the session is created. If the session is transacted, the acknowledgement mode is ignored.

Returns:
If the session is not transacted, returns the current acknowledgement mode for the session. If the session is transacted, returns SESSION_TRANSACTED.
Throws:  
   JMSException - if the JMS provider fails to return the acknowledgment mode due to some internal error.

Since:  
   1.1

   Connection.createSession(boolean, int)

---

public void commit() throws JMSException

Throws   
   JMSException: JMS

Throws   
   TransactionRolledBackException:

Throws   
   IllegalStateException:

commit

void commit()  
   throws JMSException

 Commits all messages done in this transaction and releases any locks currently held.

Throws:  
   JMSException - if the JMS provider fails to commit the transaction due to some internal error.
   TransactionRolledBackException - if the transaction is rolled back due to some internal error during commit.
   IllegalStateException - if the method is not called by a transacted session.

---

public void rollback() throws JMSException

Throws   
   JMSException: JMS

Throws   
   IllegalStateException:
rollback

```java
void rollback() throws JMSException
```

Rolls back any messages done in this transaction and releases any locks currently held.

**Throws:**

- `JMSException` - if the JMS provider fails to roll back the transaction due to some internal error.
- `IllegalStateException` - if the method is not called by a transacted session.

---

public void close() throws JMSException

---

**JVM**

```java
receive receive null
```

**Session**

```java
Session JMSException.IllegalStateException
```

**Throws**

- `JMSException`: JMS

---

**close**

```java
void close() throws JMSException
```
Closes the session.

Since a provider may allocate some resources on behalf of a session outside the JVM, clients should close the resources when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

There is no need to close the producers and consumers of a closed session.

This call will block until a receive call or message listener in progress has completed. A blocked message consumer receive call returns null when this session is closed.

Closing a transacted session must roll back the transaction in progress.

This method is the only Session method that can be called concurrently.

Invoking any other Session method on a closed session must throw a JMSExcetion.IllegalArgumentException. Closing a closed session must not throw an exception.

**Throws:**
- JMSExcetion - if the JMS provider fails to close the session due to some internal error.

```java
public void recover() throws JMSExcetion
```

- 
- “”
throws **JMSException**: JMS

Throws **IllegalStateException**: 

```java
public MessageListener getMessageListener() throws JMSEException
```

**recover**

```java
void recover() throws JMSEException
```

Stops message delivery in this session, and restarts message delivery with the oldest unacknowledged message.

All consumers deliver messages in a serial order. Acknowledging a received message automatically acknowledges all messages that have been delivered to the client.

Restarting a session causes it to take the following actions:

- Stop message delivery
- Mark all messages that might have been delivered but not acknowledged as "redelivered"
- Restart the delivery sequence including all unacknowledged messages that had been previously delivered. Redelivered messages do not have to be delivered in exactly their original delivery order.

**Throws:**

- **JMSException** - if the JMS provider fails to stop and restart message delivery due to some internal error.
- **IllegalStateException** - if the method is called by a transacted session.
Thrown by

- JMSException: JMS

See also

- setMessageListener, javax.jms.ServerSessionPool,
  javax.jms.ServerSession

getMessageListener

```java
public MessageListener getMessageListener() throws JMSException
```

Returns the session's distinguished message listener (optional).

**Returns:**

the message listener associated with this session

**Throws:**

JMSException - if the JMS provider fails to get the message listener due to an internal error.

See Also:

- setMessageListener(javax.jms.MessageListener),
  ServerSessionPool, ServerSession

public void setMessageListener(MessageListener listener) throws JMSException

JMS

```java
public void setMessageListener(MessageListener listener) throws JMSException
```

Thrown by

- JMSException: JMS

See also

- getMessageListener, javax.jms.ServerSessionPool,
  javax.jms.ServerSession
**setMessageListener**

```java
void setMessageListener(MessageListener listener)
throws JMSException
```

Sets the session's distinguished message listener (optional).

When the distinguished message listener is set, no other form of message receipt in the session can be used; however, all forms of sending messages are still supported.

This is an expert facility not used by regular JMS clients.

**Parameters:**
- `listener` - the message listener to associate with this session

**Throws:**
- `JMSException` - if the JMS provider fails to set the message listener due to an internal error.

**See Also:**
- `getMessageListener()`, `ServerSessionPool`, `ServerSession`

---

**public void run()**

**Application Server JMS**

See also `javax.jms.ServerSession`

**run**

```java
void run()
```

Optional operation, intended to be used only by Application Servers, not by ordinary JMS clients.

**Specified by:**
- `run` in interface `Runnable`

**See Also:**
- `ServerSession`
public MessageProducer createProducer(Destination destination) throws JMSException

MessageProducer

<table>
<thead>
<tr>
<th>MessageProducer</th>
<th>Queue</th>
<th>Topic</th>
<th>Destination</th>
</tr>
</thead>
<tbody>
<tr>
<td>destination</td>
<td></td>
<td></td>
<td>MessageProducer</td>
</tr>
</tbody>
</table>

Throws JMSException: MessageProducer

Throws InvalidDestinationException: 
since 1.1

createProducer

MessageProducer createProducer(Destination destination) throws JMSException

Creates a MessageProducer to send messages to the specified destination.

A client uses a MessageProducer object to send messages to a destination. Since Queue and Topic both inherit from Destination, they can be used in the destination parameter to create a MessageProducer object.

Parameters:

destination - the Destination to send to, or null if this is a producer which does not have a specified destination.

Throws:

JMSException - if the session fails to create a MessageProducer due to some internal error.

InvalidDestinationException - if an invalid destination is specified.

Since:

1.1
public MessageConsumer createConsumer(Destination destination) throws JMSException

    MessageConsumer    Queue    Topic    Destination
    destination        MessageConsumer

    Throws: JMSException:
    Throws: InvalidDestinationException:
    since            1.1

createConsumer

public MessageConsumer createConsumer(Destination destination, String messageSelector) throws JMSException

    MessageConsumer    Queue    Topic
    destination        MessageConsumer

    MessageConsumer

    Parameters:
    destination - the Destination to access.

    Throws:
    JMSException - if the session fails to create a consumer due to some internal error.
    InvalidDestinationException - if an invalid destination is specified.

    Since:
    1.1
createConsumer

MessageConsumer createConsumer(Destination destination, String messageSelector) throws JMSException

Creates a MessageConsumer for the specified destination, using a message selector. Since Queue and Topic both inherit from Destination, they can be used in the destination parameter to create a MessageConsumer.

A client uses a MessageConsumer object to receive messages that have been sent to a destination.

Parameters:
- destination - the Destination to access
- messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.

Throws:
- JMSException - if the session fails to create a MessageConsumer due to some internal error.
- InvalidDestinationException - if an invalid destination is specified.
- InvalidSelectorException - if the message selector is invalid.

Since:
1.1
public MessageConsumer createConsumer(Destination destination, String messageSelector, boolean NoLocal) throws JMSException

MessageConsumer

Queue Topic Destination destination
MessageConsumer

MessageConsumer

NoLocal
destination
messageSelector
false
true
null

Throws JMSException: MessageConsumer
Throws InvalidDestinationException:
Throws InvalidSelectorException:
since 1.1

createConsumer

MessageConsumer createConsumer(Destination destination, String messageSelector, boolean NoLocal) throws JMSException

Creates MessageConsumer for the specified destination, using a message selector. This method can specify whether messages published by its own connection should be delivered to it, if the destination is a topic.

Since Queue and Topic both inherit from Destination, they can be used in the destination parameter to create a MessageConsumer.

A client uses a MessageConsumer object to receive messages that have been published to a destination.
In some cases, a connection may both publish and subscribe to a topic. The consumer NoLocal attribute allows a consumer to inhibit the delivery of messages published by its own connection. The default value for this attribute is False. The noLocal value must be supported by destinations that are topics.

**Parameters:**
- **destination** - the Destination to access
- **messageSelector** - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
- **NoLocal** - if true, and the destination is a topic, inhibits the delivery of messages published by its own connection. The behavior for NoLocal is not specified if the destination is a queue.

**Throws:**
- **JMSException** - if the session fails to create a MessageConsumer due to some internal error.
- **InvalidDestinationException** - if an invalid destination is specified.
- **InvalidSelectorException** - if the message selector is invalid.

**Since:**
- 1.1

```java
public Queue createQueue(String queueName) throws JMSException

Queue
```

**JMS API**

- `queueName` - Queue
- `return` - Queue
- `Throws` - JMSException
- `since` - 1.1
createQueue

```java
Queue createQueue(String queueName)
  throws JMSException
```

Creates a queue identity given a queue name.

This facility is provided for the rare cases where clients need to dynamically manipulate queue identity. It allows the creation of a queue identity with a provider-specific name. Clients that depend on this ability are not portable.

Note that this method is not for creating the physical queue. The physical creation of queues is an administrative task and is not to be initiated by the JMS API. The one exception is the creation of temporary queues, which is accomplished with the createTemporaryQueue method.

**Parameters:**
- `queueName` - the name of this Queue

**Returns:**
- a `Queue` with the given name

**Throws:**
- `JMSException` - if the session fails to create a queue due to some internal error.

**Since:**
- 1.1

---

public `Topic` createTopic(String topicName) throws `JMSException`

`Topic`

---

**JMS API**

`createTemporaryTopic`
createTopic

```java
topicName

return Topic

Throws JMSException:

since 1.1
```

Creates a topic identity given a Topic name.

This facility is provided for the rare cases where clients need to dynamically manipulate topic identity. This allows the creation of a topic identity with a provider-specific name. Clients that depend on this ability are not portable.

Note that this method is not for creating the physical topic. The physical creation of topics is an administrative task and is not to be initiated by the JMS API. The one exception is the creation of temporary topics, which is accomplished with the createTemporaryTopic method.

Parameters:
- `topicName` - the name of this Topic

Returns:
- a Topic with the given name

Throws:
- JMSException - if the session fails to create a topic due to some internal error.

Since:
- 1.1

---

```java
public TopicSubscriber createDurableSubscriber(Topic topic, String name) throws JMSException
```
createDurableSubscriber

```java
TopicSubscriber createDurableSubscriber(Topics topic, String name)
throws JMSException
```

Creates a durable subscriber to the specified topic.

If a client needs to receive all the messages published on a topic, including the ones published while the subscriber is inactive, it uses a durable `TopicSubscriber`. The JMS provider retains a record of this durable subscription and insures that all messages from the topic's publishers are retained until they are acknowledged by this durable subscriber or they have expired.

Sessions with durable subscribers must always provide the same client identifier. In addition, each client must specify a name that uniquely identifies (within client identifier) each durable subscription it creates. Only one session at a time can have a `TopicSubscriber` for a particular durable subscription.
A client can change an existing durable subscription by creating a durable TopicSubscriber with the same name and a new topic and/or message selector. Changing a durable subscriber is equivalent to unsubscribing (deleting) the old one and creating a new one.

In some cases, a connection may both publish and subscribe to a topic. The subscriber NoLocal attribute allows a subscriber to inhibit the delivery of messages published by its own connection. The default value for this attribute is false.

**Parameters:**
- `topic` - the non-temporary Topic to subscribe to
- `name` - the name used to identify this subscription

**Throws:**
- `JMSException` - if the session fails to create a subscriber due to some internal error.
- `InvalidDestinationException` - if an invalid topic is specified.

**Since:**
1.1

```java
public TopicSubscriber createDurableSubscriber(Topic topic, String name, String messageSelector, boolean noLocal) throws JMSException
```

```
TopicSubscriber JMS

/ TopicSubscriber

  topic
  name
  messageSelector null
  noLocal

  Throws JMSException:
  Throws InvalidDestinationException:
```
createDurableSubscriber

**TopicSubscriber createDurableSubscriber***(Topic topic, String name, String messageSelector, boolean noLocal) throws JMSException**

Creates a durable subscriber to the specified topic, using a message selector and specifying whether messages published by its own connection should be delivered to it.

If a client needs to receive all the messages published on a topic, including the ones published while the subscriber is inactive, it uses a durable `TopicSubscriber`. The JMS provider retains a record of this durable subscription and insures that all messages from the topic's publishers are retained until they are acknowledged by this durable subscriber or they have expired.

Sessions with durable subscribers must always provide the same client identifier. In addition, each client must specify a name which uniquely identifies (within client identifier) each durable subscription it creates. Only one session at a time can have a `TopicSubscriber` for a particular durable subscription. An inactive durable subscriber is one that exists but does not currently have a message consumer associated with it.

A client can change an existing durable subscription by creating a durable `TopicSubscriber` with the same name and a new topic and/or message selector. Changing a durable subscriber is equivalent to unsubscribing (deleting) the old one and creating a new one.

**Parameters:**
- `topic` - the non-temporary `Topic` to subscribe to
- `name` - the name used to identify this subscription
messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.

noLocal - if set, inhibits the delivery of messages published by its own connection

Throws:

- JMSEException - if the session fails to create a subscriber due to some internal error.
- InvalidDestinationException - if an invalid topic is specified.
- InvalidSelectorException - if the message selector is invalid.

Since:

1.1

public QueueBrowser createBrowser(Queue queue) throws JMSException

QueueBrowser
queue
queue
Throws
 JMSEException:
Throws
InvalidDestinationException:
since
1.1

createBrowser

QueueBrowser createBrowser(Queue queue)
throws JMSEException

Creates a QueueBrowser object to peek at the messages on the specified queue.

Parameters:

queue - the queue to access

Throws:

- JMSEException - if the session fails to create a browser due to some internal error.
- InvalidDestinationException - if an invalid destination is
public QueueBrowser createBrowser(Queue queue, String messageSelector) throws JMSException

QueueBrowser
queue            queue
messageSelector  null

Throws
JMSException:
InvalidDestinationException:
InvalidSelectorException:
since       1.1

createBrowser

QueueBrowser createBrowser(Queue queue,
String messageSelector)
throws JMSException

Creates a QueueBrowser object to peek at the messages on the specified queue using a message selector.

Parameters:
queue - the queue to access
messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.

Throws:
JMSException - if the session fails to create a browser due to some internal error.
InvalidDestinationException - if an invalid destination is specified
InvalidSelectorException - if the message selector is invalid.

Since:
public TemporaryQueue createTemporaryQueue() throws JMSException

TemporaryQueue return
Throws JMSException: since 1.1

createTemporaryQueue

TemporaryQueue createTemporaryQueue() throws JMSException

Creates a TemporaryQueue object. Its lifetime will be that of the Connection unless it is deleted earlier.

Returns: a temporary queue identity
Throws: JMSException - if the session fails to create a temporary queue due to some internal error.
Since: 1.1

public TemporaryTopic createTemporaryTopic() throws JMSException

TemporaryTopic return
Throws JMSException: since 1.1

createTemporaryTopic
**TemporaryTopic** `createTemporaryTopic()` throws `JMSException`  

Creates a `TemporaryTopic` object. Its lifetime will be that of the `Connection` unless it is deleted earlier.

**Returns:**
- a temporary topic identity

**Throws:**
- `JMSException` - if the session fails to create a temporary topic due to some internal error.

**Since:**
- 1.1

---

```java
public void unsubscribe(String name) throws JMSException
```

**MessageConsumer** `TopicSubscriber`  

**name**

**Throws** `JMSException`:

**Throws** `InvalidDestinationException`:

**since** 1.1

**unsubscribe**

```java
void unsubscribe(String name)
```

Throws `JMSException`

Unsubscribes a durable subscription that has been created by a client.

This method deletes the state being maintained on behalf of the
subscriber by its provider.

It is erroneous for a client to delete a durable subscription while there is an active MessageConsumer or TopicSubscriber for the subscription, or while a consumed message is part of a pending transaction or has not been acknowledged in the session.

**Parameters:**
- name - the name used to identify this subscription

**Throws:**
- JMSException - if the session fails to unsubscribe to the durable subscription due to some internal error.
- InvalidDestinationException - if an invalid subscription name is specified.

**Since:**
- 1.1

#### javamail.address.map  javamail.default.address.map

```java
javax.mail.Address getType java.util.zip.ZipOutputStream
javax.mail.Address
javax.mail.internet.InternetAddress getType "rfc822"
news nntp Transport
javamail.address.map

rfc822=smtp
news=nntp
```

The Session class represents a mail session and is not subclassed. It collects together properties and defaults used by the mail API's. A single default session can be shared by multiple applications on the desktop. Unshared sessions can also be created.

The Session class provides access to the protocol providers that implement the Store, Transport, and related classes. The protocol providers are configured using the following files:

- javamail.providers and javamail.default.providers
- javamail.address.map and javamail.default.address.map
Each javamail.X resource file is searched for using three methods in the following order:

1. java.home/lib/javamail.X
2. META-INF/javamail.X
3. META-INF/javamail.default.X

The first method allows the user to include their own version of the resource file by placing it in the lib directory where the java.home property points. The second method allows an application that uses the JavaMail APIs to include their own resource files in their application's or jar file's META-INF directory. The javamail.default.X default files are part of the JavaMail mail.jar file.

File location depends upon how the ClassLoader method getResource is implemented. Usually, the getResource method searches through CLASSPATH until it finds the requested file and then stops. JDK 1.1 has a limitation that the number of files of each name that will be found in the CLASSPATH is limited to one. However, this only affects method two, above; method one is loaded from a specific location (if allowed by the SecurityManager) and method three uses a different name to ensure that the default resource file is always loaded successfully. J2SE 1.2 and later are not limited to one file of a given name.

The ordering of entries in the resource files matters. If multiple entries exist, the first entries take precedence over the later entries. For example, the first IMAP provider found will be set as the default IMAP implementation until explicitly changed by the application. The user- or system-supplied resource files augment, they do not override, the default files included with the JavaMail APIs. This means that all entries in all files loaded will be available.

javamail.providers and javamail.default.providers

These resource files specify the stores and transports that are available on the system, allowing an application to "discover" what store and transport implementations are available. The protocol implementations are listed one per line. The file format defines four attributes that describe a protocol implementation. Each attribute is an "="-separated name-value
pair with the name in lowercase. Each name-value pair is semi-colon (";") separated. The following names are defined.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td>Name assigned to protocol. For example, smtp for Transport.</td>
</tr>
<tr>
<td>type</td>
<td>Valid entries are store and transport.</td>
</tr>
<tr>
<td>class</td>
<td>Class name that implements this protocol.</td>
</tr>
<tr>
<td>vendor</td>
<td>Optional string identifying the vendor.</td>
</tr>
<tr>
<td>version</td>
<td>Optional string identifying the version.</td>
</tr>
</tbody>
</table>

Here's an example of META-INF/javamail.default.providers file contents:

```
protocol=imap; type=store; class=com.sun.mail.imap.IMAPStore; vendor=Sun Microsystems, Inc.;
protocol=smtp; type=transport; class=com.sun.mail.smtp.SMTPTransport;
```

`javamail.address.map` and `javamail.default.address.map`

These resource files map transport address types to the transport protocol. The `getType` method of `javax.mail.Address` returns the address type. The `javamail.address.map` file maps the transport type to the protocol. The file format is a series of name-value pairs. Each key name should correspond to an address type that is currently installed on the system; there should also be an entry for each `javax.mail.Address` implementation that is present if it is to be used. For example, the `javax.mail.internet.InternetAddress` method `getType` returns "rfc822". Each referenced protocol should be installed on the system. For the case of `news`, below, the client should install a Transport provider supporting the nntp protocol.

Here are the typical contents of a `javamail.address.map` file:

```
rfc822=smtp
news=nntp
```

**Version:**

1.76, 07/05/04

get Instance

public static Session getInstance(Properties props, Authenticator authenticator)

Get a new Session object.

Parameters:
- props - Properties object that hold relevant properties. It is expected that the client supplies values for the properties listed in Appendix A of the JavaMail spec (particularly mail.store.protocol, mail.transport.protocol, mail.host, mail.user, and mail.from) as the defaults are unlikely to work in all cases.
- authenticator - Authenticator object used to call back to the application when a user name and password is needed.

Returns:
a new Session object

props Properties Session
JavaMail A mail.store.protocol
mail.transport.protocolmail.hostmail.user mail.from

authenticator Authenticator Session Session
Authenticator Authenticator

return Session

getDefaultInstance
public static Session getDefaultInstance(Properties props, Authenticator authenticator)

Get the default Session object. If a default has not yet been setup, a new Session object is created and installed as the default.

Since the default session is potentially available to all code executing in the same Java virtual machine, and the session can contain security sensitive information such as user names and passwords, access to the default session is restricted. The Authenticator object, which must be created by the caller, is used indirectly to check access permission. The Authenticator object passed in when the session is created is compared with the Authenticator object passed in to subsequent requests to get the default session. If both objects are the same, or are from the same ClassLoader, the request is allowed. Otherwise, it is denied.

Note that if the Authenticator object used to create the session is null, anyone can get the default session by passing in null.

Note also that the Properties object is used only the first time this method is called, when a new Session object is created. Subsequent calls return the Session object that was created by the first call, and ignore the passed Properties object. Use the getInstance method to get a new Session object every time the method is called.

In JDK 1.2, additional security Permission objects may be used to control access to the default session.

Parameters:

props - Properties object. Used only if a new Session object is created.
It is expected that the client supplies values for the properties listed in Appendix A of the JavaMail spec (particularly mail.store.protocol, mail.transport.protocol, mail.host, mail.user, and mail.from) as the defaults are unlikely to work in all cases.

authenticator - Authenticator object. Used only if a new Session object is created. Otherwise, it must match the Authenticator used to create the Session.

Returns:
the default Session object

public static Session getDefaultInstance(java.util.Properties props)

Session  Session

Authenticator  Java

Properties  Session

props  JavaMail  A mail.store.protocol

mail.transport.protocolmail.hostmail.user  mail.from

return  Session

since  JavaMail 1.2

getDefaultInstance

public static Session getDefaultInstance(Properties props)

Get the default Session object. If a default has not yet been setup, a new Session object is created and installed as the default.

Note that a default session created with no Authenticator is available to all code executing in the same Java virtual machine, and the session can contain security sensitive information such as user names and passwords.

Parameters:

text

props - Properties object. Used only if a new Session object is created. It is expected that the client supplies values for the properties listed in Appendix A of the JavaMail spec (particularly mail.store.protocol, mail.transport.protocol, mail.host, mail.user, and mail.from) as the defaults are unlikely to work in all cases.

Returns:

text

the default Session object

Since:
public void setDebug(boolean debug)
Session

true mail.debug Session setDebug Session
mail.debug

setDebug

public void setDebug(boolean debug)

Set the debug setting for this Session.

Since the debug setting can be turned on only after the Session has been created, to turn on debugging in the Session constructor, set the property mail.debug in the Properties object passed in to the constructor to true. The value of the mail.debug property is used to initialize the per-Session debugging flag. Subsequent calls to the setDebug method manipulate the per-Session debugging flag and have no affect on the mail.debug property.

Parameters:

debug - Debug setting

public boolean getDebug()
Session

return

getDebug
public boolean getDebug()

Get the debug setting for this Session.

Returns:
   current debug setting

public void setDebugOut(java.io.PrintStream out)

Set the stream to be used for debugging output for this session. If out is null, System.out will be used. Note that debugging output that occurs before any session is created, as a result of setting the mail.debug system property, will always be sent to System.out.

Parameters:
   out - the PrintStream to use for debugging output

Since:
   JavaMail 1.3

public java.io.PrintStream getDebugOut()

Get the stream to be used for debugging output for this session.

Returns:
   current Debug output stream

Since:
   JavaMail 1.3
public PrintStream getDebugOut()

    Returns the stream to be used for debugging output. If no stream has been set, System.out is returned.

    Returns:
        the PrintStream to use for debugging output

    Since:
        JavaMail 1.3

---

public Provider[] getProviders()

javamail.[default.]providers ClassLoader

    return

getProviders

public Provider[] getProviders()

    This method returns an array of all the implementations installed via the javamail.[default.]providers files that can be loaded using the ClassLoader available to this application.

    Returns:
        Array of configured providers

---

public Provider getProvider(String protocol) throws NoSuchProviderException

    Provider mail.<protocol>.class Provider

    Provider NoSuchProviderException

    protocol smtpimap)

    return Provider

    Throws NoSuchProviderException:
getProvider

public Provider getProvider(String protocol) throws NoSuchProviderException

  Returns the default Provider for the protocol specified. Checks mail.<protocol>.class property first and if it exists, returns the Provider associated with this implementation. If it doesn't exist, returns the Provider that appeared first in the configuration files. If an implementation for the protocol isn't found, throws NoSuchProviderException

Parameters:
  protocol - Configured protocol (i.e. smtp, imap, etc)

Returns:
  Currently configured Provider for the specified protocol

Throws:
  NoSuchProviderException - If a provider for the given protocol is not found.

public void setProvider(Provider provider) throws NoSuchProviderException

  Set the passed Provider to be the default implementation for the protocol in Provider.protocol overriding any previous values.

Parameters:
  provider - Currently configured Provider which will be set as the default for the protocol

setProvider
public Store getStore() throws NoSuchProviderException

Get a Store object that implements this user's desired Store protocol. The mail.store.protocol property specifies the desired protocol. If an appropriate Store object is not obtained, NoSuchProviderException is thrown.

Returns:
   a Store object

Throws:
   NoSuchProviderException - If a provider for the given protocol is not found.

public Store getStore(String protocol) throws NoSuchProviderException

Throws:
   NoSuchProviderException - If the provider passed in is invalid.
public Store getStore(String protocol) throws NoSuchProviderException

Get a Store object that implements the specified protocol. If an appropriate Store object cannot be obtained, NoSuchProviderException is thrown.

Parameters:
  protocol -
Returns:
a Store object
Throws:
  NoSuchProviderException - If a provider for the given protocol is not found.

public Store getStore(URLName url) throws NoSuchProviderException

URLName Store Store
NoSuchProviderException URL "scheme" RFC 1738 Store

url
return
Throws NoSuchProviderException: URLName
See also getFolder(URLName), javax.mail.URLName

getStore

public Store getStore(URLName url) throws NoSuchProviderException

Get a Store object for the given URLName. If the requested Store object cannot be obtained, NoSuchProviderException is thrown. The "scheme" part of the URL string (Refer RFC 1738) is used to locate the Store protocol.
Parameters:
  url - URLName that represents the desired Store
Returns:
  a closed Store object
Throws:
  NoSuchProviderException - If a provider for the given URLName is not found.
See Also:
  getFolder(URLName), URLName

public Store getStore(Provider provider) throws NoSuchProviderException

Provider store store
  provider Store Provider
  return Store
  Throws NoSuchProviderException: Provider

getStore

public Store getStore(Provider provider) throws NoSuchProviderException

Get an instance of the store specified by Provider. Instantiates the store and returns it.

Parameters:
  provider - Store Provider that will be instantiated
Returns:
  Instantiated Store
Throws:
  NoSuchProviderException - If a provider for the given Provider is not found.

public Folder getFolder(URLName url) throws MessagingException
getFolder

public Folder getFolder(URLName url)
    throws MessagingException

Get a closed Folder object for the given URLName. If the requested Folder object cannot be obtained, null is returned.

The "scheme" part of the URL string (Refer RFC 1738) is used to locate the Store protocol. The rest of the URL string (that is, the "schemepart", as per RFC 1738) is used by that Store in a protocol dependent manner to locate and instantiate the appropriate Folder object.

Note that RFC 1738 also specifies the syntax for the "schemepart" for IP-based protocols (IMAP4, POP3, etc.). Providers of IP-based mail Stores should implement that syntax for referring to Folders.

Parameters:
    url - URLName that represents the desired folder
Returns:
   Folder

Throws:
   NoSuchProviderException - If a provider for the given URLName is not found.
   MessagingException - if the Folder could not be located or created.

See Also:
   getStore(URLName), URLName

public Transport getTransport() throws NoSuchProviderException

Transport MessagingException
return Transport
Throws NoSuchProviderException:

getTransport

public Transport getTransport() throws NoSuchProviderException

Get a Transport object that implements this user's desired Transport protocol. The mail.transport.protocol property specifies the desired protocol. If an appropriate Transport object cannot be obtained, MessagingException is thrown.

Returns:
   a Transport object

Throws:
   NoSuchProviderException - If the provider is not found.

public Transport getTransport(String protocol) throws NoSuchProviderException

Transport null
public Transport getTransport(String protocol) throws NoSuchProviderException

Get a Transport object that implements the specified protocol. If an appropriate Transport object cannot be obtained, null is returned.

Returns:
   a Transport object

Throws:
   NoSuchProviderException - If provider for the given protocol is not found.

public Transport getTransport(URLName url) throws NoSuchProviderException

See also
t javax.mail.URLName
Transport object cannot be obtained, NoSuchProviderException is thrown. The "scheme" part of the URL string (Refer RFC 1738) is used to locate the Transport protocol.

Parameters:
- url - URLName that represents the desired Transport

Returns:
a closed Transport object

Throws:
- NoSuchProviderException - If a provider for the given URLName is not found.

See Also:
URLName

---

```java
public Transport getTransport(Provider provider) throws NoSuchProviderException {
    Provider transportProvider = provider;
    Transport transport = transportProvider.getTransport();
    return transport;
}
```

getTransport

```java
public Transport getTransport(Provider provider) throws NoSuchProviderException {
    Provider transportProvider = provider;
    Transport transport = transportProvider.getTransport();
    return transport;
}
```

Get an instance of the transport specified in the Provider. Instantiates the transport and returns it.

Parameters:
- provider - Transport Provider that will be instantiated

Returns:
Instantiated Transport

Throws:
- NoSuchProviderException - If provider for the given provider is not found.
public Transport getTransport(Address address) throws NoSuchProviderException

Message Transport

address
return Transport
Throws NoSuchProviderException: Address
See also javax.mail.Address

getTransport

public Transport getTransport(Address address) throws NoSuchProviderException

Get a Transport object that can transport a Message to the specified address type.

Parameters: address
Returns: A Transport object
Throws: NoSuchProviderException - If provider for the Address type is not found
See Also: Address

public void setPasswordAuthentication(URLName url, PasswordAuthentication pw)
store transportURLName PasswordAuthentication pw null URLName
store transport
**setPasswordAuthentication**

```java
public void setPasswordAuthentication(URLName url, PasswordAuthentication pw)
```

Set a PasswordAuthentication for this (store or transport) URLName. If `pw` is null the entry corresponding to the URLName is removed.

This is normally used only by the store or transport implementations to allow authentication information to be shared among multiple uses of a session.

**getPasswordAuthentication**

```java
public PasswordAuthentication getPasswordAuthentication(URLName url)
```

```java
store transport
PasswordAuthentication store transport
return URLName PasswordAuthentication
```

Get any saved PasswordAuthentication for this (store or transport) URLName. Normally used only by store or transport implementations.

**Returns:**

the PasswordAuthentication corresponding to the URLName

**requestPasswordAuthentication**

```java
public PasswordAuthentication requestPasswordAuthentication(java.net.InetAddress addr, int port, String protocol, String prompt, String defaultUserName)
```
Connecting to <protocol> mail service on host <addr>, port <port>.

User Name: <defaultUserName>
Password:

<table>
<thead>
<tr>
<th>addr</th>
<th>InetAddress null</th>
</tr>
</thead>
<tbody>
<tr>
<td>protocol</td>
<td>imappop3</td>
</tr>
<tr>
<td>prompt</td>
<td>String null</td>
</tr>
<tr>
<td>defaultUserName</td>
<td>null</td>
</tr>
<tr>
<td>return</td>
<td>authenticator null</td>
</tr>
</tbody>
</table>

requestPasswordAuthentication

public PasswordAuthentication requestPasswordAuthentication(InetAddress addr, String protocol, String prompt, String defaultUserName)

Call back to the application to get the needed user name and password. The application should put up a dialog something like:

Connecting to <protocol> mail service on host <addr>, port <port>

User Name: <defaultUserName>
Password:

Parameters:
addr - InetAddress of the host. may be null.
protocol - protocol scheme (e.g. imap, pop3, etc.)
prompt - any additional String to show as part of the prompt; may be null.
defaultUserName - the default username. may be null.

Returns:
the authentication which was collected by the authenticator; may be null.
public java.util.Properties getProperties()
Session Properties
      return Properties

getProperties

public Properties getProperties()

      Returns the Properties object associated with this Session

      Returns:
      Properties object

public String getProperty(String name)
null
      return

getProperty

public String getProperty(String name)

      Returns the value of the specified property. Returns null if this
      property does not exist.

      Returns:
      String that is the property value

public void addProvider(Provider provider)

      provider
      since JavaMail 1.4

      en
addProvider

public void addProvider(Provider provider)

Add a provider to the session.

**Parameters:**

- provider - the provider to add

**Since:**

JavaMail 1.4

---

public void setProtocolForAddress(String addresstype, String protocol)

setProtocolForAddress

public void setProtocolForAddress(String addresstype, String protocol)

Set the default transport protocol to use for addresses of the specified type. Normally the default is set by the javamail.default.address.map or javamail.address.map files or resources.

**Parameters:**

- addresstype - type of address
- protocol - name of protocol

**Since:**

JavaMail 1.4

**See Also:**

getTransport(Address)
getTransport(Address)

PS:
javax.ejb Interface SessionBean

All Superinterfaces:  
EnterpriseBean, Serializable

public interface SessionBean  
extends EnterpriseBean  
Implements: EnterpriseBean

SessionBean  
Bean  SessionBean  
Bean

The SessionBean interface is implemented by every session enterprise Bean class. The container uses the SessionBean methods to notify the enterprise Bean instances of the instance's life cycle events.

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
</table>
| void ejbActivate()  
The activate method is called when the instance is activated from its "passive" state.  |
| void ejbPassivate()  
The passivate method is called before the instance enters the "passive" state.  |
| void ejbRemove()  
A container invokes this method before it ends the life of the session object.  |
| void setSessionContext(SessionContext ctx)  
Set the associated session context.  |

Method Detail
public void setSessionContext(SessionContext ctx) throws EJBException, java.rmi.RemoteException

Bean

crossed豪 SessionContext

Throws EJBException:
java.rmi.RemoteException: EJB 1.0  EJB 1.1

Throws Bean javax.ejb.EJBException EJB2.0 Bean
javax.ejb.EJBException

setSessionContext

void setSessionContext(SessionContext ctx)
throws EJBException,
RemoteException

Set the associated session context. The container calls this method
after the instance creation.

The enterprise Bean instance should store the reference to the
context object in an instance variable.

This method is called with no transaction context.

Parameters:
ctx - A SessionContext interface for the instance.

Throws:
EJBException - Thrown by the method to indicate a failure
caus ed by a system-level error.
RemoteException - This exception is defined in the method
signature to provide backward compatibility for applications
written for the EJB 1.0 specification. Enterprise beans written for
the EJB 1.1 specification should throw the
javax.ejb.EJBException instead of this exception. Enterprise
Beans written for the EJB2.0 and higher specifications must throw the `javax.ejb.EJBException` instead of this exception.

```java
public void ejbRemove() throws EJBException, java.rmi.RemoteException

@throws EJBException
Java.rmi.RemoteException: EJB 1.0 Bean  EJB
@throws 1.1 Bean  javax.ejb.EJBException EJB2.0
Bean  javax.ejb.EJBException

ejbRemove

void ejbRemove()

throws EJBException, RemoteException

A container invokes this method before it ends the life of the session object. This happens as a result of a client's invoking a remove operation, or when a container decides to terminate the session object after a timeout.

This method is called with no transaction context.

Throws:

- **EJBException** - Thrown by the method to indicate a failure caused by a system-level error.
- **RemoteException** - This exception is defined in the method signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 specification should throw the `javax.ejb.EJBException` instead of this exception. Enterprise beans written for the EJB2.0 and higher specifications must throw the `javax.ejb.EJBException` instead of this exception.
**ejbActivate**

public void ejbActivate() throws EJBException, java.rmi.RemoteException

“” ejbPassivate()

**Throws**

- **EJBException**:  
  java.rmi.RemoteException: EJB 1.0 Bean EJB

**Throws 1.1**  
  Bean javax.ejb.EJBException EJB 2.0

Bean javax.ejb.EJBException

---

**ejbActivate**

void ejbActivate()

throws EJBException,

RemoteException

The activate method is called when the instance is activated from its "passive" state. The instance should acquire any resource that it has released earlier in the ejbPassivate() method.

This method is called with no transaction context.

**Throws:**

- **EJBException** - Thrown by the method to indicate a failure caused by a system-level error.
- **RemoteException** - This exception is defined in the method signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 specification should throw the javax.ejb.EJBException instead of this exception. Enterprise beans written for the EJB 2.0 and higher specifications must throw the javax.ejb.EJBException instead of this exception.

---

**ejbPassivate**

public void ejbPassivate() throws EJBException,
java.rmi.RemoteException
	"" ejbActivate()

Java

Throws  EJBException:

java.rmi.RemoteException: EJB 1.0 Bean EJB
Throws 1.1 Bean javax.ejb.EJBException EJB2.0
Bean javax.ejb.EJBException

ejbPassivate

void ejbPassivate()
throws EJBException,
RemoteException

The passivate method is called before the instance enters the "passive" state. The instance should release any resources that it can re-acquire later in the ejbActivate() method.

After the passivate method completes, the instance must be in a state that allows the container to use the Java Serialization protocol to externalize and store away the instance's state.

This method is called with no transaction context.

Throws:

EJBException - Thrown by the method to indicate a failure caused by a system-level error.
RemoteException - This exception is defined in the method signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 specification should throw the javax.ejb.EJBException instead of this exception. Enterprise beans written for the EJB2.0 and higher specifications must throw the javax.ejb.EJBException instead of this exception.

javax.ejb Interface SessionContext

All Superinterfaces:
  EJBContext

public interface SessionContext
  extends EJBContext

Implements: EJBContext

SessionContext  Bean  SessionContext

The SessionContext interface provides access to the runtime session context that the container provides for a session enterprise Bean instance. The container passes the SessionContext interface to an instance after the instance has been created. The session context remains associated with the instance for the lifetime of the instance.

Method Summary

Method Detail

public EJBLocalObject getEJBLocalObject() throws IllegalStateException

EJB

Bean ejbCreate()  ejbRemove()  ejbCreate()  ejbRemove()

return EJB

Throws  IllegalArgumentException:

getEJBLocalObject

EJBLocalObject getEJBLocalObject() throws IllegalStateException

Obtain a reference to the EJB local object that is associated with the instance.

An instance of a session enterprise Bean can call this method at anytime between the ejbCreate() and ejbRemove() methods, including from within the ejbCreate() and ejbRemove() methods.

An instance can use this method, for example, when it wants to pass a reference to itself in a method argument or result.

Returns:  The EJB local object currently associated with the instance.

Throws:
IllegalStateException - Thrown if the instance invokes this method while the instance is in a state that does not allow the instance to invoke this method, or if the instance does not have a local interface.

public EJBObject getEJBObject() throws IllegalStateException

EJB

Bean ejbCreate() ejbRemove() ejbCreate() ejbRemove()

return EJB

Throws IllegalArgumentException:

getEJBObject

EJBObject getEJBObject() throws IllegalStateException

Obtain a reference to the EJB object that is currently associated with the instance.

An instance of a session enterprise Bean can call this method at anytime between the ejbCreate() and ejbRemove() methods, including from within the ejbCreate() and ejbRemove() methods.

An instance can use this method, for example, when it wants to pass a reference to itself in a method argument or result.

Returns:
The EJB object currently associated with the instance.

Throws:
IllegalStateException - Thrown if the instance invokes this
Get a reference to the JAX-RPC MessageContext.

An instance of a stateless session bean can call this method from any business method invoked through its web service endpoint interface.

**Returns:**
- The MessageContext for this web service invocation.

**Throws:**
- `IllegalStateException` - Thrown if this method is invoked while the instance is in a state that does not allow access to this method.
getBusinessObject(Class<T> businessInterface) throws IllegalStateException

Obtain an object that can be used to invoke the current bean through the given business interface.

**Parameters:**
- businessInterface - One of the local business interfaces or remote business interfaces for this session bean.

**Returns:**
- The business object corresponding to the given business interface.

**Throws:**
- IllegalStateException - Thrown if this method is invoked with an invalid business interface for the current bean.

getInvokedBusinessInterface() throws IllegalStateException

**Throws**
- IllegalStateException: Bean

getInvokedBusinessInterface

Class getInvokedBusinessInterface() throws IllegalStateException

Obtain the business interface through which the current business method invocation was made.

**Throws:**
- IllegalStateException - Thrown if this method is called and the bean has not been invoked through a business interface.
Submit a bug or feature

PS:
javax.ejb Interface SessionSynchronization

public interface SessionSynchronization

SessionSynchronization Bean

Bean Bean

The SessionSynchronization interface allows a session Bean instance to be notified by its container of transaction boundaries.

An session Bean class is not required to implement this interface. A session Bean class should implement this interface only if it wishes to synchronize its state with the transactions.

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void afterBegin()</td>
<td>The afterBegin method notifies a session Bean instance that a new transaction has started, and that the subsequent business methods on the instance will be invoked in the context of the transaction.</td>
</tr>
<tr>
<td>void afterCompletion(boolean committed)</td>
<td>The afterCompletion method notifies a session Bean instance that a transaction commit protocol has completed, and tells the instance whether the transaction has been committed or rolled back.</td>
</tr>
<tr>
<td>void beforeCompletion()</td>
<td>The beforeCompletion method notifies a session Bean instance that a transaction is about to be committed.</td>
</tr>
</tbody>
</table>
public void afterBegin() throws EJBException, java.rmi.RemoteException
afterBegin Bean

The afterBegin method notifies a session Bean instance that a new transaction has started, and that the subsequent business methods on the instance will be invoked in the context of the transaction.

The instance can use this method, for example, to read data from a database and cache the data in the instance fields.

This method executes in the proper transaction context.

Throws:
- EJBException - Thrown by the method to indicate a failure caused by a system-level error.
- RemoteException - This exception is defined in the method signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 and higher specifications should throw the
javax.ejb.EJBException instead of this exception. Enterprise beans written for the EJB 2.0 and higher specifications must not throw the java.rmi.RemoteException.

```java
class Bean {
    public void beforeCompletion() throws EJBException, java.rmi.RemoteException {
        // Method implementation...
    }
}
```

**setRollbackOnly()**

**Throws**

- `EJBException`:
  - java.rmi.RemoteException: EJB 1.0 Bean EJB 1.1 Bean javax.ejb.EJBException EJB 2.0 Bean java.rmi.RemoteException

**beforeCompletion**

```java
class Bean {
    public void beforeCompletion() throws EJBException, RemoteException {
        // Method implementation...
    }
}
```

The `beforeCompletion` method notifies a session Bean instance that a transaction is about to be committed. The instance can use this method, for example, to write any cached data to a database.

This method executes in the proper transaction context.

**Note:** The instance may still cause the container to rollback the transaction by invoking the `setRollbackOnly()` method on the instance context, or by throwing an exception.

**Throws:**

- `EJBException` - Thrown by the method to indicate a failure caused by a system-level error.
- `RemoteException` - This exception is defined in the method
signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 and higher specification should throw the javax.ejb.EJBException instead of this exception. Enterprise beans written for the EJB 2.0 and higher specifications must not throw the java.rmi.RemoteException.

```java
public void afterCompletion(boolean committed) throws EJBException, java.rmi.RemoteException

afterCompletion   Bean
```

<table>
<thead>
<tr>
<th>committed</th>
<th>true false</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>EJBException: java.rmi.RemoteException: EJB 1.0 Bean</td>
</tr>
<tr>
<td>Throws</td>
<td>EJB 1.1 Bean javax.ejb.EJBException EJB 2.0 Bean java.rmi.RemoteException</td>
</tr>
</tbody>
</table>

**afterCompletion**

```java
void afterCompletion(boolean committed) throws EJBException, RemoteException
```

The afterCompletion method notifies a session Bean instance that a transaction commit protocol has completed, and tells the instance whether the transaction has been committed or rolled back.

This method executes with no transaction context.

This method executes with no transaction context.

**Parameters:**

- committed: True if the transaction has been committed, false if
is has been rolled back.

**Throws:**

- **EJBException** - Thrown by the method to indicate a failure caused by a system-level error.
- **RemoteException** - This exception is defined in the method signature to provide backward compatibility for enterprise beans written for the EJB 1.0 specification. Enterprise beans written for the EJB 1.1 and higher specification should throw the javax.ejb.EJBException instead of this exception. Enterprise beans written for the EJB 2.0 and higher specifications must not throw the java.rmi.RemoteException.
javax.mail.util  Class SharedByteArrayInputStream

Implements: SharedInputStream

SharedInputStream  ByteArrayInputStream  reader  byte

version  1.5, 07/05/04
since  JavaMail 1.4

A ByteArrayInputStream that implements the SharedInputStream interface, allowing the underlying byte array to be shared between multiple readers.

Since:  
JavaMail 1.4
Version:  
1.5, 07/05/04
Author:  
Bill Shannon
### Field Summary

<table>
<thead>
<tr>
<th>protected int</th>
<th>start</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Position within shared buffer that this stream starts at.</td>
</tr>
</tbody>
</table>

### Fields inherited from class java.io.ByteArrayInputStream

- buf
- count
- mark
- pos

### Constructor Summary

- **SharedByteArrayInputStream**(byte[] buf)
  - Create a SharedByteArrayInputStream representing the entire byte array.

- **SharedByteArrayInputStream**(byte[] buf, int offset, int length)
  - Create a SharedByteArrayInputStream representing the part of the byte array from offset for length bytes.

### Method Summary

<table>
<thead>
<tr>
<th>long</th>
<th>getPosition()</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return the current position in the InputStream, as an offset from the beginning of the InputStream.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>InputStream</th>
<th>newStream(long start, long end)</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Return a new InputStream representing a subset of the data from this InputStream, starting at start (inclusive) up to end (exclusive).</td>
</tr>
</tbody>
</table>

### Methods inherited from class java.io.ByteArrayInputStream

- available, close, mark, markSupported, read, read, reset, skip

### Methods inherited from class java.io.InputStream

- read

### Methods inherited from class java.lang.Object

- clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait
protected int start

Position within shared buffer that this stream starts at.

public SharedByteArrayInputStream(byte[] buf)
byte SharedByteArrayInputStream

Create a SharedByteArrayInputStream representing the entire byte array.

Parameters:
buf - the byte array

public SharedByteArrayInputStream(byte[] buf, int offset, int length)
byte offset length
SharedByteArrayInputStream

**SharedByteArrayInputStream**

public SharedByteArrayInputStream(byte[] buf,
       int offset,
       int length)

Create a SharedByteArrayInputStream representing the part of the byte array from offset for length bytes.

**Parameters:**
- buf - the byte array
- offset - offset in byte array to first byte to include
- length - number of bytes to include

### Method Detail

**public long getPosition()**

InputStream InputStream

return

**getPosition**

public long getPosition()

Return the current position in the InputStream, as an offset from the beginning of the InputStream.

**Specified by:**

getPosition in interface SharedInputStream

**Returns:**

the current position
newStream

public InputStream newStream(long start, long end)

Return a new InputStream representing a subset of the data from this InputStream, starting at start (inclusive) up to end (exclusive). start must be non-negative. If end is -1, the new stream ends at the same place as this stream. The returned InputStream will also implement the SharedInputStream interface.

Specified by:
    newStream in interface SharedInputStream

Parameters:
    start - the starting position
    end - the ending position + 1

Returns:
    the new stream

public class SharedFileInputStream
      extends BufferedInputStream
      implements SharedInputStream

Implements: SharedInputStream

SharedFileInputStream  BufferedInputStream  mark  reset
newStream  RandomAccessFile

SharedFileInputStream  newStream
SharedFileInputStream  SharedInputStream
      since  JavaMail 1.4

A SharedFileInputStream is a BufferedInputStream that buffers data from the file and supports the mark and reset methods. It also supports the newStream method that allows you to create other streams that represent subsets of the file. A RandomAccessFile object is used to access the file data.

Note that when the SharedFileInputStream is closed, all streams created with the newStream method are also closed. This allows the creator of the SharedFileInputStream object to control access to the underlying file and
ensure that it is closed when needed, to avoid leaking file descriptors. Note also that this behavior contradicts the requirements of SharedInputStream and may change in a future release.

Since:
JavaMail 1.4

**Methods inherited from class `java.lang.Object`**

- `clone`, `equals`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`

---

**Field Detail**

- `in`

  protected `RandomAccessFile` in

  The file containing the data. Shared by all related `SharedFileInputStreams`.

---

- `bufsize`

  protected `int` `bufsize`

  The normal size of the read buffer.

---

- `bufpos`

  protected `long` `bufpos`
The file offset that corresponds to the first byte in the read buffer.

start

protected long start

The file offset of the start of data in this subset of the file.

datalen

protected long datalen

The amount of data in this subset of the file.

Constructor Detail

public SharedFileInputStream(java.io.File file) throws java.io.IOException
  
  Creates a SharedFileInputStream for the file.

  Parameters:
    file - the file

  Throws:
public SharedFileInputStream(String file) throws IOException

    SharedFileInputStream
    file

SharedFileInputStream

public SharedFileInputStream(String file) throws IOException

    Creates a SharedFileInputStream for the named file

    Parameters:
    file - the file

    Throws:
    IOException

public SharedFileInputStream(java.io.File file, int size) throws java.io.IOException

    SharedFileInputStream
    file
    size

    Throws
    IllegalArgumentException: size <= 0

SharedFileInputStream

public SharedFileInputStream(File file, int size) throws IOException

    Creates a SharedFileInputStream with the specified buffer size.
public SharedFileInputStream(String file, int size) throws IOException

Creates a SharedFileInputStream with the specified buffer size.

Parameters:
   file - the file
   size - the buffer size.

Throws:
   IllegalArgumentException - if size <= 0.
   IOException

Method Detail

public int read() throws java.io.IOException

InputStream read

return -1

Throws java.io.IOException: I/O
read

public int read() throws IOException

See the general contract of the read method of InputStream.

Overrides:
    read in class BufferedInputStream
Returns:
    the next byte of data, or -1 if the end of the stream is reached.
Throws:
    IOException - if an I/O error occurs.

read

public int read(byte[] b, int off, int len) throws java.io.IOException

Reads bytes from this stream into the specified byte array, starting at the given offset.

public int read(byte[] b, int off, int len) throws java.io.IOException

java.io.InputStream read
    b
    off
    len
return

Throws
    java.io.IOException: I/O
This method implements the general contract of the corresponding read method of the InputStream class.

**Overrides:**
read in class BufferedInputStream

**Parameters:**
b - destination buffer.
off - offset at which to start storing bytes.
len - maximum number of bytes to read.

**Returns:**
the number of bytes read, or -1 if the end of the stream has been reached.

**Throws:**
IOException - if an I/O error occurs.

```java
public long skip(long n) throws IOException
```

See the general contract of the skip method of InputStream.

**Overrides:**
skip in class BufferedInputStream

**Parameters:**
n - the number of bytes to be skipped.

**Returns:**
the actual number of bytes skipped.

**Throws:**
IOException - if an I/O error occurs.
public int available() throws java.io.IOException

        return
    Throws          java.io.IOException: I/O

available

public int available() throws IOException

    Returns the number of bytes that can be read from this input stream without blocking.

    Overrides: available in class BufferedInputStream
    Returns: the number of bytes that can be read from this input stream without blocking.
    Throws: IOException - if an I/O error occurs.

public void mark(int readlimit)

    InputStream mark
    readlimit
    See also     reset()

mark

public void mark(int readlimit)

    See the general contract of the mark method of InputStream.

    Overrides: mark in class BufferedInputStream
Parameters:
readlimit - the maximum limit of bytes that can be read before the mark position becomes invalid.

See Also:
reset()

public void reset() throws java.io.IOException
InputStream reset

markpos -1 IOException pos markpos

Throws java.io.IOException: See also mark(int)

reset

public void reset() throws IOException

See the general contract of the reset method of InputStream.

If markpos is -1 (no mark has been set or the mark has been invalidated), an IOException is thrown. Otherwise, pos is set equal to markpos.

Overrides:
reset in class BufferedInputStream

Throws:
IOException - if this stream has not been marked or if the mark has been invalidated.

See Also:
mark(int)

public boolean markSupported()
mark Supported

public boolean markSupported()

Tests if this input stream supports the mark and reset methods. The markSupported method of SharedFileInputStream returns true.

Overrides:

markSupported in class BufferedInputStream

Returns:

a boolean indicating if this stream type supports the mark and reset methods.

See Also:

InputStream.mark(int), InputStream.reset()

public void close() throws java.io.IOException

Throws

java.io.IOException: I/O

close

public void close()

throws IOException

Closes this input stream and releases any system resources associated with the stream.

Specified by:

close in interface Closeable

Overrides:
close in class BufferedInputStream

Throws:
IOException - if an I/O error occurs.

public long getPosition()
InputStream InputStream
return

g getPosition

public long getPosition()

Return the current position in the InputStream, as an offset from the beginning of the InputStream.

Specified by:
getPosition in interface SharedInputStream

Returns:
the current position

public java.io.InputStream newStream(long start, long end)
InputStream InputStream
start
InputStream SharedInputStream
start
end
-1 InputStream
SharedInputStream
start
end
+ 1
return

newStream

public InputStream newStream(long start, long end)
Return a new InputStream representing a subset of the data from this InputStream, starting at `start` (inclusive) up to `end` (exclusive). `start` must be non-negative. If `end` is -1, the new stream ends at the same place as this stream. The returned InputStream will also implement the `SharedInputStream` interface.

**Specified by:**

`newStream` in interface `SharedInputStream`

**Parameters:**

- `start` - the starting position
- `end` - the ending position + 1

**Returns:**

the new stream

```java
protected void finalize() throws Throwable
```

**finalize**

protected void `finalize()` throws `Throwable`

Force this stream to close.

**Overrides:**

`finalize` in class `Object`

**Throws:**

`Throwable`

</tbody>
</table>
An InputStream that is backed by data that can be shared by multiple readers may implement this interface. This allows users of such an InputStream to determine the current position in the InputStream, and to create new InputStreams representing a subset of the data in the original InputStream. The new InputStream will access the same underlying data as the original, without copying the data.

Note that implementations of this interface must ensure that the close method does not close any underlying stream that might be shared by multiple instances of SharedInputStream until all shared instances have been closed.

Method Detail

```java
public long getPosition()

InputStream inputStream

return

g getPosition()

long getPosition()

Return the current position in the InputStream, as an offset from the beginning of the InputStream.

Returns: the current position
```

```java
public java.io.InputStream newStream(long start, long end)

InputStream inputStream

start

SharedInputStream

start

end

+1
```
newStream

`InputStream newStream(long start, long end)`

Return a new InputStream representing a subset of the data from this InputStream, starting at `start` (inclusive) up to `end` (exclusive). `start` must be non-negative. If `end` is -1, the new stream ends at the same place as this stream. The returned InputStream will also implement the SharedInputStream interface.

**Parameters:**
- `start` - the starting position
- `end` - the ending position + 1

**Returns:**
- the new stream
javax.resource.spi  Class SharingViolationException

java.lang.Object
  ▼ java.lang.Throwable
    ▼ java.lang.Exception
      ▼ javax.resource.ResourceException
        ▼ javax.resource.spi.SharingViolationException

All Implemented Interfaces:
  Serializable

public class SharingViolationException
  extends ResourceException

Extends: Throwable > Exception > ResourceException

version 1.0

This is thrown to indicate a connection sharing violation.

This may be thrown by a resource adapter when an application uses a shareable connection in an unshareable manner.

public ShortConverter()

Method Detail

public Object getAsObject(FacesContext context, UIComponent component, String value)

Throws ConverterException: NullPointerException
Throws NullPointerException: NullPointerException in context component

getAsObject

public Object getAsObject(FacesContext context, UIComponent component, String value)

Description copied from interface: Converter

Convert the specified string value, which is associated with the specified UIComponent, into a model data object that is appropriate for being stored during the Apply Request Values phase of the request processing lifecycle.

Specified by:
getAsObject in interface Converter

Parameters:
context - FacesContext for the request being processed
cOMPONENT component - UIComponent with which this model object value is associated
dvalue - String value to be converted (may be null)

Returns:
null if the value to convert is null, otherwise the result of the
public String getAsString(FacesContext context, UIComponent component, Object value)

Throws ConverterException: Nullable

Throws NullPointerException: Nullable

getAsString

public String getAsString(FacesContext context, UIComponent component, Object value)

Description copied from interface: Converter

Convert the specified model object value, which is associated with the specified UIComponent, into a String that is suitable for being included in the response generated during the Render Response phase of the request processing lifecycle.

Specified by: getAsString in interface Converter

Parameters:
context - FacesContext for the request being processed
component - UIComponent with which this model object value is associated
value - Model object value to be converted (may be null)

Returns:
a zero-length String if value is null, otherwise the result of the conversion

Throws:
ConverterException - if conversion cannot be successfully performed
NullPointerException - if context or component is null
performed

NullPointerException - if context or component is null

All Known Implementing Classes:
   SimpleTagSupport

public interface SimpleTag
   extends JspTag

   Implements: JspTag
   Implemented by: SimpleTagSupport

   doStartTag()  doEndTag()  SimpleTag  doTag()  BodyTag
   setJspBody()  JspFragment  setJspBody()  invoke()

SimpleTag  SimpleTag  SimpleTagSupport

SimpleTag  JSP

1. JSP
2. setJspContext()  setParent()  setParent()
3. setter
4. setJspBody()  JspFragment
5. doTag()
6. doTag()

   since 2.0

See also javax.servlet.jsp.tagext.SimpleTagSupport
Interface for defining Simple Tag Handlers.

Simple Tag Handlers differ from Classic Tag Handlers in that instead of supporting `doStartTag()` and `doEndTag()`, the `SimpleTag` interface provides a simple `doTag()` method, which is called once and only once for any given tag invocation. All tag logic, iteration, body evaluations, etc. are to be performed in this single method. Thus, simple tag handlers have the equivalent power of `BodyTag`, but with a much simpler lifecycle and interface.

To support body content, the `setJspBody()` method is provided. The container invokes the `setJspBody()` method with a `JspFragment` object encapsulating the body of the tag. The tag handler implementation can call `invoke()` on that fragment to evaluate the body as many times as it needs.

A SimpleTag handler must have a public no-args constructor. Most SimpleTag handlers should extend `SimpleTagSupport`.

**Lifecycle**

The following is a non-normative, brief overview of the SimpleTag lifecycle. Refer to the JSP Specification for details.

1. A new tag handler instance is created each time by the container by calling the provided zero-args constructor. Unlike classic tag handlers, simple tag handlers are never cached and reused by the JSP container.
2. The `setJspContext()` and `setParent()` methods are called by the container. The `setParent()` method is only called if the element is nested within another tag invocation.
3. The setters for each attribute defined for this tag are called by the container.
4. If a body exists, the `setJspBody()` method is called by the container to set the body of this tag, as a `JspFragment`. If the action element is empty in the page, this method is not called at all.
5. The `doTag()` method is called by the container. All tag logic, iteration, body evaluations, etc. occur in this method.
6. The `doTag()` method returns and all variables are synchronized.

Since:
JSP 2.0

</tbody>
</table>

### Method Detail

```java
public void doTag() throws JspException, java.io.IOException
```

`doTag()` JSP AT_BEGIN AT_END
TagExtraInfo TLD

**Throws**

- `JspException`:
- `SkipPageException`: SKIP_PAGE
- `SkipPageException` JSP `SkipPageException` `java.io.IOException`:
doTag

void doTag()
    throws JspException, IOException

Called by the container to invoke this tag. The implementation of this method is provided by the tag library developer, and handles all tag processing, body iteration, etc.

The JSP container will resynchronize any AT_BEGIN and AT_END variables (defined by the associated tag file, TagExtraInfo, or TLD) after the invocation of doTag().

Throws:
    JspException - If an error occurred while processing this tag.
    SkipPageException - If the page that (either directly or indirectly) invoked this tag is to cease evaluation. A Simple Tag Handler generated from a tag file must throw this exception if an invoked Classic Tag Handler returned SKIP_PAGE or if an invoked Simple Tag Handler threw SkipPageException or if an invoked Jsp Fragment threw a SkipPageException.
    IOException - If there was an error writing to the output stream.

public void setParent(JspTag parent)

setParent

void setParent(JspTag parent)
Sets the parent of this tag, for collaboration purposes.

The container invokes this method only if this tag invocation is nested within another tag invocation.

**Parameters:**

parent - the tag that encloses this tag

---

**public JspTag getParent()**

```
return
```

**getParent**

**JspTag getParent()**

Returns the parent of this tag, for collaboration purposes.

**Returns:**

the parent of this tag

---

**public void setJspContext(JspContext pc)**

```
JspContext
pc
```

See also **setPageContext**

**setJspContext**

```
void setJspContext(JspContext pc)
```

Called by the container to provide this tag handler with the `JspContext` for this invocation. An implementation should save this value.
Parameters:
   pc - the page context for this invocation

See Also:
   Tag.setPageContext(javax.servlet.jsp.PageContext)

public void setJspBody(JspFragment jspBody)

JspFragment

JSP
   doTag()

   jspBody

setJspBody

void setJspBody(JspFragment jspBody)

Provides the body of this tag as a JspFragment object, able to be invoked zero or more times by the tag handler.

This method is invoked by the JSP page implementation object prior to doTag(). If the action element is empty in the page, this method is not called at all.

Parameters:
   jspBody - The fragment encapsulating the body of this tag.
PS:
Class SimpleTagSupport

public class SimpleTagSupport

extends Object
implements SimpleTag

Implements: SimpleTag

SimpleTag

SimpleTagSupport SimpleTagSupport  SimpleTag
SimpleTag  getter

since 2.0

A base class for defining tag handlers implementing SimpleTag.

The SimpleTagSupport class is a utility class intended to be used as the base class for new simple tag handlers. The SimpleTagSupport class implements the SimpleTag interface and adds additional convenience methods including getter methods for the properties in SimpleTag.

Since:

JSP 2.0

- notifyAll
- toString
- wait
- wait
- wait

### Constructor Detail

**public SimpleTagSupport()**
SimpleTagSupport

```java
public SimpleTagSupport()
```

Sole constructor. (For invocation by subclass constructors, typically implicit.)

### Method Detail

```java
public void doTag() throws JspException, java.io.IOException
```

Throws:
- `JspException`: JspException
- `SkipPageException`: SKIP_PAGE

`SkipPageException`:
- JSP SkipPageException
- JspException JSP SkipPageException
- java.io.IOException: IOException

See also `doTag()`

### doTag

```java
public void doTag()
```

Throws:
- `JspException`: JspException
- `IOException`: IOException

Default processing of the tag does nothing.

Specified by:
- `doTag` in interface `SimpleTag`

Throws:
- `JspException` - Subclasses can throw JspException to indicate an error occurred while processing this tag.
- `SkipPageException` - If the page that (either directly or indirectly) invoked this tag is to cease evaluation. A Simple Tag Handler generated from a tag file must throw this exception if an invoked Classic Tag Handler returned SKIP_PAGE or if an invoked Simple Tag Handler threw SkipPageException or if an invoked
Jsp Fragment threw a SkipPageException.  
 IOException - Subclasses can throw IOException if there was an error writing to the output stream.

See Also:  
 SimpleTag.doTag()

---

public void setParent(JspTag parent)

parent

setParent

public void setParent(JspTag parent)

Sets the parent of this tag, for collaboration purposes.

The container invokes this method only if this tag invocation is nested within another tag invocation.

Specified by:  
 setParent in interface SimpleTag

Parameters:  
parent - the tag that encloses this tag

---

public JspTag getParent()

return

g getParent

public JspTag getParent()
Returns the parent of this tag, for collaboration purposes.

Specified by:

getParent in interface SimpleTag

Returns:

the parent of this tag

---

**public void setJspContext(JspContext pc)**

**jspContext** JSP

**pc**

Get JspContext

See also

setJspContext

---

**setJspContext**

**public void setJspContext(JspContext pc)**

Stores the provided JSP context in the private jspContext field. Subclasses can access the JspContext via getJspContext().

Specified by:

setJspContext in interface SimpleTag

Parameters:

**pc** - the page context for this invocation

See Also:

---

**protected JspContext getJspContext()**

Get JspContext

---

**getJspContext**

**protected JspContext getJspContext()**
Returns the page context passed in by the container via `setJspContext`.

**Returns:**
the page context for this invocation

---

```java
public void setJspBody(JspFragment jspBody)
JspFragment
jspBody
See also
setJspBody
```

**setJspBody**

```java
public void setJspBody(JspFragment jspBody)
```

Stores the provided JspFragment.

**Specified by:**
`setJspBody` in interface `SimpleTag`

**Parameters:**
jspBody - The fragment encapsulating the body of this tag. If the action element is empty in the page, this method is not called at all.

**See Also:**
`SimpleTag.setJspBody(javax.servlet.jsp.tagext.JspFragment)`

---

```java
protected JspFragment getJspBody()
```

```java
setJspBody
return null
```

**getJspBody**

```java
protected JspFragment getJspBody()
```
Returns the body passed in by the container via setJspBody.

**Returns:**
- the fragment encapsulating the body of this tag, or null if the action element is empty in the page.

```java
final public static JspTag findAncestorWithClass(JspTag from, Class<T> klass)
Tag / SimpleTag getParent
TagAdapter TagAdapter.getAdaptee()
TagAdpater klass TagAdapter
observable observable void
JSP

findAncestorWithClass
observable
from klass JspTag
return
```

Find the instance of a given class type that is closest to a given instance. This method uses the getParent method from the Tag and/or SimpleTag interfaces. This method is used for coordination among cooperating tags.

For every instance of TagAdapter encountered while traversing the ancestors, the tag handler returned by TagAdapter.getAdaptee() -
instead of the TagAdapter itself - is compared to \texttt{klass}. If the tag handler matches, it - and not its TagAdapter - is returned.

The current version of the specification only provides one formal way of indicating the observable type of a tag handler: its tag handler implementation class, described in the tag-class subelement of the tag element. This is extended in an informal manner by allowing the tag library author to indicate in the description subelement an observable type. The type should be a subtype of the tag handler implementation class or void. This additional constraint can be exploited by a specialized container that knows about that specific tag library, as in the case of the JSP standard tag library.

When a tag library author provides information on the observable type of a tag handler, client programmatic code should adhere to that constraint. Specifically, the Class passed to \texttt{findAncestorWithClass} should be a subtype of the observable type.

\textbf{Parameters:}
\begin{itemize}
  \item \texttt{from} - The instance from where to start looking.
  \item \texttt{klass} - The subclass of JspTag or interface to be matched
\end{itemize}

\textbf{Returns:}
the nearest ancestor that implements the interface or is an instance of the class specified

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to \texttt{license terms}.
Interface `SingleThreadModel`

**Deprecated.** As of Java Servlet API 2.4, with no direct replacement.

```java
public interface SingleThreadModel
```

Ensures that servlets handle only one request at a time. This interface has no methods.

If a servlet implements this interface, you are *guaranteed* that no two threads will execute concurrently in the servlet's `service` method. The servlet container can make this guarantee by synchronizing access to a single instance of the servlet, or by maintaining a pool of servlet instances and dispatching each new request to a free servlet.

Note that `SingleThreadModel` does not solve all thread safety issues. For example, session attributes and static variables can still be accessed by multiple requests on multiple threads at the same time, even when `SingleThreadModel` servlets are used. It is recommended that a developer take other means to resolve those issues instead of implementing this interface, such as avoiding the usage of an instance variable or synchronizing the block of the code accessing those resources. This interface is deprecated in Servlet API version 2.4.

**Constructor Detail**

`public SizeTerm(int comparison, int size)`

comparison

size

Comparison

**SizeTerm**

`public SizeTerm(int comparison, int size)`

Constructor.
Parameters:
- comparison - the Comparison type
- size - the size

Method Detail

public boolean match(Message msg)

    msg Message
    return true false

match

public boolean match(Message msg)

    The match method.

    Specified by:
    match in class SearchResult

    Parameters:
    msg - the size comparator is applied to this Message's size

    Returns:
    true if the size is equal, otherwise false

public boolean equals(Object obj)

equals

public boolean equals(Object obj)

    Equality comparison.

    Overrides:
equals in class IntegerComparisonTerm

**Extends:** Throwable > Exception > [JspException](https://docs.oracle.com/en/java/javase/11/docs/api/jdk/api/jdk/jsp/jsp/JspException.html)

**doEndTag()** Tag.SKIP_PAGE Jsp
JSP - SimpleTag JSP

**since** 2.0

Exception to indicate the calling page must cease evaluation. Thrown by a simple tag handler to indicate that the remainder of the page must not be evaluated. The result is propagated back to the page in the case where one tag invokes another (as can be the case with tag files). The effect is similar to that of a Classic Tag Handler returning Tag.SKIP_PAGE from doEndTag(). Jsp Fragments may also throw this exception. This exception should not be thrown manually in a JSP page or tag file - the behavior is undefined. The exception is intended to be thrown inside SimpleTag handlers and in JSP fragments.

**Since:**
JSP 2.0

**See Also:**
Constructor Summary

SkipPageException()
   Creates a SkipPageException with no message.

SkipPageException(String message)
   Creates a SkipPageException with the provided message.

SkipPageException(String message, Throwable rootCause)

SkipPageException
**SkipPageException**

```java
public SkipPageException()

    Creates a SkipPageException with no message.
```

```java
public SkipPageException(String message)

    Creates a SkipPageException with the provided message.

    Parameters:
    message - the detail message
```

```java
public SkipPageException(String message, Throwable rootCause)

    Creates a SkipPageException with the provided message and root
    cause.

    Parameters:
```
public SkipPageException(Throwable rootCause)

SkipPageException

rootCause

SkipPageException

public SkipPageException(Throwable rootCause)

Creates a SkipPageException with the provided root cause.

Parameters:

rootCause - the originating cause of this exception
public interface Slot

Slot RegistryObject RegistryObject (Registry Information Model)

RegistryObject 0 Slot Slot slotType Collection
Slot RegistryObject Slot Slot Slot
Collection Slot CollectionslotType Slot

See also javax.xml.registry.infomodel.ExtensibleObject

Slot instances provide a dynamic way to add arbitrary attributes to RegistryObject instances. This ability to add attributes dynamically to RegistryObject instances enables extensibility within the Registry Information Model.

A RegistryObject may have 0 or more Slots. A slot is composed of a name, a slotType and a collection of values. The name of a slot is locally unique within the RegistryObject instance. Similarly, the value of a Slot is locally unique within a slot instance. Since a Slot represents an extensible attribute whose value may be a collection, a Slot is allowed to have a collection of values rather than a single value. The slotType attribute may optionally specify a type or category for the slot.

OPERATOR_SLOT

static final String OPERATOR SLOT

Name for pre-defined Slot used in Organization and
public String getName() throws JAXRException
Slot NULL

0

return

Throws JAXRException: JAXR

getName

String getName() throws JAXRException

Gets the name for this Slot. Default is a NULL String.

Capability Level: 0

Returns: the name

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setName(String name) throws JAXRException
Slot NULL

0
**setName**

```java
void setName(String name)
    throws JAXRException
```

Sets the name for this Slot. Default is a NULL String.

**Capability Level: 0**

**Parameters:**
- name - the name

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

**public String getSlotType() throws JAXRException**

Slot slotType NULL

```
return String Slot
```

**getSlotType**

```java
String getSlotType()
    throws JAXRException
```

Gets the slotType for this Slot. Default is a NULL String.

**Capability Level: 0**

**Returns:**
the slot type which is an arbitrary String

**Throws:**
*JAXRException* - If the JAXR provider encounters an internal error

```java
public void setSlotType(String slotType) throws JAXRException

Slot slotType
```

Sets the slotType for this Slot.

**Capability Level:** 0

**Parameters:**
- `slotType` - the slot type which is an arbitrary String

**Throws:**
*JAXRException* - If the JAXR provider encounters an internal error

```java
public java.util.Collection<E> getValues() throws JAXRException

Slot
```

```java
void setSlotType(String slotType)
throws JAXRException
```

```java
setSlotType
```

- `String slotType` - the slot type which is an arbitrary String

- *JAXRException* - If the JAXR provider encounters an internal error
getValues

Collection getValues() throws JAXRException

Gets the values for this Slot.

Capability Level: 0

Returns:
Collection of String instances representing the values for this Slot. The Collection may be empty but not null.

Throws:
JAXRException - If the JAXR provider encounters an internal error

See Also:
String

public void setValues(java.util.Collection<E> values)
throws JAXRException

setValues

void setValues(Collection values)
throws JAXRException
Sets the values for this Slot.

**Capability Level: 0**

**Parameters:**
values - the values for this Slot

**Throws:**
JAXRException - If the JAXR provider encounters an internal error

public java.util.Set<E> getRoles()

return Set

getRoles

Set<String> getRoles()

Gets the roles played by the SOAP binding instance.

Returns:
Set The set of roles played by the binding instance.

setRoles

void setRoles(Set<String> roles)

Sets the roles played by the SOAP binding instance.

Parameters:
roles - The set of roles played by the binding instance.

Throws:
WebServiceException - On an error in the configuration of the list of roles.

public boolean isMTOMEnabled()

return MTOM true

isMTOMEnabled

boolean isMTOMEnabled()
Returns true if the use of MTOM is enabled.

Returns: 
true if and only if the use of MTOM is enabled.

public void setMTOMEnabled(boolean flag)

<table>
<thead>
<tr>
<th>MTOM</th>
<th>flag</th>
<th>MTOM</th>
<th>MTOM</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>boolean</td>
</tr>
</tbody>
</table>

Throws WebServiceException:

setMTOMEnabled

void setMTOMEnabled(boolean flag)

Enables or disables use of MTOM.

Parameters:
flag - A boolean specifying whether the use of MTOM should be enabled or disabled.

Throws:
WebServiceException - If the specified setting is not supported by this binding instance.

public SOAPFactory getSOAPFactory()

<table>
<thead>
<tr>
<th>SOAP</th>
<th>SAAJ</th>
<th>SOAPFactory</th>

getSOAPFactory

SOAPFactory getSOAPFactory()

Gets the SAAJ SOAPFactory instance used by this SOAP binding.

Returns:
SOAPFactory instance used by this SOAP binding.

```java
public MessageFactory getMessageFactory()

SOAP SAAJ MessageFactory
return SOAP MessageFactory
```

getMessageFactory

```java
MessageFactory getMessageFactory()

Gets the SAAJ MessageFactory instance used by this SOAP binding.

Returns:

MessageFactory instance used by this SOAP binding.
```

## Enum Constant Detail

**BARE**

public static final \texttt{SOAPBinding.ParameterStyle} \texttt{BARE}

**WRAPPED**

public static final \texttt{SOAPBinding.ParameterStyle} \texttt{WRAPPED}

## Method Detail

final public static \texttt{SOAPBinding.ParameterStyle[]} \texttt{values()}

values

public static final \texttt{SOAPBinding.ParameterStyle[]} \texttt{values()}
Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(SOAPBinding.ParameterStyle c : SOAPBinding.ParameterStyle.values())
    System.out.println(c);
```

**Returns:**
an array containing the constants of this enum type, in the order they're declared

---

**public static SOAPBinding.ParameterStyle valueOf(String name)**

**valueOf**

**valueOf**

**public static SOAPBinding.ParameterStyle valueOf(String name)**

Returns the enum constant of this type with the specified name. The string must match *exactly* an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**
name - the name of the enum constant to be returned.

**Returns:**
the enum constant with the specified name

**Throws:**
IllegalArgumentException - if this enum type has no constant with the specified name

Implements: SOAPElement

SOAP  SOAP  SOAP  XML

SOAPBody  SOAPBodyElement  SOAP /  SOAPFault
SOAPBodyElement

See also  javax.xml.soap.SOAPFault

An object that represents the contents of the SOAP body element in a SOAP message. A SOAP body element consists of XML data that affects the way the application-specific content is processed.

A SOAPBody object contains SOAPBodyElement objects, which have the content for the SOAP body. A SOAPFault object, which carries status and/or error information, is an example of a SOAPBodyElement object.

Method Detail

public SOAPFault addFault() throws SOAPException

SOAPFault SOAPBody SOAPFault (mandatory)
SOAPFault SOAP 1.1 SOAP 1.2 SOAPFault

MessageFactory protocol

SOAPBody SOAPFault
return SOAPFault

Throws SOAPException: SOAP

addFault

SOAPFault addFault() throws SOAPException
Creates a new SOAPFault object and adds it to this SOAPBody object. The new SOAPFault will have default values set for the mandatory child elements. The type of the SOAPFault will be a SOAP 1.1 or a SOAP 1.2 SOAPFault depending on the protocol specified while creating the MessageFactory instance.

A SOAPBody may contain at most one SOAPFault child element.

**Returns:**
the new SOAPFault object

**Throws:**
SOAPException - if there is a SOAP error

```java
public SOAPFault addFault(Name faultCode, String faultString, java.util.Locale locale) throws SOAPException

SOAPFault     SOAPBody     SOAPFault   SOAP 1.1
SOAP 1.2    SOAPFault    MessageFactory    protocol

SOAP 1.2    faultCode    Fault/Code/Value
faultString    Fault/Reason/Text    SOAP
1.1    faultCode    faultcode    faultString    faultstring
```

**SOAPBody**     **SOAPFault**

| faultCode | Name | SOAP |
| faultString | String |     |
| locale | java.util.Locale | faultString |
| return | SOAPFault |        |
| Throws | SOAPException: SOAP |
| since | SAAJ 1.2 |
| See also | setFaultCode, setFaultString |

**addFault**
SOAPFault addFault(Name faultCode, String faultString, Locale locale) throws SOAPException

Creates a new SOAPFault object and adds it to this SOAPBody object. The type of the SOAPFault will be a SOAP 1.1 or a SOAP 1.2 SOAPFault depending on the protocol specified while creating the MessageFactory instance.

For SOAP 1.2 the faultCode parameter is the value of the Fault/Code/Value element and the faultString parameter is the value of the Fault/Reason/Text element. For SOAP 1.1 the faultCode parameter is the value of the faultcode element and the faultString parameter is the value of the faultstring element.

A SOAPBody may contain at most one SOAPFault child element.

Parameters:
- faultCode - a Name object giving the fault code to be set; must be one of the fault codes defined in the Version of SOAP specification in use
- faultString - a String giving an explanation of the fault
- locale - a Locale object indicating the native language of the faultString

Returns:
- the new SOAPFault object

Throws:
- SOAPException - if there is a SOAP error

Since:
- SAAJ 1.2

See Also:
- SOAPFault.setFaultCode(javax.xml.soap.Name)
- SOAPFault.setFaultString(java.lang.String)

public SOAPFault addFault(javax.xml.namespace.QName faultCode, String faultString, java.util.Locale locale) throws SOAPException

See also setFaultCode, setFaultString, addFault(Name faultCode, String faultString, Locale locale)

addFault

SOAPFault addFault(QName faultCode,
String faultString,
Locale locale)
throws SOAPException

Creates a new SOAPFault object and adds it to this SOAPBody object. The type of the SOAPFault will be a SOAP 1.1 or a SOAP 1.2 SOAPFault depending on the protocol specified while creating the MessageFactory instance.

For SOAP 1.2 the faultCode parameter is the value of the Fault/Code/Value element and the faultString parameter is the value of the Fault/Reason/Text element. For SOAP 1.1 the faultCode parameter is the value of the faultcode element and the faultString parameter is the value of the faultstring element.

A SOAPBody may contain at most one SOAPFault child element.
Parameters:
faultCode - a QName object giving the fault code to be set; must be one of the fault codes defined in the version of SOAP specification in use.
faultString - a String giving an explanation of the fault
locale - a Locale object indicating the native language of the faultString

Returns:
the new SOAPFault object

Throws:
SOAPException - if there is a SOAP error

Since:
SAAJ 1.3

See Also:

java.util.Locale.getDefault()

SOAPBody SOAPFault
faultCode Name SOAP
faultString String
return SOAPFault
Throws SOAPException: SOAP
addFault

SOAPFault addFault(Name faultCode, String faultString)
throws SOAPException

Creates a new SOAPFault object and adds it to this SOAPBody object. The type of the SOAPFault will be a SOAP 1.1 or a SOAP 1.2 SOAPFault depending on the protocol specified while creating the MessageFactory instance.

For SOAP 1.2 the faultCode parameter is the value of the Fault/Code/Value element and the faultString parameter is the value of the Fault/Reason/Text element. For SOAP 1.1 the faultCode parameter is the value of the faultcode element and the faultString parameter is the value of the faultstring element.

In case of a SOAP 1.2 fault, the default value for the mandatory xml:lang attribute on the Fault/Reason/Text element will be set to java.util.Locale.getDefault()

A SOAPBody may contain at most one SOAPFault child element.

Parameters:
  - faultCode - a Name object giving the fault code to be set; must be one of the fault codes defined in the version of SOAP specification in use
  - faultString - a String giving an explanation of the fault

Returns:
  the new SOAPFault object

Throws:
  SOAPException - if there is a SOAP error

Since:
  SAAJ 1.2

faultCode  QName SOAP
faultString  String
return  SOAPFault
Throws SOAPException: SOAP
since  SAAJ 1.3
See also  setFaultCode, setFaultString, addFault(Name faultCode, String faultString)

addFault

SOAPFault addFault(QName faultCode,
String faultString)
throws SOAPException

Creates a new SOAPFault object and adds it to this SOAPBody object. The type of the SOAPFault will be a SOAP 1.1 or a SOAP 1.2 SOAPFault depending on the protocol specified while creating the
MessageFactory instance.

For SOAP 1.2 the faultCode parameter is the value of the Fault/Code/Value element and the faultString parameter is the value of the Fault/Reason/Text element. For SOAP 1.1 the faultCode parameter is the value of the faultcode element and the faultString parameter is the value of the faultstring element.

In case of a SOAP 1.2 fault, the default value for the mandatory xml:lang attribute on the Fault/Reason/Text element will be set to java.util.Locale.getDefault()

A SOAPBody may contain at most one SOAPFault child element

Parameters:
- faultCode - a QName object giving the fault code to be set; must be one of the fault codes defined in the version of SOAP specification in use
- faultString - a String giving an explanation of the fault

Returns:
- the new SOAPFault object

Throws:
- SOAPException - if there is a SOAP error

Since:
- SAAJ 1.3

See Also:

---

public boolean hasFault()

SOAPBody SOAPFault
return SOAPBody SOAPFault true false

hasFault

boolean hasFault()
Indicates whether a SOAPFault object exists in this SOAPBody object.

Returns:
true if a SOAPFault object exists in this SOAPBody object; false otherwise.

```java
public SOAPFault getFault()
    SOAPBody SOAPFault
    return SOAPBody SOAPFault null
```

getFault

SOAPFault getFault()

Returns the SOAPFault object in this SOAPBody object.

Returns:
the SOAPFault object in this SOAPBody object if present, null otherwise.

```java
public SOAPBodyElement addBodyElement(Name name)
    throws SOAPException
```

addBodyElement

SOAPBodyElement addBodyElement(Name name)
    throws SOAPException

Creates a new SOAPBodyElement object with the specified name and
addBodyElement

Parameters:
name - a Name object with the name for the new SOAPBodyElement object

Returns:
the new SOAPBodyElement object

Throws:
SOAPException - if a SOAP error occurs

See Also:
addBodyElement(javax.xml.namespace.QName)

public SOAPBodyElement addBodyElement(javax.xml.namespace.QName qname)
throws SOAPException

QName SOAPBodyElement SOAPBody
qname QName SOAPBodyElement
return SOAPBodyElement
Throws SOAPException: SOAP
since SAAJ 1.3
See also addBodyElement(Name)

addBodyElement

SOAPBodyElement addBodyElement(QName qname)
throws SOAPException

Creates a new SOAPBodyElement object with the specified QName and adds it to this SOAPBody object.

Parameters:
qname - a QName object with the qname for the new SOAPBodyElement object

Returns:
the new SOAPBodyElement object

Throws:
SOAPException - if a SOAP error occurs

Since:
SAAJ 1.3

See Also:
addBodyElement(Name)

---

```java
default

public SOAPBodyElement addDocument(org.w3c.dom.Document document) throws SOAPException

DOM org.w3c.dom.Document SOAPBody
document addDocument Document
return
Threws SOAPException: Document
since SAAJ 1.2
```

**addDocument**

SOAPBodyElement addDocument(Document document) throws SOAPException

Adds the root node of the DOM Document to this SOAPBody object.

Calling this method invalidates the document parameter. The client application should discard all references to this Document and its contents upon calling addDocument. The behavior of an application that continues to use such references is undefined.

**Parameters:**
- document - the Document object whose root node will be added to this SOAPBody.

**Returns:**
- the SOAPBodyElement that represents the root node that was added.
Throws:

SOAPException - if the Document cannot be added

Since:

SAAJ 1.2

---

public org.w3c.dom.Document extractContentAsDocument() throws SOAPException

DOM org.w3c.dom.Document SOAPBody SOAPElement

return SOAPBody org.w3c.dom.Document

Throws SOAPException: SOAPBody SOAPElement

since SAAJ 1.3

extractContentAsDocument

Document extractContentAsDocument() throws SOAPException

Creates a new DOM Document and sets the first child of this SOAPBody as its document element. The child SOAPElement is removed as part of the process.

Returns:

the Document representation of the SOAPBody content.

Throws:

SOAPException - if there is not exactly one child SOAPElement of the SOAPBody.

Since:

SAAJ 1.3

PS:
javax.xml.soap  **Class SOAPConnection**

```java
java.lang.Object
   - javax.xml.soap.SOAPConnection
```

**public abstract class SOAPConnection**

**extends Object**

**URL**

```java
SOAPConnectionFactory factory = SOAPConnectionFactory.newInstance();
SOAPConnection con = factory.createConnection();
```

A **point-to-point** connection that a client can use for sending messages directly to a remote party (represented by a URL, for instance).

The SOAPConnection class is optional. Some implementations may not implement this interface in which case the call to `SOAPConnectionFactory.newInstance()` (see below) will throw an `UnsupportedOperationException`.

A client can obtain a **SOAPConnection** object using a **SOAPConnectionFactory** object as in the following example:

```java
SOAPConnectionFactory factory = SOAPConnectionFactory.newInstance();
SOAPConnection con = factory.createConnection();
```

A **SOAPConnection** object can be used to send messages directly to a URL
following the request/response paradigm. That is, messages are sent using the method call, which sends the message and then waits until it gets a reply.

### Constructor Summary

<table>

<td><strong>SOAPException</strong>: SOAP</td>
</tr>
</tbody>
</table>

**call**

public abstract **SOAPMessage** call(**SOAPMessage** request, Object to) throws **SOAPException**

Sends the given message to the specified endpoint and blocks until it has returned the response.

**Parameters:**
- request - the SOAPMessage object to be sent
- to - an Object that identifies where the message should be sent.
  It is required to support Objects of type `java.lang.String`, `java.net.URL`, and when JAXM is present `javax.xml.messaging.URL Endpoint`

**Returns:**
- the SOAPMessage object that is the response to the message that was sent

**Throws:**
- **SOAPException** - if there is a SOAP error

public **SOAPMessage** get(Object to) throws **SOAPException**
get

public SOAPMessage get(Object to)
    throws SOAPException

    Gets a message from a specific endpoint and blocks until it receives,

Parameters:
    to - an Object that identifies where the request should be sent. Objects of type java.lang.String and java.net.URL must be supported.

Returns:
    the SOAPMessage object that is the response to the get message request

Throws:
    SOAPException - if there is a SOAP error

Since:
    SAAJ 1.3

abstract public void close() throws SOAPException

SoapConnection

Throws
    SOAPException: SOAP

close

public abstract void close()
    throws SOAPException

Closes this SOAPConnection object.

Throws:
SOAPException - if there is a SOAP error

javax.xml.soap Class SOAPConnectionFactory

java.lang.Object
  javax.xml.soap.SOAPConnectionFactory

public abstract class SOAPConnectionFactory extends Object

SOAPConnection SOAPConnectionFactory.newInstance()

UnsupportedOperationException SAAJ SOAPConnectionFactory.createConnection()

A factory for creating SOAPConnection objects. Implementation of this class is optional. If SOAPConnectionFactory.newInstance() throws an UnsupportedOperationException then the implementation does not support the SAAJ communication infrastructure. Otherwise SOAPConnection objects can be created by calling createConnection() on the newly created SOAPConnectionFactory object.

Constructor Summary

SOAPConnectionFactory()}

Method Summary

abstract SOAPConnection createConnection() Create a new SOAPConnection.

static SOAPConnectionFactory newInstance() Creates an instance of the default SOAPConnectionFactory object.
Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Constructor Detail

public SOAPConnectionFactory()

SOAPConnectionFactory

public SOAPConnectionFactory()

Method Detail

public static SOAPConnectionFactory newInstance()
throws SOAPException, UnsupportedOperationException

SOAPConnectionFactory

return SOAPConnectionFactory

Throws SOAPException: SOAPConnectionFactory

Throws UnsupportedOperationException: SOAPConnectionFactory

newInstance

Create an instance of the default SOAPConnectionFactory object.

Returns:
a new instance of a default SOAPConnectionFactory object

Throws:
SOAPException - if there was an error creating the
SOAPConnectionFactory

UnsupportedOperationException - if newInstance is not supported.

abstract public SOAPConnection createConnection()

throws SOAPException

SOAPConnection

return SOAPConnection

Throws SOAPException: SOAPConnection

createConnection

public abstract SOAPConnection createConnection()

throws SOAPException

Create a new SOAPConnection.

Returns: the new SOAPConnection object.

Throws: SOAPException - if there was an exception creating the SOAPConnection object.
public interface SOAPConstants

SOAP

The definition of constants pertaining to the SOAP protocol.

The URI identifying the next application processing a SOAP request as the intended actor for a SOAP 1.1 header entry (see section 4.2.2 of the SOAP 1.1 specification).

### DYNAMIC_SOAP_PROTOCOL

```java
static final String DYNAMIC_SOAP_PROTOCOL
```

Used to create `MessageFactory` instances that create `SOAPMessage` whose concrete type is based on the `Content-Type` MIME header passed to the `createMessage` method. If no `Content-Type` header is passed then the `createMessage` may throw an `IllegalArgumentException` or, in the case of the no argument version of `createMessage`, an `UnsupportedOperationException`.

**Since:**

SAAJ 1.3

**See Also:**

- [Constant Field Values](#)

### SOAP_1_1_PROTOCOL

```java
static final String SOAP_1_1_PROTOCOL
```

Used to create `MessageFactory` instances that create `SOAPMessage` whose behavior supports the SOAP 1.1 specification.

**Since:**

SAAJ 1.3
SOAP_1_2_PROTOCOL

static final String SOAP_1_2_PROTOCOL

Used to create MessageFactory instances that create SOAPMessages whose behavior supports the SOAP 1.2 specification

Since:
SAAJ 1.3
See Also:
Constant Field Values

DEFAULT_SOAP_PROTOCOL

static final String DEFAULT_SOAP_PROTOCOL

The default protocol: SOAP 1.1 for backwards compatibility.

Since:
SAAJ 1.3
See Also:
Constant Field Values

URI_NS_SOAP_1_1_ENVELOPE

static final String URI_NS_SOAP_1_1_ENVELOPE

The namespace identifier for the SOAP 1.1 envelope.
URI_NS_SOAP_1_2_ENVELOPE

static final String URI_NS_SOAP_1_2_ENVELOPE

The namespace identifier for the SOAP 1.2 envelope.

Since:
SAAJ 1.3
See Also:
Constant Field Values

URI_NS_SOAP_ENVELOPE

static final String URI_NS_SOAP_ENVELOPE

The namespace identifier for the SOAP 1.1 envelope, All SOAPElements in this namespace are defined by the SOAP 1.1 specification.

See Also:
Constant Field Values

URI_NS_SOAP_ENCODING

static final String URI_NS_SOAP_ENCODING
The namespace identifier for the SOAP 1.1 encoding. An attribute named encodingStyle in the URI_NS_SOAP_ENVELOPE namespace and set to the value URI_NS_SOAP_ENCODING can be added to an element to indicate that it is encoded using the rules in section 5 of the SOAP 1.1 specification.

See Also:
Constant Field Values

---

URI_NS_SOAP_1_2_ENCODING

static final String URI_NS_SOAP_1_2_ENCODING

The namespace identifier for the SOAP 1.2 encoding.

Since:
SAAJ 1.3

See Also:
Constant Field Values

---

SOAP_1_1_CONTENT_TYPE

static final String SOAP_1_1_CONTENT_TYPE

The media type of the Content-Type MIME header in SOAP 1.1.

Since:
SAAJ 1.3

See Also:
Constant Field Values
SOAP_1_2_CONTENT_TYPE

static final String SOAP_1_2_CONTENT_TYPE

The media type of the Content-Type MIME header in SOAP 1.2.

Since:
SAAJ 1.3
See Also:
Constant Field Values

URI_SOAP_ACTOR_NEXT

static final String URI_SOAP_ACTOR_NEXT

The URI identifying the next application processing a SOAP request as the intended actor for a SOAP 1.1 header entry (see section 4.2.2 of the SOAP 1.1 specification).

This value can be passed to
SOAPHeader.examineMustUnderstandHeaderElements(String),
SOAPHeader.examineHeaderElements(String) and
SOAPHeader.extractHeaderElements(String)

See Also:
Constant Field Values

URI_SOAP_1_2_ROLE_NEXT

static final String URI_SOAP_1_2_ROLE_NEXT

The URI identifying the next application processing a SOAP request as the intended role for a SOAP 1.2 header entry (see section 2.2 of part 1 of the SOAP 1.2 specification).
URI_SOAP_1_2_ROLE_NONE

static final String URI_SOAP_1_2_ROLE_NONE

The URI specifying the role None in SOAP 1.2.

Since: SAAJ 1.3
See Also: Constant Field Values

------------------------------------------------------

URI_SOAP_1_2_ROLE_ULTIMATE_RECEIVER

static final String URI_SOAP_1_2_ROLE_ULTIMATE_RECEIVER

The URI identifying the ultimate receiver of the SOAP 1.2 message.

Since: SAAJ 1.3
See Also: Constant Field Values

------------------------------------------------------

SOAP_ENV_PREFIX

static final String SOAP_ENV_PREFIX
The default namespace prefix for http://www.w3.org/2003/05/soap-envelope

**Since:**
SAAJ 1.3

**See Also:**
Constant Field Values

---

**SOAP_VERSIONMISMATCH_FAULT**

static final QName SOAP_VERSIONMISMATCH_FAULT

SOAP 1.2 VersionMismatch Fault

**Since:**
SAAJ 1.3

---

**SOAP_MUSTUNDERSTAND_FAULT**

static final QName SOAP_MUSTUNDERSTAND_FAULT

SOAP 1.2 MustUnderstand Fault

**Since:**
SAAJ 1.3

---

**SOAP_DATAENCODINGUNKNOWN_FAULT**

static final QName SOAP_DATAENCODINGUNKNOWN_FAULT

SOAP 1.2 DataEncodingUnknown Fault
Since:
   SAAJ 1.3

SOAP_SENDER_FAULT

static final QName SOAP_SENDER_FAULT

SOAP 1.2 Sender Fault

Since:
   SAAJ 1.3

SOAP_RECEIVER_FAULT

static final QName SOAP_RECEIVER_FAULT

SOAP 1.2 Receiver Fault

Since:
   SAAJ 1.3
javax.xml.soap Interface SOAPElement

All Superinterfaces:
   Element, Node

All Known Subinterfaces:
   Detail, DetailEntry, SOAPBody, SOAPBodyElement, SOAPEnvelope, SOAPFault, SOAPFaultElement, SOAPHeader, SOAPHeaderElement

public interface SOAPElement
   extends Node, Element

Implements: Node, org.w3c.dom.Element
Implemented by: DetailEntry, SOAPBody, SOAPBodyElement, SOAPEnvelope, SOAPFaultElement, SOAPHeader, SOAPHeaderElement

SOAP SOAP SOAP

SAAJ "" summary.html#package_description">javax.xml.soap

An object representing an element of a SOAP message that is allowed but not specifically prescribed by a SOAP specification. This interface serves as the base interface for those objects that are specifically prescribed by a SOAP specification.

Methods in this interface that are required to return SAAJ specific objects may "silently" replace nodes in the tree as required to successfully return objects of the correct type. See getChildElements() and javax.xml.soap for details.

### addChildElement

**SOAPElement addChildElement(Name name) throws SOAPException**

Creates a new SOAPElement object initialized with the given Name object and adds the new element to this SOAPElement object.

This method may be deprecated in a future release of SAAJ in favor of addChildElement(javax.xml.namespace.QName)

**Parameters:**

- **name**: a Name object with the XML name for the new element

**Returns:**

- the new SOAPElement object that was created

**Throws:**

- SOAPException - if there is an error in creating the SOAPElement object

**See Also:**

- addChildElement(javax.xml.namespace.QName)
public <var>SOAPElement</var> addChildElement(<var>javax.xml.namespace.QName</var> qname) throws <var>SOAPException</var>

    QName SOAPElement SOAPElement SOAPElement
namespace localname prefix qname
    qname QName XML
return SOAPElement
Throws <var>SOAPException</var>: SOAPElement
since SAAJ 1.3
See also <var>addChildElement(Name)</var>

**addChildElement**

<var>SOAPElement</var> addChildElement(<var>QName</var> qname) throws <var>SOAPException</var>

Creates a new <var>SOAPElement</var> object initialized with the given <var>QName</var> object and adds the new element to this <var>SOAPElement</var> object. The namespace, localname and prefix of the new <var>SOAPElement</var> are all taken from the qname argument.

**Parameters:**
qname - a QName object with the XML name for the new element

**Returns:**
the new <var>SOAPElement</var> object that was created

**Throws:**
<var>SOAPException</var> - if there is an error in creating the <var>SOAPElement</var> object

**Since:**
SAAJ 1.3

**See Also:**
<var>addChildElement(Name)</var>

---

public <var>SOAPElement</var> addChildElement(<var>String</var> localName) throws <var>SOAPException</var>
addChildElement

SOAPElement addChildElement(String localName) throws SOAPException

Creates a new SOAPElement object initialized with the specified local name and adds the new element to this SOAPElement object. The new SOAPElement inherits any in-scope default namespace.

Parameters:
  localName - a String giving the local name for the element

Returns:
  the new SOAPElement object that was created

Throws:
  SOAPException - if there is an error in creating the SOAPElement object

public SOAPElement addChildElement(String localName, String prefix) throws SOAPException

SOAPElement addChildElement(String localName, String prefix)

SOAPElement addChildElement(SOAPElement localName, SOAPElement prefix) throws SOAPException

addChildElement

SOAPElement addChildElement(String localName, String prefix)
throws SOAPException

Creates a new SOAPElement object initialized with the specified local name and prefix and adds the new element to this SOAPElement object.

Parameters:
localName - a String giving the local name for the new element
prefix - a String giving the namespace prefix for the new element

Returns:
the new SOAPElement object that was created

Throws:
SOAPException - if the prefix is not valid in the context of this SOAPElement or if there is an error in creating the SOAPElement object

public SOAPElement addChildElement(String localName, String prefix, String uri) throws SOAPException

URI

localName
prefix
uri

return

SOAPElement

Throws

SOAPException

SOAPElement

addChildElement

SOAPElement addChildElement(String localName,
String prefix,
String uri)
throws SOAPException

Creates a new SOAPElement object initialized with the specified local name, prefix, and URI and adds the new element to this SOAPElement object.
Parameters:
- **localName** - a **String** giving the local name for the new element
- **prefix** - a **String** giving the namespace prefix for the new element
- **uri** - a **String** giving the URI of the namespace to which the new element belongs

Returns:
- the new **SOAPElement** object that was created

Throws:
- **SOAPException** - if there is an error in creating the **SOAPElement** object

```java
public **SOAPElement** addChildElement(**SOAPElement** element) throws **SOAPException**
```

**SOAPElement** **soapElement** **SOAPFactory**

**SOAPElement** **XML**

**SOAPElement** **SOAPElement**

**SOAPHeader** **addChildElement**() **element**

**SOAPHeaderElement**

**element**

**element** "Envelope""Header" "Body" SOAP

**element** **SOAPElement**

**Throws** **SOAPException**:

```java
return **SOAP**
```

**addChildElement**

**SOAPElement** **addChildElement**(**SOAPElement** element) throws **SOAPException**

**SOAPElement** **addChildElement**(**SOAPElement** element)

**throws** **SOAPException**

Add a **SOAPElement** as a child of this **SOAPElement** instance. The **SOAPElement** is expected to be created by a **SOAPFactory**. Callers
should not rely on the element instance being added as is into the XML tree. Implementations could end up copying the content of the SOAPElement passed into an instance of a different SOAPElement implementation. For instance if addChildElement() is called on a SOAPHeader, element will be copied into an instance of a SOAPHeaderElement.

The fragment rooted in element is either added as a whole or not at all, if there was an error.

The fragment rooted in element cannot contain elements named "Envelope", "Header" or "Body" and in the SOAP namespace. Any namespace prefixes present in the fragment should be fully resolved using appropriate namespace declarations within the fragment itself.

**Parameters:**
- element - the SOAPElement to be added as a new child

**Returns:**
- an instance representing the new SOAP element that was actually added to the tree.

**Throws:**
- SOAPException - if there was an error in adding this element as a child

```java
public void removeContents()

SOAPElement

SOAPElement

SOAPHeaders  SOAPBodys  SOAP

since  SAAJ 1.2

removeContents

void removeContents()

Detaches all children of this SOAPElement.
This method is useful for rolling back the construction of partially completed SOAPHeaders and SOAPBodys in preparation for sending a fault when an error condition is detected. It is also useful for recycling portions of a document within a SOAP message.

Since:
  SAAJ 1.2

```java
public SOAPElement addTextNode(String text) throws SOAPException

String text
return SOAPElement

Throws: SOAPException
```

```
addTextNode

SOAPElement addTextNode(String text)
throws SOAPException

Creates a new Text object initialized with the given String and adds it to this SOAPElement object.

Parameters:
  text - a String object with the textual content to be added

Returns:
  the SOAPElement object into which the new Text object was inserted

Throws:
  SOAPException - if there is an error in creating the new Text object or if it is not legal to attach it as a child to this SOAPElement
```

```java
public SOAPElement addAttribute(Name name, String value) throws SOAPException

SOAPElement
```
**addAttribute**

```java
SOAPElement addAttribute(Name name, String value) throws SOAPException
```

Adds an attribute with the specified name and value to this `SOAPElement` object.

**Parameters:**
- `name` - a `Name` object with the name of the attribute
- `value` - a `String` giving the value of the attribute

**Returns:**
the `SOAPElement` object into which the attribute was inserted

**Throws:**
- `SOAPException` - if there is an error in creating the Attribute, or it is invalid to set an attribute with `Name` name on this `SOAPElement`.

**See Also:**
`addAttribute(javax.xml.namespace.QName, String)`

---

**public SOAPElement**

```java
addAttribute(javax.xml.namespace.QName qname, String value) throws SOAPException
```

```java
SOAPElement
qname QName
value String
return SOAPElement
```

**Throws**
- `SOAPException` - `SOAPElement`

**since**
SAAJ 1.3

**See also**
`addAttribute(Name, String)`
addAttribute

**SOAPElement addAttribute**(QName qname, String value) throws SOAPException

Adds an attribute with the specified name and value to this SOAPElement object.

**Parameters:**
- qname - a QName object with the name of the attribute
- value - a String giving the value of the attribute

**Returns:**
the SOAPElement object into which the attribute was inserted

**Throws:**
SOAPException - if there is an error in creating the Attribute, or it is invalid to set an attribute with QName qname on this SOAPElement.

**Since:**
SAAJ 1.3

**See Also:**
addAttribute(Name, String)

---

public **SOAPElement addNamespaceDeclaration**(String prefix, String uri) throws SOAPException

**URI**

prefix String

uri String

**Return**

SOAPElement

**Throws**

SOAPException:

addNamespaceDeclaration

**SOAPElement addNamespaceDeclaration**(String prefix, String uri)
Adds a namespace declaration with the specified prefix and URI to this SOAPElement object.

**Parameters:**
- prefix - a String giving the prefix of the namespace
- uri - a String giving the uri of the namespace

**Returns:**
the SOAPElement object into which this namespace declaration was inserted.

**Throws:**
SOAPException - if there is an error in creating the namespace

---

**public String getAttributeValue(Name name)**

- **name** Name
- **return** String Null

See also [getAttributeValue(javax.xml.namespace.QName)]

---

**getAttributeValue**

**Public String getAttributeValue(Name name)**

Returns the value of the attribute with the specified name.

**Parameters:**
- name - a Name object with the name of the attribute

**Returns:**
- a String giving the value of the specified attribute, Null if there is no such attribute

See Also:
- [getAttributeValue(javax.xml.namespace.QName)]
**getAttributeValue(java.xml.namespace.QName qname)**

Parameter:
- qname - a QName object with the qname of the attribute

Returns:
- a String giving the value of the specified attribute, Null if there is no such attribute

Since:
- SAAJ 1.3

See Also:
- `getAttributeValue(Name)`

---

**public java.util.Iterator&lt;E&gt; getAllAttributes()**

Parameters:
- SOAPElement - Name

Returns:
- an Iterator over all of the attribute Name objects in this
SOAPElement object. The iterator can be used to get the attribute names, which can then be passed to the method `getAttributeValue` to retrieve the value of each attribute.

**Returns:**

an iterator over the names of the attributes

**See Also:**

`getAllAttributesAsQNames()`

---

```java
public java.util.Iterator<E> getAllAttributesAsQNames()
```

**SOAPElement QName Iterator QName**

`getAttributeValue`

```java
return
```

QNames

```java
since SAAJ 1.3
```

**See also**

`getAllAttributesAsQNames()`

---

**getAllAttributesAsQNames**

```java
Iterator getAllAttributesAsQNames()
```

Returns an `Iterator` over all of the attributes in this `SOAPElement` as `QName` objects. The iterator can be used to get the attribute `QName`, which can then be passed to the method `getAttributeValue` to retrieve the value of each attribute.

**Returns:**

an iterator over the `QNames` of the attributes

**Since:**

SAAJ 1.3

**See Also:**

`getAllAttributes()`

---

```java
public String getNamespaceURI(String prefix)
```

**URI**

```java
prefix String
```

prefix
getNamespaceURI

String getNamespaceURI(String prefix)

Returns the URI of the namespace that has the given prefix.

Parameters:
prefix - a String giving the prefix of the namespace for which to search

Returns:
a String with the uri of the namespace that has the given prefix

public java.util.Iterator<E> getNamespacePrefixes()

String Iterator getNamespaceURI

return SOAPElement

generatePrefixes

Iterator getNamespacePrefixes()

Returns an Iterator over the namespace prefix strings declared by this element. The prefixes returned by this iterator can be passed to the method getNamespaceURI to retrieve the URI of each namespace.

Returns:
an iterator over the namespace prefixes in this SOAPElement object

public java.util.Iterator<E> getVisibleNamespacePrefixes()

String Iterator getNamespaceURI

return SOAPElement

since SAAJ 1.2
**getVisibleNamespacePrefixes**

```
Iterator getVisibleNamespacePrefixes()
```

Returns an `Iterator` over the namespace prefix `String`s visible to this element. The prefixes returned by this iterator can be passed to the method `getNamespaceURI` to retrieve the URI of each namespace.

Returns:
- an `Iterator` over the namespace prefixes are within scope of this `SOAPElement` object

Since:
- SAAJ 1.2

---

**publicjavax.xml.namespace.QName createQName(String localName, String prefix) throws SOAPException**

```
QName QName URI SOAPElement prefix QName
localName prefix
localName String prefix String
return QName localName prefix SOAPElement prefix
prefix #getNamespaceURI(String) exception
```

Throws: `SOAPException`

Since: SAAJ 1.3

---

**createQName**

```
QName createQName(String localName, String prefix) throws SOAPException
```

Creates a `QName` whose namespace URI is the one associated with the parameter, `prefix`, in the context of this `SOAPElement`. The remaining elements of the new `QName` are taken directly from the
Parameters:

localName - a String containing the local part of the name.
prefix - a String containing the prefix for the name.

Returns:

a QName with the specified localName and prefix, and with a namespace that is associated with the prefix in the context of this SOAPElement. This namespace will be the same as the one that would be returned by getNamespaceURI(String) if it were given prefix as its parameter.

Throws:

SOAPException - if the QName cannot be created.

Since:

SAAJ 1.3

public Name getElementName()   

SOAPElement  

return  

SOAPElement   Name

g getElementName

Name  getgetElementName()    

Returns the name of this SOAPElement object.

Returns:

a Name object with the name of this SOAPElement object

g public javax.xml.namespace.QName getElementQName()   

SOAPElement  qname

return  

SOAPElement   QName

since  

SAAJ 1.3

See also  

g getElementName()
getElementQName

QName getElementQName()

Returns the qname of this SOAPElement object.

Returns:
   a QName object with the qname of this SOAPElement object

Since:
   SAAJ 1.3

See Also:
   getElementName()

public SOAPElement setElementQName(javax.xml.namespace.QName newName) throws SOAPException

setElementQName(QName newName)

Changes the name of this Element to newName if possible. SOAP Defined elements such as SOAPEnvelope, SOAPHeader, SOAPBody etc. cannot have their names changed using this method. Any attempt to do so will result in a SOAPException being
thrown.

Callers should not rely on the element instance being renamed as is. Implementations could end up copying the content of the SOAPElement to a renamed instance.

**Parameters:**
- `newName` - the new name for the `Element`.

**Returns:**
The renamed Node

**Throws:**
- `SOAPException` - if changing the name of this `Element` is not allowed.

**Since:**
SAAJ 1.3

---

**public boolean removeAttribute(Name name)**

**name**
- Name

**return**
- true false

**See also**
- `removeAttribute(javax.xml.namespace.QName)`

---

**removeAttribute**

boolean **removeAttribute**(Name name)

Removes the attribute with the specified name.

**Parameters:**
- `name` - the `Name` object with the name of the attribute to be removed

**Returns:**
- true if the attribute was removed successfully; false if it was not removed

**See Also:**
- `removeAttribute(javax.xml.namespace.QName)`
public boolean removeAttribute(javax.xml.namespace.QName qname)

        qname

        return

        since

        See also

        removeAttribute(Name)

removeAttribute

boolean removeAttribute(QName qname)

    Removes the attribute with the specified qname.

    Parameters:
    qname - the QName object with the qname of the attribute to be removed

    Returns:
    true if the attribute was removed successfully; false if it was not

Since:
SAAJ 1.3
See Also:
removeAttribute(Name)

public boolean removeNamespaceDeclaration(String prefix)

        prefix

        return

        String

        true  false

removeNamespaceDeclaration

boolean removeNamespaceDeclaration(String prefix)
Removes the namespace declaration corresponding to the given prefix.

**Parameters:**
- `prefix` - a String giving the prefix for which to search

**Returns:**
- true if the namespace declaration was removed successfully;
- false if it was not

---

```java
public java.util.Iterator<E> getChildElements()
```

Returns an Iterator over all the immediate child [Nodes] of this element. This includes `javax.xml.soap.Text` objects as well as `SOAPElement` objects.

Calling this method may cause child `Element`, `SOAPElement` and `org.w3c.dom.Text` nodes to be replaced by `SOAPElement`, `SOAPHeaderElement`, `SOAPBodyElement` or `javax.xml.soap.Text` nodes as appropriate for the type of this parent node. As a result the calling application must treat any existing references to these child nodes that have been obtained through DOM APIs as invalid and either
discard them or refresh them with the values returned by this Iterator. This behavior can be avoided by calling the equivalent DOM APIs. See javax.xml.soap for more details.

**Returns:**
an iterator with the content of this SOAPElement object

```java
public java.util.Iterator<E> getChildElements(Name name)
```

ElementSOAPElement org.w3c.dom.Text SOAPElementSOAPHeaderElementSOAPBodyElement javax.xml.soap.Text DOM API Iterator

HREF="package-summary.html#package_description">javax.xml.soap

**name** Name

**return** SOAPElement Iterator

See also getChildElements(javax.xml.namespace.QName)

getChildElements

```java
Iterator getChildElements(Name name)
```

Returns an Iterator over all the immediate child Nodes of this element with the specified name. All of these children will be SOAPElement nodes.

Calling this method may cause child Element, SOAPElement and org.w3c.dom.Text nodes to be replaced by SOAPElement, SOAPHeaderElement, SOAPBodyElement or javax.xml.soap.Text nodes as appropriate for the type of this parent node. As a result the calling application must treat any existing references to these child nodes that have been obtained through DOM APIs as invalid and either discard them or refresh them with the values returned by this
Iterator. This behavior can be avoided by calling the equivalent DOM APIs. See javax.xml.soap for more details.

**Parameters:**
- `name` - a `Name` object with the name of the child elements to be returned

**Returns:**
- an `Iterator` object over all the elements in this `SOAPElement` object with the specified name

**See Also:**
- `get Child Elements(javax.xml.namespace.QName)`

```java
public java.util.Iterator<E>
getChildElements(javax.xml.namespace.QName qname)
```

Returns an `Iterator` over all the immediate child `Node`s of this element with the specified `qname`. All of these children will be `SOAPElement` nodes.
Calling this method may cause child Element, SOAPElement and org.w3c.dom.Text nodes to be replaced by SOAPElement, SOAPHeaderElement, SOAPBodyElement or javax.xml.soap.Text nodes as appropriate for the type of this parent node. As a result the calling application must treat any existing references to these child nodes that have been obtained through DOM APIs as invalid and either discard them or refresh them with the values returned by this Iterator. This behavior can be avoided by calling the equivalent DOM APIs. See javax.xml.soap for more details.

Parameters:
   qname - a QName object with the qname of the child elements to be returned

Returns:
   an Iterator object over all the elements in this SOAPElement object with the specified qname

Since:
   SAAJ 1.3

See Also:
   getChildElements(Name)

public void setEncodingStyle(String encodingStyle) throws SOAPException

Sets the encoding style for this SOAPElement object to one specified.
Parameters:

- `encodingStyle` - a String giving the encoding style

Throws:

- `IllegalArgumentException` - if there was a problem in the encoding style being set.
- `SOAPException` - if setting the `encodingStyle` is invalid for this `SOAPElement`.

See Also:

- `getEncodingStyle()`

---

```java
public String getEncodingStyle()
```

```java
SOAPElement

return String
```

See also `setEncodingStyle`

---

**getEncodingStyle**

```java
String getEncodingStyle()
```

Returns the encoding style for this `SOAPElement` object.

**Returns:**

- a String giving the encoding style

See Also:

- `setEncodingStyle(java.lang.String)`

javax.xml.soap  **Class SOAPElementFactory**

**java.lang.Object**

| javax.xml.soap.SOAPElementFactory |

---

**Deprecated.** - *Use javax.xml.soap.SOAPFactory for creating SOAPElements.*

SOAPElementFactory  SOAP  XML  SOAPHeader  SOAPBody

SOAPXML
deprecated - javax.xml.soap.SOAPFactory SOAPElements

See also  javax.xml.soap.SOAPFactory

**public class SOAPElementFactory**

extends **Object**

SOAPElementFactory is a factory for XML fragments that will eventually end up in the SOAP part. These fragments can be inserted as children of the SOAPHeader or SOAPBody or SOAPEnvelope.

Elements created using this factory do not have the properties of an element that lives inside a SOAP header document. These elements are copied into the XML document tree when they are inserted.

See Also:  SOAPFactory

---

**Method Summary**

| **create**(Name name) |
SOAPElement

**Deprecated.** Use `javax.xml.soap.SOAPFactory.createElement(javax.xml.soap.Name)` instead

```java
SOAPElement create(String localName)

**Deprecated.** Use `javax.xml.soap.SOAPFactory.createElement(String)` instead

```java
SOAPElement create(String localName, String prefix, String uri)

**Deprecated.** Use `javax.xml.soap.SOAPFactory.createElement(String, String, String)` instead
```

```java
static SOAPElementFactory newInstance()

**Deprecated.** Creates a new instance of SOAPElementFactory
```

PS :
javax.xml.soap  Interface SOAPEnvelope

All Superinterfaces:
   Element, Node, SOAPElement

public interface SOAPEnvelope
extends SOAPElement

Implements: SOAPElement

SOAPPart  SOAPHeader  SOAPBody  SOAPEnvelope
SOAPPart  SOAPMessage  SOAPEnvelope  SOAPBody  SOAPHeader
   SOAPBody  SOAPHeader  SOAPHeader
   SOAPEnvelope  se

SOAPPart  sp = message.getSOAPPart();
SOAPEnvelope  se = sp.getEnvelope();
SOAPHeader  sh = se.getHeader();
SOAPBody  sb = se.getBody();

SOAPEnvelope  se
   se.getBody().detachNode();

SOAPEnvelope  se
   se.addHeader();
   se.getBody().detachNode();

SOAPHeader  sh
   se.addBody();
The container for the SOAPHeader and SOAPBody portions of a SOAPPart object. By default, a SOAPMessage object is created with a SOAPPart object that has a SOAPEnvelope object. The SOAPEnvelope object by default has an empty SOAPBody object and an empty SOAPHeader object. The SOAPBody object is required, and the SOAPHeader object, though optional, is used in the majority of cases. If the SOAPHeader object is not needed, it can be deleted, which is shown later.

A client can access the SOAPHeader and SOAPBody objects by calling the methods SOAPEnvelope.getHeader and SOAPEnvelope.getBody. The following lines of code use these two methods after starting with the SOAPMessage object message to get the SOAPPart object sp, which is then used to get the SOAPEnvelope object se.

```java
SOAPPart sp = message.getSOAPPart();
SOAPEnvelope se = sp.getEnvelope();
SOAPHeader sh = se.getHeader();
SOAPBody sb = se.getBody();
```

It is possible to change the body or header of a SOAPEnvelope object by retrieving the current one, deleting it, and then adding a new body or header. The javax.xml.soap.Node method deleteNode deletes the XML element (node) on which it is called. For example, the following line of code deletes the SOAPBody object that is retrieved by the method getBody.

```java
se.getBody().detachNode();
```

To create a SOAPHeader object to replace the one that was removed, a client uses the method SOAPEnvelope.addHeader, which creates a new

```java
SOAPEnvelope se = ...; SOAPHeader sh = ...; se.addHeader(sh);
```
header and adds it to the SOAPEnvelope object. Similarly, the method addBody creates a new SOAPBody object and adds it to the SOAPEnvelope object. The following code fragment retrieves the current header, removes it, and adds a new one. Then it retrieves the current body, removes it, and adds a new one.

```java
SOAPPart sp = message.getSOAPPart();
SOAPEnvelope se = sp.getEnvelope();
se.getHeader().detachNode();
SOAPHeader sh = se.addHeader();
se.getBody().detachNode();
SOAPBody sb = se.addBody();
```

It is an error to add a SOAPBody or SOAPHeader object if one already exists.

The SOAPEnvelope interface provides three methods for creating Name objects. One method creates Name objects with a local name, a namespace prefix, and a namespace URI. The second method creates Name objects with a local name and a namespace prefix, and the third creates Name objects with just a local name. The following line of code, in which se is a SOAPEnvelope object, creates a new Name object with all three.

```java
Name name = se.createName("GetLastTradePrice", "WOMBAT", "http://www.wombat.org/trader");
```

**Method Detail**
public Name createName(String localName, String prefix, String uri) throws SOAPException

createName

Name createName(String localName, String prefix, String uri)
throws SOAPException

Creates a new Name object initialized with the given local name, namespace prefix, and namespace URI.

This factory method creates Name objects for use in the SOAP/XML document.

Parameters:
- localName - a String giving the local name
- prefix - a String giving the prefix of the namespace
- uri - a String giving the URI of the namespace

Returns:
- a Name object initialized with the given local name, namespace prefix, and namespace URI

Throws:
- SOAPException - if there is a SOAP error
SOAPException

SOAP/XML

createName

```java
Name createName(String localName)
throws SOAPException
```

Creates a new `Name` object initialized with the given local name.

This factory method creates `Name` objects for use in the SOAP/XML document.

**Parameters:**
- `localName` - a `String` giving the local name

**Returns:**
- a `Name` object initialized with the given local name

**Throws:**
- `SOAPException` - if there is a SOAP error

public `SOAPHeader` getHeader() throws `SOAPException`

```java
SOAPHeader getHeader()
throws SOAPException
```

**Return:**
- `SOAPHeader` null

**Throws:**
- `SOAPException` - `SOAPHeader`
**getHeader**

```java
SOAPHeader getHeader() throws SOAPException
```

Returns the SOAPHeader object for this SOAPEnvelope object.

A new SOAPMessage object is by default created with a SOAPEnvelope object that contains an empty SOAPHeader object. As a result, the method getHeader will always return a SOAPHeader object unless the header has been removed and a new one has not been added.

**Returns:**
the SOAPHeader object or null if there is none

**Throws:**
SOAPException - if there is a problem obtaining the SOAPHeader object

---

**public** SOAPBody getBody() throws SOAPException

```java
SOAPEnvelope SOAPBody
```

```java
SOAPBody SOAPEnvelope SOAPMessage
getBody SOAPBody
return
SOAPEnvelope SOAPBody null

**Throws**
SOAPException: SOAPBody

---

**getBody**

```java
SOAPBody getBody() throws SOAPException
```

Returns the SOAPBody object associated with this SOAPEnvelope object.

A new SOAPMessage object is by default created with a SOAPEnvelope object that contains an empty SOAPBody object. As a result, the method getBody will always return a SOAPBody object unless the body
has been removed and a new one has not been added.

**Returns:**
the SOAPBody object for this SOAPEnvelope object or null if there is none

**Throws:**
SOAPException - if there is a problem obtaining the SOAPBody object

---

```java
public SOAPHeader addHeader() throws SOAPException

SOAPHeader SOAPEnvelope SOAPHeader
```

---

**public SOAPHeader addHeader() throws SOAPException**

**SOAPHeader** **SOAPEnvelope** **SOAPHeader**

**return** **SOAPHeader**

**Throws** **SOAPException:** **SOAPEnvelope** **SOAPHeader**

---

**addHeader**

**SOAPHeader addHeader()** **throws SOAPException**

Creates a SOAPHeader object and sets it as the SOAPHeader object for this SOAPEnvelope object.

It is illegal to add a header when the envelope already contains a header. Therefore, this method should be called only after the existing header has been removed.

**Returns:**
the new SOAPHeader object

**Throws:**
SOAPException - if this SOAPEnvelope object already contains a valid SOAPHeader object
public SOAPBody addBody() throws SOAPException

SOAPBody
SOAPEnvelope
SOAPBody

return SOAPBody

Throws SOAPException: SOAPEnvelope SOAPBody

addBody

SOAPBody addBody() throws SOAPException

Creates a SOAPBody object and sets it as the SOAPBody object for this SOAPEnvelope object.

It is illegal to add a body when the envelope already contains a body. Therefore, this method should be called only after the existing body has been removed.

Returns: the new SOAPBody object

Throws: 
SOAPException - if this SOAPEnvelope object already contains a valid SOAPBody object
javax.xml.soap  Class SOAPException

java.lang.Object  ↳ java.lang.Throwable  ↳ java.lang.Exception  ↳ javax.xml.soap.SOAPException

All Implemented Interfaces:
Serializable

public class SOAPException
extends Exception

Extends: Throwable > Exception

SOAP Throwable SOAPException String Throwable

SOAPException Throwable /

An exception that signals that a SOAP exception has occurred. A
SOAPException object may contain a String that gives the reason for the exception, an embedded Throwable object, or both. This class provides
methods for retrieving reason messages and for retrieving the embedded Throwable object.

Typical reasons for throwing a SOAPException object are problems such as difficulty setting a header, not being able to send a message, and not
being able to get a connection with the provider. Reasons for embedding a Throwable object include problems such as input/output errors or a
parsing problem, such as an error in parsing a header.

Constructor Detail

public SOAPException()

SOAPException

public SOAPException()

Constructs a SOAPException object with no reason or embedded Throwable object.

public SOAPException(String reason)

SOAPException String reason

SOAPException

public SOAPException(String reason)

Constructs a SOAPException object with the given String as the reason for the exception being thrown.

Parameters:
reason - a description of what caused the exception

public SOAPException(String reason, Throwable cause)

SOAPException String Throwable reason cause

SOAPException Throwable
SOAPException

public SOAPException(String reason, Throwable cause)

Constructs a SOAPException object with the given string as the reason for the exception being thrown and the given Throwable object as an embedded exception.

Parameters:
- reason - a description of what caused the exception
- cause - a Throwable object that is to be embedded in this SOAPException object

public SOAPException(Throwable cause)

Constructs a SOAPException object initialized with the given Throwable object.

Method Detail

public String getMessage()

Throws: SOAPException
public String getMessage()

Returns the detail message for this SOAPException object.

If there is an embedded Throwable object, and if the SOAPException object has no detail message of its own, this method will return the detail message from the embedded Throwable object.

Overrides:
getMessage in class Throwable

Returns:
the error or warning message for this SOAPException or, if it has none, the message of the embedded Throwable object, if there is one

public Throwable getCause()

SOAPException Throwable null
return Throwable null

getCause

gpublic Throwable getCause()

Returns the Throwable object embedded in this SOAPException if there is one. Otherwise, this method returns null.

Overrides:
getCause in class Throwable

Returns:
the embedded Throwable object or null if there is none

public Throwable initCause(Throwable cause)

Throwable SOAPException cause
initCause

public Throwable initCause(Throwable cause)

Initializes the cause field of this SOAPException object with the given Throwable object.

This method can be called at most once. It is generally called from within the constructor or immediately after the constructor has returned a new SOAPException object. If this SOAPException object was created with the constructor SOAPException(Throwable) or SOAPException(String, Throwable), meaning that its cause field already has a value, this method cannot be called even once.

Overrides:

initCause in class Throwable

Parameters:

cause - the Throwable object that caused this SOAPException object to be thrown. The value of this parameter is saved for later retrieval by the getCause() method. A null value is permitted and indicates that the cause is nonexistent or unknown.

Returns:

a reference to this SOAPException instance

Throws:

IllegalArgumentException - if cause is this Throwable object. (A Throwable object cannot be its own cause.)
IllegalStateException - if the cause for this SOAPException object has already been initialized
public abstract class SOAPFactory extends Object

SOAPFactory is a factory for creating various objects that exist in the SOAP XML tree. SOAPFactory can be used to create XML fragments that will eventually end up in the SOAP part. These fragments can be inserted as children of the SOAPHeaderElement or SOAPBodyElement or SOAPEnvelope or other SOAPElement objects. SOAPFactory also has methods to create javax.xml.soap.Detail objects as well as java.xml.soap.Name objects.

**Constructor Summary**

Constructor Detail

public SOAPFactory()

SOAPFactory

public SOAPFactory()

Method Detail

public SOAPElemen creates an Element from an existing DOM Element. If the DOM Element that is passed in as an argument is already a
SOAPElement then this method must return it unmodified without any further work. Otherwise, a new SOAPElement is created and a deep copy is made of the domElement argument. The concrete type of the return value will depend on the name of the domElement argument. If any part of the tree rooted in domElement violates SOAP rules, a SOAPException will be thrown.

Parameters:
  domElement -- the Element to be copied.

Returns:
a new SOAPElement that is a copy of domElement.

Throws:
  SOAPException - if there is an error in creating the SOAPElement object

Since:
  SAAJ 1.3

```java
abstract public SOAPElement createElement(Name name)
throws SOAPException
```

`Soap 1.2` SOAPElement "{http://www.w3.org/2003/05/soap-envelope}Envelope"

SOAPElement SOAP 1.2 SOAPEnvelope

name XML Name

return SOAPElement

Throws SOAPException: SOAPElement

See also createElement(javax.xml.namespace.QName)

createElement

```java
public abstract SOAPElement createElement(Name name)
throws SOAPException
```

Creates a SOAPElement object initialized with the given Name object. The concrete type of the return value will depend on the name given to the new SOAPElement. For instance, a new SOAPElement with the name "{http://www.w3.org/2003/05/soap-envelope}Envelope" would
cause a SOAPEnvelope that supports SOAP 1.2 behavior to be created.

**Parameters:**
- `name` - a Name object with the XML name for the new element

**Returns:**
- the new SOAPElement object that was created

**Throws:**
- SOAPException - if there is an error in creating the SOAPElement object

**See Also:**
- `createElement(javax.xml.namespace.QName)`

---

```java
public SOAPElement createElement(javax.xml.namespace.QName qname)
throws SOAPException
```

QName SOAPElement SOAPElement "
{http://www.w3.org/2003/05/soap-envelope}Envelope"

SOAPElement SOAP 1.2 SOAPEnvelope
qname XML QName
return SOAPElement

Throws SOAPException: SOAPElement

since SAAJ 1.3

See also `createElement(Name)`

---

**createElement**

```java
public SOAPElement createElement(QName qname)
throws SOAPException
```

Creates a SOAPElement object initialized with the given QName object. The concrete type of the return value will depend on the name given to the new SOAPElement. For instance, a new SOAPElement with the name "{http://www.w3.org/2003/05/soap-envelope}Envelope" would cause a SOAPEnvelope that supports SOAP 1.2 behavior to be created.
Parameters:
qname - a QName object with the XML name for the new element

Returns:
the new SOAPElement object that was created

Throws:
SOAPException - if there is an error in creating the SOAPElement object

Since:
SAAJ 1.3

See Also:
createElement(Name)

abstract public SOAPElement createElement(String localName) throws SOAPException

SOAPElement

localName

String

return

SOAPElement

Throws

SOAPException:

SOAPElement

createElement

public abstract SOAPElement createElement(String localName) throws SOAPException

Creates a SOAPElement object initialized with the given local name.

Parameters:
localName - a String giving the local name for the new element

Returns:
the new SOAPElement object that was created

Throws:
SOAPException - if there is an error in creating the SOAPElement object

abstract public SOAPElement createElement(String
createElement

public abstract SOAPElement createElement(String localName, String prefix, String uri) throws SOAPException

Creates a new SOAPElement object with the given local name, prefix and uri. The concrete type of the return value will depend on the name given to the new SOAPElement. For instance, a new SOAPElement with the name "{http://www.w3.org/2003/05/soap-envelope}Envelope" would cause a SOAPEnvelope that supports SOAP 1.2 behavior to be created.

Parameters:
- localName - a String giving the local name for the new element
- prefix - the prefix for this SOAPElement
- uri - a String giving the URI of the namespace to which the new element belongs

Throws:
- SOAPException - if there is an error in creating the SOAPElement object
createDetail

public abstract Detail createDetail() throws SOAPException

Creates a new Detail object which serves as a container for DetailEntry objects.

This factory method creates Detail objects for use in situations where it is not practical to use the SOAPFault abstraction.

Returns:
a Detail object

Throws:
   SOAPException - if there is a SOAP error
   UnsupportedOperationException - if the protocol specified for the SOAPFactory was DYNAMIC_SOAP_PROTOCOL

abstract public SOAPFault createFault(String reasonText, javax.xml.namespace.QName faultCode) throws SOAPException

reasonText   faultCode   SOAPFault
reasonText   ReasonText/FaultString
faultCode    FaultCode
return       SOAPFault
Throws       SOAPException: SOAP
since        SAAJ 1.3

createFault
public abstract SOAPFault createFault(String reasonText, QName faultCode) throws SOAPException

Creates a new SOAPFault object initialized with the given reasonText and faultCode

Parameters:
- reasonText - the ReasonText/FaultString for the fault
- faultCode - the FaultCode for the fault

Returns:
a SOAPFault object

Throws:
- SOAPException - if there is a SOAP error

Since:
SAAJ 1.3

abstract public SOAPFault createFault() throws SOAPException

SOAPFault

return SOAPFault

Throws

SOAPException: SOAP

since SAAJ 1.3

createFault

public abstract SOAPFault createFault() throws SOAPException

Creates a new default SOAPFault object

Returns:
a SOAPFault object

Throws:
- SOAPException - if there is a SOAP error

Since:
SAAJ 1.3
abstract public Name createName(String localName, String prefix, String uri) throws SOAPException

createName

public abstract Name createName(String localName, String prefix, String uri)

throws SOAPException

Creates a new Name object initialized with the given local name, namespace prefix, and namespace URI.

This factory method creates Name objects for use in situations where it is not practical to use the SOAPEnvelope abstraction.

Parameters:
- localName - a String giving the local name
- prefix - a String giving the prefix of the namespace
- uri - a String giving the URI of the namespace

Returns:
- a Name object initialized with the given local name, namespace prefix, and namespace URI

Throws:
- SOAPException - if there is a SOAP error
abstract public Name createName(String localName) throws SOAPException

createName

public abstract Name createName(String localName) throws SOAPException

Creates a new Name object initialized with the given local name.

This factory method creates Name objects for use in situations where it is not practical to use the SOAPEnvelope abstraction.

Parameters:
localName - a String giving the local name

Returns:
a Name object initialized with the given local name

Throws:
SOAPException - if there is a SOAP error

public static SOAPFactory newInstance() throws SOAPException

SOAPFactory (SOAP 1.1) SOAP

- javax.xml.soap.SOAPFactory
- JRE "lib/jaxm.properties" java.util.Properties
- Services API JAR Services API jar
META-INF/services/javax.xml.soap.SOAPFactory

- **SAAJMetaFactory**  SOAPFactory

```
return SOAPFactory
Throws SOAPException: SOAPFactory
See also javax.xml.soap.SAAJMetaFactory
```

**newInstance**

```
public static SOAPFactory newInstance() throws SOAPException
```

Creates a new SOAPFactory object that is an instance of the default implementation (SOAP 1.1). This method uses the following ordered lookup procedure to determine the SOAPFactory implementation class to load:

- Use the javax.xml.soap.SOAPFactory system property.
- Use the properties file "lib/jaxm.properties" in the JRE directory. This configuration file is in standard java.util.Properties format and contains the fully qualified name of the implementation class with the key being the system property defined above.
- Use the Services API (as detailed in the JAR specification), if available, to determine the classname. The Services API will look for a classname in the file META-INF/services/javax.xml.soap.SOAPFactory in jars available to the runtime.
- Use the SAAJMetaFactory instance to locate the SOAPFactory implementation class.

**Returns:**
a new instance of a SOAPFactory

**Throws:**
SOAPException - if there was an error creating the default SOAPFactory

**See Also:**
SAAJMetaFactory
public static SOAPFactory newInstance(String protocol) throws SOAPException

SOAPFactory SAAJMetaFactory

SOAPFactory return SOAPFactory

protocol DYNAMIC_SOAP_PROTOCOL DEFAULT_SOAP_PROTOCOL
SOAP_1_1_PROTOCOL SOAP_1_2_PROTOCOL

Throws SOAPException: SOAPFactory

since SAAJ 1.3
See also javax.xml.soap.SAAJMetaFactory

newInstance

public static SOAPFactory newInstance(String protocol) throws SOAPException

Creates a new SOAPFactory object that is an instance of the specified implementation, this method uses the SAAJMetaFactory to locate the implementation class and create the SOAPFactory instance.

Parameters:

protocol - a string constant representing the protocol of the specified SOAP factory implementation. May be either DYNAMIC_SOAP_PROTOCOL, DEFAULT_SOAP_PROTOCOL (which is the same as) SOAP_1_1_PROTOCOL, or SOAP_1_2_PROTOCOL.

Returns:
a new instance of a SOAPFactory

Throws:

SOAPException - if there was an error creating the specified SOAPFactory

Since:
SAAJ 1.3

PS:
javax.xml.soap Interface SOAPFault

All Superinterfaces:
   Element, Node, SOAPBodyElement, SOAPElement

public interface SOAPFault
extends SOAPBodyElement

Implements: SOAPBodyElement

SOAPBody / SOAPMessage

SOAPFault SOAP 1.1 SOAP 1.2 MessageFactory

An element in the SOAPBody object that contains error and/or status information. This information may relate to errors in the SOAPMessage object or to problems that are not related to the content in the message itself. Problems not related to the message itself are generally errors in processing, such as the inability to communicate with an upstream server.

Depending on the protocol specified while creating the MessageFactory instance, a SOAPFault has sub-elements as defined in the SOAP 1.1/SOAP 1.2 specification.

Method Summary

Detail
addDetail() Creates an optional Detail object and sets it as the
Detail object for this SOAPFault object.

void
addFaultReasonText(String text, Locale locale) Appends or replaces a Reason Text item containing the
specified text message and an xml:lang derived from locale.

void
appendFaultSubcode(QName subcode) Adds a Subcode to the end of the sequence of Subcodes
contained by this SOAPFault.

Detail
getDetail() Returns the optional detail element for this SOAPFault
object.

String
getFaultActor() Gets the fault actor for this SOAPFault object.

String
getFaultCode() Gets the fault code for this SOAPFault object.

Name
getFaultCodeAsName() Gets the mandatory SOAP 1.1 fault code for this
SOAPFault object as a SAAJ Name object.

QName
getFaultCodeAsQName() Gets the fault code for this SOAPFault object as a QName

public void setFaultCode(Name faultCodeQName) throws SOAPException

    SOAPFault

SOAP 1.1 (mandatory)

SOAPEnvelope se = ...;
// Create a qualified name in the SOAP namespace with a local
// of "Client". Note that prefix parameter is optional and is
// here which causes the implementation to use an appropriate
Name qname = se.createName("Client", null,
SOAPConstants.URI_NS_SOAP_ENVELOPE);
SOAPFault fault = ...;
fault.setFaultCode(qname);
setFaultCode

void setFaultCode(Name faultCodeQName) throws SOAPException

Sets this SOAPFault object with the given fault code.

Fault codes, which give information about the fault, are defined in the SOAP 1.1 specification. A fault code is mandatory and must be of type Name. This method provides a convenient way to set a fault code. For example,

SOAPEnvelope se = ...;
// Create a qualified name in the SOAP namespace with a localName
// of "Client". Note that prefix parameter is optional and is r
// here which causes the implementation to use an appropriate p
Name qname = se.createName("Client", null,
    SOAPConstants.URI_NS_SOAP_ENVELOPE);

SOAPFault fault = ...;
fault.setFaultCode(qname);

It is preferable to use this method over setFaultCode(String).

Parameters:
    faultCodeQName - a Name object giving the fault code to be set. It
    must be namespace qualified.

Throws:
    SOAPException - if there was an error in adding the faultcode
    element to the underlying XML tree.

Since:
    SAAJ 1.2

See Also:
    getFaultCodeAsName()
public void setFaultCode(javax.xml.namespace.QName faultCodeQName) throws SOAPException

faultCodeQName

Throws

SOAPException: faultcode XML

since

SAAJ 1.3

See also
gFaultCodeAsQName, setFaultCode(Name), getFaultCodeAsQName()

setFaultCode

void setFaultCode(QName faultCodeQName)

throws SOAPException

Sets this SOAPFault object with the given fault code. It is preferable to use this method over setFaultCode(Name).

Parameters:

faultCodeQName - a QName object giving the fault code to be set. It must be namespace qualified.

Throws:

SOAPException - if there was an error in adding the faultcode element to the underlying XML tree.

Since:

SAAJ 1.3

See Also:
gFaultCodeAsQName(), setFaultCode(Name), getFaultCodeAsQName()
**setFaultCode(String)**

Sets this SOAPFault object with the give fault code.

Fault codes, which given information about the fault, are defined in the SOAP 1.1 specification. This element is mandatory in SOAP 1.1. Because the fault code is required to be a QName it is preferable to use the `setFaultCode(Name)` form of this method.

**Parameters:**
- `faultCode` - a String giving the fault code to be set. It must be of the form "prefix:localName" where the prefix has been defined in a namespace declaration.

**Throws:**
- `SOAPException` - if there was an error in adding the `faultCode` to the underlying XML tree.

**See Also:**
- `setFaultCode(Name)`, `getFaultCode()`,
- `SOAPElement.addNamespaceDeclaration(java.lang.String, java.lang.String)`

---

**public Name getFaultCodeAsName()**

SAAJ Name SOAPFault SOAP 1.1 SOAP 1.1 "faultcode" QName SAAJ Name QName

gFaultCode

return Name
getFaultCodeAsName

Name getFaultCodeAsName()

Gets the mandatory SOAP 1.1 fault code for this SOAPFault object as a SAAJ Name object. The SOAP 1.1 specification requires the value of the "faultcode" element to be of type QName. This method returns the content of the element as a QName in the form of a SAAJ Name object. This method should be used instead of the getFaultCode method since it allows applications to easily access the namespace name without additional parsing.

Returns:
   a Name representing the faultcode

Since:
   SAAJ 1.2

See Also:
   setFaultCode(Name)

public javax.xml.namespace.QName getFaultCodeAsQName

Get the fault code for this SOAPFault object as a QName object.
Returns:
   a QName representing the faultcode

Since:
   SAAJ 1.3

See Also:
   setFaultCode(QName)

---

public java.util.Iterator<E> getFaultSubcodes()

QNames    SOAPFault Subcode

   return    QNames    Iterator    Iterator    remove    Subcode

   Subcode

Throws: UnsupportedOperationException: SOAP 1.2 Subcode
   since: SAAJ 1.3

---

getFaultSubcodes

   Iterator getFaultSubcodes()

   Gets the Subcodes for this SOAPFault as an iterator over QNames.

Returns:
   an Iterator that accesses a sequence of QNames. This Iterator should not support the optional remove method. The order in which the Subcodes are returned reflects the hierarchy of Subcodes present in the fault from top to bottom.

Throws:
   UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Subcode.

Since:
   SAAJ 1.3

---

public void removeAllFaultSubcodes()

   SOAPFault Subcode appendFaultSubcode

getFaultSubcodes

   Throws UnsupportedOperationException: SOAP 1.2 Subcode
removeAllFaultSubcodes

void removeAllFaultSubcodes()

Removes any Subcodes that may be contained by this SOAPFault. Subsequent calls to getFaultSubcodes will return an empty iterator until a call to appendFaultSubcode is made.

Throws:
- `UnsupportedOperationException` - if this message does not support the SOAP 1.2 concept of Subcode.

Since:
- SAAJ 1.3

---

public void appendFaultSubcode(javax.xml.namespace.QName subcode) throws SOAPException

Subcode SOAPFault Subcode SOAP 1.2
Subcode SOAP Fault Code
subcode Subcode QName

Throws
- SOAPException: Subcode
Throws `UnsupportedOperationException`: SOAP 1.2 Subcode
since SAAJ 1.3

---

appendFaultSubcode

void appendFaultSubcode(QName subcode)

throws SOAPException

Adds a Subcode to the end of the sequence of Subcodes contained by this SOAPFault. Subcodes, which were introduced in SOAP 1.2, are represented by a recursive sequence of subelements rooted in the mandatory Code subelement of a SOAP Fault.
Parameters:
  subcode - a QName containing the Value of the Subcode.

Throws:
  SOAPException - if there was an error in setting the Subcode
  UnsupportedOperationException - if this message does not
  support the SOAP 1.2 concept of Subcode.

Since:
  SAAJ 1.3

public String getFaultCode()

SOAPFault
return
See also
getFaultCodeAsName, setFaultCode

getFaultCode

String getFaultCode()

Gets the fault code for this SOAPFault object.

Returns:
  a String with the fault code

See Also:
  getFaultCodeAsName(), setFaultCode(javax.xml.soap.Name)

public void setFaultActor(String faultActor) throws
SOAPException (actor)

SOAPFault

SOAP 1.2

#setFaultRole(String)

faultActor

Throws

SOAPException: faultActor XML
setFaultActor

void setFaultActor(String faultActor) throws SOAPException

Sets this SOAPFault object with the given fault actor.

The fault actor is the recipient in the message path who caused the fault to happen.

If this SOAPFault supports SOAP 1.2 then this call is equivalent to setFaultRole(String)

Parameters:
  faultActor - a String identifying the actor that caused this SOAPFault object

Throws:
  SOAPException - if there was an error in adding the faultActor to the underlying XML tree.

See Also:
  getFaultActor()

public String getFaultActor()

SOAPFault

SOAPFault  SOAP 1.2  #getFaultRole()

return

See also

getFaultActor

String getFaultActor()
Gets the fault actor for this SOAPFault object.

If this SOAPFault supports SOAP 1.2 then this call is equivalent to `getFaultRole()`

**Returns:**

- A String giving the actor in the message path that caused this SOAPFault object

**See Also:**
- `setFaultActor(java.lang.String)`

```java
default void setFaultString(String faultString) throws SOAPException
```

**SOAPFault**

`SOAPFault`  **SOAP 1.2**

```
addFaultReasonText(faultString, Locale.getDefault());
```

**faultString** String

**Throws**  
- `SOAPException`: faultString XML

**See also**
- `getFaultString`

**setFaultString**

```java
void setFaultString(String faultString) throws SOAPException
```

Sets the fault string for this SOAPFault object to the given string.

If this SOAPFault is part of a message that supports SOAP 1.2 then this call is equivalent to:

```
addFaultReasonText(faultString, Locale.getDefault());
```
faultString - a String giving an explanation of the fault

Throws:

SOAPException - if there was an error in adding the faultString to the underlying XML tree.

See Also:

getFaultString()

public void setFaultString(String faultString, java.util.Locale locale) throws SOAPException

SOAPFault

SOAPFault

SOAP 1.2

addFaultReasonText(faultString, locale);

setFaultString

void setFaultString(String faultString, Locale locale) throws SOAPException

Sets the fault string for this SOAPFault object to the given string and localized to the given locale.

If this SOAPFault is part of a message that supports SOAP 1.2 then this call is equivalent to:

addFaultReasonText(faultString, locale);
Parameters:
- faultString - a String giving an explanation of the fault
- locale - a Locale object indicating the native language of the faultString

Throws:
- SOAPException - if there was an error in adding the faultString to the underlying XML tree.

Since:
- SAAJ 1.2

See Also:
- getFaultString()

public String getFaultString()

SOAPFault

SOAPFault SOAP 1.2

String reason = null;
try {
    reason = (String) getFaultReasonTexts().next();
} catch (SOAPException e) {}
return reason;

return

See also setFaultString(String), setFaultString(String, Locale)

g FaultString

String getFaultString()

Gets the fault string for this SOAPFault object.

If this SOAPFault is part of a message that supports SOAP 1.2 then this call is equivalent to:

    String reason = null;
    try {

reason = (String) getFaultReasonTexts().next();
} catch (SOAPException e) {}
return reason;

Returns:

a String giving an explanation of the fault

See Also:

setFaultString(String), setFaultString(String, Locale)

public java.util.Locale getFaultStringLocale()

SOAPFault

SOAPFault  SOAP 1.2

Locale locale = null;
try {
locale = (Locale) getFaultReasonLocales().next();
} catch (SOAPException e) {
return locale;

return Locale null
since SAAJ 1.2
See also setFaultString(String, Locale)

getFaultStringLocale

Locale getFaultStringLocale()

Gets the locale of the fault string for this SOAPFault object.

If this SOAPFault is part of a message that supports SOAP 1.2 then this call is equivalent to:

Locale locale = null;
try {
    locale = (Locale) getFaultReasonLocales().next();
} catch (SOAPException e) {}
return locale;

**Returns:**

A `Locale` object indicating the native language of the fault string or `null` if no locale was specified

**Since:**

SAAJ 1.2

**See Also:**

`setFaultString(String, Locale)`

---

**public boolean hasDetail()**

SOAPFault Detail true false

`(getDetail() != null)`

```
return SOAPFault Detail true false
since SAAJ 1.3
```

**hasDetail**

```java
boolean hasDetail()
```

Returns true if this `SOAPFault` has a `Detail` subelement and false otherwise. Equivalent to `(getDetail() != null)`.

**Returns:**

true if this `SOAPFault` has a `Detail` subelement and false otherwise.

**Since:**

SAAJ 1.3

---

**public `Detail` getDetail()**

SOAPFault detail

```
Detail SOAP 1.1 Fault
return
```

SOAPBodyElement Detail null
getDetail

**Detail getDetail()**

Returns the optional detail element for this SOAPFault object.

A `Detail` object carries application-specific error information, the scope of the error information is restricted to faults in the `SOAPBodyElement` objects if this is a SOAP 1.1 Fault.

**Returns:**

a `Detail` object with application-specific error information if present, null otherwise

---

**public** `Detail` **addDetail() throws SOAPException**

**Detail** `SOAPFault` **Detail**

**return**

**Throws** `SOAPException`: `SOAPFault` **Detail**

---

addDetail

**Detail addDetail() throws SOAPException**

Creates an optional `Detail` object and sets it as the `Detail` object for this `SOAPFault` object.

It is illegal to add a detail when the fault already contains a detail. Therefore, this method should be called only after the existing detail has been removed.

**Returns:**
the new Detail object

**Throws:**
- **SOAPException** - if this SOAPFault object already contains a valid Detail object

```java
public java.util.Iterator<E> getFaultReasonLocales() throws SOAPException
```

<table>
<thead>
<tr>
<th>Iterator</th>
<th>Reason Text</th>
<th>Locale</th>
<th>Locale</th>
</tr>
</thead>
<tbody>
<tr>
<td>getFaultReasonText</td>
<td>Reason Text</td>
<td>Locale</td>
<td>Locale</td>
</tr>
<tr>
<td>return</td>
<td>Iterator Reason Text</td>
<td>Locale</td>
<td></td>
</tr>
</tbody>
</table>

**Throws**
- **SOAPException**: Reason
- **UnsupportedOperationException**: SOAP 1.2 Fault Reason

since SAAJ 1.3

**getFaultReasonLocales**

```java
Iterator getFaultReasonLocales() throws SOAPException
```

Returns an `Iterator` over a distinct sequence of `Locale` objects for which there are associated Reason Text items. Any of these `Locale` objects can be used in a call to `getFaultReasonText` in order to obtain a localized version of the Reason Text string.

**Returns:**
- an `Iterator` over a sequence of `Locale` objects for which there are associated Reason Text items.

**Throws:**
- **SOAPException** - if there was an error in retrieving the fault Reason locales.
- **UnsupportedOperationException** - if this message does not support the SOAP 1.2 concept of Fault Reason.

**Since:**
- SAAJ 1.3
public java.util.Iterator<E> getFaultReasonTexts() throws SOAPException

Iterator SOAPFault Reason Text String
return Iterator env:Fault/env:Reason/env:Text
Throws SOAPException: Reason
Throws UnsupportedOperationException: SOAP 1.2 Fault Reason
since SAAJ 1.3

getFaultReasonTexts

Iterator getFaultReasonTexts() throws SOAPException

Returns an Iterator over a sequence of String objects containing all of the Reason Text items for this SOAPFault.

Throws: SOAPException - if there was an error in retrieving the fault Reason texts.
UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Reason.
Since: SAAJ 1.3

public String getFaultReasonText(java.util.Locale locale) throws SOAPException

Locale Reason Text Reason Text Text
Reason Text
locale Reason Text Locale
return locale Reason Text
Throws SOAPException: Reason
UnsupportedOperationException: SOAP 1.2 Fault
getFaultReasonText

String getFaultReasonText(Locale locale)
throws SOAPException

Returns the Reason Text associated with the given Locale. If more than one such Reason Text exists the first matching Text is returned

Parameters:
locale -- the Locale for which a localized Reason Text is desired

Returns:
the Reason Text associated with locale

Throws:
SOAPException - if there was an error in retrieving the fault Reason text for the specified locale.
UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Reason.

Since:
SAAJ 1.3

See Also:
getFaultString()

public void addFaultReasonText(String text, java.util.Locale locale) throws SOAPException

Reason Text locale
Reason Text text locale null

SOAPFault fault = ...;
void addFaultReasonText(String text,
        Locale locale)
    throws SOAPException

Appends or replaces a Reason Text item containing the specified text message and an xml:lang derived from locale. If a Reason Text item with this xml:lang already exists its text value will be replaced with text. The locale parameter should not be null

Code sample:

SOAPFault fault = ...;
fault.addFaultReasonText("Version Mismatch", Locale.ENGLISH);

Parameters:

text - -- reason message string
locale - -- Locale object representing the locale of the message

Throws:

SOAPException - if there was an error in adding the Reason text or the locale passed was null.

UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Reason.

Since:

SAAJ 1.3
public String getFaultNode()

SOAPFault  Node Node  SOAP 1.2

    return String env:Fault/env:Node  null

Throws UnsupportedOperationException:  SOAP 1.2  Fault Node
since  SAAJ 1.3

getFaultNode

String getFaultNode()

    Returns the optional Node element value for this SOAPFault object. The Node element is optional in SOAP 1.2.

    Returns:
    Content of the env:Fault/env:Node element as a String or null if none

    Throws:
    UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Node.

Since:
    SAAJ 1.3

public void setFaultNode(String uri) throws SOAPException

SOAPFault  Node Node  SOAP 1.2

    Throws  SOAPException:  SOAPFault  Node

    Throws UnsupportedOperationException:  SOAP 1.2  Fault Node

since  SAAJ 1.3

setFaultNode

void setFaultNode(String uri)
    throws SOAPException
Creates or replaces any existing Node element value for this SOAPFault object. The Node element is optional in SOAP 1.2.

Throws:

SOAPException - if there was an error in setting the Node for this SOAPFault object.
UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Node.

Since:
SAAJ 1.3

public String getFaultRole()

SOAPFault  Role Role  SOAP 1.2

dereturn String env:Fault/env:Role
null

Throws UnsupportedOperationException: SOAP 1.2  Fault Role

since SAAJ 1.3

getFaultRole

String getFaultRole()

Returns the optional Role element value for this SOAPFault object. The Role element is optional in SOAP 1.2.

Returns:

Content of the env:Fault/env:Role element as a String or null if none

Throws:

UnsupportedOperationException - if this message does not support the SOAP 1.2 concept of Fault Role.

Since:
SAAJ 1.3

public void setFaultRole(String uri) throws SOAPException

SOAPFault  Role Role  SOAP 1.2
setFaultRole

void setFaultRole(String uri)

throws SOAPException

Creates or replaces any existing Role element value for this
SOAPFault object. The Role element is optional in SOAP 1.2.

Parameters:
uri - the URI of the Role

Throws:
SOAPException - if there was an error in setting the Role for this
SOAPFault object.
UnsupportedOperationException - if this message does not
support the SOAP 1.2 concept of Fault Role.

Since:
SAAJ 1.3
javax.xml.soap  Interface SOAPFaultElement

All Superinterfaces:  
   Element, Node, SOAPElement

All Known Subinterfaces:  
   Detail

public interface SOAPFaultElement  
extends SOAPElement

Implements: SOAPElement  
Implemented by: Detail

SOAPFault Detail SOAPFaultElement

   SOAPElement addTextNode SOAPFaultElement

A representation of the contents in a SOAPFault object. The Detail interface is a SOAPFaultElement.

Content is added to a SOAPFaultElement using the SOAPElement method addTextNode.

  │   └ java.lang.RuntimeException  
  └ javax.xml.rpc.soap.SOAPFaultException

All Implemented Interfaces:  Serializable

public class SOAPFaultException
  extends RuntimeException

Extends:  Throwable > Exception > RuntimeException

SOAPFaultException  SOAP

SOAP  faultdetail  SOAPFaultException  getDetail
  javax.xml.soap.SOAPFactory  createDetail
javax.xml.soap.Detail

faultstring  SOAP  faultcode  SOAP

SOAP  SOAP 1.1  WSDL 1.1
  version  1.0

See also  javax.xml.soap.Detail, createDetail

The SOAPFaultException exception represents a SOAP fault.

The message part in the SOAP fault maps to the contents of faultdetail element accessible through the getDetail method on the SOAPFaultException. The method createDetail on the javax.xml.soap.SOAPFactory creates an instance of the javax.xml.soap.Detail.
The faultstring provides a human-readable description of the SOAP fault. The faultcode element provides an algorithmic mapping of the SOAP fault.

Refer to SOAP 1.1 and WSDL 1.1 specifications for more details of the SOAP faults.

SOAPFaultException

public SOAPFaultException(QName faultcode, String faultstring, String faultactor, Detail faultdetail)

Constructor for the SOAPFaultException

Parameters:

faultCode - QName for the SOAP faultcode
faultstring - faultstring element of SOAP fault
faultactor - faultactor element of SOAP fault
faultdetail - faultdetail element of SOAP fault

See Also:
SOAPFactory.createDetail()
public javax.xml.namespace.QName getFaultCode()

    faultcode  faultcode SOAP  SOAP  SOAP

    return  faultcode  QName

getAddress

public QName getFaultCode()

    Gets the faultcode element. The faultcode element provides an algorithmic mechanism for identifying the fault. SOAP defines a small set of SOAP fault codes covering basic SOAP faults.

    Returns:
    QName of the faultcode element

public String getFaultString()

    faultstring  faultstring  SOAP
    return  SOAP  faultstring

getAddress

public String getFaultString()

    Gets the faultstring element. The faultstring provides a human-readable description of the SOAP fault and is not intended for algorithmic processing.

    Returns:
    faultstring element of the SOAP fault

public String getFaultActor()

    faultactor  faultactor  SOAP  SOAP
**getFaultActor**

```java
public String getFaultActor()
```

Gets the `faultactor` element. The `faultactor` element provides information about which SOAP node on the SOAP message path caused the fault to happen. It indicates the source of the fault.

**Returns:**
`faultactor` element of the SOAP fault

See also javax.xml.soap.Detail, createDetail

The SOAPFaultException exception represents a SOAP 1.1 or 1.2 fault.

A SOAPFaultException wraps a SAAJ SOAPFault that manages the SOAP-specific representation of faults. The createFault method of javax.xml.soap.SOAPFactory may be used to create an instance of javax.xml.soap.SOAPFault for use with the constructor. SOAPBinding
contains an accessor for the SOAPFactory used by the binding instance.

Note that the value of getFault is the only part of the exception used when searializing a SOAP fault.

Refer to the SOAP specification for a complete description of SOAP faults.

Since:
JAX-WS 2.0

Implements: SOAPElement

SOAP SOAP XML

SOAPEnvelope SOAPHeader SOAPHeader SE
SOAPEnvelope

se.getHeader().detachNode();

SOAPHeader SOAPEnvelope addHeader

se.getHeader().detachNode();
SOAPHeader sh = se.addHeader();

SOAPHeader SOAPHeaderElement addHeaderElement
HeaderElement SOAPHeader addHeaderElement Name
HeaderElement

SOAPHeaderElement shElement = sh.addHeaderElement(name);

See also  javax.xml.soap.SOAPHeaderElement

A representation of the SOAP header element. A SOAP header element consists of XML data that affects the way the application-specific content is processed by the message provider. For example, transaction semantics, authentication information, and so on, can be specified as the content of a SOAPHeader object.
A SOAPEnvelope object contains an empty SOAPHeader object by default. If the SOAPHeader object, which is optional, is not needed, it can be retrieved and deleted with the following line of code. The variable se is a SOAPEnvelope object.

```java
se.getHeader().detachNode();
```

A SOAPHeader object is created with the SOAPEnvelope method `addHeader`. This method, which creates a new header and adds it to the envelope, may be called only after the existing header has been removed.

```java
se.getHeader().detachNode();
SOAPHeader sh = se.addHeader();
```

A SOAPHeader object can have only SOAPHeaderElement objects as its immediate children. The method `addHeaderElement` creates a new HeaderElement object and adds it to the SOAPHeader object. In the following line of code, the argument to the method `addHeaderElement` is a Name object that is the name for the new HeaderElement object.

```java
SOAPHeaderElement shElement = sh.addHeaderElement(name);
```

Method Detail

public SOAPHeaderElement addHeaderElement(Name name) throws SOAPException

<table>
<thead>
<tr>
<th>name</th>
<th>SOAPHeaderElement</th>
<th>SOAPHeader</th>
</tr>
</thead>
</table>

Throws

SOAPException: SOAP
See also

addHeaderElement(javax.xml.namespace.QName)
addHeaderElement

SOAPHeaderElement addHeaderElement(Name name)
throws SOAPException

Creates a new SOAPHeaderElement object initialized with the specified name and adds it to this SOAPHeader object.

Parameters:
   name - a Name object with the name of the new SOAPHeaderElement object

Returns:
   the new SOAPHeaderElement object that was inserted into this SOAPHeader object

Throws:
   SOAPException - if a SOAP error occurs

See Also:
   addHeaderElement(javax.xml.namespace.QName)

public SOAPHeaderElement addHeaderElement(javax.xml.namespace.QName qname)
throws SOAPException

qname   SOAPHeaderElement    SOAPHeader

   qname    SOAPHeaderElement    qname    QName
return    SOAPHeader    SOAPHeaderElement

Throws:
   SOAPException: SOAP
since    SAAJ 1.3
See also
   addHeaderElement(Name)

addHeaderElement

SOAPHeaderElement addHeaderElement(QName qname)
throws SOAPException
Creates a new SOAPHeaderElement object initialized with the specified qname and adds it to this SOAPHeader object.

Parameters:
  qname - a QName object with the qname of the new SOAPHeaderElement object

Returns:
  the new SOAPHeaderElement object that was inserted into this SOAPHeader object

Throws:
  SOAPException - if a SOAP error occurs

Since:
  SAAJ 1.3

See Also:
  addHeaderElement(Name)

public java.util.Iterator<E>
examineMustUnderstandHeaderElements(String actor)

  SOAPHeader  SOAPHeaderElement  Iterator  actor
  true  MustUnderstand

SOAP 1.2      env:actor  env:role
  actor  String  actor/role  URI
return  Iterator  SOAPHeaderElement  actor / role
since  MustUnderstand  SAAJ 1.2
See  examineHeaderElements, extractHeaderElements,
also  URI_SOAP_ACTOR_NEXT

examineMustUnderstandHeaderElements

Iterator examineMustUnderstandHeaderElements(String actor)

  Returns an Iterator over all the SOAPHeaderElement objects in this
SOAPHeader object that have the specified actor and that have a
MustUnderstand attribute whose value is equivalent to true.

In SOAP 1.2 the `env:actor` attribute is replaced by the `env:role` attribute, but with essentially the same semantics.

**Parameters:**
- `actor` - a String giving the URI of the actor / role for which to search

**Returns:**
- an Iterator object over all the SOAPHeaderElement objects that contain the specified actor / role and are marked as MustUnderstand

**Since:**
- SAAJ 1.2

**See Also:**
- `examineHeaderElements(java.lang.String)`, `extractHeaderElements(java.lang.String)`, `SOAPConstants.URI_SOAP_ACTOR_NEXT`

```java
public java.util.Iterator<E> examineHeaderElements(String actor)
```

```
SOAPHeader actor SOAPHeaderElement Iterator
actor actor actor
actor message
```

**SOAP 1.2**

```
env:actor env:role
actor String actor/role URI
return Iterator actor / role SOAPHeaderElement
See also extractHeaderElements, URI_SOAP_ACTOR_NEXT
```

**examineHeaderElements**

```java
Iterator examineHeaderElements(String actor)
```

Returns an Iterator over all the SOAPHeaderElement objects in this
SOAPHeader object that have the specified `actor`. An `actor` is a global attribute that indicates the intermediate parties that should process a message before it reaches its ultimate receiver. An actor receives the message and processes it before sending it on to the next actor. The default actor is the ultimate intended recipient for the message, so if no `actor` attribute is included in a `SOAPHeader` object, it is sent to the ultimate receiver along with the message body.

In SOAP 1.2 the `env:actor` attribute is replaced by the `env:role` attribute, but with essentially the same semantics.

**Parameters:**
- `actor` - a `String` giving the URI of the `actor`/`role` for which to search

**Returns:**
- an `Iterator` object over all the `SOAPHeaderElement` objects that contain the specified `actor`/`role`

**See Also:**
- `extractHeaderElements(java.lang.String)`, `SOAPConstants.URI_SOAP_ACTOR_NEXT`

```java
public java.util.Iterator<E> extractHeaderElements(String actor)
```

**SOAP 1.2**
```
env:actor    env:role
actor        String    actor/role    URI
return       Iterator    actor/role    SOAPHeaderElement
See also     examineHeaderElements, URI_SOAP_ACTOR_NEXT
```

`extractHeaderElements`
Iterator extractHeaderElements(String actor)

Returns an Iterator over all the SOAPHeaderElement objects in this SOAPHeader object that have the specified actor and detaches them from this SOAPHeader object.

This method allows an actor to process the parts of the SOAPHeader object that apply to it and to remove them before passing the message on to the next actor.

In SOAP 1.2 the env:actor attribute is replaced by the env:role attribute, but with essentially the same semantics.

Parameters:
actor - a String giving the URI of the actor / role for which to search

Returns:
an Iterator object over all the SOAPHeaderElement objects that contain the specified actor / role

See Also:
examineHeaderElements(java.lang.String), SOAPConstants.URI_SOAP_ACTOR_NEXT

public SOAPHeaderElement addNotUnderstoodHeaderElement(javax.xml.namespace.QName name) throws SOAPException
NotUnderstood
SOAP 1.2

name SOAPHeaderElement QName
return SOAPHeader SOAPHeaderElement

Throws SOAPException: SOAP

Throws UnsupportedOperationException: SOAP 1.1 Header

since SAAJ 1.3
**SOAPHeaderElement addNotUnderstoodHeaderElement(QName name)**

Throws **SOAPException**

Creates a new NotUnderstood SOAPHeaderElement object initialized with the specified name and adds it to this SOAPHeader object. This operation is supported only by SOAP 1.2.

**Parameters:**

name - a QName object with the name of the SOAPHeaderElement object that was not understood.

**Returns:**

the new SOAPHeaderElement object that was inserted into this SOAPHeader object

**Throws:**

**SOAPException** - if a SOAP error occurs.

**UnsupportedOperationException** - if this is a SOAP 1.1 Header.

**Since:**

SAAJ 1.3

---

**public SOAPHeaderElement addUpgradeHeaderElement(java.util.Iterator<E> supportedSOAPURIs) throws SOAPException**

SOAP URI Upgrade

**SOAPHeader SOAP 1.1 SOAP 1.2**

**supportedSOAPURIs** SOAP URI Iterator

**return** SOAPHeader SOAPHeaderElement

**Throws** **SOAPException**: SOAP

**since** SAAJ 1.3

**addUpgradeHeaderElement**

Creates a new Upgrade SOAPHeaderElement object initialized with the specified List of supported SOAP URIs and adds it to this SOAPHeader
object. This operation is supported on both SOAP 1.1 and SOAP 1.2 header.

**Parameters:**

- supportedSOAPURIs - an Iterator object with the URIs of SOAP versions supported.

**Returns:**

- the new SOAPHeaderElement object that was inserted into this SOAPHeader object

**Throws:**

- SOAPException - if a SOAP error occurs.

**Since:**

SAAJ 1.3

```java
public SOAPHeaderElement addUpgradeHeaderElement(String[] supportedSoapUris)
throws SOAPException
```

**SOAP URI** Upgrade

**SOAPHeader** SOAP 1.1 SOAP 1.2

**supportedSoapUris** SOAP URI

**return** SOAPHeader SOAPHeaderElement

**Throws** SOAPException SOAP

**since** SAAJ 1.3

---

**addUpgradeHeaderElement**

```
SOAPHeaderElement addUpgradeHeaderElement(String[] supportedSoapUris)
throws SOAPException
```

Creates a new Upgrade SOAPHeaderElement object initialized with the specified array of supported SOAP URIs and adds it to this SOAPHeader object. This operation is supported on both SOAP 1.1 and SOAP 1.2 header.

**Parameters:**

- supportedSoapUris - an array of the URIs of SOAP versions
public SOAPHeaderElement addUpgradeHeaderElement(String supportedSoapUri) throws SOAPException

SOAP URI Upgrade

SOAPHeader SOAP 1.1 SOAP 1.2

<table>
<thead>
<tr>

<tr>
<td>since</td>
<td>SAAJ 1.3</td>
</tr>
</tbody>
</table>

addUpgradeHeaderElement

SOAPHeaderElement addUpgradeHeaderElement(String supportedSoapUri) throws SOAPException

Creates a new Upgrade SOAPHeaderElement object initialized with the specified supported SOAP URI and adds it to this SOAPHeader object. This operation is supported on both SOAP 1.1 and SOAP 1.2 header.

Parameters:

- supportedSoapUri - the URI of SOAP the version that is supported.

Returns:

- the new SOAPHeaderElement object that was inserted into this SOAPHeader object

Throws:
**SOAPException** - if a SOAP error occurs.

**Since:**
SAAJ 1.3

PS:
javax.xml.soap Interface SOAPHeaderElement

All Superinterfaces:
   Element, Node, SOAPElement

public interface SOAPHeaderElement
   extends SOAPElement

Implements: SOAPElement

SOAP  SOAP
   SOAPHeader  SOAPHeaderElement
   SOAPHeaderElement  SOAPElement

An object representing the contents in the SOAP header part of the SOAP envelope. The immediate children of a SOAPHeader object can be represented only as SOAPHeaderElement objects.

A SOAPHeaderElement object can have other SOAPElement objects as its children.

public void setActor(String actorURI)

SOAPHeaderElement actor actor
SOAPConstants.URI_SOAP_ACTOR_NEXT

SOAPHeaderElement actorURI actor URI
Throws IllegalArgumentException: actor
See also getActor

setActor

void setActor(String actorURI)

Sets the actor associated with this SOAPHeaderElement object to the specified actor. The default value of an actor is:
SOAPConstants.URI_SOAP_ACTOR_NEXT

If this SOAPHeaderElement supports SOAP 1.2 then this call is equivalent to setRole(String)

Parameters:
actorURI - a String giving the URI of the actor to set

Throws:
IllegalArgumentException - if there is a problem in setting the actor.

See Also:
getActor()

public void setRole(String uri) throws SOAPException
setRole

```java
void setRole(String uri)
    throws SOAPException
```

Sets the Role associated with this SOAPHeaderElement object to the specified Role.

**Parameters:**
- `uri` -- the URI of the Role

**Throws:**
- `SOAPException` - if there is an error in setting the role
- `UnsupportedOperationException` - if this message does not support the SOAP 1.2 concept of Fault Role.

**Since:**
- SAAJ 1.3

---

getActor

```java
public String getActor()
```

**See also**
- `setActor`
Returns the uri of the *actor* attribute of this SOAPHeaderElement.

If this SOAPHeaderElement supports SOAP 1.2 then this call is equivalent to *getRole(*)

**Returns:**
a String giving the URI of the actor

**See Also:**
*setActor(java.lang.String)*

### public String getRole()

**SOAPHeaderElement** *Role*

**return**

Role URI  String

**Throws** UnsupportedOperation Exception: SOAP 1.2 Fault Role

**since**  SAAJ 1.3

getRole

**String** getRole()

Returns the value of the *Role* attribute of this SOAPHeaderElement.

**Returns:**
a String giving the URI of the Role

**Throws:**
  *UnsupportedOperationException* - if this message does not support the SOAP 1.2 concept of Fault Role.

**Since:**
  SAAJ 1.3

### public void setMustUnderstand(boolean mustUnderstand)

**SOAPHeaderElement** *mustUnderstand*  true  false

**mustUnderstand**

**SOAPHeaderElement**
public boolean getMustUnderstand()

SOAPHeaderElement mustUnderstand boolean

return SOAPHeaderElement mustUnderstand true false

getMustUnderstand

boolean getMustUnderstand()
Returns the boolean value of the mustUnderstand attribute for this SOAPHeaderElement.

Returns:
true if the mustUnderstand attribute of this SOAPHeaderElement object is turned on; false otherwise

```java
public void setRelay(boolean relay) throws SOAPException

SOAPHeaderElement  relay  true  false
SOAP relay  true  SOAP mustUnderstand  false

relay  relay
Throws  SOAPException: relay
Throws  UnsupportedOperationException: SOAP 1.2  Relay
since  SAAJ 1.3
See also  setMustUnderstand, getRelay
```

**setRelay**

```java
void setRelay(boolean relay)
throws SOAPException
```

Sets the relay attribute for this SOAPHeaderElement to be either true or false.

The SOAP relay attribute is set to true to indicate that the SOAP header block must be relayed by any node that is targeted by the header block but not actually process it. This attribute is ignored on header blocks whose mustUnderstand attribute is set to true or that are targeted at the ultimate reciever (which is the default). The default value of this attribute is false.

**Parameters:**
relay - the new value of the relay attribute
Throws:

- SOAPException - if there is a problem in setting the relay attribute.
- UnsupportedOperationExceptio

Since:
SAAJ 1.3

See Also:

setMustUnderstand(boolean), getRelay()
Submit a bug or feature

PS:
javax.xml.soap  Class SOAPMessage

  java.lang.Object
   javax.xml.soap.SOAPMessage

  public abstract class SOAPMessage
  extends Object

  SOAP  SOAP "" XML   XML/SOAP  MIME

  SOAPMessage  SOAP  SOAPMessage  SOAP  SOAPPart
  SOAP  XML

  SOAPMessage

  •  SOAPPart
  •  SOAPEnvelope
  •  SOAPBody
  •  SOAPHeader

  SOAPMessage.getSOAPPart()  SOAP  SOAPEnvelope  SOA
  SOAPEnvelope  SOAPBody  SOAPHeader

  SOAPPart sp = message.getSOAPPart();
  SOAPEnvelope se = sp.getEnvelope();
  SOAPBody sb = se.getBody();
  SOAPHeader sh = se.getHeader();

  SOAPMessage  SOAP  SOAPMessage  AttachmentPart  AttachmentPart
  SOAPMessage  AttachmentPart  SOAPMessage

  SOAP  XML  XML

  MessageFactory  SAAJ  SOAPMessage  MessageFactory
  ebXML  SOAPMessage  MessageFactory  ebXML
The root class for all SOAP messages. As transmitted on the "wire", a SOAP message is an XML document or a MIME message whose first body part is an XML/SOAP document.

A SOAPMessage object consists of a SOAP part and optionally one or more attachment parts. The SOAP part for a SOAPMessage object is a SOAPPart object, which contains information used for message routing and identification, and which can contain application-specific content. All data in the SOAP Part of a message must be in XML format.

A new SOAPMessage object contains the following by default:

- A SOAPPart object
- A SOAPEnvelope object
- A SOAPBody object
- A SOAPHeader object

The SOAP part of a message can be retrieved by calling the method SOAPMessage.getSOAPPart(). The SOAPEnvelope object is retrieved from the SOAPPart object, and the SOAPEnvelope object is used to retrieve the SOAPBody and SOAPHeader objects.

```java
SOAPPart sp = message.getSOAPPart();
SOAPEnvelope se = sp.getEnvelope();
SOAPBody sb = se.getBody();
SOAPHeader sh = se.getHeader();
```

In addition to the mandatory SOAPPart object, a SOAPMessage object may contain zero or more AttachmentPart objects, each of which contains application-specific data. The SOAPMessage interface provides methods for
creating `AttachmentPart` objects and also for adding them to a `SOAPMessage` object. A party that has received a `SOAPMessage` object can examine its contents by retrieving individual attachment parts.

Unlike the rest of a SOAP message, an attachment is not required to be in XML format and can therefore be anything from simple text to an image file. Consequently, any message content that is not in XML format must be in an `AttachmentPart` object.

A `MessageFactory` object may create `SOAPMessage` objects with behavior that is specialized to a particular implementation or application of SAAJ. For instance, a `MessageFactory` object may produce `SOAPMessage` objects that conform to a particular Profile such as ebXML. In this case a `MessageFactory` object might produce `SOAPMessage` objects that are initialized with ebXML headers.

In order to ensure backward source compatibility, methods that are added to this class after version 1.1 of the SAAJ specification are all concrete instead of abstract and they all have default implementations. Unless otherwise noted in the JavaDocs for those methods the default implementations simply throw an `UnsupportedOperationException` and the SAAJ implementation code must override them with methods that provide the specified behavior. Legacy client code does not have this restriction, however, so long as there is no claim made that it conforms to some later version of the specification than it was originally written for. A legacy class that extends the `SOAPMessage` class can be compiled and/or run against succeeding versions of the SAAJ API without modification. If such a class was correctly implemented then it will continue to behave correctly relative to the version of the specification against which it was written.

**See Also:**

`MessageFactory`, `AttachmentPart`

### Field Summary

| static String | `CHARACTER_SET_ENCODING` | Specifies the character type encoding for the SOAP |
| static String WRITE_XML_DECLARATION | Specifies whether the SOAP Message will contain an XML declaration when it is sent. |

**Constructor Summary**

**SOAPMessage()**

**Method Summary**

**abstract void addAttachmentPart(AttachmentPart AttachmentPart)**

Adds the given AttachmentPart object to this SOAPMessage object.

**abstract int countAttachments()**

Gets a count of the number of attachments in this message.

**abstract AttachmentPart createAttachmentPart()**

Creates a new empty AttachmentPart object.

**AttachmentPart createAttachmentPart(DataHandler dataHandler)**

Creates an AttachmentPart object and populates it using the given DataHandler object.

**AttachmentPart createAttachmentPart(Object content, String contentType)**

Creates an AttachmentPart object and populates it with the specified data of the specified content type.

**abstract AttachmentPart getAttachment(SOAPElement element)**

Returns an AttachmentPart object that is associated with an attachment that is referenced by this SOAPElement or null if no such attachment exists.

**abstract Iterator getAttachments()**

Retrieves all the AttachmentPart objects that are part of this SOAPMessage object.

**abstract Iterator getAttachments(MimeHeaders headers)**

Retrieves all the AttachmentPart objects that have
header entries that match the specified headers.

abstract String getContentDescription()
       Retrieves a description of this SOAPMessage object's content.

abstract MimeHeaders getMimeHeaders()
       Returns all the transport-specific MIME headers for this SOAPMessage object in a transport-independent fashion.

Object getProperty(String property)
       Retrieves value of the specified property.

SOAPBody getSOAPBody()
       Gets the SOAP Body contained in this SOAPMessage object.

SOAPHeader getSOAPHeader()
       Gets the SOAP Header contained in this SOAPMessage object.

abstract SOAPPart getSOAPPart()
       Gets the SOAP part of this SOAPMessage object.

abstract void removeAllAttachments()
       Removes all AttachmentPart objects that have been added to this SOAPMessage object.

abstract void removeAttachments(MimeHeaders headers)
       Removes all the AttachmentPart objects that have header entries that match the specified headers.

abstract void saveChanges()
       Updates this SOAPMessage object with all the changes that have been made to it.

abstract boolean saveRequired()
       Indicates whether this SOAPMessage object needs to have the method saveChanges called on it.

abstract void setContentDescription(String description)
       Sets the description of this SOAPMessage object's content with the given description.

void setProperty(String property, Object value)
       Associates the specified value with the specified property.
abstract void writeTo(OutputStream out)

Writes this SOAPMessage object to the given output stream.

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Field Detail

CHARACTER_SET_ENCODING

public static final String CHARACTER_SET_ENCODING

Specifies the character type encoding for the SOAP Message. Valid values include "utf-8" and "utf-16". See vendor documentation for additional supported values. The default is "utf-8".

Since:
SAAJ 1.2

See Also:
SOAPMessage.setProperty, Constant Field Values

WRITE_XML_DECLARATION

public static final String WRITE_XML_DECLARATION

Specifies whether the SOAP Message will contain an XML declaration when it is sent. The only valid values are "true" and "false". The default is "false".

Since:
public SOAPMessage()

SOAPMessage

public SOAPMessage()

Method Detail

setContentDescription

public abstract void setContentDescription(String description)

Sets the description of this SOAPMessage object's content with the given description.

Parameters:

description - a String describing the content of this message

See Also:

g getContentDescription()

getContentDescription

public abstract String getContentDescription()

Retrieves a description of this SOAPMessage object's content.
Returns:
a String describing the content of this message or null if no description has been set

See Also:
setContentDescription(java.lang.String)

getSOAPPart

public abstract SOAPPart getSOAPPart()

Gets the SOAP part of this SOAPMessage object.

SOAPMessage object contains one or more attachments, the SOAP Part must be the first MIME body part in the message.

Returns:
the SOAPPart object for this SOAPMessage object

getSOAPBody

public SOAPBody getSOAPBody()

throws SOAPException

Gets the SOAP Body contained in this SOAPMessage object.

Returns:
the SOAPBody object contained by this SOAPMessage object

Throws:
SOAPException - if the SOAP Body does not exist or cannot be retrieved

Since:
SAAJ 1.2
getSOAPHeader

public SOAPHeader getSOAPHeader() throws SOAPException

Gets the SOAP Header contained in this SOAPMessage object.

**Returns:**
the SOAPHeader object contained by this SOAPMessage object

**Throws:**
SOAPException - if the SOAP Header does not exist or cannot be retrieved

**Since:**
SAAJ 1.2

---

abstract public void removeAllAttachments()

SOAPMessage AttachmentPart

SOAP

removeAllAttachments

public abstract void removeAllAttachments()

Removes all AttachmentPart objects that have been added to this SOAPMessage object.

This method does not touch the SOAP part.

---

abstract public int countAttachments()

SOAP

return SOAPMessage AttachmentPart
**countAttachments**

```java
public abstract int countAttachments()
```

Gets a count of the number of attachments in this message. This count does not include the SOAP part.

**Returns:**
- the number of AttachmentPart objects that are part of this SOAPMessage object

---

**getAttachments**

```java
public abstract Iterator getAttachments()
```

Retrieves all the AttachmentPart objects that are part of this SOAPMessage object.

**Returns:**
- an iterator over all the attachments in this message

---

**getAttachments**

```java
public abstract Iterator getAttachments(MimeHeaders headers)
```

Retrieves all the AttachmentPart objects that have header entries that match the specified headers. Note that a returned attachment could have headers in addition to those specified.

**Parameters:**
- headers - a MimeHeaders object containing the MIME headers for which to search
Returns:
an iterator over all attachments that have a header that matches
one of the given headers

abstract public void removeAttachments(MimeHeaders headers)

Parameters:
headers - a MimeHeaders object containing the MIME headers for
which to search

Since:
SAAJ 1.3

abstract public AttachmentPart getAttachment(SOAPElemen...
getAttachment

public abstract AttachmentPart getAttachment(SOAPElement element) throws SOAPException

Returns an AttachmentPart object that is associated with an attachment that is referenced by this SOAPElement or null if no such attachment exists. References can be made via an href attribute as described in SOAP Messages with Attachments, or via a single Text child node containing a URI as described in the WS-I Attachments Profile 1.0 for elements of schema type ref:swaRef(ref:swaRef). These two mechanisms must be supported. The support for references via href attribute also implies that this method should also be supported on an element that is an xop:Include element (XOP). other reference mechanisms may be supported by individual implementations of this standard. Contact your vendor for details.

Parameters:

    element - The SOAPElement containing the reference to an Attachment

Returns:

    the referenced AttachmentPart or null if no such AttachmentPart exists or no reference can be found in this SOAPElement.
abstract public void addAttachmentPart(AttachmentPart AttachmentPart)

    attachment - if there is an error in the attempt to access the attachment

Since: SAAJ 1.3

abstract public AttachmentPart createAttachmentPart()

    return SOAPMessage AttachmentPart

createAttachmentPart

addAttachmentPart

public abstract void addAttachmentPart(AttachmentPart AttachmentPart)

Adds the given AttachmentPart object to this SOAPMessage object. An AttachmentPart object must be created before it can be added to a message.

Parameters:
    AttachmentPart - an AttachmentPart object that is to become part of this SOAPMessage object

Throws:
    IllegalArgumentException

public abstract AttachmentPart createAttachmentPart()

Creates a new empty AttachmentPart object. Note that the method addAttachmentPart must be called with this new AttachmentPart object as the parameter in order for it to become an attachment to this SOAPMessage object.

Returns:

a new AttachmentPart object that can be populated and added to this SOAPMessage object

public AttachmentPart createAttachmentPart(DataHandler dataHandler)

createAttachmentPart

public AttachmentPart createAttachmentPart(DataHandler dataHandler)

Creates an AttachmentPart object and populates it using the given DataHandler object.

Parameters:

dataHandler - the javax.activation.DataHandler object that will generate the content for this SOAPMessage object

Returns:

a new AttachmentPart object that contains data generated by the given DataHandler object

Throws:

IllegalArgumentException - if there was a problem with the specified DataHandler object

See also

javax.activation.DataHandler,
javax.activation.DataContentHandler
See Also:
DataHandler, DataContentHandler

getMimeHeaders

```java
public abstract MimeHeaders getMimeHeaders()
```

Returns all the transport-specific MIME headers for this SOAPMessage object in a transport-independent fashion.

Returns:

a MimeHeaders object containing the MimeHeader objects

```java
public AttachmentPart createAttachmentPart(Object content, String contentType)
```

Creates an AttachmentPart object and populates it with the specified data of the specified content type. The type of the Object should correspond to the value given for the Content-Type.

Parameters:

Throws

IllegalArgumentException: contentType

See also

javax.activation.DataHandler, javax.activation.DataContentHandler

createAttachmentPart

```java
public AttachmentPart createAttachmentPart(Object content, String contentType)
```

Creates an AttachmentPart object and populates it with the specified data of the specified content type. The type of the Object should correspond to the value given for the Content-Type.

Parameters:
content - an Object containing the content for the AttachmentPart object to be created
contentType - a String object giving the type of content; examples are "text/xml", "text/plain", and "image/jpeg"

Returns:
a new AttachmentPart object that contains the given data

Throws:
IllegalArgumentException - may be thrown if the contentType does not match the type of the content object, or if there was no DataContentHandler object for the given content object

See Also:
DataHandler, DataContentHandler

abstract public void saveChanges() throws SOAPException

saveChanges
saveChanges id
Messageld
saveChanges MIME
AttachmentPart

Throws
SOAPException:

saveChanges

public abstract void saveChanges() throws SOAPException

Updates this SOAPMessage object with all the changes that have been made to it. This method is called automatically when writeTo(OutputStream) is called. However, if changes are made to a message that was received or to one that has already been sent, the method saveChanges needs to be called explicitly in order to save the changes. The method saveChanges also generates any changes that can be read back (for example, a Messageld in profiles that support
a message id). All MIME headers in a message that is created for sending purposes are guaranteed to have valid values only after saveChanges has been called.

In addition, this method marks the point at which the data from all constituent AttachmentPart objects are pulled into the message.

**Throws:**

- SOAPException - if there was a problem saving changes to this message.

```java
abstract public boolean saveRequired()

public abstract boolean saveRequired()

Indicates whether this SOAPMessage object needs to have the method saveChanges called on it.

Returns:

- true if saveChanges needs to be called; false otherwise.
```

```java
abstract public void writeTo(java.io.OutputStream out)

throws SOAPException, java.io.IOException

XML MIME

MIME Header

Throws java.io.IOException: I/O *
writeTo

public abstract void writeTo(OutputStream out)
   throws SOAPException, IOException

Writes this SOAPMessage object to the given output stream. The externalization format is as defined by the SOAP 1.1 with Attachments specification.

If there are no attachments, just an XML stream is written out. For those messages that have attachments, writeTo writes a MIME-encoded byte stream.

Note that this method does not write the transport-specific MIME Headers of the Message

Parameters:
   out - the OutputStream object to which this SOAPMessage object will be written

Throws:
   IOException - if an I/O error occurs
   SOAPException - if there was a problem in externalizing this SOAP message

setProperty

public void setProperty(String property, Object value)
   throws SOAPException

Associates the specified value with the specified property. If there was already a value associated with this property, the old value is
The valid property names include `WRITE_XML_DECLARATION` and `CHARACTER_SET_ENCODING`. All of these standard SAAJ properties are prefixed by "javax.xml.soap". Vendors may also add implementation specific properties. These properties must be prefixed with package names that are unique to the vendor.

Setting the property `WRITE_XML_DECLARATION` to "true" will cause an XML Declaration to be written out at the start of the SOAP message. The default value of "false" suppresses this declaration.

The property `CHARACTER_SET_ENCODING` defaults to the value "utf-8" which causes the SOAP message to be encoded using UTF-8. Setting `CHARACTER_SET_ENCODING` to "utf-16" causes the SOAP message to be encoded using UTF-16.

Some implementations may allow encodings in addition to UTF-8 and UTF-16. Refer to your vendor's documentation for details.

**Parameters:**
- `property` - the property with which the specified value is to be associated.
- `value` - the value to be associated with the specified property

**Throws:**
- `SOAPException` - if the property name is not recognized.

**Since:**
- SAAJ 1.2

---

getProperty

```java
public Object getProperty(String property)
    throws SOAPException
```
property - the name of the property to retrieve

**Returns:**
the value associated with the named property or `null` if no such property exists.

**Throws:**
`SOAPException` - if the property name is not recognized.

**Since:**
SAAJ 1.2
javax.xml.rpc.handler.soap  

**Interface SOAPMessageContext**

**All Superinterfaces:**  
MessageContext

```
public interface SOAPMessageContext
extends MessageContext
```

**Implements:** MessageContext

instances.

```java
void setMessage(SOAPMessage message)
    Sets the SOAPMessage in this message context
```

Methods inherited from interface `javax.xml.rpc.handler.MessageContext`
- `containsProperty`, `getProperty`, `getPropertyNames`, `removeProperty`, `setProperty`

## Method Detail

### public SOAPMessage getMessage()

```java
SOAPMessage getMessage()
```

Returns the SOAPMessage from this message context.

**Returns:**
- Returns the SOAPMessage; returns null if no SOAPMessage is present in this message context.

### public void setMessage(SOAPMessage message)

```java
setMessage(SOAPMessage message)
```

**Throws:**
- `JAXRPCException`: SOAPMessage
- `UnsupportedOperationException`
void setMessage(SOAPMessage message)

Sets the SOAPMessage in this message context

**Parameters:**

message - SOAP message

**Throws:**

JAXRPCException - If any error during the setting of the SOAPMessage in this message context

UnsupportedOperationException - If this operation is not supported

public String[] getRoles()

getRoles

String[] getRoles()

Gets the SOAP actor roles associated with an execution of the HandlerChain and its contained Handler instances. Note that SOAP actor roles apply to the SOAP node and are managed using HandlerChain.setRoles and HandlerChain.getRoles. Handler instances in the HandlerChain use this information about the SOAP actor roles to process the SOAP header blocks. Note that the SOAP actor roles are invariant during the processing of SOAP message through the HandlerChain.

**Returns:**

Array of URIs for SOAP actor roles

getHeaders

Object[] getHeaders(QName header,
                     JAXBContext context,
                     boolean allRoles)

Gets headers that have a particular qualified name from the message in the message context. Note that a SOAP message can contain multiple headers with the same qualified name.

Parameters:
header - The XML qualified name of the SOAP header(s).
context - The JAXBContext that should be used to unmarshall the header
allRoles - If true then returns headers for all SOAP roles, if false then only returns headers targetted at the roles currently being played by this SOAP node, see getRoles.

Returns:
An array of unmarshalled headers; returns an empty array if no message is present in this message context or no headers match the supplied qualified name.

Throws:
WebServiceException - If an error occurs when using the supplied JAXBContext to unmarshall. The cause of the WebServiceException is the original JAXBException.

public String[] getRoles()
getRoles

Set<String> getRoles()

Gets the SOAP actor roles associated with an execution of the handler chain. Note that SOAP actor roles apply to the SOAP node and are managed using SOAPBinding.setRoles and SOAPBinding.getRoles. Handler instances in the handler chain use this information about the SOAP actor roles to process the SOAP header blocks. Note that the SOAP actor roles are invariant during the processing of SOAP message through the handler chain.

Returns:
Array of String for SOAP actor roles

## Element Detail

abstract public String `className()`

className

deprecated public abstract String `className`

**Deprecation.**
Name of the handler class.

abstract public String `name()`

name

deprecated public abstract String `name`

**Deprecation.**
Name of the handler. Defaults to the name of the handler class.

**Default:**
```
"
``` 实现了 SOAP 角色/角色的列表。

abstract public `InitParam`[] `initParams()`

```
**initParams**

```java
public abstract InitParam[] initParams
```

*Deprecated.*
Array of name/value pairs that should be passed to the handler during initialization.

**Default:**

```java
{}
```

---

**abstract public String[] roles()**

*SOAP /*

**roles**

```java
public abstract String[] roles
```

*Deprecated.*
List of SOAP roles/actors implemented by the handler

**Default:**

```java
{}
```

---

**abstract public String[] headers()**

*SOAP QName QName QName QName javax.xml.namespace.QName javax.xml.namespace.QName.*

```java
javax.xml.namespace.QName.valueOf(String qNameAsString)
```

**headers**

```java
public abstract String[] headers
```

*Deprecated.*
List of SOAP headers processed by the handler. Each element in this array contains a QName which defines the header element processed by the handler. The QNames are specified using the string notation described in the documentation for javax.xml.namespace.QName.valueOf(String qNameAsString)

**Default:**

```java
{}
```

javax.xml.soap  Class SOAPPart

java.lang.Object  
  javax.xml.soap.SOAPPart

All Implemented Interfaces:
  Document, Node

public abstract class SOAPPart
  extends Object
  implements Document, Node

Implements: org.w3c.dom.Document, Node

SOAPMessage  SOAP  SOAP
SOAPMessage  SOAP  SOAPPart

SOAPPart  MIME  MIME  Content-Id  Content-Location
Content-Type  Content-Type  "text/xml"
SOAP  Mime  Content-Type  "text/xml"  SOAP  XML
"text/xml"  "text/xml"

SOAP  MIME  Content-Type  "text/xml"  SOAP
"text/xml"  MIME  Content-Type

SOAPMessage.getSOAPPart  SOAPMessage  SOAPPart
message  SOAPMessage  SOAP

SOAPPart soapPart = message.getSOAPPart();

SOAPPart  SOAPEnvelope  SOAPEnvelope  SOAPBody
SOAPHeader  SOAPPart  getEnvelope  SOAPEnvelope

The container for the SOAP-specific portion of a SOAPMessage object. All messages are required to have a SOAP part, so when a SOAPMessage
object is created, it will automatically have a SOAPPart object.

A SOAPPart object is a MIME part and has the MIME headers Content-Id, Content-Location, and Content-Type. Because the value of Content-Type must be "text/xml", a SOAPPart object automatically has a MIME header of Content-Type with its value set to "text/xml". The value must be "text/xml" because content in the SOAP part of a message must be in XML format. Content that is not of type "text/xml" must be in an AttachmentPart object rather than in the SOAPPart object.

When a message is sent, its SOAP part must have the MIME header Content-Type set to "text/xml". Or, from the other perspective, the SOAP part of any message that is received must have the MIME header Content-Type with a value of "text/xml".

A client can access the SOAPPart object of a SOAPMessage object by calling the method SOAPMessage.getSOAPPart. The following line of code, in which message is a SOAPMessage object, retrieves the SOAP part of a message.

```java
SOAPPart soapPart = message.getSOAPPart();
```

A SOAPPart object contains a SOAPEnvelope object, which in turn contains a SOAPBody object and a SOAPHeader object. The SOAPPart method getEnvelope can be used to retrieve the SOAPEnvelope object.

Throws  SOAPException:  SOAP

getContentId

public String getContentId()
"Content-Id"  MIME
return  String "Content-Id"  MIME
See also  setContentId

getContentId

public String getContentId()

Retrieves the value of the MIME header whose name is "Content-Id".

Returns:
public String getContentLocation()
"Content-Location" MIME

    return String "Content-Location" MIME

See also
setContentLocation

getContentLocation

public String getContentLocation()

    Retrieves the value of the MIME header whose name is "Content-Location".

    Returns:
    a String giving the value of the MIME header whose name is "Content-Location"

    See Also:
    setContentLocation

setContentId

public void setContentId(String contentId)
"Content-Id" MIME String
    contentId String MIME "Content-Id"

    Throws
    IllegalArgumentException: id

    See also
    getContentId

setContentId

public void setContentId(String contentId)

    Sets the value of the MIME header named "Content-Id" to the given
String.

**Parameters:**
- `contentId` - a String giving the value of the MIME header "Content-Id"

**Throws:**
- `IllegalArgumentException` - if there is a problem in setting the content id

**See Also:**
- `getContentId()`

```java
public void setContentLocation(String contentLocation)
MIME "Content-Location" String
contentLocation String MIME "Content-Location"
Throws IllegalArgumentException: getContentLocation
See also
```

**setContentLocation**

```java
public void setContentLocation(String contentLocation)
```

Sets the value of the MIME header "Content-Location" to the given String.

**Parameters:**
- `contentLocation` - a String giving the value of the MIME header "Content-Location"

**Throws:**
- `IllegalArgumentException` - if there is a problem in setting the content location.

**See Also:**
- `getContentLocation()`

```java
abstract public void removeMimeHeader(String header)
MIME
```
removeMimeHeader

public abstract void removeMimeHeader(String header)

Removes all MIME headers that match the given name.

Parameters:
  header - a String giving the name of the MIME header(s) to be removed

abstract public void removeAllMimeHeaders()

SOAPEnvelope MimeHeader

removeAllMimeHeaders

public abstract void removeAllMimeHeaders()

Removes all the MimeHeader objects for this SOAPEnvelope object.

abstract public String[] getMimeHeader(String name)

SOAPPart String MimeHeader
  name "Content-Type"
  return String
  See also setMimeHeader

getMimeHeader

public abstract String[] getMimeHeader(String name)

Gets all the values of the MimeHeader object in this SOAPPart object that is identified by the given String.
Parameters:

- name - the name of the header; example: "Content-Type"

Returns:

- a String array giving all the values for the specified header

See Also:

- setMimeHeader(java.lang.String, java.lang.String)

---

abstract public void setMimeHeader(String name, String value)

| Throws             | IllegalArgumentException: MIME |

See also

- getMimeHeader

---

setMimeHeader

public abstract void setMimeHeader(String name, String value)

Changes the first header entry that matches the given header name so that its value is the given value, adding a new header with the given name and value if no existing header is a match. If there is a match, this method clears all existing values for the first header that matches and sets the given value instead. If more than one header has the given name, this method removes all of the matching headers after the first one.

Note that RFC822 headers can contain only US-ASCII characters.

Parameters:

- name - a String giving the header name for which to search
- value - a String giving the value to be set. This value will be
substituted for the current value(s) of the first header that is a match if there is one. If there is no match, this value will be the value for a new MimeHeader object.

Throws:

IllegalArgumentException - if there was a problem with the specified mime header name or value

See Also:

getMimeHeader(java.lang.String)

abstract public void addMimeHeader(String name, String value)

MimeHeader SOAPPart MimeHeader

RFC822 US-ASCII

name String
value String

Throws IllegalArgumentException: MIME

addMimeHeader

public abstract void addMimeHeader(String name, String value)

Creates a MimeHeader object with the specified name and value and adds it to this SOAPPart object. If a MimeHeader with the specified name already exists, this method adds the specified value to the already existing value(s).

Note that RFC822 headers can contain only US-ASCII characters.

Parameters:

name - a String giving the header name
value - a String giving the value to be set or added

Throws:

IllegalArgumentException - if there was a problem with the
abstract public java.util.Iterator<E> getAllMimeHeaders()

MimeHeader SOAPPart
return Iterator SOAPPart Mime

g GetAllMimeHeaders

public abstract Iterator getAllMimeHeaders()

Retrieves all the headers for this SOAPPart object as an iterator over the MimeHeader objects.

Returns:
- an Iterator object with all of the Mime headers for this SOAPPart object

abstract public java.util.Iterator<E> getMatchingMimeHeaders(String[] names)

MimeHeader
names String Mime
return Iterator MIME

g getMatchingMimeHeaders

public abstract Iterator getMatchingMimeHeaders(String[] names)

Retrieves all MimeHeader objects that match a name in the given array.

Parameters:
- names - a String array with the name(s) of the MIME headers to be returned

Returns:
abstract public java.util.Iterator<E>
getNonMatchingMimeHeaders(String[] names)

Retrieves all MimeHeader objects whose name does not match a name in the given array.

Parameters:
names - a String array with the name(s) of the MIME headers not to be returned

Returns:
all of the MIME headers in this SOAPPart object except those that match one of the names in the given array. The nonmatching MIME headers are returned as an Iterator object.

abstract public void
setContent(javax.xml.transform.Source source) throws SOAPException

Throws:
SOAPException:
getContent
public abstract void setContent(Source source) throws SOAPException

Sets the content of the SOAPEnvelope object with the data from the given Source object. This Source must contain a valid SOAP document.

Parameters:
source - the javax.xml.transform.Source object with the data to be set

Throws:
SOAPException - if there is a problem in setting the source

PS :
javax.xml.registry.infomodel  Interface SpecificationLink

All Superinterfaces:
   ExtensibleObject, RegistryObject

public interface SpecificationLink
extends RegistryObject

Implements: RegistryObject

SpecificationLink  ServiceBinding  ServiceBinding
ServiceBinding  SpecificationLink  WSDL  CORBA  IDL
UDDI  tModelInstanceInfo  instanceDetails

See also  javax.xml.registry.infomodel.Concept

A SpecificationLink provides the linkage between a ServiceBinding and one of its technical specifications that describes how to use the service using the ServiceBinding. For example, a ServiceBinding may have a SpecificationLink instance that describes how to access the service using a technical specification in the form of a WSDL document or a CORBA IDL document. It serves the same purpose as the union of the tModelInstanceInfo and instanceDetails structures in UDDI.

Method Detail

public RegistryObject getSpecificationObject() throws JAXRException
getSpecificationObject

*RegistryObject* getSpecificationObject() throws *JAXRException*

Gets the specification object for this object.

**Capability Level:** 0

**Returns:**
the RegistryObject that is the specification object. For a UDDI provider the specification object must be a Concept with no parent. For an ebXML provider it is likely to be an ExtrinsicObject.

**Throws:**
*JAXRException* - If the JAXR provider encounters an internal error

public void setSpecificationObject(*RegistryObject* obj) throws *JAXRException*

*obj* RegistryObject UDDI Concept ebXML ExtrinsicObject

**Throws**
*JAXRException* - JAXR
**setSpecificationObject**

```java
void setSpecificationObject(RegistryObject obj)
    throws JAXRException
```

Sets the specification object for this object.

**Capability Level: 0**

**Parameters:**
- `obj` - the RegistryObject that is the specification object. For a UDDI provider the specification object must be a Concept with no parent. For an ebXML provider it is likely to be an ExtrinsicObject.

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public InternationalString getUsageDescription() throws JAXRException**

```java
0

    return null

Throws `JAXRException`: JAXR
```

**getUsageDescription**

```java
InternationalString getUsageDescription()
    throws JAXRException
```

Gets the description of usage parameters. Default is an empty String.
Returns:
the usage description for this object, which must not be null

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public void setUsageDescription(InternationalString usageDescription) throws JAXRException

Sets the description of usage parameters.

Parameters:
  usageDescription - the description of usage parameters for this object

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getUsageParameters() throws JAXRException
getUsageParameters

`Collection getUsageParameters() throws JAXRException`

Gets any usage parameters. A usage parameter is an arbitrary String that describes how to use the technical specification accessed via this SpecificationLink. Each parameter is a String.

**Capability Level: 0**

**Returns:**
the Collection of String instances. The Collection may be empty but not null.

**Throws:**
`JAXRException` - If the JAXR provider encounters an internal error

---

`public void setUsageParameters(java.util.Collection<E> usageParameters) throws JAXRException`
setUsageParameters

void setUsageParameters(Collection usageParameters)
    throws JAXRException

Sets any usage parameters. Each parameter is a String

Capability Level: 0

Parameters:
    usageParameters - the Collection of usage parameter Strings

Throws:
    JAXRException - If the JAXR provider encounters an internal error

public ServiceBinding getServiceBinding() throws JAXRException

SpecificationLink  ServiceBinding 0

    return ServiceBinding

Throws JAXRException: JAXR

getServiceBinding

ServiceBinding  getServiceBinding() throws JAXRException

Gets the parent ServiceBinding for this SpecificationLink.

Capability Level: 0

Returns:
    the parent ServiceBinding within which this object is composed

Throws:
    JAXRException - If the JAXR provider encounters an internal
javax.persistence  Annotation Type SqlResultSetMapping

@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface SqlResultSetMapping

**Implements:** Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)

**SQL**

```java
Query q = em.createNativeQuery(
    "SELECT o.id AS order_id, " +
    "o.quantity AS order_quantity, " +
    "o.item AS order_item, " +
    "i.name AS item_name, " +
    "FROM Order o, Item i " +
    "WHERE (order_quantity > 25) AND (order_item = i.id)",
    "OrderResults");

@SqlResultSetMapping(name="OrderResults",
    entities={
        @EntityResult(entityClass=com.acme.Order.class, fields={
            @FieldResult(name="id", column="order_id"),
            @FieldResult(name="quantity", column="order_quantity",
            @FieldResult(name="item", column="order_item"))},
        columns={
            @ColumnResult(name="item_name")}
    )
)
```

**since** Java Persistence 1.0

This annotation is used to specify the mapping of the result of a native SQL query.

Example:

```java
Query q = em.createNativeQuery(
```
"SELECT o.id AS order_id, " +  
"o.quantity AS order_quantity, " +  
"o.item AS order_item, " +  
"i.name AS item_name, " +  
"FROM Order o, Item i " +  
"WHERE (order_quantity > 25) AND (order_item = i.id)",  
"OrderResults");  

@SqlResultSetMapping(name="OrderResults",  
   entities={  
      @EntityResult(entityClass=com.acme.Order.class, fields={  
         @FieldResult(name="id", column="order_id"),  
         @FieldResult(name="quantity", column="order_quantity"  
         @FieldResult(name="item", column="order_item"}}),  
   columns={  
      @ColumnResult(name="item_name")}  
})  

Since:  
Java Persistence 1.0

javax.xml.stream.events Interface StartDocument

All Superinterfaces:
   XMLEvent, XMLStreamConstants

public interface StartDocument
   extends XMLEvent

Implements: XMLEvent

version 1.0

An interface for the start document event

Version:
   1.0

Author:
   Copyright (c) 2003 by BEA Systems. All Rights Reserved.

Field Summary

Fields inherited from interface
javax.xml.stream.XMLStreamConstants
ATTRIBUTE, CDATA, CHARACTERS, COMMENT, DTD, END_DOCUMENT,
END_ELEMENT, ENTITY_DECLARATION, ENTITY_REFERENCE, NAMESPACE,
NOTATION_DECLARATION, PROCESSING_INSTRUCTION, SPACE,
START_DOCUMENT, START_ELEMENT

Method Summary

   boolean encodingSet()
      Returns true if CharacterEncodingScheme was set in the
encoding declaration of the document

| String `getCharacterEncodingScheme()` | Returns the encoding style of the XML data |
| String `getSystemId()` | Returns the system ID of the XML data |
| String `getVersion()` | Returns the version of XML of this XML stream |
| boolean `isStandalone()` | Returns if this XML is standalone |
| boolean `standaloneSet()` | Returns true if the standalone attribute was set in the encoding declaration of the document. |

Methods inherited from interface
javax.xml.stream.events.XMLEvent
asCharacters, asEndElement, asStartElement, getEventType, getLocation, getSchemaType, isAttribute, isCharacters, isEndDocument, isEndElement, isEntityReference, isNamespace, isProcessingInstruction, isStartDocument, isStartElement, writeAsEncodedUnicode

Method Detail

public String `getSystemId()`
XML ID

    return ID ""

getSystemId

`String getSystemId()`

Returns the system ID of the XML data

Returns:
the system ID, defaults to ""

public String getCharacterEncodingScheme()
XML
        return "UTF-8"

getCharacterEncodingScheme

String getCharacterEncodingScheme()

        Returns the encoding style of the XML data

        Returns:
        the character encoding, defaults to "UTF-8"

public boolean encodingSet()
CharacterEncodingScheme true

encodingSet

boolean encodingSet()

        Returns true if CharacterEncodingScheme was set in the encoding declaration of the document

public boolean isStandalone()
XML true
        return XML "no"

isStandalone
boolean isStandalone()

Returns if this XML is standalone

Returns:
the standalone state of XML, defaults to "no"

public boolean standaloneSet()

ture

standaloneSet

boolean standaloneSet()

Returns true if the standalone attribute was set in the encoding declaration of the document.

public String getVersion()

XML XML

return XML "1.0"

getVersion

String getVersion()

Returns the version of XML of this XML stream

Returns:
the version of XML, defaults to "1.0"
javax.xml.stream.events Interface StartElement

All Superinterfaces:  
   XMLEvent, XMLStreamConstants

public interface StartElement
extends XMLEvent

Implements: XMLEvent

StartElement StartElement
   version 1.0

The StartElement interface provides access to information about start elements. A StartElement is reported for each Start Tag in the document.

Version:  
   1.0
Author:  
   Copyright (c) 2003 by BEA Systems. All Rights Reserved.

Field Summary

Fields inherited from interface javax.xml.stream.XMLStreamConstants
ATTRIBUTE, CDATA, CHARACTERS, COMMENT, DTD, END_DOCUMENT, 
END_ELEMENT, ENTITY_DECLARATION, ENTITY_REFERENCE, NAMESPACE, 
NOTATION_DECLARATION, PROCESSING_INSTRUCTION, SPACE, 
START_DOCUMENT, START_ELEMENT

Method Summary

getAttributeByName(QName name)
### Method Detail

```java
public javax.xml.namespace.QName getName()

    return

getName
```

```java
QName getName()
```
Get the name of this event

**Returns:**
the qualified name of this event

```java
public java.util.Iterator<E> getAttributes()
```

**getAttributes**

**Iterator** getAttributes()

Returns an Iterator of non-namespace declared attributes declared on this `START_ELEMENT`, returns an empty iterator if there are no attributes. The iterator must contain only implementations of the `javax.xml.stream.Attribute` interface. Attributes are fundamentally unordered and may not be reported in any order.

**Returns:**
a readonly Iterator over `Attribute` interfaces, or an empty iterator

```java
public java.util.Iterator<E> getNamespaces()
```

**getNamespaces**

```java
Iterator getNamespaceContext()
```

**javax.xml.stream.Namespace**

```java
return Iterator
```
getNamespaces

Iterator getNamespaces()

Returns an Iterator of namespaces declared on this element. This Iterator does not contain previously declared namespaces unless they appear on the current START_ELEMENT. Therefore this list may contain redeclared namespaces and duplicate namespace declarations. Use the getNamespaceContext() method to get the current context of namespace declarations.

The iterator must contain only implementations of the javax.xml.stream.Namespace interface.

A Namespace is a Attribute. One can iterate over a list of namespaces as a list of attributes. However this method returns only the list of namespaces declared on this START_ELEMENT and does not include the attributes declared on this START_ELEMENT. Returns an empty iterator if there are no namespaces.

Returns:
a readonly Iterator over Namespace interfaces, or an empty iterator

public Attribute getAttributeByQName(javax.xml.namespace.QName name)

name qname
return null

getAttributeByQName

Attribute getAttributeByQName(QName name)

Returns the attribute referred to by this name

Parameters:
name - the qname of the desired name

Returns:
the attribute corresponding to the name value or null

public javax.xml.namespace.NamespaceContext
getNamespaceContext()
NamespaceContext StartElement
return

getNamespaceContext

NamespaceContext getNamespaceContext()

Gets a read-only namespace context. If no context is available this method will return an empty namespace context. The NamespaceContext contains information about all namespaces in scope for this StartElement.

Returns:
the current namespace context

public String getNamespaceURI(String prefix)
null

prefix
return URI null

getNamespaceURI

String getNamespaceURI(String prefix)

Gets the value that the prefix is bound to in the context of this element. Returns null if the prefix is not bound in this context

Parameters:
prefix - the prefix to lookup

Returns:
the uri bound to the prefix or null
javax.ejb  Annotation Type Stateful

@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface Stateful

**Implements**: Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)

Bean

Component-defining annotation for a stateful session bean.

public interface StateHolder

Implemented by: DateTimeConverter, DoubleRangeValidator, EnumConverter, LengthValidator, LongRangeValidator, MethodExpressionActionListener, MethodExpressionValidator, MethodExpressionValueChangeListener, NumberConverter, UIComponent

#saveState  #restoreState  #saveState  #restoreState
This interface is implemented by classes that need to save their state between requests.

An implementor **must** implement both
`saveState(javax.faces.context.FacesContext)` and
`restoreState(javax.faces.context.FacesContext, java.lang.Object)` methods in this class, since these two methods have a tightly coupled contract between themselves. In other words, if there is an inheritance hierarchy, it is not permissible to have the
`saveState(javax.faces.context.FacesContext)` and
`restoreState(javax.faces.context.FacesContext, java.lang.Object)` methods reside at different levels of the hierarchy.

An implementor must have a public no-args constructor.

---

### Method Summary

<table>

<tr>
<td></td>
<td>Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.</td>
</tr>
</tbody>
</table>

---

### Method Detail

**public Object saveState(FacesContext context)**
Serializable

**StateHolder**

UIComponent  

#saveState

facet  

[javax.faces.application.StateManager](https://docs.oracle.com/javaee/spec_9/javax/faces/application/StateManager.html)

Object state = component.saveState(facesContext);

component

Serializable

**Throws**

NullPointeException: context null

**saveState**

Object saveState([FacesContext](https://docs.oracle.com/javaee/spec_9/javax/faces/context/FacesContext.html) context)

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the saveState([javax.faces.context.FacesContext](https://docs.oracle.com/javaee/spec_9/javax/faces/context/FacesContext.html)) method on all those instances as well. **This method must not save the state of children and facets.** That is done via the [StateManager](https://docs.oracle.com/javaee/spec_9/javax/faces/application/StateManager.html)

This method must not alter the state of the implementing object. In other words, after executing this code:

Object state = component.saveState(facesContext);

component should be the same as before executing it.

The return from this method must be Serializable
public void restoreState(FacesContext context, Object state)

Object

StateHolder

UIComponent #restoreState

Throws: NullPointerException - if context is null

restoreState

void restoreState(FacesContext context, Object state)

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Throws: NullPointerException - if either context or state are null

public boolean isTransient()

true Object
isTransient

boolean isTransient()

If true, the Object implementing this interface must not participate in state saving or restoring.

public void setTransient(boolean newTransientValue)

Object

newTransientValue Object boolean true

setTransient

void setTransient(boolean newTransientValue)

Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

Parameters:
newTransientValue - boolean pass true if this Object will participate in state saving or restoring, otherwise pass false.
javax.ejb  **Annotation Type Stateless**

```java
@Target(value=TYPE)
@Retention(value=RUNTIME)
public @interface Stateless
```

**Implements:** Annotation  
@Target(value=TYPE)

PS:
javax.faces.application ClassStateManager

java.lang.Object
   - javax.faces.application.StateManager

Direct Known Subclasses:
   StateManagerWrapper

public abstract class StateManager
   extends Object

Inner classes: StateManager.SerializedView
Extended by: StateManagerWrapper

StateManager StateManager Application RenderKit
  StateManager ( ResponseStateManager ) RenderKit

StateManager directs the process of saving and restoring the view between requests. The StateManager instance for an application is retrieved from the Application instance, and thus cannot know any details of the markup language created by the RenderKit being used to render a view. The StateManager utilizes a helper object (ResponseStateManager), that is provided by the RenderKit implementation and is therefore aware of the markup language details.

**Methods inherited from class java.lang.Object**: clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

**Field Detail**
The `ServletContext` init parameter consulted by the `StateManager` to tell where the state should be saved. Valid values are given as the values of the constants: `STATE_SAVING_METHOD_CLIENT` or `STATE_SAVING_METHOD_SERVER`.

If this parameter is not specified, the default value is the value of the constant `STATE_SAVING_METHOD_CLIENT`.

**See Also:**
- [Constant Field Values](#)

---

**STATE_SAVING_METHOD_CLIENT**

Constant value for the initialization parameter named by the `STATE_SAVING_METHOD_PARAM_NAME` that indicates state saving should take place on the client.

**See Also:**
- [Constant Field Values](#)

---

**STATE_SAVING_METHOD_SERVER**

Constant value for the initialization parameter named by the `STATE_SAVING_METHOD_PARAM_NAME` that indicates state saving should take place on the server.
public StateManager()

StateManager

public StateManager()

Method Detail

public StateManager.SerializedView saveSerializedView(FacesContext context)

null

transient true facet

null id NamingContainer

context

Throws IllegalStateException: NamingContainer facet

deprecated

saveSerializedView

public StateManager.SerializedView saveSerializedView(FacesContext context)

Deprecated. this has been replaced by
saveView( javax.faces.context.FacesContext ). The default implementation returns null.

Return the tree structure and component state information for the view contained in the specified FacesContext instance as an object of type StateManager.SerializedView. If there is no state information to be saved, return null instead.

Components may opt out of being included in the serialized view by setting their transient property to true. This must cause the component itself, as well as all of that component's children and facets, to be omitted from the saved tree structure and component state information.

This method must also enforce the rule that, for components with non-null ids, all components that are descendants of the same nearest NamingContainer must have unique identifiers.

Parameters:
context - FacesContext for the current request

Throws:
IllegalStateException - if more than one component or facet within the same NamingContainer in this view has the same non-null component id

public Object saveView( FacesContext context )

Object UIViewRoot java.io.Serializable null

transient true facet

null id NamingContainer

StateManager #saveSerializedView Object 0
structure 1SerializedView state

custom FacesContext
saveView

public Object saveView(FacesContext context)

Return an opaque object containing sufficient information for this same instance to restore the state of the current UIViewRoot on a subsequent request. The returned object must implement java.io.Serializable. If there is no state information to be saved, return null instead.

Components may opt out of being included in the serialized view by setting their transient property to true. This must cause the component itself, as well as all of that component’s children and facets, to be omitted from the saved tree structure and component state information.

This method must also enforce the rule that, for components with non-null ids, all components that are descendants of the same nearest NamingContainer must have unique identifiers.

For backwards compatibility with existing StateManager implementations, the default implementation of this method calls saveSerializedView(javax.faces.context.FacesContext) and creates and returns a two element object array with element zero containing the structure property and element one containing the state property of the SerializedView.

Parameters:
context - FacesContext for the current request

Throws:
IllegalStateException - if more than one component or facet within the same NamingContainer in this view has the same non-null component id

Since:
protected Object getTreeStructureToSave(FacesContext context)

    saveSerializedView()   Serializable facet

    transient   true facet

        context   FacesContext
        deprecated

getTreeStructureToSave

protected Object getTreeStructureToSave(FacesContext context)

    Deprecated. the distinction between tree structure and component state is now an implementation detail. The default implementation returns null.

    Convenience method, which must be called by saveSerializedView(), to construct and return a Serializable object that represents the structure of the entire component tree (including children and facets) of this view.

    Components may opt-out of being included in the tree structure by setting their transient property to true. This must cause the component itself, as well as all of that component's children and facets, to be omitted from the saved tree structure information.

    Parameters:

        context - FacesContext for the current request

protected Object getComponentStateToSave(FacesContext context)
saveSerializedView()   Serializable facet

transient   true facet

context
FacesContext
deprecated

gGetComponentStateToSave

protected Object getComponentStateToSave(FacesContext context)

Deprecated. the distinction between tree structure and component state is now an implementation detail. The default implementation returns null.

Convenience method, which must be called by saveSerializedView(), to construct and return a Serializable object that represents the state of all component properties, attributes, and attached objects, for the entire component tree (including children and facets) of this view.

Components may opt-out of being included in the component state by setting their transient property to true. This must cause the component itself, as well as all of that component's children and facets, to be omitted from the saved component state information.

Parameters:
context - FacesContext for the current request

public void writeState(FacesContext context, Object state) throws java.io.IOException

Object

ResponseStateManager   writeState()   RenderKit
ResponseWriter
writeState

public void writeState(FacesContext context, Object state)
    throws IOException

Save the state represented in the specified state Object instance, in an implementation dependent manner.

This method will typically simply delegate the actual writing to the writeState() method of the ResponseStateManager instance provided by the RenderKit being used to render this view. This method assumes that the caller has positioned the ResponseWriter at the correct position for the saved state to be written.

For backwards compatibility with existing StateManager implementations, the default implementation of this method checks if the argument is an instance of Object [] of length greater than or equal to two. If so, it creates a SerializedView instance with the tree structure coming from element zero and the component state coming from element one and calls through to writeState(javax.faces.context.FacesContext, javax.faces.application.StateManager.SerializedView) If not, does nothing.

Parameters:

context - FacesContext for the current request
state - the Serializable state to be written, as returned by saveSerializedView(javax.faces.context.FacesContext)

Throws:
public void writeState(FacesContext context,
StateManager.SerializedView state) throws java.io.IOException

SerializedView

StateManager.STATE_SAVING_METHOD_PARAMETER_NAME

init
ResponseStateManager writeState()
RenderKit ResponseWriter

context FacesContext
state

deprecated #writeState(javax.faces.context.FacesContext,java.lang.Object)

writeState

public void writeState(FacesContext context,
StateManager.SerializedView state)
throws IOException

Deprecated. This method has been replaced by
The default implementation of this method does nothing.

Save the state represented in the specified SerializedView instance,
in an implementation dependent manner.

This method must consult the context initialization parameter named
by the symbolic constant
StateManager.STATE_SAVING_METHOD_PARAMETER_NAME to determine
whether state should be saved on the client or the server. If not
present, client side state saving is assumed.

If the init parameter indicates that client side state saving should be
used, this method must delegate the actual writing to the
writeState() method of the ResponseStateManager instance provided
by the RenderKit being used to render this view. This method
assumes that the caller has positioned the ResponseWriter at the
correct position for the saved state to be written.

Parameters:
   context - FacesContext for the current request
   state - the serialized state to be written

Throws:
    IOException

abstract public UIViewRoot restoreView(FacesContext context, String viewId, String renderKitId)

    viewId      UIViewRoot  viewId      null
    StateManager.STATE_SAVING_METHOD_PARAMETER_NAME

    init      ResponseStateManager
    getTreeStructureToRestore()  null
    getComponentStateToRestore()   RenderKit

    context       FacesContext
    viewId
    renderKitId   renderKitId
    null

    Throws    IllegalArgumentException:  renderKitId  null
public abstract UIViewRoot restoreView(FacesContext context, String viewId, String renderKitId)

Restore the tree structure and the component state of the view for the specified viewId, in an implementation dependent manner, and return the restored UIViewRoot. If there is no saved state information available for this viewId, return null instead.

This method must consult the context initialization parameter named by the symbolic constant StateManager.STATE_SAVING_METHOD_PARAMETER_NAME to determine whether state should be saved on the client or the server. If not present, client side state saving is assumed.

If the init parameter indicates that client side state saving should be used, this method must call the getTreeStructureToRestore() and (if the previous method call returned a non-null value) getComponentStateToRestore() methods of the ResponseStateManager instance provided by the RenderKit responsible for this view.

Parameters:
context - FacesContext for the current request
viewId - View identifier of the view to be restored
renderKitId - the renderKitId used to render this response. Must not be null.

Throws:
IllegalArgumentException - if renderKitId IS null.

protected UIViewRoot restoreTreeStructure(FacesContext context, String viewId, String renderKitId)

restoreView() UIViewRoot facet null

context FacesContext
restoreTreeStructure

protected `UIViewRoot restoreTreeStructure(FacesContext context, String viewId, String renderKitId)`

**Deprecated.** *the distinction between tree structure and component state is now an implementation detail. The default implementation returns null.*

Convenience method, which must be called by `restoreView()`, to construct and return a `UIViewRoot` instance (populated with children and facets) representing the tree structure of the component tree being restored. If no saved state information is available, return `null` instead.

**Parameters:**
- `context` - `FacesContext` for the current request
- `viewId` - View identifier of the view to be restored
- `renderKitId` - the renderKitId used to render this response. Must not be `null`.

**Throws:**
- `IllegalArgumentException` - if `renderKitId` is `null`.

protected void restoreComponentState(FacesContext context, UIViewRoot viewRoot, String renderKitId)

`restoreView()`
restoreComponentState

protected void restoreComponentState(FacesContext context,
                                      UIViewRoot viewRoot,
                                      String renderKitId)

Deprecated. the distinction between tree structure and component state is now an implementation detail. The default implementation does nothing.

Convenience method, which must be called by restoreView(), to restore the attributes, properties, and attached objects of all components in the restored component tree.

Parameters:
- context - FacesContext for the current request
- viewRoot - UIViewRoot returned by a previous call to restoreTreeStructure()
- renderKitId - the renderKitId used to render this response. Must not be null.

Throws:
- IllegalArgumentException - if renderKitId is null.

public boolean isSavingStateInClient(FacesContext context)

return #STATE_SAVING_METHOD_PARAM_NAME ServletContext init
#STATE_SAVING_METHOD_CLIENT true false

Throws
- NullPointerException: context null

isSavingStateInClient

public boolean isSavingStateInClient(FacesContext context)
Returns:

true if and only if the value of the ServletContext init parameter
named by the value of the constant
STATE_SAVING_METHOD_PARAM_NAME is equal to the value of the
constant STATE_SAVING_METHOD_CLIENT. false otherwise.

Throws:

NullPointerException - if context is null.
javax.faces.application  **Class StateManagerWrapper**

**java.lang.Object**
- javax.faces.application.StateManager
  - javax.faces.application.StateManagerWrapper

public abstract class **StateManagerWrapper**

extends **StateManager**

**Extends:** **StateManager**

StateManager  StateManager  StateManager

#**getWrapped**

since 1.2

Provides a simple implementation of **StateManager** that can be subclassed by developers wishing to provide specialized behavior to an existing **StateManager** instance. The default implementation of all methods is to call through to the wrapped **StateManager**.

Usage: extend this class and override **getWrapped()** to return the instance we are wrapping.

**Since:**

1.2

---

Constructor Summary

StateManagerWrapper()
StateManager.restoreTreeStructure(javax.faces.context.FacesContext, String, String) on the wrapped StateManager object.

restoreView(FacesContext context, String viewId)

The default behavior of this method is to call StateManager.restoreView(javax.faces.context.FacesContext, String) on the wrapped StateManager object.

UIViewRoot

StateManager.restoreView(FacesContext context, String viewId)

The default behavior of this method is to call StateManager.restoreView(javax.faces.context.FacesContext, String) on the wrapped StateManager object.

StateManager.SerializedView

StateManager.saveSerializedView(FacesContext context)

The default behavior of this method is to call StateManager.saveSerializedView(javax.faces.context.FacesContext) on the wrapped StateManager object.

Object

StateManager.saveView(FacesContext context)

The default behavior of this method is to call StateManager.saveView(javax.faces.context.FacesContext) on the wrapped StateManager object.

void

StateManager.writeState(FacesContext context, Object state)

The default behavior of this method is to call StateManager.writeState(javax.faces.context.FacesContext, java.lang.Object) on the wrapped StateManager object.

void

StateManager.writeState(FacesContext context, StateManager.SerializedView state)

The default behavior of this method is to call StateManager.writeState(javax.faces.context.FacesContext, javax.faces.application.StateManager.SerializedView) on the wrapped StateManager object.

public StateManagerWrapper()

### Method Detail

abstract protected **StateManager** getWrapped()

```java
return getWrapped()
```

getWrapped

protected abstract **StateManager** getWrapped()

`Returns:`

the instance that we are wrapping.

---

public **StateManager.SerializedView** saveSerializedView(FacesContext context)

```java
StateManager saveSerializedView(javax.faces.context.FacesContext)
```

since 1.2

See also **saveSerializedView(javax.faces.context.FacesContext)**

--

saveSerializedView

public **StateManager.SerializedView** saveSerializedView(FacesContext context)

The default behavior of this method is to call **StateManager.saveSerializedView(javax.faces.context.FacesContext)** on the wrapped **StateManager** object.

** Overrides:**

**saveSerializedView** in class **StateManager**

**Parameters:**
public Object saveView(FacesContext context)

StateManager
saveView(javax.faces.context.FacesContext)
since 1.2
See also saveView(javax.faces.context.FacesContext)

saveView

public Object saveView(FacesContext context)

The default behavior of this method is to call
StateManager.saveView(javax.faces.context.FacesContext) on the
wrapped StateManager object.

Overrides:
saveView in class StateManager

Parameters:
context - FacesContext for the current request

Since:
1.2
See Also:
StateManager.saveView(javax.faces.context.FacesContext)

protected Object getTreeStructureToSave(FacesContext context)

StateManager
getTreeStructureToSave

protected Object getTreeStructureToSave(FacesContext context)

The default behavior of this method is to call
StateManager.getTreeStructureToSave(javax.faces.context.FacesContext)
on the wrapped StateManager object.

Overrides:
getTreeStructureToSave in class StateManager

Parameters:
context - FacesContext for the current request

Since:
1.2

See Also:
StateManager.getTreeStructureToSave(javax.faces.context.FacesContext)

getComponentStateToSave

protected Object getComponentStateToSave(FacesContext context)

StateManager

GetComponentStateToSave(javax.faces.context.FacesContext)

since
1.2

See also GetComponentStateToSave(javax.faces.context.FacesContext)

getComponentStateToSave

protected Object getComponentStateToSave(FacesContext context)
The default behavior of this method is to call `StateManager.getComponentStateToSave(javax.faces.context.FacesContext)` on the wrapped `StateManager` object.

**Overrides:**
- `StateManager.getComponentStateToSave` in class `StateManager`

**Parameters:**
- `context` - `FacesContext` for the current request

**Since:**
1.2

**See Also:**
- `StateManager.getComponentStateToSave(javax.faces.context.FacesContext)`

---

```java
public void writeState(FacesContext context, Object state)
throws java.io.IOException
```

- `StateManager`
- `writeState(javax.faces.context.FacesContext, java.lang.Object)`

**since**
1.2

**See also**
- `writeState(javax.faces.context.FacesContext, java.lang.Object)`

---

**writeState**

```java
public void writeState(FacesContext context, Object state)
throws IOException
```

The default behavior of this method is to call `StateManager.writeState(javax.faces.context.FacesContext, java.lang.Object)` on the wrapped `StateManager` object.

**Overrides:**
- `writeState` in class `StateManager`

**Parameters:**
- `context` - `FacesContext` for the current request
public void writeState(FacesContext context, StateManager.SerializedView state) throws java.io.IOException

StateManager
writeState(javax.faces.context.FacesContext, javax.faces.application.StateManager.SerializedView)

since 1.2
See also writeState(javax.faces.context.FacesContext, javax.faces.application.StateManager.SerializedView)

writeState

public void writeState(FacesContext context, StateManager.SerializedView state) throws IOException

The default behavior of this method is to call StateManager.writeState(javax.faces.context.FacesContext, javax.faces.application.StateManager.SerializedView) on the wrapped StateManager object.

Overrides:
writeState in class StateManager

Parameters:
context - FacesContext for the current request
state - the serialized state to be written

Throws:
   IOException

Since:
   1.2

See Also:
   StateManager.writeState(javax.faces.context.FacesContext,
                           javax.faces.application.StateManager.SerializedView)

public UIViewRoot restoreView(FacesContext context, String viewId, String renderKitId)

StateManager
restoreView(javax.faces.context.FacesContext, String, String)

since 1.2

See also  restoreView(javax.faces.context.FacesContext, String, String)

restoreView

public UIViewRoot restoreView(FacesContext context,
                              String viewId,
                              String renderKitId)

The default behavior of this method is to call
StateManager.restoreView(javax.faces.context.FacesContext, String, String) on the wrapped StateManager object.

Specified by:
   restoreView in class StateManager

Parameters:
context - FacesContext for the current request
viewId - View identifier of the view to be restored
renderKitId - the renderKitId used to render this response. Must not be null.

Since:
protected `UIViewRoot` `restoreTreeStructure(FacesContext` context, String viewId, String renderKitId)

StateManager
`restoreTreeStructure(javax.faces.context.FacesContext, String, String)`

since 1.2
See also `restoreTreeStructure(javax.faces.context.FacesContext, String, String)`

The default behavior of this method is to call
StateManager.restoreTreeStructure(javax.faces.context.FacesContext, String, String) on the wrapped StateManager object.

Overrides:
`restoreTreeStructure` in class StateManager

Parameters:
context - FacesContext for the current request
viewId - View identifier of the view to be restored
renderKitId - the renderKitId used to render this response. Must not be null.

Since:
1.2

See Also:
StateManager.restoreTreeStructure(javax.faces.context.FacesContext, String, String)
protected void restoreComponentState(FacesContext context, UIViewRoot viewRoot, String renderKitId)

StateManager
restoreComponentState(javax.faces.context.FacesContext,
javax.faces.component.UIViewRoot, String)

since 1.2
See also
StateManager.restoreComponentState(javax.faces.context.FacesContext,
javax.faces.component.UIViewRoot, String)

restoreComponentState

protected void restoreComponentState(FacesContext context,
UIViewRoot viewRoot, String renderKitId)

The default behavior of this method is to call
StateManager.restoreComponentState(javax.faces.context.FacesCont
javax.faces.component.UIViewRoot, String) on the wrapped
StateManager object.

Overrides:
restoreComponentState in class StateManager

Parameters:
context - FacesContext for the current request
viewRoot - UIViewRoot returned by a previous call to
restoreTreeStructure()
renderKitId - the renderKitId used to render this response. Must
not be null.

Since:
1.2
See Also:
StateManager.restoreComponentState(javax.faces.context.FacesCont
javax.faces.component.UIViewRoot, String)
public boolean isSavingStateInClient(FacesContext context)

StateManager

isSavingStateInClient(javax.faces.context.FacesContext)

since 1.2

See also isSavingStateInClient(javax.faces.context.FacesContext)

isSavingStateInClient

public boolean isSavingStateInClient(FacesContext context)

The default behavior of this method is to call StateManager.isSavingStateInClient(javax.faces.context.FacesContext) on the wrapped StateManager object.

Overrides:

isSavingStateInClient in class StateManager

Returns:

true if and only if the value of the ServletContext init parameter named by the value of the constant StateManager.STATE_SAVING_METHOD_PARAM_NAME is equal to the value of the constant StateManager.STATE_SAVING_METHOD_CLIENT. false otherwise.

Since:

1.2

See Also:

StateManager.isSavingStateInClient(javax.faces.context.FacesContext)

### Field Detail

**RUNNING**

public static final StateType RUNNING

The action operation is running normally.
public static final StateType COMPLETED

    The action operation has completed normally.

---

public static final StateType FAILED

    The action operation has failed.

---

public static final StateType RELEASED

    The DeploymentManager is running in disconnected mode.

### Constructor Detail

**protected StateType(int value)**

    value

**StateType**

**protected StateType(int value)**

    Construct a new enumeration value with the given integer value.
Parameters:
   value - Integer value.

Method Detail

public int getValue()

   return

getValue

public int getValue()

   Returns this enumeration value's integer value.

   Returns:
       the value

protected String[] getStringTable()

getStateType

protected String[] getStringTable()

   Returns the string table for class StateType

protected StateType[] getEnumValueTable()

getStateEnumValueTable
protected `StateType[]` `getEnumValueTable()`

    Returns the enumeration value table for class `StateType`

---

**public static `StateType` `getStateType(int value)`**

    `value`

**getStateType**

**public static `StateType` `getStateType(int value)`**

    Return an object of the specified value.

    **Parameters:**
    `value` - a designator for the object.

---

**public String `toString()`**

**`StateType`**

**toString**

**public `String` `toString()`**

    Return the string name of this `StateType` or the integer value if outside the bounds of the table

    **Overrides:**
    `toString` in class `Object`

---

**protected `int` `getOffset()`**
protected int getOffset()

Returns the lowest integer value used by this enumeration value's enumeration class.

The default implementation returns 0.

Returns:
   the offset of the lowest enumeration value.
javax.management.j2ee.statistics Interface Statistic

All Known Subinterfaces:
  BoundaryStatistic, BoundedRangeStatistic, CountStatistic, RangeStatistic, TimeStatistic

public interface Statistic

Implemented by: BoundaryStatistic, CountStatistic, RangeStatistic, TimeStatistic

Statistic Stats

The Statistic model and its sub-models specify the data models which are required to be used to provide the performance data described by the specific attributes in the Stats models.

Method Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>getDescription()</td>
<td>A human-readable description of the Statistic.</td>
</tr>
<tr>
<td>long</td>
<td>getLastSampleTime()</td>
<td>The time of the last measurement represented as a long, whose value is the number of milliseconds since January 1, 1970, 00:00:00.</td>
</tr>
<tr>
<td>String</td>
<td>getName()</td>
<td>The name of this Statistic.</td>

<td>getUnit()</td>
<td>The unit of measurement for this Statistic.</td>
</tr>
</tbody>
</table>
public String getName()
Statistic

getName

String getName()
The name of this Statistic.

public String getUnit()
Statistic TimeStatistic
"HOUR""MINUTE""SECOND""MILLISECOND""MICROSECOND""NANOSECOND"

getUnit

String getUnit()
The unit of measurement for this Statistic. Valid values for TimeStatistic measurements are "HOUR", "MINUTE", "SECOND", "MILLISECOND", "MICROSECOND" and "NANOSECOND".

public String getDescription()
Statistic

description

String getDescription()
String getDescription()

A human-readable description of the Statistic.

public long getStartTime()
long 1970 1 1 00:00:00

getStartTime

long getStartTime()

The time of the first measurement represented as a long, whose
value is the number of milliseconds since January 1, 1970, 00:00:00.

public long getLastSampleTime()
long 1970 1 1 00:00:00

getLastSampleTime

long getLastSampleTime()

The time of the last measurement represented as a long, whose
value is the number of milliseconds since January 1, 1970, 00:00:00.
PS:
javax.management.j2ee.statistics Interface Stats

All Known Subinterfaces:

EJBStats, EntityBeanStats, JCACollectionPoolStats,
JCAConnectionStats, JCAStats, JDBCConnectionPoolStats,
JDBCConnectionStats, JDBCStats, JMSCollectionStats,
JMSCollectionStats, JMSEndpointStats, JMSProducerStats,

</thead>
<tbody>
<tr>
<td><strong>Statistic getStatistic(String statisticName)</strong></td>
</tr>
<tr>
<td><strong>String[] getStatisticNames()</strong></td>
</tr>
<tr>
<td><strong>Statistic[] getStatistics()</strong></td>
</tr>
</tbody>
</table>
Method Detail

public Statistic getStatistic(String statisticName)

getStatistic

Statistic getStatistic(String statisticName)

Get a Statistic by name.

public String[] getStatisticNames()

String Stats Statistic
statisticNames Stats null statisticNames
Statistic

getStatisticNames

String[] getStatisticNames()

Returns an array of Strings which are the names of the attributes from the specific Stats submodel that this object supports. Attributes named in the list must correspond to attributes that will return a Statistic object of the appropriate type which contains valid performance data. The return value of attributes in the Stats submodel that are not included in the statisticNames list must be null. For each name in the statisticNames list there must be one Statistic with the same name in the statistics list.

public Statistic[] getStatistics()
getStatistics

\texttt{Statistic[]} \texttt{getStatistics()}

Returns an array containing all of the Statistic objects supported by this Stats object.

<td></td>
<td>A transaction is associated with the target object and it is in the process of rolling back.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>static int</th>
<th>STATUS_UNKNOWN</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A transaction is associated with the target object but its current status cannot be determined.</td>
</tr>
</tbody>
</table>

**Field Detail**

**STATUS_ACTIVE**

static final int **STATUS_ACTIVE**

A transaction is associated with the target object and it is in the active state. An implementation returns this status after a transaction has been started and prior to a Coordinator issuing any prepares, unless the transaction has been marked for rollback.

**See Also:**

Constant Field Values

**STATUS_MARKED_ROLLBACK**

static final int **STATUS_MARKED_ROLLBACK**

A transaction is associated with the target object and it has been marked for rollback, perhaps as a result of a setRollbackOnly
operation.

See Also:

Constant Field Values

STATUS_PREPARED

static final int STATUS_PREPARED

    A transaction is associated with the target object and it has been prepared. That is, all subordinates have agreed to commit. The target object may be waiting for instructions from a superior as to how to proceed.

See Also:

Constant Field Values

STATUS_COMMITTED

static final int STATUS_COMMITTED

    A transaction is associated with the target object and it has been committed. It is likely that heuristics exist; otherwise, the transaction would have been destroyed and NoTransaction returned.

See Also:

Constant Field Values

STATUS_ROLLED_BACK

static final int STATUS_ROLLED_BACK
A transaction is associated with the target object and the outcome has been determined to be rollback. It is likely that heuristics exist; otherwise, the transaction would have been destroyed and NoTransaction returned.

See Also:
Constant Field Values

STATUS_UNKNOWN

static final int STATUS_UNKNOWN

A transaction is associated with the target object but its current status cannot be determined. This is a transient condition and a subsequent invocation will ultimately return a different status.

See Also:
Constant Field Values

STATUS_NO_TRANSACTION

static final int STATUS_NO_TRANSACTION

No transaction is currently associated with the target object. This will occur after a transaction has completed.

See Also:
Constant Field Values

STATUS_PREPARING
static final int STATUS_PREPARING

A transaction is associated with the target object and it is in the process of preparing. An implementation returns this status if it has started preparing, but has not yet completed the process. The likely reason for this is that the implementation is probably waiting for responses to prepare from one or more Resources.

See Also:
Constant Field Values

_________________________________________________________________

STATUS_COMMITTING

static final int STATUS_COMMITTING

A transaction is associated with the target object and it is in the process of committing. An implementation returns this status if it has decided to commit but has not yet completed the committing process. This occurs because the implementation is probably waiting for responses from one or more Resources.

See Also:
Constant Field Values

_________________________________________________________________

STATUS_ROLLING_BACK

static final int STATUS_ROLLING_BACK

A transaction is associated with the target object and it is in the process of rolling back. An implementation returns this status if it has decided to rollback but has not yet completed the process. The implementation is probably waiting for responses from one or more Resources.

Constructor Detail

protected Store(Session session, URLName urlName)

session
Store Session
urlName
Store URLName

Store

protected Store(Session session, URLName urlName)

Constructor.
Parameters:
- session - Session object for this Store.
- urlName - URLName object to be used for this Store.

Method Detail

abstract public Folder getDefaultFolder() throws MessagingException

Stores

public abstract Folder getDefaultFolder()

Returns a Folder object that represents the 'root' of the default namespace presented to the user by the Store.

Returns:
the root Folder

Throws:
- IllegalStateException - if this Store is not connected.
- MessagingException

abstract public Folder getFolder(String name) throws MessagingException

Folder Store Folder Folder

name Folder Store ""

return Folder
getFolder

public abstract Folder getFolder(String name) throws MessagingException

Return the Folder object corresponding to the given name. Note that a Folder object is returned even if the named folder does not physically exist on the Store. The exists() method on the folder object indicates whether this folder really exists.

Folder objects are not cached by the Store, so invoking this method on the same name multiple times will return that many distinct Folder objects.

Parameters:
  name - The name of the Folder. In some Stores, name can be an absolute path if it starts with the hierarchy delimiter. Else it is interpreted relative to the 'root' of this namespace.

Returns:
  Folder object

Throws:
  IllegalStateException - if this Store is not connected. MessagingException

See Also:
  Folder.exists(), Folder.create(int)
getFolder

public abstract Folder getFolder(URLName url) throws MessagingException

Return a closed Folder object, corresponding to the given URLName. The store specified in the given URLName should refer to this Store object.

Implementations of this method may obtain the name of the actual folder using the getFile() method on URLName, and use that name to create the folder.

Parameters:
url - URLName that denotes a folder

Returns:
Folder object

Throws:
IllegalStateException - if this Store is not connected.
MessagingException

See Also:
URLName

public Folder[] getPersonalNamespaces() throws MessagingException

INBOX Store

getDefaultFolder

Throws
IllegalStateException: Store
Folder
getPersonalNamespaces

public Folder[] getPersonalNamespaces() throws MessagingException

Return a set of folders representing the personal namespaces for the current user. A personal namespace is a set of names that is considered within the personal scope of the authenticated user. Typically, only the authenticated user has access to mail folders in their personal namespace. If an INBOX exists for a user, it must appear within the user's personal namespace. In the typical case, there should be only one personal namespace for each user in each Store.

This implementation returns an array with a single entry containing the return value of the getDefaultFolder method. Subclasses should override this method to return appropriate information.

Returns:
array of Folder objects

Throws:
IllegalStateException - if this Store is not connected.
MessagingException

Since:
JavaMail 1.2

getUserNamespaces

public Folder[] getUserNamespaces(String user) throws MessagingException

user

Throws
IllegalStateException: Store
return Folder
getUserNamespaces

public Folder[] getUserNamespaces(String user) throws MessagingException

Return a set of folders representing the namespaces for user. The namespaces returned represent the personal namespaces for the user. To access mail folders in the other user's namespace, the currently authenticated user must be explicitly granted access rights. For example, it is common for a manager to grant to their secretary access rights to their mail folders.

This implementation returns an empty array. Subclasses should override this method to return appropriate information.

Returns:
array of Folder objects

Throws:
IllegalStateException - if this Store is not connected.
MessagingException

Since:
JavaMail 1.2

public Folder[] getSharedNamespaces() throws MessagingException

Throws
IllegalStateException: Store Folder return
since
JavaMail 1.2
getSharedNamespaces

public Folder[] getSharedNamespaces()

throws MessagingException

Return a set of folders representing the shared namespaces. A shared namespace is a namespace that consists of mail folders that are intended to be shared amongst users and do not exist within a user's personal namespace.

This implementation returns an empty array. Subclasses should override this method to return appropriate information.

Returns:
array of Folder objects

Throws:
IllegalStateException - if this Store is not connected.
MessagingException

Since:
JavaMail 1.2

public void addStoreListener(StoreListener l)

Store StoreEvent

StoreListener
/

See also javax.mail.event.StoreEvent

addStoreListener

public void addStoreListener(StoreListener l)

Add a listener for StoreEvents on this Store.

The default implementation provided here adds this listener to an internal list of StoreListeners.
public void removeStoreListener(StoreListener l)
Store

StoreListener

/ 

See also addStoreListener

removeStoreListener

public void removeStoreListener(StoreListener l)

Remove a listener for Store events.

The default implementation provided here removes this listener from the internal list of StoreListeners.

Parameters:
1 - the listener

See Also: addStoreListener(javax.mail.event.StoreListener)

protected void notifyStoreListeners(int type, String message)
StoreListenerStore StoreEvent

StoreListener
notifyStoreListeners

protected void notifyStoreListeners(int type, String message)

Notify all StoreListeners. Store implementations are expected to use this method to broadcast StoreEvents.

The provided default implementation queues the event into an internal event queue. An event dispatcher thread dequeues events from the queue and dispatches them to the registered StoreListeners. Note that the event dispatching occurs in a separate thread, thus avoiding potential deadlock problems.

public void addFolderListener(FolderListener l)

Add a listener for Folder events on any Folder object obtained from this Store. FolderEvents are delivered to FolderListeners on the affected Folder as well as to FolderListeners on the containing Store.

The default implementation provided here adds this listener to an internal list of FolderListeners.

Parameters:
public void removeFolderListener(FolderListener l)
Folder
FolderListener
/
See also addFolderListener

removeFolderListener

public void removeFolderListener(FolderListener l)

Remove a listener for Folder events.

The default implementation provided here removes this listener from the internal list of FolderListeners.

Parameters:
1 - the listener
See Also:
addFolderListener(javax.mail.event.FolderListener)

protected void notifyFolderListeners(int type, Folder folder)
FolderListenerStore  Folder
FolderListener

See also notifyFolderRenamedListeners
notifyFolderListeners

protected void notifyFolderListeners(int type, Folder folder)

Notify all FolderListeners. Store implementations are expected to use this method to broadcast Folder events.

The provided default implementation queues the event into an internal event queue. An event dispatcher thread dequeues events from the queue and dispatches them to the registered FolderListeners. Note that the event dispatching occurs in a separate thread, thus avoiding potential deadlock problems.

Parameters:
- type - type of FolderEvent
- folder - affected Folder

See Also:
notifyFolderRenamedListeners(javax.mail.Folder, javax.mail.Folder)

protected void notifyFolderRenamedListeners(Folder oldF, Folder newF)

FolderListener Store Folder

FolderListener
- oldF
- newF

since JavaMail 1.1

notifyFolderRenamedListeners

protected void notifyFolderRenamedListeners(Folder oldF, Folder newF)

Notify all FolderListeners about the renaming of a folder. Store
implementations are expected to use this method to broadcast
Folder events indicating the renaming of folders.

The provided default implementation queues the event into an
internal event queue. An event dispatcher thread dequeues events
from the queue anddispatches them to the registered
FolderListeners. Note that the event dispatching occurs in a separate
thread, thus avoiding potential deadlock problems.

**Parameters:**
- oldF - the folder being renamed
- newF - the folder representing the new name.

**Since:**
JavaMail 1.1

javax.mail  **Class StoreClosedException**

java.lang.Object  
  └ java.lang.Throwable  
    └ java.lang.Exception  
      └ javax.mail.MessagingException  
        └ javax.mail.StoreClosedException

All Implemented Interfaces:
  Serializable

---

public class StoreClosedException

extends MessagingException

**Extends:** Throwable > Exception > MessagingException

Messaging  Store  Store  Messaging

Store  connect

getMessage()

This exception is thrown when a method is invoked on a Messaging object and the Store that owns that object has died due to some reason. This exception should be treated as a fatal error; in particular any messaging object belonging to that Store must be considered invalid.

The connect method may be invoked on the dead Store object to revive it.

The getMessage() method returns more detailed information about the error that caused this exception.

public interface Streamable

Streamable Record Record
Streamable Record
Streamable Record
Streamable Record

since 0.8
See also javax.resource.cci.Record

Streamable interface enables a resource adapter to extract data from an input Record or set data into an output Record as a stream of bytes.

The Streamable interface provides a resource adapter's view of the data that has been set in a Record instance by a component.

The Streamable interface is not directly used by a component. It is used by a resource adapter implementation. A component uses Record or any derived interfaces to manage records.

Since: 0.8

</tbody>
</table>
void write(OutputStream ostream)
Write fields of a Streamable object to an OutputStream

Method Detail

public void read(java.io.InputStream istream) throws java.io.IOException
InputStream  Streamable
  istream    Streamable  InputStream

read

void read(InputStream istream)
  throws IOException

Read data from an InputStream and initialize fields of a Streamable object.

Parameters:
  istream - InputStream that represents a resource adapter specific internal representation of fields of a Streamable object

Throws:
  IOException

public void write(java.io.OutputStream ostream) throws java.io.IOException
Streamable  OutputStream
  ostream    Streamable  OutputStream

write
void write(OutputStream ostream) throws IOException

Write fields of a Streamable object to an OutputStream

Parameters:
ostream - OutputStream that holds value of a Streamable object

Throws:
IOException

This interface declares a simple filter interface that one can create to filter XMLStreamReaders.
boolean accept(XMLStreamReader reader)

Tests whether the current state is part of this stream. This method will return true if this filter accepts this event and false otherwise. The method should not change the state of the reader when accepting a state.

**Parameters:**
reader - the event to test

**Returns:**
true if this filter accepts this event, false otherwise

A `StreamMessage` object is used to send a stream of primitive types in the Java programming language. It is filled and read sequentially. It inherits from the `Message` interface and adds a stream message body. Its methods are based largely on those found in `java.io.DataInputStream` and `java.io.DataOutputStream`.

The primitive types can be read or written explicitly using methods for each type. They may also be read or written generically as objects. For instance, a call to `StreamMessage.writeInt(6)` is equivalent to `StreamMessage.writeObject(new Integer(6))`. Both forms are provided, because the explicit form is convenient for static programming, and the object form is needed when types are not known at compile time.

When the message is first created, and when `clearBody` is called, the body of the message is in write-only mode. After the first call to `reset` has been made, the message body is in read-only mode. After a message has been sent, the client that sent it can retain and modify it without affecting the message that has been sent. The same message object can be sent multiple times. When a message has been received, the provider has called `reset` so that the message body is in read-only mode for the client.

If `clearBody` is called on a message in read-only mode, the message body is cleared and the message body is in write-only mode.

If a client attempts to read a message in write-only mode, a
MessageNotReadableException is thrown.

If a client attempts to write a message in read-only mode, a MessageNotWriteableException is thrown.

StreamMessage objects support the following conversion table. The marked cases must be supported. The unmarked cases must throw a JMSException. The String-to-primitive conversions may throw a runtime exception if the primitive’s `valueOf()` method does not accept it as a valid String representation of the primitive.

A value written as the row type can be read as the column type.

</table>

Attempting to read a null value as a primitive type must be treated as calling the primitive's corresponding `valueOf(String)` conversion method with a null value. Since `char` does not support a `String` conversion, attempting to read a null value as a `char` must throw a `NullPointerException`.

Method Detail

public boolean readBoolean() throws JMSException

    boolean return

    Throws JMSException: JMS
    Throws MessageEOFException:
    Throws MessageFormatException:
    Throws MessageNotReadableException:

readBoolean

boolean readBoolean() throws JMSException

    Reads a boolean from the stream message.

Returns:
    the boolean value read

Throws:
    JMSException - if the JMS provider fails to read the message due to some internal error.
    MessageEOFException - if unexpected end of message stream has been reached.
    MessageFormatException - if this type conversion is invalid.
    MessageNotReadableException - if the message is in write-only mode.

public byte readByte() throws JMSException
byte

return 8

Throws JMSException: JMS

Throws MessageEOFException:

Throws MessageFormatException:

Throws MessageNotReadableException:

readByte

byte readByte()

throws JMSException

Reads a byte value from the stream message.

Returns:
the next byte from the stream message as a 8-bit byte

Throws:
JMSException - if the JMS provider fails to read the message due to some internal error.
MessageEOFException - if unexpected end of message stream has been reached.
MessageFormatException - if this type conversion is invalid.
MessageNotReadableException - if the message is in write-only mode.

-----------

public short readShort() throws JMSException

16

return 16

Throws JMSException: JMS

Throws MessageEOFException:

Throws MessageFormatException:

Throws MessageNotReadableException:
short readShort() throws JMSException

Reads a 16-bit integer from the stream message.

Returns:  
a 16-bit integer from the stream message

Throws:  
  JMSException - if the JMS provider fails to read the message due to some internal error.
  MessageEOFException - if unexpected end of message stream has been reached.
  MessageFormatException - if this type conversion is invalid.
  MessageNotReadableException - if the message is in write-only mode.

public char readChar() throws JMSException

Unicode

<table>
<thead>
<tr>
<th>return</th>
<th>Unicode</th>
</tr>
</thead>
</table>

Throws  
  JMSException: JMS
  MessageEOFException:  
  MessageFormatException:  
  MessageNotReadableException: 

readChar

char readChar() throws JMSException

Reads a Unicode character value from the stream message.

Returns:  
a Unicode character from the stream message

Throws:  
  JMSException - if the JMS provider fails to read the message due to some internal error.
  MessageEOFException - if unexpected end of message stream
public int readInt() throws JMSException

32

return 32

int

Throws: JMSException: JMS

Throws: MessageEOFException:

Throws: MessageFormatException:

Throws: MessageNotReadableException:

readInt

int readInt() throws JMSException

Reads a 32-bit integer from the stream message.

Returns:

a 32-bit integer value from the stream message, interpreted as an int

Throws:

JMSException - if the JMS provider fails to read the message due to some internal error.

MessageEOFException - if unexpected end of message stream has been reached.

MessageFormatException - if this type conversion is invalid.

MessageNotReadableException - if the message is in write-only mode.

public long readLong() throws JMSException

64

return 64

long
Throws JMSException: JMS
Throws MessageEOFException:
Throws MessageFormatException:
Throws MessageNotReadableException:

**readLong**

long readLong() throws JMSException

Reads a 64-bit integer from the stream message.

**Returns:**
- a 64-bit integer value from the stream message, interpreted as a long

**Throws:**
- JMSException - if the JMS provider fails to read the message due to some internal error.
- MessageEOFException - if unexpected end of message stream has been reached.
- MessageFormatException - if this type conversion is invalid.
- MessageNotReadableException - if the message is in write-only mode.

**public float readFloat() throws JMSException**

float return

float

**Throws**
- JMSException: JMS
- MessageEOFException:
- MessageFormatException:
- MessageNotReadableException:

**readFloat**

float readFloat()
public double readDouble() throws JMSException

double return double

Throws

JMSException: JMS
MessageEOFException:
MessageFormatException:
MessageNotReadableException:

readDouble

double readDouble() throws JMSException

Reads a double from the stream message.

Returns:

a double value from the stream message

Throws:

JMSException - if the JMS provider fails to read the message due to some internal error.
MessageEOFException - if unexpected end of message stream has been reached.
MessageFormatException - if this type conversion is invalid.
MessageNotReadableException - if the message is in write-only mode.
public String readString() throws JMSException

String return Unicode

Throws JMSException: JMS
Throws MessageEOFException:
Throws MessageFormatException:
Throws MessageNotReadableException:

readString

String readString() throws JMSException

Reads a String from the stream message.

Returns: a Unicode string from the stream message

Throws: JMSException - if the JMS provider fails to read the message due to some internal error.
MessageEOFException - if unexpected end of message stream has been reached.
MessageFormatException - if this type conversion is invalid.
MessageNotReadableException - if the message is in write-only mode.

public int readBytes(byte[] value) throws JMSException

byte readBytes
readBytes readBytes -1

byte null readBytes -1

byte readBytes 0

byte[] readBytes

MessageFormatException

byte byte[] readObject

return byte -1

Throws JMSException: JMS

Throws MessageEOFException:

Throws MessageFormatException:

Throws MessageNotReadableException:

See also readObject()
If the byte array field value is empty, `readBytes` returns 0.

Once the first `readBytes` call on a `byte[]` field value has been made, the full value of the field must be read before it is valid to read the next field. An attempt to read the next field before that has been done will throw a `MessageFormatException`.

To read the byte field value into a new `byte[]` object, use the `readObject` method.

**Parameters:**
- `value` - the buffer into which the data is read

**Returns:**
the total number of bytes read into the buffer, or -1 if there is no more data because the end of the byte field has been reached

**Throws:**
- `JMSException` - if the JMS provider fails to read the message due to some internal error.
- `MessageEOFException` - if unexpected end of message stream has been reached.
- `MessageFormatException` - if this type conversion is invalid.
- `MessageNotReadableException` - if the message is in write-only mode.

**See Also:**
- `readObject()`

**MessageFormatException**: 

Throws  

**MessageNotReadableException**: 

See also  

readBytes(byte[] value)

---

**readObject**

```
Object readObject()  
throws JMSException
```

Reads an object from the stream message.

This method can be used to return, in objectified format, an object in the Java programming language ("Java object") that has been written to the stream with the equivalent `writeObject` method call, or its equivalent primitive `write` method.

Note that byte values are returned as `byte[]`, not `Byte[]`.

An attempt to call `readObject` to read a byte field value into a new `byte[]` object before the full value of the byte field has been read will throw a `MessageFormatException`.

**Returns:**

a Java object from the stream message, in objectified format (for example, if the object was written as an `int`, an `Integer` is returned)

**Throws:**

- **JMSException** - if the JMS provider fails to read the message due to some internal error.
- **MessageEOFException** - if unexpected end of message stream has been reached.
- **MessageFormatException** - if this type conversion is invalid.
- **MessageNotReadableException** - if the message is in write-only mode.

**See Also:**
public void writeBoolean(boolean value) throws JMSException

boolean true (byte)1 false (byte)0

value boolean

Throws JMSException: JMS

Throws MessageNotWriteableException:

writeBoolean

void writeBoolean(boolean value)

throws JMSException

Writes a boolean to the stream message. The value true is written as the value (byte)1; the value false is written as the value (byte)0.

Parameters:
value - the boolean value to be written

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
MessageNotWriteableException - if the message is in read-only mode.

public void writeByte(byte value) throws JMSException

byte

value byte

Throws JMSException: JMS

Throws MessageNotWriteableException:

writeByte
void writeByte(byte value) throws JMSException

Writes a byte to the stream message.

Parameters:
value - the byte value to be written

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
MessageNotWriteableException - if the message is in read-only mode.

public void writeShort(short value) throws JMSException

short
value
short

Throws
JMSException: JMS
MessageNotWriteableException:

writeShort

void writeShort(short value) throws JMSException

Writes a short to the stream message.

Parameters:
value - the short value to be written

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
MessageNotWriteableException - if the message is in read-only mode.

public void writeChar(char value) throws JMSException

char
```java
void writeChar(char value)
  throws JMSException

Writes a char to the stream message.

Parameters:
  value - the char value to be written

Throws:
  JMSException - if the JMS provider fails to write the message due to some internal error.
  MessageNotWriteableException - if the message is in read-only mode.
```

```java
public void writeInt(int value) throws JMSException
int

void writeInt(int value)
  throws JMSException

Writes an int to the stream message.

Parameters:
  value - the int value to be written

Throws:
```

JMSException - if the JMS provider fails to write the message due to some internal error.
MessageNotWriteableException - if the message is in read-only mode.

```java
public void writeLong(long value) throws JMSException

void writeLong(long value)
    throws JMSException

writeLong

Parameters:
value - the long value to be written

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
MessageNotWriteableException - if the message is in read-only mode.
```

```java
public void writeFloat(float value) throws JMSException

void writeFloat(float value)
    throws JMSException

writeFloat
```
void `writeFloat`(float value) throws `JMSException`

Writes a float to the stream message.

**Parameters:**
value - the float value to be written

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `MessageNotWriteableException` - if the message is in read-only mode.

```
public void writeDouble(double value) throws `JMSException`

double
value double

throws `JMSException`: JMS
Throws `MessageNotWriteableException`:
```

writeDouble

void `writeDouble`(double value) throws `JMSException`

Writes a double to the stream message.

**Parameters:**
value - the double value to be written

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `MessageNotWriteableException` - if the message is in read-only mode.

```
public void writeString(String value) throws `JMSException`
```

```
public void writeBytes(byte[] value) throws JMSException
byte

void writeBytes(byte[] value)
throws JMSException

void writeString(String value)
throws JMSException

writeString

throws JMSException

void writeString(String value)
throws JMSException

public void writeBytes(byte[] value) throws JMSException

Write a byte array field to the stream message.

void writeBytes(byte[] value)
throws JMSException

Write a String to the stream message.

Parameters:
value - the String value to be written

Throws:
JMSException - if the JMS provider fails to write the message due to some internal error.
messageNotWriteableException - if the message is in read-only mode.

Throws:
JMSException: JMS

Throws:
MessageNotWriteableException: JMS
The byte array `value` is written to the message as a byte array field. Consecutively written byte array fields are treated as two distinct fields when the fields are read.

**Parameters:**
- `value` - the byte array value to be written

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `MessageNotWriteableException` - if the message is in read-only mode.

```java
public void writeBytes(byte[] value, int offset, int length)
    throws JMSException
```

Writes a portion of a byte array as a byte array field to the stream message.

The a portion of the byte array `value` is written to the message as a byte array field. Consecutively written byte array fields are treated as
two distinct fields when the fields are read.

**Parameters:**
- value - the byte array value to be written
- offset - the initial offset within the byte array
- length - the number of bytes to use

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due to some internal error.
- `MessageNotWriteableException` - if the message is in read-only mode.

```java
public void writeObject(Object value) throws JMSException
```

<table>
<thead>
<tr>
<th>Integer</th>
<th>Double</th>
<th>Long</th>
<th>String</th>
<th>byte</th>
</tr>
</thead>
</table>

Java

**Throws**
- `JMSException`: JMS
- `MessageFormatException`: 
- `MessageNotWriteableException`: 

**writeObject**

```java
void writeObject(Object value)
``` throws `JMSException`

Writes an object to the stream message.

This method works only for the objectified primitive object types (Integer, Double, Long ...), String objects, and byte arrays.

**Parameters:**
- value - the Java object to be written

**Throws:**
- `JMSException` - if the JMS provider fails to write the message due
to some internal error.

MessageFormatException - if the object is invalid.

MessageNotWriteableException - if the message is in read-only mode.

---

public void reset() throws JMSException

Throws JMSException: JMS

Throws MessageFormatException:

reset

void reset() throws JMSException

Puts the message body in read-only mode and repositions the stream to the beginning.

Throws:

JMSException - if the JMS provider fails to reset the message due to some internal error.

MessageFormatException - if the message has an invalid format.
javax.xml.stream.util  **Class StreamReaderDelegate**

java.lang.Object  
  javax.xml.stream.util.StreamReaderDelegate

**All Implemented Interfaces:**
  XMLStreamConstants, XMLStreamReader

```
public class StreamReaderDelegate
extends Object
implements XMLStreamReader

Implements: XMLStreamReader
```

XMLStreamReader  
XMLStreamReader

version  
1.0

See  
javax.xml.stream.XMLStreamReader,
also  
javax.xml.stream.util.EventReaderDelegate

This is the base class for deriving an XMLStreamReader filter This class is designed to sit between an XMLStreamReader and an application's XMLStreamReader. By default each method does nothing but call the corresponding method on the parent interface.

**Version:**  
1.0

**Author:**  
Copyright (c) 2003 by BEA Systems. All Rights Reserved.

<tr>
<td><code>getProperty(String name)</code></td>
<td>Get the value of a feature/property from the underlying implementation.</td>
</tr>
<tr>
<td><code>getText()</code></td>
<td>Returns the current value of the parse event as a string, this returns the string value of a CHARACTERS event, returns the value of a COMMENT, the replacement value for an ENTITY_REFERENCE, the string value of a CDATA section, the string value for a SPACE event, or the String value of the internal subset of the DTD.</td>
</tr>
<tr>
<td><code>getTextCharacters()</code></td>
<td>Returns an array which contains the characters from this event.</td>
</tr>
<tr>
<td><code>getTextCharacters(int sourceStart, char[] target, int targetStart, int length)</code></td>
<td></td>
</tr>
</tbody>
</table>

**Note:** The above table contains the methods and their descriptions extracted from the text.
### getTextLength() Method
- **Description:**
  - Gets the length of the sequence of characters for this Text event within the text character array.
- **Returns:**
  - An `int` representing the length of the sequence of characters.

### getTextStart() Method
- **Description:**
  - Returns the offset into the text character array where the first character (of this text event) is stored.
- **Returns:**
  - An `int` representing the offset into the text character array.

### getVersion() Method
- **Description:**
  - Gets the XML version declared on the XML declaration.
  - Returns `null` if none was declared.
- **Returns:**
  - A `String` representing the XML version or `null`.

### hasName() Method
- **Description:**
  - Returns true if the current event has a name (is a START_ELEMENT or END_ELEMENT); otherwise, false.
- **Returns:**
  - A `boolean` indicating whether the current event has a name.

### hasNext() Method
- **Description:**
  - Returns true if there are more parsing events and false if there are no more events.
- **Returns:**
  - A `boolean` indicating whether there are more parsing events.

### hasText() Method
- **Description:**
  - Return true if the current event has text, false otherwise. The following events have text: CHARACTERS, DTD, ENTITY_REFERENCE, COMMENT, SPACE.
- **Returns:**
  - A `boolean` indicating whether the current event has text.

### isAttributeSpecified(int index) Method
- **Description:**
  - Returns a boolean which indicates if this attribute was created by default.
- **Parameters:**
  - `index` (int)
- **Returns:**
  - A `boolean` indicating if the attribute was created by default.

### isCharacters() Method
- **Description:**
  - Returns true if the cursor points to a character data event.
- **Returns:**
  - A `boolean` indicating whether the cursor points to a character data event.

### isEndElement() Method
- **Description:**
  - Returns true if the cursor points to an end tag (otherwise false).
- **Returns:**
  - A `boolean` indicating whether the cursor points to an end tag.

### isStandalone() Method
- **Description:**
  - Gets the standalone declaration from the XML declaration.
- **Returns:**
  - A `boolean` indicating whether the XML declaration is standalone.
<table>

</table>

Methods inherited from class java.lang.Object:
- clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

**Constructor Detail**

public `StreamReaderDelegate()`
StreamReaderDelegate

public StreamReaderDelegate()

Construct an empty filter with no parent.

public StreamReaderDelegate(XMLStreamReader reader)

reader

StreamReaderDelegate

public StreamReaderDelegate(XMLStreamReader reader)

Construct an filter with the specified parent.

Parameters:
reader - the parent

Method Detail

public void setParent(XMLStreamReader reader)

reader

setParent

public void setParent(XMLStreamReader reader)

Set the parent of this instance.

Parameters:
reader - the new parent
public **XMLElement** getParent()

    return null

getParent

public **XMLElement** getParent()

    Get the parent of this instance.

    **Returns:**
    the parent or null if none is set

public int next() throws **XMLStreamException**

next

public int next()
    throws **XMLStreamException**

    **Description copied from interface:** **XMLElement**
    Get next parsing event - a processor may return all contiguous
    character data in a single chunk, or it may split it into several chunks.
    If the property javax.xml.stream.isCoalescing is set to true element
    content must be coalesced and only one CHARACTERS event must
    be returned for contiguous element content or CDATA Sections. By
    default entity references must be expanded and reported
    transparently to the application. An exception will be thrown if an
    entity reference cannot be expanded. If element content is empty
    (i.e. content is "") then no CHARACTERS event will be reported.

    Given the following XML:
    <foo><!--description-->content text<!
    [CDATA[<greeting>Hello</greeting>]]>other content</foo>
    The behavior of calling next() when being on foo will be:
1- the comment (COMMENT)  
2- then the characters section (CHARACTERS)  
3- then the CDATA section (another CHARACTERS)  
4- then the next characters section (another CHARACTERS)  
5- then the END_ELEMENT  

**NOTE:** empty element (such as <tag/>) will be reported with two separate events: START_ELEMENT, END_ELEMENT - This preserves parsing equivalency of empty element to <tag></tag>. This method will throw an IllegalStateException if it is called after hasNext() returns false.  

**Specified by:**  
next in interface `XMLStreamReader`  

**Returns:**  
the integer code corresponding to the current parse event  

**Throws:**  
`XMLStreamException` - if there is an error processing the underlying XML source  

**See Also:**  
`XMLEvent`  

```java  
public int nextTag() throws XMLStreamException  
```

**nextTag**

```java  
public int nextTag()  
throws XMLStreamException  
```

**Description copied from interface:** `XMLStreamReader`  
Skips any white space (isWhiteSpace() returns true), COMMENT, or PROCESSING_INSTRUCTION, until a START_ELEMENT or END_ELEMENT is reached. If other than white space characters, COMMENT, PROCESSING_INSTRUCTION, START_ELEMENT, END_ELEMENT are encountered, an exception is thrown. This method should be used when processing element-only content seperated by white space.
Precondition: none
Postcondition: the current event is START_ELEMENT or END_ELEMENT and cursor may have moved over any whitespace event.
Essentially it does the following (implementations are free to optimized but must do equivalent processing):

```java
int eventType = next();
while((eventType == XMLStreamConstants.CHARACTERS && isWhiteSpace()) // skip whitespace
    || (eventType == XMLStreamConstants.CDATA && isWhiteSpace()) // skip whitespace
    || eventType == XMLStreamConstants.SPACE
    || eventType == XMLStreamConstants.PROCESSING_INSTRUCTION
    || eventType == XMLStreamConstants.COMMENT)
{
    eventType = next();
}
if (eventType != XMLStreamConstants.START_ELEMENT && eventType != XMLStreamConstants.END_ELEMENT)
    throw new String XMLStreamException("expected start or end tag"
} return eventType;
```

**Specified by:**
nextTag in interface XMLStreamReader

**Returns:**
the event type of the element read (START_ELEMENT or END_ELEMENT)

**Throws:**
XMLStreamException - if the current event is not white space, PROCESSING_INSTRUCTION, START_ELEMENT or END_ELEMENT

```
public String getElementText() throws XMLStreamException

getElementText
```

```
public String getElementText() throws XMLStreamException
```
Description copied from interface: `XMLStreamReader`

Reads the content of a text-only element, an exception is thrown if this is not a text-only element. Regardless of value of javax.xml.stream.isCoalescing this method always returns coalesced content.

Precondition: the current event is START_ELEMENT.

Postcondition: the current event is the corresponding END_ELEMENT.

The method does the following (implementations are free to optimized but must do equivalent processing):

```java
if(getEventType() != XMLStreamConstants.START_ELEMENT) {
    throw new XMLStreamException("parser must be on START_ELEMENT to read next text", getLocation());
}
int eventType = next();
StringBuffer content = new StringBuffer();
while(eventType != XMLStreamConstants.END_ELEMENT ) {
    if(eventType == XMLStreamConstants.CHARACTERS
        || eventType == XMLStreamConstants.CDATA
        || eventType == XMLStreamConstants.SPACE
        || eventType == XMLStreamConstants.ENTITY_REFERENCE) {
        buf.append(getText());
    } else if(eventType == XMLStreamConstants.PROCESSING_INSTRUCTION
        || eventType == XMLStreamConstants.COMMENT) {
        // skipping
    } else if(eventType == XMLStreamConstants.END_DOCUMENT) {
        throw new XMLStreamException("unexpected end of document when reading element text content",
            getLocation());
    } else if(eventType == XMLStreamConstants.START_ELEMENT) {
        throw new XMLStreamException("element text content may not contain START_ELEMENT",
            getLocation());
    } else {
        throw new XMLStreamException("Unexpected event type "+eventType, getLocation());
    }
    eventType = next();
} return buf.toString();
```

Specified by:
`getElementText` in interface `XMLStreamReader`

Throws:
`XMLStreamException` - if the current event is not a
START_ELEMENT or if a non text element is encountered

```java
public void require(int type, String namespaceURI, String localName) throws XMLStreamException

Description copied from interface: XMLStreamReader
Test if the current event is of the given type and if the namespace and name match the current namespace and name of the current event. If the namespaceURI is null it is not checked for equality, if the localName is null it is not checked for equality.

Specified by:
require in interface XMLStreamReader
Parameters:
type - the event type
namespaceURI - the uri of the event, may be null
localName - the localName of the event, may be null
Throws:
XMLStreamException - if the required values are not matched.
```

```java
public boolean hasNext() throws XMLStreamException

Description copied from interface: XMLStreamReader
```
Returns true if there are more parsing events and false if there are no more events. This method will return false if the current state of the XMLStreamReader is END_DOCUMENT

**Specified by:**
`hasNext` in interface `XMLStreamReader`

**Returns:**
true if there are more events, false otherwise

**Throws:**
`XMLStreamException` - if there is a fatal error detecting the next state

---

**public void close() throws `XMLStreamException`**

**close**

`public void close()`  
`throws XMLStreamException`

**Description copied from interface: `XMLStreamReader`**
Frees any resources associated with this Reader. This method does not close the underlying input source.

**Specified by:**
`close` in interface `XMLStreamReader`

**Throws:**
`XMLStreamException` - if there are errors freeing associated resources

---

**public String getNamespaceURI(String prefix)**

**getNamespaceURI**

`public String getNamespaceURI(String prefix)`
Description copied from interface: **XMLStreamReader**
Return the uri for the given prefix. The uri returned depends on the current state of the processor.

**NOTE:** The 'xml' prefix is bound as defined in [Namespaces in XML](http://www.w3.org/XML/1998/namespace) specification to "http://www.w3.org/XML/1998/namespace".

**NOTE:** The 'xmlns' prefix must be resolved to following namespace http://www.w3.org/2000/xmlns/

Specified by: 
  [getNamespaceURI](http://www.w3.org/XML/1998/namespace) in interface **XMLStreamReader**

**Parameters:**
 prefix - The prefix to lookup, may not be null

**Returns:**
 the uri bound to the given prefix or null if it is not bound

### public javax.xml.namespace.NamespaceContext getNamespaceContext()

**getNamespaceContext**

**Description copied from interface: **XMLStreamReader**

Returns a read only namespace context for the current position. The context is transient and only valid until a call to next() changes the state of the reader.

**Specified by:**
  [getNamespaceContext](http://www.w3.org/XML/1998/namespace) in interface **XMLStreamReader**

**Returns:**
 return a namespace context

### public boolean isStartElement()
isStartElement

public boolean isStartElement()

Description copied from interface: XMLStreamReader
Returns true if the cursor points to a start tag (otherwise false)

Specified by:
    isStartElement in interface XMLStreamReader
Returns:
    true if the cursor points to a start tag, false otherwise

isEndElement

public boolean isEndElement()

isCharacters

public boolean isCharacters()

Description copied from interface: XMLStreamReader
Returns true if the cursor points to an end tag (otherwise false)

Specified by:
    isEndElement in interface XMLStreamReader
Returns:
    true if the cursor points to an end tag, false otherwise
Returns true if the cursor points to a character data event

Specified by:
    isCharacters in interface XMLStreamReader

Returns:
    true if the cursor points to character data, false otherwise

public boolean isWhiteSpace()

isWhiteSpace

public boolean isWhiteSpace()

    Description copied from interface: XMLStreamReader
    Returns true if the cursor points to a character data event that consists of all whitespace

    Specified by:
        isWhiteSpace in interface XMLStreamReader

    Returns:
        true if the cursor points to all whitespace, false otherwise

public String getAttributeValue(String namespaceUri,
                                  String localName)

getAttributeValue

public String getAttributeValue(String namespaceUri,
                                  String localName)

    Description copied from interface: XMLStreamReader
    Returns the normalized attribute value of the attribute with the namespace and localName If the namespaceURI is null the namespace is not checked for equality
Specified by: 
`getAttributeValue` in interface `XMLStreamReader` 

Parameters:
- namespaceUri - the namespace of the attribute
- localName - the local name of the attribute, cannot be null

Returns:
returns the value of the attribute, returns null if not found

---

```java
public int getAttributeCount()
```

**getAttributeCount**

```java
public int getAttributeCount()
```

**Description copied from interface: XMLStreamReader**
Returns the count of attributes on this START_ELEMENT, this method is only valid on a START_ELEMENT or ATTRIBUTE. This count excludes namespace definitions. Attribute indices are zero-based.

**Specified by:**
`getAttributeCount` in interface `XMLStreamReader`

**Returns:**
returns the number of attributes

---

```java
public javax.xml.namespace.QName getAttributeName(int index)
```

**getAttributeName**

```java
public QName getAttributeName(int index)
```

**Description copied from interface: XMLStreamReader**
Returns the qname of the attribute at the provided index
**public String getAttributePrefix(int index)**

**getAttributePrefix**

```java
public String getAttributePrefix(int index)
```

**Description copied from interface: XMLStreamReader**

Returns the prefix of this attribute at the provided index.

**Specified by:**

```java
getAttributePrefix in interface XMLStreamReader
```

**Parameters:**

- `index` - the position of the attribute

**Returns:**

- the prefix of the attribute

---

**public String getAttributeNamespace(int index)**

**getAttributeNamespace**

```java
public String getAttributeNamespace(int index)
```

**Description copied from interface: XMLStreamReader**

Returns the namespace of the attribute at the provided index.

**Specified by:**

```java
getAttributeNamespace in interface XMLStreamReader
```

**Parameters:**

- `index` - the position of the attribute

**Returns:**

- the namespace of the attribute
index - the position of the attribute

**Returns:**
the namespace URI (can be null)

---

**public String getAttributeLocalName(int index)**

**getAttributeLocalName**

**public String getAttributeLocalName(int index)**

**Description copied from interface:** [XMLStreamReader](https://docs.oracle.com/en/java/javase/11/docs/api/java.xml/jaxen/flushable/impl/DefaultXMLStreamReader.html)
Returns the localName of the attribute at the provided index

**Specified by:**  
getAttributeLocalName in interface [XMLStreamReader](https://docs.oracle.com/en/java/javase/11/docs/api/java.xml/jaxen/flushable/impl/DefaultXMLStreamReader.html)

**Parameters:**
- **index** - the position of the attribute

**Returns:**  
the localName of the attribute

---

**public String getAttributeType(int index)**

**getAttributeType**

**public String getAttributeType(int index)**

**Description copied from interface:** [XMLStreamReader](https://docs.oracle.com/en/java/javase/11/docs/api/java.xml/jaxen/flushable/impl/DefaultXMLStreamReader.html)
Returns the XML type of the attribute at the provided index

**Specified by:**  
getAttributeType in interface [XMLStreamReader](https://docs.oracle.com/en/java/javase/11/docs/api/java.xml/jaxen/flushable/impl/DefaultXMLStreamReader.html)

**Parameters:**
- **index** - the position of the attribute

**Returns:**  
the XML type of the attribute
public String getAttributeValue(int index)

getAttributeValue

public String getAttributeValue(int index)

Description copied from interface: XMLStreamReader
Returns the value of the attribute at the index

Specified by: getAttributeValue in interface XMLStreamReader

Parameters:
  index - the position of the attribute

Returns:
  the attribute value

public boolean isAttributeSpecified(int index)

isAttributeSpecified

public boolean isAttributeSpecified(int index)

Description copied from interface: XMLStreamReader
Returns a boolean which indicates if this attribute was created by default

Specified by: isAttributeSpecified in interface XMLStreamReader

Parameters:
  index - the position of the attribute

Returns:
  true if this is a default attribute
public int getNamespaceCount()

getNamespaceCount

public int getNamespaceCount()

Description copied from interface: XMLStreamReader
Returns the count of namespaces declared on this
START_ELEMENT or END_ELEMENT, this method is only valid on
a START_ELEMENT, END_ELEMENT or NAMESPACE. On an
END_ELEMENT the count is of the namespaces that are about to go
out of scope. This is the equivalent of the information reported by
SAX callback for an end element event.

Specified by:
    getNamespaceCount in interface XMLStreamReader

Returns:
    returns the number of namespace declarations on this specific
element

public String getNamespacePrefix(int index)

getNamespacePrefix

public String getNamespacePrefix(int index)

Description copied from interface: XMLStreamReader
Returns the prefix for the namespace declared at the index. Returns
null if this is the default namespace declaration

Specified by:
    getNamespacePrefix in interface XMLStreamReader

Parameters:
    index - the position of the namespace declaration

Returns:
    returns the namespace prefix
public String getNamespaceURI(int index)

getNamespaceURI

public String getNamespaceURI(int index)

Description copied from interface: XMLStreamReader
Returns the uri for the namespace declared at the index.

Specified by:
getNamespaceURI in interface XMLStreamReader

Parameters:
index - the position of the namespace declaration

Returns:
returns the namespace uri

public int getEventType()

getEventType

public int getEventType()

Description copied from interface: XMLStreamReader
Returns an integer code that indicates the type of the event the cursor is pointing to.

Specified by:
getEventType in interface XMLStreamReader

public String getText()

getText
public String getText()

Description copied from interface: XMLStreamReader
Returns the current value of the parse event as a string, this returns the string value of a CHARACTERS event, returns the value of a COMMENT, the replacement value for an ENTITYREFERENCE, the string value of a CDATA section, the string value for a SPACE event, or the String value of the internal subset of the DTD. If an ENTITYREFERENCE has been resolved, any character data will be reported as CHARACTERS events.

Specified by:
   getText in interface XMLStreamReader
Returns:
   the current text or null

public int getTextCharacters(int sourceStart, char[] target, int targetStart, int length) throws XMLStreamException

ggetTextCharacters

Description copied from interface: XMLStreamReader
Gets the the text associated with a CHARACTERS, SPACE or CDATA event. Text starting a "sourceStart" is copied into "target" starting at "targetStart". Up to "length" characters are copied. The number of characters actually copied is returned. The "sourceStart" argument must be greater or equal to 0 and less than or equal to the number of characters associated with the event. Usually, one requests text starting at a "sourceStart" of 0. If the number of characters actually copied is less than the "length", then there is no more text. Otherwise, subsequent calls need to be made until all text has been retrieved. For example: int length = 1024; char[]
myBuffer = new char[ length ]; for ( int sourceStart = 0 ; ;
sourceStart += length ) { int nCopied =
stream.getTextCharacters( sourceStart, myBuffer, 0, length );
if ( nCopied < length ) break; } XMLStreamException may be
thrown if there are any XML errors in the underlying source. The
"targetStart" argument must be greater than or equal to 0 and less
than the length of "target", Length must be greater than 0 and
"targetStart + length" must be less than or equal to length of "target".

Specified by:
   getTextCharacters in interface XMLStreamReader
Parameters:
   sourceStart - the index of the first character in the source array
to copy
target - the destination array
targetStart - the start offset in the target array
length - the number of characters to copy
Returns:
   the number of characters actually copied
Throws:
   XMLStreamException - if the underlying XML source is not well-
formed

public char[] getTextCharacters()
**getTextCharacters** in interface [XMLStreamReader](https://www.w3.org/TR/xml-stream/#get-text-characters)

**Returns:**
the current text or an empty array

---

**public int getTextStart()**

ggetTextStart

**public int getTextStart()**

Description copied from interface: [XMLStreamReader](https://www.w3.org/TR/xml-stream/#get-text-start)

Returns the offset into the text character array where the first character (of this text event) is stored.

**Specified by:**
ggetTextStart in interface [XMLStreamReader](https://www.w3.org/TR/xml-stream/#get-text-start)

---

**public int getTextLength()**

ggetTextLength

**public int getTextLength()**

Description copied from interface: [XMLStreamReader](https://www.w3.org/TR/xml-stream/#get-text-length)

Returns the length of the sequence of characters for this Text event within the text character array.

**Specified by:**
ggetTextLength in interface [XMLStreamReader](https://www.w3.org/TR/xml-stream/#get-text-length)

---

**public String getEncoding()**
getEncoding

public String getEncoding()

Description copied from interface: XMLStreamReader
Return input encoding if known or null if unknown.

Specified by: getEncoding in interface XMLStreamReader

Returns:
the encoding of this instance or null

---------------------

public boolean hasText()

hasText

public boolean hasText()

Description copied from interface: XMLStreamReader
Return true if the current event has text, false otherwise The following events have text: CHARACTERS,DTD ,ENTITY_REFERENCE, COMMENT, SPACE

Specified by: hasText in interface XMLStreamReader

---------------------

public Location getLocation()

getLocation

public Location getLocation()

Description copied from interface: XMLStreamReader
Return the current location of the processor. If the Location is unknown the processor should return an implementation of Location
that returns -1 for the location and null for the publicId and systemId. The location information is only valid until next() is called.

**Specified by:**
*getLocation* in interface *XMLStreamReader*

---

**public javax.xml.namespace.QName getName()**

*getName*

**public QName getName()**

*Description copied from interface: XMLStreamReader*
Returns a QName for the current START_ELEMENT or END_ELEMENT event

**Specified by:**
*getName* in interface *XMLStreamReader*

**Returns:**
the QName for the current START_ELEMENT or END_ELEMENT event

---

**public String getLocalName()**

*getLocalName*

**public String getLocalName()**

*Description copied from interface: XMLStreamReader*
Returns the (local) name of the current event. For START_ELEMENT or END_ELEMENT returns the (local) name of the current element. For ENTITY_REFERENCE it returns entity name. The current event must be START_ELEMENT or END_ELEMENT, or ENTITY_REFERENCE
Specified by:
   `getLocalName` in interface `XMLStreamReader`  

Returns:
   the localName

---

**public boolean hasName()**

hasName

public boolean hasName()

Description copied from interface: `XMLStreamReader`
returns true if the current event has a name (is a START_ELEMENT or END_ELEMENT) returns false otherwise

Specified by:
   `hasName` in interface `XMLStreamReader`  

---

**public String getNamespaceURI()**

getNamespaceURI

public `String` getNamespaceURI()

Description copied from interface: `XMLStreamReader`
If the current event is a START_ELEMENT or END_ELEMENT this method returns the URI of the prefix or the default namespace. Returns null if the event does not have a prefix.

Specified by:
   `getNamespaceURI` in interface `XMLStreamReader`  

Returns:
   the URI bound to this elements prefix, the default namespace, or null
public String getPrefix()

getPrefix

public String getPrefix()

    Description copied from interface: XMLStreamReader
    Returns the prefix of the current event or null if the event does not have a prefix

    Specified by: getPrefix in interface XMLStreamReader
    Returns: the prefix or null

public String getVersion()

getVersion

public String getVersion()

    Description copied from interface: XMLStreamReader
    Get the xml version declared on the xml declaration Returns null if none was declared

    Specified by: getVersion in interface XMLStreamReader
    Returns: the XML version or null

public boolean isStandalone()

isStandalone
public boolean isStandalone()

Description copied from interface: XMLStreamReader
Get the standalone declaration from the xml declaration

Specified by:
   isStandalone in interface XMLStreamReader

Returns:
   true if this is standalone, or false otherwise

public boolean standaloneSet()

standaloneSet

public boolean standaloneSet()

Description copied from interface: XMLStreamReader
Checks if standalone was set in the document

Specified by:
   standaloneSet in interface XMLStreamReader

Returns:
   true if standalone was set in the document, or false otherwise

public String getCharacterEncodingScheme()

getCharacterEncodingScheme

public String getCharacterEncodingScheme()

Description copied from interface: XMLStreamReader
Returns the character encoding declared on the xml declaration
Returns null if none was declared

Specified by:
getCharacterEncodingScheme in interface XMLStreamReader
Returns:
the encoding declared in the document or null

public String getPITarget()

g getPITarget

public String getPITarget()

Description copied from interface: XMLStreamReader
Get the target of a processing instruction

Specified by:
getPITarget in interface XMLStreamReader
Returns:
the target or null

public String getPIData()

g getPIData

public String getPIData()

Description copied from interface: XMLStreamReader
Get the data section of a processing instruction

Specified by:
getPIData in interface XMLStreamReader
Returns:
the data or null

public Object getProperty(String name)
getProperty

public Object getProperty(String name)

Description copied from interface: XMLStreamReader
Get the value of a feature/property from the underlying implementation

Specified by: getProperties in interface XMLStreamReader

Parameters:
  name - The name of the property, may not be null

Returns:
  The value of the property
javax.xml.rpc.holders  Class StringHolder

javax.mail.search  Class StringTerm

java.lang.Object  
  javax.mail.search.SearchTerm  
    javax.mail.search.StringTerm

All Implemented Interfaces:
  Serializable

Direct Known Subclasses:
  AddressStringTerm, BodyTerm, HeaderTerm, MessageIDTerm, SubjectTerm

public abstract class StringTerm
extends SearchTerm

Extends: SearchTerm
Extended by: AddressStringTerm, BodyTerm, HeaderTerm, MessageIDTerm, SubjectTerm

String  strcmp ......

This class implements the match method for Strings. The current implementation provides only for substring matching. We could add comparisons (like strcmp ...).

Author:
  Bill Shannon, John Mani

  Serialized Form

Field Summary

<table>
<thead>
<tr>
<th>protected  boolean  ignoreCase</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ignore case when comparing?</td>
</tr>
</tbody>
</table>
**protected String**

The pattern.

## Constructor Summary

| protected | StringTerm(String pattern) |
| protected | StringTerm(String pattern, boolean ignoreCase) |

## Method Summary

| boolean | equals(Object obj) |
| boolean | getIgnoreCase() |
| String | getPattern() |
| int | hashCode() |
| protected boolean | match(String s) |

Equality comparison.

Return true if we should ignore case when matching.

Return the string to match with.

Compute a hashCode for this object.

## Field Detail
pattern

protected String pattern

    The pattern.

ignoreCase

protected boolean ignoreCase

    Ignore case when comparing?

### Constructor Detail

protected StringTerm(String pattern)

**StringTerm**

protected StringTerm(String pattern)

protected StringTerm(String pattern, boolean ignoreCase)

**StringTerm**

protected StringTerm(String pattern, boolean ignoreCase)

### Method Detail

public String getPattern()
**getPattern**

```java
public String getPattern()
```

Return the string to match with.

**getIgnoreCase**

```java
public boolean getIgnoreCase()
```

```java
true
```

**getIgnoreCase**

```java
public boolean getIgnoreCase()
```

Return true if we should ignore case when matching.

**match**

```java
protected boolean match(String s)
```

**equals**

```java
public boolean equals(Object obj)
```

Equality comparison.
Overrides:

equals in class Object

public int hashCode()
hashCode

hashCode

public int hashCode()

Compute a hashCode for this object.

Overrides:

hashCode in class Object
javax.xml.rpc Interface Stub

public interface Stub

javax.xml.rpc.Stub

Stub

javax.xml.rpc.Stub

version 0.1

See also javax.xml.rpc.Service

The interface javax.xml.rpc.Stub is the common base interface for the stub classes. All generated stub classes are required to implement the javax.xml.rpc.Stub interface. An instance of a stub class represents a client side proxy or stub instance for the target service endpoint.

The javax.xml.rpc.Stub interface provides an extensible property mechanism for the dynamic configuration of a stub instance.

Version:

0.1

### Field Detail

USERNAME_PROPERTY

static final String USERNAME_PROPERTY

    Standard property: User name for authentication.

    Type: java.lang.String

**See Also:**

Constant Field Values
PASSWORD_PROPERTY

static final String PASSWORD_PROPERTY

Standard property: Password for authentication.

Type: java.lang.String

See Also: Constant Field Values

ENDPOINT_ADDRESS_PROPERTY

static final String ENDPOINT_ADDRESS_PROPERTY

Standard property: Target service endpoint address. The URI scheme for the endpoint address specification must correspond to the protocol/transport binding for this stub class.

Type: java.lang.String

See Also: Constant Field Values

SESSION_MAINTAIN_PROPERTY

static final String SESSION_MAINTAIN_PROPERTY

Standard property: This boolean property is used by a service client to indicate whether or not it wants to participate in a session with a service endpoint. If this property is set to true, the service client indicates that it wants the session to be maintained. If set to false, the session is not maintained. The default value for this property is false.
Type: java.lang.Boolean

Constant Field Values

Method Detail

public void _setProperty(String name, Object value)
Stub  Stub

_setProperty

name
value

_setProperty Stub

JAXRPCException:

Throws

- Stub

- 

_setProperty

void _setProperty(String name, Object value)

Sets the name and value of a configuration property for this Stub instance. If the Stub instances contains a value of the same property, the old value is replaced.

Note that the _setProperty method may not perform validity check on a configured property value. An example is the standard property for the target service endpoint address that is not checked for validity in the _setProperty method. In this case, stub configuration errors are detected at the remote method invocation.

Parameters:
name - Name of the configuration property
value - Value of the property

Throws:

JAXRPCException -
  • If an optional standard property name is specified, however this Stub implementation class does not support the configuration of this property.
  • If an invalid or unsupported property name is specified or if a value of mismatched property type is passed.
  • If there is any error in the configuration of a valid property.

public Object _getProperty(String name)

name
return
Throws JAXRPCException:

_getProperty

Object _getProperty(String name)

Gets the value of a specific configuration property.

Parameters:
  name - Name of the property whose value is to be retrieved

Returns:
  Value of the configuration property

Throws:
  JAXRPCException - if an invalid or unsupported property name is passed.

public java.util.Iterator<E> _getPropertyNames()

Stub

return java.lang.String Iterator
_getPropertyNames

*Iterator _getPropertyNames()*

Returns an *Iterator* view of the names of the properties that can be configured on this stub instance.

**Returns:**
Iterator for the property names of the type `java.lang.String`

PS:
javax.transaction Interface Synchronization

public interface Synchronization

registerSynchronization Transaction Synchronization

The transaction manager supports a synchronization mechanism that allows the interested party to be notified before and after the transaction completes. Using the registerSynchronization method, the application server registers a Synchronization object for the transaction currently associated with the target Transaction object.

**Method Summary**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void afterCompletion(int status)</td>
<td>This method is called by the transaction manager after the transaction is committed or rolled back.</td>
</tr>
<tr>
<td>void beforeCompletion()</td>
<td>The beforeCompletion method is called by the transaction manager prior to the start of the two-phase transaction commit process.</td>
</tr>
</tbody>
</table>

**Method Detail**

```java
class Synchronization {
    public void beforeCompletion() {
        // Method implementation
    }
}```
void beforeCompletion()

The beforeCompletion method is called by the transaction manager prior to the start of the two-phase transaction commit process. This call is executed with the transaction context of the transaction that is being committed.

public void afterCompletion(int status)

status

afterCompletion

void afterCompletion(int status)

This method is called by the transaction manager after the transaction is committed or rolled back.

Parameters:
status - The status of the transaction completion.
javax.transaction  **Class SystemException**

**java.lang.Object**
- **java.lang.Throwable**
  - **java.lang.Exception**
    - **javax.transaction.SystemException**

**All Implemented Interfaces:**
- **Serializable**

```java
public class SystemException
    extends Exception

Extends: Throwable > Exception

SystemException
```

The SystemException is thrown by the transaction manager to indicate that it has encountered an unexpected error condition that prevents future transaction services from proceeding.

- `wait`

## Field Detail

**errorCode**

```java
class SystemException {
    public int errorCode;
    // The error code with which to create the SystemException.
}
```

## Constructor Detail

**public SystemException()**

**SystemException**

```java
class SystemException {
    public SystemException() {
        // Constructor to create a SystemException.
    }
}
```
public SystemException(String s)

XAException

s

SystemException

public SystemException(String s)

Create a SystemException with a given string.

Parameters:

s - The string message for the exception

public SystemException(int errcode)

SystemException

ercode

SystemException

public SystemException(int errcode)

Create a SystemException with a given error code.

Parameters:

errcode - The error code for the exception
PS:
javax.persistence  **Annotation Type Table**

@Target(value=TYPE)  
@Retention(value=RUNTIME)  
public @interface Table

**Implements:** Annotation  
@Target(value=TYPE)  
@Retention(value=RUNTIME)

<table>
<thead>
<tr>
<th>Implementations</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>SecondaryTable</td>
<td>SecondaryTables</td>
</tr>
</tbody>
</table>

Table

@Target
@Retention
public class Customer { ...

<table>
<thead>
<tr>
<th>since</th>
<th>Java Persistence 1.0</th>
<th>en</th>
</tr>
</thead>
</table>

This annotation specifies the primary table for the annotated entity. Additional tables may be specified using **SecondaryTable** or **SecondaryTables** annotation.

If no **Table** annotation is specified for an entity class, the default values apply.

Example:

```java
@Entity
@Table(name="CUST", schema="RECORDS")
public class Customer { ...
```

**Since:**  
Java Persistence 1.0
Optional Element Summary

<table>
<thead>
<tr>
<th>Type</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>String</td>
<td>catalog</td>
<td>(Optional) The catalog of the table.</td>
</tr>
<tr>
<td>String</td>
<td>name</td>
<td>(Optional) The name of the table.</td>
</tr>
<tr>
<td>String</td>
<td>schema</td>
<td>(Optional) The schema of the table.</td>
</tr>
<tr>
<td>UniqueConstraint[]</td>
<td>uniqueConstraints</td>
<td>(Optional) Unique constraints that are to be placed on the table.</td>
</tr>
</tbody>
</table>

abstract public String name()

name

public abstract String name

(Optional) The name of the table.

Defaults to the entity name.

Default: ""

abstract public String catalog()
**catalog**

public abstract String catalog

(Optional) The catalog of the table.

Defaults to the default catalog.

**Default:**

```
""
```

---

**abstract public String schema()**

---

**schema**

public abstract String schema

(Optional) The schema of the table.

Defaults to the default schema for user.

**Default:**

```
""
```

---

**abstract public UniqueConstraint[] uniqueConstraints()**
public abstract UniqueConstraint[] uniqueConstraints

(Optional) Unique constraints that are to be placed on the table. These are only used if table generation is in effect. These constraints apply in addition to any constraints specified by the Column andJoinColumn annotations and constraints entailed by primary key mappings.

Defaults to no additional constraints.

Default:

{}
javax.persistence  **Annotation Type TableGenerator**

```java
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface TableGenerator

**Implements:** Annotation
@Target(value={TYPE, METHOD, FIELD})
@Retention(value=RUNTIME)

**GeneratedValue**

1

@Entity public class Employee {
  ...
  @TableGenerator(
      name="empGen",
      table="ID_GEN",
      pkColumnName="GEN_KEY",
      valueColumnName="GEN_VALUE",
      pkColumnValue="EMP_ID",
      allocationSize=1)
  @Id
  @GeneratedValue(strategy=TABLE, generator="empGen")
  public int id;
  ...
}

2

@Entity public class Address {
  ...
  @TableGenerator(
      name="addressGen",
      table="ID_GEN",
      pkColumnName="GEN_KEY",
      valueColumnName="GEN_VALUE",
      pkColumnValue="ADDR_ID")
  @Id
  @GeneratedValue(strategy=TABLE, generator="addressGen")
  public int id;
  ...
}
```
This annotation defines a primary key generator that may be referenced by name when a generator element is specified for the `GeneratedValue` annotation. A table generator may be specified on the entity class or on the primary key field or property. The scope of the generator name is global to the persistence unit (across all generator types).

Example 1:

```java
@Entity public class Employee {
    ...
    @TableGenerator(
        name="empGen",
        table="ID_GEN",
        pkColumnName="GEN_KEY",
        valueColumnName="GEN_VALUE",
        pkColumnValue="EMP_ID",
        allocationSize=1)
    @Id
    @GeneratedValue(strategy=TABLE, generator="empGen")
    public int id;
    ...
}
```

Example 2:

```java
@Entity public class Address {
    ...
    @TableGenerator(
        name="addressGen",
        table="ID_GEN",
        pkColumnName="GEN_KEY",
        valueColumnName="GEN_VALUE",
        pkColumnValue="ADDR_ID")
    @Id
    @GeneratedValue(strategy=TABLE, generator="addressGen")
    public int id;
    ...
}
```

public interface Tag
extends JspTag

Implements: JspTag
Implemented by: IterationTag, TagAdapter, UIComponentELTag, UIComponentTag

Tag JSP

current JSP pageContext setter getter

JSP setPageContext setParent doStartTag() doEndTag()
The interface of a classic tag handler that does not want to manipulate its body. The Tag interface defines the basic protocol between a Tag handler and JSP page implementation class. It defines the life cycle and the methods to be invoked at start and end tag.

**Properties**

The Tag interface specifies the setter and getter methods for the core pageContext and parent properties.

The JSP page implementation object invokes setPageContext and setParent, in that order, before invoking doStartTag() or doEndTag().

**Methods**
There are two main actions: doStartTag and doEndTag. Once all appropriate properties have been initialized, the doStartTag and doEndTag methods can be invoked on the tag handler. Between these invocations, the tag handler is assumed to hold a state that must be preserved. After the doEndTag invocation, the tag handler is available for further invocations (and it is expected to have retained its properties).

**Lifecycle**

Lifecycle details are described by the transition diagram below, with the following comments:

- [1] This transition is intended to be for releasing long-term data. No guarantees are assumed on whether any properties have been retained or not.
- [2] This transition happens if and only if the tag ends normally without raising an exception.
- [3] Some setters may be called again before a tag handler is reused. For instance, setParent() is called if it's reused within the same page but at a different level, setPageContext() is called if it's used in another page, and attribute setters are called if the values differ or are expressed as request-time attribute values.
- Check the TryCatchFinally interface for additional details related to exception handling and resource management.

Once all invocations on the tag handler are completed, the release method is invoked on it. Once a release method is invoked all properties, including parent and pageContext, are assumed to have been reset to an unspecified value. The page compiler guarantees that release() will be invoked on the Tag handler before the handler is released to the GC.

**Empty and Non-Empty Action**

If the TagLibraryDescriptor file indicates that the action must always have an empty action, by an <body-content> entry of "empty", then the doStartTag() method must return SKIP_BODY.

Otherwise, the doStartTag() method may return SKIP_BODY or
If \texttt{SKIP\_BODY} is returned the body, if present, is not evaluated.

If \texttt{EVAL\_BODY\_INCLUDE} is returned, the body is evaluated and "passed through" to the current out.

Field Detail

SKIP_BODY

static final int SKIP_BODY

Skip body evaluation. Valid return value for doStartTag and doAfterBody.

See Also:
Constant Field Values

EVAL_BODY_INCLUDE

static final int EVAL_BODY_INCLUDE

Evaluate body into existing out stream. Valid return value for doStartTag.

See Also:
Constant Field Values

SKIP_PAGE

static final int SKIP_PAGE

Skip the rest of the page. Valid return value for doEndTag.

See Also:
Constant Field Values
static final int EVAL_PAGE

Continue evaluating the page. Valid return value for doEndTag().

See Also:
Constant Field Values

Method Detail

public void setPageContext(PageContext pc)

JSP  doStartTag()

doStartTag() ** doEndTag()

  pc

setPageContext

void setPageContext(PageContext pc)

  Set the current page context. This method is invoked by the JSP
  page implementation object prior to doStartTag().

  This value is *not* reset by doEndTag() and must be explicitly reset
  by a page implementation if it changes between calls to
  doStartTag().

  Parameters:
    pc - The page context for this tag handler.

public void setParent(Tag t)
JSP  doStartTag()

** doEndTag()

\[ t \quad \text{null} \]

setParent

```java
void setParent(Tag t)
```

Set the parent (closest enclosing tag handler) of this tag handler. Invoked by the JSP page implementation object prior to doStartTag().

This value is *not* reset by doEndTag() and must be explicitly reset by a page implementation.

**Parameters:**
- t - The parent tag, or null.

```java
public Tag getParent()
```

getParent() TagSupport findAncestorWithClass()

observable observable void JSP

\[ \text{return null} \]

See also findAncestorWithClass

getParent
getParent()

Get the parent (closest enclosing tag handler) for this tag handler.

The getParent() method can be used to navigate the nested tag handler structure at runtime for cooperation among custom actions; for example, the findAncestorWithClass() method in TagSupport provides a convenient way of doing this.

The current version of the specification only provides one formal way of indicating the observable type of a tag handler: its tag handler implementation class, described in the tag-class subelement of the tag element. This is extended in an informal manner by allowing the tag library author to indicate in the description subelement an observable type. The type should be a subtype of the tag handler implementation class or void. This additional constraint can be exploited by a specialized container that knows about that specific tag library, as in the case of the JSP standard tag library.

Returns:

the current parent, or null if none.

TagSupport.findAncestorWithClass(javax.servlet.jsp.tagext.Tag, java.lang.Class)

public int doStartTag() throws JspException

JSP
doStartTag  pageContext

Tag.EVAL_BODY_INCLUDE
BodyTag.EVAL_BODY_BUFFERED SKIP_BODY

Tag EVAL_BODY_INCLUDE "out"
JspWriter doEndTag()
doStartTag()  JSP  AT-BEGIN  NESTED
TagExtraInfo  TLD  BodyTag  BodyTag
doStartTag()  BodyTag.EVAL_BODY_BUFFERED

return  EVAL_BODY_INCLUDE  SKIP_BODY
Throws  JspException:
See also  javax.servlet.jsp.tagext.BodyTag

doStartTag

int  doStartTag()
    throws  JspException

Process the start tag for this instance. This method is invoked by the
JSP page implementation object.

The doStartTag method assumes that the properties pageContext
and parent have been set. It also assumes that any properties
exposed as attributes have been set too. When this method is
invoked, the body has not yet been evaluated.

This method returns Tag.EVAL_BODY_INCLUDE or
BodyTag.EVAL_BODY_BUFFERED to indicate that the body of the
action should be evaluated or SKIP_BODY to indicate otherwise.

When a Tag returns EVAL_BODY_INCLUDE the result of evaluating
the body (if any) is included into the current "out" JspWriter as it
happens and then doEndTag() is invoked.

BodyTag.EVAL_BODY_BUFFERED is only valid if the tag handler
implements BodyTag.

The JSP container will resynchronize the values of any AT_BEGIN
and NESTED variables (defined by the associated TagExtraInfo or
TLD) after the invocation of doStartTag(), except for a tag handler
implementing BodyTag whose doStartTag() method returns
BodyTag.EVAL_BODY_BUFFERED.
Returns:
  EVAL_BODY_INCLUDE if the tag wants to process body,
  SKIP_BODY if it does not want to process it.

Throws:
  JspException - if an error occurred while processing this tag

See Also:
  BodyTag

---

public int doEndTag() throws JspException

JSP
doStartTag doStartTag

EVAL_PAGE SKIP_PAGE doEndTag()
Servlet
doEndTag() JSP AT_BEGIN AT_END
TagExtraInfo TLD

  return

  JspException: Threws

---

doEndTag

int doEndTag() throws JspException

Process the end tag for this instance. This method is invoked by the
JSP page implementation object on all Tag handlers.

This method will be called after returning from doStartTag. The body
of the action may or may not have been evaluated, depending on the
return value of doStartTag.

If this method returns EVAL_PAGE, the rest of the page continues to
be evaluated. If this method returns SKIP_PAGE, the rest of the
page is not evaluated, the request is completed, and the doEndTag() methods of enclosing tags are not invoked. If this request was forwarded or included from another page (or Servlet), only the current page evaluation is stopped.

The JSP container will resynchronize the values of any AT_BEGIN and AT_END variables (defined by the associated TagExtraInfo or TLD) after the invocation of doEndTag().

**Returns:**

Indication of whether to continue evaluating the JSP page.

**Throws:**

*JspException* - if an error occurred while processing this tag

```java
public void release()
JSP   doStartTag   doEndTag
```

**release**

```java
void release()
```

Called on a Tag handler to release state. The page compiler guarantees that JSP page implementation objects will invoke this method on all tag handlers, but there may be multiple invocations on doStartTag and doEndTag in between.

PS:
javax.servlet.jsp.tagext  **Class TagAdapter**

java.lang.Object

java.servlet.jsp.tagext.TagAdapter

**All Implemented Interfaces:**

  JspTag, Tag

---

public class TagAdapter

extends Object

implements Tag

**Implements:** Tag

  SimpleTag Tag  SimpleTag

  SimpleTag  Tag  Tag.setParent()  Tag  Tag
  SimpleTag  TagAdapter  SimpleTag  setParent()
  getAdaptee()  SimpleTag

since 2.0

Wraps any SimpleTag and exposes it using a Tag interface. This is used to allow collaboration between classic Tag handlers and SimpleTag handlers.

Because SimpleTag does not extend Tag, and because Tag.setParent() only accepts a Tag instance, a classic tag handler (one that implements Tag) cannot have a SimpleTag as its parent. To remedy this, a TagAdapter is created to wrap the SimpleTag parent, and the adapter is passed to setParent() instead. A classic Tag Handler can call getAdaptee() to retrieve the encapsulated SimpleTag instance.

**Since:**

  JSP 2.0
### Field Summary

public TagAdapter(SimpleTag adaptee)
SimpleTag TagAdapter getParent()

Creates a new TagAdapter that wraps the given SimpleTag and returns the parent tag when getParent() is called.

Parameters:
adaptee - The SimpleTag being adapted as a Tag.

public void setPageContext(PageContext pc)

pc

Throws UnsupportedOperationException:

setPageContext

public void setPageContext(PageContext pc)

Must not be called.

Specified by:
setPageContext in interface Tag

Parameters:
pc - ignored.

Throws:
public void setParent(Tag parentTag)
getAdaptee().getParent()

parentTag

Throws

UnsupportedOperationException:

setParent

public void setParent(Tag parentTag)

Must not be called. The parent of this tag is always
getAdaptee().getParent().

Specified by:

setParent in interface Tag

Parameters:

parentTag - ignored.

Throws:

UnsupportedOperationException - Must not be called.

public Tag getParent()

getAdaptee().getParent()

getAdaptee().getParent() Tag

getAdaptee().getParent() Tag

return

getParent

public Tag getParent()

Returns the parent of this tag, which is always
getAdaptee().getParent(). This will either be the enclosi
getAdaptee().getParent() implements Tag), or an adapter to the enclosing Tag (if getAdaptee().getParent() does not implement Tag).

**Specified by:**
- `getParent` in interface `Tag`

**Returns:**
The parent of the tag being adapted.

**See Also:**
- `TagSupport.findAncestorWithClass(javax.servlet.jsp.tagext.Tag, java.lang.Class)`

```
public JspTag getAdaptee()
Tag JSP 2.0 SimpleTag
return
```

**getAdaptee**

```
public JspTag getAdaptee()

Gets the tag that is being adapted to the Tag interface. This should be an instance of SimpleTag in JSP 2.0, but room is left for other kinds of tags in future spec versions.

**Returns:**
the tag that is being adapted
```

```
public int doStartTag() throws JspException

return UnsupportedOperationException
Throws UnsupportedOperationException:
JspException:
```

**doStartTag**
public int doStartTag() throws JspException

Must not be called.

Specified by:

Throws:

UnsupportedOperationException - Must not be called
javax.servlet.jsp.tagext  

Class TagAttributeInfo

java.lang.Object  
└ javax.servlet.jsp.tagext.TagAttributeInfo

public class TagAttributeInfo
extends Object

Tag (TLD)

SCHEMA

Information on the attributes of a Tag, available at translation time. This class is instantiated from the Tag Library Descriptor file (TLD).

Only the information needed to generate code is included here. Other information like SCHEMA for validation belongs elsewhere.

Note from the Expert Group:
This should have been designed as an interface. Every time we change the TLD, we need to add a new constructor to this class (not good). This class should only be instantiated by container implementations (not by JSP developers).

name
required
type
reqTime

**TagAttributeInfo**

```java
public TagAttributeInfo(String name,
    boolean required,
    String type,
    boolean reqTime)
```

Constructor for TagAttributeInfo. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor).

**Parameters:**
- **name** - The name of the attribute.
- **required** - If this attribute is required in tag instances.
- **type** - The name of the type of the attribute.
- **reqTime** - Whether this attribute holds a request-time Attribute.

```java
public TagAttributeInfo(String name, boolean required, String type, boolean reqTime, boolean fragment)
```

TagAttributeInfo JSP 2.0 TLD (Tag Library Descriptor) JSP TagLibrary

```java
name
required
type
reqTime
fragment JspFragment
since 2.0
```
TagAttributeInfo

```java
public TagAttributeInfo(String name,
                        boolean required,
                        String type,
                        boolean reqTime,
                        boolean fragment)
```

JSP 2.0 Constructor for TagAttributeInfo. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor).

**Parameters:**
- `name` - The name of the attribute.
- `required` - If this attribute is required in tag instances.
- `type` - The name of the type of the attribute.
- `reqTime` - Whether this attribute holds a request-time Attribute.
- `fragment` - Whether this attribute is of type JspFragment

**Since:**
JSP 2.0

---

TagAttributeInfo

```java
public TagAttributeInfo(String name, 
                        boolean required, 
                        String type, 
                        boolean reqTime, 
                        boolean fragment, 
                        String description, 
                        boolean deferredValue, 
                        boolean deferredMethod, 
                        String expectedTypeName, 
                        String methodSignature)
```

JSP 2.1 Constructor for TagAttributeInfo. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor).

**Parameters:**
name - The name of the attribute.
required - If this attribute is required in tag instances.
type - The name of the type of the attribute.
reqTime - Whether this attribute holds a request-time Attribute.
fragment - Whether this attribute is of type JspFragment
description - The description of the attribute.
deferredValue - Whether this attribute is a deferred value.
deferredMethod - Whether this attribute is a deferred method.
rtexpr or deferred value.
expectedTypeName - The name of the expected type of this
deferred value (or null if this is not a deferred value).
methodSignature - The expected method signature of this
deferred method (or null if this is not a deferred method).

Since:
JSP 2.1

### Method Detail

**public String getName()**

```
public String getName()
```

return

g getName

**public String getTypeName()**

```
public String getTypeName()
```

String

```
String
```
**getTypeName**

```java
public String getTypeName()
```

The type (as a String) of this attribute.

This method must return "javax.el.ValueExpression" if `isDeferredValue()` returns true and `canBeRequestTime()` returns false. It must return "javax.el.MethodExpression" if `isDeferredMethod()` returns true. It must return "java.lang.Object" if `isDeferredValue()` returns true and `canBeRequestTime()` returns true.

**Returns:**
the type of the attribute

---

**public boolean canBeRequestTime()**

```java
return false
```

**canBeRequestTime**

```java
public boolean canBeRequestTime()
```

Whether this attribute has been specified in the TLD as rtexprvalue. If true, this means the attribute can hold a request-time value.

**Returns:**
true if the attribute has been specified in the TLD as rtexprvalue

---

**public boolean isRequired()**

```java
return false
```

**isRequired**
public boolean **isRequired**()  

Whether this attribute is required.  

**Returns:**  

if the attribute is required.  

---

public static **TagAttributeInfo** **getIdAttribute**(TagAttributeInfo[] a)  

TagAttributeInfo "id"  

    a                              TagAttributeInfo  
    return                         "id"  TagAttributeInfo  

**getIdAttribute**

---

public static **TagAttributeInfo** **getIdAttribute**(TagAttributeInfo[] a)  

Convenience static method that goes through an array of  
TagAttributeInfo objects and looks for "id".  

**Parameters:**  

a - An array of TagAttributeInfo  

**Returns:**  

The TagAttributeInfo reference with name "id"

---

public boolean **isFragment**()  

JspFragment  

    return                        JspFragment  
    since                         2.0  

**isFragment**

---

public boolean **isFragment**()
Whether this attribute is of type JspFragment.

**Returns:**
if the attribute is of type JspFragment

**Since:**
JSP 2.0

---

getDescription

```java
public String getDescription()
```

Gets the description string of this tag attribute.

**Returns:**
the description string of this tag attribute

---

isDeferredValue

```java
public boolean isDeferredValue()
```

Returns true if this attribute is to be passed a ValueExpression so that expression evaluation can be deferred.

If this method returns true, then `getExpectedType()` must return "javax.el.ValueExpression".

The `getExpectedType()` method can be used to retrieve the expected type this value expression will be constructed with.

**Returns:**
true if this attribute accepts a deferred value; false otherwise.

**Since:**
JSP 2.1
isDeferredMethod
public boolean isDeferredMethod()

Returns true if this attribute is to be passed a MethodExpression so that expression evaluation can be deferred.

If this method returns true, then getTypeName() must return "javax.el.MethodExpression".

The getMethodSignature() method can be used to retrieve the expected method signature this method expression will be constructed with.

Returns:
true if this attribute accepts a deferred method; false otherwise.

Since:
JSP 2.1

getExpectedTypeName
public String getExpectedTypeName()

Returns the name of the expected type (as a String) of this deferred value attribute.

This method returns null if isDeferredValue() returns false.

Returns:
the name of the expected type

Since:
JSP 2.1
getMethodSignature

public String getMethodSignature()

Returns the expected method signature of this deferred method attribute.

This method returns null if isDeferredMethod() returns false.

Returns: the method signature

Since: JSP 2.1

public String toString()

TagAttributeInfo String

return TagAttributeInfo String

toString

public String toString()

Returns a String representation of this TagAttributeInfo, suitable for debugging purposes.

Overrides: toString in class Object

Returns: a String representation of this TagAttributeInfo
to license terms.

PS:
javax.servlet.jsp.tagext  **Class TagData**

java.lang.Object  
  - javax.servlet.jsp.tagext.TagData

**All Implemented Interfaces:**  
  Cloneable

```java
public class TagData

extends Object
implements Cloneable

Implements: Cloneable
```

The (translation-time only) attribute/value information for a tag instance.

TagData is only used as an argument to the isValid, validate, and getVariableInfo methods of TagExtraInfo, which are invoked at translation time.

<table>

### Field Detail

REQUEST_TIME_VALUE

public static final Object REQUEST_TIME_VALUE

Distinguished value for an attribute to indicate its value is a request-time expression (which is not yet available because TagData instances are used at translation-time).
**Constructor Detail**

```java
public TagData(Object[][] atts)
TagData
```

```java
static final Object[][] att = {{"connection", "conn0"}, {"id", "id0"}};
static final TagData td = new TagData(att);
```

### REQUEST_TIME_VALUE String
- **atts**
- **null**

**TagData**

```java
public TagData(Object[][] atts)
```

Constructor for TagData.

A typical constructor may be

```java
static final Object[][] att = {{"connection", "conn0"}, {"id", "id0"}};
static final TagData td = new TagData(att);
```

All values must be Strings except for those holding the distinguished object REQUEST_TIME_VALUE.

**Parameters:**
- **atts** - the static attribute and values. May be null.

```java
public TagData(java.util.Hashtable<K, V> attrs)
TagData
```

```java
atts
```
TagData

public TagData(Hashtable<String, Object> attrs)

Constructor for a TagData. If you already have the attributes in a hashtable, use this constructor.

Parameters:
attrs - A hashtable to get the values from.

Method Detail

public String getId()

id

return id null

getId

public String getId()

The value of the tag's id attribute.

Returns:
the value of the tag's id attribute, or null if no such attribute was specified.

public Object getAttribute(String attName)

REQUEST_TIME_VALUE null

attName

return

getAttribute
public Object getAttribute(String attName)

The value of the attribute. If a static value is specified for an attribute that accepts a request-time attribute expression then that static value is returned, even if the value is provided in the body of a <jsp:attribute> action. The distinguished object REQUEST_TIME_VALUE is only returned if the value is specified as a request-time attribute expression or via the <jsp:attribute> action with a body that contains dynamic content (scriptlets, scripting expressions, EL expressions, standard actions, or custom actions). Returns null if the attribute is not set.

Parameters:
attName - the name of the attribute

Returns:
the attribute's value

public void setAttribute(String attName, Object value)

setAttribute

public void setAttribute(String attName, Object value)

Set the value of an attribute.

Parameters:
attName - the name of the attribute
value - the value.

public String getAttributeString(String attName)
public String getAttributeString(String attName)

Get the value for a given attribute.

Parameters:
attName - the name of the attribute

Returns:
the attribute value string

Throws:
ClassCastException - if attribute value is not a String

public java.utilEnumeration getAttributes()

return TagData

Enumerates the attributes.

Returns:
An enumeration of the attributes in a TagData
Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS:
Optional class provided by the tag library author to describe additional translation-time information not described in the TLD. The TagExtraInfo class is mentioned in the Tag Library Descriptor file (TLD).

This class can be used:

- to indicate that the tag defines scripting variables
- to perform translation-time validation of the tag attributes.

It is the responsibility of the JSP translator that the initial value to be returned by calls to getTagInfo() corresponds to a TagInfo object for the
tag being translated. If an explicit call to setTagInfo() is done, then the object passed will be returned in subsequent calls to getTagInfo().

The only way to affect the value returned by getTagInfo() is through a setTagInfo() call, and thus, TagExtraInfo.setTagInfo() is to be called by the JSP translator, with a TagInfo object that corresponds to the tag being translated. The call should happen before any invocation on validate() and before any invocation on getVariableInfo().

**NOTE:** It is a (translation time) error for a tag definition in a TLD with one or more variable subelements to have an associated TagExtraInfo implementation that returns a VariableInfo array with one or more elements from a call to getVariableInfo().

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait
**Constructor Detail**

```java
public TagExtraInfo()
```

**TagExtraInfo**

```java
public TagExtraInfo()
```

Sole constructor. (For invocation by subclass constructors, typically implicit.)

**Method Detail**

```java
public VariableInfo[] getVariableInfo(TagData data)
```

**getVariableInfo**

```java
public VariableInfo[] getVariableInfo(TagData data)
```

information on scripting variables defined by the tag associated with this TagExtraInfo instance. Request-time attributes are indicated as such in the TagData parameter.

**Parameters:**

data - The TagData instance.

**Returns:**
An array of VariableInfo data, or null or a zero length array if no scripting variables are to be defined.
public boolean isValid(TagData data)
TagData validate()
data	TagData
return
See also
isValid

isValid

public boolean isValid(TagData data)
Translation-time validation of the attributes. Request-time attributes are indicated as such in the TagData parameter. Note that the preferred way to do validation is with the validate() method, since it can return more detailed information.

Parameters:
    data - The TagData instance.

Returns:
    Whether this tag instance is valid.

See Also:
    validate(javax.servlet.jsp.tagext.TagData)

public ValidationMessage[] validate(TagData data)
TagData isValid()

JSP 2.0 validate() isValid() isValid() isValid()
false isValid() false ValidationMessage[]
public ValidationMessage[] validate(TagData data)

Translation-time validation of the attributes. Request-time attributes are indicated as such in the TagData parameter. Because of the higher quality validation messages possible, this is the preferred way to do validation (although isValid() still works).

JSP 2.0 and higher containers call validate() instead of isValid(). The default implementation of this method is to call isValid(). If isValid() returns false, a generic ValidationMessage[] is returned indicating isValid() returned false.

Parameters:
data - The TagData instance.

Returns:
A null object, or zero length array if no errors, an array of ValidationMessages otherwise.

Since:
JSP 2.0

---------------------------------------------------------------

final public void setTagInfo(TagInfo tagInfo)
TagInfo

tagName
TagInfo

setTagInfo

public final void setTagInfo(TagInfo tagInfo)

Set the TagInfo for this class.

Parameters:
tagInfo - The TagInfo this instance is extending

---------------------------------------------------------------

final public TagInfo getTagInfo()
TagInfo

default
TagInfo
getTagInfo

public final TagInfo getTagInfo()

Get the TagInfo for this class.

**Returns:**
the taginfo instance this instance is extending
public class TagFileInfo

extends Object

(TLD)

since 2.0

Tag information for a tag file in a Tag Library; This class is instantiated from the Tag Library Descriptor file (TLD) and is available only at translation time.

Since:
    JSP 2.0

Constructor Summary

TagFileInfo(String name, String path, TagInfo tagInfo)

Constructor for TagFileInfo from data in the JSP 2.0 format for TLD.

Method Summary

String getName()

The unique action name of this tag.

String getPath()

Where to find the .tag file implementing this action.

TagInfo getTagInfo()

Returns information about this tag, parsed from the

\item [\textit{path}]\hfill TagFileInfo
\item [\textit{tagInfo}]\hfill TagFileInfo
\end{itemize}

\texttt{TagFileInfo}

\texttt{public TagFileInfo(String name, String path, TagInfo tagInfo)}

Constructor for TagFileInfo from data in the JSP 2.0 format for TLD. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor). Note that, since TagLibraryInfo reflects both TLD information and taglib directive information, a TagFileInfo instance is dependent on a taglib directive. This is probably a design error, which may be fixed in the future.

\textbf{Parameters:}

\begin{itemize}
\item [\textit{name}] - The unique action name of this tag
\end{itemize}
path - Where to find the .tag file implementing this action, relative to the location of the TLD file.
tagInfo - The detailed information about this tag, as parsed from the directives in the tag file.

<table>

getName

public String getName()

The unique action name of this tag.

Returns:
The (short) name of the tag.

public String getPath()
.tag
return TLD "." 

getPath

public String getPath()

Where to find the .tag file implementing this action.

Returns:
The path of the tag file, relative to the TLD, or "." if the tag file was defined in an implicit tag file.
public TagInfo getTagInfo()

    return TagInfo

getTagInfo

public TagInfo getTagInfo()

    Returns information about this tag, parsed from the directives in the tag file.

    Returns:
    a TagInfo object containing information about this tag
javax.servlet.jsp.tagext  

Class TagInfo

java.lang.Object  
   \ javax.servlet.jsp.tagext.TagInfo

public class TagInfo
extends Object

(TLD)

Tag information for a tag in a Tag Library; This class is instantiated from the Tag Library Descriptor file (TLD) and is available only at translation time.

Constructor Detail
public TagInfo(String tagName, String tagClassName, String bodycontent, String infoString, TagLibraryInfo taglib, TagExtraInfo tagExtraInfo, TagAttributeInfo[] attributeInfo)

TagInfo JSP 1.1 TLD TLD (Tag Library Descriptor) JSP TagLibrary TagLibibraryInfo TLD taglib TagInfo taglib
tagName
tagClassName
bodycontent
infoString
taglib
tagExtraInfo null
attributeInfo AttributeInfo null

TagInfo

public TagInfo(String tagName, String tagClassName, String bodycontent, String infoString, TagLibraryInfo taglib, TagExtraInfo tagExtraInfo, TagAttributeInfo[] attributeInfo)

Constructor for TagInfo from data in the JSP 1.1 format for TLD. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor). Note that, since TagLibibraryInfo reflects both TLD information and taglib directive information, a TagInfo instance is dependent on a taglib directive. This is probably a design error, which may be fixed in the future.

Parameters:
tagName - The name of this tag
tagClassName - The name of the tag handler class
bodycontent - Information on the body content of these tags
infoString - The (optional) string information for this tag
taglib - The instance of the tag library that contains us.
tagExtraInfo - The instance providing extra Tag info. May be null
attributeInfo - An array of AttributeInfo data from descriptor. May be null;

```
public TagInfo(String tagName, String tagClassName,
String bodycontent, String infoString, TagLibraryInfo taglib, TagExtraInfo tagExtraInfo, TagAttributeInfo[] attributeInfo, String displayName, String smallIcon, String largeIcon, TagVariableInfo[] tvi)
```

TagInfo TagInfo JSP 1.2 TLD TLD (Tag Library Descriptor) JSP TagLibrary TagLibLibraryInfo TLD taglib TagInfo taglib

tagName
tagClassName
bodycontent
infoString
taglib
tagExtraInfo null
attributeInfo AttributeInfo null
displayName
smallIcon
largeIcon
tvi TagVariableInfo null

**TagInfo**

```
public TagInfo(String tagName,
String tagClassName,
String bodycontent,
String infoString,
```
Constructor for TagInfo from data in the JSP 1.2 format for TLD. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor). Note that, since TagLibraryInfo reflects both TLD information and taglib directive information, a TagInfo instance is dependent on a taglib directive. This is probably a design error, which may be fixed in the future.

**Parameters:**

- **tagName** - The name of this tag
- **tagClassName** - The name of the tag handler class
- **bodycontent** - Information on the body content of these tags
- **infoString** - The (optional) string information for this tag
- **taglib** - The instance of the tag library that contains us.
- **tagExtraInfo** - The instance providing extra Tag info. May be null
- **attributeInfo** - An array of AttributeInfo data from descriptor. May be null;
- **displayName** - A short name to be displayed by tools
- **smallIcon** - Path to a small icon to be displayed by tools
- **largeIcon** - Path to a large icon to be displayed by tools
- **tvi** - An array of a TagVariableInfo (or null)

TagInfo

public TagInfo(String tagName,
       String tagClassName,
       String bodycontent,
       String infoString,
       TagLibraryInfo taglib,
       TagExtraInfo tagExtraInfo,
       TagAttributeInfo[] attributeInfo,
       String displayName,
       String smallIcon,
       String largeIcon,
       TagVariableInfo[] tvi,
       boolean dynamicAttributes)

Constructor for TagInfo from data in the JSP 2.0 format for TLD. This class is to be instantiated only from the TagLibrary code under request from some JSP code that is parsing a TLD (Tag Library Descriptor). Note that, since TagLiblibraryInfo reflects both TLD information and taglib directive information, a TagInfo instance is dependent on a taglib directive. This is probably a design error, which may be fixed in the future.
Parameters:

tagName - The name of this tag
tagClassName - The name of the tag handler class
bodycontent - Information on the body content of these tags
infoString - The (optional) string information for this tag
taglib - The instance of the tag library that contains us.
tagExtraInfo - The instance providing extra Tag info. May be null
attributeInfo - An array of AttributeInfo data from descriptor. May be null;
displayName - A short name to be displayed by tools
smallIcon - Path to a small icon to be displayed by tools
largeIcon - Path to a large icon to be displayed by tools
tvi - An array of a TagVariableInfo (or null)
dynamicAttributes - True if supports dynamic attributes

Since:
JSP 2.0

Method Detail

public String getTagName()
Tag

return

getTagName

public String getTagName()

The name of the Tag.

Returns:
The (short) name of the tag.

public TagAttributeInfo[] getAttributes()
TLD TLD
getAttributes

public TagAttributeInfo[] getAttributes()

Attribute information (in the TLD) on this tag. The return is an array describing the attributes of this tag, as indicated in the TLD.

Returns:
- The array of TagAttributeInfo for this tag, or a zero-length array if the tag has no attributes.

getVariableInfo

public VariableInfo[] getVariableInfo(TagData data)

Information on the scripting objects created by this tag at runtime. This is a convenience method on the associated TagExtraInfo class.

Parameters:
- data - TagData describing this action.

Returns:
- if a TagExtraInfo object is associated with this TagInfo, the result of getTagExtraInfo().getVariableInfo( data ), otherwise null.

isValid

public boolean isValid(TagData data)

TagExtraInfo
isValid

public boolean isValid(TagData data)

Translation-time validation of the attributes. This is a convenience method on the associated TagExtraInfo class.

Parameters:
   data - The translation-time TagData instance.

Returns:
   Whether the data is valid.

validate

public ValidationMessage[] validate(TagData data)

Translation-time validation of the attributes. This is a convenience method on the associated TagExtraInfo class.

Parameters:
   data - The translation-time TagData instance.

Returns:
   A null object, or zero length array if no errors, an array of ValidationMessages otherwise.

Since:
   JSP 2.0
public void setTagExtraInfo(TagExtraInfo tei)

    tei TagExtraInfo

setTagExtraInfo

public void setTagExtraInfo(TagExtraInfo tei)

    Set the instance for extra tag information.

    Parameters:
        tei - the TagExtraInfo instance

public TagExtraInfo getTagExtraInfo()

    return TagExtraInfo

getTagExtraInfo

public TagExtraInfo getTagExtraInfo()

    The instance (if any) for extra tag information.

    Returns:
        The TagExtraInfo instance, if any.

gpublic String getTagClassName()

    return

ggetTagClassName
public String getTagClassName()

    Name of the class that provides the handler for this tag.

    **Returns:**
    The name of the tag handler class.

public String getBodyContent()

    bodycontent  bodycontent  JSP
    return

getBodyContent

public String getBodyContent()

    The bodycontent information for this tag. If the bodycontent is not defined for this tag, the default of JSP will be returned.

    **Returns:**
    the body content string.

public String getInfoString()

    return  null

getInfoString

public String getInfoString()

    The information string for the tag.

    **Returns:**
    the info string, or null if not defined
public void setTagLibrary(TagLibraryInfo tl)

**TagLibraryInfo**

TagLibraryInfo  
TagLibraryInfo  
TLD

**taglib**  
TagLib  

setter tl

tl  
TagLibraryInfo

**setTagLibrary**

public void setTagLibrary(TagLibraryInfo tl)

Set the TagLibraryInfo property. Note that a TagLibraryInfo element is dependent not just on the TLD information but also on the specific taglib instance used. This means that a fair amount of work needs to be done to construct and initialize TagLib objects. If used carefully, this setter can be used to avoid having to create new TagInfo elements for each taglib directive.

**Parameters:**
tl - the TagLibraryInfo to assign

---

public **TagLibraryInfo** getTagLibrary()

**TagLibraryInfo**

return

**getTagLibrary**

public **TagLibraryInfo** getTagLibrary()

The instance of TagLibraryInfo we belong to.

**Returns:**
the tag library instance we belong to
public String getDisplayName()

    displayName
    return null

getDisplayName

public String getDisplayName()

    Get the displayName.

    Returns:
    A short name to be displayed by tools, or null if not defined

public String getSmallIcon()

    return null

getSmallIcon

public String getSmallIcon()

    Get the path to the small icon.

    Returns:
    Path to a small icon to be displayed by tools, or null if not defined

public String getLargeIcon()

    return null

getLargeIcon

public String getLargeIcon()
public String getLargeIcon()

Get the path to the large icon.

**Returns:**
Path to a large icon to be displayed by tools, or null if not defined

---

public TagVariableInfo[] getTagVariableInfos()
TagInfo TagVariableInfo

return TagVariableInfo 0

getagVariableInfos

public TagVariableInfo[] getTagVariableInfos()

Get TagVariableInfo objects associated with this TagInfo.

**Returns:**
Array of TagVariableInfo objects corresponding to variables declared by this tag, or a zero length array if no variables have been declared

---

public boolean hasDynamicAttributes()
TagInfo dynamicAttributes

return true

since 2.0

hasDynamicAttributes

public boolean hasDynamicAttributes()

Get dynamicAttributes associated with this TagInfo.
Returns:
   True if tag handler supports dynamic attributes

Since:
   JSP 2.0
public abstract class TagLibraryInfo
extends Object

taglib TLD TLD taglib uri

Translation-time information associated with a taglib directive, and its underlying TLD file. Most of the information is directly from the TLD, except for the prefix and the uri values used in the taglib directive

Field Detail

prefix
protected `String` `prefix`

The prefix assigned to this taglib from the taglib directive.

---

`uri`

protected `String` `uri`

The value of the uri attribute from the taglib directive for this library.

---

`tags`

protected `TagInfo[]` `tags`

An array describing the tags that are defined in this tag library.

---

`tagFiles`

protected `TagFileInfo[]` `tagFiles`

An array describing the tag files that are defined in this tag library.

**Since:**

JSP 2.0

---

`functions`

protected `FunctionInfo[]` `functions`
An array describing the functions that are defined in this tag library.

**Since:**
JSP 2.0

---

tlibversion

protected *String* `tlibversion`

The version of the tag library.

---

jspversion

protected *String* `jspversion`

The version of the JSP specification this tag library is written to.

---

shortname

protected *String* `shortname`

The preferred short name (prefix) as indicated in the TLD.

---

urn

protected *String* `urn`

The "reliable" URN indicated in the TLD.
protected String info

Information (documentation) for this TLD.

**Constructor Detail**

protected TagLibraryInfo(String prefix, String uri)

TagInfo TLD TagAttributeInfo

  prefix taglib
  uri taglib URI

TagLibraryInfo

protected TagLibraryInfo(String prefix, String uri)

Constructor.

**Parameters:**

  prefix - the prefix actually used by the taglib directive
  uri - the URI actually used by the taglib directive

**Method Detail**

public String getURI()

taglib uri

return uri

getURI
public String getURI()

    The value of the uri attribute from the taglib directive for this library.

    Returns:
    the value of the uri attribute

public String getPrefixString()

    The prefix assigned to this taglib from the taglib directive

    Returns:
    the prefix assigned to this taglib from the taglib directive

public String getShortName()

    The preferred short name (prefix) as indicated in the TLD. This may be used by authoring tools as the preferred prefix to use when creating an taglib directive for this library.

    Returns:
    the preferred short name for the library
public String getReliableURN()
TLD ""URNuri URN taglib
   return TLD URN

getReliableURN

public String getReliableURN()

   The "reliable" URN indicated in the TLD (the uri element). This may be used by authoring tools as a global identifier to use when creating a taglib directive for this library.

   Returns:
   a reliable URN to a TLD like this

public String getInfoString()
TLD
   return

getInfoString

public String getInfoString()

   Information (documentation) for this TLD.

   Returns:
   the info string for this tag lib

public String getRequiredVersion()
JSP
   return JSP
See also javax.servlet.jsp.JspEngineInfo
getRequiredVersion

public String getRequiredVersion()

A string describing the required version of the JSP container.

Returns:
the (minimal) required version of the JSP container.

See Also:
JspEngineInfo

public TagInfo[] getTags()

return TagInfo 0

getTags

public TagInfo[] getTags()

An array describing the tags that are defined in this tag library.

Returns:
the TagInfo objects corresponding to the tags defined by this tag library, or a zero length array if this tag library defines no tags

public TagFileInfo[] getTagFiles()

return TagFileInfo 0

since 2.0

getTagFiles
public TagFileInfo[] getTagFiles()

An array describing the tag files that are defined in this tag library.

**Returns:**
the TagFileInfo objects corresponding to the tag files defined by this tag library, or a zero length array if this tag library defines no tags files

**Since:**
JSP 2.0

---

public TagInfo getTag(String shortname)

TagInfo

```
shortname
return TagInfo null
```

getTag

public TagInfo getTag(String shortname)

Get the TagInfo for a given tag name, looking through all the tags in this tag library.

**Parameters:**
shortname - The short name (no prefix) of the tag

**Returns:**
the TagInfo for the tag with the specified short name, or null if no such tag is found

---

public TagFileInfo getTagFile(String shortname)

TagFileInfo

```
shortname
return TagFileInfo null
since 2.0
```
**getTagFile**

public [TagFileInfo](#) `getTagFile(String shortname)`

Get the TagFileInfo for a given tag name, looking through all the tag files in this tag library.

**Parameters:**
- `shortname` - The short name (no prefix) of the tag

**Returns:**
the TagFileInfo for the specified Tag file, or null if no Tag file is found

**Since:**
JSP 2.0

---

**getFunctions**

public `FunctionInfo[] getFunctions()`

```
    return 0
    since 2.0
```

**getFunctions**

public `FunctionInfo[] getFunctions()`

An array describing the functions that are defined in this tag library.

**Returns:**
the functions defined in this tag library, or a zero length array if the tag library defines no functions.

**Since:**
JSP 2.0

---

**getFunction**

public `FunctionInfo getFunction(String name)`

`FunctionInfo`

`name`
getFunction

```java
public FunctionInfo getFunction(String name)
```

Get the FunctionInfo for a given function name, looking through all the functions in this tag library.

**Parameters:**
- `name` - The name (no prefix) of the function

**Returns:**
- the FunctionInfo for the function with the given name, or null if no such function exists

**Since:**
- JSP 2.0

getTagLibraryInfos

```java
public abstract TagLibraryInfo[] getTagLibraryInfos()
```

Returns an array of TagLibraryInfo objects representing the entire set of tag libraries (including this TagLibraryInfo) imported by taglib directives in the translation unit that references this TagLibraryInfo. If a tag library is imported more than once and bound to different prefixes, only the TagLibraryInfo bound to the first prefix must be included in the returned array.

**Returns:**
- Array of TagLibraryInfo objects representing the entire set of tag libraries (including this TagLibraryInfo) imported by taglib directives in the translation unit that references this TagLibraryInfo.

**Since:**
javax.servlet.jsp.tagext  **Class TagLibraryValidator**

java.lang.Object  
  ↓ javax.servlet.jsp.tagext.TagLibraryValidator

```java
public abstract class TagLibraryValidator
    extends Object
```

JSP JSP XML

TLD TagLibraryValidator init

JSP

URI XML URI TagLibraryValidator uri

TagLibraryValidator XSchema

JSP validate() TagLibraryValidator

  JSP 2.0 JSP jsp:id JSP "id" id jsp:id
XML XML TagLibraryValidator ValidationMessage

id jsp http://java.sun.com/JSP/PageTagLibraryValidator id
uri

Translation-time validator class for a JSP page. A validator operates on the XML view associated with the JSP page.
The TLD file associates a TagLibraryValidator class and some init arguments with a tag library.

The JSP container is responsible for locating an appropriate instance of the appropriate subclass by

- new a fresh instance, or reuse an available one
- invoke the setInitParams(Map) method on the instance

Once initialized, the validate(String, String, PageData) method will be invoked, where the first two arguments are the prefix and uri for this tag library in the XML View. The prefix is intended to make it easier to produce an error message. However, it is not always accurate. In the case where a single URI is mapped to more than one prefix in the XML view, the prefix of the first URI is provided. Therefore, to provide high quality error messages in cases where the tag elements themselves are checked, the prefix parameter should be ignored and the actual prefix of the element should be used instead. TagLibraryValidators should always use the uri to identify elements as belonging to the tag library, not the prefix.

A TagLibraryValidator instance may create auxiliary objects internally to perform the validation (e.g. an XSchema validator) and may reuse it for all the pages in a given translation run.

The JSP container is not guaranteed to serialize invocations of validate() method, and TagLibraryValidators should perform any synchronization they may require.

As of JSP 2.0, a JSP container must provide a jsp:id attribute to provide higher quality validation errors. The container will track the JSP pages as passed to the container, and will assign to each element a unique "id", which is passed as the value of the jsp:id attribute. Each XML element in the XML view available will be extended with this attribute. The TagLibraryValidator can then use the attribute in one or more ValidationMessage objects. The container then, in turn, can use these values to provide more precise information on the location of an error.

The actual prefix of the id attribute may or may not be jsp but it will always map to the namespace http://java.sun.com/JSP/Page. A
TagLibraryValidator implementation must rely on the uri, not the prefix, of the id attribute.

### Constructor Detail

```java
public TagLibraryValidator()
```

TagLibraryValidator
public TagLibraryValidator()

Sole constructor. (For invocation by subclass constructors, typically implicit.)

Method Detail

public void setInitParameters(java.util.Map<K, V> map)

TLD init

map init Map

setInitParameters

public void setInitParameters(Map<String, Object> map)

Set the init data in the TLD for this validator. Parameter names are keys, and parameter values are the values.

Parameters:
map - A Map describing the init parameters

public java.util.Map<K, V> getInitParameters()

Map init

return init

getInitParameters

public Map<String, Object> getInitParameters()

Get the init parameters data as an immutable Map. Parameter names are keys, and parameter values are the values.

Returns:
The init parameters as an immutable map.
public ValidationMessage[] validate(String prefix, String uri, PageData page)

JSP XML URI null

ValidationMessage 0

prefix XML
uri
page JspData
return null 0 ValidationMessage

validate

public ValidationMessage[] validate(String prefix, String uri, PageData page)

Validate a JSP page. This will get invoked once per unique tag library URI in the XML view. This method will return null if the page is valid; otherwise the method should return an array of ValidationMessage objects. An array of length zero is also interpreted as no errors.

Parameters:
prefix - the first prefix with which the tag library is associated, in the XML view. Note that some tags may use a different prefix if the namespace is redefined.
uri - the tag library’s unique identifier
page - the JspData page object

Returns:
A null object, or zero length array if no errors, an array of ValidationMessages otherwise.

public void release()
public void release()

Release any data kept by this instance for validation purposes.

Tag

TagSupport TagSupport  Tag  IterationTag  Tag
getter TagSupport

TagSupport

A base class for defining new tag handlers implementing Tag.

The TagSupport class is a utility class intended to be used as the base class for new tag handlers. The TagSupport class implements the Tag and IterationTag interfaces and adds additional convenience methods including getter methods for the properties in Tag. TagSupport has one static method that is included to facilitate coordination among cooperating tags.
Many tag handlers will extend TagSupport and only redefine a few methods.

</tbody>
</table>
### findAncestorWithClass

The public static method `findAncestorWithClass` accepts two `Tag`-type parameters, `Tag from` and `Class klass`, and returns a `Tag` instance. The method finds the instance of a given class type that is closest to a given instance.

```java
static Tag findAncestorWithClass(Tag from, Class klass)
```

**Example**: This method is often used in tag libraries to find the root `Tag` instance of a given type, such as `html:div`, in the hierarchy of `Tag` instances.

### getId

The method `getId` returns the value of the id attribute of this tag; or null.

```java
String getId()
```

**Example**: To access the id attribute of a `Tag` instance:

```java
String id = myTag.getId();
```

### getParent

The method `getParent` returns the `Tag` instance most closely enclosing this tag instance.

```java
Tag getParent()
```

**Example**: To find the parent `Tag` instance of a given `Tag`:

```java
Tag parent = myTag.getParent();
```

### getValue

The method `getValue` retrieves the value associated with a key.

```java
Object getValue(String k)
```

**Example**: To access a value associated with a key:

```java
Object value = myTag.getValue(key);
```

### getValues

The method `getValues` retrieves all the values kept by this tag handler.

```java
Enumeration<String> getValues()
```

**Example**: To retrieve all the values:

```java
Enumeration<String> values = myTag.getValues();
```

### release

The method `release` releases the state of this `Tag` instance.

```java
void release()
```

**Example**: To release the state:

```java
myTag.release();
```

### removeValue

The method `removeValue` removes a value associated with a key.

```java
void removeValue(String k)
```

**Example**: To remove a value:

```java
myTag.removeValue(key);
```

### setId

The method `setId` sets the id attribute for this `Tag` instance.

```java
void setId(String id)
```

**Example**: To set the id attribute:

```java
myTag.setId(id);
```

### setPageContext

The method `setPageContext` sets the page context.

```java
void setPageContext(PageContext pageContext)
```

**Example**: To set the page context:

```java
myTag.setPageContext(context);
```

### setParent

The method `setParent` sets the nesting `Tag` of this `Tag` instance.

```java
void setParent(Tag t)
```

**Example**: To set the nesting `Tag`:

```java
myTag.setParent(nestingTag);
```

### setValue

The method `setValue` associates a value with a `String` key.

```java
void setValue(String k, Object o)
```

**Example**: To associate a value with a key:

```java
myTag.setValue(key, value);
```

### Methods inherited from class java.lang.Object

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`
id

protected String id

The value of the id attribute of this tag; or null.

pageContext

protected PageContext pageContext

The PageContext.

### Constructor Detail

public TagSupport()

TagSupport

public TagSupport()

Default constructor, all subclasses are required to define only a public constructor with the same signature, and to call the superclass constructor. This constructor is called by the code generated by the JSP translator.

### Method Detail

final public static Tag findAncestorWithClass(Tag from, Class<T> klass)
Tag getParent

observable observable void

JSP

observable findAncestorWithClass

observable

    from
    klass
    return

findAncestorWithClass

public static final Tag findAncestorWithClass(Tag from,
                                               Class klass)

    Find the instance of a given class type that is closest to a given instance. This method uses the getParent method from the Tag interface. This method is used for coordination among cooperating tags.

    The current version of the specification only provides one formal way of indicating the observable type of a tag handler: its tag handler implementation class, described in the tag-class subelement of the tag element. This is extended in an informal manner by allowing the tag library author to indicate in the description subelement an observable type. The type should be a subtype of the tag handler implementation class or void. This additional constraint can be exploited by a specialized container that knows about that specific tag library, as in the case of the JSP standard tag library.

    When a tag library author provides information on the observable type of a tag handler, client programmatic code should adhere to that constraint. Specifically, the Class passed to findAncestorWithClass should be a subtype of the observable type.
Parameters:
  from - The instance from where to start looking.
  klass - The subclass of Tag or interface to be matched

Returns:
  the nearest ancestor that implements the interface or is an
  instance of the class specified

public int doStartTag() throws JspException

SKIP_BODY

    return SKIP_BODY

Throws
    JspException:

See also
    doStartTag()

doStartTag

public int doStartTag() throws JspException

Default processing of the start tag, returning SKIP_BODY.

Specified by:
    doStartTag in interface Tag

Returns:
    SKIP_BODY

Throws:
    JspException - if an error occurs while processing this tag

See Also:
    Tag.doStartTag()

public int doEndTag() throws JspException

EVAL_PAGE

    return EVAL_PAGE

Throws
    JspException:

See also
    doEndTag()
doEndTag

public int doEndTag()
    throws JspException

Default processing of the end tag returning EVAL_PAGE.

Specified by:
    doEndTag in interface Tag

Returns:
    EVAL_PAGE

Throws:
    JspException - if an error occurs while processing this tag

See Also:
    Tag.doEndTag()  

public int doAfterBody() throws JspException

    return SKIP_BODY

    Throws
    JspException:

    See also
    doAfterBody()

doAfterBody

public int doAfterBody()
    throws JspException

Default processing for a body.

Specified by:
    doAfterBody in interface IterationTag

Returns:
    SKIP_BODY

Throws:
    JspException - if an error occurs while processing this tag

See Also:
    IterationTag.doAfterBody()
public void release()

See also release()

release

public void release()

Release state.

Specified by: release in interface Tag
See Also: Tag.release()

public void setParent(Tag t)

See also setParent(Tag)

setParent

public void setParent(Tag t)

Set the nesting tag of this tag.

Specified by: setParent in interface Tag
Parameters: t - The parent Tag.
See Also: Tag.setParent(Tag)
**public Tag getParent()**

    return null

See also  
getParent()

---

**getParent**

**public Tag getParent()**

    The Tag instance most closely enclosing this tag instance.

    **Specified by:**
    getParents in interface Tag

    **Returns:**
    the parent tag instance or null

    **See Also:**
    Tag.getParent()

---

**public void setId(String id)**

    **id**

    id      String

**setId**

**public void setId(String id)**

    Set the id attribute for this tag.

    **Parameters:**
    id - The String for the id.

---

**public String getId()**

    **id**  null

    return     id  null
**getId**

public String getId()

The value of the id attribute of this tag; or null.

Returns:
the value of the id attribute, or null

---

**public void setPageContext(PageContext pageContext)**

*pageContext* PageContext
See also *setPageContext*

---

**setPageContext**

public void setPageContext(PageContext pageContext)

Set the page context.

Specified by:
*setPageContext* in interface *Tag*

Parameters:
pageContext - The PageContext.

See Also:
*Tag.setPageContext(javax.servlet.jsp.PageContext)*

---

**public void setValue(String k, Object o)**

String

k String
o
setValue

public void setValue(String k, Object o)

Associate a value with a String key.

Parameters:
  k - The key String.
  o - The value to associate.

getValue

public Object getValue(String k)

    k
    return null

getValue

public Object getValue(String k)

    Get the value associated with a key.

Parameters:
    k - The string key.

Returns:
    The value associated with the key, or null.

removeValue

public void removeValue(String k)

    k

removeValue

public void removeValue(String k)
Remove a value associated with a key.

Parameters:
  k - The string key.

public java.util.Enumeration<E> getValues()

  return null Enumeration

getValues

public Enumeration<String> getValues()

  Enumerate the keys for the values kept by this tag handler.

Returns:
  An enumeration of all the keys for the values set, or null or an empty Enumeration if no values have been set.
public class TagVariableInfo
extends Object

(Object)

Variable information for a tag in a Tag Library; This class is instantiated from the Tag Library Descriptor file (TLD) and is available only at translation time. This object should be immutable. This information is only available in JSP 1.2 format TLDs or above.

Constructor Summary

TagVariableInfo

public TagVariableInfo(String nameGiven, String nameFromAttribute, String className, boolean declare, int scope)

Constructor for TagVariableInfo.

**Parameters:**

nameGiven - value of `<name-given>`
nameFromAttribute - value of `<name-from-attribute>`
className - value of `<variable-class>`
declare - value of `<declare>`
scope - value of `<scope>`
public String getNameGiven()

    return

getNameGiven

public String getNameGiven()

    The body of the <name-given> element.

    Returns:
    The variable name as a constant

public String getNameFromAttribute()

    return

getNameFromAttribute

public String getNameFromAttribute()

    The body of the <name-from-attribute> element. This is the name of an attribute whose (translation-time) value will give the name of the variable. One of <name-given> or <name-from-attribute> is required.

    Returns:
    The attribute whose value defines the variable name

public String getClassName()
getClassName

public String getClassName()

The body of the <variable-class> element.

Returns:
The name of the class of the variable or 'java.lang.String' if not defined in the TLD.

getDeclare

public boolean getDeclare()

The body of the <declare> element.

Returns:
Whether the variable is to be declared or not. If not defined in the TLD, 'true' will be returned.

getScope

public int getScope()

The body of the <scope> element.

Returns:
The scope of the variable.
public int getScope()

    The body of the <scope> element.

    **Returns:**
    The scope to give the variable. NESTED scope will be returned if not defined in the TLD.

PS:
javax.enterprise.deploy.spi  Interface TargetModuleID

public interface TargetModuleID

TargetModuleID EARJARWAR RAR
TargetModuleID EAR TargetModuleID J2EE
    TargetModuleID

A TargetModuleID interface represents a unique identifier for a deployed application module. A deployable application module can be an EAR, JAR, WAR or RAR file. A TargetModuleID can represent a root module or a child module. A root module TargetModuleID has no parent. It represents a deployed EAR file or stand alone module. A child module TargetModuleID represents a deployed sub module of a J2EE application. A child TargetModuleID has only one parent, the super module it was bundled and deployed with. The identifier consists of the target name and the unique identifier for the deployed application module.

</table>
### Method Detail

**public Target getTarget()**

```
  return Target
```

**getTarget**

```
Target getTarget()
```

Retrieve the name of the target server this module was deployed to.

**Returns:**

- Target an object representing a server target.

**public String getModuleID()**

```
  ID
```

**getModuleID**

```
String getModuleID()
```

Retrieve the id assigned to represent the deployed module.
public String getWebURL()

String getWebURL()

If this TargetModulID represents a web module retrieve the URL for it.

Returns:
the URL of a web module or null if the module is not a web module.

public String toString()

String toString()

Retrieve the identifier representing the deployed module.

Overrides:
toString in class Object

public TargetModuleID getParentTargetModuleID()

TargetModuleID getParentTargetModuleID()

return null
TargetModuleID getParentTargetModuleID()

Retrieve the identifier of the parent object of this deployed module. If there is no parent then this is the root object deployed. The root could represent an EAR file or it could be a stand alone module that was deployed.

Returns:
the TargetModuleID of the parent of this object. A null value means this module is the root object deployed.

public TargetModuleID[] getChildTargetModuleID()

return TargetModuleID null

getChildTargetModuleID

TargetModuleID[] getChildTargetModuleID()

Retrieve a list of identifiers of the children of this deployed module.

Returns:
a list of TargetModuleIDs identifying the children of this object. A null value means this module has no children.
public interface TelephoneNumber

A simple re-usable entity class that defines attributes of a telephone number.

</table>
void Sets the internal extension.

void setNumber(String number) Sets the telephone number suffix, not including the country or area code.

void setType(String type) Sets the type of telephone number (for example, "fax").

void setUrl(String url) Sets the URL that can dial this number electronically.

Method Detail

public String getCountryCode() throws JAXRException

1

   return

Throws JAXRException: JAXR

getCountryCode

String countryCode() throws JAXRException

   Gets the country code. Default is an empty String.

   Capability Level: 1

   Returns:
   the country code

   Throws:
   JAXRException - If the JAXR provider encounters an internal error
public String getAreaCode() throws JAXRException

1

    return
    Throws JAXRException: JAXR

getAreaCode

String getAreaCode() throws JAXRException

Gets the area code. Default is an empty String.

Capability Level: 1

Returns: the area code

Throws: JAXRException - If the JAXR provider encounters an internal error

-------------------

public String getNumber() throws JAXRException

0

    return
    Throws JAXRException: JAXR

getNumber

String getNumber() throws JAXRException
Gets the telephone number suffix, not including the country or area code. Default is an empty String.

**Capability Level: 0**

**Returns:**
the telephone number

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

**public String getExtension() throws JAXRException**

1

```
return

Throws JAXRException: JAXR
```

---

**getExtension**

**String getExtension()**

throws JAXRException

Gets the internal extension. Default is an empty String.

**Capability Level: 1**

**Returns:**
the internal extension number

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

---

**public String getUrl() throws JAXRException**
URL NULL

1

```java
public String getType() throws JAXRException
"fax" String
```

0

```java
String getType()
```

getURL

```java
String getURL() throws JAXRException
```

Gets the URL that can dial this number electronically. Default is a NULL String.

**Capability Level: 1**

**Returns:**
the url

**Throws:**

JAXRException - If the JAXR provider encounters an internal error

```
```
The type of telephone number (for example, “fax”). Any String would do.

**Capability Level:** 0

**Returns:**
the type for this TelephoneNumber, which is an arbitrary String

**Throws:**

*JAXRException* - If the JAXR provider encounters an internal error

```java
public void setCountryCode(String countryCode) throws JAXRException
```

1

`countryCode`

**Throws**

*JAXRException*: JAXR

**setCountryCode**

```java
void setCountryCode(String countryCode)
```

Sets country code.

**Capability Level:** 1

**Parameters:**
countryCode - the country code

**Throws:**

*JAXRException* - If the JAXR provider encounters an internal error
public void setAreaCode(String areaCode) throws JAXRException

  areaCode
  Throws  JAXRException:  JAXR

setAreaCode

void setAreaCode(String areaCode)
   throws JAXRException

Sets the area code.

Capability Level: 1

Parameters:
  areaCode - the area code

Throws:
  JAXRException - If the JAXR provider encounters an internal error

public void setNumber(String number) throws JAXRException

  number
  Throws  JAXRException:  JAXR

setNumber
void setNumber(String number) throws JAXRException

Sets the telephone number suffix, not including the country or area code.

Capability Level: 0

Parameters:
number - the telephone number

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setExtension(String extension) throws JAXRException

1

extension

Throws JAXRException: JAXR

setExtension

void setExtension(String extension) throws JAXRException

Sets the internal extension.

Capability Level: 1

Parameters:
extension - the internal extension number

Throws:
JAXRException - If the JAXR provider encounters an internal error
public void setUrl(String url) throws JAXRException

Sets the URL that can dial this number electronically.

**Capability Level: 1**

**Parameters:**
- url - the URL string

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

public void setType(String type) throws JAXRException

Sets the type of this number.

**Parameters:**
- type - the type string

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error
void setType(String type)
throws JAXRException

Sets the type of telephone number (for example, "fax"). Any String will do.

**Capability Level: 0**

**Parameters:**
- type - the type for this TelephoneNumber, which is an arbitrary String

**Throws:**
- JAXRException - If the JAXR provider encounters an internal error

PS:
`javax.persistence Annotation Type Temporal`

```java
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface Temporal

Implements: Annotation
@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

    java.util.Date    java.util.Calendar

Temporal    Basic

    @Temporal(DATE)
    protected java.util.Date endDate;

    since    Java Persistence 1.0

This annotation must be specified for persistent fields or properties of type `Date` and `Calendar`. It may only be specified for fields or properties of these types.

The `Temporal` annotation may be used in conjunction with the `Basic` annotation.

Example:

    @Temporal(DATE)
    protected java.util.Date endDate;

Since:
Java Persistence 1.0

### Enum Constant Detail

**DATE**

public static final TemporalType DATE

Map as java.sql.Date

**TIME**

public static final TemporalType TIME

Map as java.sql.Time
public static final TemporalType TIMESTAMP

Map as java.sql.Timestamp

**Method Detail**

final public static TemporalType[] values()

values

public static final TemporalType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```
for(TemporalType c : TemporalType.values())
    System.out.println(c);
```

**Returns:**
an array containing the constants of this enum type, in the order they're declared

public static TemporalType valueOf(String name)

valueOf

public static TemporalType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)
Parameters:
   name - the name of the enum constant to be returned.

Returns:
   the enum constant with the specified name

Throws:
   IllegalArgumentException - if this enum type has no constant
   with the specified name
javax.jms Interface TemporaryQueue

All Superinterfaces:
   Destination, Queue

public interface TemporaryQueue
extends Queue

Implements: Queue

TemporaryQueue Connection Queue Connection
TemporaryQueue Session QueueSession Session
TemporaryQueue Pub/Sub QueueSession PTP

version 1.1 - February 2, 2002
See also createTemporaryQueue(), createTemporaryQueue()

A TemporaryQueue object is a unique queue object created for the duration of a Connection. It is a system-defined queue that can be consumed only by the Connection that created it.

A TemporaryQueue object can be created at either the Session or QueueSession level. Creating it at the Session level allows to the TemporaryQueue to participate in transactions with objects from the Pub/Sub domain. If it is created at the QueueSession, it will only be able to participate in transactions with objects from the PTP domain.

Version:
   1.1 - February 2, 2002

**Methods inherited from interface javax.jms.Queue**

- getQueueName
- toString

**Method Detail**

```java
public void delete() throws JMSException
```

**Throws**

- JMSException: JMS

**delete**

```java
void delete()
```

Throws JMSException

Deletes this temporary queue. If there are existing receivers still using it, a JMSException will be thrown.

**Throws:**

- JMSException - if the JMS provider fails to delete the temporary queue due to some internal error.

PS:
javax.jms  Interface  TextMessage

All Superinterfaces: Message

public interface TextMessage extends Message

Implements: Message

TextMessage  java.lang.String  Message

XML

TextMessage  MessageNotWriteableException  clearBody
version  1.1 - February 2, 2002

See  javax.jms.BytesMessage, javax.jms.MapMessage,
also  javax.jms.Message, javax.jms.ObjectMessage,
javax.jms.StreamMessage, java.lang.String

A TextMessage object is used to send a message containing a java.lang.String. It inherits from the Message interface and adds a text message body.

This message type can be used to transport text-based messages, including those with XML content.

When a client receives a TextMessage, it is in read-only mode. If a client attempts to write to the message at this point, a MessageNotWriteableException is thrown. If clearBody is called, the message can now be both read from and written to.

Version:
Field Summary

Method Detail

public void cancel() throws IllegalStateException, NoSuchObjectLocalException, EJBException
Throws IllegalStateException:
Throws NoSuchObjectLocalException:
Throws EJBException:

cancel

void cancel() throws IllegalStateException,
NoSuchObjectLocalException,
EJBException

Cause the timer and all its associated expiration notifications to be cancelled.

Throws:
IllegalStateException - If this method is invoked while the instance is in a state that does not allow access to this method.
NoSuchObjectLocalException - If invoked on a timer that has expired or has been cancelled.
EJBException - If this method could not complete due to a system-level failure.

public long getTimeRemaining() throws
IllegalStateException, NoSuchObjectLocalException,
EJBException

return
Throws IllegalStateException:
Throws NoSuchObjectLocalException:
Throws EJBException:

getTimeRemaining

long getTimeRemaining()
Get the number of milliseconds that will elapse before the next scheduled timer expiration.

Returns:
the number of milliseconds that will elapse before the next scheduled timer expiration.

Throws:

 IllegalArgumentException - If this method is invoked while the instance is in a state that does not allow access to this method.
 NoSuchObjectLocalException - If invoked on a timer that has expired or has been cancelled.
 EJBException - If this method could not complete due to a system-level failure.

public java.util.Date getNextTimeout() throws IllegalArgumentException, NoSuchObjectLocalException, EJBException

return

Throws IllegalArgumentException:
Throws NoSuchObjectLocalException:
Throws EJBException:

getNextTimeout

Date getNextTimeout() throws IllegalArgumentException, NoSuchObjectLocalException, EJBException

Get the point in time at which the next timer expiration is scheduled to occur.
Returns:
the point in time at which the next timer expiration is scheduled to occur.

Throws:

- **IllegalStateException** - If this method is invoked while the instance is in a state that does not allow access to this method.
- **NoSuchObjectLocalException** - If invoked on a timer that has expired or has been cancelled.
- **EJBException** - If this method could not complete due to a system-level failure.

```java
public java.io.Serializable getInfo() throws
    IllegalStateException, NoSuchObjectLocalException, EJBException
```

- **return** Serializable info null null
- **Throws**  
  - **IllegalStateException**: 
  - **NoSuchObjectLocalException**: 
  - **EJBException**: 

GetInfo

```java
Serializable getINFO()
```

- **throws**  
  - **IllegalStateException**, **NoSuchObjectLocalException**, **EJBException**

Get the information associated with the timer at the time of creation.

**Returns:**
The Serializable object that was passed in at timer creation, or null if the info argument passed in at timer creation was null.

**Throws:**

- **IllegalStateException** - If this method is invoked while the instance is in a state that does not allow access to this method.
- **NoSuchObjectLocalException** - If invoked on a timer that has expired or has been cancelled.
- **EJBException** - If this method could not complete due to a system-level failure.
expired or has been cancelled.

**EJBException** - If this method could not complete due to a system-level failure.

```java
public TimerHandle getHandle() throws
IllegalStateException, NoSuchObjectLocalException, EJBException

return

Throws  
IllegalStateException:

Throws  NoSuchObjectLocalException:

Throws  EJBException:
```

**getHandle**

**TimerHandle** getHandle()

**Throws**

**IllegalStateException** - If this method is invoked while the instance is in a state that does not allow access to this method.

**NoSuchObjectLocalException** - If invoked on a timer that has expired or has been cancelled.

**EJBException** - If this method could not complete due to a system-level failure.

Get a serializable handle to the timer. This handle can be used at a later time to re-obtain the timer reference.

**Returns:**

a serializable handle to the timer.

**Throws:**

**IllegalStateException** - If this method is invoked while the instance is in a state that does not allow access to this method.

**NoSuchObjectLocalException** - If invoked on a timer that has expired or has been cancelled.

**EJBException** - If this method could not complete due to a system-level failure.
javax.ejb Interface TimerHandle

All Superinterfaces:  
Serializable

public interface TimerHandle
extends Serializable

Implements: java.io.Serializable

The TimerHandle interface is implemented by all EJB timer handles.

Method Summary

<tr>
<td><code>getTimers()</code></td>
<td>Get all the active timers associated with this bean.</td>
</tr>
</tbody>
</table>
public Timer createTimer(long duration, java.io.Serializable info) throws IllegalArgumentException, IllegalStateException, EJBException

createTimer

Create a single-action timer that expires after a specified duration.

Parameters:
- duration - The number of milliseconds that must elapse before the timer expires.
- info - Application information to be delivered along with the timer expiration notification. This can be null.

Returns:
- The newly created Timer.

Throws:
- IllegalArgumentException - If duration is negative
- IllegalStateException - If this method is invoked while the instance is in a state that does not allow access to this method.
EJBException - If this method fails due to a system-level failure.

```java
public Timer createTimer(long initialDuration, long intervalDuration, java.io.Serializable info) throws IllegalArgumentException, IllegalStateException, EJBException
```

- `initialDuration` - The number of milliseconds that must elapse before the first timer expiration notification.
- `intervalDuration` - The number of milliseconds that must elapse between timer expiration notifications. Expiration notifications are scheduled relative to the time of the first expiration. If expiration is delayed (e.g. due to the interleaving of other method

Create an interval timer whose first expiration occurs after a specified duration, and whose subsequent expirations occur after a specified interval.

**Parameters:**
- `initialDuration` - The number of milliseconds that must elapse before the first timer expiration notification.
- `intervalDuration` - The number of milliseconds that must elapse between timer expiration notifications. Expiration notifications are scheduled relative to the time of the first expiration. If expiration is delayed (e.g. due to the interleaving of other method
calls on the bean) two or more expiration notifications may occur in close succession to "catch up".

info - Application information to be delivered along with the timer expiration. This can be null.

**Returns:**
The newly created Timer.

**Throws:**
- `IllegalArgumentException` - If initialDuration is negative, or intervalDuration is negative.
- `IllegalStateException` - If this method is invoked while the instance is in a state that does not allow access to this method.
- `EJBException` - If this method could not complete due to a system-level failure.

```java
public Timer createTimer(java.util.Date expiration, java.io.Serializable info) throws IllegalArgumentException, IllegalStateException, EJBException
```

Create a single-action timer that expires at a given point in time.
Parameters:
The expiration - The point in time at which the timer must expire.
info - Application information to be delivered along with the timer expiration notification. This can be null.

Returns:
The newly created Timer.

Throws:
IllegalStateException - If this method is invoked while the instance is in a state that does not allow access to this method.
EJBException - If this method could not complete due to a system-level failure.

```java
public Timer createTimer(java.util.Date initialExpiration, long intervalDuration, java.io.Serializable info) throws IllegalArgumentException, IllegalStateException, EJBException
```

```
initialExpiration
intervalDuration
info null
```

```
Throws IllegalArgumentException: initialExpiration null
initialExpiration.getTime() intervalDuration
Throws IllegalStateException: EJBException:
```

createTimer

```java
Timer createTimer(Date initialExpiration, long intervalDuration, Serializable info) throws IllegalArgumentException, IllegalStateException, EJBException
```
Create an interval timer whose first expiration occurs at a given point in time and whose subsequent expirations occur after a specified interval.

**Parameters:**
- `initialExpiration` - The point in time at which the first timer expiration must occur.
- `intervalDuration` - The number of milliseconds that must elapse between timer expiration notifications. Expiration notifications are scheduled relative to the time of the first expiration. If expiration is delayed (e.g. due to the interleaving of other method calls on the bean) two or more expiration notifications may occur in close succession to "catch up".
- `info` - Application information to be delivered along with the timer expiration. This can be null.

**Returns:**
The newly created Timer.

**Throws:**
- `IllegalArgumentException` - If `initialExpiration` is null, or `initialExpiration.getTime()` is negative, or `intervalDuration` is negative.
- `IllegalStateException` - If this method is invoked while the instance is in a state that does not allow access to this method.
- `EJBEException` - If this method could not complete due to a system-level failure.

```java
public java.util.Collection<E> getTimers() throws IllegalStateException, EJBEException
Bean
return javax.ejb.Timer
Throws IllegalArgumentException: IllegalStateException: 
Throws EJBEException:
```

gTimers

`Collection getTimers()`
Get all the active timers associated with this bean.

**Returns:**
A collection of javax.ejb.Timer objects.

**Throws:**
- `IllegalStateException` - If this method is invoked while the instance is in a state that does not allow access to this method.
- `EJBException` - If this method could not complete due to a system-level failure.
javax.management.j2ee.statistics Interface TimeStatistic

Methods inherited from interface
javax.management.j2ee.statistics.Statistic
getDescription, getLastSampleTime, getName, getStartTime, getUnit

Method Detail

public long getCount()

getCount

long getCount()

Number of times the operation was invoked since the beginning of this measurement.

public long getMaxTime()

getMaxTime

long getMaxTime()

The maximum amount of time taken to complete one invocation of this operation since the beginning of this measurement.

public long getMinTime()

getMinTime
long `getMinTime()`

The minimum amount of time taken to complete one invocation of this operation since the beginning of this measurement.

---

`public long getTotalTime()`

`totalTime`

---

`getTotalTime`  

long `getTotalTime()`

This is the sum total of time taken to complete every invocation of this operation since the beginning of this measurement. Dividing `totalTime` by `count` will give you the average execution time for this operation.

- Session.CreateProducer(Destination destination)

/ (pub/sub) JMS API

pub/sub JMS API

version 1.1 - February 2, 2002

See createConsumer(Destination), createProducer(Destination), createTopic(String)

A Topic object encapsulates a provider-specific topic name. It is the way a client specifies the identity of a topic to JMS API methods. For those methods that use a Destination as a parameter, a Topic object may be used as an argument. For example, a Topic can be used to create a MessageConsumer and a MessageProducer by calling:

- Session.CreateConsumer(Destination destination)
Many publish/subscribe (pub/sub) providers group topics into hierarchies and provide various options for subscribing to parts of the hierarchy. The JMS API places no restriction on what a `Topic` object represents. It may be a leaf in a topic hierarchy, or it may be a larger part of the hierarchy.

The organization of topics and the granularity of subscriptions to them is an important part of a pub/sub application’s architecture. The JMS API does not specify a policy for how this should be done. If an application takes advantage of a provider-specific topic-grouping mechanism, it should document this. If the application is installed using a different provider, it is the job of the administrator to construct an equivalent topic architecture and create equivalent `Topic` objects.

**Version:**
1.1 - February 2, 2002

</tr>
</tbody>
</table>

### Method Detail

`public String getTopicName() throws JMSException`
getTopicName

String getTopicName() throws JMSException

Gets the name of this topic.

Clients that depend upon the name are not portable.

Returns:
the topic name

Throws:
JMSException - if the JMS provider implementation of Topic fails to return the topic name due to some internal error.

public String toString()

return

toString

String toString()

Returns a string representation of this object.

Overrides:
toString in class Object

Returns:
the provider-specific identity values for this topic
A TopicConnection object is an active connection to a publish/subscribe JMS provider. A client uses a TopicConnection object to create one or more TopicSession objects for producing and consuming messages.

A TopicConnection can be used to create a TopicSession, from which specialized topic-related objects can be created. A more general, and recommended approach is to use the Connection object.

The TopicConnection object should be used to support existing code.

Methods inherited from interface `javax.jms.Connection`

`close, createConnectionConsumer, createSession, getClientID, getExceptionListener, getMetaData, setClientID, setExceptionListener, start, stop`

Method Detail

```java
public TopicSession createTopicSession(boolean transacted, int acknowledgeMode) throws JMSException
    TopicSession
        transacted
```
acknowledgeMode Session.AUTO_ACKNOWLEDGE
Session.CLIENT_ACKNOWLEDGE
Session.DUPS_OK_ACKNOWLEDGE

return
Throws JMSException: TopicConnection
AUTO_ACKNOWLEDGE,
CLIENT_ACKNOWLEDGE,
DUPS_OK_ACKNOWLEDGE

See also
AUTO_ACKNOWLEDGE,
CLIENT_ACKNOWLEDGE,
DUPS_OK_ACKNOWLEDGE

createTopicSession

TopicSession createTopicSession(boolean transacted,
int acknowledgeMode)
throws JMSException

Creates a TopicSession object.

Parameters:
transacted - indicates whether the session is transacted
acknowledgeMode - indicates whether the consumer or the client
will acknowledge any messages it receives; ignored if the
session is transacted. Legal values are
Session.AUTO_ACKNOWLEDGE, Session.CLIENT_ACKNOWLEDGE, and
Session.DUPS_OK_ACKNOWLEDGE.

Returns:
a newly created topic session

Throws:
JMSException - if the TopicConnection object fails to create a
session due to some internal error or lack of support for the
specific transaction and acknowledgement mode.

public ConnectionConsumer createConnectionConsumer(Topic topic, String
messageSelector, ServerSessionPool sessionPool, int
maxMessages) throws JMSException
JMS

**createConnectionConsumer**

```java
ConnectionConsumer createConnectionConsumer(Topic topic,
                                          String messageSelector,
                                          ServerSessionPool sessionPool,
                                          int maxMessages)

throws JMSException
```

Creates a connection consumer for this connection (optional operation). This is an expert facility not used by regular JMS clients.

**Parameters:**
- `topic` - the topic to access
- `messageSelector` - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
- `sessionPool` - the server session pool to associate with this connection consumer
- `maxMessages` - the maximum number of messages that can be assigned to a server session at one time

**Returns:**
the connection consumer

**Throws:**
- `JMSException` - if the TopicConnection object fails to create a connection consumer due to some internal error or invalid
arguments for sessionPool and messageSelector.

InvalidDestinationException - if an invalid topic is specified.
InvalidSelectorException - if the message selector is invalid.

Throws InvalidDestinationException:

Throws InvalidSelectorException:

See also javax.jms.ConnectionConsumer

createDurableConnectionConsumer

ConnectionConsumer createDurableConnectionConsumer(Topic topic, String subscriptionName, String messageSelector, ServerSessionPool sessionPool, int maxMessages) throws JMSException

Create a durable connection consumer for this connection (optional operation). This is an expert facility not used by regular JMS clients.
Specified by:
createDurableConnectionConsumer in interface Connection

Parameters:
- topic - the topic to access
- subscriptionName - durable subscription name
- messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
- sessionPool - the server session pool to associate with this durable connection consumer
- maxMessages - the maximum number of messages that can be assigned to a server session at one time

Returns:
the durable connection consumer

Throws:
- JMSEexception - if the TopicConnection object fails to create a connection consumer due to some internal error or invalid arguments for sessionPool and messageSelector.
- InvalidDestinationException - if an invalid topic is specified.
- InvalidSelectorException - if the message selector is invalid.

## Method Detail

public TopicConnection createTopicConnection() throws JMSException

```
return
```

Throws

- JMSException: JMS
- JMSSecurityException:

createTopicConnection

```
TopicConnection createTopicConnection() throws JMSException
```
Creates a topic connection with the default user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

**Returns:**
- a newly created topic connection

**Throws:**
- `JMSException` - if the JMS provider fails to create a topic connection due to some internal error.
- `JMSSecurityException` - if client authentication fails due to an invalid user name or password.

```java
public TopicConnection createTopicConnection(String userName, String password) throws JMSException
```

**createTopicConnection**

```java
TopicConnection createTopicConnection(String userName, String password) throws JMSException
```

Creates a topic connection with the specified user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

**Parameters:**
- `userName` - the caller's user name
- `password` - the caller's password

**Returns:**
- a newly created topic connection
Throws:

- `JMSException` - if the JMS provider fails to create a topic connection due to some internal error.
- `JMSSecurityException` - if client authentication fails due to an invalid user name or password.

   JMSMessageID JMSTimeStamp

   MessageProducer  TopicPublisher  MessageProducer
   TopicPublisher   TopicPublisher

   TopicPublisher  MessageProducer  MessageProducer send
   send   publish

version 1.1 February 2, 2002
See also createProducer(Destination), createPublisher(Topic)
A client uses a TopicPublisher object to publish messages on a topic. A TopicPublisher object is the publish-subscribe form of a message producer.

Normally, the Topic is specified when a TopicPublisher is created. In this case, an attempt to use the publish methods for an unidentified TopicPublisher will throw a java.lang.UnsupportedOperationException.

If the TopicPublisher is created with an unidentified Topic, an attempt to use the publish methods that assume that the Topic has been identified will throw a java.lang.UnsupportedOperationException.

During the execution of its publish method, a message must not be changed by other threads within the client. If the message is modified, the result of the publish is undefined.

After publishing a message, a client may retain and modify it without affecting the message that has been published. The same message object may be published multiple times.

The following message headers are set as part of publishing a message: JMSDestination, JMSDeliveryMode, JMSExpiration, JMSPriority, JMSMessageID and JMSTimeStamp. When the message is published, the values of these headers are ignored. After completion of the publish, the headers hold the values specified by the method publishing the message. It is possible for the publish method not to set JMSMessageID and JMSTimeStamp if the setting of these headers is explicitly disabled by the MessageProducer.setDisableMessageID or MessageProducer.setDisableMessageTimestamp method.

Creating a MessageProducer provides the same features as creating a TopicPublisher. A MessageProducer object is recommended when creating new code. The TopicPublisher is provided to support existing code.

Because TopicPublisher inherits from MessageProducer, it inherits the send methods that are a part of the MessageProducer interface. Using the send methods will have the same effect as using the publish methods: they are functionally the same.
### Method Summary

### Method Detail

```java
public Topic getTopic() throws JMSException
```
### getTopic

```java
public Topic getTopic() throws JMSException {
    // Implementation
}
```

**Returns:**
- this publisher's topic

**Throws:**
- `JMSException` - if the JMS provider fails to get the topic for this `TopicPublisher` due to some internal error.

### publish

```java
public void publish(Message message) throws JMSException {
    // Implementation
}
```

**Throws:**
- `JMSException`: JMS
- `MessageFormatException`
- `InvalidDestinationException`
- `UnsupportedOperationException`: TopicPublisher

**See also:**
- `getDeliveryMode()`, `getTimeToLive()`, `getPriority()`

**Publishes a message to the topic. Uses the `TopicPublisher's default delivery mode, priority, and time to live.`**
Parameters:
message - the message to publish

Throws:

- **JMSException** - if the JMS provider fails to publish the message due to some internal error.
- **MessageFormatException** - if an invalid message is specified.
- **InvalidDestinationException** - if a client uses this method with a TopicPublisher with an invalid topic.
- **UnsupportedOperationException** - if a client uses this method with a TopicPublisher that did not specify a topic at creation time.

public void publish(Message message, int deliveryMode, int priority, long timeToLive) throws JMSException

message
deliveryMode
priority
timeToLive

Throws  JMSException: JMS

Throws  MessageFormatException:

Throws  InvalidDestinationException: Topic

Publish

do void publish(Message message, int deliveryMode, int priority, long timeToLive)

throws JMSException
Publishes a message to the topic, specifying delivery mode, priority, and time to live.

**Parameters:**
- `message` - the message to publish
- `deliveryMode` - the delivery mode to use
- `priority` - the priority for this message
- `timeToLive` - the message's lifetime (in milliseconds)

**Throws:**
- `JMSException` - if the JMS provider fails to publish the message due to some internal error.
- `MessageFormatException` - if an invalid message is specified.
- `InvalidDestinationException` - if a client uses this method with a `TopicPublisher` with an invalid topic.
- `UnsupportedOperationException` - if a client uses this method with a `TopicPublisher` that did not specify a topic at creation time.

```java
public void publish(Topic topic, Message message) throws JMSException
```

**JMS API**
- `topic`
- `message`

**Throws**
- `JMSException`: JMS
- `MessageFormatException`: 
- `InvalidDestinationException`: 

**See also**
- `getDeliveryMode()`, `getTimeToLive()`, `getPriority()`

```java
void publish(Topic topic,
            Message message)
```

**Throws**
- `JMSException`: 

Publishes a message to a topic for an unidentified message producer. Uses the TopicPublisher's default delivery mode, priority, and time to live.

Typically, a message producer is assigned a topic at creation time; however, the JMS API also supports unidentified message producers, which require that the topic be supplied every time a message is published.

**Parameters:**
- `topic` - the topic to publish this message to
- `message` - the message to publish

**Throws:**
- `JMSException` - if the JMS provider fails to publish the message due to some internal error.
- `MessageFormatException` - if an invalid message is specified.
- `InvalidDestinationException` - if a client uses this method with an invalid topic.

**See Also:**
- `MessageProducer.getDeliveryMode()`
- `MessageProducer.getTimeToLive()`
- `MessageProducer.getPriority()`

```java
public void publish(Topic topic, Message message, int deliveryMode, int priority, long timeToLive) throws JMSException
```

**JMS API**

- `topic`
- `message`
- `deliveryMode`
- `priority`
- `timeToLive`

**Throws**
- `JMSException`: JMS
- `MessageFormatException`
- `InvalidDestinationException`
publish

void publish(Topic topic,
             Message message,
             int deliveryMode,
             int priority,
             long timeToLive)
        throws JMSException

Publishes a message to a topic for an unidentified message producer, specifying delivery mode, priority and time to live.

Typically, a message producer is assigned a topic at creation time; however, the JMS API also supports unidentified message producers, which require that the topic be supplied every time a message is published.

Parameters:
- topic - the topic to publish this message to
- message - the message to publish
- deliveryMode - the delivery mode to use
- priority - the priority for this message
- timeToLive - the message's lifetime (in milliseconds)

Throws:
- JMSException - if the JMS provider fails to publish the message due to some internal error.
- MessageFormatException - if an invalid message is specified.
- InvalidDestinationException - if a client uses this method with an invalid topic.

PS:
javax.jms Class TopicRequestor

java.lang.Object
   └─javax.jms.TopicRequestor

    public class TopicRequestor
       extends Object

TopicRequestor
TopicRequestor TopicSession Topic TemporaryTopic request

/JMS

   version 1.0 - 8 July 1998
   See also javax.jms.QueueRequestor

The TopicRequestor helper class simplifies making service requests.

The TopicRequestor constructor is given a non-transacted TopicSession
and a destination Topic. It creates a TemporaryTopic for the responses
and provides a request method that sends the request message and
waits for its reply.

This is a basic request/reply abstraction that should be sufficient for most
uses. JMS providers and clients are free to create more sophisticated
versions.

Version:
   1.0 - 8 July 1998

Author:
   Mark Hapner, Rich Burridge

See Also:
   QueueRequestor
Constructor Summary

```java
public TopicRequestor(TopicSession session, Topic topic)

Constructor for the TopicRequestor class.
```

Method Summary

```java
void close()

Closes the TopicRequestor and its session.
```

```java
Message request(Message message)

Sends a request and waits for a reply.
```

Methods inherited from class java.lang.Object

`clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait`
Constructor for the TopicRequestor class.

This implementation assumes the session parameter to be non-transacted, with a delivery mode of either AUTO_ACKNOWLEDGE or DUPS_OK_ACKNOWLEDGE.

Parameters:
- `session`: the TopicSession the topic belongs to
- `topic`: the topic to perform the request/reply call on

Throws:
- `JMSException`: if the JMS provider fails to create the TopicRequestor due to some internal error.
- `InvalidDestinationException`: if an invalid topic is specified.

### Method Detail

#### public `Message` request(`Message` message) throws `JMSException`

Sends a request and waits for a reply. The temporary topic is used for the JMSReplyTo destination; the first reply is returned, and any following replies are discarded.

Parameters:
- `message`: the message to send
Returns:
the reply message

Throws:
   JMSException - if the JMS provider fails to complete the request due to some internal error.

public void close() throws JMSException

TopicRequestor

Java

TopicRequestor   TopicSession
Throws   JMSException: JMS

Closes the TopicRequestor and its session.

Since a provider may allocate some resources on behalf of a TopicRequestor outside the Java virtual machine, clients should close them when they are not needed. Relying on garbage collection to eventually reclaim these resources may not be timely enough.

Note that this method closes the TopicSession object passed to the TopicRequestor constructor.

Throws:
   JMSException - if the JMS provider fails to close the TopicRequestor due to some internal error.

PS:
**javax.jms Interface TopicSession**

**All Superinterfaces:**  [Runnable, Session]

```java
public interface TopicSession
    extends Session

Implements: Session
```

**TopicSession** TopicPublisher TopicSubscriber TemporaryTopic

**Pub/Sub** Session

```java
TopicSession createBrowser
createQueue
createTemporaryQueue
```

**IllegalStateException**

- createBrowser
- createQueue
- createTemporaryQueue

**version** 1.1 - April 9, 2002

**See**  [javax.jms.Session, createSession(boolean, int), createTopicSession(boolean, int), getTopicSession()]

**A TopicSession object provides methods for creating TopicPublisher, TopicSubscriber, and TemporaryTopic objects. It also provides a method for deleting its client's durable subscribers.**

**A TopicSession is used for creating Pub/Sub specific objects. In general, use the Session object, and use TopicSession only to support existing code. Using the Session object simplifies the programming model, and allows transactions to be used across the two messaging domains.**
A `TopicSession` cannot be used to create objects specific to the point-to-point domain. The following methods inherit from `Session`, but must throw an `IllegalStateException` if used from `TopicSession`:

- `createBrowser`
- `createQueue`
- `createTemporaryQueue`

**Version:**
1.1 - April 9, 2002

createTopic

**Topic** createTopic(String topicName)

**Throws:** JMSException

Creates a topic identity given a Topic name.

This facility is provided for the rare cases where clients need to dynamically manipulate topic identity. This allows the creation of a topic identity with a provider-specific name. Clients that depend on this ability are not portable.

Note that this method is not for creating the physical topic. The physical creation of topics is an administrative task and is not to be initiated by the JMS API. The one exception is the creation of temporary topics, which is accomplished with the createTemporaryTopic method.

**Specified by:**
createTopic in interface Session

**Parameters:**
topicName - the name of this Topic

**Returns:**
a Topic with the given name

**Throws:**
JMSException - if the session fails to create a topic due to some internal error.

---

public **TopicSubscriber** createSubscriber(Topic topic)

**Throws:** JMSException

**Returns:**
TopicSubscriber
createSubscriber

`TopicSubscriber createSubscriber(Topic topic) throws JMSException`

Creates a nondurable subscriber to the specified topic.

A client uses a `TopicSubscriber` object to receive messages that have been published to a topic.

Regular `TopicSubscriber` objects are not durable. They receive only messages that are published while they are active.

In some cases, a connection may both publish and subscribe to a topic. The subscriber `NoLocal` attribute allows a subscriber to inhibit the delivery of messages published by its own connection. The default value for this attribute is false.

**Parameters:**

- `topic` - the Topic to subscribe to

**Throws:**

- `JMSException` - if the session fails to create a subscriber due to some internal error.
- `InvalidDestinationException` - if an invalid topic is specified.

```java
public TopicSubscriber createSubscriber(Topic topic, String messageSelector, boolean noLocal) throws JMSException
```
createSubscriber

```
TopicSubscriber createSubscriber(Topic topic, String messageSelector, boolean noLocal) throws JMSException
```

Creates a nondurable subscriber to the specified topic, using a message selector or specifying whether messages published by its own connection should be delivered to it.

A client uses a TopicSubscriber object to receive messages that have been published to a topic.

Regular TopicSubscriber objects are not durable. They receive only messages that are published while they are active.

Messages filtered out by a subscriber's message selector will never be delivered to the subscriber. From the subscriber's perspective, they do not exist.
In some cases, a connection may both publish and subscribe to a topic. The subscriber NoLocal attribute allows a subscriber to inhibit the delivery of messages published by its own connection. The default value for this attribute is false.

**Parameters:**

- `topic` - the Topic to subscribe to
- `messageSelector` - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
- `noLocal` - if set, inhibits the delivery of messages published by its own connection

**Throws:**

- `JMSException` - if the session fails to create a subscriber due to some internal error.
- `InvalidDestinationException` - if an invalid topic is specified.
- `InvalidSelectorException` - if the message selector is invalid.

```java
public TopicSubscriber createDurableSubscriber(Topic topic, String name) throws JMSException
```

```
TopicSubscriber JMS

TopicSubscriber

/ TopicSubscriber

  NoLocal false

  topic Topic

  name

  Throws JMSException:

  Throws InvalidDestinationException:
```
createDurableSubscriber

TopicSubscriber createDurableSubscriber(Topic topic, String name)
throws JMSException

Creates a durable subscriber to the specified topic.

If a client needs to receive all the messages published on a topic, including the ones published while the subscriber is inactive, it uses a durable TopicSubscriber. The JMS provider retains a record of this durable subscription and insures that all messages from the topic’s publishers are retained until they are acknowledged by this durable subscriber or they have expired.

Sessions with durable subscribers must always provide the same client identifier. In addition, each client must specify a name that uniquely identifies (within client identifier) each durable subscription it creates. Only one session at a time can have a TopicSubscriber for a particular durable subscription.

A client can change an existing durable subscription by creating a durable TopicSubscriber with the same name and a new topic and/or message selector. Changing a durable subscriber is equivalent to unsubscribing (deleting) the old one and creating a new one.

In some cases, a connection may both publish and subscribe to a topic. The subscriber NoLocal attribute allows a subscriber to inhibit the delivery of messages published by its own connection. The default value for this attribute is false.

Specified by:
createDurableSubscriber in interface Session

Parameters:
- topic - the non-temporary Topic to subscribe to
- name - the name used to identify this subscription

Throws:
- JMSException - if the session fails to create a subscriber due to some internal error.
- InvalidDestinationException - if an invalid topic is specified.
public TopicSubscriber createDurableSubscriber(Topic topic, String name, String messageSelector, boolean noLocal) throws JMSException

createDurableSubscriber

createDurableSubscriber(Topic topic, String name, String messageSelector, boolean noLocal) throws JMSException

createDurableSubscriber(Topic topic, String name, String messageSelector, boolean noLocal) throws JMSException

Creates a durable subscriber to the specified topic, using a message selector or specifying whether messages published by its own connection should be delivered to it.

If a client needs to receive all the messages published on a topic, including the ones published while the subscriber is inactive, it uses a durable TopicSubscriber. The JMS provider retains a record of this durable subscription and insures that all messages from the topic's publishers are retained until they are acknowledged by this durable
subscriber or they have expired.

Sessions with durable subscribers must always provide the same client identifier. In addition, each client must specify a name which uniquely identifies (within client identifier) each durable subscription it creates. Only one session at a time can have a TopicSubscriber for a particular durable subscription. An inactive durable subscriber is one that exists but does not currently have a message consumer associated with it.

A client can change an existing durable subscription by creating a durable TopicSubscriber with the same name and a new topic and/or message selector. Changing a durable subscriber is equivalent to unsubscribing (deleting) the old one and creating a new one.

Specified by:
createDurableSubscriber in interface Session

Parameters:
- topic - the non-temporary Topic to subscribe to
- name - the name used to identify this subscription
- messageSelector - only messages with properties matching the message selector expression are delivered. A value of null or an empty string indicates that there is no message selector for the message consumer.
- noLocal - if set, inhibits the delivery of messages published by its own connection

Throws:
- JMSEException - if the session fails to create a subscriber due to some internal error.
- InvalidDestinationException - if an invalid topic is specified.
- InvalidSelectorException - if the message selector is invalid.

```java
public TopicPublisher createPublisher(Topic topic) throws JMSException
```
createPublisher

**TopicPublisher** createPublisher(**Topic** topic) throws **JMSException**

Creates a publisher for the specified topic.

A client uses a *TopicPublisher* object to publish messages on a topic. Each time a client creates a *TopicPublisher* on a topic, it defines a new sequence of messages that have no ordering relationship with the messages it has previously sent.

**Parameters:**
- `topic` - the *Topic* to publish to, or null if this is an unidentified producer

**Throws:**
- **JMSException** - if the session fails to create a publisher due to some internal error.
- **InvalidDestinationException** - if an invalid topic is specified.

---

public **TemporaryTopic** createTemporaryTopic() throws **JMSException**

**TemporaryTopic** createTemporaryTopic() throws **JMSException**

createTemporaryTopic

**TemporaryTopic** createTemporaryTopic() throws **JMSException**
Creates a TemporaryTopic object. Its lifetime will be that of the TopicConnection unless it is deleted earlier.

**Specified by:**
`createTemporaryTopic` in interface `Session`

**Returns:**
a temporary topic identity

**Throws:**
`JMSException` - if the session fails to create a temporary topic due to some internal error.

```java
public void unsubscribe(String name) throws JMSException
```

**Throws**
- `JMSException`
- `InvalidDestinationException`:

```java
unsubscribe(String name)
```

Unsubscribes a durable subscription that has been created by a client.

This method deletes the state being maintained on behalf of the subscriber by its provider.

It is erroneous for a client to delete a durable subscription while there is an active TopicSubscriber for the subscription, or while a
consumed message is part of a pending transaction or has not been acknowledged in the session.

**Specified by:**
unsubscribe in interface Session

**Parameters:**
name - the name used to identify this subscription

**Throws:**
JMSException - if the session fails to unsubscribe to the durable subscription due to some internal error.
InvalidDestinationException - if an invalid subscription name is specified.
public interface TopicSubscriber
extends MessageConsumer

Implements: MessageConsumer

Session.createConsumer
TopicSession TopicSubscriber

Session.CreateDurableSubscriber

See also createConsumer, createDurableSubscriber, javax.jms.TopicSession, createSubscriber, javax.jms.MessageConsumer
A client uses a TopicSubscriber object to receive messages that have been published to a topic. A TopicSubscriber object is the publish/subscribe form of a message consumer. A MessageConsumer can be created by using Session.createConsumer.

A TopicSession allows the creation of multiple TopicSubscriber objects per topic. It will deliver each message for a topic to each subscriber eligible to receive it. Each copy of the message is treated as a completely separate message. Work done on one copy has no effect on the others; acknowledging one does not acknowledge the others; one message may be delivered immediately, while another waits for its subscriber to process messages ahead of it.

Regular TopicSubscriber objects are not durable. They receive only messages that are published while they are active.

Messages filtered out by a subscriber's message selector will never be delivered to the subscriber. From the subscriber's perspective, they do not exist.

In some cases, a connection may both publish and subscribe to a topic. The subscriber NoLocal attribute allows a subscriber to inhibit the delivery of messages published by its own connection.

If a client needs to receive all the messages published on a topic, including the ones published while the subscriber is inactive, it uses a durable TopicSubscriber. The JMS provider retains a record of this durable subscription and insures that all messages from the topic's publishers are retained until they are acknowledged by this durable subscriber or they have expired.

Sessions with durable subscribers must always provide the same client identifier. In addition, each client must specify a name that uniquely identifies (within client identifier) each durable subscription it creates. Only one session at a time can have a TopicSubscriber for a particular durable subscription.

A client can change an existing durable subscription by creating a
durable TopicSubscriber with the same name and a new topic and/or message selector. Changing a durable subscription is equivalent to unsubscribing (deleting) the old one and creating a new one.

The unsubscribe method is used to delete a durable subscription. The unsubscribe method can be used at the Session or TopicSession level. This method deletes the state being maintained on behalf of the subscriber by its provider.

Creating a MessageConsumer provides the same features as creating a TopicSubscriber. To create a durable subscriber, use of Session.CreateDurableSubscriber is recommended. The TopicSubscriber is provided to support existing code.

### Method Detail
public Topic getTopic() throws JMSException

    Topic
    return
    Throws    JMSException: JMS

getTopic

    Topic getTopic()
    throws JMSException

    Gets the Topic associated with this subscriber.

    Returns:  
               this subscriber's Topic

    Throws:
               JMSException - if the JMS provider fails to get the topic for this topic subscriber due to some internal error.

public boolean getNoLocal() throws JMSException

    NoLocal false
    return  true
    Throws  JMSException: JMS

getNoLocal

    boolean getNoLocal()
    throws JMSException

    Gets the NoLocal attribute for this subscriber. The default value for this attribute is false.

    Returns:  
               true if locally published messages are being inhibited

    Throws:
**JMSException** - if the JMS provider fails to get the `NoLocal` attribute for this topic subscriber due to some internal error.

PS:
The Transaction interface allows operations to be performed against the transaction in the target Transaction object. A Transaction object is created corresponding to each global transaction creation. The Transaction object can be used for resource enlistment, synchronization registration, transaction completion, and status query operations.

<td>Thrown to indicate that a heuristic</td>
</tr>
</tbody>
</table>

**commit**

**void commit() throws** *RollbackException, HeuristicMixedException, HeuristicRollbackException, SecurityException, IllegalStateException, SystemException*

Complete the transaction represented by this Transaction object.

**Throws:**

- **RollbackException** - Thrown to indicate that the transaction has been rolled back rather than committed.
- **HeuristicMixedException** - Thrown to indicate that a heuristic
decision was made and that some relevant updates have been committed while others have been rolled back. 

**HeuristicRollbackException** - Thrown to indicate that a heuristic decision was made and that all relevant updates have been rolled back.

**SecurityException** - Thrown to indicate that the thread is not allowed to commit the transaction.

**IllegalStateException** - Thrown if the transaction in the target object is inactive.

**SystemException** - Thrown if the transaction manager encounters an unexpected error condition.

---

```java
public boolean delistResource(XAResource xaRes, int flag) throws IllegalStateException, SystemException
```

Transaction

- **xaRes**: XAResource
- **flag**: TMSUCCESS, TMSUSPEND, TMFAIL

**Throws**:
- **IllegalStateException**: 
- **SystemException**: 

**return**:  
```
true  false
```

---

**delistResource**

```java
boolean delistResource(XAResource xaRes, int flag) throws IllegalStateException, SystemException
```

Disassociate the resource specified from the transaction associated with the target Transaction object.

**Parameters:**
- **xaRes**: The XAResource object associated with the resource (connection).
- **flag**: One of the values of TMSUCCESS, TMSUSPEND, or TMFAIL.
Returns: 
true if the resource was delisted successfully; otherwise false.

Throws:
IllegalStateException - Thrown if the transaction in the target object is inactive.
SystemException - Thrown if the transaction manager encounters an unexpected error condition.

```java
public boolean enlistResource(XAResource xaRes) throws RollbackException, IllegalStateException, SystemException {
    // Enlist the resource specified with the transaction associated with the target Transaction object.
    xaRes XAResource
    return true false

    Throws RollbackException:
    Throws IllegalStateException:
    Throws SystemException:
}
```

enlistResource

boolean enlistResource(XAResource xaRes)
throws RollbackException, IllegalStateException, SystemException

Enlist the resource specified with the transaction associated with the target Transaction object.

Parameters:
xaRes - The XAResource object associated with the resource (connection).

Returns: 
true if the resource was enlisted successfully; otherwise false.

Throws: 
RollbackException - Thrown to indicate that the transaction has been marked for rollback only.
**IllegalStateException** - Thrown if the transaction in the target object is in the prepared state or the transaction is inactive.

**SystemException** - Thrown if the transaction manager encounters an unexpected error condition.

```java
public int getStatus() throws SystemException
Transaction

return Status.NoTransaction

Throws SystemException:
```

**getStatus**

```java
int getStatus()
throws SystemException

Obtain the status of the transaction associated with the target Transaction object.

Returns:
The transaction status. If no transaction is associated with the target object, this method returns the Status.NoTransaction value.

Throws:
SystemException - Thrown if the transaction manager encounters an unexpected error condition.
```

```java
public void registerSynchronization(Synchronization sync) throws RollbackException, IllegalStateException, SystemException

beforeCompletion afterCompletion

 sync Synchronization

Throws RollbackException:

Throws IllegalStateException:

Throws SystemException:
```
registerSynchronization

```java
void registerSynchronization(Synchronization sync)
    throws RollbackException,
            IllegalStateException,
            SystemException
```

Register a synchronization object for the transaction currently associated with the target object. The transaction manager invokes the beforeCompletion method prior to starting the two-phase transaction commit process. After the transaction is completed, the transaction manager invokes the afterCompletion method.

**Parameters:**
- `sync` - The Synchronization object for the transaction associated with the target object.

**Throws:**
- `RollbackException` - Thrown to indicate that the transaction has been marked for rollback only.
- `IllegalStateException` - Thrown if the transaction in the target object is in the prepared state or the transaction is inactive.
- `SystemException` - Thrown if the transaction manager encounters an unexpected error condition.

```
public void rollback() throws IllegalStateException,
                        SystemException
```

**Transaction**

- Throws `IllegalStateException`:
- Throws `SystemException`:

**rollback**

```java
void rollback()
    throws RollbackException,
            SystemException
```
Rollback the transaction represented by this Transaction object.

Throws:

- `IllegalStateException` - Thrown if the transaction in the target object is in the prepared state or the transaction is inactive.
- `SystemException` - Thrown if the transaction manager encounters an unexpected error condition.

---

public void setRollbackOnly() throws `IllegalStateException`, `SystemException`

Throws

- `IllegalStateException`:  
- `SystemException`:

---

`setRollbackOnly`

void `setRollbackOnly()` throws `IllegalStateException`, `SystemException`

Modify the transaction associated with the target object such that the only possible outcome of the transaction is to roll back the transaction.

Throws:

- `IllegalStateException` - Thrown if the target object is not associated with any transaction.
- `SystemException` - Thrown if the transaction manager encounters an unexpected error condition.

**final public static** TransactionAttributeType[] **values()**

**values**

public static final TransactionAttributeType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(TransactionAttributeType c : TransactionAttributeType.values
    System.out.println(c);
```

**Returns:**

an array containing the constants of this enum type, in the order they're declared
public static TransactionAttributeType valueOf(String name)

valueOf

public static TransactionAttributeType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

Parameters:
name - the name of the enum constant to be returned.

Returns:  
the enum constant with the specified name

Throws:  
IllegalArgumentException - if this enum type has no constant with the specified name

<tr>
<td>void setRollbackOnly()</td>
<td>Modify the transaction associated with the current thread.</td>
</tr>
</tbody>
</table>
void thread such that the only possible outcome of the transaction is to roll back the transaction.

void setTransactionTimeout(int seconds)

Modify the timeout value that is associated with transactions started by the current thread with the begin method.

Transaction suspend()

Suspend the transaction currently associated with the calling thread and return a Transaction object that represents the transaction context being suspended.

## Method Detail

public void begin() throws NotSupportedException, SystemException

Throws NotSupportedException: TransactionManager

Throws SystemException:

begin

void begin()

throws NotSupportedException, SystemException

Create a new transaction and associate it with the current thread.

**Throws:**
- NotSupportedException - Thrown if the thread is already associated with a transaction and the Transaction Manager implementation does not support nested transactions.
- SystemException - Thrown if the transaction manager encounters an unexpected error condition.
public void commit() throws RollbackException, HeuristicMixedException, HeuristicRollbackException, SecurityException, IllegalStateException, SystemException

Throws

- RollbackException
- HeuristicMixedException
- HeuristicRollbackException
- SecurityException
- IllegalStateException
- SystemException

commit

Complete the transaction associated with the current thread. When this method completes, the thread is no longer associated with a transaction.

Throws:

- RollbackException - Thrown to indicate that the transaction has been rolled back rather than committed.
- HeuristicMixedException - Thrown to indicate that a heuristic decision was made and that some relevant updates have been committed while others have been rolled back.
- HeuristicRollbackException - Thrown to indicate that a heuristic decision was made and that all relevant updates have been rolled back.
- SecurityException - Thrown to indicate that the thread is not allowed to commit the transaction.
- IllegalStateException - Thrown if the current thread is not associated with a transaction.
SystemException - Thrown if the transaction manager encounters an unexpected error condition.

public int getStatus() throws SystemException

    return Status.NoTransaction
    Throws SystemException:

getStatus

int getStatus()
    throws SystemException

Obtain the status of the transaction associated with the current thread.

Returns:
The transaction status. If no transaction is associated with the current thread, this method returns the Status.NoTransaction value.

Throws:
SystemException - Thrown if the transaction manager encounters an unexpected error condition.

public Transaction getTransaction() throws SystemException

    return Transaction
    Throws SystemException:

getTransaction

Transaction getTransaction()
    throws SystemException
Get the transaction object that represents the transaction context of the calling thread.

**Returns:**
the Transaction object representing the transaction associated with the calling thread.

**Throws:**
[SystemException](#) - Thrown if the transaction manager encounters an unexpected error condition.

---

```java
public void resume(Transaction obj) throws
InvalidTransactionException, IllegalStateException, SystemException
Transaction
obj
Throws
InvalidTransactionException:
Throws
IllegalStateException:
Throws
SystemException:
```

Resume the transaction context association of the calling thread with the transaction represented by the supplied Transaction object. When this method returns, the calling thread is associated with the transaction context specified.

**Parameters:**
obj - The Transaction object that represents the transaction to be resumed.

**Throws:**
[InvalidTransactionException](#) - Thrown if the parameter
transaction object contains an invalid transaction.

**IllegalStateException** - Thrown if the thread is already associated with another transaction.
**SystemException** - Thrown if the transaction manager encounters an unexpected error condition.

```java
public void rollback() throws IllegalStateException, SecurityException, SystemException
```

Throws:
- **SecurityException**: 
- **IllegalStateException**: 
- **SystemException**: 

**rollback**

```java
void rollback()
    throws IllegalStateException, SecurityException, SystemException
```

Roll back the transaction associated with the current thread. When this method completes, the thread is no longer associated with a transaction.

**Throws:**
- **SecurityException** - Thrown to indicate that the thread is not allowed to roll back the transaction.
- **IllegalStateException** - Thrown if the current thread is not associated with a transaction.
- **SystemException** - Thrown if the transaction manager encounters an unexpected error condition.

```java
public void setRollbackOnly() throws IllegalStateException, SystemException
```
Throws:  
  
**setRollbackOnly**  

```java
void setRollbackOnly()
  throws IllegalStateException, SystemException
```

Modify the transaction associated with the current thread such that the only possible outcome of the transaction is to roll back the transaction.

**Throws:**

- **IllegalStateException** - Thrown if the current thread is not associated with a transaction.
- **SystemException** - Thrown if the transaction manager encounters an unexpected error condition.

---

**public void setTransactionTimeout(int seconds) throws SystemException**

```java
begin
  seconds 0 SystemException

Throws  SystemException:
```

---

**setTransactionTimeout**  

```java
void setTransactionTimeout(int seconds)
  throws SystemException
```

Modify the timeout value that is associated with transactions started by the current thread with the begin method.
If an application has not called this method, the transaction service uses some default value for the transaction timeout.

**Parameters:**
- seconds - The value of the timeout in seconds. If the value is zero, the transaction service restores the default value. If the value is negative a SystemException is thrown.

** Throws:**
- SystemException - Thrown if the transaction manager encounters an unexpected error condition.

```java
public Transaction suspend() throws SystemException {
    return null;
}
```

**suspend**

Suspend the transaction currently associated with the calling thread and return a Transaction object that represents the transaction context being suspended. If the calling thread is not associated with a transaction, the method returns a null object reference. When this method returns, the calling thread is not associated with a transaction.

**Returns:**
- Transaction object representing the suspended transaction.

** Throws:**
- SystemException - Thrown if the transaction manager encounters an unexpected error condition.

PS:
This interface is intended for use by system level application server components such as persistence managers, resource adapters, as well as EJB and Web application components. This provides the ability to register synchronization objects with special ordering semantics, associate resource objects with the current transaction, get the transaction context of the current transaction, get current transaction status, and mark the current transaction for rollback. This interface is implemented by the application server by a stateless service object. The same object can be used by any number of components with thread safety.

In standard application server environments, an instance implementing this interface can be looked up by a standard name via JNDI. The standard name is java:comp/TransactionSynchronizationRegistry.

Since: JTA 1.1

</tbody>
</table>

**Method Detail**

```java
public Object getTransactionKey()
hashCode  equals hashMap  null

hashCode

toString  StringtoString  toString

return since  JTA 1.1
```
getTransactionKey

Object getTransactionKey()

Return an opaque object to represent the transaction bound to the current thread at the time this method is called. This object overrides hashCode and equals to allow its use as the key in a hashMap for use by the caller. If there is no transaction currently active, return null.

This object will return the same hashCode and compare equal to all other objects returned by calling this method from any component executing in the same transaction context in the same application server.

The toString method returns a String that might be usable by a human reader to usefully understand the transaction context. The toString result is otherwise not defined. Specifically, there is no forward or backward compatibility guarantee of the results of toString.

The object is not necessarily serializable, and has no defined behavior outside the virtual machine whence it was obtained.

Returns:
an opaque object representing the transaction bound to the current thread at the time this method is called.

Since:
JTA 1.1

public void putResource(Object key, Object value)
Map hashCode equals
null null Map put(Object, Object) value

key Map
putResource

void putResource(Object key, Object value)

Add or replace an object in the Map of resources being managed for the transaction bound to the current thread at the time this method is called. The supplied key should be of an caller-defined class so as not to conflict with other users. The class of the key must guarantee that the hashCode and equals methods are suitable for use as keys in a map. The key and value are not examined or used by the implementation. The general contract of this method is that of Map.put(Object, Object) for a Map that supports non-null keys and null values. For example, if there is already an value associated with the key, it is replaced by the value parameter.

Parameters:
  key - the key for the Map entry.
  value - the value for the Map entry.

Throws:
  IllegalStateException - if no transaction is active.
  NullPointerException - if the parameter key is null.

Since:
  JTA 1.1

public Object getResource(Object key)
Map putResouce Map null
null null Map get(Object) null null
key Map
return
Throws IllegalStateException:
Throws

NullPointerException: key null

since

JTA 1.1

getResource

Object getResource(Object key)

Get an object from the Map of resources being managed for the transaction bound to the current thread at the time this method is called. The key should have been supplied earlier by a call to putResource in the same transaction. If the key cannot be found in the current resource Map, null is returned. The general contract of this method is that of Map.get(Object) for a Map that supports non-null keys and null values. For example, the returned value is null if there is no entry for the parameter key or if the value associated with the key is actually null.

Parameters:
key - the key for the Map entry.

Returns:
the value associated with the key.

Throws:

IllegalStateException - if no transaction is active.
NullPointerExcetion - if the parameter key is null.

Since:
JTA 1.1

public void
registerInterposedSynchronization(Synchronization sync)
Synchronization beforeCompletion
SessionSynchronization beforeCompletion Transaction
afterCompletion SessionSynchronization
Transaction afterCompletion

beforeCompletion Connector““
Bean registerInterposedSynchronization
registerInterposedSynchronization

afterCompletion ""

IllegalStateException

IllegalStateException

throws

IllegalStateException: 

since

JTA 1.1

registerInterposedSynchronization

void registerInterposedSynchronization(Synchronization sync)

Register a Synchronization instance with special ordering semantics. Its beforeCompletion will be called after all SessionSynchronization beforeCompletion callbacks and callbacks registered directly with the Transaction, but before the 2-phase commit process starts. Similarly, the afterCompletion callback will be called after 2-phase commit completes but before any SessionSynchronization and Transaction afterCompletion callbacks.

The beforeCompletion callback will be invoked in the transaction context of the transaction bound to the current thread at the time this method is called. Allowable methods include access to resources, e.g. Connectors. No access is allowed to "user components" (e.g. timer services or bean methods), as these might change the state of data being managed by the caller, and might change the state of data that has already been flushed by another caller of registerInterposedSynchronization. The general context is the component context of the caller of registerInterposedSynchronization.

The afterCompletion callback will be invoked in an undefined
context. No access is permitted to "user components" as defined above. Resources can be closed but no transactional work can be performed with them.

If this method is invoked without an active transaction context, an IllegalStateException is thrown.

If this method is invoked after the two-phase commit processing has started, an IllegalStateException is thrown.

**Parameters:**
- `sync` - the Synchronization instance.

**Throws:**
- `IllegalStateException` - if no transaction is active.

**Since:**
- JTA 1.1

```java
public int getTransactionStatus()
TransactionManager.getStatus()
    return
    since
JTA 1.1
```

**getTransactionStatus**

```java
int getTransactionStatus()
```

Return the status of the transaction bound to the current thread at the time this method is called. This is the result of executing `TransactionManager.getStatus()` in the context of the transaction bound to the current thread at the time this method is called.

**Returns:**
- the status of the transaction bound to the current thread at the time this method is called.

**Since:**
- JTA 1.1
public void setRollbackOnly()

void setRollbackOnly()

Set the rollbackOnly status of the transaction bound to the current thread at the time this method is called.

Throws:
IllegalStateException - if no transaction is active.

Since:
JTA 1.1

public boolean getRollbackOnly()

boolean getRollbackOnly()

Get the rollbackOnly status of the transaction bound to the current thread at the time this method is called.

Returns:
the rollbackOnly status.

Throws:
IllegalStateException - if no transaction is active.

Since:
javax.persistence Annotation Type Transient

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)
public @interface Transient

**Implements:** Annotation

@Target(value={METHOD, FIELD})
@Retention(value=RUNTIME)

@Entity
public class Employee {
    @Id int id;
    @Transient User currentUser;
    ...
}

since Java Persistence 1.0

This annotation specifies that the property or field is not persistent. It is used to annotate a property or field of an entity class, mapped superclass, or embeddable class.

Example:

@Entity
public class Employee {
    @Id int id;
    @Transient User currentUser;
    ...
}

### Constructor Detail

**public Transport(Session session, URLName urlName)**

- **session** - Transport Session
- **urlName** - Transport URLName

### Transport

**public Transport(Session session, URLName urlName)**

Constructor.

**Parameters:**
- **session** - Session object for this Transport.
- **urlName** - URLName object to be used for this Transport

### Method Detail

**public static void send(Message msg) throws MessagingException**

```
Transport sendFailedException = Transport.send(msg);
```

**Throws**
- **SendFailedException**
- **MessagingException**
send

public static void send(Message msg)
throws MessagingException

Send a message. The message will be sent to all recipient addresses specified in the message (as returned from the Message method getAllRecipients), using message transports appropriate to each address. The send method calls the saveChanges method on the message before sending it.

If any of the recipient addresses is detected to be invalid by the Transport during message submission, a SendFailedException is thrown. Clients can get more detail about the failure by examining the exception. Whether or not the message is still sent successfully to any valid addresses depends on the Transport implementation. See SendFailedException for more details. Note also that success does not imply that the message was delivered to the ultimate recipient, as failures may occur in later stages of delivery. Once a Transport accepts a message for delivery to a recipient, failures that occur later should be reported to the user via another mechanism, such as returning the undeliverable message.

Note that send is a static method that creates and manages its own connection. Any connection associated with any Transport instance used to invoke this method is ignored and not used. This method should only be invoked using the form Transport.send(msg);, and should never be invoked using an instance variable.

Parameters:
  - msg - the message to send

Throws:
  - SendFailedException - if the message could not be sent to some or any of the recipients.
public static void send(Message msg, Address[] addresses) throws MessagingException

Throws:
- SendFailedException - if the message could not be sent to some or any of the recipients.
- MessagingException

See Also:
- Message.saveChanges(), send(Message), SendFailedException

send

public static void send(Message msg, Address[] addresses) throws MessagingException

Parameters:
- msg - the message to send
- addresses - the addresses to which to send the message

Throws:
- SendFailedException - if the message could not be sent to some or any of the recipients.
- MessagingException

See Also:
- Message.saveChanges(), send(Message), SendFailedException
abstract public void sendMessage(Message msg, Address[] addresses) throws MessagingException

Message Transport TransportListener
TransportEvent SendFailedException
Transport

sendMessage

public abstract void sendMessage(Message msg, Address[] addresses) throws MessagingException

Throws SendFailedException:
Throws MessagingException:
See also javax.mail.event.TransportEvent

sendMessage

public abstract void sendMessage(Message msg, Address[] addresses) throws MessagingException

Send the Message to the specified list of addresses. An appropriate TransportEvent indicating the delivery status is delivered to any TransportListener registered on this Transport. Also, if any of the addresses is invalid, a SendFailedException is thrown. Whether or not the message is still sent successfully to any valid addresses depends on the Transport implementation.

Unlike the static send method, the sendMessage method does not call the saveChanges method on the message; the caller should do so.

Parameters:
msg - The Message to be sent
addresses - array of addresses to send this message to

Throws:
SendFailedException - if the send failed because of invalid addresses.
MessagingException - if the connection is dead or not in the
public void addTransportListener(TransportListener l)

Transport

TransportListener

/  

See also javax.mail.event.TransportEvent

addTransportListener

public void addTransportListener(TransportListener l)

Add a listener for Transport events.

The default implementation provided here adds this listener to an internal list of TransportListeners.

Parameters:

l - the Listener for Transport events

See Also:

TransportEvent

public void removeTransportListener(TransportListener l)

Transport

TransportListener

/  

See also addTransportListener
removeTransportListener

public void removeTransportListener(TransportListener l)

Remove a listener for Transport events.

The default implementation provided here removes this listener from the internal list of TransportListeners.

Parameters:
   l - the listener

See Also:
   addTransportListener(javax.mail.event.TransportListener)

protected void notifyTransportListeners(int type, Address[] validSent, Address[] validUnsent, Address[] invalid, Message msg)
TransportListenerTransport  TransportEvent
TransportListener

notifyTransportListeners

protected void notifyTransportListeners(int type, Address[] validSent, Address[] validUnsent, Address[] invalid, Message msg)

Notify all TransportListeners. Transport implementations are expected to use this method to broadcast TransportEvents.

The provided default implementation queues the event into an internal event queue. An event dispatcher thread dequeues events from the queue and dispatches them to the registered TransportListeners. Note that the event dispatching occurs in a separate thread, thus avoiding potential deadlock problems.
javax.mail.event Class TransportAdapter

java.lang.Object
   ^ javax.mail.event.TransportAdapter

All Implemented Interfaces:
   EventListener, TransportListener

public abstract class TransportAdapter
extends Object
implements TransportListener

Implements: TransportListener

Transport

The adapter which receives Transport events. The methods in this class are empty; this class is provided as a convenience for easily creating listeners by extending this class and overriding only the methods of interest.

TransportAdapter

public TransportAdapter()

Method Detail

public void messageDelivered(TransportEvent e)

messageDelivered

public void messageDelivered(TransportEvent e)

Description copied from interface: TransportListener
Invoked when a Message is succesfully delivered.

Specified by:
messageDelivered in interface TransportListener

Parameters:
e - TransportEvent
public void messageNotDelivered(TransportEvent e)

Description copied from interface: TransportListener
Invoked when a Message is not delivered.

Specified by:
messageNotDelivered in interface TransportListener
Parameters:
e - TransportEvent
See Also:
TransportEvent

public void messagePartiallyDelivered(TransportEvent e)

Description copied from interface: TransportListener
Invoked when a Message is partially delivered.

Specified by:
messagePartiallyDelivered in interface TransportListener
Parameters:
e - TransportEvent

### Field Summary

<table>
<thead>
<tr>
<th>Field</th>
<th>Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>protected <code>Address[]</code></td>
<td><code>invalid</code></td>
</tr>
<tr>
<td>static <code>int</code></td>
<td><code>MESSAGE_DELIVERED</code></td>
</tr>
</tbody>
</table>

Message has been successfully delivered to all recipients by the transport firing this event. `validSent[]` contains all the addresses this transport sent to successfully.
validUnsent[] and invalid[] should be null,

static int MESSAGE_NOT_DELIVERED
Message was not sent for some reason. validSent[] should be null.

static int MESSAGE_PARTIALLY_DELIVERED
Message was successfully sent to some recipients but not to all.

protected Message msg

protected int type
The event type.

protected Address[] validSent

protected Address[] validUnsent

Fields inherited from class java.util.EventObject
source

Constructor Summary
TransportEvent(Transport transport, int type, Address[] validSent, Address[] validUnsent, Address[] invalid, Message msg)
Constructor.

Method Summary
void dispatch(Object listener)
Invokes the appropriate TransportListener method.

Address[] getInvalidAddresses()
Return the addresses to which this message could not be sent.

Message getMessage()
Get the Message object associated with this Transport Event.
**MessageType**

Return the type of this event.

**getValidSentAddresses()**

Return the addresses to which this message was sent successfully.

**getValidUnsentAddresses()**

Return the addresses that are valid but to which this message was not sent.

### Field Detail

**MESSAGE_DELIVERED**

public static final int MESSAGE_DELIVERED

Message has been successfully delivered to all recipients by the transport firing this event. validSent[] contains all the addresses this transport sent to successfully. validUnsent[] and invalid[] should be null,

**See Also:**

Constant Field Values
MESSAGE_NOT_DELIVERED

public static final int MESSAGE_NOT_DELIVERED

    Message was not sent for some reason. validSent[] should be null. validUnsent[] may have addresses that are valid (but the message wasn't sent to them). invalid[] should likely contain invalid addresses.

See Also:
    Constant Field Values

MESSAGE_PARTIALLY_DELIVERED

public static final int MESSAGE_PARTIALLY_DELIVERED

    Message was successfully sent to some recipients but not to all. validSent[] holds addresses of recipients to whom the message was sent. validUnsent[] holds valid addresses to which the message was not sent. invalid[] holds invalid addresses, if any.

See Also:
    Constant Field Values

TransportEvent

public TransportEvent(Transport transport, int type,
Address[] validSent,
Address[] validUnsent,
Address[] invalid, Message msg)

Constructor.

Parameters:
transport - The Transport object

Method Detail

public int getType()

  return

getType

public int getType()

  Return the type of this event.

  Returns:
  type

public Address[] getValidSentAddresses()

  return null

getValidSentAddresses

public Address[] getValidSentAddresses()

  Return the addresses to which this message was sent successfully.

  Returns:
  Addresses to which the message was sent successfully or null
public Address[] getValidUnsentAddresses()
    return null

getValidUnsentAddresses

public Address[] getValidUnsentAddresses()
    Return the addresses that are valid but to which this message was not sent.

    Returns:
    Addresses that are valid but to which the message was not sent successfully or null

public Address[] getInvalidAddresses()
    return null

getInvalidAddresses

public Address[] getInvalidAddresses()
    Return the addresses to which this message could not be sent.

    Returns:
    Addresses to which the message sending failed or null

public Message getMessage()
    return Message

    since JavaMail 1.2

    en
getMessage

public Message getMessage()

Get the Message object associated with this Transport Event.

Returns:
the Message object

Since:
JavaMail 1.2

  TransportEvent
javax.servlet.jsp.tagext Interface TryCatchFinally

public interface TryCatchFinally

(hook) TagIterationTag BodyTag
doCatch(Throwbaible) doFinally()

h = get a Tag(); // get a tag handler, perhaps from pool
h setPageContext(pc); // initialize as desired
h.setParent(null);
h.setFoo("foo");

// tag invocation protocol; see Tag.java
try {
  doStartTag()...
  ....
  doEndTag()...
} catch (Throwable t) {
  // react to exceptional condition
  h.doCatch(t);
} finally {
  // restore data invariants and release per-invocation resources
  h.doFinally();
}

... other invocations perhaps with some new setters
...

h.release(); // release long-term resources

The auxiliary interface of a Tag, IterationTag or BodyTag tag handler that wants additional hooks for managing resources.

This interface provides two new methods: doCatch(Throwbaible) and doFinally(). The prototypical invocation is as follows:

h = get a Tag(); // get a tag handler, perhaps from pool
h.setPageContext(pc); // initialize as desired
h.setParent(null);
h.setFoo("foo");

// tag invocation protocol; see Tag.java
try {
    doStartTag()...
    ....
    doEndTag()...
} catch (Throwable t) {
    // react to exceptional condition
    h.doCatch(t);
} finally {
    // restore data invariants and release per-invocation resources
    h.doFinally();
}

... other invocations perhaps with some new setters
...

h.release(); // release long-term resources

---

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>doCatch(Throwables t)</code></td>
<td>Invoked if a Throwable occurs while evaluating the BODY inside a tag or in any of the following methods: Tag.doStartTag(), Tag.doEndTag(), IterationTag.doAfterBody() and BodyTag.doInitBody.</td>
</tr>
<tr>
<td><code>doFinally()</code></td>
<td>Invoked in all cases after doEndTag() for any class implementing Tag, IterationTag or BodyTag.</td>
</tr>
</tbody>
</table>

---

### Method Detail

```java
public void doCatch(Throwables t) throws Throwable
Tag.doStartTag()Tag.doEndTag()
IterationTag.doAfterBody() BodyTag.doInitBody() Throwable
```
setter Throwable

doFinally()

    t        throwable
Throws       Throwable:

doCatch

void doCatch(Throwable t)
        throws Throwable

Invoked if a Throwable occurs while evaluating the BODY inside a
tag or in any of the following methods: Tag.doStartTag(),
Tag.doEndTag(), IterationTag.doAfterBody() and
BodyTag.doInitBody().

This method is not invoked if the Throwable occurs during one of the
setter methods.

This method may throw an exception (the same or a new one) that
will be propagated further up the nest chain. If an exception is
thrown, doFinally() will be invoked.

This method is intended to be used to respond to an exceptional
condition.

Parameters:
    t - The throwable exception navigating through this tag.

Throws:
    Throwable - if the exception is to be rethrown further up the nest
    chain.

public void doFinally()
doFinally

void doFinally()

Invoked in all cases after doEndTag() for any class implementing Tag, IterationTag or BodyTag. This method is invoked even if an exception has occurred in the BODY of the tag, or in any of the following methods: Tag.doStartTag(), Tag.doEndTag(), IterationTag.doAfterBody() and BodyTag.doInitBody().

This method is not invoked if the Throwable occurs during one of the setter methods.

This method should not throw an Exception.

This method is intended to maintain per-invocation data integrity and resource management actions.
to license terms.

---

public class TypeConstraintException

extends RuntimeException

**Extends:** Throwable > Exception > RuntimeException

Java JAXB

version $Revision: 1.1 $

since JAXB1.0

See also [javax.xml.bind.ValidationEvent](#)

This exception indicates that a violation of a dynamically checked type constraint was detected.

This exception can be thrown by the generated setter methods of the schema derived Java content classes. However, since fail-fast validation is an optional feature for JAXB Providers to support, not all setter methods will throw this exception when a type constraint is violated.

If this exception is throw while invoking a fail-fast setter, the value of the property is guaranteed to remain unchanged, as if the setter were never
called.

</table>
public TypeConstraintException(String message)
TypeConstraintException errorCode
linkedException
null

message
Construct a TypeConstraintException with the specified detail message. The errorCode and linkedException will default to null.

**Parameters:**
message - a description of the exception

```java
public TypeConstraintException(String message, String errorCode)
errorCode TypeConstraintException linkedException null
message
errorCode
```

TypeConstraintException

Construct a TypeConstraintException with the specified detail message and vendor specific errorCode. The linkedException will default to null.

**Parameters:**
message - a description of the exception
errorCode - a string specifying the vendor specific error code

```java
public TypeConstraintException(Throwable exception)
linkedException TypeConstraintException errorCode null
exception
```

TypeConstraintException
public TypeConstraintException(Throwable exception)

Construct a TypeConstraintException with a linkedException. The detail message and vendor specific errorCode will default to null.

Parameters:
   exception - the linked exception

-----

equality

public TypeConstraintException(String message, Throwable exception)

Construct a TypeConstraintException with the specified detail message and linkedException. The errorCode will default to null.

Parameters:
   message - a description of the exception
   exception - the linked exception

-----

public TypeConstraintException(String message, String errorCode, Throwable exception)

Construct a TypeConstraintException with the specified detail message and linkedException. The errorCode will default to null.

Parameters:
   message - a description of the exception
   errorCode - the vendor specific error code
   exception - the linked exception
TypeConstraintException

public TypeConstraintException(String message, String errorCode, Throwable exception)

Construct a TypeConstraintException with the specified detail message, vendor specific errorCode, and linkedException.

Parameters:
message - a description of the exception
errorCode - a string specifying the vendor specific error code
exception - the linked exception

Method Detail

public String getErrorCode()

    return

getErrorCode

public String getErrorCode()

    Get the vendor specific error code

    Returns:
    a string specifying the vendor specific error code

    public Throwable getLinkedException()

        return null
**getLinkedException**

public Throwable getLinkedException()

Get the linked exception

**Returns:**
the linked Exception, null if none exists

**public void setLinkedException(Throwable exception)**

    exception    null

**setLinkedException**

public void setLinkedException(Throwable exception)

Add a linked Exception.

**Parameters:**
exception - the linked Exception (A null value is permitted and indicates that the linked exception does not exist or is unknown).

**public String toString()**

TypeConstraintException

**toString**

public String toString()

Returns a short description of this TypeConstraintException.

**Overrides:**
toString in class Throwable
public void printStackTrace(java.io.OutputStream s)
TypeConstraintException PrintStream null
linkedException

public void printStackTrace(java.io.PrintStream s)

printStackTrace

public void printStackTrace(java.io.PrintStream s)

Overrides:

printStackTrace in class Throwable

Parameters:

s - PrintStream to use for output

public void printStackTrace()
TypeConstraintException System.err null
linkedException

printStackTrace

public void printStackTrace()

Overrides:

printStackTrace in class Throwable

Parameters:

javax.xml.rpc.encoding Interface TypeMapping

public interface TypeMapping

javax.xml.rpc.encoding.TypeMapping TypeMapping

TypeMapping {Java, SerializerFactory, DeserializerFactory, XML}

version 1.0

The javax.xml.rpc.encoding.TypeMapping is the base interface for the representation of a type mapping. A TypeMapping implementation class may support one or more encoding styles.

For its supported encoding styles, a TypeMapping instance maintains a set of tuples of the type {Java type, SerializerFactory, DeserializerFactory, XML type}.

Version:
1.0
Author:
Rahul Sharma

Method Summary

<table>
<thead>
<tr>
<th>Class</th>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DeserializerFactory</td>
<td>getDeserializer(Class javaType, QName xmlType)</td>
<td>Gets the DeserializerFactory registered for the specified pair of Java type and XML data type.</td>
</tr>

</tr>
<tr>
<td><code>void removeSerializer(Class javaType, QName xmlType)</code></td>
<td>Removes the SerializerFactory registered for the specified pair of Java type and XML data type.</td>
<td></td>
</tr>
<tr>
<td><code>void setSupportedEncodings(String[] encodingStyleURIs)</code></td>
<td>Sets the encodingStyle URIs supported by this TypeMapping instance.</td>
<td></td>
</tr>
</tbody>
</table>

**Method Detail**

```java
public String[] getSupportedEncodings()
TypeMapping encodingStyle URI String[]
Serializer Deserializer TypeMapping
return encodingStyle URI
```

**getSupportedEncodings**

`String[] getSupportedEncodings()`

Returns the encodingStyle URIs (as String[]) supported by this TypeMapping instance. A TypeMapping that contains only encoding style independent serializers and deserializers returns `null` from this.
method.

Returns:
Array of encodingStyle URIs for the supported encoding styles

```java
public void setSupportedEncodings(String[] encodingStyleURIs)
```

Sets the encodingStyle URIs supported by this TypeMapping instance. A TypeMapping that contains only encoding independent serializers and deserializers requires `null` as the parameter for this method.

**Parameters:**
- `encodingStyleURIs` - Array of encodingStyle URIs for the supported encoding styles

```java
public boolean isRegistered(Class<T> javaType, javax.xml.namespace.QName xmlType)
```

**XML Java**
```
javaType           Java
QName             XML
return            boolean XML Java
```

isRegistered
boolean **isRegistered**(Class javaType,
    QName xmlType)

Checks whether or not type mapping between specified XML type and Java type is registered.

**Parameters:**
- javaType - Class of the Java type
- QName - Qualified name of the XML data type

**Returns:**
- boolean; true if type mapping between the specified XML type and Java type is registered; otherwise false

```java
public void register(Class<T> javaType,
    javax.xml.namespace.QName xmlType, SerializerFactory sf,
    DeserializerFactory dsf)
XML  Java  SerializerFactory
DeserializerFactory SerializerFactory

javaType  Java
QName    XML
sf  SerializerFactory
dsf  DeserializerFactory

**Throws**
- JAXRPCException:
```

```java
void register(Class javaType,
    QName xmlType,
    SerializerFactory sf,
    DeserializerFactory dsf)

Registers SerializerFactory and DeserializerFactory for a specific type mapping between an XML type and Java type. This method replaces any existing registered SerializerFactory DeserializerFactory instances.
```
public SerializerFactory getSerializer(Class<T> javaType, javax.xml.namespace.QName xmlType)

Java XML SerializerFactory

javaType Java
QName XML

return SerializerFactory

null

getSerializer

SerializerFactory getSerializer(Class javaType,
QName xmlType)

Gets the SerializerFactory registered for the specified pair of Java type and XML data type.

Parameters:
javaType - Class of the Java type
QName - Qualified name of the XML data type

Returns:
Registered SerializerFactory or null if there is no registered factory

public DeserializerFactory getDeserializer(Class<T> javaType, javax.xml.namespace.QName xmlType)

Java XML DeserializerFactory

javaType Java
getDeseralizer

DeserializerFactory getDeseralizer(Class javaType, QName xmlType)

Gets the DeserializerFactory registered for the specified pair of Java type and XML data type.

Parameters:
  javaType - Class of the Java type
  QName - Qualified name of the XML data type

Returns:
  Registered DeserializerFactory or null if there is no registered factory

public void removeSerializer(Class<T> javaType, javax.xml.namespace.QName xmlType)

Java XML SerializerFactory

Throws JAXRPCException: SerializerFactory

removeSerialser

void removeSerializer(Class javaType, QName xmlType)

Removes the SerializerFactory registered for the specified pair of Java type and XML data type.

Throws:
  JAXRPCException - If there is error in removing the registered SerializerFactory
public void removeDeserializer(Class<T> javaType, javax.xml.namespace.QName xmlType)

Throws JAXRPCException: DeserializerFactory

removeDeserializer

void removeDeserializer(Class javaType, QName xmlType)

Removes the DeserializerFactory registered for the specified pair of Java type and XML data type.

Throws:

JAXRPCException - If there is error in removing the registered DeserializerFactory

</tr>
</tbody>
</table>

### Method Detail

```java
public TypeMapping register(String encodingStyleURI, TypeMapping mapping)
```

- **encodingStyleURI**: URI
- **mapping**: TypeMapping
- **return**: TypeMapping

Throws: JAXRPCException

```
TypeMapping register(String encodingStyleURI, TypeMapping mapping)
```
Registers a `TypeMapping` instance with the `TypeMappingRegistry`. This method replaces any existing registered `TypeMapping` instance for the specified `encodingStyleURI`.

**Parameters:**
- `encodingStyleURI` - An encoding style specified as an URI. An example is "http://schemas.xmlsoap.org/soap/encoding/"
- `mapping` - `TypeMapping` instance

**Returns:**
Previous `TypeMapping` associated with the specified `encodingStyleURI`, or `null` if there was no `TypeMapping` associated with the specified `encodingStyleURI`

**Throws:**
- `JAXRPCException` - If there is an error in the registration of the `TypeMapping` for the specified `encodingStyleURI`.

```java
public void registerDefault(TypeMapping mapping)
```

Registers the `TypeMapping` instance that is default for all encoding styles supported by the `TypeMappingRegistry`. A default `TypeMapping` should include serializers and deserializers that are independent of and usable with any encoding style. Successive invocations of the `registerDefault` method replace any existing default `TypeMapping`.
If the default `TypeMapping` is registered, any other `TypeMapping` instances registered through the `TypeMappingRegistry.register` method (for a set of encodingStyle URIs) override the default `TypeMapping`.

**Parameters:**
- `mapping` - `TypeMapping` instance

**Throws:**
- `JAXRPCException` - If there is an error in the registration of the default `TypeMapping`

```java
public `TypeMapping` getDefaultTypeMapping() {
  `TypeMapping` defaultMapping = TypeMappingRegistry.getDefaultTypeMapping();
  return defaultMapping;
}
```

**getRegisteredEncodingStyleURIs**

```java
public `String[]` getRegisteredEncodingStyleURIs()`
  `TypeMappingRegistry` encodingStyleURIs = TypeMappingRegistry.getRegisteredEncodingStyleURIs();
  return encodingStyleURIs;
```

String[] getRegisteredEncodingStyleURIs()

Returns a list of registered encodingStyle URIs in this TypeMappingRegistry instance.

Returns:
Array of the registered encodingStyle URIs

public TypeMapping getTypeMapping(String encodingStyleURI)

Returns the registered TypeMapping for the specified encodingStyle URI. If there is no registered TypeMapping for the specified encodingStyleURI, this method returns null.

Parameters:
encodingStyleURI - Encoding style specified as an URI

Returns:
TypeMapping for the specified encodingStyleURI or null

public TypeMapping createTypeMapping()

Returns the registered TypeMapping for the specified encodingStyle URI. If there is no registered TypeMapping for the specified encodingStyleURI, this method returns null.

Parameters:
encodingStyleURI - Encoding style specified as an URI

Returns:
TypeMapping for the specified encodingStyleURI or null
**TypeMapping** createTypeMapping()

Creates a new empty TypeMapping object.

**Returns:**
TypeMapping instance

---

```java
public TypeMapping unregisterTypeMapping(String encodingStyleURI)
```

Unregisters a TypeMapping instance, if present, from the specified encodingStyleURI.

**Parameters:**
- `encodingStyleURI` - Encoding style specified as an URI

**Returns:**
TypeMapping instance that has been unregistered or null if there was no TypeMapping registered for the specified encodingStyleURI

---

```java
public boolean removeTypeMapping(TypeMapping mapping)
```

```java
return TypeMappingRegistry encodingStyleURI TypeMapping encodingStyleURIs Ty TypeMapping
```

```java
return TypeMappingRegistry TypeMapping true TypeMapping
```
removeTypeMapping

boolean removeTypeMapping(TypeMapping mapping)

Removes a TypeMapping from the TypeMappingRegistry. A TypeMapping is associated with 1 or more encodingStyleURIs. This method unregisters the specified TypeMapping instance from all associated encodingStyleURIs and then removes this TypeMapping instance from the registry.

Parameters:
  mapping - TypeMapping to be removed

Returns:
  true if specified TypeMapping is removed from the TypeMappingRegistry; false if the specified TypeMapping was not in the TypeMappingRegistry

public void clear()

Removes all registered TypeMappings and encodingStyleURIs from this TypeMappingRegistry.

Constructor Detail

public UIColumn()

UIColumn
**UIColumn**

```java
public UIColumn()
```

Create a new `UIColumn` instance with default property values.

## Method Detail

**public String getFamily()**

### getFamily

```java
public String getFamily()
```

**Description copied from class: `UIComponent`**

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

**Specified by:**

`getFamily` in class `UIComponent`

```java
public UIColumn getFooter()
```

### facet getFacet("footer")

**getFooter**

```java
public UIColumn getFooter()
```
Return the footer facet of the column (if any). A convenience method for getFacet("footer").

```java
public void setFooter(UIComponent footer)

facet getFacets().put("footer", footer)

footer facet

Throws NullPointerException: footer null
```

**setFooter**

```java
public void setFooter(UIComponent footer)

Set the footer facet of the column. A convenience method for getFacets().put("footer", footer).

Parameters:
footer - the new footer facet

Throws:
NullPointerException - if footer is null
```

```java
public UIComponent getHeader()

facet getFacet("header")
```

**getHeader**

```java
public UIComponent getHeader()

Return the header facet of the column (if any). A convenience method for getFacet("header").
```
public void setHeader(UIComponent header)

facet getFacets().put("header", header)

Throws NullPointerException: header null

setHeader

public void setHeader(UIComponent header)

Set the header facet of the column. A convenience method for getFacets().put("header", header).

Parameters:
  header - the new header facet

Throws:
  NullPointerException - if header is null

javax.faces.component Class UICommand

java.lang.Object
   ↘ javax.faces.component.UIComponent
      ↘ javax.faces.component.UIComponentBase
         ↘ javax.faces.component.UICommand

All Implemented Interfaces:
   ActionSource, ActionSource2, StateHolder

Direct Known Subclasses:
   HtmlCommandButton, HtmlCommandLink

public class UICommand
extends UIComponentBase
implements ActionSource2

Extends: UIComponent > UIComponentBase
Implements: ActionSource2
Extended by: HtmlCommandButton, HtmlCommandLink

UICommand  UIComponent "command" "action"

  decode()  Renderer  ActionEvent
  broadcast()

1. ActionListener
2. "actionListener" MethodExpression  MethodBinding
   "actionListener"
3. Application  ActionListener - "action" MethodExpression

rendererType "javax.faces.Button"  setRendererType()
**UICommand** is a **UIComponent** that represents a user interface component which, when activated by the user, triggers an application specific "command" or "action". Such a component is typically rendered as a push button, a menu item, or a hyperlink.

When the `decode()` method of this **UICommand**, or its corresponding **Renderer**, detects that this control has been activated, it will queue an **ActionEvent**. Later on, the `broadcast()` method will ensure that this event is broadcast to all interested listeners.

Listeners will be invoked in the following order:

1. **ActionListener**, in the order in which they were registered.
2. The "actionListener" **MethodExpression** (which will cover the "actionListener" that was set as a MethodBinding).
3. The default **ActionListener**, retrieved from the **Application** - and therefore, any attached "action" **MethodExpression**.

By default, the `rendererType` property must be set to "javax.faces.Button". This value can be changed by calling the `setRendererType()` method.

</tbody>
</table>
| `boolean/isImmediate()` | Return a flag indicating that the default `ActionListener` provided by the JavaServer Faces implementation should be executed immediately (that is, during `Apply Request Values` phase of the request processing lifecycle), rather than waiting until the `Invoke`...
**Application phase.**

```java
void queueEvent(FacesEvent e)
    Intercept queueEvent and, for ActionEvents, mark the phaseld for the event to be PhaseId.APPLY_REQUEST_VALUES if the immediate flag is true, PhaseId.INVOKE_APPLICATION otherwise.
```

```java
void removeActionListener(ActionListener listener)
    Remove an existing ActionListener (if any) from the set of listeners interested in being notified when ActionEvents occur.
```

```java
void restoreState(FacesContext context, Object state)
    Perform any processing required to restore the state from the entries in the state Object.
```

```java
Object saveState(FacesContext context)
    Gets the state of the instance as a Serializable Object.
```

```java
void setAction(MethodBinding action)
    Deprecated. This has been replaced by setActionExpression(javax.el.MethodExpression).
```

```java
void setActionExpression(MethodExpression actionExpression)
    Set the MethodExpression pointing at the application action to be invoked, if this UIComponent is activated by the user, during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending on the value of the immediate property.
```

```java
void setImmediate(boolean immediate)
    Set the "immediate execution" flag for this UIComponent.
```

```java
void setValue(Object value)
    Sets the value property of the UICommand.
```

Constant Field Values

Constructor Detail

public UICommand()

UICommand

UICommand

public UICommand()

Create a new UICommand instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UIComponent

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Specified by:

getFamily in class UIComponent
public MethodBinding getAction()

NullPointerException

ActionSource2 ActionSource2#getActionExpression
#setAction MethodBinding MethodBinding
javax.el.MethodExpression

UIComponent MethodBinding MethodBinding
immediate

deprecated #getActionExpression

getAction

public MethodBinding getAction()

Deprecated. This has been replaced by getActionExpression().

If the implementing class also implements ActionSource2, the implementation of this method must call through to ActionSource2.getActionExpression() and examine the result. If the result came from a previous call to ActionSource2.setAction(javax.faces.el.MethodBinding), extract the MethodBinding from it and return it. Otherwise, wrap the returned MethodExpression in a MethodBinding implementation, and return it.

If the implementing class does not implement ActionSource2, return the MethodBinding pointing at the application action to be invoked, if this UIComponent is activated by the user, during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending on the value of the immediate property.

Specified by:
    getAction in interface ActionSource
public void setAction(MethodBinding action)

NullPointerException

ActionSource2 javax.el.MethodExpression action

ActionSource2#setActionExpression action

ActionSource2 MethodBinding MethodBinding

UIComponent immediate

String

deprecated #setActionExpression(javax.el.MethodExpression)

setAction

public void setAction(MethodBinding action)

Deprecated. This has been replaced by

If the implementing class also implements ActionSource2, the implementation of this method must wrap the argument action in a class that implements MethodExpression and call through to

ActionSource2.setActionExpression(javax.el.MethodExpression),

passing the wrapped action.

If the implementing class does not implement ActionSource2, set the MethodBinding pointing at the application action to be invoked, if this UIComponent is activated by the user, during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending on the value of the immediate property.

Any method referenced by such an expression must be public, with a return type of String, and accept no parameters.

Specified by:

setAction in interface ActionSource
Parameters:
  action - The new MethodBinding expression

public MethodBinding getActionListener()

NullPointerException

#setActionListener null #setActionListener
#setActionListener MethodBinding

UIComponent immediate

deprecated #getActionListeners

getActionListener

public MethodBinding getActionListener()

Deprecated. Use getActionListeners() instead.

If ActionSource.setActionListener(javax.faces.el.MethodBinding) was not previously called for this instance, this method must return null. If it was called, this method must return the exact MethodBinding instance that was passed to ActionSource.setActionListener(javax.faces.el.MethodBinding).

The method to be invoked, if this UIComponent is activated by the user, will be called during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending upon the value of the immediate property.

Specified by:
  getActionListener in interface ActionSource

public void setActionListener(MethodBinding actionListener)
NullPointerException

**ActionListener**  ActionListener  #getActionListeners

**setActionListener**

```java
public void setActionListener(MethodBinding actionListener)
```

**Deprecated. This has been replaced by**

```java
addActionListener(javax.faces.event.ActionListener)
```

Wrap the argument `actionListener` in an implementation of `ActionListener` and store it in the internal data structure that backs the `ActionSource.getActionListeners()` method, taking care to overwrite any instance that was stored by a previous call to `setActionListener`.

Any method referenced by such an expression must be public, with a return type of `void`, and accept a single parameter of type `ActionEvent`.

**Specified by:**

`setActionListener` in interface `ActionSource`

**Parameters:**

- `actionListener` - The new method binding expression

---

**public boolean isImmediate()**

**isImmediate**
public boolean isImmediate()

Description copied from interface: ActionSource

Return a flag indicating that the default ActionListener provided by the JavaServer Faces implementation should be executed immediately (that is, during Apply Request Values phase of the request processing lifecycle), rather than waiting until the Invoke Application phase. The default value for this property must be false.

Specified by:
   isImmediate in interface ActionSource

public void setImmediate(boolean immediate)

setImmediate

public void setImmediate(boolean immediate)

Description copied from interface: ActionSource

Set the "immediate execution" flag for this UIComponent.

Specified by:
   setImmediate in interface ActionSource

Parameters:
   immediate - The new immediate execution flag

public Object getValue()

UICommand   value

getValue
public Object getValue()

    Returns the value property of the UICommand. This is most often rendered as a label.

    public void setValue(Object value)

        UICommand value

            value

    setValue

    public void setValue(Object value)

        Sets the value property of the UICommand. This is most often rendered as a label.

        Parameters:
            value - the new value

    public MethodExpression getActionExpression()

    getActionExpression

    public MethodExpression getActionExpression()

        Description copied from interface: ActionSource2

        Return the MethodExpression pointing at the application action to be invoked, if this UIComponent is activated by the user, during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending on the value of the immediate property.
Note that it's possible that the returned MethodExpression is just a wrapper around a MethodBinding instance which was set by a call to ActionSource.setAction(javax.faces.el.MethodBinding). This makes it possible for the default ActionListener to continue to work properly with older components.

Specified by:
getActionExpression in interface ActionSource2

public void setActionExpression(MethodExpression actionExpression)

setActionExpression

public void setActionExpression(MethodExpression actionExpression)

Description copied from interface: ActionSource2

Set the MethodExpression pointing at the application action to be invoked, if this UIComponent is activated by the user, during the Apply Request Values or Invoke Application phase of the request processing lifecycle, depending on the value of the immediate property.

Any method referenced by such an expression must be public, with a return type of String, and accept no parameters.

Specified by:
setActionExpression in interface ActionSource2

Parameters:
actionExpression - The new method expression

public void addActionListener(ActionListener listener)

Throws NullPointerException: NullPointerException

listener null
**addActionListener**

public void addActionListener(ActionListener listener)

**Description copied from interface: ActionSource**

Add a new ActionListener to the set of listeners interested in being notified when ActionEvent s occur.

**Specified by:**

addActionListener in interface ActionSource

**Parameters:**

listener - The ActionListener to be added

**Throws:**

NullPointerException - if listener is null

**public ActionListener[] getActionListeners()**

**getActionListeners**

public ActionListener[] getActionListeners()

**Description copied from interface: ActionSource**

Return the set of registered ActionListeners for this ActionSource instance. If there are no registered listeners, a zero-length array is returned.

**Specified by:**

getActionListeners in interface ActionSource

**public void removeActionListener(ActionListener listener)**

**Throws**

NullPointerException: NullPointerException

**removeActionListener**
public void removeActionListener(ActionListener listener)

Description copied from interface: ActionSource

Remove an existing ActionListener (if any) from the set of listeners interested in being notified when ActionEventS occur.

Specified by:
   removeActionListener in interface ActionSource

Parameters:
   listener - The ActionListener to be removed

Throws:
   NullPointerException - if listener is null

public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via theStateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

Object state = component.saveState(facesContext);
component should be the same as before executing it.

The return from this method must be Serializable

**Specified by:**
- `saveState` in interface `StateHolder`

**Overrides:**
- `saveState` in class `UIComponentBase`

---

```java
public void restoreState(FacesContext context, Object state)
```

**restoreState**

```java
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface:** `StateHolder`

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.

**Specified by:**
- `restoreState` in interface `StateHolder`

**Overrides:**
- `restoreState` in class `UIComponentBase`

---

```java
public void broadcast(FacesEvent event) throws AbortProcessingException
```
**broadcast**

```java
public void broadcast(FacesEvent event)
throws AbortProcessingException
```

In addition to the default `UIComponent.broadcast(javax.faces.event.FacesEvent)` processing, pass the `ActionEvent` being broadcast to the method referenced by `actionListener` (if any), and to the default `ActionListener` registered on the `Application`.

**Overrides:**
- `broadcast` in class `UIComponentBase`

**Parameters:**
- `event` - `FacesEvent` to be broadcast

**Throws:**
- `AbortProcessingException` - Signal the JavaServer Faces implementation that no further processing on the current event should be performed
- `IllegalArgumentException` - if the implementation class of this `FacesEvent` is not supported by this component
- `NullPointerException` - if `event` is `null`

---

**queueEvent**

```java
public void queueEvent(FacesEvent e)
```

- `ActionEvent queueEvent immediate true phaseId
  PhaseId.APPLY_REQUEST_VALUES PhaseId.INVOKE_APPLICATION`
queueEvent

public void queueEvent(FacesEvent e)

    Intercept queueEvent and, for ActionEvents, mark the phaseId for the event to be PhaseId.APPLY_REQUEST_VALUES if the immediate flag is true, PhaseId.INVOKE_APPLICATION otherwise.

Overrides:
    queueEvent in class UIComponentBase

Parameters:
    e - FacesEvent to be queued
UIComponent is the base class for all user interface components in JavaServer Faces. The set of UIComponent instances associated with a particular request and response are organized into a component tree under a UIViewRoot that represents the entire content of the request or response.

For the convenience of component developers, UICOMPONENTBase provides the default behavior that is specified for a UIComponent, and is the base class for all of the concrete UIComponent "base" implementations. Component writers are encouraged to subclass UICOMPONENTBase, instead
of directly implementing this abstract class, to reduce the impact of any future changes to the method signatures.

</tbody>
</table>
abstract void encodeEnd(FacesContext context)

If our rendered property is true, render the end of this UIComponent.

abstract UIComponent findComponent(String expr)

Search for and return the UIComponent with an specified search expression (if any), according to the below.

abstract Map<String, Object> getAttributes()

Return a mutable Map representing the attribute below) associated with this UIComponent, keyed by attribute a String).

abstract int getChildCount()

Return the number of child UIComponent s that a UIComponent.

abstract List<UIComponent> getChildren()

Return a mutable List representing the child UIComponent with this component.

abstract String getClientId(FacesContext context)

Return a client-side identifier for this component, generating necessary.

abstract String getContainerClientId(FacesContext context)

Allow components that implement NamingConta disable prepending their clientId to their descendent's the prepending logic into a separately callable method.

protected abstract FacesContext getFacesContext()

Convenience method to return the current request.

protected abstract FacesListener[] getFacesListeners(Class clazz)

Return an array of registered FacesListener s that specified class.

abstract UIComponent getFacet(String name)

Convenience method to return the named face otherwise.

abstract int getFacetCount()

Return the number of facet UIComponent s that a UIComponent.
abstract Map<String, UIComponent> getFacets()  
Return a mutable Map representing the facet UIComponent with this UIComponent, keyed by facet name (which must be a String).

abstract Iterator<UIComponent> getFacetsAndChildren()  
Return an Iterator over the facet followed by children this UIComponent.

abstract String getFamily()  
Return the identifier of the component family to which this belongs.

abstract String getId()  
Return the component identifier of this UIComponent.

abstract UIComponent getParent()  
Return the parent UIComponent of this UIComponent.

protected abstract Renderer getRenderer(FacesContext context)  
Convenience method to return the Renderer instance this component, if any; otherwise, return null.

abstract String getRendererType()  
Return the Renderer type for this UIComponent (if any).

abstract boolean getRendersChildren()  
Return a flag indicating whether this component is responsible for rendering its child components.

abstract ValueBinding getValueBinding(String name)  
Deprecated. This has been replaced by
getValueExpression(java.lang.String).

abstract ValueExpression getValueExpression(String name)  
Return the ValueExpression used to calculate the specified attribute or property name, if any.

boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback)  
Starting at this component in the View hierarchy, search for a component with a clientId equal to the argument clientId, then call the
ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) method on the
passing the current FacesContext and the found component.

boolean isRendered()
abstract boolean processDecodes(FacesContext context)
Return true if this component (and its children) should be "decoded" during the Render Response phase of the request processing lifecycle.

abstract void processDecodes(FacesContext context)
Perform the component tree processing required by the Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

abstract void processRestoreState(FacesContext context, Object state)
Perform the component tree processing required by the state portion of the Render Response phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

abstract Object processSaveState(FacesContext context)
Perform the component tree processing required by the Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

abstract void processUpdates(FacesContext context)
Perform the component tree processing required by the Validations phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

abstract void processValidators(FacesContext context)
Perform the component tree processing required by the Validations phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

abstract void queueEvent(FacesEvent event)
Queue an event for broadcast at the end of the request processing lifecycle phase.

protected abstract void removeFacesListener(FacesListener listener)
Remove the specified FacesListener from the set of listeners registered to receive event notifications from this UIComponent.

abstract void setId(String id)
Set the component identifier of this UIComponent.

abstract void setParent(UIComponent parent)
Set the parent UIComponent of this UIComponent.
abstract void setRendered(boolean rendered)
    Set the rendered property of this UIComponent.

abstract void setRendererType(String rendererType)
    Set the Renderer type for this UIComponent, or null to
    render themselves.

abstract void setValueBinding(String name, ValueBinding binding)
    Deprecated. This has been replaced by
    setValueExpression(java.lang.String, javax.el.ValueExpression)

void setValueExpression(String name, ValueExpression binding)
    Set the ValueExpression used to calculate the value
    attribute or property name, if any.

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll,
toString, wait, wait, wait

Methods inherited from interface javax.faces.component.StateHolder

Field Detail

bindings

protected Map<String, ValueExpression> bindings

Constructor Detail

public UIComponent()
public UIComponent()

Method Detail

abstract public java.util.Map<K, V> getAttributes()

UIComponent Map String Map

- Map java.io.Serializable
- null NullPointerException
- String ClassCastException
- UIComponent
  - containsKey - false
  - get() - IllegalArgumentException
  - put() - null
    IllegalArgumentException
  - remove - IllegalArgumentException

getAttributes

public abstract Map<String, Object> getAttributes()

Return a mutable Map representing the attributes (and properties, see below) associated with this UIComponent, keyed by attribute name (which must be a String). The returned implementation must support all of the standard and optional Map methods, plus support the following additional requirements:

- The Map implementation must implement the java.io.Serializable interface.
- Any attempt to add a null key or value must throw a NullPointerException.
- Any attempt to add a key that is not a String must throw a
ClassCastException.

- If the attribute name specified as a key matches a property of this UIClassComponent's implementation class, the following methods will have special behavior:
  - containsKey - Return false.
  - get() - If the property is readable, call the getter method and return the returned value (wrapping primitive values in their corresponding wrapper classes); otherwise throw IllegalArgumentException.
  - put() - If the property is writeable, call the setter method to set the corresponding value (unwrapping primitive values in their corresponding wrapper classes). If the property is not writeable, or an attempt is made to set a property of primitive type to null, throw IllegalArgumentException.
  - remove - THROW IllegalArgumentException.

getValueBinding

public abstract ValueBinding getValueBinding(String name)

**Deprecated. This has been replaced by** getValueExpression(java.lang.String).

Call through to getValueExpression(java.lang.String) and examine the result. If the result is an instance of the wrapper class mandated in setValueBinding(java.lang.String).
javax.faces.el.ValueBinding), extract the ValueBinding instance and return it. Otherwise, wrap the result in an implementation of ValueBinding, and return it.

Parameters:
- name - Name of the attribute or property for which to retrieve a ValueBinding

Throws:
- NullPointerException - if name is null

abstract public void setValueBinding(String name, ValueBinding binding)

Parameters:
- name - Name of the attribute or property for which to set a ValueBinding
- binding - The ValueBinding to set, or null to remove any

setValueBinding

public abstract void setValueBinding(String name, ValueBinding binding)

Deprecated. This has been replaced by setValueExpression(java.lang.String, javax.el.ValueExpression).

Wrap the argument binding in an implementation of ValueExpression and call through to setValueExpression(java.lang.String, javax.el.ValueExpression).

Parameters:
- name - Name of the attribute or property for which to set a ValueBinding
- binding - The ValueBinding to set, or null to remove any
currently set `ValueBinding`

**Throws:**
- `IllegalArgumentException` - if name is one of `id` or `parent`
- `NullPointerException` - if name is `null`

---

```java
public ValueExpression getValueExpression(String name)
```

**ValueExpression**

**JSF 1.2**

```java
since 1.2

name ValueExpression

Throws

NullPointerException: name null
```

---

```java
public ValueExpression getValueExpression(String name)
```

**Return the `ValueExpression` used to calculate the value for the specified attribute or property name, if any.**

This method must be overridden and implemented for components that comply with JSF 1.2 and later.

**Parameters:**
- `name` - Name of the attribute or property for which to retrieve a `ValueExpression`

**Throws:**
- `NullPointerException` - if name is `null`

**Since:**
- 1.2

---

```java
public void setValueExpression(String name, ValueExpression binding)
```
Set the `ValueExpression` used to calculate the value for the specified attribute or property name, if any.

The implementation must call `Expression.isLiteralText()` on the argument expression. If `isLiteralText()` returns true, invoke `ValueExpression.getValue(javax.el.ELContext)` on the argument expression and pass the result as the `value` parameter in a call to `this.#getAttributes().put(name, value)` where `name` is the argument name. If an exception is thrown as a result of calling `ValueExpression.getValue(javax.el.ELContext)`, wrap it in a `FacesException` and re-throw it. If `isLiteralText()` returns false, simply store the un-evaluated expression argument in the collection of `ValueExpression`s under the key given by the argument name.
This method must be overridden and implemented for components that comply with JSF 1.2 and later.

Parameters:
- name - Name of the attribute or property for which to set a ValueExpression
- binding - The ValueExpression to set, or null to remove any currently set ValueExpression

Throws:
- IllegalArgumentException - if name is one of id or parent
- NullPointerException - if name is null

Since: 1.2

```
abstract public String getClientId(FacesContext context)

Renderer clientId

id NamingContainer ID UIData
clientId

NamingContainer getContainerClientId() parentId
#if getID myId myId null
context.getViewRoot().createUniqueId() myId parentId
null myId parentId + NamingContainer.SEPARATOR_CHAR +
myId Renderer#convertClientId myId

context FacesContext
Throws
NullPointerExcep

getClientId

public abstract String getClientId(FacesContext context)

return a client-side identifier for this component, generating one if
necessary. The associated Renderer, if any, will be asked to convert the clientId to a form suitable for transmission to the client.

The return from this method must be the same value throughout the lifetime of the instance, unless the id property of the component is changed, or the component is placed in a NamingContainer whose client ID changes (for example, UIData). However, even in these cases, consecutive calls to this method must always return the same value. The implementation must follow these steps in determining the clientId:

Find the closest ancestor to this component in the view hierarchy that implements NamingContainer. Call getContainerClientId() on it and save the result as the parentId local variable. Call getId() on this component and save the result as the myId local variable. If myId is null, call context.getViewRoot().createUniqueId() and assign the result to myId. If parentId is non-null, let myId equal parentId + NamingContainer.SEPARATOR_CHAR + myId. Call Renderer.convertClientId(javax.faces.context.FacesContext, java.lang.String), passing myId, and return the result.

Parameters:
context - The FacesContext for the current request

Throws:
NullPointerException - if context is null

public String getContainerClientId(FacesContext context)

NamingContainer clientId clientId

#getClientId

since 1.2

Throws _NullPointerException: context null
**getContainerClientId**

```java
public String getContainerClientId(FacesContext context)
```

Allow components that implement `NamingContainer` to selectively disable prepending their clientId to their descendent's clientIds by breaking the prepending logic into a separately callable method. See `getClientId(javax.faces.context.FacesContext)` for usage.

By default, this method will call through to `getClientId(javax.faces.context.FacesContext)` and return the result.

**Throws:**
- `NullPointerException` - if context is null

**Since:**
1.2

---

**abstract public String getFamily()**

```java
rendererType Renderer
```

**getFamily**

```java
public abstract String getFamily()
```

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the `rendererType` property, may be used to select the appropriate `Renderer` for this component instance.

---

**abstract public String getId()**

```java
UIComponent
```
**getID**

```java
gpublic abstract String getId()
```

Return the component identifier of this UIComponent.

**abstract public void setId(String id)**

**UIComponent**

- 0 String
- ('_')
- ('_') ('-')

```java
setId()
```

- **facet** NamingContainer UIComponent

```java
NamingContainer
```

**Throws** IllegalArgumentException: id

**setID**

```java
public abstract void setId(String id)
```

Set the component identifier of this UIComponent (if any). Component identifiers must obey the following syntax restrictions:

- Must not be a zero-length String.
- First character must be a letter or an underscore ('_').
- Subsequent characters must be a letter, a digit, an underscore
Component identifiers must also obey the following semantic restrictions (note that this restriction is **NOT** enforced by the `setId()` implementation):

- The specified identifier must be unique among all the components (including facets) that are descendents of the nearest ancestor `UIComponent` that is a `NamingContainer`, or within the scope of the entire component tree if there is no such ancestor that is a `NamingContainer`.

**Parameters:**

- `id` - The new component identifier, or `null` to indicate that this `UIComponent` does not have a component identifier

**Throws:**

- `IllegalArgumentException` - if `id` is not syntactically valid

---

**abstract public** `UIComponent` `getParent()`

```java
UIComponent getParent()
```

null

**getParent**

**public abstract** `UIComponent` `getParent()`

Return the parent `UIComponent` of this `UIComponent`, if any. A component must allow child components to be added to and removed from the list of children of this component, even though the child component returns `null` from `getParent()`.  

---

**abstract public void** `setParent(UIComponent parent)`
UIComponent  UIComponent  List facet  Map

UIComponent

parent  null

setParent

public abstract void setParent(UIComponent parent)

Set the parent UIComponent of this UIComponent. This method must never be called by developers; a UIComponent's internal implementation will call it as components are added to or removed from a parent's child List or facet Map.

Parameters:
  parent - The new parent, or null for the root node of a component tree

-----------------------------------------------

abstract public boolean isRendered()

true

-----------------------------------------------

isRendered

public abstract boolean isRendered()

Return true if this component (and its children) should be rendered during the Render Response phase of the request processing lifecycle.

-----------------------------------------------

abstract public void setRendered(boolean rendered)

UIComponent  rendered
setRendered

public abstract void setRendered(boolean rendered)

Set the rendered property of this UIComponent.

Parameters:
rendered - If true render this component; otherwise, do not render this component

abstract public String getRendererType()

UIComponent      Renderer

getRendererType

public abstract String getRendererType()

Return the Renderer type for this UIComponent (if any).

abstract public void setRendererType(String rendererType)

UIComponent      Renderer      null

rendererType      Renderer      null

setRendererType

public abstract void setRendererType(String rendererType)
Set the Renderer type for this UIComponent, or null for components that render themselves.

Parameters:
 rendererType - Logical identifier of the type of Renderer to use, or null for components that render themselves.

abstract public boolean getRendersChildren()

Return a flag indicating whether this component is responsible for rendering its child components. The default implementation in UIComponentBase.getRendersChildren() tries to find the renderer for this component. If it does, it calls Renderer.getRendersChildren() and returns the result. If it doesn't, it returns false. As of version 1.2 of the JavaServer Faces Specification, component authors are encouraged to return true from this method and rely on UIComponentBase.encodeChildren(javax.faces.context.FacesContext).

abstract public java.util.List<E> getChildren()
getChildren

public abstract List<UIComponent> getChildren()

Return a mutable List representing the child UIComponents associated with this component. The returned implementation must support all of the standard and optional List methods, plus support the following additional requirements:

- The List implementation must implement the java.io.Serializable interface.
- Any attempt to add a null must throw a NullPointerException.
- Any attempt to add an object that does not implement UIComponent must throw a ClassCastException.
- Whenever a new child component is added, the parent property of the child must be set to this component instance. If the parent property of the child was already non-null, the child must first be removed from its previous parent (where it may have been either a child or a facet).
- Whenever an existing child component is removed, the parent property of the child must be set to null.

abstract public int getChildCount()

UIComponent UIComponent 0

getchildCount

public abstract int getChildCount()
Return the number of child UIComponents that are associated with this UIComponent. If there are no children, this method must return 0. The method must not cause the creation of a child component list.

abstract public UIComponent findComponent(String expr)

id   UIComponent

clientId   #invokeOnComponent

NamingContainer   NamingContainer
NamingContainer   NamingContainer

UIComponent   id
NamingContainer#SEPARATOR_CHAR

- UIComponent
  - ""   UIComponent"
  - UIComponent   NamingContainer
  - NamingContainer
  - NamingContainer   UIComponent

- ""
  - id   UIComponent   facet
  - NamingContainer   facet
  - NamingContainer   NamingContainer

findComponent()

expr   UIComponent
return   UIComponent   null

Throws IllegalArgumentException: NamingContainer
Throws NullPointerException: expr   null

findComponent
public abstract void findComponent(String expr)

    Search for and return the UIComponent with an id that matches the specified search expression (if any), according to the algorithm described below.

    For a method to find a component given a simple clientId, see invokeOnComponent(javax.faces.context.FacesContext, java.lang.String, javax.faces.component.ContextCallback).

    Component identifiers are required to be unique within the scope of the closest ancestor NamingContainer that encloses this component (which might be this component itself). If there are no NamingContainer components in the ancestry of this component, the root component in the tree is treated as if it were a NamingContainer, whether or not its class actually implements the NamingContainer interface.

    A search expression consists of either an identifier (which is matched exactly against the id property of a UIComponent, or a series of such identifiers linked by the NamingContainer.SEPARATOR_CHAR character value. The search algorithm should operate as follows, though alternate algorithms may be used as long as the end result is the same:

    - Identify the UIComponent that will be the base for searching, by stopping as soon as one of the following conditions is met:
      - If the search expression begins with the the separator character (called an "absolute" search expression), the base will be the root UIComponent of the component tree. The leading separator character will be stripped off, and the remainder of the search expression will be treated as a "relative" search expression as described below.
      - Otherwise, if this UIComponent is a NamingContainer it will serve as the basis.
      - Otherwise, search up the parents of this component. If a NamingContainer is encountered, it will be the base.
      - Otherwise (if no NamingContainer is encountered) the root UIComponent will be the base.
    - The search expression (possibly modified in the previous step)
is now a "relative" search expression that will be used to locate the component (if any) that has an id that matches, within the scope of the base component. The match is performed as follows:

- If the search expression is a simple identifier, this value is compared to the id property, and then recursively through the facets and children of the base UIComponent (except that if a descendant NamingContainer is found, its own facets and children are not searched).
- If the search expression includes more than one identifier separated by the separator character, the first identifier is used to locate a NamingContainer by the rules in the previous bullet point. Then, the findComponent() method of this NamingContainer will be called, passing the remainder of the search expression.

Parameters:
expr - Search expression identifying the UIComponent to be returned

Returns:
the found UIComponent, or null if the component was not found.

Throws:
IllegalArgumentException - if an intermediate identifier in a search expression identifies a UIComponent that is not a NamingContainer
NullPointerException - if expr is null

public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback) throws FacesException

clientId clientId callback
ContextCallback#invokeContextCallback FacesContext
#findComponent NamingContainer#SEPARATOR_CHAR

this.getClientId() clientId callback
private void doFind(FacesContext context, String clientId) {
    context.getViewRoot().invokeOnComponent(context, clientId,
        new ContextCallback() {
            public void invokeOnComponent(FacesContext context,
                UIComponent component)
            {
                found = component;
            }
        });
}
**invokeOnComponent**

public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback) throws FacesException

Starting at this component in the View hierarchy, search for a component with a clientId equal to the argument clientId and, if found, call the ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) method on the argument callback, passing the current FacesContext and the found component as arguments. This method is similar to findComponent(java.lang.String) but it does not support the leading NamingContainer.SEPARATOR_CHAR syntax for searching from the root of the View.

The default implementation will first check if this.getClientId() is equal to the argument clientId. If so, call the ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) method on the argument callback, passing through the FacesContext argument and passing this as the component argument. If an Exception is thrown by the callback, wrap it in a FacesException and re-throw it. Otherwise, return true.

Otherwise, for each component returned by getFacetsAndChildren(), call invokeOnComponent() passing the arguments to this method, in order. The first time invokeOnComponent() returns true, abort traversing the rest of the Iterator and return true.

When calling ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) the implementation of this method must guarantee that the state of the component passed to the callback correctly reflects the component's position in the View hierarchy with respect to any state found in the argument clientId. For example, an iterating component such as UIData will need to set its row index to correctly reflect the argument clientId before finding the appropriate child component backed by the correct row. When
the callback returns, either normally or by throwing an Exception the implementation of this method must restore the state of the view to the way it was before invoking the callback.

If none of the elements from `getFacetsAndChildren()` returned `true` from `invokeOnComponent()`, return `false`.

Simple usage example to find a component by `clientId`.

```java
private UIComponent found = null;

private void doFind(FacesContext context, String clientId) {
    context.getViewRoot().invokeOnComponent(context, clientId,
        new ContextCallback() {
            public void invokeOnComponent(FacesContext context,
                UIComponent component) {
                found = component;
            }
        });
}
```

**Parameters:**
- `context` - the `FacesContext` for the current request
- `clientId` - the client identifier of the component to be passed to the argument callback.
- `callback` - an implementation of the Callback interface.

**Returns:**
- `true` if the a component with the given `clientId` is found, the callback method was successfully invoked passing that component as an argument, and no Exception was thrown.
- `false` if no component with the given `clientId` is found.

**Throws:**
- `NullPointerException` - if any of the arguments are null
- `FacesException` - if the argument Callback throws an Exception, it is wrapped in a `FacesException` and re-thrown.

**Since:**
- 1.2

```java
abstract public java.util.Map<K, V> getFacets()
```
### getFacets

```java
public abstract Map<String, UIComponent> getFacets()
```

Return a mutable `Map` representing the `UIComponent` facets associated with this `UIComponent`, keyed by facet name (which must be a `String`). The returned implementation must support all of the standard and optional `Map` methods, plus support the following additional requirements:

- The `Map` implementation must implement the `java.io.Serializable` interface.
- Any attempt to add a `null` key or value must throw a `NullPointerException`.
- Any attempt to add a key that is not a `String` must throw a `ClassCastException`.
- Any attempt to add a value that is not a `UIComponent` must throw a `ClassCastException`.
- Whenever a new facet `UIComponent` is added:
  - The `parent` property of the component must be set to this component instance.
  - If the `parent` property of the component was already non-
null, the component must first be removed from its previous parent (where it may have been either a child or a facet).

- Whenever an existing facet `UIComponent` is removed:
  - The `parent` property of the facet must be set to `null`.

```java
public int getFacetCount()

UIComponent facet UIComponent facet 0
facet

UIComponent #getFacets Map size()
UIComponentBase#getFacetCount
since 1.2
```

**getFacetCount**

```java
public int getFacetCount()

Return the number of facet `UIComponent`s that are associated with this `UIComponent`. If there are no facets, this method must return 0. The method must not cause the creation of a facet component map.

For backwards compatibility with classes that extend `UIComponent` directly, a default implementation is provided that simply calls `getFacets()` and then calls the `size()` method on the returned `Map`. A more optimized version of this method is provided in `UIComponentBase.getFacetCount()`.

Since:
1.2
```

```java
abstract public UIComponent getFacet(String name)

facet facet null facet facet Map
```
getFacet

```java
public abstract UIComponent getFacet(String name)
```

Convenience method to return the named facet, if it exists, or null otherwise. If the requested facet does not exist, the facets Map must not be created.

**Parameters:**

- `name` - Name of the desired facet

---

abstract public java.util.Iterator<E> getFacetsAndChildren()

```java
facet   Iterator facet   UIComponent   UIComponent
facet   facet   facet

Iterator   remove()
```

---

getFacetsAndChildren

```java
public abstract Iterator<UIComponent> getFacetsAndChildren()
```

Return an `Iterator` over the facet followed by child `UIComponent`s of this `UIComponent`. Facets are returned in an undefined order, followed by all the children in the order they are stored in the child list. If this component has no facets or children, an empty `Iterator` is returned.

The returned `Iterator` must not support the `remove()` operation.

---

abstract public void broadcast(FacesEvent event) throws
AbortProcessingException

FacesEvent

event

Throws AbortProcessingException: JavaServer Face

Throws IllegalArgument Exception: FacesEvent

Throws NullPointerException: event null

broadcast

public abstract void broadcast(FacesEvent event)

throws AbortProcessingException

Broadcast the specified FacesEvent to all registered event listeners who have expressed an interest in events of this type. Listeners are called in the order in which they were added.

Parameters:

   event - The FacesEvent to be broadcast

Throws:

AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed

IllegalArgumentException - if the implementation class of this FacesEvent is not supported by this component

NullPointerException - if event is null

abstract public void decode(FacesContext context)

FacesContext  UIComponent

queueEvent()

context

Throws

NullPointerException: context null
**decode**

```java
public abstract void decode(FacesContext context)
```

Decode any new state of this `UIComponent` from the request contained in the specified `FacesContext`, and store this state as needed.

During decoding, events may be enqueued for later processing (by event listeners who have registered an interest), by calling `queueEvent()`.

**Parameters:**
- `context` - `FacesContext` for the request we are processing

**Throws:**
- `NullPointerException` - if `context` is null

---

**abstract public void encodeBegin(FacesContext context) throws java.io.IOException**

```java
rendered true UIComponent FacesContext
```

`Renderer UIComponent encodeBegin(FacesContext, UIComponent)`

- `context` - `FacesContext`
- `Throws` - `java.io.IOException: /`
- `Throws` - `NullPointerException: context null`

---

**encodeBegin**

```java
public abstract void encodeBegin(FacesContext context) throws IOException
```
If our rendered property is true, render the beginning of the current state of this UIComponent to the response contained in the specified FacesContext.

If a Renderer is associated with this UIComponent, the actual encoding will be delegated to Renderer.encodeBegin(FacesContext, UIComponent).

Parameters:
- context - FacesContext for the response we are creating

Throws:
- IOException - if an input/output error occurs while rendering
- NullPointerException - if context is null

abstract public void encodeChildren(FacesContext context) throws java.io.IOException

rendered true UIComponent UIComponent
rendersChildren true

Renderer UIComponent
encodeChildren(FacesContext, UIComponent)

context FacesContext
Throws java.io.IOException: /
Throws NullPointerException: context null

encodeChildren

public abstract void encodeChildren(FacesContext context) throws IOException

If our rendered property is true, render the child UIComponents of this UIComponent. This method will only be called if the rendersChildren property is true.
If a `Renderer` is associated with this `UIComponent`, the actual encoding will be delegated to `Renderer.encodeChildren(FacesContext, UIComponent)`.

**Parameters:**
- `context` - `FacesContext` for the response we are creating

**Throws:**
- `IOException` - if an input/output error occurs while rendering
- `NullPointerException` - if `context` is null

```java
abstract public void encodeEnd(FacesContext context)
throws java.io.IOException
```

rendered true `UIComponent`

```java
Renderer UIComponent encodeEnd(FacesContext, UIComponent)
```

**context** `FacesContext`

**Throws**
- `java.io.IOException`: /
- `NullPointerException`: `context` null

**encodeEnd**

```java
public abstract void encodeEnd(FacesContext context)
throws IOException
```

If our `rendered` property is true, render the ending of the current state of this `UIComponent`.

If a `Renderer` is associated with this `UIComponent`, the actual encoding will be delegated to `Renderer.encodeEnd(FacesContext, UIComponent)`.

**Parameters:**
- `context` - `FacesContext` for the response we are creating
public void encodeAll(FacesContext context) throws IOException

#isRendered true isRendered() true
#getRendersChildren

since 1.2
Throws java.io.IOException: /
Throws NullPointerException: context null

encodeAll

public void encodeAll(FacesContext context) throws IOException

If this component returns true from isRendered(), render this component and all its children that return true from isRendered(), regardless of the value of the getRendersChildren() flag.

Throws:

IOException - if an input/output error occurs while rendering
NullPointerException - if context is null

Since:
1.2

abstract protected void addFacesListener(FacesListener listener)

FacesListener UICOMPONENT UICOMPONENT API
public class FooEvent extends FacesEvent {
    ...
}

public interface FooListener extends FacesListener {
    public void processFoo(FooEvent event);
}

public class FooComponent extends UIComponentBase {
    ...
    public void addFooListener(FooListener listener) {
        addFacesListener(listener);
    }
    public void removeFooListener(FooListener listener) {
        removeFacesListener(listener);
    }
    ...
}

**addFacesListener**

protected abstract void addFacesListener(FacesListener listener)

Add the specified FacesListener to the set of listeners registered to receive event notifications from this UIComponent. It is expected that UIComponent classes acting as event sources will have corresponding typesafe APIs for registering listeners of the required type, and the implementation of those registration methods will delegate to this method. For example:

```
public class FooEvent extends FacesEvent {
    ...
}

public interface FooListener extends FacesListener {
    public void processFoo(FooEvent event);
}

public class FooComponent extends UIComponentBase {
    ...
    public void addFooListener(FooListener listener) {
```
addFacesListener(listener);
}
public void removeFooListener(FooListener listener) {
    removeFacesListener(listener);
}
...

Parameters:
   listener - The FacesListener to be registered

Throws:
   NullPointerException - if listener is null

abstract protected FacesListener[] getFacesListeners(Class<T> clazz)

   FacesListener 0                     clazz
   clazz          FacesListener

   Throws IllegalArgumentException: clazz FacesListener
   Throws NullPointerException: clazz null

getFacesListeners

protected abstract FacesListener[] getFacesListeners(Class clazz)

Return an array of registered FacesListeners that are instances of the specified class. If there are no such registered listeners, a zero-length array is returned. The returned array can be safely be cast to an array strongly typed to an element type of clazz.

Parameters:
   clazz - Class that must be implemented by a FacesListener for it to be returned

Throws:
   IllegalArgumentException - if class is not, and does not
abstract protected void removeFacesListener(FacesListener listener)

Remove the specified FacesListener from the set of listeners registered to receive event notifications from this UIComponent.

Parameters:
listener - The FacesListener to be deregistered

Throws:
NullPointerException - if listener is null

abstract public void queueEvent(FacesEvent event)

IllegalStateException: UIViewRoot

Throws
NullPointerException: event null

queueEvent
public abstract void queueEvent(FacesEvent event)

Queue an event for broadcast at the end of the current request processing lifecycle phase. The default implementation in UIComponentBase must delegate this call to the queueEvent() method of the parent UIComponent.

Parameters:
   event - FacesEvent to be queued

Throws:
   IllegalStateException - if this component is not a descendant of a UIViewRoot
   NullPointerException - if event is null

abstract public void processRestoreState(FacesContext context, Object state)

facet

- getFacetsAndChildren()  
  UIComponent facet
- processRestoreState()
- restoreState()

Throws

context FacesContext

Throws

NullPointerException: context null

processRestoreState

public abstract void processRestoreState(FacesContext context, Object state)

Perform the component tree processing required by the Restore View phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself,
as follows.

- Call the `processRestoreState()` method of all facets and children of this `UIComponent` in the order determined by a call to `getFacetsAndChildren()`.
- Call the `restoreState()` method of this component.

This method may not be called if the state saving method is set to server.

**Parameters:**
- `context` - `FacesContext` for the request we are processing

**Throws:**
- `NullPointerException` - if `context` is null

---

```java
abstract public void processDecodes(FacesContext context)
```

**facet**

- `UIComponent` rendered `false`
- `getFacetsAndChildren()` `UIComponent` facet
- `processDecodes()`
- `decode()`
- `RuntimeException` `FacesContext#renderResponse`

```java
context FacesContext
Throws NullPointerException: context null
```

**processDecodes**

```java
public abstract void processDecodes(FacesContext context)
```

Perform the component tree processing required by the *Apply Request Values* phase of the request processing lifecycle for all
facets of this component, all children of this component, and this component itself, as follows.

- If the rendered property of this UIComponent is false, skip further processing.
- Call the processDecodes() method of all facets and children of this UIComponent, in the order determined by a call to getFacetsAndChildren().
- Call the decode() method of this component.
- If a RuntimeException is thrown during decode processing, call FacesContext.renderResponse() and re-throw the exception.

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null

abstract public void processValidators(FacesContext context)

facet

- UIComponent rendered false
- getFacetsAndChildren() UIComponent facet
- processValidators()

context FacesContext

Throws

NullPointerException: context null

processValidators

public abstract void processValidators(FacesContext context)

Perform the component tree processing required by the Process Validations phase of the request processing lifecycle for all facets of this component, all children of this component, and this component
abstract public void processUpdates(FacesContext context)

Perform the component tree processing required by the Update Model Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- If the rendered property of this UIComponent is false, skip further processing.

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null
Call the `processUpdates()` method of all facets and children of this `UIComponent`, in the order determined by a call to `getFacetsAndChildren()`.

**Parameters:**
- `context` - `FacesContext` for the request we are processing

**Throws:**
- `NullPointerException` - if `context` is null

### `abstract public Object processSaveState(FacesContext context)`

#### facet

- `transient true` null
- `getFacetsAndChildren()` `UIComponent` facet
- `processSaveState()` `facet`
- `saveState()`
- `Serializable` `Object`

**context** `FacesContext`

**Throws** `NullPointerException`: `context` null

### `processSaveState`

`public abstract Object processSaveState(FacesContext context)`

Perform the component tree processing required by the state saving portion of the `Render Response` phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- consult the `transient` property of this component. If true, just
return null.

- Call the `processSaveState()` method of all facets and children of this `UIComponent` in the order determined by a call to `getFacetsAndChildren()`, skipping children and facets that are transient.
- Call the `saveState()` method of this component.
- Encapsulate the child state and your state into a Serializable Object and return it.

This method may not be called if the state saving method is set to server.

**Parameters:**
- `context` - `FacesContext` for the request we are processing

**Throws:**
- `NullPointerException` - if `context` is `null`

---

**abstract protected `FacesContext` getFacesContext()**

`FacesContext`

**getFacesContext**

**protected abstract `FacesContext` getFacesContext()**

Convenience method to return the `FacesContext` instance for the current request.

---

**abstract protected `Renderer` getRenderer(`FacesContext` context)**

`Renderer`  
`null`  

`context`  
`FacesContext`
getRenderer

protected abstract Renderer getRenderer(FacesContext context)

Convenience method to return the Renderer instance associated with this component, if any; otherwise, return null.

Parameters:
context - FacesContext for the current request

PS:
javax.faces.component  **Class UIComponentBase**

java.lang.Object
   ├ javax.faces.component.UIComponent
   │   └ javax.faces.component.UIComponentBase

All Implemented Interfaces:
   StateHolder

Direct Known Subclasses:
   UIColumn, UICommand, UIData, UIForm, UIGraphic, UIMessage, UIMessages, UINamingContainer, UIOutput, UIPanel, UIParameter, UISelectItem, UISelectItems, UIViewRoot

---

public abstract class **UIComponentBase**

extends **UIComponent**

*Extends:* **UIComponent**

*Extended by:* **UIComponent**, UIColumn, UICommand, UIData, UIForm, UIGraphic, UIMessage, UIMessages, UINamingContainer, UIOutput, UIPanel, UIParameter, UISelectItem, UISelectItems, UIViewRoot

**UIComponentBase** is a convenience base class that implements the default concrete behavior of all methods defined by **UIComponent**.

By default, this class defines `getRendersChildren()` to find the renderer for this component and call its `getRendersChildren()` method. The default implementation on the Renderer returns `false`. As of version 1.2 of the
JavaServer Faces Specification, component authors are encouraged to return `true` from this method and rely on the implementation of `encodeChildren(javax.faces.context.FacesContext)` in this class and in the Renderer
`Renderer.encodeChildren(javax.faces.context.FacesContext, javax.faces.component.UIComponent`). Subclasses that wish to manage the rendering of their children should override this method to return `true` instead.

---

## Field Summary

### Fields inherited from class javax.faces.component.UIComponent

- `bindings`

## Constructor Summary

- `UIComponentBase()`

## Method Summary

- `addFacesListener(FacesListener listener)`

  Add the specified `FacesListener` to the set of listeners that receive event notifications from this `UIComponent`.

- `broadcast(FacesEvent event)`

  Broadcast the specified `FacesEvent` to all registered listeners who have expressed an interest in events of this type.

- `decode(FacesContext context)`

  Decode any new state of this `UIComponent` from the specified `FacesContext`, and store this state as needed.

- `encodeBegin(FacesContext context)`

  If our rendered property is `true`, render the beginning state of this `UIComponent` to the response contained in `FacesContext`.

- `encodeChildren(FacesContext context)`

```java
void performComponentTreeProcessingRequiredByTheValuesPhaseOfTheRequestProcessingLifecycleForAllFacetsOfThisComponent,AllChildrenOfThisComponent,AndThisComponentItselfAsFollows.

void processRestoreState(FacesContext context, Object)
Perform the component tree processing required by the Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself as follows.

Object processSaveState(FacesContext context)
Perform the component tree processing required by the state portion of the Render Response phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

void processUpdates(FacesContext context)
Perform the component tree processing required by the Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

void processValidators(FacesContext context)
Perform the component tree processing required by the Validations phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

void queueEvent(FacesEvent event)
Queue an event for broadcast at the end of the request processing lifecycle phase.

protected void removeFacesListener(FacesListener listener)
Remove the specified FacesListener from the set of listeners registered to receive event notifications from this UIComponent.

static Object restoreAttachedState(FacesContext context, Object)
This method is called by UIComponent subclasses to restore the objects they saved using saveAttachedState(javax.faces.context.FacesContext, java.lang.Object).

void restoreState(FacesContext context, Object state)
Perform any processing required to restore the state in the state Object.
```
static Object saveAttachedState(FacesContext context, Object attachedObject)

This method is called by UIComponent subclasses for more attached objects.

Object saveState(FacesContext context)

Gets the state of the instance as a Serializable.

void setId(String id)

Set the component identifier of this UIComponent.

void setParent(UIComponent parent)

Set the parent UIComponent of this UIComponent.

void setRendered(boolean rendered)

Set the rendered property of this UIComponent.

void setRendererType(String rendererType)

Set the Renderer type for this UIComponent, or null to render themselves.

void setTransient(boolean transientFlag)

Denotes whether or not the Object implementing this interface must not participate in state saving or restoring.

void setValueBinding(String name, ValueBinding binding)

Deprecated. This has been replaced by UIComponent.setValueExpression(java.lang.String, javax.el.ValueExpression).

Constructor Detail

public UIComponentBase()
UIComponentBase

public UIComponentBase()

Method Detail

public java.util.Map<K, V> getAttributes()

getAttributes

public Map<String, Object> getAttributes()

Description copied from class: UIComponent

Return a mutable Map representing the attributes (and properties, see below) associated with this UIComponent, keyed by attribute name (which must be a String). The returned implementation must support all of the standard and optional Map methods, plus support the following additional requirements:

- The Map implementation must implement the java.io.Serializable interface.
- Any attempt to add a null key or value must throw a NullPointerException.
- Any attempt to add a key that is not a String must throw a ClassCastException.
- If the attribute name specified as a key matches a property of this UIComponent's implementation class, the following methods will have special behavior:
  - containsKey - Return false.
  - get() - If the property is readable, call the getter method and return the returned value (wrapping primitive values in their corresponding wrapper classes); otherwise throw IllegalArgumentException.
  - put() - If the property is writeable, call the setter method to set the corresponding value (unwrapping primitive values in their corresponding wrapper classes). If the property is not
writeable, or an attempt is made to set a property of primitive type to null, throw IllegalArgumentException.

- remove - Throw IllegalArgumentException.

Specified by:
getAttributes in class UICOMPONENT

```java
public ValueBinding getValueBinding(String name)
```

**NullPointerException**

Throws: NullPointeException: NullPointerException

```
#getValueExpression
```

**getvalueExpression**

**getvalueExpression**

```
public ValueBinding getValueBinding(String name)
```

**Deprecated. This has been replaced by**
UICOMPONENT.getValueExpression(java.lang.String).

Call through to UICOMPONENT.getValueExpression(java.lang.String) and examine the result. If the result is an instance of the wrapper class mandated in UICOMPONENT.setValueBinding(java.lang.String, javax.faces.el.ValueBinding), extract the ValueBinding instance and return it. Otherwise, wrap the result in an implementation of ValueBinding, and return it.

Specified by:
getValueBinding in class UICOMPONENT

Parameters:
name - Name of the attribute or property for which to retrieve a ValueBinding

Throws:
NullPointerException - if name is null

```
public void setValueBinding(String name, ValueBinding binding)
```

NullPointerException

```
ValueExpression binding #setValueExpression
```

Throws

- IllegalArgumentException: name id parent
- NullPointerException: name null

deprecated

```
setValueBinding
```

```
setValueBinding(String name, ValueBinding binding)
```

**Deprecated. This has been replaced by**

```
UIComponent.setValueExpression(java.lang.String, javax.el.ValueExpression)
```

Wrap the argument binding in an implementation of ValueExpression and call through to

```
UIComponent.setValueExpression(java.lang.String, javax.el.ValueExpression)
```

**Specified by:**

setValueBinding in class UIComponent

**Parameters:**

- name - Name of the attribute or property for which to set a ValueBinding
- binding - The ValueBinding to set, or null to remove any currently set ValueBinding

**Throws:**

- IllegalArgumentException - if name is one of id or parent
- NullPointerException - if name is null
public String getClientId(FacesContext context)

Throws  NullPointerException: NullPointerException

clientId

g getClientId

g getClientId(FacesContext context)

Description copied from class: UIComponent

Return a client-side identifier for this component, generating one if necessary. The associated Renderer, if any, will be asked to convert the clientId to a form suitable for transmission to the client.

The return from this method must be the same value throughout the lifetime of the instance, unless the id property of the component is changed, or the component is placed in a NamingContainer whose client ID changes (for example, UIData). However, even in these cases, consecutive calls to this method must always return the same value. The implementation must follow these steps in determining the clientId:

Find the closest ancestor to this component in the view hierarchy that implements NamingContainer. Call getContainerClientId() on it and save the result as the parentId local variable. Call

UIComponent.getId() on this component and save the result as the

myId local variable. If myId is null, call

context.getViewRoot().createUniqueId() and assign the result to

myId. If parentId is non-null, let myId equal parentId +

NamingContainer.SEPARATOR_CHAR + myId. Call

Renderer.convertClientId(javax.faces.context.FacesContext, java.lang.String), passing myId, and return the result.

Specified by:

g getClientId in class UIComponent

Parameters:

context - The FacesContext for the current request

Throws:
NullPointerException - if context is null

public String getId()

getId

public String getId()

Description copied from class: UICOMPONENT

Return the component identifier of this UICOMPONENT.

Specified by:

getID in class UICOMPONENT

public void setId(String id)

Throws IllegalArgumentException: NullPointerException id

Throws IllegalStateException: NullPointerException

setId

public void setId(String id)

Description copied from class: UICOMPONENT

Set the component identifier of this UICOMPONENT (if any). Component identifiers must obey the following syntax restrictions:

- Must not be a zero-length String.
- First character must be a letter or an underscore ('_').
- Subsequent characters must be a letter, a digit, an underscore ('_'), or a dash ('-').

Component identifiers must also obey the following semantic
restrictions (note that this restriction is **NOT** enforced by the `setId()` implementation):

- The specified identifier must be unique among all the components (including facets) that are descendents of the nearest ancestor `UIComponent` that is a `NamingContainer`, or within the scope of the entire component tree if there is no such ancestor that is a `NamingContainer`.

**Specified by:**
`setId` in class `UIComponent`

**Parameters:**
- `id` - The new component identifier, or `null` to indicate that this `UIComponent` does not have a component identifier

**Throws:**
- `IllegalArgumentException` - if `id` is not syntactically valid
- `IllegalStateException`

---

```java
public UIComponent getParent()
```

**getParent**

```java
public UIComponent getParent()
```

**Description copied from class:** `UIComponent`

Return the parent `UIComponent` of this `UIComponent`, if any. A component must allow child components to be added to and removed from the list of children of this component, even though the child component returns `null` from `getParent()`.

**Specified by:**
`getParent` in class `UIComponent`

---

```java
public void setParent(UIComponent parent)
```
setParent

public void.setParent(UIComponent parent)

Description copied from class: UIComponent

Set the parent UIComponent of this UIComponent. This method must never be called by developers; a UIComponent's internal implementation will call it as components are added to or removed from a parent's child List or facet Map.

Specified by:
  setParent in class UIComponent
Parameters:
  parent - The new parent, or null for the root node of a component tree

public boolean isRendered()
public void setRendered(boolean rendered)

**Description copied from class:** [UIComponent]

Set the rendered property of this [UIComponent].

**Specified by:**

`setRendered` in class [UIComponent]

**Parameters:**

rendered - If true render this component; otherwise, do not render this component

---

public String getRendererType()

**getRendererType**

public String getRendererType()

**Description copied from class:** [UIComponent]

Return the Renderer type for this [UIComponent] (if any).

**Specified by:**

`getRendererType` in class [UIComponent]

---

public void setRendererType(String rendererType)

**setRendererType**

public void setRendererType(String rendererType)

**Description copied from class:** [UIComponent]

Set the Renderer type for this [UIComponent], or null for components that render themselves.
public boolean getRendersChildren()

getRendersChildren

public boolean getRendersChildren()

Description copied from class: UIComponent

Return a flag indicating whether this component is responsible for rendering its child components. The default implementation in getRendersChildren() tries to find the renderer for this component. If it does, it calls Renderer.getRendersChildren() and returns the result. If it doesn't, it returns false. As of version 1.2 of the JavaServer Faces Specification, component authors are encouraged to return true from this method and rely on encodeChildren(javax.faces.context.FacesContext).

Specified by: getRendersChildren in class UIComponent

public java.util.List<E> getChildren()

getChildren

public List<UIComponent> getChildren()

Description copied from class: UIComponent

Return a mutable List representing the child UIComponents
associated with this component. The returned implementation must support all of the standard and optional List methods, plus support the following additional requirements:

- The List implementation must implement the java.io.Serializable interface.
- Any attempt to add a null must throw a NullPointerException
- Any attempt to add an object that does not implement UIComponent must throw a ClassCastException.
- Whenever a new child component is added, the parent property of the child must be set to this component instance. If the parent property of the child was already non-null, the child must first be removed from its previous parent (where it may have been either a child or a facet).
- Whenever an existing child component is removed, the parent property of the child must be set to null.

Specified by:

getChildren in class UICOMPONENT

---

public int getChildCount()

getChildCount

public int getChildCount()

Description copied from class: UICOMPONENT

Return the number of child UICOMPONENTs that are associated with this UICOMPONENT. If there are no children, this method must return 0. The method must not cause the creation of a child component list.

Specified by:

getChildCount in class UICOMPONENT

---

public UICOMPONENT findComponent(String expr)
findComponent

public UIComponent findComponent(String expr)

Description copied from class: UIComponent

Search for and return the UIComponent with an id that matches the specified search expression (if any), according to the algorithm described below.

For a method to find a component given a simple clientId, see UIComponent.invokeOnComponent(javax.faces.context.FacesContext, java.lang.String, javax.faces.component.ContextCallback).

Component identifiers are required to be unique within the scope of the closest ancestor NamingContainer that encloses this component (which might be this component itself). If there are no NamingContainer components in the ancestry of this component, the root component in the tree is treated as if it were a NamingContainer, whether or not its class actually implements the NamingContainer interface.

A search expression consists of either an identifier (which is matched exactly against the id property of a UIComponent, or a series of such identifiers linked by the NamingContainer.SEPARATOR_CHAR character value. The search algorithm should operate as follows, though alternate algorithms may be used as long as the end result is the same:

- Identify the UIComponent that will be the base for searching, by stopping as soon as one of the following conditions is met:
  - If the search expression begins with the separator character (called an "absolute" search expression), the base will be the root UIComponent of the component tree. The leading separator character will be stripped off, and the remainder of the search expression will be treated as a "relative" search expression as described below.
- Otherwise, if this UIComponent is a NamingContainer it will serve as the basis.
- Otherwise, search up the parents of this component. If a NamingContainer is encountered, it will be the base.
- Otherwise (if no NamingContainer is encountered) the root UIComponent will be the base.

- The search expression (possibly modified in the previous step) is now a "relative" search expression that will be used to locate the component (if any) that has an id that matches, within the scope of the base component. The match is performed as follows:
  - If the search expression is a simple identifier, this value is compared to the id property, and then recursively through the facets and children of the base UIComponent (except that if a descendant NamingContainer is found, its own facets and children are not searched).
  - If the search expression includes more than one identifier separated by the separator character, the first identifier is used to locate a NamingContainer by the rules in the previous bullet point. Then, the findComponent() method of this NamingContainer will be called, passing the remainder of the search expression.

Specified by:
findComponent in class UIComponent

Parameters:
expr - Search expression identifying the UIComponent to be returned

Returns:
the found UIComponent, or null if the component was not found.

Throws:
NullPointerException - if expr is null

public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback) throws FacesException
NullPointerException
private UIComponent found = null;

private void doFind(FacesContext context, String clientId) {
    context.getViewRoot().invokeOnComponent(context, clientId,
        new ContextCallback() {
            public void invokeOnComponent(FacesContext context,
                UIComponent component) {
                found = component;
            }
        });
}

since 1.2
Throws NullPointerException: NullPointerException null
Throws FacesException: NullPointerException Callback Exception FacesException
public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback) throws FacesException

Starting at this component in the View hierarchy, search for a component with a clientId equal to the argument clientId and, if found, call the ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) method on the argument callback, passing the current FacesContext and the found component as arguments. This method is similar to UICOMPONENT.findComponent(java.lang.String) but it does not support the leading NamingContainer.SEPARATOR_CHAR syntax for searching from the root of the View.

The default implementation will first check if this.getClientId() is equal to the argument clientId. If so, call the ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) method on the argument callback, passing through the FacesContext argument and passing this as the component argument. If an Exception is thrown by the callback, wrap it in a FacesException argument and re-throw it. Otherwise, return true.

Otherwise, for each component returned by UICOMPONENT.getFacetsAndChildren(), call invokeOnComponent() passing the arguments to this method, in order. The first time invokeOnComponent() returns true, abort traversing the rest of the iterator and return true.

When calling ContextCallback.invokeContextCallback(javax.faces.context.FacesContext, javax.faces.component.UIComponent) the implementation of this method must guarantee that the state of the component passed to the callback correctly reflects the component's position in the View.
hierarchy with respect to any state found in the argument clientId. For example, an iterating component such as UIData will need to set its row index to correctly reflect the argument clientId before finding the appropriate child component backed by the correct row. When the callback returns, either normally or by throwing an Exception the implementation of this method must restore the state of the view to the way it was before invoking the callback.

If none of the elements from UIComponent.getFacetsAndChildren() returned true from invokeOnComponent(), return false.

Simple usage example to find a component by clientId.

```java
private UIComponent found = null;

private void doFind(FacesContext context, String clientId) {
    context.getViewRoot().invokeOnComponent(context, clientId,
        new ContextCallback() {
            public void invokeOnComponent(FacesContext context,
                UIComponent component) {
                found = component;
            }
        });
}
```

Overrides: invokeOnComponent in class UIComponent

Parameters:
context - the FacesContext for the current request
clientId - the client identifier of the component to be passed to the argument callback.
callback - an implementation of the Callback interface.

Returns:
true if the a component with the given clientId is found, the callback method was successfully invoked passing that component as an argument, and no Exception was thrown. Returns false if no component with the given clientId is found.

Throws:
NullPointerException - if any of the arguments are null
FacesException - if the argument Callback throws an Exception,
it is wrapped in a FacesException and re-thrown.

Since:
1.2

public java.util.Map<K, V> getFacets()

getFacets

public Map<String, UIComponent> getFacets()

Description copied from class: UIComponent

Return a mutable Map representing the facet UIComponent s associated with this UIComponent, keyed by facet name (which must be a String). The returned implementation must support all of the standard and optional Map methods, plus support the following additional requirements:

- The Map implementation must implement the java.io.Serializable interface.
- Any attempt to add a null key or value must throw a NullPointerException.
- Any attempt to add a key that is not a String must throw a ClassCastException.
- Any attempt to add a value that is not a UIComponent must throw a ClassCastException.
- Whenever a new facet UIComponent is added:
  - The parent property of the component must be set to this component instance.
  - If the parent property of the component was already non-null, the component must first be removed from its previous parent (where it may have been either a child or a facet).
- Whenever an existing facet UIComponent is removed:
  - The parent property of the facet must be set to null.

Specified by:
getFacets in class UIComponent
public int getFacetCount()

g FACET COUNT

getFacetCount

public int getFacetCount()

Description copied from class: UIC com ponent

Return the number of facet UIC omponents that are associated with this UIC omponent. If there are no facets, this method must return 0. The method must not cause the creation of a facet component map.

For backwards compatibility with classes that extend UIC omponent directly, a default implementation is provided that simply calls UIC omponent.getFacets() and then calls the size() method on the returned Map. A more optimized version of this method is provided in getFacetCount().

Overrides:

g FACET COUNT in class UIC omponent

public UIC omponent getFacet(String name)

g FACET

getFacet

public UIC omponent getFacet(String name)

Description copied from class: UIC omponent

Convenience method to return the named facet, if it exists, or null otherwise. If the requested facet does not exist, the facets Map must not be created.

Specified by:

g FACET in class UIC omponent
Parameters:
   name - Name of the desired facet

public java.util.Iterator<E> getFacetsAndChildren()

getFacetsAndChildren

public Iterator<UIComponent> getFacetsAndChildren()

   Description copied from class: UIComponent

   Return an Iterator over the facet followed by child UIComponents of this UIComponent. Facets are returned in an undefined order, followed by all the children in the order they are stored in the child list. If this component has no facets or children, an empty Iterator is returned.

   The returned Iterator must not support the remove() operation.

   Specified by:
      getFacetsAndChildren in class UIComponent

public void broadcast(FacesEvent event) throws AbortProcessingException

   Throws AbortProcessingException: NullPointerException JavaServer Face
   Throws IllegalStateException: NullPointerException
   Throws NullPointerException: NullPointerException event null

broadcast

public void broadcast(FacesEvent event)
   throws AbortProcessingException

   Description copied from class: UIComponent
Broadcast the specified FacesEvent to all registered event listeners who have expressed an interest in events of this type. Listeners are called in the order in which they were added.

**Specified by:**
*broadcast* in class UIComponent

**Parameters:**
event - The FacesEvent to be broadcast

**Throws:**
AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed
IllegalStateException
NullPointerException - if event is null

---

public void decode(FacesContext context)  
Throws NullPointerException: NullPointerException  
context  
null

decode

public void decode(FacesContext context)

**Description copied from class:** UIComponent

Decode any new state of this UIComponent from the request contained in the specified FacesContext, and store this state as needed.

During decoding, events may be enqueued for later processing (by event listeners who have registered an interest), by calling queueEvent().

**Specified by:**
decode in class UIComponent

**Parameters:**
context - FacesContext for the request we are processing

**Throws:**
public void encodeBegin(FacesContext context) throws IOException

Throws: NullPointerException: NullPointerException context null

Description copied from class: UIComponent

If our rendered property is true, render the beginning of the current state of this UIComponent to the response contained in the specified FacesContext.

If a Renderer is associated with this UIComponent, the actual encoding will be delegated to Renderer.encodeBegin(FacesContext, UIComponent).

Specified by: encodeBegin in class UIComponent

Parameters:
context - FacesContext for the response we are creating

Throws:
NullPointerException - if context is null
IOException - if an input/output error occurs while rendering

public void encodeChildren(FacesContext context) throws IOException

Throws: NullPointerException: NullPointerException context null

encodeChildren
public void encodeChildren(FacesContext context) throws IOException

Description copied from class: UICOMPONENT

If our rendered property is true, render the child UICOMPONENTs of this UICOMPONENT. This method will only be called if the rendersChildren property is true.

If a Renderer is associated with this UICOMPONENT, the actual encoding will be delegated to Renderer.encodeChildren(FacesContext, UICOMPONENT).

Specified by:
encodeChildren in class UICOMPONENT
Parameters:
context - FacesContext for the response we are creating
Throws:
NullPointerException - if context is null
IOException - if an input/output error occurs while rendering

public void encodeEnd(FacesContext context) throws java.io.IOException

Throws java.io.IOException: NullPointerException /
Throws NullPointerException: NullPointerException context null

codeEnd

public void encodeEnd(FacesContext context) throws IOException

Description copied from class: UICOMPONENT

If our rendered property is true, render the ending of the current state of this UICOMPONENT.

If a Renderer is associated with this UICOMPONENT, the actual encoding
will be delegated to `Renderer.encodeEnd(FacesContext, UIComponent)`.

**Specified by:**
`encodeEnd` in class `UIComponent`  

**Parameters:**
> context - `FacesContext` for the response we are creating 

**Throws:**
> `IOException` - if an input/output error occurs while rendering  
> `NullPointerException` - if context is null 

---

protected void addFacesListener(`FacesListener` listener)

`FacesListener` `UIComponent` `UIComponent` API

```java
public class FooEvent extends FacesEvent {
    ...
    protected boolean isAppropriateListener(FacesListener listener) {
        return (listener instanceof FooListener);
    }
    protected void processListener(FacesListener listener) {
        ((FooListener) listener).processFoo(this);
    }
    ...
}

public interface FooListener extends FacesListener {
    public void processFoo(FooEvent event);
}

public class FooComponent extends UIComponentBase {
    ...
    public void addFooListener(FooListener listener) {
        addFacesListener(listener);
    }
    public void removeFooListener(FooListener listener) {
        removeFacesListener(listener);
    }
```
addFacesListener

protected void addFacesListener(FacesListener listener)

Add the specified FacesListener to the set of listeners registered to receive event notifications from this UIComponent. It is expected that UIComponent classes acting as event sources will have corresponding typesafe APIs for registering listeners of the required type, and the implementation of those registration methods will delegate to this method. For example:

public class FooEvent extends FacesEvent {
    ...
    protected boolean isAppropriateListener(FacesListener listener) {
        return (listener instanceof FooListener);
    }
    protected void processListener(FacesListener listener) {
        ((FooListener) listener).processFoo(this);
    }
    ...
}

public interface FooListener extends FacesListener {
    public void processFoo(FooEvent event);
}

public class FooComponent extends UIComponentBase {
    ...
    public void addFooListener(FooListener listener) {
        addFacesListener(listener);
    }
    public void removeFooListener(FooListener listener) {
        removeFacesListener(listener);
    }
    ...
}
Specified by:
   addFacesListener in class UICOMPONENT
Parameters:
   listener - The FacesListener to be registered
Throws:
   NullPointerException - if listener is null

protected FacesListener[] getFacesListeners(Class<T> clazz)

Throws
   IllegalArgumentException: NullPointerException
   FacesListener
   FacesListener
Throws
   NullPointerException: NullPointerException
   clazz
   null

getFacesListeners

protected FacesListener[] getFacesListeners(Class clazz)

Description copied from class: UICOMPONENT

Return an array of registered FacesListener s that are instances of the specified class. If there are no such registered listeners, a zero-length array is returned. The returned array can be safely be cast to an array strongly typed to an element type of clazz.

Specified by:
   getFacesListeners in class UICOMPONENT
Parameters:
   clazz - Class that must be implemented by a FacesListener for it to be returned
Throws:
   IllegalArgumentException - if clazz is not, and does not implement, FacesListener
   NullPointerException - if clazz is null

protected void removeFacesListener(FacesListener
removeFacesListener

protected void removeFacesListener(FacesListener listener)

Remove the specified FacesListener from the set of listeners registered to receive event notifications from this UIComponent.

Specified by:
removeFacesListener in class UIComponent

Parameters:
listener - The FacesListener to be deregistered

Throws:
NullPointerException - if listener is null

queueEvent

public void queueEvent(FacesEvent event)

Description copied from class: UIComponent

Queue an event for broadcast at the end of the current request processing lifecycle phase. The default implementation in UIComponentBase must delegate this call to the queueEvent() method of the parent UIComponent.
public void processDecodes(FacesContext context)

Arguments copied from class: UIComponent

Perform the component tree processing required by the Apply Request Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- If the rendered property of this UIComponent is false, skip further processing.
- Call the processDecodes() method of all facets and children of this UIComponent, in the order determined by a call to getFacetsAndChildren().
- Call the decode() method of this component.
- If a RuntimeException is thrown during decode processing, call FacesContext.renderResponse() and re-throw the exception.
NullPointerException - if context is null

public void processValidators(FacesContext context)

Throws  NullPointerException: NullPointerException  context  null

processValidators

public void processValidators(FacesContext context)

Description copied from class: UIComponent

Perform the component tree processing required by the Process Validations phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- If the rendered property of this UIComponent is false, skip further processing.
- Call the processValidators() method of all facets and children of this UIComponent, in the order determined by a call to getFacetsAndChildren().

Specified by:
processValidators in class UIComponent

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null

public void processUpdates(FacesContext context)

Throws  NullPointerException: NullPointerException  context  null

processUpdates
public void processUpdates(FacesContext context)

Description copied from class: UIComponent

Perform the component tree processing required by the Update Model Values phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- If the rendered property of this UIComponent is false, skip further processing.
- Call the processUpdates() method of all facets and children of this UIComponent, in the order determined by a call to getFacetsAndChildren().

Specified by:
processUpdates in class UIComponent

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null

public Object processSaveState(FacesContext context)

Throws NullPointerException: NullPointerException context null

processSaveState

public Object processSaveState(FacesContext context)

Description copied from class: UIComponent

Perform the component tree processing required by the state saving portion of the Render Response phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- consult the transient property of this component. If true, just
return null.

- Call the `processSaveState()` method of all facets and children of this `UIComponent` in the order determined by a call to `getFacetsAndChildren()`, skipping children and facets that are transient.
- Call the `saveState()` method of this component.
- Encapsulate the child state and your state into a `Serializable` Object and return it.

This method may not be called if the state saving method is set to server.

**Specified by:**
`processSaveState` in class `UIComponent`

**Parameters:**
- `context` - `FacesContext` for the request we are processing

**Throws:**
- `NullPointerException` - if `context` is `null`

```java
public void processRestoreState(FacesContext context, Object state)
    throws NullPointerException
```

**processRestoreState**

```java
public void processRestoreState(FacesContext context, Object state)
```

**Description copied from class:** `UIComponent`

Perform the component tree processing required by the Restore View phase of the request processing lifecycle for all facets of this component, all children of this component, and this component itself, as follows.

- Call the `processRestoreState()` method of all facets and children of this `UIComponent` in the order determined by a call to
getFacetsAndChildren().

- Call the restoreState() method of this component.

This method may not be called if the state saving method is set to server.

Specified by:
  - processRestoreState in class UIComponent

Parameters:
  context - FacesContext for the request we are processing

Throws:
  - NullPointerException - if context is null

protected FacesContext getFacesContext()

getFacesContext

protected FacesContext getFacesContext()

Description copied from class: UIComponent

Convenience method to return the FacesContext instance for the current request.

Specified by:
  - getFacesContext in class UIComponent

protected Renderer getRenderer(FacesContext context)

getRenderer

protected Renderer getRenderer(FacesContext context)

Description copied from class: UIComponent
Convenience method to return the Renderer instance associated with this component, if any; otherwise, return null.

**Specified by:**
```
getRenderer in class UICOMPONENT
```

**Parameters:**
```
context - FacesContext for the current request
```

```java
public Object saveState(FacesContext context)
```

**saveState**

```java
public Object saveState(FacesContext context)
```

**Description copied from interface: StateHolder**

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UICOMPONENT with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext)` method on all those instances as well. **This method must not save the state of children and facets.** That is done via the `StateManager`.

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be `Serializable`

```java
public void restoreState(FacesContext context, Object state)
```

**restoreState**
public void **restoreState**(FacesContext context, Object state)

Description copied from interface: **StateHolder**

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the **StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)** method on all those instances as well.

---

**public boolean isTransient()**

**isTransient**

public boolean isTransient()

Description copied from interface: **StateHolder**

If true, the Object implementing this interface must not participate in state saving or restoring.

---

**public void setTransient(boolean transientFlag)**

**setTransient**

public void setTransient(boolean transientFlag)
Description copied from interface: **StateHolder**

Denotes whether or not the Object implementing this interface must or must not participate in state saving or restoring.

**Parameters:**
- `transientFlag` - boolean pass `true` if this Object will participate in state saving or restoring, otherwise pass `false`.

```
public static Object saveAttachedState(FacesContext context, Object attachedObject)
```

**UICOMPONENT**

`StateHolder`

`#restoreAttachedState`

**Object**

`null`

`Lists`

`Lists`

`StateHolder`

**context**

`FacesContext`

`attachedObject`

`List`

`Object`

`attachedObject`

`StateHolder`

**Throws**

`NullPointerException: null`

**saveAttachedState**

```
public static Object saveAttachedState(FacesContext context, Object attachedObject)
```

This method is called by **UICOMPONENT** subclasses that want to save one or more attached objects. It is a convenience method that does the work of saving attached objects that may or may not implement the **StateHolder** interface. Using this method implies the use of `restoreAttachedState(javax.faces.context.FacesContext, java.lang.Object)` to restore the attached objects.

This method supports saving attached objects of the following type: `Objects`, `null` values, and `Lists` of these objects. If any contained
objects are not Lists and do not implement StateHolder, they must have zero-argument public constructors. The exact structure of the returned object is undefined and opaque, but will be serializable.

**Parameters:**
- context - the FacesContext for this request.
- attachedObject - the object, which may be a List instance, or an Object. The attachedObject (or the elements that comprise attachedObject) may implement StateHolder.

**Throws:**
- NullPointerException - if the context argument is null.

```java
public static Object restoreAttachedState(FacesContext context, Object stateObj) throws IllegalStateException

UIComponent #saveAttachedState
#saveAttachedState

#saveAttachedState

context FacesContext
stateObj #saveAttachedState
Throws NullPointerException: context null
Throws IllegalArgumentException: context null

restoreAttachedState

public static Object restoreAttachedState(FacesContext context, Object stateObj) throws IllegalStateException

This method is called by UIComponent subclasses that need to restore the objects they saved using saveAttachedState(javax.faces.context.FacesContext, java.lang.Object). This method is tightly coupled with saveAttachedState(javax.faces.context.FacesContext, java.lang.Object).```
This method supports restoring all attached objects types supported by `saveAttachedState(javax.faces.context.FacesContext, java.lang.Object)`.

**Parameters:**
- `context` - the `FacesContext` for this request
- `stateObj` - the opaque object returned from `saveAttachedState(javax.faces.context.FacesContext, java.lang.Object)`

**Throws:**
- `NullPointerException` - if context is null.
- `IllegalStateException` - if the object is not previously returned by `saveAttachedState(javax.faces.context.FacesContext, java.lang.Object)`.
javax.faces.webapp Class UIComponentBodyTag

<h:outputText value="component 1"/>
CASE 2
<h:outputText value="component 2"/>
<f:verbatim>CASE 3</f:verbatim>
<c:out value="${pageScope.CASE4}" />
</h:panelGrid>

faces  ${pageScope.CASE4}  "  CASE 4"
<table border="4" style="color:red">
<tbody>
<tr><td>CASE 1</td></tr>
<tr><td>component 1</td></tr>
<tr><td>CASE 2</td>
<tr><td>component 2</td></tr>
<tr><td>CASE 3</td>
<td>CASE 4</td></tr>
</tbody>
</table>

UIComponentTagBase is the base class for all JSP tags that use the "classic" JSP tag interface that correspond to a UIComponent instance in the view. In Faces 1.2, all component tags are BodyTag instances to allow for the execution of the page to build the component tree, but not render it. Rendering happens only after the component tree is completely built.

UIComponentTag extends UIComponentClassicTagBase to add support for properties that conform to the Faces 1.1 EL.

UIComponentELTag extends UIComponentClassicTagBase class to add support for properties that conform to the EL API.
The default implementation allows the proper interweaving of template text, non-Faces JSP tag output, and Faces component tag output in the same page, as expected by the page author.

The CASE markers in the following example will be cited in the method descriptions of this class.

- **CASE 1** describes template text and/or non-component custom tag output occurring as the child of a component tag, but before the first component tag child of that component tag.

- **CASE 2** describes template text and/or non-component custom tag output occurring between two sibling component tags.

- **CASE 3** describes template text and/or non-component custom tag output occurring as the child content of an `<f:verbatim>` tag at any point in the page.

- **CASE 4** describes template text and/or non-component custom tag output occurring between the last child component tag and its enclosing parent component tag's end tag.

```xml
<h:panelGrid style="color:red" border="4" columns="2">
  CASE 1
  <h:outputText value="component 1"/>
  CASE 2
  <h:outputText value="component 2"/>
  <f:verbatim>CASE 3</f:verbatim>
  <c:out value="${pageScope.CASE4}" />
</h:panelGrid>
```

The preceding arrangement of faces component tags, must yield markup that will render identically to the following (assuming that `${pageScope.CASE4}` evaluates to "CASE 4" without the quotes).

```xml
<table border="4" style="color:red">
  <tbody>
    <tr><td>CASE 1</td></tr>
    <tr><td>component 1</td></tr>
  </tbody>
</table>
```

</tbody>
</table>
Perform any processing necessary to find the UIComponent instance in the page corresponding to this tag instance in the page and, if and only if a component was not found, the tree at the proper location as expected by the page author.

**encodeBegin()**

*Deprecated.* No encoding is done during JSP page execution. Encoding is deferred until the page is executing to allow the entire tree to be built before any encoding occurs.

**encodeChildren()**

*Deprecated.* No encoding is done during JSP page execution. Encoding is deferred until the page is executing to allow the entire tree to be built before any encoding occurs.

**encodeEnd()**

*Deprecated.* No encoding is done during JSP page execution. Encoding is deferred until the page is executing to allow the entire tree to be built before any encoding occurs.

**findComponent(FacesContext context)**

Find and return the UIComponent, from the component that corresponds to this tag handler instance.

**getBodyContent()**

**getComponentInstance()**

Return the UIComponent instance that is associated with tag instance.

**getCreated()**

Return true if we dynamically created a component instance during execution of this tag.

**getCreatedComponents()**

Returns the List of UIComponent ids created or nested UIComponentTagS while processing the current tag instance.

**getDoAfterBodyValue()**

Return the flag value that should be returned from the child tag handler of this tag handler.
doAfterBody() method when it is called.

protected int 

getDoEndValue()

Return the flag value that should be returned when it is called.

protected int

getDoStartValue()

Return the flag value that should be returned when doStart() method is called.

protected FacesContext

getFacesContext()

Return the FacesContext instance for the current tag.

protected String

getFacesJspId()

If this method has been called before on the tag's lifetime (before release() was called), return the value.

protected String

getFacetName()

Return the facet name that we should be stored under, if any; otherwise, return null (indicating that we will be a child component).

protected String

getId()

Return the id value assigned by the page author.

protected int

getIndexOfNextChildTag()

Return the index of the next child to be added as a child of this tag.

String

getJspId()

Tag

getParent()

Return the Tag that is the parent of this instance.

static UICOMPONENTCLASSICTAGBASE

getParentUICOMPONENTCLASSICTAGBASE(PageContext)

Locate and return the nearest enclosing UICOMPONENTCLASSICTAGBASE if any; otherwise, return null.

JspWriter

getPreviousOut()

Get the JspWriter from our BodyContent.

protected abstract boolean

hasBinding()

Return true if this component has a non-attribute.

void

release()

Release any resources allocated during
void setBodyContent(BodyContent bodyContent)
Set the bodyContent for this tag handler.

void setId(String id)
Set the component identifier for our component.

void setJspId(String id)
Defined on JspIdConsumer.

void setPageContext(PageContext pageContext)
Set the PageContext of the page containing this component.

void setParent(Tag parent)
Set the Tag that is the parent of this instance.

protected abstract void setProperties(UIComponent component)
Override properties and attributes of the component if the corresponding properties of this tag handler were explicitly set.

protected void setupResponseWriter()
Set up the ResponseWriter for the current response, if this has not been done already.

Methods inherited from class javax.faces.webapp.UIComponentTagBase
getComponentType, getELContext, getRendererType

Methods inherited from class java.lang.Object
cloned, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Field Detail

UNIQUE_ID_PREFIX
protected static final String UNIQUE_ID_PREFIX
Used as the prefix for ids. This is necessary to avoid uniqueness conflicts with the transient verbatim components.

See Also:
 Constant Field Values

bodyContent

protected BodyContent bodyContent

The bodyContent for this tag handler.

pageContext

protected PageContext pageContext

The JSP PageContext for the page we are embedded in.

Constructor Detail

public UIComponentClassicTagBase()

UIComponentClassicTagBase

public UIComponentClassicTagBase()

Method Detail

protected int getDoStartValue() throws JspException
doStart()

Throws

JspException: doStart()

getDoStartValue

protected int getDoStartValue()

throws JspException

Return the flag value that should be returned from the doStart() method when it is called. Subclasses may override this method to return the appropriate value.

Throws:

JspException - to cause doStart() to throw an exception

protected int getDoEndValue() throws JspException

doEnd()

Throws

JspException: doEnd()

getDoEndValue

protected int getDoEndValue()

throws JspException

Return the flag value that should be returned from the doEnd() method when it is called. Subclasses may override this method to return the appropriate value.

Throws:

JspException - to cause doEnd() to throw an exception
protected void encodeBegin() throws java.io.IOException

UIComponent encodeBegin() doStartTag()

Throws java.io.IOException: /
deprecated JSP

encodeBegin

protected void encodeBegin()
throws IOException

Deprecated. No encoding is done during JSP page execution. Encoding is deferred until the page has completed executing to allow the entire tree to be built before any encoding occurs.

Delegate to the encodeBegin() method of our corresponding UIComponent. This method is called from doStartTag(). Normally, delegation occurs unconditionally; however, this method is abstracted out so that advanced tags can conditionally perform this call.

Throws: IOException - if an input/output error occurs

protected void encodeChildren() throws java.io.IOException

UIComponent encodeChildren() doStartTag()

Throws java.io.IOException: /
deprecated JSP
**encodeChildren**

```java
protected void encodeChildren()
    throws IOException
```

**Deprecated.** No encoding is done during JSP page execution. Encoding is deferred until the page has completed executing to allow the entire tree to be built before any encoding occurs.

Delegate to the `encodeChildren()` method of our corresponding `UIComponent`. This method is called from `doStartTag()`. Normally, delegation occurs unconditionally; however, this method is abstracted out so that advanced tags can conditionally perform this call.

**Throws:**

- `IOException` - if an input/output error occurs

---

**protected void encodeEnd() throws java.io.IOException**

```java
UIComponent encodeEnd() doStartTag()
```

Throws: `java.io.IOException: /
deprecated JSP`

---

**encodeEnd**

```java
protected void encodeEnd()
    throws IOException
```

**Deprecated.** No encoding is done during JSP page execution. Encoding is deferred until the page has completed executing to allow the entire tree to be built before any encoding occurs.

Delegate to the `encodeEnd()` method of our corresponding `UIComponent`. This method is called from `doStartTag()`. Normally,
delegation occurs unconditionally; however, this method is abstracted out so that advanced tags can conditionally perform this call.

**Throws:**

- `IOException` - if an input/output error occurs

--

**public void setPageContext(PageContext pageContext)**

Set the PageContext of the page containing this tag instance.

**Specified by:**

`setPageContext` in interface `Tag`

**Parameters:**

- `pageContext` - The enclosing `PageContext`

--

**public Tag getParent()**

Return the `Tag` that is the parent of this instance.
public void setParent(Tag parent)

Tag

```java

parent
```

setParent

public void setParent(Tag parent)

Set the Tag that is the parent of this instance.

Specified by:  
setParent in interface Tag

Parameters:  
parent - The new parent Tag

protected void setupResponseWriter()

javax.faces.context.ResponseWriter

setupResponseWriter

protected void setupResponseWriter()
Set up the ResponseWriter for the current response, if this has not been done already.

@deprecated.
ViewHandler.renderView(javax.faces.context.FacesContext, javax.faces.component.UIViewRoot) is now responsible for setting up the response writer. This method is now a no-op.

protected UIComponent findComponent(FacesContext context) throws JspException

1. UIComponentUIComponentUIComponent facet

2. UIComponentTagUIComponentTag Tree

3. UIComponentTag facetName UIComponent facet setProperties

4. ID UIComponentTag id

5. UIComponent id UIComponentTag

6. UIComponent setProperties()

UIComponent

1. UIComponentTag#getComponentType

2. binding FacesContext

   Application#createComponent "binding"

3. Application#createComponent

4. setProperties()

5.facet
findComponent

protected UICOMPONENT findComponent(FacesContext context) throws JspException

Find and return the UICOMPONENT, from the component tree, that corresponds to this tag handler instance. If there is no such UICOMPONENT, create one and add it as a child or facet of the UICOMPONENT associated with our nearest enclosing UICOMPONENTTag.

The process for locating or creating the component is:

1. If we have previously located this component, return it.
2. Locate the parent component by looking for a parent UICOMPONENTTag instance, and ask it for its component. If there is no parent UICOMPONENTTag instance, this tag represents the root component, so get it from the current Tree and return it.
3. If this UICOMPONENTTag instance has the facetName attribute set, ask the parent UICOMPONENT for a facet with this name. If not found, create one, call setProperties() with the new component as a parameter, and register it under this name. Return the found or created facet UICOMPONENT.
4. Determine the component id to be assigned to the new component, as follows: if this UICOMPONENTTag has an id attribute set, use that value; otherwise, generate an identifier that is guaranteed to be the same for this UICOMPONENT every time this page is processed (i.e. one based on the location of all UICOMPONENTTag instances without an id attribute set).
5. Ask the parent UICOMPONENT for a child with this identifier. If not found, create one, call setProperties() with the new component as a parameter, and register it as a child with this identifier. Return the found or created child UICOMPONENT.

When creating a component, the process is:

1. Retrieve the component type by calling UICOMPONENTTagBase.getComponentType().
2. If the component has a binding attribute, create an expression from it, and call Application.createComponent(java.lang.String) with that
expression, the `FacesContext`, and the component type. Store the expression using the key "binding".

3. Otherwise, call `Application.createComponent(java.lang.String)` with only the component type.
5. Add the new component as a child or facet of its parent

Throws: `JspException`

```java
public static UIComponentClassicTagBase getParentUIComponentClassicTagBase(PageContext context)

UIComponentClassicTagBase null
context PageContext

getParentUIComponentClassicTagBase

public static UIComponentClassicTagBase getParentUIComponentClassicTagBase(PageContext context)

    Locate and return the nearest enclosing `UIComponentClassicTagBase` if any; otherwise, return null.

Parameters:
    context - PageContext for the current page

protected int getIndexOfNextChildTag()

getIndexOfNextChildTag

protected int getIndexOfNextChildTag()
```
Description copied from class: `UIComponentTagBase`

Return the index of the next child to be added as a child of this tag. The default implementation maintains a list of created components and returns the size of the list.

Specified by:
`getIndexOfNextChildTag` in class `UIComponentTagBase`

protected void `addChild(UIComponent child)`

`addChild`

protected void `addChild(UIComponent child)`

Description copied from class: `UIComponentTagBase`

Add the component identifier of the specified `UIComponent` to the list of component identifiers created or located by nested `UIComponentTags` processing this request.

Specified by:
`addChild` in class `UIComponentTagBase`

Parameters:
child - New child whose identifier should be added

protected void `addFacet(String name)`

`addFacet`

protected void `addFacet(String name)`

Description copied from class: `UIComponentTagBase`

Add the facet name of the specified facet to the list of facet names
specified by: addFacet in class UIComponentTagBase

Parameters:
name - Facet name to be added

protected UIComponent createVerbatimComponentFromBodyContent()

UIOutput null

createVerbatimComponentFromBodyContent

protected UIComponent createVerbatimComponentFromBodyContent()

Create a transient UIOutput component from the body content, of this tag instance or return null if there is no body content, the body content is whitespace, or the body content is a comment.

protected UIOutput createVerbatimComponent()

Application

componentType javax.faces.HtmlOutputText

transient true

escape false

id FacesContext.getViewRoot().createUniqueId()
createVerbatimComponent

protected UIOutput createVerbatimComponent()

Use the Application instance to create a new component with the following characteristics.

- `componentType` is `javax.faces.HtmlOutputText`.
- `transient` is `true`.
- `escape` is `false`.
- `id` is `FacesContext.getViewRoot().createUniqueId()`.

addVerbatimBeforeComponent

protected void addVerbatimBeforeComponent(UIComponentClassicTagBase parentTag, UIComponent verbatim, UIComponent component)

Add `verbatim` as a sibling of `component` in `component` in the parent's child list. `verbatim` is added to the list at the position immediately preceding `component`.

addVerbatimBeforeComponent

protected void addVerbatimBeforeComponent(UIComponentClassicTagBase parentTag, UIComponent verbatim, UIComponent component)
protected void addVerbatimAfterComponent(UIComponentClassicTagBase parentTag, UIComponent verbatim, UIComponent component)

component verbatim component verbatim component

addVerbatimAfterComponent

protected void addVerbatimAfterComponent(UIComponentClassicTagBase p, UIComponent verbatim, UIComponent component)

Add verbatim as a sibling of component in component in the parent's child list. verbatim is added to the list at the position immediately following component.

public int doStartTag() throws JspException

(UIComponent UIOutput)
(UIComponent UIOutput CASE 1 CASE 2)

#getParentUIComponentClassicTagBase
#createVerbatimComponentFromBodyContent
#adVerbatimBeforeComponent

#getParentUIComponentClassicTagBase

getDoStartValue()

Throws JspException:
doStartTag

public int doStartTag()
    throws JspException

Perform any processing necessary to find (or create) the UIComponent instance in the view corresponding to this tag instance in the page and, if and only if a component was created, insert it into the tree at the proper location as expected by the page author. Secondarily, cause a transient UIOutput component to be created and placed in the tree before the UIComponent instance for this tag. The value of this UIOutput component must include anything covered by CASE 1 OR CASE 2 in the class description.

The default implementation, which is intended to be sufficient for most components, implements this secondary requirement by calling getParentUIComponentClassicTagBase(javax.servlet.jsp.PageContext) and calling createVerbatimComponentFromBodyContent() on the result. It then adds the returned component to the tree before the actual component for this tag instance instance by calling addVerbatimBeforeComponent(javax.faces.webapp.UIComponentClassicTagBase, javax.faces.component.UIComponent, javax.faces.component.UIComponent).

Before returning, the component is pushed onto the component stack for this response to enable the getParentUIComponentClassicTagBase(javax.servlet.jsp.PageContext) method to work properly.

The flag value to be returned is acquired by calling the getDoStartValue() method, which tag subclasses may override if they do not want the default value.

Specified by:
    doStartTag in interface Tag

Returns:
    EVAL_BODY_INCLUDE if the tag wants to process body, SKIP_BODY if it does not want to process it.

Throws:
    JspException - if an error occurs
public int doEndTag() throws JspException

CASE 3

#createVerbatimComponentFromBodyContent

- UIComponent UIComponentTag ID
- UIComponent UIComponentTag facet facet facet facet
- getDoEndValue()

Throws JspException:

doEndTag

public int doEndTag() throws JspException

Perform any processing necessary to handle the content implications of CASE 3 in the class description.

The default implementation, which is intended to be sufficient for most components, calls createVerbatimComponentFromBodyContent() on this instance and adds it as a child of the component for this tag's component at the end of the child list. In addition, the following housekeeping steps are taken.

- Retrieve from the UIComponent the set of component ids of child components created by UIComponentTag instances the last time this page was processed (if any). Compare it to the list of
children created during this page processing pass, and remove all children present in the old list but not the new. Save the new list as a component attribute so that it gets saved as part of the component's state.

- Retrieve from the UIComponent the set of facet names of facets created by UIComponentTag instances the last time this page was processed (if any). Compare it to the list of facets created during this page processing pass, and remove all facets present in the old list but not the new. Save the new list as a component attribute so that it gets saved as part of the component's state.
- Release all references to the component, and pop it from the component stack for this response, removing the stack if this was the outermost component.

The flag value to be returned is acquired by calling the getDoEndValue() method, which tag subclasses may override if they do not want the default value.

Specified by:  
doEndTag in interface Tag  
Returns:  
indication of whether to continue evaluating the JSP page.  
Throws:  
jspException - if an error occurs

public void release()

release

public void release()

Release any resources allocated during the execution of this tag handler.
protected int getDoAfterBodyValue() throws JspException

doAfterBody()

getDoAfterBodyValue

protected int getDoAfterBodyValue() throws JspException

    Return the flag value that should be returned from the doAfterBody() method when it is called. Subclasses may override this method to return the appropriate value.

    Throws: JspException

public void setBodyContent(BodyContent bodyContent)

    bodyContent JSP doInitiBody() doStartTag()
    SKIP_BODY EVAL_BODY_INCLUDE

    bodyContent BodyContent

setBodyContent

public void setBodyContent(BodyContent bodyContent)

    Set the bodyContent for this tag handler. This method is invoked by the JSP page implementation object at most once per action invocation, before doInitiBody(). This method will not be invoked for
empty tags or for non-empty tags whose doStartTag() method returns SKIP_BODY OR EVAL_BODY_INCLUDE.

Specified by:
  setBodyContent in interface BodyTag

Parameters:
  bodyContent - The new BodyContent for this tag

See Also:
  BodyTag.doInitBody(), IterationTag.doAfterBody()

public JspWriter getPreviousOut()

getBodyContent

public BodyContent getBodyContent()

public void doInitBody() throws JspException

Throws JspException
doInitBody

public void doInitBody() throws JspException

Prepare for evaluation of the body. This method is invoked by the JSP page implementation object after setBodyContent() and before the first time the body is to be evaluated. This method will not be invoked for empty tags or for non-empty tags whose doStartTag() method returns SKIP_BODY OR EVAL_BODY_INCLUDE.

Specified by: doInitBody in interface BodyTag

Throws: JspException - if an error is encountered

See Also: IterationTag.doAfterBody()

doAfterBody

public int doAfterBody() throws JspException

CASE 4

#getDoAfterBodyValue

Throws JspException:

public int doAfterBody() throws JspException

Perform any processing necessary to handle the content implications of CASE 4 in the class description.

Return result from getDoAfterBodyValue()
public void setId(String id)

setId

protected String get(Id())
getId

protected String getId()

Return the id value assigned by the page author.

getFacesJspId

protected String getFacesJspId()

#release #getJspId null #UNIQUE_ID_PREFIX jspId

getFacesJspId

protected String getFacesJspId()

If this method has been called before on this tag's useful lifetime (before release() was called), return the previously returned value. Otherwise, if getJspId() returns non-null, prepend UNIQUE_ID_PREFIX to the jspId and return the result.

getCreatedComponents

protected java.util.List<E> getCreatedComponents()

Returns the List of UIComponent ids created or located by nested
UIComponentTag while processing the current request.

```java
public void setJspId(String id)
```

Defined on JspIdConsumer. This method is called by the container before doStartTag(). The argument is guaranteed to be unique within the page.

IMPLEMENTATION NOTE: This method will detect where we are in an include and assign a unique ID for each include in a particular 'logical page'. This allows us to avoid possible duplicate ID situations for included pages that have components without explicit IDs.

Specified by:

```java
public String getJspId()
```

Specified by:

```java
public String getJspId()
```
abstract protected void setProperties(UIComponent component)

    protected void setProperties(UIComponent component)
    {
        super.setProperties(component);
        if (foo != null) {
            component.setAttribute("foo", foo);
        }
        if (bar != null) {
            component.setAttribute("bar", bar);
        }
    }

setProperties

protected abstract void setProperties(UIComponent component)

    Override properties and attributes of the specified component, if the corresponding properties of this tag handler instance were explicitly set. This method must be called **ONLY** if the specified UIComponent was in fact created during the execution of this tag handler instance, and this call will occur **BEFORE** the UIComponent is added to the view.
Tag subclasses that want to support additional set properties must ensure that the base class `setProperties()` method is still called. A typical implementation that supports extra properties `foo` and `bar` would look something like this:

```java
protected void setProperties(UIComponent component) {
    super.setProperties(component);
    if (foo != null) {
        component.setAttribute("foo", foo);
    }
    if (bar != null) {
        component.setAttribute("bar", bar);
    }
}
```

The default implementation overrides the following properties:

- `rendered` - Set if a value for the `rendered` property is specified for this tag handler instance.
- `rendererType` - Set if the `getRendererType()` method returns a non-null value.

**Parameters:**

- `component` - `UIComponent` whose properties are to be overridden

```java
abstract protected UIComponent createComponent(FacesContext context, String newId)
throws JspException
```

```java
getComponentType() UIComponentTag null
binding binding Application#createComponent
Application#createComponent ID
context FacesContext
newId ID
```

`createComponent`
protected abstract UIComponent createComponent(FacesContext context, String newId) throws JspException

Create and return a new child component of the type returned by calling getComponentType(). If this UIComponentTag has a non-null binding attribute, this is done by call
Application.createComponent(java.lang.String) with the expression created for the binding attribute, and the expression will be stored on the component. Otherwise, Application.createComponent(java.lang.String) is called with only the component type. Finally, initialize the components id and other properties.

Parameters:
context - FacesContext for the current request
newId - id of the component

Throws:
JspException

abstract protected boolean hasBinding()

null binding true binding Faces 1.1 EL
EL API

hasBinding

protected abstract boolean hasBinding()

Return true if this component has a non-null binding attribute. This method is necessary to allow subclasses that expose the binding property as an Faces 1.1 style EL property as well as subclasses that expose it as an EL API property.

public UIComponent getComponentInstance()
**UIComponent**  
doStartTag()  
doEndTag()

### getComponentInstance

```java
public UIComponent getComponentInstance()
```

Return the `UIComponent` instance that is associated with this tag instance. This method is designed to be used by tags nested within this tag, and only returns useful results between the execution of `doStartTag()` and `doEndTag()` on this tag instance.

**Specified by:**  
`getComponentInstance` in class `UIComponentTagBase`

### public boolean getCreated()

```java
true doStartTag() doEndTag()
```

### getCreated

```java
public boolean getCreated()
```

Return `true` if we dynamically created a new component instance during execution of this tag. This method is designed to be used by tags nested within this tag, and only returns useful results between the execution of `doStartTag()` and `doEndTag()` on this tag instance.

**Specified by:**  
`getCreated` in class `UIComponentTagBase`

### protected FacesContext getFacesContext()

```java
protected FacesContext getFacesContext()
```
getFacesContext

protected FacesContext getFacesContext()

Description copied from class: UIComponentTagBase

Return the FacesContext instance for the current request. This value will be non-null only from the beginning of doStartTag() through the end of doEndTag() for each tag instance.

Specified by:
    getFacesContext in class UIComponentTagBase

protected String getFacetName()

facet null

getFacetName

protected String getFacetName()

    Return the facet name that we should be stored under, if any; otherwise, return null (indicating that we will be a child component).
javax.faces.webapp  Class UIComponentELTag

Constructor Detail

public UIComponentELTag()
UIComponentELTag

public UIComponentELTag()

Method Detail

public void setBinding(ValueExpression binding) throws JspException

Parameter:

binding - The new value expression

Throws:

JspException - if an error occurs

protected boolean hasBinding()

hasBinding

protected boolean hasBinding()
Return true if this component has a non-null binding attribute. This method is necessary to allow subclasses that expose the binding property as an Faces 1.1 style EL property as well as subclasses that expose it as an EL API property.

**Specified by:**
- hasBinding in class UICOMPONENTCLASSICTAGBASE

```java
public void setRendered(ValueExpression rendered)
```

*rendered*

**setRendered**

```java
public void setRendered(ValueExpression rendered)
```

Set an override for the rendered attribute.

**Parameters:**
- rendered - The new value for rendered attribute

```java
protected ELContext getELContext()
```

**getELContext**

```java
protected ELContext getELContext()
```
Return the `ELContext` for the `FacesContext` for this request.

This is a convenience for `getFacesContext().getELContext()`.

**Overrides:**
- `getELContext` in class `UIComponentTagBase`

---

```java
public void release()
```

**release**

```java
public void release()
```

Release any resources allocated during the execution of this tag handler.

**Specified by:**
- `release` in interface `Tag`

**Overrides:**
- `release` in class `UIComponentClassicTagBase`

---

```java
protected void setProperties(UIComponent component)
```

```java
protected void setProperties(UIComponent component) {
    super.setProperties(component);
    if (foo != null) {
        component.setAttribute("foo", foo);
    }
    if (bar != null) {
```
protected void setProperties(UIComponent component) {
    super.setProperties(component);
    if (foo != null) {
        component.setAttribute("foo", foo);
    }
    if (bar != null) {
        component.setAttribute("bar", bar);
    }
}

The default implementation overrides the following properties:

- rendered - rendered
- rendererType - getRendererType() null
- rendered - Set if a value for the rendered property is specified for this tag handler instance.
- rendererType - Set if the getRendererType() method returns a non-null value.

Specified by:

setProperties in class UIComponentClassicTagBase

Parameters:

component - UIComponent whose properties are to be overridden

protected UIComponent.createComponent(FacesContext context, String newId) throws JspException

```
getComponentType()  UIComponentELTag null
binding  binding  ValueExpression
Application#createComponent  ValueExpression
Application#createComponent ID

context  FacesContext
newId  ID
```

createComponent

protected UIComponent createComponent(FacesContext context, String newId) throws JspException

Create and return a new child component of the type returned by calling getComponentType(). If this UIComponentELTag has a non-null binding attribute, this is done by call Application.createComponent(java.lang.String) with the ValueExpression created for the binding attribute, and the ValueExpression will be stored on the component. Otherwise, Application.createComponent(java.lang.String) is called with only the component type. Finally, initialize the components id and other properties.
Specified by:
createComponent in class UIComponentClassicTagBase

Parameters:
context - FacesContext for the current request
newId - id of the component

Throws:
JspException

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.
public abstract class `UIComponentTag`

extends `UIComponentClassicTagBase`

implements `Tag`

`UIComponentTag` is the base class for all JSP custom actions that correspond to user interface components in a page that is rendered by JavaServer Faces.
In this version of the specification, UIComponentTag extends UIComponentClassicTagBase to add properties that use the Faces 1.1 Expression Language.

### Field Summary

Constructor Detail

public UIComponentTag()

UIComponentTag

public UIComponentTag()

    Deprecated.

Method Detail

public void setBinding(String binding) throws JspException

    binding
Throws IllegalArgumentException:

**setBinding**

```java
public void setBinding(String binding) throws JspException
```

Deprecated.

Set the value binding expression for our component.

**Parameters:**
- binding - The new value binding expression

**Throws:**
- IllegalArgumentException - if the specified binding is not a valid value binding expression.
- JspException

---

**protected boolean hasBinding()**

**hasBinding**

```java
protected boolean hasBinding()
```

**Deprecated.**

Description copied from class: `UIComponentClassicTagBase`

Return true if this component has a non-null binding attribute. This method is necessary to allow subclasses that expose the binding property as an Faces 1.1 style EL property as well as subclasses that expose it as an EL API property.

**Specified by:**
- `hasBinding` in class `UIComponentClassicTagBase`
public void setRendered(String rendered)

rendered

setRendered

public void setRendered(String rendered)

 Deprecated.

 Set an override for the rendered attribute.

 Parameters:
 rendered - The new value for rendered attribute

protected boolean isSuppressed()

isSuppressed

protected boolean isSuppressed()

 Deprecated.

public static boolean isValueReference(String value)

 true ` *

 value

 Throws

 NullPointerException: value null
public static boolean isValueReference(String value)

Deprecated.

Return true if the specified value conforms to the syntax requirements of a value binding expression. Such expressions `*` may be used on most component tag attributes to signal a desire for deferred evaluation of the attribute or property value to be set on the underlying UIComponent.

Parameters:
   value - The value to evaluate

Throws:
   NullPointerException - if value is null

public void release()

release

public void release()

Deprecated.

Release any resources allocated during the execution of this tag handler.

Specified by:
   release in interface Tag

Overrides:
   release in class UIComponentClassicTagBase
protected void setProperties(UIComponent component)

Description copied from class: UIComponentClassicTagBase

Override properties and attributes of the specified component, if the corresponding properties of this tag handler instance were explicitly set. This method must be called ONLY if the specified UIComponent was in fact created during the execution of this tag handler instance, and this call will occur BEFORE the UIComponent is added to the view.

Tag subclasses that want to support additional set properties must ensure that the base class setProperties() method is still called. A typical implementation that supports extra properties foo and bar would look something like this:

protected void setProperties(UIComponent component) {
    super.setProperties(component);
    if (foo != null) {
        component.setAttribute("foo", foo);
    }
    if (bar != null) {
        component.setAttribute("bar", bar);
    }
}

The default implementation overrides the following properties:

- rendered - Set if a value for the rendered property is specified for this tag handler instance.
- rendererType - Set if the getRendererType() method returns a non-null value.
protected **UIComponent** `createComponent`(FacesContext context, String newId)

Faces 1.1 EL API

<table>

</tbody>
</table>

**createComponent**

protected **UIComponent** `createComponent`(FacesContext context, String newId)

**Deprecated.**

Implement `createComponent` using Faces 1.1 EL API.

Specified by: `createComponent` in class **UIComponentClassicTagBase**

Parameters:
- `context` - FacesContext for the current request
- `newId` - id of the component

public static **UIComponentTag** `getParentUIComponentTag`(PageContext context)

<table>
<thead>
<tr>
<th>Method</th>
<th>Signature</th>

</thead>
<tbody>
<tr>
<td><code>context</code></td>
<td></td>
<td>PageContext</td>
</tr>
</tbody>
</table>
getParentUIComponentTag

public static UIComponentTag getParentUIComponentTag(PageContext context)

Deprecated.

Locate and return the nearest enclosing UIComponentTag if any; otherwise, return null.

Parameters:
context - PageContext for the current page

Extended by: UIComponentClassicTagBase

UIComponentTagBase  JSP  javax.faces.component.UIComponent
                      UIComponentELTag  UIComponentTag  JSP

UIComponentTagBase is the base class for all JSP tags that correspond to a
UIComponent instance in the view. This base class allows a single view to
be described in a JSP page consisting of both UIComponentELTag and
UIComponentTag instances.

**UIComponentTagBase**

**public UIComponentTagBase()**

### Method Detail

abstract protected FacesContext getFacesContext()

*FacesContext* doStartTag() doEndTag() null

getFacesContext
protected abstract FacesContext getFacesContext()

Return the FacesContext instance for the current request. This value will be non-null only from the beginning of doStartTag() through the end of doEndTag() for each tag instance.

protected ELContext getELContext()

FacesContext ELContext

g getFacesContext().getELContext()

getELContext

protected ELContext getELContext()

Return the ELContext for the FacesContext for this request.

This is a convenience for getFacesContext().getELContext().

abstract protected void addChild(UIComponent child)

UIComponent UICOMPONENTTAG

child

addChild

protected abstract void addChild(UIComponent child)

Add the component identifier of the specified UIComponent to the list of component identifiers created or located by nested UICOMPONENTTAGs processing this request.
abstract protected void addFacet(String name)

Add the facet name of the specified facet to the list of facet names created or located by nested UIComponentTag processing this request.

Parameters:
name - Facet name to be added

abstract public void setId(String id)

Throws
IllegalArgumentException

setId

public abstract void setId(String id)

Set the component identifier for the component corresponding to this
tag instance. If the argument begins with `UIViewRoot.UNIQUE_ID_PREFIX` throw an `IllegalArgumentException`.

**Parameters:**
- `id` - The new component identifier. This may not start with `UIViewRoot.UNIQUE_ID_PREFIX`.

**Throws:**
- `IllegalArgumentException` - if the argument is non-null and starts with `UIViewRoot.UNIQUE_ID_PREFIX`.

---

```java
abstract public String getComponentType()
```

**getComponentType**

```java
public abstract String getComponentType()
```

Return the component type for the component that is or will be bound to this tag. This value can be passed to `javax.faces.application.Application#createComponent(UIComponent)` to create the `UIComponent` instance for this tag. Subclasses must override this method to return the appropriate value.

---

```java
abstract public String getRendererType()
```

**getRendererType**

```java
public abstract String getRendererType()
```

```java
rendererType Renderer null
```

getRendererType
Return the `rendererType` property that selects the `Renderer` to be used for encoding this component, or `null` to ask the component to render itself directly. Subclasses must override this method to return the appropriate value.

```
abstract public UIComponent getComponentInstance()
```

```
UIComponent doStartTag() doEndTag()
```

**getComponentInstance**

```
public abstract UIComponent getComponentInstance()
```

Return the `UIComponent` instance that is associated with this tag instance. This method is designed to be used by tags nested within this tag, and only returns useful results between the execution of `doStartTag()` and `doEndTag()` on this tag instance.

```
abstract public boolean getCreated()
```

```
true doStartTag() doEndTag()
```

**getCreated**

```
public abstract boolean getCreated()
```

Return `true` if we dynamically created a new component instance during execution of this tag. This method is designed to be used by tags nested within this tag, and only returns useful results between the execution of `doStartTag()` and `doEndTag()` on this tag instance.
abstract protected int getIndexOfNextChildTag()

getIndexOfNextChildTag

protected abstract int getIndexOfNextChildTag()

Return the index of the next child to be added as a child of this tag. The default implementation maintains a list of created components and returns the size of the list.
javax.faces.component  **Class UIData**

java.lang.Object

      └ javax.faces.component.UIComponentBase  
      └ javax.faces.component.UIData

**All Implemented Interfaces:**  
NamingContainer, StateHolder

**Direct Known Subclasses:**  
HtmlDataTable

---

class **UIData**

extends UIComponentBase
implements NamingContainer

Extends: UIComponent > UIComponentBase  
Implements: NamingContainer  
Extended by: HtmlDataTable

**UIData**  
DataModel   Collection   UIColumn   renderer

rendererType   javax.faces.Table   setRendererType()

**UIData** is a **UIComponent** that supports data binding to a collection of data objects represented by a **DataModel** instance, which is the current value of this component itself (typically established via a **ValueExpression**). During iterative processing over the rows of data in the data model, the object for the current row is exposed as a request attribute under the key specified by the **var** property.
Only children of type `UIColumn` should be processed by renderers associated with this component.

By default, the `rendererType` property is set to `javax.faces.Table`. This value can be changed by calling the `setRendererType()` method.

### Fields inherited from interface `javax.faces.component.NamingContainer` SEPARATOR_CHAR

### Constructor Summary

**UIData()**  
Create a new `UIData` instance with default property values.

### Method Summary

**void broadcast(FacesEvent event)**
Override the default `UIComponentBase.broadcast(javax.faces.event.FacesEvent)` procedure to unwrap any wrapped `FacesEvent` and reset the current row index before the event is actually broadcast.

**void encodeBegin(FacesContext context)**
In addition to the default behavior, ensure that any saved state for our child input components is discarded unless it is needed.
<table>

</tr>
</tbody>
</table>
special care for positioning the data properly before finding the component and invoking the callback on it.

`boolean isRowAvailable()`  
Return a flag indicating whether there is `rowData` available at the current `rowIndex`.

`void processDecodes(FacesContext context)`  
Override the default `UIComponentBase.processDecodes(javax.faces.context.FacesContext)` processing to perform the following steps.

`void processUpdates(FacesContext context)`  
Override the default `UIComponentBase.processUpdates(javax.faces.context.FacesContext)` processing to perform the following steps.

`void processValidators(FacesContext context)`  
Override the default `UIComponentBase.processValidators(javax.faces.context.FacesContext)` processing to perform the following steps.

`void queueEvent(FacesEvent event)`  
Override the default `UIComponentBase.queueEvent(javax.faces.event.FacesEvent)` processing to wrap any queued events in a wrapper so that we can reset the row index in `broadcast()`.

`void restoreState(FacesContext context, Object state)`  
Perform any processing required to restore the state from the entries in the state `Object`.

`Object saveState(FacesContext context)`  
Gets the state of the instance as a `Serializable Object`.

`protected void setDataModel(DataModel dataModel)`  
Set the internal `DataModel`.

`void setFirst(int first)`  
Set the zero-relative row number of the first row to be displayed.

`void setFooter(UIComponent footer)`  
Set the footer facet of this component.

`void setHeader(UIComponent header)`  
Set the header facet of this component.
void **setRowIndex**(int rowIndex)
Set the zero relative index of the current row, or -1 to indicate no row is currently selected, by implementing the following algorithm.

void **setRows**(int rows)
Set the number of rows to be displayed, or zero for all remaining rows in the table.

void **setValue**(Object value)
Set the value of the UIData.

void **setValueBinding**(String name, ValueBinding binding)
 Deprecated. This has been replaced by setValueExpression(java.lang.String, javax.el.ValueExpression)

void **setValueExpression**(String name, ValueExpression binding)
Set the ValueExpression used to calculate the value for the specified attribute or property name, if any.

void **setVar**(String var)
Set the request-scope attribute under which the data object for the current row will be exposed when iterating.

**COMPONENT_FAMILY**

```java
public static final String COMPONENT_FAMILY
```

The standard component family for this component.

**See Also:**

- [Constant Field Values](#)

### Constructor Detail

**public UIData()**

- [UIData](#)

**UIData**

```java
public UIData()
```
Create a new `UIData` instance with default property values.

### Method Detail

**public String getFamily()**

**getFamily**

**public String getFamily()**

**Description copied from class:** `UIComponent`

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the `rendererType` property, may be used to select the appropriate `Renderer` for this component instance.

**Specified by:**

`getFamily` in class `UIComponent`

---

**public int getFirst()**

**0**

**getFirst**

**public int getFirst()**

Return the zero-relative row number of the first row to be displayed.

---

**public void setFirst(int first)**
**setFirst**

```java
public void setFirst(int first)
```

Set the zero-relative row number of the first row to be displayed.

**Parameters:**
- `first` - New first row number

**Throws:**
- `IllegalArgumentException` - if `first` is negative

**getFooter**

```java
public UIComponent getFooter()
```

```java
facet getFacet("footer")
```

**getFooter**

```java
public UIComponent getFooter()
```

Return the footer facet of this component (if any). A convenience method for `getFacet("footer")`.

**setFooter**

```java
public void setFooter(UIComponent footer)
```

```java
facet getFacets().put("footer", footer)
```

** Throws:**
- `NullPointerException` - if `footer` is null
**setFooter**

```java
public void setFooter(UIComponent footer)
```

Set the footer facet of this component. A convenience method for `getFacets().put("footer", footer)`.

**Parameters:**
- `footer` - the new footer facet

**Throws:**
- `NullPointerException` - if `footer` is null

**getHeader**

```java
public UIComponent getHeader()
```

```java
facet getFacet("header")
```

**getHeader**

```java
public UIComponent getHeader()
```

Return the header facet of this component (if any). A convenience method for `getFacet("header")`.

**setHeader**

```java
public void setHeader(UIComponent header)
```

```java
facet getFacets().put("header", header)
```

**setHeader**

- `header` - The new header facet
- `getFacets().put("header", header)`

**Throws:**
- `NullPointerException: header` - if header is null

---

**setFooter**

```java
public void setFooter(UIComponent footer)
```

Set the footer facet of this component. A convenience method for `getFacets().put("footer", footer)`.

**Parameters:**
- `footer` - the new footer facet

**Throws:**
- `NullPointerException` - if `footer` is null

**getHeader**

```java
public UIComponent getHeader()
```

```java
facet getFacet("header")
```

**getHeader**

```java
public UIComponent getHeader()
```

Return the header facet of this component (if any). A convenience method for `getFacet("header")`.

**setHeader**

```java
public void setHeader(UIComponent header)
```

```java
facet getFacets().put("header", header)
```

**setHeader**

- `header` - The new header facet
- `getFacets().put("header", header)`

**Throws:**
- `NullPointerException: header` - if header is null

---

**setFooter**

```java
public void setFooter(UIComponent footer)
```

Set the footer facet of this component. A convenience method for `getFacets().put("footer", footer)`.

**Parameters:**
- `footer` - the new footer facet

**Throws:**
- `NullPointerException` - if `footer` is null

**getHeader**

```java
public UIComponent getHeader()
```

```java
facet getFacet("header")
```

**getHeader**

```java
public UIComponent getHeader()
```

Return the header facet of this component (if any). A convenience method for `getFacet("header")`.

**setHeader**

```java
public void setHeader(UIComponent header)
```

```java
facet getFacets().put("header", header)
```

**setHeader**

- `header` - The new header facet
- `getFacets().put("header", header)`

**Throws:**
- `NullPointerException: header` - if header is null
public void setHeader(UIComponent header)

Set the header facet of this component. A convenience method for
getFacets().put("header", header).

Parameters:
header - the new header facet

Throws:
NullPointerException - if header is null

public boolean isRowAvailable()

rowIndex rowData wrappedData false

Throws         FacesException:

isRowAvailable

public boolean isRowAvailable()

Return a flag indicating whether there is rowData available at the
current rowIndex. If no wrappedData is available, return false.

Throws:
FacesException - if an error occurs getting the row availability

public int getRowCount()

-1

Throws         FacesException:

getRowCount
public int getRowCount()

    Return the number of rows in the underlying data model. If the number of available rows is unknown, return -1.

    Throws:  
    FacesException - if an error occurs getting the row count

public Object getRowData()

    Throws  FacesException:
    Throws  IllegalArgumentException:

getRowData

public Object getRowData()

    Return the data object representing the data for the currently selected row index, if any.

    Throws:  
    FacesException - if an error occurs getting the row data
    IllegalArgumentException - if now row data is available at the currently specified row index

public int getRowIndex()

    0 -1

    Throws  FacesException:

getRowIndex
public int getRowIndex()

    Return the zero-relative index of the currently selected row. If we are not currently positioned on a row, return -1. This property is not enabled for value binding expressions.

    Throws:
        FacesException - if an error occurs getting the row index

public void setRowIndex(int rowIndex)

0 -1 Collection
getRowData() isRowAvailable()
Throws **FacesException**:

Throws **IllegalArgumentException**: rowIndex -1

**setRowIndex**

```java
class UIData {

    public void setRowIndex(int rowIndex) {

        Set the zero relative index of the current row, or -1 to indicate that no row is currently selected, by implementing the following algorithm. It is possible to set the row index at a value for which the underlying data collection does not contain any row data. Therefore, callers may use the **isRowAvailable()** method to detect whether row data will be available for use by the **getRowData()** method.

        - Save current state information for all descendant components (as described below).
        - Store the new row index, and pass it on to the **DataModel** associated with this **UIData** instance.
        - If the new **rowIndex** value is -1:
            - If the **var** property is not null, remove the corresponding request scope attribute (if any).
            - Reset the state information for all descendant components (as described below).
        - If the new **rowIndex** value is not -1:
            - If the **var** property is not null, call **getRowData()** and expose the resulting data object as a request scope attribute whose key is the **var** property value.
            - Reset the state information for all descendant components (as described below).

To save current state information for all descendant components, **UIData** must maintain per-row information for each descendant as follows:

    - If the descendant is an instance of **EditableValueHolder**, save the state of its **localValue** property.
    - If the descendant is an instance of **EditableValueHolder**, save the state of the **localValueSet** property.
    - If the descendant is an instance of **EditableValueHolder**, save the
state of the valid property.

- If the descendant is an instance of EditableValueHolder, save the state of the submittedValue property.

To restore current state information for all descendant components, **UIData** must reference its previously stored information for the current rowIndex and call setters for each descendant as follows:

- If the descendant is an instance of EditableValueHolder, restore the value property.
- If the descendant is an instance of EditableValueHolder, restore the state of the localValueSet property.
- If the descendant is an instance of EditableValueHolder, restore the state of the valid property.
- If the descendant is an instance of EditableValueHolder, restore the state of the submittedValue property.

**Parameters:**

- rowIndex - The new row index value, or -1 for no associated row

**Throws:**

- FacesException - if an error occurs setting the row index
- IllegalArgumentException - if rowIndex is less than -1

---

**public int getRows()**

0 0

**getRows**

**public int getRows()**

Return the number of rows to be displayed, or zero for all remaining rows in the table. The default value of this property is zero.

---

**public void setRows(int rows)**
setRows

public void setRows(int rows)

Set the number of rows to be displayed, or zero for all remaining rows in the table.

Parameters:
rows - New number of rows

Throws:
IllegalArgumentException - if rows is negative

public String getVar()

gVar

public String getVar()

Return the request-scope attribute under which the data object for the current row will be exposed when iterating. This property is not enabled for value binding expressions.

public void setVar(String var)
setVar

public void setVar(String var)

Set the request-scope attribute under which the data object for the current row will be exposed when iterating.

Parameters:
  var - The new request-scope attribute name

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via theStateManager.

This method must not alter the state of the implementing object. In other words, after executing this code:

    Object state = component.saveState(facesContext);

component should be the same as before executing it.
The return from this method must be `Serializable`.

**Specified by:**
- `saveState` in interface `StateHolder`

**Overrides:**
- `saveState` in class `UIComponentBase`

```java
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface: `StateHolder`**

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement `StateHolder` (such as a `UIComponent` with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.

**Specified by:**
- `restoreState` in interface `StateHolder`

**Overrides:**
- `restoreState` in class `UIComponentBase`

```java
public Object getValue()
```

**UI Data**
- `DataModel`
- `DataModel`
- `UIData`

-
- java.util.List
- java.sql.ResultSet
- javax.servlet.jsp.jstl.sql.Result

**ScalarDataModel**

**getValue**

```java
generic public Object getValue()
```

Return the value of the UIData. This value must either be of type `DataModel`, or a type that can be adapted into a `DataModel`. UIData will automatically adapt the following types:

- Arrays
- java.util.List
- java.sql.ResultSet
- javax.servlet.jsp.jstl.sql.Result

All other types will be adapted using the `ScalarDataModel` class, which will treat the object as a single row of data.

**public void setValue(Object value)**

**setValue**

```java
void setValue(Object value)
```

Set the value of the UIData. This value must either be of type `DataModel`, or a type that can be adapted into a `DataModel`. 
public void setValueBinding(String name, ValueBinding binding)

"name" "value" "var" "rowIndex"

ValueBinding ValueExpression

name ValueBinding
binding ValueExpression null ValueBinding

Throws IllegalArgumentException: name id parent var rowIndex

Throws NullPointerException: name null

deprecated

#setValueExpression(java.lang.String, javax.el.ValueExpression)

setValueBinding

public void setValueBinding(String name, ValueBinding binding)

Deprecated. This has been replaced by

If "name" is something other than "value", "var", or "rowIndex", rely on the superclass conversion from ValueBinding to ValueExpression.

Overrides:

setValueBinding in class UICOMPONENTBASE

Parameters:

name - Name of the attribute or property for which to set a ValueBinding
binding - The ValueBinding to set, or null to remove any currently set ValueBinding

Throws:
public void setValueExpression(String name, ValueExpression binding)

<table>
<thead>
<tr>
<th>DataModel</th>
<th>ValueExpression</th>
<th>value</th>
<th>ValueExpression</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>ValueExpression</td>
<td>null</td>
<td>ValueExpression</td>
</tr>
<tr>
<td>binding</td>
<td>ValueExpression</td>
<td>null</td>
<td>ValueExpression</td>
</tr>
</tbody>
</table>

Throws: 
IllegalArgumentException: name id parent var var

Throws: 
NullPointerException: name null

since 1.2

setValueExpression

public void setValueExpression(String name, ValueExpression binding)

Set the ValueExpression used to calculate the value for the specified attribute or property name, if any. In addition, if a ValueExpression is set for the value property, remove any synthesized DataModel for the data previously bound to this component.

Overrides: 
setValueExpression in class UIComponent

Parameters: 
name - Name of the attribute or property for which to set a ValueExpression
binding - The ValueExpression to set, or null to remove any currently set ValueExpression

Throws: 
IllegalArgumentException - if name is one of id, parent, var, or rowIndex
NullPointerException - if name is null

Since:
1.2

public String getClientId(FacesContext context)

Throws
Null POINTER EXCEPTION: context null

getClientId

public String getClientId(FacesContext context)

Return a client identifier for this component that includes the current value of the rowIndex property, if it is not set to -1. This implies that multiple calls to getClientId() may return different results, but ensures that child components can themselves generate row-specific client identifiers (since UIData is a NamingContainer).

Overrrides:
getClientId in class UIComponentBase

Parameters:
context - The FacesContext for the current request

Throws:
Null POINTER EXCEPTION - if context is null

public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback) throws FacesException

this.getClientId() contextCallback context this
public boolean invokeOnComponent(FacesContext context, String clientId, ContextCallback callback)
    throws FacesException

Override behavior from
UIComponentBase.invokeOnComponent(javax.faces.context.FacesContext,
java.lang.String, javax.faces.component.ContextCallback) to
provide special care for positioning the data properly before finding
the component and invoking the callback on it. If the argument
clientId is equal to this.getClientId() simply invoke the
callback, passing the context argument and this as
arguments, and return true. Otherwise, attempt to extract a
rowIndex from the clientId. For example, if the argument clientId
was form:data:3:customerHeader the rowIndex would be 3. Let this
value be called newIndex. The current rowIndex of this instance must
be saved aside and restored before returning in all cases, regardless
of the outcome of the search or if any exceptions are thrown in the
process.

The implementation of this method must never return true if setting
the rowIndex of this instance to be equal to newIndex causes this
instance to return false from isRowAvailable().
Overrides:  
  invokeOnComponent in class UICOMPONENTBASE

Parameters:
  context - the FacesContext for the current request
  clientId - the client identifier of the component to be passed to
  the argument callback.
  callback - an implementation of the Callback interface.

Returns:
  true if the a component with the given clientId is found, the
  callback method was successfully invoked passing that
  component as an argument, and no Exception was thrown.
  Returns false if no component with the given clientId is found.

Throws:
  NullPointerException - if any of the arguments are null
  FacesException - if the argument Callback throws an Exception, it is
  wrapped in a FacesException and re-thrown. Also throws
  FacesException if any exception is thrown when deriving the
  rowIndex from the argument clientId.

Since:
  1.2

---

public void queueEvent(FacesEvent event)

<table>
<thead>
<tr>
<th>UICOMPONENTBASE#queueEvent</th>
<th>broadcast()</th>
</tr>
</thead>
<tbody>
<tr>
<td>event</td>
<td>FacesEvent</td>
</tr>
<tr>
<td>Throws</td>
<td>IllegalStateException: UIViewRoot</td>
</tr>
<tr>
<td>Throws</td>
<td>NullPointerException: event null</td>
</tr>
</tbody>
</table>

queueEvent

public void queueEvent(FacesEvent event)

Override the default
UICOMPONENTBASE.queueEvent(javax.faces.event.FacesEvent)
processing to wrap any queued events in a wrapper so that we can
reset the current row index in broadcast().

**Overrides:**
- `queueEvent` in class `UIComponentBase`

**Parameters:**
- `event` - `FacesEvent` to be queued

**Throws:**
- `IllegalStateException` - if this component is not a descendant of a `UIViewRoot`
- `NullPointerException` - if `event` is null

---

**public void broadcast(FacesEvent event) throws AbortProcessingException**

**UIComponentBase#broadcast**

**queueEvent()**

- `event` - `FacesEvent`

**Throws:**
- `AbortProcessingException`: JavaServer Face
- `IllegalArgumentException`: `FacesEvent`
- `NullPointerException`: `event null`

---

**broadcast**

**public void broadcast(FacesEvent event)**

**throws** `AbortProcessingException`

Override the default `UIComponentBase.broadcast(javax.faces.event.FacesEvent)` processing to unwrap any wrapped `FacesEvent` and reset the current row index, before the event is actually broadcast. For events that we did not wrap (in `queueEvent()`), default processing will occur.

**Overrides:**
- `broadcast` in class `UIComponentBase`

**Parameters:**
event - The FacesEvent to be broadcast

Throws:

AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed
IllegalArgumentException - if the implementation class of this FacesEvent is not supported by this component
NullPointerException - if event is null

public void encodeBegin(FacesContext context) throws java.io.IOException

context | FacesContext
Throws | java.io.IOException: /
Throws | NullPointerException: context null

encodeBegin

public void encodeBegin(FacesContext context)
throws IOException

In addition to the default behavior, ensure that any saved per-row state for our child input components is discarded unless it is needed to rerender the current page with errors.

Overrides:
encodeBegin in class UIComponentBase

Parameters:
context - FacesContext for the current request

Throws:
IOException - if an input/output error occurs while rendering
NullPointerException - if context is null
public void processDecodes(FacesContext context)

Override the default UIComponentBase.processDecodes method to perform the following steps.

- If the rendered property of this UIComponent is false, skip further processing.
- Set the current rowIndex to -1.
- Call the processDecodes() method of all facets of this UIData, in the order determined by a call to getFacets().keySet().iterator().
- Call the processDecodes() method of all facets of the UIColumn.
Iterate over the set of rows that were included when this component was rendered (i.e. those defined by the first and rows properties), performing the following processing for each row:

- Set the current rowIndex to the appropriate value for this row.
- If isRowAvailable() returns true, iterate over the children components of each UIColumn child of this UIData component, calling the processDecodes() method for each such child.
- Set the current rowIndex to -1.
- Call the decode() method of this component.
- If a RuntimeException is thrown during decode processing, call FacesContext.renderResponse() and re-throw the exception.

Override:

processDecodes in class UICOMPONENTBASE

Parameters:
context - FacesContext for the current request

Throws:
NullPointerException - if context is null

public void processValidators(FacesContext context)

UICOMPONENTBASE#processValidators
processValidators

public void processValidators(FacesContext context)

Override the default UICOMPONENTBase.processValidators(javax.faces.context.FacesContext) processing to perform the following steps.

- If the rendered property of this UICOMPONENT is false, skip further processing.
- Set the current rowIndex to -1.
- Call the processValidators() method of all facets of this UIDATA, in the order determined by a call to getFacets().keySet().iterator().
- Call the processValidators() method of all facets of the UICOLUMN children of this UIDATA.
- Iterate over the set of rows that were included when this component was rendered (i.e. those defined by the first and rows properties), performing the following processing for each row:
  - Set the current rowIndex to the appropriate value for this row.
  - If isRowAvailable() returns true, iterate over the children components of each UICOLUMN child of this UIDATA component, calling the processValidators() method for each such child.
- Set the current rowIndex to -1.

Overrides:
  processValidators in class UICOMPONENTBase

Parameters:
  context - FacesContext for the current request

Throws:
public void processUpdates(FacesContext context)

UIComponentBase#processUpdates

- **UIComponent** rendered false
- rowIndex -1
- getFacets().keySet().iterator() UIData facet processUpdates()
- **UIData** **UIColumn** facet processUpdates()
- first rows
  - rowIndex
  - isRowAvailable() true **UIData** **UIColumn** processUpdates()
- rowIndex -1

context FacesContext
Throws NullPointerException: context null

processUpdates

public void processUpdates(FacesContext context)

Override the default
UIComponentBase.processUpdates(javax.faces.context.FacesContext) processing to perform the following steps.

- If the rendered property of this **UIComponent** is false, skip further processing.
- Set the current rowIndex to -1.
- Call the processUpdates() method of all facets of this **UIData**, in the order determined by a call to getFacets().keySet().iterator().
- Call the processUpdates() method of all facets of the **UIColumn**
Iterate over the set of rows that were included when this component was rendered (i.e. those defined by the first and rows properties), performing the following processing for each row:

- Set the current rowIndex to the appropriate value for this row.
- If isRowAvailable() returns true, iterate over the children components of each UIColumn child of this UIData component, calling the processUpdates() method for each such child.
- Set the current rowIndex to -1.

Overrides:

   processUpdates in class UICOMPONENTBASE

Parameters:

   context - FacesContext for the current request

Throws:

   NullPointerException - if context IS null

```
protected DataModel getDataModel()
```

```
#setDataModel null #getValue ListDataModel
```

#### getDataModel

protected DataModel getDataModel()

Return the internal DataModel object representing the data objects that we will iterate over in this component's rendering.

If the model has been cached by a previous call to

children of this UIData.
setDataModel(javax.faces.model.DataModel), return it. Otherwise call getValue(). If the result is null, create an empty ListDataModel and return it. If the result is an instance of DataModel, return it. Otherwise, adapt the result as described in getValue() and return it.

protected void setDataModel(DataModel dataModel)

<table>
<thead>
<tr>
<th>DataModel</th>
<th>UIData</th>
<th>DataModel</th>
<th>setDataModel</th>
</tr>
</thead>
<tbody>
<tr>
<td>DataModel</td>
<td>null</td>
<td>DataModel</td>
<td>#getDataModel</td>
</tr>
<tr>
<td>DataModel</td>
<td>DataModel</td>
<td>null</td>
<td></td>
</tr>
</tbody>
</table>

dataModel

setDataModel

protected void setDataModel(DataModel dataModel)

Set the internal DataModel. This UIData instance must use the given DataModel as its internal value representation from now until the next call to setDataModel. If the given DataModel is null, the internal DataModel must be reset in a manner so that the next call to getDataModel() causes lazy instantiation of a newly refreshed DataModel.

Subclasses might call this method if they either want to restore the internal DataModel during the Restore View phase or if they want to explicitly refresh the current DataModel for the Render Response phase.

Parameters:

dataModel - the new DataModel or null to cause the model to be refreshed.

PS :
javax.mail Interface UIDFolder

public interface UIDFolder

Inner classes: UIDFolder.FetchProfileItem

UIDFolder "disconnected" Folder id IMAP disconnected

(UID) long

RFC 2060 http://www.ietf.org/rfc/rfc2060.txt

The UIDFolder interface is implemented by Folders that can support the "disconnected" mode of operation, by providing unique-ids for messages in the folder. This interface is based on the IMAP model for supporting disconnected operation.

A Unique identifier (UID) is a positive long value, assigned to each message in a specific folder. Unique identifiers are assigned in a strictly ascending fashion in the mailbox. That is, as each message is added to the mailbox it is assigned a higher UID than the message(s) which were added previously. Unique identifiers persist across sessions. This permits a client to resynchronize its state from a previous session with the server.

Associated with every mailbox is a unique identifier validity value. If unique identifiers from an earlier session fail to persist to this session, the unique identifier validity value must be greater than the one used in the earlier session.

Refer to RFC 2060 http://www.ietf.org/rfc/rfc2060.txt for more information.

Author: John Mani
Nested Class Summary

| static class | UIDFolder.FetchProfileItem | A fetch profile item for fetching UIDs. |

Field Summary

| static long | LASTUID | This is a special value that can be used as the end parameter in `getMessagesByUID(start, end)`, to denote the UID of the last message in the folder. |

Method Summary

| Message | getMessageByUID(long uid) | Get the Message corresponding to the given UID. |
| Message[] | getMessagesByUID(long[] uids) | Get the Messages specified by the given array of UIDs. |
| Message[] | getMessagesByUID(long start, long end) | Get the Messages specified by the given range. |
| long | getUID(Message message) | Get the UID for the specified message. |
| long | getUIDValidity() | Returns the UIDValidity value associated with this folder. |

Field Detail

LASTUID

static final long LASTUID

This is a special value that can be used as the end parameter in
getMessagesByUID(start, end), to denote the UID of the last message in the folder.

See Also:
- getMessagesByUID(long, long), Constant Field Values

### Method Detail

```java
public long getUIDValidity() throws MessagingException
```

**UIDValidity**

```java
UIDValidity
```

```java
return
```

```java
UIDValidity
```

### getUIDValidity

```java
long getUIDValidity() throws MessagingException
```

Returns the UIDValidity value associated with this folder.

Clients typically compare this value against a UIDValidity value saved from a previous session to insure that any cached UIDs are not stale.

**Returns:**
- UIDValidity

**Throws:**
- MessagingException

```java
public Message getMessageByUID(long uid) throws MessagingException
```

**UID**

```java
Message
```

```java
uid
```

**UID**

```java
null
```
getMessageByUID

getMessageByUID(Message getMessagesByUID(long uid)
                     throws MessagingException

  Get the Message corresponding to the given UID. If no such message exists, null is returned.

  Parameters:
  uid - UID for the desired message

  Returns:
  the Message object. null is returned if no message corresponding to this UID is obtained.

  Throws:
  MessagingException

public Message[] getMessagesByUID(long start, long end)
                     throws MessagingException

  Get the Messages specified by the given range. The special value LASTUID can be used for the end parameter to indicate the UID of
the last message in the folder.

**Parameters:**
- start - start UID
- end - end UID

**Returns:**
- array of Message objects

**Throws:**
- MessagingException

**See Also:**
- LASTUID

---

```java
public Message[] getMessagesByUID(long[] uids) throws MessagingException
```

```java
UID    Message UID
null   UID
```

**getMessagesByUID**

Get the Messages specified by the given array of UIDs. If any UID is invalid, null is returned for that entry.

Note that the returned array will be of the same size as the specified array of UIDs, and null entries may be present in the array to indicate invalid UIDs.

**Parameters:**
- uids - array of UIDs

**Returns:**
public long getUID(Message message) throws MessagingException

Get the UID for the specified message. Note that the message must belong to this folder. Otherwise java.util.NoSuchElementException is thrown.

Parameters:
message - Message from this folder

Returns:
UID for this message

Throws:
java.util.NoSuchElementException - if the given Message is not in this Folder.
MessagingException

<tbody>
<tr>
<td>static <strong>UIDFolder.FetchProfileItem</strong></td>
<td><strong>UID</strong> is a fetch profile item that can be included in a FetchProfile during a fetch request to a Folder.</td>
</tr>
</tbody>
</table>

**Fields inherited from class javax.mail.FetchProfile.Item**
UID

public static final UIDFolder.FetchProfileItem UID

UID is a fetch profile item that can be included in a FetchProfile during a fetch request to a Folder. This item indicates that the UIDs for messages in the specified range are desired to be prefetched.

An example of how a client uses this is below:

```java
FetchProfile fp = new FetchProfile();
fp.add(UIDFolder.FetchProfileItem.UID);
folder.fetch(msgs, fp);
```
protected UIDFolder.FetchProfileItem(String name)

javax.faces.component Class UIForm

java.lang.Object  
   javax.faces.component.UIComponent  
      javax.faces.component.UIComponentBase  
         javax.faces.component.UIForm

All Implemented Interfaces:
   NamingContainer, StateHolder

Direct Known Subclasses:
   HtmlForm

public class UIForm
extends UIComponentBase
implements NamingContainer

Extends: UIComponent > UIComponentBase
Implements: NamingContainer
Extended by: HtmlForm

UIForm UIComponent

   rendererType "javax.faces.Form"   setRendererType()

UIForm is a UIComponent that represents an input form to be presented to the user, and whose child components represent (among other things) the input fields to be included when the form is submitted.

By default, the rendererType property must be set to "javax.faces.Form". This value can be changed by calling the setRendererType() method.

Field Summary
### Constructor Summary

**UIForm()**  
Create a new `UIForm` instance with default property values.

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>getContainerClientId(FacesContext context)</code></td>
<td>Override the <code>UIComponent.getContainerClientId(javax.faces.context.FacesContext)</code> to allow users to disable this form from prepending its <code>clientId</code> to descendant's <code>clientIds</code> depending on the value of this form's <code>isPrependId()</code> property.</td>

### Constructor Detail

```java
public UIForm()
```

- **UIForm**
public UIForm()

    Create a new UIForm instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

    Description copied from class: UIComponent

    Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

    Specified by:
        getFamily in class UIComponent

public boolean isSubmitted()

    submitted false #setSubmitted

isSubmitted

public boolean isSubmitted()

    Returns the current value of the submitted property. The default value is false. See setSubmitted(boolean) for details.
public void setSubmitted(boolean submitted)

If this UIForm instance (as opposed to other forms in the page) is experiencing a submit during this request processing lifecycle, this method must be called, with true as the argument, during the UIComponent.decode(javax.faces.context.FacesContext) for this UIForm instance. If this UIForm instance is not experiencing a submit, this method must be called, with false as the argument, during the UIComponent.decode(javax.faces.context.FacesContext) for this UIForm instance.

The value of a UIForm's submitted property must not be saved as part of its state.

public boolean isPrependId()

public void setPrependId(boolean prependId)
setPrependId

public void setPrependId(boolean prependId)

public void processDecodes(FacesContext context)

Throws

NullPointerException: NullPointerException
NullPointerException context null

processDecodes

public void processDecodes(FacesContext context)

Override

UIComponent.processDecodes(javax.faces.context.FacesContext) to ensure that the form is decoded before its children. This is necessary to allow the submitted property to be correctly set.

Overrides:

processDecodes in class UIComponentBase

Parameters:

context - FacesContext for the request we are processing

Throws:

NullPointerException - if context is null

public void processValidators(FacesContext context)

throws

NullPointerException: NullPointerException
NullPointerException context null
processValidators

public void processValidators(FacesContext context)

Override
UIComponent.processValidators(javax.faces.context.FacesContext)
to ensure that the children of this UIForm instance are only processed if isSubmitted() returns true.

Overrides:  
processValidators in class UICOMPONENTBASE

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null

processUpdates

public void processUpdates(FacesContext context)

Override
UIComponent#processUpdates #isSubmitted true
UIForm

Throws
NullPointerException: NullPointerException
NullPointerException context null

processUpdates

public void processUpdates(FacesContext context)

Override
UIComponent.processUpdates(javax.faces.context.FacesContext) to ensure that the children of this UIForm instance are only processed if isSubmitted() returns true.

Overrides:  
processUpdates in class UICOMPONENTBASE

Parameters:
context - FacesContext for the request we are processing
Throws:

`NullPointerException` - if context is null

```java
public String getContainerClientId(FacesContext context)
```

**UIComponent#getContainerClientId**  **#isPrependId**

`clientId`  `clientIds`

**getContainerClientId**

```java
public String getContainerClientId(FacesContext context)
```

Override the `UIComponent.getContainerClientId(javax.faces.context.FacesContext)` to allow users to disable this form from prepending its `clientId` to its descendent's `clientIds` depending on the value of this form's `isPrependId()` property.

**Overrides:**

`getContainerClientId` in class `UIComponent`
javax.faces.component Class UIGraphic

java.lang.Object
    ▼ javax.faces.component.UIComponent
        ▼ javax.faces.component.UIComponentBase
            ▼ javax.faces.component.UIGraphic

All Implemented Interfaces:
    StateHolder

Direct Known Subclasses:
    HtmlGraphicImage

public class UIGraphic
extends UIComponentBase

Extends: UIComponent > UIComponentBase
Extended by: HtmlGraphicImage

UIGraphic  UIComponent

    rendererType "javax.faces.Image"  setRendererType()

UIGraphic is a UIComponent that displays a graphical image to the user. The user cannot manipulate this component; it is for display purposes only.

By default, the rendererType property must be set to "javax.faces.Image". This value can be changed by calling the setRendererType() method.

COMPONENT_TYPE

public static final String COMPONENT_TYPE

   The standard component type for this component.

See Also:
   Constant Field Values

COMPONENT_FAMILY

public static final String COMPONENT_FAMILY

   The standard component family for this component.

See Also:
   Constant Field Values

### Constructor Detail

public UIGraphic()

   UIGraphic

UIGraphic

public UIGraphic()

   Create a new UIGraphic instance with default property values.

### Method Detail
public String getFamily()

getFamily

public String getFamily()

Description copied from class: UICOMPONENT

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Specified by:
   getFamily in class UICOMPONENT

public String getUrl()

getValue()

getUrl()

public String getUrl()

Return the image URL for this UIGraphic. This method is a typesafe alias for getValue().

public void setUrl(String url)

setValue()
**setUrl**

```java
public void setUrl(String url)
```

Set the image URL for this `UIImage`. This method is a typesafe alias for `setValue()`.

**Parameters:**
- `url` - The new image URL

---

**public Object getValue()**

```java
public Object getValue()
```

Returns the `value` property of the `UIImage`. This will typically be rendered as an URL.

---

**public void setValue(Object value)**

```java
public void setValue(Object value)
```

Sets the `value` property of the `UIImage`. This will typically be rendered as an URL.
public **ValueBinding** getValueBinding(String name)

url   ValueBinding   value   ValueBinding

name   ValueBinding

Declares name - Name of the attribute or property for which to retrieve a **ValueBinding**

Throws:  
**NullPointerException** - if name is null

**Deprecated.** *This has been replaced by getValueExpression(java.lang.String).*

Return any **ValueBinding** set for value if a **ValueBinding** for url is requested; otherwise, perform the default superclass processing for this method.

Override:getValueBinding in class UICOMPONENTBase

Parameters:

Throws:

**NumberFormatException** - if name is null

public void setValueBinding(String name, **ValueBinding** binding)

value   url   ValueBinding   ValueBinding

ValueExpression
setValueBinding

```java
public void setValueBinding(String name, ValueBinding binding)
```

**Deprecated.** *This has been replaced by*

```java
setValueExpression(java.lang.String, javax.el.ValueExpression)
```

Store any `ValueBinding` specified for `url` under `value` instead; otherwise, perform the default superclass processing for this method. In all cases, the superclass is relied on to convert the `ValueBinding` to a `ValueExpression`.

**Overrides:**

`setValueBinding` in class `UIComponentBase`

**Parameters:**

- `name` - Name of the attribute or property for which to set a `ValueBinding`
- `binding` - The `ValueBinding` to set, or `null` to remove any currently set `ValueBinding`

**Throws:**

- `NullPointerException` - if `name` is `null`

------------------------

```java
public ValueExpression getValueExpression(String name)
```

```java
url ValueExpression value ValueExpression
```

**Name**

```java
ValueExpression
```

**Throws**

`NullPointerException: name null`

**since**

1.2
getValueExpression

public ValueExpression getValueExpression(String name)

Return any ValueExpression set for value if a ValueExpression for url is requested; otherwise, perform the default superclass processing for this method.

Overrides:
getValueExpression in class UIComponent

Parameters:
name - Name of the attribute or property for which to retrieve a ValueExpression

Throws:
NullPointerException - if name is null

Since:
1.2

public void setValueExpression(String name, ValueExpression binding)

value url ValueExpression

name ValueExpression
binding ValueExpression null ValueExpression

Throws
NullPointerException - name null

since
1.2

setValueExpression

public void setValueExpression(String name, ValueExpression binding)

Store any ValueExpression specified for url under value instead; otherwise, perform the default superclass processing for this method.
Overrides:

```
setValueExpression in class UIComponent
```

Parameters:

```
name - Name of the attribute or property for which to set a ValueExpression
binding - The ValueExpression to set, or null to remove any currently set ValueExpression
```

Throws:

```
NullPointerException - if name is null
```

Since:

```
1.2
```

```java
public Object saveState(FacesContext context)
```

**saveState**

```java
public Object saveState(FacesContext context)
```

**Description copied from interface:** StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UICOMPONENT with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext)` method on all those instances as well. **This method must not save the state of children and facets.** That is done via the `StateManager`

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be `Serializable`
public void restoreState(FacesContext context, Object state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by: restoreState in interface StateHolder
Overrides: restoreState in class UIComponentBase
PS:
javax.faces.component  Class UIInput

java.lang.Object
  └─javax.faces.component.UIComponent
      └─javax.faces.component.UIComponentBase
          └─javax.faces.component.UIOutput
              └─javax.faces.component.UIInput

All Implemented Interfaces:
   EditableValueHolder, StateHolder, ValueHolder

Direct Known Subclasses:
   HtmlInputHidden, HtmlInputSecret, HtmlInputText,
   HtmlInputTextarea, UISelectBoolean, UISelectMany, UISelectOne

public class UIInput
extends UIOutput
implements EditableValueHolder

Extends: UIComponent > UIComponentBase > UIOutput
Implements: EditableValueHolder
Extended by: HtmlInputHidden, HtmlInputSecret, HtmlInputText,
            HtmlInputTextarea, UISelectBoolean, UISelectMany, UISelectOne

UIInput  UIComponent  UIOutput
javax.faces.render.Renderer

    setSubmittedValue() String  null
    setValue()        immediate  true

UIOutput

UIInput  validate()  ValueChangeEvent
broadcast()  immediate  true

rendererType "Text"  setRendererType()
**UIInput** is a **UIComponent** that represents a component that both displays output to the user (like **UIOutput** components do) and processes request parameters on the subsequent request that need to be decoded. There are no restrictions on the data type of the local value, or the object referenced by the value binding expression (if any); however, individual **Renderer**s will generally impose restrictions on the type of data they know how to display.

During the **Apply Request Values** phase of the request processing lifecycle, the decoded value of this component, usually but not necessarily a String, must be stored - but not yet converted - using `setSubmittedValue()`. If the component wishes to indicate that no particular value was submitted, it can either do nothing, or set the submitted value to `null`.

By default, during the **Process Validators** phase of the request processing lifecycle, the submitted value will be converted to a typesafe object, and, if validation succeeds, stored as a local value using `setValue()`. However, if the `immediate` property is set to `true`, this processing will occur instead at the end of the **Apply Request Values** phase.

During the **Render Response** phase of the request processing lifecycle, conversion for output occurs as for **UIOutput**.

When the `validate()` method of this **UIInput** detects that a value change has actually occurred, and that all validations have been successfully passed, it will queue a **ValueChangeEvent**. Later on, the `broadcast()` method will ensure that this event is broadcast to all interested listeners. This event will be delivered by default in the **Process Validators** phase, but can be delivered instead during **Apply Request Values** if the `immediate` property is set to `true`.

By default, the `rendererType` property must be set to "Text". This value can be changed by calling the `setRendererType()` method.

</tbody>
</table>
void Decode any new state of this UIComponent from the specified FacesContext, and store this state as needed.

protected Object getConvertedValue(FacesContext context, Object newSubmittedValue)
Convert the submitted value into a "local value" of the type, if necessary.

String getConverterMessage()
If there has been a call to setConverterMessage(), this instance, return the message.

String getFamily()
Return the identifier of the component family to which this belongs.

String getRequiredMessage()
If there has been a call to setRequiredMessage(), this instance, return the message.

Object getSubmittedValue()
Return the submittedValue value of this UIInput component.

MethodBinding getValidator()
Deprecated. getValidators() should be used instead.

String getValidatorMessage()
If there has been a call to setRequiredMessage(), this instance, return the message.

Validator[] getValidators()
Return the set of registered Validators for this UIInput component.

MethodBinding getValueChangeListener()
If EditableValueHolder.setValueChangeListener() was not previously called for this instance, this method

ValueChangeListener[] getValueChangeListeners()
Return the set of registered ValueChangeListener instance.

boolean isImmediate()
Return the "immediate" state for this component.

boolean isLocalValueSet()
Return the "local value set" state for this component.

boolean isRequired()

**Constructor Detail**

public UIInput()

UIInput

UIInput

public UIInput()

Create a new UIInput instance with default property values.

---

**Method Detail**

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UICOMPONENT
Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Overrides:

\texttt{getFamily} in class \texttt{UIOutput}

---

\textbf{public Object getSubmittedValue()}

\underline{UIInput} \texttt{submittedValue} \hspace{1cm} \underline{Renderer} \texttt{decode()}

\texttt{validate()}

---

\textbf{getSubmittedValue}

\textbf{public Object getSubmittedValue()}

Return the submittedValue value of this \texttt{UIInput} component. This method should only be used by the \texttt{decode()} and \texttt{validate()} method of this component, or its corresponding \texttt{Renderer}.

\textbf{Specified by:}

\texttt{getSubmittedValue} in interface \texttt{EditableValueHolder}

---

\textbf{public void setSubmittedValue(Object submittedValue)}

\underline{UIInput} \texttt{submittedValue} \hspace{1cm} \underline{Renderer} \texttt{decode()}

\texttt{validate()}

\textit{submittedValue}

---

\textbf{setSubmittedValue}
public void `setSubmittedValue`(`Object` submittedValue)

Set the submittedValue value of this `UIInput` component. This method should only be used by the `decode()` and `validate()` method of this component, or its corresponding `Renderer`.

**Specified by:**  
`setSubmittedValue` in interface `EditableValueHolder`  
**Parameters:**  
submittedValue - The new submitted value

---

public void `setValue`(`Object` value)

**setValue**

public void `setValue`(`Object` value)

Description copied from interface: `ValueHolder`

Set the value of this `UIComponent` (if any).

**Specified by:**  
`setValue` in interface `ValueHolder`  
**Overrides:**  
`setValue` in class `UIOutput`  
**Parameters:**  
value - The new local value

---

public void `resetValue`()

#`setValue` null

#`setSubmittedValue` null
resetValue

public void resetValue()

    Convenience method to reset this component's value to the uninitialized state. This method does the following:

    Call setValue(java.lang.Object) passing null.
    Call setSubmittedValue(java.lang.Object) passing null.
    Call setLocalValueSet(boolean) passing false.
    Call setValid(boolean) passing true.

    Upon return from this call if the instance had a ValueBinding associated with it for the "value" property, this binding is evaluated when UIOutput.getValue() is called. Otherwise, null is returned from getValue().

public boolean isLocalValueSet()
"local value set" setValue() true

isLocalValueSet

public boolean isLocalValueSet()
Return the "local value set" state for this component. Calls to setValue() automatically reset this property to true.

**Specified by:**
`isLocalValueSet` in interface `EditableValueHolder`

```java
public void setLocalValueSet(boolean localValueSet)

"local value set"
```

**setLocalValueSet**

```java
public void setLocalValueSet(boolean localValueSet)

Sets the "local value set" state for this component.

**Specified by:**
`setLocalValueSet` in interface `EditableValueHolder`
```

```java
public boolean isRequired()

"required field"
```

**isRequired**

```java
public boolean isRequired()

Return the "required field" state for this component.

**Specified by:**
`isRequired` in interface `EditableValueHolder`
```

```java
public String getRequiredMessage()
```
getRequiredMessage

public String getRequiredMessage()

If there has been a call to setRequiredMessage(java.lang.String) on this instance, return the message. Otherwise, call UIComponent.getValueExpression(java.lang.String) passing the key "requiredMessage", get the result of the expression, and return it. Any ELExceptions thrown during the call to getValue() must be wrapped in a FacesException and rethrown.

setRequiredMessage

public void setRequiredMessage(String message)

Override any ValueExpression set for the "requiredMessage" with the literal argument provided to this method. Subsequent calls to getRequiredMessage() will return this value;

Parameters:
message - the literal message value to be displayed in the event the user hasn't supplied a value and one is required.
public String getConverterMessage()

    #setConverterMessage #getValueExpression
    "converterMessage" getVa] FacesException

getConverterMessage

public String getConverterMessage()

    If there has been a call to setConverterMessage(java.lang.String) on this instance, return the message. Otherwise, call UIComponent.getValueExpression(java.lang.String) passing the key "converterMessage", get the result of the expression, and return it. Any ELExceptions thrown during the call to getValue() must be wrapped in a FacesException and rethrown.

public void setConverterMessage(String message)

    "converterMessage" ValueExpression #getConverterMessage

    message

setConverterMessage

public void setConverterMessage(String message)

    Override any ValueExpression set for the "converterMessage" with the literal argument provided to this method. Subsequent calls to getConverterMessage() will return this value;

    Parameters:
        message - the literal message value to be displayed in the event
public String getValidatorMessage()

    #setRequiredMessage  #getValueExpression
"requiredMessage"  getValue()
FacesException

getValidatorMessage

public String getValidatorMessage()

    If there has been a call to setRequiredMessage(java.lang.String) on this instance, return the message. Otherwise, call UICOMPONENT.getVALUEEXPRESSION(java.lang.String) passing the key "requiredMessage", get the result of the expression, and return it. Any ELException s thrown during the call to getValue() must be wrapped in a FacesException and rethrown.

public void setValidatorMessage(String message)

    "validatorMessage"  valueExpression
#getValueExpression
message

setValidatorMessage

public void setValidatorMessage(String message)

    Override any ValueExpression set for the "validatorMessage" with the literal argument provided to this method. Subsequent calls to
getValidatorMessage() will return this value;

**Parameters:**
message - the literal message value to be displayed in the event validation fails.

```
public boolean isValid()
```

**isValid**

```
public boolean isValid()
```

**Description copied from interface:** EditableValueHolder

Return a flag indicating whether the local value of this component is valid (no conversion error has occurred).

**Specified by:**
isValid in interface EditableValueHolder

```
public void setValid(boolean valid)
```

**setValid**

```
public void setValid(boolean valid)
```

**Description copied from interface:** EditableValueHolder

Set a flag indicating whether the local value of this component is valid (no conversion error has occurred).

**Specified by:**
setValid in interface EditableValueHolder

**Parameters:**
valid - The new valid flag
public void setRequired(boolean required)

"required field"

required "required field"

setRequired

class

class

public void setRequired(boolean required)

Set the "required field" state for this component.

Specified by:

setRequired in interface EditableValueHolder

Parameters:

required - The new "required field" state

Description copied from interface: EditableValueHolder

Return the "immediate" state for this component.

Specified by:

isImmediate in interface EditableValueHolder

isImmediate

public boolean isImmediate()

public void setImmediate(boolean immediate)
**setImmediate**

```java
public void setImmediate(boolean immediate)
```

**Description copied from interface:** [EditableValueHolder](#)

Set the "immediate" state for this component. When set to true, the component's value will be converted and validated immediately in the Apply Request Values phase, and [ValueChangeEvent](#)s will be delivered in that phase as well. The default value for this property must be false.

**Specified by:**
- [setImmediate](#) in interface [EditableValueHolder](#)

**Parameters:**
- immediate - The new "immediate" state

---

**public MethodBinding getValidator()**

```java
MethodBinding getValidator()
```

**MethodBinding**

```java
deprecated
```

**getValidator**

```java
public MethodBinding getValidator()
```

**Deprecated. getValidators() should be used instead.**

Return a MethodBinding pointing at a method that will be called during Process Validations phase of the request processing lifecycle, to validate the current value of this component.

**Specified by:**
- [getValidator](#) in interface [EditableValueHolder](#)
public void setValidator(MethodBinding validatorBinding)

MethodBinding

void FacesContext UIComponent Object

validatorBinding MethodBinding

deprecated javax.faces.validator.MethodExpressionValidator

Validator

setValidator

public void setValidator(MethodBinding validatorBinding)

Deprecated. Use addValidator(javax.faces.validator.Validator) instead, obtaining the argument Validator by creating an instance of MethodExpressionValidator.

Set a MethodBinding pointing at a method that will be called during Process Validations phase of the request processing lifecycle, to validate the current value of this component.

Any method referenced by such an expression must be public, with a return type of void, and accept parameters of type FacesContext, UIComponent, and Object.

Specified by:
setValidator in interface EditableValueHolder

Parameters:
validatorBinding - The new MethodBinding instance

public MethodBinding getValueChangeListener()

g getValueChangeListe
public MethodBinding getValueChangeListener()

Description copied from interface: EditableValueHolder

If EditableValueHolder.setValueChangeListener(javax.faces.el.MethodBinding) was not previously called for this instance, this method must return null. If it was called, this method must return the exact MethodBinding instance that was passed to EditableValueHolder.setValueChangeListener(javax.faces.el.MethodBinding)

Specified by:
   getValueChangeListener in interface EditableValueHolder

public void setValueChangeListener(MethodBinding valueChangeListener)

NullPointerException

ValueChangeListener valueChangeMethod

#getValueChangeListeners setValueChangeListener

immediate

void javax.faces.event.ValueChangeEvent

deprecated javax.faces.event.MethodExpressionValueChangeListener

setValueChangeListener

public void setValueChangeListener(MethodBinding valueChangeListener)

Deprecated. Use addValueChangeListener(javax.faces.event.ValueChangeListener) instead, obtaining the argument ValueChangeListener by creating an instance of MethodExpressionValueChangeListener.
Wrap the argument valueChangeMethod in an implementation of ValueChangeListener and store it in the internal data structure that backs the EditableValueHolder.getValueChangeListeners() method, taking care to over-write any instance that was stored by a previous call to setValueChangeListener.

This argument method will be called during the Process Validations or Apply Request Values phases (depending on the value of the immediate property).

Any method referenced by such an expression must be public, with a return type of void, and accept a parameter of type ValueChangeEvent.

Specified by:
setValueChangeListener in interface EditableValueHolder

Parameters:
valueChangeListener - The new method binding instance

```
public void processDecodes(FacesContext context)

setErrorComponentProperty(UIComponentBase component, String property, String newValue, UIComponent originalComponent)

processDecodes(FacesContext context)

UIComponentBase processDecodes immediate
true validate() RuntimeException
FacesContext#renderResponse

throws

NullPointerException: NullPointerException

processDecodes

public void processDecodes(FacesContext context)

Specialized decode behavior on top of that provided by the superclass. In addition to the standard processDecodes behavior inherited from UIComponentBase, calls validate() if the immediate property is true; if the component is invalid afterwards or a
 RuntimeException is thrown, calls FacesContext.renderResponse().

Overrides: processDecodes in class UIComponentBase

Parameters: context - FacesContext for the request we are processing

Throws: NullPointerException - if context is null

public void processValidators(FacesContext context)

 In addition to the standard processValidators behavior inherited from UIComponentBase, calls validate() if the immediate property is false (which is the default); if the component is invalid afterwards, calls FacesContext.renderResponse(). If a RuntimeException is thrown during validation processing, calls FacesContext.renderResponse() and re-throw the exception.

Overrides: processValidators in class UIComponentBase

Parameters: context - FacesContext for the request we are processing

Throws: NullPointerException - if context is null
public void processUpdates(FacesContext context)

    public void processUpdates(FacesContext context)

    In addition to the standard processUpdates behavior inherited from UIComponentBase, calls updateModel(). If the component is invalid afterwards, calls FacesContext.renderResponse(). If a RuntimeException is thrown during update processing, calls FacesContext.renderResponse() and re-throw the exception.

    Overrides:
        processUpdates in class UIComponentBase

    Parameters:
        context - FacesContext for the request we are processing

    Throws:
        NullPointerException - if context is null

public void decode(FacesContext context)

    public void decode(FacesContext context)
Description copied from class: `UIComponent`

Decode any new state of this `UIComponent` from the request contained in the specified `FacesContext`, and store this state as needed.

During decoding, events may be enqueued for later processing (by event listeners who have registered an interest), by calling `queueEvent()`.

**Overrides:**

`decode` in class `UIComponentBase`

**Parameters:**

- `context` - `FacesContext` for the request we are processing

**Throws:**

- `NullPointerException` - if `context` is `null`

---

```java
public void updateModel(FacesContext context)
```

- `UIInput`

  - `valid` false
  - `localValueSet` false
  - `value` `ValueExpression`
  - `ValueExpression` `setValue()` `ValueExpression`
  - `setValue()`
    - `UIInput`
    - `UIInput` `localValueSet` false
  - `setValue()`
    - `FacesContext` `addMessage()`
    - `UIInput` `valid` false

**Throws**

`NullPointerException: context null`
updateModel

public void updateModel(FacesContext context)

Perform the following algorithm to update the model data associated with this UIInput, if any, as appropriate.

- If the valid property of this component is false, take no further action.
- If the localValueSet property of this component is false, take no further action.
- If no ValueExpression for value exists, take no further action.
- Call setValue() method of the ValueExpression to update the value that the ValueExpression points at.
- If the setValue() method returns successfully:
  - Clear the local value of this UIInput.
  - Set the localValueSet property of this UIInput to false.
- If the setValue() method call fails:
  - Enqueue an error message by calling addMessage() on the specified FacesContext instance.
  - Set the valid property of this UIInput to false.

Parameters:
context - FacesContext for the request we are processing

Throws:
NullPointerException - if context is null

public void validate(FacesContext context)

UIInput

- getSubmittedValue() null
- #getConvertedValue "local value"
- #validateValue
- valid true getValue() setValue()
- null ValueChangeEvent
validate

```java
public void validate(FacesContext context)
```

Perform the following algorithm to validate the local value of this `UIInput`.

- Retrieve the submitted value with `getSubmittedValue()`. If this returns null, exit without further processing. (This indicates that no value was submitted for this component.)
- Convert the submitted value into a "local value" of the appropriate data type by calling `getConvertedValue(javax.faces.context.FacesContext, java.lang.Object)`.
- Validate the property by calling `validateValue(javax.faces.context.FacesContext, java.lang.Object)`.
- If the `valid` property of this component is still `true`, retrieve the previous value of the component (with `getValue()`), store the new local value using `setValue()`, and reset the submitted value to null. If the local value is different from the previous value of this component, fire a `ValueChangeEvent` to be broadcast to all interested listeners.

Application components implementing `UIInput` that wish to perform validation with logic embedded in the component should perform their own correctness checks, and then call the `super.validate()` method to perform the standard processing described above.

**Parameters:**
- `context` - The `FacesContext` for the current request

**Throws:**
- `NullPointerException` - if `context` is null
protected Object getConvertedValue(FacesContext context, Object newSubmittedValue) throws ConverterException

"local value"

- Renderer getConvertedValue()
- Renderer String Converter
  - getConverter() null Converter
  - value getType()
    - null String
    - Application.createConverter(Class)
      Converter
- ConvertergetAsObject()
  - FacesContext addMessage()
  - valid false

getConvertedValue

protected Object getConvertedValue(FacesContext context, Object newSubmittedValue) throws ConverterException

Convert the submitted value into a "local value" of the appropriate data type, if necessary. Employ the following algorithm to do so:

- If a Renderer is present, call getConvertedValue() to convert the submitted value.
- If no Renderer is present, and the submitted value is a String, locate a Converter as follows:
  - If getConverter() returns a non-null Converter, use that
instance.
  • Otherwise, if a value binding for value exists, call getType() on it.
    • If this call returns null, assume the output type is String and perform no conversion.
    • Otherwise, call Application.createConverter(Class) to locate any registered Converter capable of converting data values of the specified type.
  • If a Converter instance was located, call itsgetAsObject() method to perform the conversion. If conversion fails:
    • Enqueue an appropriate error message by calling the addMessage() method on the FacesContext.
    • Set the valid property on this component to false
  • Otherwise, use the submitted value without any conversion

This method can be overridden by subclasses for more specific behavior.

Throws:
  ConverterException

protected void validateValue(FacesContext context, Object newValue)

"valid"

  • valid true required true"empty"
  null 0 String
    • FacesContext addMessage()
      #getRequiredMessage null FacesContext
      FacesMessage summary detail
      #REQUIRED_MESSAGE_ID
    • valid false

  • valid true UIInput Validator validate()
    validatorBinding ValidatorException
      FacesContext valid false
validateValue

protected void validateValue(FacesContext context, Object newValue)

Set the "valid" property according to the below algorithm.

- If the valid property on this component is still true, and the required property is also true, ensure that the local value is not empty (where "empty" is defined as null or a zero-length String). If the local value is empty:
  - Enqueue an appropriate error message by calling the addMessage() method on the FacesContext instance for the current request. If the getRequiredMessage() returns non-null, use the value as the summary and detail in the FacesMessage that is enqueued on the FacesContext, otherwise use the message for the REQUIRED_MESSAGE_ID.
  - Set the valid property on this component to false.
- If the valid property on this component is still true, and the local value is not empty, call the validate() method of each Validator registered for this UIInput, followed by the method pointed at by the validatorBinding property (if any). If any of these validators or the method throws a ValidatorException, catch the exception, add its message (if any) to the FacesContext, and set the valid property of this component to false.

protected boolean compareValues(Object previous, Object value)

  true

    previous
    value
compareValues

protected boolean compareValues(Object previous, Object value)

Return true if the new value is different from the previous value.

Parameters:
previous - old value of this component (if any)
value - new value of this component (if any)

public void addValidator(Validator validator)

Validator UIInput

validator
Throws
Validator
NullPointerException: validator null

addValidator

public void addValidator(Validator validator)

Add a Validator instance to the set associated with this UIInput.

Specified by:
addValidator in interface EditableValueHolder

Parameters:
validator - The Validator to add

Throws:
NullPointerException - if validator is null

public Validator[] getValidators()
getValidators

public Validator[] getValidators()

Return the set of registered Validators for this UIInput instance. If there are no registered validators, a zero-length array is returned.

Specified by: getValidators in interface EditableValueHolder

public void removeValidator(Validator validator)

Remove a Validator instance from the set associated with this UIInput, if it was previously associated. Otherwise, do nothing.

Specified by: removeValidator in interface EditableValueHolder
Parameters:
 validator - The Validator to remove

public void addValueChangeListener(ValueChangeListener listener)

ValueChangeEvent ValueChangeListener
addValueChangeListener

public void addValueChangeListener(ValueChangeListener listener)

Add a new ValueChangeListener to the set of listeners interested in being notified when ValueChangeEvent occurs.

Specified by:
    addValueChangeListener in interface EditableValueHolder

Parameters:
    listener - The ValueChangeListener to be added

Throws:
    NullPointerException - if listener is null

-------------------------------------------

public ValueChangeListener[] getValueChangeListeners()

UIInput    ValueChangeListener  0

getValueChangeListeners

public ValueChangeListener[] getValueChangeListeners()

Return the set of registered ValueChangeListenerS for this UIInput instance. If there are no registered listeners, a zero-length array is returned.

Specified by:
    getValueChangeListeners in interface EditableValueHolder

-------------------------------------------

public void
removeValueChangeListener

**ValueChangeEvent**  **ValueChangeListener**

<table>
<thead>
<tr>
<th>listener</th>
<th>ValueChangeListener</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td>NullPointerException: listener null</td>
</tr>
</tbody>
</table>

**removeValueChangeListener**

```java
public void removeValueChangeListener(ValueChangeListener listener)
```

Remove an existing `ValueChangeListener` (if any) from the set of listeners interested in being notified when `ValueChangeEvent`s occur.

**Specified by:**

`removeValueChangeListener` in interface `EditableValueHolder`

**Parameters:**

- `listener` - The `ValueChangeListener` to be removed

**Throws:**

- `NullPointerException` - if `listener` is null

---

**public Object saveState(FacesContext context)**

**saveState**

```java
public Object saveState(FacesContext context)
```

**Description copied from interface: StateHolder**

Gets the state of the instance as a `Serializable` Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a `UIComponent` with event handlers, validators, etc.) this method must call the
StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. **This method must not save the state of children and facets.** That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

```
Object state = component.saveState(facesContext);
```

component should be the same as before executing it.

The return from this method must be Serializable

**Specified by:**
saveState in interface StateHolder

**Overrides:**
saveState in class UIOutput

---

**public void restoreState(FacesContext context, Object state)**

restoreState

**public void restoreState(FacesContext context,**
**Object state)**

**Description copied from interface:** StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.
Specified by:  
`restoreState` in interface `StateHolder`

Overrides:  
`restoreState` in class `UIOutput`
javax.faces.component Class UIMessage

java.lang.Object
   └─javax.faces.component.UIComponent
       └─javax.faces.component.UIComponentBase
           └─javax.faces.component.UIMessage

All Implemented Interfaces:
   StateHolder

Direct Known Subclasses:
   HtmlMessage

public class UIMessage
    extends UIComponentBase

Extends: UIComponent > UIComponentBase
Extended by: HtmlMessage

    clientId   UIComponent   FacesContext
    
    rendererType "javax.faces.Message"   setRendererType()

This component is responsible for displaying messages for a specific UIComponent, identified by a clientId. The component obtains the messages from the FacesContext.

By default, the rendererType property must be set to "javax.faces.Message". This value can be changed by calling the setRendererType() method.

Field Summary
### Constructor Summary

**UIMessage()**
Create a new UIMessage instance with default property values.

### Method Summary

COMPONENT_FAMILY

public static final String COMPONENT_FAMILY

The standard component family for this component.

See Also:
Constant Field Values

Constructor Detail

public UIMessage()

UIMessage

UIMessage

public UIMessage()

Create a new UIMessage instance with default property values.

Method Detail

public String getFamily()

ggetFamily

public String getFamily()
Description copied from class: [UIComponent](#)

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Specified by:  
  [getFamily](#) in class [UIComponent](#)

---

**public String getFor()**

---

### getFor

**public String getFor()**

Return the client identifier of the component for which this component represents associated message(s) (if any).

---

**public void setFor(String newFor)**

---

### setFor

**public void setFor(String newFor)**

Set the client identifier of the component for which this component represents associated message(s) (if any). This property must be set
before the message is displayed.

**Parameters:**
- `newFor` - The new client id

---

```java
public boolean isShowDetail()
{
    return true;
}
```

**isShowDetail**

Public boolean `isShowDetail()`

Return the flag indicating whether the `detail` property of the associated message(s) should be displayed. Defaults to `true`.

---

```java
public void setShowDetail(boolean showDetail)
{
    this.showDetail = showDetail;
}
```

**setShowDetail**

Public void `setShowDetail(boolean showDetail)`

Set the flag indicating whether the `detail` property of the associated message(s) should be displayed.

**Parameters:**
- `showDetail` - The new flag
public boolean isShowSummary()

    summary false

isShowSummary

public boolean isShowSummary()

    Return the flag indicating whether the summary property of the associated message(s) should be displayed. Defaults to false.

public void setShowSummary(boolean showSummary)

    summary

        showSummary

setShowSummary

public void setShowSummary(boolean showSummary)

    Set the flag indicating whether the summary property of the associated message(s) should be displayed.

    Parameters:
        showSummary - The new flag value

public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)
Description copied from interface: **StateHolder**

Gets the state of the instance as a **Serializable** Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a **UIComponent** with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext)` method on all those instances as well. **This method must not save the state of children and facets.** That is done via the **StateManager**

This method must not alter the state of the implementing object. In other words, after executing this code:

```java
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be **Serializable**

**Specified by:**

- `saveState` in interface **StateHolder**

**Overrides:**

- `saveState` in class **UIComponentBase**

---

**public void restoreState(FacesContext context, Object state)**

**restoreState**

**public void restoreState(FacesContext context, Object state)**

**Description copied from interface: **StateHolder**

Perform any processing required to restore the state from the entries in the state Object.
If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by:
restoreState in interface StateHolder

Overrides:
restoreState in class UIComponentBase
javax.faces.component Class UIMessages

java.lang.Object
   └─javax.faces.component.UIComponent
        └─javax.faces.component.UIComponentBase
            └─javax.faces.component.UIMessages

All Implemented Interfaces:
   StateHolder

Direct Known Subclasses:
   HtmlMessages

public class UIMessages
    extends UIComponentBase

Extends: UIComponent > UIComponentBase
Extended by: HtmlMessages

renderer    FacesContext

   Messages renderer

   rendererType "javax.faces.Messages"    setRendererType()

The renderer for this component is responsible for obtaining the messages from the FacesContext and displaying them to the user.

This component supports the Messages renderer-type.

By default, the rendererType property must be set to "javax.faces.Messages". This value can be changed by calling the setRendererType() method.

- Constant Field Values

**Constructor Detail**

```java
public UINamingContainer()
```

**UINamingContainer**

```java
public UINamingContainer()
```
Create a new `UINamingContainer` instance with default property values.

**Method Detail**

```java
public String getFamily()
```

### getFamily

```java
public String getFamily()
```

**Description copied from class:** `UIComponent`

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the `rendererType` property, may be used to select the appropriate `Renderer` for this component instance.

**Specified by:**

`getFamily` in class `UIComponent`

          └─ javax.faces.component.UIOutput

All Implemented Interfaces:
  StateHolder, ValueHolder

Direct Known Subclasses:
  HtmlOutputFormat, HtmlOutputLabel, HtmlOutputLink, HtmlOutputText, UIInput

public class UIOutput

extends UIComponentBase
implements ValueHolder

Extends: UIComponent > UIComponentBase
Implements: ValueHolder
Extended by: HtmlOutputFormat, HtmlOutputLabel, HtmlOutputLink, HtmlOutputText, UIInput

UIOutput  UIComponent Bean

String String

  • null String Converter
      ◦ getConverter() null Converter Converter
      ◦ Application.createConverter(Class) null Converter Converter
  • null Converter getString()
  • null Converter toString()

rendererType "javax.faces.Text" setRendererType()
UIOutput is a UIComponent that has a value, optionally retrieved from a model tier bean via a value expression, that is displayed to the user. The user cannot directly modify the rendered value; it is for display purposes only.

During the Render Response phase of the request processing lifecycle, the current value of this component must be converted to a String (if it is not already), according to the following rules:

- If the current value is not null, and is not already a String, locate a Converter (if any) to use for the conversion, as follows:
  - If getConverter() returns a non-null Converter, use that one, otherwise
  - If Application.createConverter(Class), passing the current value's class, returns a non-null Converter, use that one.
- If the current value is not null and a Converter was located, call its getAsString() method to perform the conversion.
- If the current value is not null but no Converter was located, call toString() on the current value to perform the conversion.

By default, the rendererType property must be set to "javax.faces.Text". This value can be changed by calling the setRendererType() method.

public UIOutput()

UIOutput

public UIOutput()

Create a new UIOutput instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UIComponent

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Specified by:

getFamily in class UIComponent

public Converter getConverter()

getConverter
public Converter getConverter()

Description copied from interface: ValueHolder

Return the Converter (if any) that is registered for this UIComponent.

Specified by: getConverter in interface ValueHolder

public void setConverter(Converter converter)

setConverter

public void setConverter(Converter converter)

Description copied from interface: ValueHolder

Set the Converter (if any) that is registered for this UIComponent.

Specified by: setConverter in interface ValueHolder

Parameters:
  converter - New Converter (or null)

public Object getLocalValue()

getLocalValue

public Object getLocalValue()

Description copied from interface: ValueHolder

Return the local value of this UIComponent (if any), without evaluating any associated ValueExpression.
public Object getValue()

getValue

public Object getValue()

Description copied from interface: ValueHolder

 Gets the value of this UICOMPONENT. First, consult the local value property of this component. If non-null return it. If null, see if we have a ValueExpression for the value property. If so, return the result of evaluating the property, otherwise return null. Note that because the specification for UICOMPONENT.setValueBinding(java.lang.String, javax.faces.el.ValueBinding) requires a call through to UICOMPONENT.setValueExpression(java.lang.String, javax.el.ValueExpression), legacy tags will continue to work.

Specified by: getValue in interface ValueHolder

public void setValue(Object value)

setValue

public void setValue(Object value)

Description copied from interface: ValueHolder

Set the value of this UICOMPONENT (if any).

Specified by: setValue in interface ValueHolder
Parameters:
  value - The new local value

public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via theStateManager.

This method must not alter the state of the implementing object. In other words, after executing this code:

    Object state = component.saveState(facesContext);

component should be the same as before executing it.

The return from this method must be Serializable

Specified by: saveState in interface StateHolder

Overrides: saveState in class UIComponentBase

public void restoreState(FacesContext context, Object
public void restoreState(FacesContext context, Object state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.

Specified by:
restoreState in interface StateHolder

Overrides:
restoreState in class UICOMPONENTBASE
javax.faces.component Class UIPanel

java.lang.Object
  └─javax.faces.component.UIComponent
    └─javax.faces.component.UIComponentBase
        └─javax.faces.component.UIPanel

All Implemented Interfaces:
  StateHolder

Direct Known Subclasses:
  HtmlPanelGrid, HtmlPanelGroup

public class UIPanel
  extends UIComponentBase

Extends: UIComponent > UIComponentBase
Extended by: HtmlPanelGrid, HtmlPanelGroup

UIPanel is a UIComponent that manages the layout of its child components.

javax.faces.component Class UIParameter

java.lang.Object
  ↑  javax.faces.component.UIComponent
  |  ↑  javax.faces.component.UIComponentBase
  |  ↑  javax.faces.component.UIParameter

All Implemented Interfaces:
  StateHolder

public class UIParameter
    extends UIComponentBase

Extends: UIComponent > UIComponentBase

UIParameter  UIComponent,

    getValue()         setValue()

    getValue()   UIParameter
javax.faces.render_RENDERER

UIParameter is a UIComponent that represents an optionally named configuration parameter for a parent component.

Parent components should retrieve the value of a parameter by calling getValue(). In this way, the parameter value can be set directly on the component (via setValue()), or retrieved indirectly via the value binding expression.

In some scenarios, it is necessary to provide a parameter name, in addition to the parameter value that is accessible via the getValue() method. Renderers that support parameter names on their nested UIParameter child components should document their use of this property.

Constructor Detail

public UIParameter()

UIParameter

UIParameter

public UIParameter()

Create a new UIParameter instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UIComponent

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.
public String getName()

getName

public String getName()

Return the optional parameter name for this parameter.

public void setName(String name)

setName

public void setName(String name)

Set the optional parameter name for this parameter.

Parameters:
  name - The new parameter name, or null for no name

public Object getValue()

getValue

public Object getValue()

UIParameter value
getValue

public Object getValue()

Returns the value property of the UIParameter.

setValue

public void setValue(Object value)

UIParameter value

Sets the value property of the UIParameter.

Parameters:
value - the new value

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to
instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via the StateManager.

This method must not alter the state of the implementing object. In other words, after executing this code:

```java
Object state = component.saveState(facesContext);
```

component should be the same as before executing it.

The return from this method must be Serializable.

Specified by:
- saveState in interface StateHolder

Overrides:
- saveState in class UIComponentBase

```java
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface:** StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, Object state).
java.lang.Object) method on all those instances as well.

Specified by:
   restoreState in interface StateHolder

Overrides:
   restoreState in class UIComponentBase
javax.faces.component  Class UISelectBoolean

java.lang.Object
  ▼ javax.faces.component.UIComponent
    ▼ javax.faces.component.UIComponentBase
      ▼ javax.faces.component.UIOutput
        ▼ javax.faces.component.UIInput
          ▼ javax.faces.component.UISelectBoolean

All Implemented Interfaces:
  EditableValueHolder, StateHolder, ValueHolder

Direct Known Subclasses:
  HtmlSelectBooleanCheckbox

public class UISelectBoolean
  extends UIInput

Extends: UIComponent > UIComponentBase > UIOutput > UIInput
Extended by: HtmlSelectBooleanCheckbox

UISelectBoolean  boolean  true  false  UIComponent

  rendererType "javax.faces.Checkbox"  setRendererType()

UISelectBoolean is a UIComponent that represents a single boolean (true or false) value. It is most commonly rendered as a checkbox.

By default, the rendererType property must be set to "javax.faces.Checkbox". This value can be changed by calling the setRendererType() method.

**Constructor Detail**

public UISelectBoolean()
public UISelectBoolean()

Create a new UISelectBoolean instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UICOMPONENT

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Overrides:

getFamily in class UINPUT

public boolean isSelected()

isSelected

getValue()
public boolean isSelected()

    Return the local value of the selected state of this component. This method is a typesafe alias for getValue().

public void setSelected(boolean selected)

    setValue()

    selected

setSelected

public void setSelected(boolean selected)

    Set the local value of the selected state of this component. This method is a typesafe alias for setValue().

    Parameters:
    selected - The new selected state

public ValueBinding getValueBinding(String name)

    selected   ValueBinding  value   ValueBinding
    ValueBinding  ValueExpression

    name
    NullPointerException:  name  null
    deprecated

getValueBinding

public ValueBinding getValueBinding(String name)
Deprecated. This has been replaced by `getValueExpression(java.lang.String)`.

Return any ValueBinding set for value if a ValueBinding for selected is requested; otherwise, perform the default superclass processing for this method.

Rely on the superclass implementation to wrap the returned ValueExpression in a ValueBinding.

Overrides: `getValueBinding` in class `UIComponentBase`

Parameters:
- `name` - Name of the attribute or property for which to retrieve a ValueBinding

Throws:
- `NullPointerException` - if name is null

```java
public void setValueBinding(String name, ValueBinding binding)
```

value selected ValueBinding

ValueExpression ValueBinding

```java
name ValueBinding
binding ValueBinding null ValueBinding
```

Throws
- `NullPointerException` - name null

deprecated

#setValueExpression

**set ValueBinding**

```java
public void setValueBinding(String name, ValueBinding binding)
```

**Deprecated. This has been replaced by**
**setValueExpression**(*java.lang.String, javax.el.ValueExpression*).

Store any **ValueBinding** specified for **selected** under **value** instead; otherwise, perform the default superclass processing for this method.

Rely on the superclass implementation to wrap the argument **ValueBinding** in a **ValueExpression**.

**Overrides:**

**setValueBinding** in class **UIComponentBase**

**Parameters:**

- name - Name of the attribute or property for which to set a **ValueBinding**
- binding - The **ValueBinding** to set, or null to remove any currently set **ValueBinding**

**Throws:**

- **NullPointerException** - if name is null

---

**public** **ValueExpression** **getValueExpression**(*String name*)

**selected**  **ValueExpression**  **value**  **ValueExpression**

**name**  **ValueExpression**

**Throws**

- **NullPointerException**

**since**

- 1.2

**getValueExpression**

**public** **ValueExpression** **getValueExpression**(*String name*)

Return any **ValueExpression** set for **value** if a **ValueExpression** for **selected** is requested; otherwise, perform the default superclass processing for this method.

**Overrides:**
getValueExpression in class UIComponent

Parameters:
name - Name of the attribute or property for which to retrieve a ValueExpression

Throws:
NullPointerException - if name is null

Since:
1.2

public void setValueExpression(String name, ValueExpression binding)

value selected ValueExpression

name ValueExpression
binding ValueExpression null ValueExpression

Throws
NullPointerException: name null

since
1.2

setValueExpression

public void setValueExpression(String name, ValueExpression binding)

Store any ValueExpression specified for selected under value instead; otherwise, perform the default superclass processing for this method.

Overrides:
setValueExpression in class UIComponent

Parameters:
name - Name of the attribute or property for which to set a ValueExpression
binding - The ValueExpression to set, or null to remove any currently set ValueExpression

Throws:
NullPointerException - if name is null
Since:
1.2

PS:
javax.faces.component  Class UISelectItem

java.lang.Object  
  └ javax.faces.component.UIComponent  
    └ javax.faces.component.UIComponentBase  
      └ javax.faces.component.UISelectItem

All Implemented Interfaces:  
  StateHolder

public class UISelectItem  
  extends UIComponentBase

Extends: UIComponent  >  UIComponentBase

UISelectItem  UISelectMany  UISelectOne  SelectItem  SelectItem

- value  SelectItem
- javax.el.ValueExpression  SelectItem
- itemDescription  itemDisabled  itemLabel  itemValue  SelectItem

UISelectItem is a component that may be nested inside a UISelectMany  
or UISelectOne component, and causes the addition of a SelectItem  
instance to the list of available options for the parent component. The  
contents of the SelectItem can be specified in one of the following ways:

- The value attribute's value is an instance of SelectItem.
- The associated ValueExpression points at a model data item of type 
  SelectItem.
- A new SelectItem instance is synthesized from the values of the 
  itemDescription, itemDisabled, itemLabel, and itemValue attributes.

### Constructor Summary

**UISelectItem()**

Create a new UISelectItem instance with default property values.

### Method Summary

- **String getFamily()**
  
  Return the identifier of the component family to which this component belongs.

- **String getItemDescription()**
  
  Return the description for this selection item.

- **String getItemLabel()**
  
  Return the localized label for this selection item.

- **Object getItemValue()**
  
  Return the server value for this selection item.

- **Object getValue()**
  
  Returns the value property of the UISelectItem.

- **boolean isItemDisabled()**
  
  Return the disabled setting for this selection item.

- **boolean isItemEscaped()**
  
  Return the escape setting for the label of this selection item.

- **void restoreState(FacesContext context, Object state)**
  
  Perform any processing required to restore the state from
the entries in the state Object.

Constant Field Values

Constructor Detail

public UISelectItem()

UISelectItem

UISelectItem

public UISelectItem()
Create a new `UISelectItem` instance with default property values.

### Method Detail

**public String getFamily()**

#### getFamily

**public String getFamily()**

**Description copied from class:** `UIComponent`

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the `rendererType` property, may be used to select the appropriate `Renderer` for this component instance.

**Specified by:**

- `getFamily` in class `UIComponent`

---

**public String getItemDescription()**

#### getItemDescription

**public String getItemDescription()**

Return the description for this selection item.

---

**public void setItemDescription(String itemDescription)**
public void setItemDescription(String itemDescription)

Set the description for this selection item.

Parameters:
  itemDescription - The new description

public boolean isItemDisabled()

public void setItemDisabled(boolean itemDisabled)

public boolean isItemDisabled()
Set the disabled value for this selection item.

**Parameters:**
- itemDisabled - The new disabled flag

---

**public boolean isItemEscaped()**

**isItemEscaped**

**public boolean isItemEscaped()**

Return the escape setting for the label of this selection item.

---

**public void setItemEscaped(boolean itemEscaped)**

**setItemEscaped**

**public void setItemEscaped(boolean itemEscaped)**

Set the escape value for the label of this selection item.

**Parameters:**
- itemEscaped - The new disabled flag

---

**public String getItemLabel()**
**getImltemLabel**

```java
public String getItemLabel()
```

Return the localized label for this selection item.

---

**public void setItemLabel(String itemLabel)**

```java

```

---

**setItemLabel**

```java
public void setItemLabel(String itemLabel)
```

Set the localized label for this selection item.

**Parameters:**

- `itemLabel` - The new localized label

---

**public Object getItemValue()**

---

**getImltemValue**

```java
public Object getItemValue()
```

---
Return the server value for this selection item.

```java
public void setItemValue(Object itemValue)
```

_setItemValue_

```
public void setItemValue(Object itemValue)
```

Set the server value for this selection item.

**Parameters:**

- `itemValue` - The new server value

```java
public Object getValue()
```

_getValue_

```
public Object getValue()
```

Returns the `value` property of the `UISelectItem`.

```java
public void setValue(Object value)
```

dSetValue_

```
public void setValue(Object value)
```

`UISelectItem` value

`value`
setValue

public void setValue(Object value)

Sets the value property of the UISelectItem.

Parameters:
value - the new value

saveState

public Object saveState(FacesContext context)

Description copied from interface: StateHolder

Gets the state of the instance as a Serializable Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the state of children and facets. That is done via the StateManager

This method must not alter the state of the implementing object. In other words, after executing this code:

Object state = component.saveState(facesContext);

component should be the same as before executing it.

The return from this method must be Serializable
public void restoreState(FacesContext context, Object state)

Description copied from interface: StateHolder

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object) method on all those instances as well.
PS:
javax.faces.component  **Class UISelectItems**

java.lang.Object
| ↓ | javax.faces.component.UIComponent
| ↓ | javax.faces.component.UIComponentBase
| ↓ | javax.faces.component.UISelectItems

All Implemented Interfaces:
- **StateHolder**

```java
class UISelectItems
extends UIComponentBase
```

**Extends:** **UIComponent** > **UIComponentBase**

**UISelectItems**  **UISelectMany**  **UISelectOne**  **UISelectItem**

- **value**
  - javax.el.ValueExpression
  - *SelectItem*
  - *SelectItem* Collection
  - *Map* - String String *SelectItem*

**UISelectItems** is a component that may be nested inside a **UISelectMany** or **UISelectOne** component, and causes the addition of one or more **SelectItem** instances to the list of available options in the parent component. The **value** of this component (set either directly, or acquired indirectly a **ValueExpression**), can be of any of the following types:

- **Single instance of SelectItem** - This instance is added to the set of available options for the parent tag.
- **Array of SelectItem** - This set of instances is added to the set of available options for the parent component, in ascending subscript
order.
- *Collection of SelectItem* - This set of instances is added to the set of available options for the parent component, in the order provided by an iterator over them.
- *Map* - The keys of this object (once converted to Strings) are assumed to be labels, and the values of this object (once converted to Strings) are assumed to be values, of *SelectItem* instances that will be constructed dynamically and added to the set of available options for the parent component, in the order provided by an iterator over the keys.

public class UISelectMany
  extends UIInput

Extends: UIComponent > UIComponentBase > UIOutput > UIInput
Extended by: HtmlSelectManyCheckbox, HtmlSelectManyListbox, HtmlSelectManyMenu

UISelectMany 0  UIComponent 0  value

rendererType "javax.faces.Listbox"  setRendererType()

javax.faces.render.Renderer  getConvertedValue()

javax.faces.convert.Converter

javax.faces.convert.Converter

value ValueExpression  ValueExpression
UISelectMany is a UIComponent that represents the user's choice of a zero or more items from among a discrete set of available options. The user can modify the selected values. Optionally, the component can be preconfigured with zero or more currently selected items, by storing them as an array in the value property of the component.

This component is generally rendered as a select box or a group of checkboxes.

By default, the rendererType property must be set to "javax.faces.Listbox". This value can be changed by calling the setRendererType() method.

The Renderer for this component must perform the following logic on getConvertedValue():

Obtain the Converter using the following algorithm:

- If the component has an attached Converter, use it.
- If not, look for a ValueExpression for value (if any). The ValueExpression must point to something that is:
  - An array of primitives (such as int[]). Look up the registered by-class Converter for this primitive type.
  - An array of objects (such as Integer[] or String[]). Look up the registered by-class Converter for the underlying element type.
- A `java.util.List`. Assume that the element type is `java.lang.String`, so no conversion is required.

If for any reason a `Converter` cannot be found, assume the type to be a String array.

Use the selected `Converter` (if any) to convert each element in the values array or list from the request to the proper type. If the component has a `ValueBinding` for value, create an array of the expected type to hold the converted values. If the component does not have a `ValueBinding` for value, create an array of type `Object`. Store the created array as the local value of the component, set the component’s `valid` state to `true` and return.

### Constructor Detail

public UISelectMany()

UISelectMany

public UISelectMany()

Create a new UISelectMany instance with default property values.

### Method Detail

public String getFamily()

getFamily

public String getFamily()

**Description copied from class: UIComponent**

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

**Overrides:**

g Familie in class UIInput

public Object[] getSelectedValues()
null getValue()

**getSelectedValues**

```java
public Object[] getSelectedValues()
```

Return the currently selected values, or `null` if there are no currently selected values. This is a typesafe alias for `getValue()`.

---

**public void setSelectedValues(Object[] selectedValues)**

```java
null setValue()
```

```
selectedValues
```

**setSelectedValues**

```java
public void setSelectedValues(Object[] selectedValues)
```

Set the currently selected values, or `null` to indicate that there are no currently selected values. This is a typesafe alias for `setValue()`.

**Parameters:**

- `selectedValues` - The new selected values (if any)

---

**public ValueBinding getValueBinding(String name)**

```java
selectedValues ValueBinding value ValueBinding
```

```
ValueExpression ValueBinding
```

```
name ValueBinding
```
Throws  NullPointerException:  name  null
deprecated  #getValueExpression(java.lang.String)

getValueBinding

public  ValueBinding  getValueBinding(String  name)

   Deprecated.  this has been replaced by
   getValueExpression(java.lang.String).

Return any ValueBinding set for value if a ValueBinding for
selectedValues is requested; otherwise, perform the default
superclass processing for this method.

This method relies on the superclass to provide the ValueExpression
to ValueBinding wrapping.

Overrides:
   getValueBinding  in class  UICOMPONENTBASE

Parameters:
   name - Name of the attribute or property for which to retrieve a
   ValueBinding

Throws:
   NullPointerException - if name is null

---

public  void  setValueBinding(String  name,  ValueBinding
binding)

value  selectedValues  ValueBinding

ValueExpression  ValueBinding

   name  ValueBinding
binding  ValueBinding  null  ValueBinding
Threws  NullPointerException:  name  null

#setValueExpression(java.lang.String)
setValueBinding

public void setValueBinding(String name, ValueBinding binding)

Deprecated. This has been replaced by setValueExpression(java.lang.String, javax.el.ValueExpression).

Store any ValueBinding specified for selectedValues under value instead; otherwise, perform the default superclass processing for this method.

This method relies on the superclass to wrap the argument ValueBinding in a ValueExpression.

Overrides:
setValueBinding in class UIComponentBase

Parameters:
- name - Name of the attribute or property for which to set a ValueBinding
- binding - The ValueBinding to set, or null to remove any currently set ValueBinding

Throws:
- NullPointerException - if name is null

public ValueExpression getValueExpression(String name)

selectedValues ValueExpression value
ValueExpression

name ValueExpression

Throws
- NullPointerException: name null

since 1.2
**getValueExpression**

```java
public ValueExpression getValueExpression(String name)
```

Return any `ValueExpression` set for value if a `ValueExpression` for `selectedValues` is requested; otherwise, perform the default superclass processing for this method.

**Overrides:**
- `getValueExpression` in class `UIComponent`

**Parameters:**
- `name` - Name of the attribute or property for which to retrieve a `ValueExpression`

**Throws:**
- `NullPointerException` - if `name` is null

**Since:**
1.2

---

**setValueExpression**

```java
public void setValueExpression(String name, ValueExpression binding)
```

Store any `ValueExpression` specified for `selectedValues` under `value` instead; otherwise, perform the default superclass processing for this method.

**Throws:**
- `NullPointerException` - if name is null

**Since:**
1.2
Overrides:

setValueExpression in class UIComponent

Parameters:

name - Name of the attribute or property for which to set a ValueExpression
binding - The ValueExpression to set, or null to remove any currently set ValueExpression

Throws:

NullPointerException - if name is null

Since:

1.2

protected boolean compareValues(Object previous, Object value)

true

previous

value

compareValues

protected boolean compareValues(Object previous, Object value)

Return true if the new value is different from the previous value. Value comparison must not be sensitive to element order.

Overrides:

compareValues in class UIInput

Parameters:

previous - old value of this component
value - new value of this component

protected void validateValue(FacesContext context, Object
validateValue

protected void validateValue(FacesContext context, Object value)

In addition to the standard validation behavior inherited from UIInput, ensure that any specified values are equal to one of the available options. Before comparing each option, coerce the option value type to the type of this component's value following the Expression Language coercion rules. If the specified value is not equal to any of the options, enqueue an error message and set the valid property to false.

Overrides:
validateValue in class UIInput

Parameters:
context - The FacesContext for the current request
value - The converted value to test for membership.

Throws:
NullPointerException - if context is null
PS:
javax.faces.component Class UISelectOne

java.lang.Object
  ↓ javax.faces.component.UIComponent
       ↓ javax.faces.component.UIComponentBase
            ↓ javax.faces.component.UIOutput
                 ↓ javax.faces.component.UIInput
                      ↓ javax.faces.component.UISelectOne

All Implemented Interfaces:
  EditableValueHolder, StateHolder, ValueHolder

Direct Known Subclasses:
  HtmlSelectOneListbox, HtmlSelectOneMenu, HtmlSelectOneRadio

public class UISelectOne
  extends UIInput

Extends: UIComponent > UIComponentBase > UIOutput > UIInput
Extended by: HtmlSelectOneListbox, HtmlSelectOneMenu, HtmlSelectOneRadio

UISelectOne 0 1  UIComponent value

  rendererType "javax.faces.Menu"  setRendererType()

UISelectOne is a UIComponent that represents the user's choice of zero or one items from among a discrete set of available options. The user can modify the selected value. Optionally, the component can be preconfigured with a currently selected item, by storing it as the value property of the component.

This component is generally rendered as a select box or a group of radio
buttons.

By default, the `rendererType` property is set to "javax.faces.Menu". This value can be changed by calling the `setRendererType()` method.

Field Detail

COMPONENT_TYPE

public static final String COMPONENT_TYPE

The standard component type for this component.

See Also:
Constant Field Values

COMPONENT_FAMILY

public static final String COMPONENT_FAMILY

The standard component family for this component.

See Also:
Constant Field Values

INVALID_MESSAGE_ID

public static final String INVALID_MESSAGE_ID

The message identifier of the FacesMessage to be created if a value not matching the available options is specified.
See Also:
Constant Field Values

## Constructor Detail

```java
public UISelectOne()
```

**UISelectOne**

```java
public UISelectOne()
```

Create a new **UISelectOne** instance with default property values.

## Method Detail

```java
public String getFamily()
```

**getFamily**

```java
public String getFamily()
```

**Description copied from class: UIComponent**

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

**Overrides:**
```
getFamily in class UIInput
```
protected void validateValue(FacesContext context, Object value)

UIInput Expression valid false

custom context FacesContext
value
Throws NullPointerException: context null

validateValue

protected void validateValue(FacesContext context, Object value)

In addition to the standard validation behavior inherited from UIInput, ensure that any specified value is equal to one of the available options. Before comparing each option, coerce the option value type to the type of this component's value following the Expression Language coercion rules. If the specified value is not equal to any of the options, enqueue an error message and set the valid property to false.

Overrides:
validateValue in class UIInput

Parameters:
context - The FacesContext for the current request
value - The converted value to test for membership.

Throws:
NullPointerException - if context is null

PS:
javax.faces.component  **Class UIViewRoot**

java.lang.Object
   └─javax.faces.component.UIComponent
       └─javax.faces.component.UIComponentBase
           └─javax.faces.component.UIViewRoot

**All Implemented Interfaces:**
   StateHolder

```java
public class UIViewRoot
    extends UIComponentBase

Extends: UIComponent > UIComponentBase

UIViewRoot UIComponent UIComponent
PhaseListener
```

- #processDecodes
- #processValidators
- #processUpdates
- #processApplication
- RenderResponse  #encodeBegin  #encodeEnd

PhaseListener

false

#getBeforePhaseListener   null   PhaseId

FacesContext#getResponseComplete
UIViewRoot is the UIComponent that represents the root of the UIComponent tree. This component has no rendering, it just serves as the root of the component tree, and as a place to hang per-view PhaseListenerS.

For each of the following lifecycle phase methods:

- `processDecodes(javax.faces.context.FacesContext)`
- `processValidators(javax.faces.context.FacesContext)`
- `processUpdates(javax.faces.context.FacesContext)`
- `processApplication(javax.faces.context.FacesContext)`
- RenderResponse, via
  - `encodeBegin(javax.faces.context.FacesContext)` and
  - `encodeEnd(javax.faces.context.FacesContext)`

Take the following action regarding PhaseListenerS.

Initialize a state flag to `false`.

If `getBeforePhaseListener()` returns non-null, invoke the listener,
passing in the correct corresponding PhaseId for this phase.

Upon return from the listener, call 
FacesContext.getResponseComplete() and 
FacesContext.getRenderResponse(). If either return true set the internal state flag to true.

If or one or more listeners have been added by a call to 
addPhaseListener(javax.faces.event.PhaseListener), invoke the beforePhase method on each one whose PhaseListener.getPhaseId() matches the current phaseId, passing in the same PhaseId as in the previous step.

Upon return from each listener, call 
FacesContext.getResponseComplete() and 
FacesContext.getRenderResponse(). If either return true set the internal state flag to true.

Execute any processing for this phase if the internal state flag was not set.

If getAfterPhaseListener() returns non-null, invoke the listener, passing in the correct corresponding PhaseId for this phase.

If or one or more listeners have been added by a call to 
addPhaseListener(javax.faces.event.PhaseListener), invoke the afterPhase method on each one whose PhaseListener.getPhaseId() matches the current phaseId, passing in the same PhaseId as in the previous step.

**getViewId()**

Return the view identifier for this view.

**processApplication(FacesContext context)**

Broadcast any events that have been queued for the Application phase of the request processing lifecycle and to any events for later phases if the event processing for this FacesContext.renderResponse() or FacesContext.responseComplete() be called.

**processDecodes(FacesContext context)**

Override the default UIComponentBase.processDecodes(javax.faces.context.FacesContext) behavior to broadcast any queued events after the default has been completed and to clear out any events for later phases if the event processing for this phase caused FacesContext.renderResponse() or FacesContext.responseComplete() to be called.

**processUpdates(FacesContext context)**

Override the default UIComponentBase behavior to broadcast queued events after the default processing has been completed and to clear out any events for later phases if the event processing for this phase caused FacesContext.renderResponse() or FacesContext.responseComplete() to be called.

**processValidators(FacesContext context)**

Override the default UIComponentBase.processValidators(javax.faces.context.FacesContext) behavior to broadcast any queued events after the default has been completed and to clear out any events for later phases if the event processing for this phase caused FacesContext.renderResponse() or FacesContext.responseComplete() to be called.

**queueEvent(FacesEvent event)**

Override the default UIComponentBase.queueEvent(javax.faces.event.FacesEvent) accumulate the queued events for later broadcasting.

**removePhaseListener(PhaseListener toRemove)**

**restoreState(FacesContext context, Object state)**

Perform any processing required to restore the state.

Constructor Detail

public UIViewRoot()

UIViewRoot

public UIViewRoot()

Create a new UIViewRoot instance with default property values.

Method Detail

public String getFamily()

getFamily

public String getFamily()

Description copied from class: UIComponent

Return the identifier of the component family to which this component belongs. This identifier, in conjunction with the value of the rendererType property, may be used to select the appropriate Renderer for this component instance.

Specified by:

getchFamily in class UIComponent

public String getRenderKitId()
public String getViewId()
getViewById

public String getViewId()

Return the view identifier for this view.

public void setViewId(String viewId)

setViewById

public void setViewId(String viewId)

Set the view identifier for this view.

Parameters:

viewId - The new view identifier

getBeforePhaseListener

public MethodExpression getBeforePhaseListener()

return

getBeforePhaseListener

public MethodExpression getBeforePhaseListener()

Returns:

the MethodExpression that will be invoked before this view is
public void setBeforePhaseListener(MethodExpression newBeforePhase)

UIViewRoot "beforePhase"

PhaseId#RESTORE_VIEW PhaseListener PhaseEvent

PhaseListener#beforePhase

newBeforePhase

MethodExpression

setBeforePhaseListener

public void setBeforePhaseListener(MethodExpression newBeforePhase)

Allow an arbitrary method to be called for the "beforePhase" event as the UIViewRoot runs through its lifecycle. This method will be called for all phases except PhaseId.RESTORE_VIEW. Unlike a true PhaseListener, this approach doesn't allow for only receiving PhaseEventS for a given phase.

The method must conform to the signature of PhaseListener.beforePhase(javax.faces.event.PhaseEvent).

Parameters:

newBeforePhase - the MethodExpression that will be invoked before this view is rendered.

public MethodExpression getAfterPhaseListener()

return

MethodExpression

getAfterPhaseListener
public MethodExpression getAfterPhaseListener()

    Returns:
    the MethodExpression that will be invoked after this view is rendered.

public void setAfterPhaseListener(MethodExpression newAfterPhase)

    UIViewRoot "afterPhase"
    PhaseId#RESTORE_VIEW PhaseListener PhaseEvent

        PhaseListener#afterPhase

            newAfterPhase MethodExpression

setAfterPhaseListener

public void setAfterPhaseListener(MethodExpression newAfterPhase)

    Allow an arbitrary method to be called for the "afterPhase" event as
    the UIViewRoot runs through its lifecycle. This method will be called
    for all phases except PhaseId.RESTORE_VIEW. Unlike a true
    PhaseListener, this approach doesn't allow for only receiving
    PhaseEventS for a given phase.

    The method must conform to the signature of
    PhaseListener.afterPhase(javax.faces.event.PhaseEvent).

    Parameters:
    newAfterPhase - the MethodExpression that will be invoked after
    this view is rendered.

public void removePhaseListener(PhaseListener toRemove)
removePhaseListener

public void removePhaseListener(PhaseListener toRemove)

addPhaseListener

public void addPhaseListener(PhaseListener newPhaseListener)

queueEvent

public void queueEvent(FacesEvent event)

UIComponentBase#queueEvent

event FacesEvent
Throws IllegalStateException: UIViewRoot
Throws NullPointerException: event null

queueEvent

public void queueEvent(FacesEvent event)

Override the default
UIComponentBase.queueEvent(javax.faces.event.FacesEvent) behavior to accumulate the queued events for later broadcasting.

Overrides:
queueEvent in class UIComponentBase

Parameters:
event - FacesEvent to be queued

Throws:
IllegalStateException - if this component is not a descendant of a UIViewRoot
NullPointerException - if event is null

public void processDecodes(FacesContext context)

FacesContext#renderResponse
FacesContext#responseComplete
UIComponentBase#processDecodes

context
Throws

FacesContext

Throws

NullPointerException: context null

processDecodes

public void processDecodes(FacesContext context)

Override the default UIComponentBase.processDecodes(javax.faces.context.FacesContext) behavior to broadcast any queued events after the default processing has been completed and to clear out any events for later phases if the event processing for this phase caused FacesContext.renderResponse() or FacesContext.responseComplete() to be called.

Overrides:
processDecodes in class UIComponentBase

Parameters:
context - FacesContext for the request we are processing

Throws:

NullPointerException - if context is null

public void encodeBegin(FacesContext context) throws java.io.IOException
encodeBegin

public void encodeBegin(FacesContext context) throws IOException

    Override the default UICOMPONENTBASE.encodeBegin (javax.faces.context.FacesContext) behavior. If getBeforePhaseListener () returns non-null, invoke it, passing a PhaseEvent for the PhaseId.RENDER_RESPONSE phase. If the internal list populated by calls to addPhaseListener (javax.faces.event.PhaseListener) is non-empty, any listeners in that list must have their PhaseListener.beforePhase (javax.faces.event.PhaseEvent) method called, passing the PhaseEvent. Any errors that occur during invocation of any of the the beforePhase listeners must be logged and swallowed. After listeners are invoked call superclass processing.

    Overrides: encodeBegin in class UICOMPONENTBASE

    Parameters: 
        context - FacesContext for the response we are creating

    Throws: 
        IOException - if an input/output error occurs while rendering

public void encodeEnd(FacesContext context) throws java.io.IOException

    OVERRIDE UICOMPONENTBASE.encodeEnd (javax.faces.context.FacesContext)
afterPhase

encodeEnd

public void encodeEnd(FacesContext context)
    throws IOException

  Override the default UIComponentBase.encodeEnd(javax.faces.context.FacesContext) behavior. If getAfterPhaseListener() returns non-null, invoke it, passing a PhaseEvent for the PhaseId.RENDER_RESPONSE phase. Any errors that occur during invocation of the afterPhase listener must be logged and swallowed.

  Overrides:
  encodeEnd in class UIComponentBase

  Parameters:
  context - FacesContext for the response we are creating

  Throws:
  IOException - if an input/output error occurs while rendering

public void processValidators(FacesContext context)

  FacesContext#renderResponse
  FacesContext#responseComplete
  UIComponentBase#processValidators

  context - FacesContext
  Throws
  NullPointerException: context null

processValidators

public void processValidators(FacesContext context)
Override the default `UIComponentBase.processValidators(javax.faces.context.FacesContext)` behavior to broadcast any queued events after the default processing has been completed and to clear out any events for later phases if the event processing for this phase caused `FacesContext.renderResponse()` or `FacesContext.responseComplete()` to be called.

Overrides:
- `processValidators` in class `UIComponentBase`

Parameters:
- `context` - `FacesContext` for the request we are processing

Throws:
- `NullPointerException` - if `context` is `null`

---

```java
public void processUpdates(FacesContext context)
```

```java
FacesContext#renderResponse
FacesContext#responseComplete
UIComponentBase
```

- `context` - `FacesContext` for the request
- Throws `NullPointerException`: `context` is `null`

---

processUpdates

```java
public void processUpdates(FacesContext context)
```

Override the default `UIComponentBase` behavior to broadcast any queued events after the default processing has been completed and to clear out any events for later phases if the event processing for this phase caused `FacesContext.renderResponse()` or `FacesContext.responseComplete()` to be called.

Overrides:
- `processUpdates` in class `UIComponentBase`

Parameters:
public void processApplication(FacesContext context)

Broadcast any events that have been queued for the *Invoke Application* phase of the request processing lifecycle and to clear out any events for later phases if the event processing for this phase caused `FacesContext.renderResponse()` or `FacesContext.responseComplete()` to be called.

Parameters:
context - *FacesContext* for the request we are processing

Throws:
`NullPointException` - if context is null

public String createUniqueId()

*UNIQUE_ID_PREFIX* UIViewRoot

createUniqueId
public String createUniqueId()

Generate an identifier for a component. The identifier will be prefixed with UNIQUE_ID_PREFIX, and will be unique within this UIViewRoot.

public java.util.Locale getLocale()

Locale

locale ivar "locale" null
javax.faces.application.ViewHandler#calculateLocale
java.util.Locale String java.util.Locale "locale"
javax.faces.application.ViewHandler#calculateLocale

return Locale

getLocale

public Locale getLocale()

Return the Locale to be used in localizing the response being created for this view.

Algorithm:

If we have a locale ivar, return it. If we have a value expression for "locale", get its value. If the value is null, return the result of calling ViewHandler.calculateLocale(javax.faces.context.FacesContext). If the value is an instance of java.util.Locale return it. If the value is a String, convert it to a java.util.Locale and return it. If there is no value expression for "locale", return the result of calling ViewHandler.calculateLocale(javax.faces.context.FacesContext).
Returns:
The current `Locale` obtained by executing the above algorithm.

```java
public void setLocale(java.util.Locale locale)

Locale
locale
locale
Locale

setLocale

public void setLocale(Locale locale)

Set the `Locale` to be used in localizing the response being created for this view.

Parameters:
locale - The new localization `Locale`

public Object saveState(FacesContext context)

saveState

public Object saveState(FacesContext context)

Description copied from interface: `StateHolder`

Gets the state of the instance as a `Serializable` Object.

If the class that implements this interface has references to instances that implement StateHolder (such as a `UIComponent` with event handlers, validators, etc.) this method must call the `StateHolder.saveState(javax.faces.context.FacesContext) method on all those instances as well. This method must not save the
**state of children and facets.** That is done via the `StateManager`.

This method must not alter the state of the implementing object. In other words, after executing this code:

```java
Object state = component.saveState(facesContext);
```

`component` should be the same as before executing it.

The return from this method must be `Serializable`.

**Specified by:**
`saveState` in interface `StateHolder`  
**Overrides:**
`saveState` in class `UIComponentBase`

---

**public void restoreState(FacesContext context, Object state)**

**restoreState**

```java
public void restoreState(FacesContext context, Object state)
```

**Description copied from interface: StateHolder**

Perform any processing required to restore the state from the entries in the state Object.

If the class that implements this interface has references to instances that also implement StateHolder (such as a UIComponent with event handlers, validators, etc.) this method must call the `StateHolder.restoreState(javax.faces.context.FacesContext, java.lang.Object)` method on all those instances as well.

**Specified by:**
`restoreState` in interface `StateHolder`
Overrides:

restoreState in class UICOMPONENTBASE

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

### Constructor Detail

- `public UnavailableException()`
  `null`

---

**UnavailableException**

- `public UnavailableException()`
Constructs a new instance with null as its detail message.

```java
public UnavailableException(String message)
```

*message*

**UnavailableException**

```java
public UnavailableException(String message)
```

Constructs a new instance with the specified detail message.

**Parameters:**

*message* - the detail message.

```java
public UnavailableException((Throwable cause)
```

*cause* throwable

```java
public UnavailableException(Throwable cause)
```

Constructs a new throwable with the specified cause.

**Parameters:**

*cause* - a chained exception of type Throwable.

```java
public UnavailableException(String message, Throwable cause)
```

*cause* throwable

```java
public UnavailableException(String message, Throwable cause)
```

*message*
UnavailableException

public UnavailableException(String message, Throwable cause)

Constructs a new Throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public UnavailableException(String message, String errorCode)

Constructs a new Throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

   ^ java.lang.Throwable
      ^ java.lang.Exception
         ^ javax.servlet.ServletException
            ^ javax.servlet.UnavailableException

All Implemented Interfaces:
   Serializable

public class UnavailableException

extends ServletException

Extends: Throwable > Exception > ServletException

servlet servlet

servlet servlet servlet servlet

servlet servlet

servlet servlet servlet servlet servlet

Defines an exception that a servlet or filter throws to indicate that it is permanently or temporarily unavailable.

When a servlet or filter is permanently unavailable, something is wrong with it, and it cannot handle requests until some action is taken. For example, a servlet might be configured incorrectly, or a filter's state may be corrupted. The component should log both the error and the corrective action that is needed.

A servlet or filter is temporarily unavailable if it cannot handle requests momentarily due to some system-wide problem. For example, a third-tier
server might not be accessible, or there may be insufficient memory or disk storage to handle requests. A system administrator may need to take corrective action.

Servlet containers can safely treat both types of unavailable exceptions in the same way. However, treating temporary unavailability effectively makes the servlet container more robust. Specifically, the servlet container might block requests to the servlet or filter for a period of time suggested by the exception, rather than rejecting them until the servlet container restarts.

</tr>
</tbody>
</table>
**UnavailableException**

public UnavailableException(Servlet servlet, String msg)

**Deprecation:**
Java Servlet API 2.2

**UnavailableException(String)**

Servlet
String

Deprecated. As of Java Servlet API 2.2, use UnavailableException(String) instead.
public UnavailableException(int seconds, Servlet servlet, String msg)

Deprecated. As of Java Servlet API 2.2, use UnavailableException(String, int) instead.

Parameters:
seconds - an integer specifying the number of seconds the servlet expects to be unavailable; if zero or negative, indicates that the servlet can't make an estimate
servlet - the Servlet that is unavailable
msg - a String specifying the descriptive message, which can be written to a log file or displayed for the user.
public UnavailableException(String msg)

Constructs a new exception with a descriptive message indicating that the servlet is permanently unavailable.

Parameters:
  msg - a String specifying the descriptive message

public UnavailableException(String msg, int seconds)

Constructs a new exception with a descriptive message indicating that the servlet is temporarily unavailable and giving an estimate of how long it will be unavailable.

In some cases, the servlet cannot make an estimate. For example, the servlet might know that a server it needs is not running, but not be able to report how long it will take to be restored to functionality. This can be indicated with a negative or zero value for the seconds argument.

Parameters:
  msg - a String specifying the descriptive message, which can be written to a log file or displayed for the user.
  seconds - an integer specifying the number of seconds the servlet expects to be unavailable; if zero or negative, indicates that the servlet can't make an estimate
public boolean isPermanent()

Returns a boolean indicating whether the servlet is permanently unavailable. If so, something is wrong with the servlet, and the system administrator must take some corrective action.

Returns:
true if the servlet is permanently unavailable; false if the servlet is available or temporarily unavailable

getServlet

public Servlet getServlet()

Deprecated. As of Java Servlet API 2.2, with no replacement. Returns the servlet that is reporting its unavailability.

Returns:
the Servlet object that is throwing the UnavailableException
getUnavailableSeconds

```
public int getUnavailableSeconds()
```

Returns the number of seconds the servlet expects to be temporarily unavailable.

If this method returns a negative number, the servlet is permanently unavailable or cannot provide an estimate of how long it will be unavailable. No effort is made to correct for the time elapsed since the exception was first reported.

**Returns:**

an integer specifying the number of seconds the servlet will be temporarily unavailable, or a negative number if the servlet is permanently unavailable or cannot make an estimate.
javax.xml.registry Class UnexpectedObjectException

java.lang.Object
  └ java.lang.Throwable
      └ java.lang.Exception
          └ javax.xml.registry.JAXRException
              └ javax.xml.registry.UnexpectedObjectException

All Implemented Interfaces:
    Serializable, JAXRResponse

public class UnexpectedObjectException
  extends JAXRException

Extends: Throwable > Exception > JAXRException

JAXR Object BusinessLifeCycleManager
saveOrganizations Object Collection Exception

This exception is thrown when the JAXR provider finds a Object that is out-of-place or of the wrong type within the context of a user request. For example a saveOrganizations request in BusinessLifeCycleManager would throw this Exception if it found an Object other than Organization in the Collection of Objects provided by client to be saved by the request.

Field Summary

Fields inherited from class javax.xml.registry.JAXRException
cause
Fields inherited from interface javax.xml.registry.JAXRResponse
STATUS_FAILURE, STATUS_SUCCESS, STATUS_UNAVAILABLE, STATUS_WARNING

Constructor Summary

UnexpectedObjectException()
Constructs a JAXRException object with no reason or embedded Throwable.

UnexpectedObjectException(String reason)
Constructs a JAXRException object with the given String as the reason for the exception being thrown.

UnexpectedObjectException(String reason, Throwable cause)
Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

UnexpectedObjectException(Throwable cause)
Constructs a JAXRException object initialized with the given Throwable object.

Method Summary

Methods inherited from class javax.xml.registry.JAXRException
getCause, getMessage, getRequestID, getStatus, initCause, isAvailable

Methods inherited from class java.lang.Throwable
fillInStackTrace, getLocalizedMessage, getStackTrace, printStackTrace, printStackTrace, setStackTrace, toString

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, wait, wait, wait
public UnexpectedObjectException()
	Throwable JAXRException

**UnexpectedObjectException**

public UnexpectedObjectException()

Constructs a JAXRException object with no reason or embedded Throwable.

---

public UnexpectedObjectException(String reason)

**JAXRException** **String** reason

**UnexpectedObjectException**

public UnexpectedObjectException(String reason)

Constructs a JAXRException object with the given String as the reason for the exception being thrown.

**Parameters:**

- **reason** - a description of what caused the exception

---

public UnexpectedObjectException(String reason, Throwable cause)

**JAXRException** **String** Throwable

**Throwable**

- **reason**
- **cause** 

---

**JAXRException** **Throwable**
public UnexpectedObjectException(String reason, Throwable cause)

Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

Parameters:
  reason - a description of what caused the exception
  cause - a Throwable object that is to be embedded in this JAXRException object

public UnexpectedObjectException(Throwable cause)

Constructs a JAXRException object initialized with the given Throwable object.

Parameters:
  cause - the Throwable that caused this Exception

javax.persistence  **Annotation Type UniqueConstraint**  

@Target(value={})  
@Retention(value=RUNTIME)  
public @interface UniqueConstraint  

**Implements:** Annotation  
@Target(value={})  
@Retention(value=RUNTIME)  

**DDL**  

```java  
@Entity  
@Table(  
    name="EMPLOYEE",  
    uniqueConstraints=  
        @UniqueConstraint(columnNames={"EMP_ID", "EMP_NAME"})  
)  
public class Employee { ... }  
```

**since**  
Java Persistence 1.0  

This annotation is used to specify that a unique constraint is to be included in the generated DDL for a primary or secondary table.  

**Example:**  
@Target  
@Retention  
public class Employee { ... }  

**Since:**  
Java Persistence 1.0

version $Revision: 1.32 $ $Date: 2005/08/18 15:18:26 $
since JAXB1.0
See javax.xml.bind.JAXBContext, javax.xml.bind.Marshaller,
also javax.xml.bind.Validator

The Unmarshaller class governs the process of deserializing XML data into newly created Java content trees, optionally validating the XML data as it is unmarshalled. It provides an overloading of unmarshal methods for many different input kinds.

Unmarshalling from a File:

    JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
    Unmarshaller u = jc.createUnmarshaller();
    Object o = u.unmarshal( new File( "nosferatu.xml" ) );

Unmarshalling from an InputStream:

    InputStream is = new FileInputStream( "nosferatu.xml" );
    JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
    Unmarshaller u = jc.createUnmarshaller();
    Object o = u.unmarshal( is );

Unmarshalling from a URL:
JAXBContext jc = JAXBContext.newInstance("com.acme.foo");
Unmarshaller u = jc.createUnmarshaller();
URL url = new URL("http://beaker.east/nosferatu.xml");
Object o = u.unmarshal(url);

Unmarshalling from a StringBuffer using a
javax.xml.transform.stream.StreamSource:

JAXBContext jc = JAXBContext.newInstance("com.acme.foo");
Unmarshaller u = jc.createUnmarshaller();
StringBuffer xmlStr = new StringBuffer("<?xml version="1.0"
Object o = u.unmarshal(new StreamSource(new StringReader(xmlStr.toString()));

Unmarshalling from a org.w3c.dom.Node:

JAXBContext jc = JAXBContext.newInstance("com.acme.foo");
Unmarshaller u = jc.createUnmarshaller();

DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
dbf.setNamespaceAware(true);
DocumentBuilder db = dbf.newDocumentBuilder();
Document doc = db.parse(new File("nosferatu.xml"));
Object o = u.unmarshal(doc);

Unmarshalling from a javax.xml.transform.sax.SAXSource using a client
specified validating SAX2.0 parser:

    // configure a validating SAX2.0 parser (Xerces2)
    static final String JAXB_SCHEMA_LANGUAGE =
        "http://java.sun.com/xml/jaxp/properties/schemaLanguage
    static final String JAXB_SCHEMA_LOCATION =
        "http://java.sun.com/xml/jaxp/properties/schemaSource"
    static final String W3C_XML_SCHEMA =
        "http://www.w3.org/2001/XMLSchema"
    System.setProperty("javax.xml.parsers.SAXParserFactory",
        "org.apache.xerces.jaxp.SAXParserFactory"
    SAXParserFactory spf = SAXParserFactory.newInstance();
    spf.setNamespaceAware(true);
    spf.setValidating(true);
    SAXParser saxParser = spf.newSAXParser();
try {
    saxParser.setProperty(JAXP_SCHEMA_LANGUAGE, W3C_XML_SCHEMA);
    saxParser.setProperty(JAXP_SCHEMA_LOCATION, "http://...");
} catch (SAXNotRecognizedException x) {
    // exception handling omitted
}

XMLReader xmlReader = saxParser.getXMLReader();
SAXSource source =
    new SAXSource( xmlReader, new InputSource( "http://..." ) );

// Setup JAXB to unmarshal
JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
Unmarshaller u = jc.createUnmarshaller();
ValidationEventCollector vec = new ValidationEventCollector();
u.setEventHandler( vec );

// turn off the JAXB provider's default validation mechanism
// avoid duplicate validation
u.setValidating( false )

// unmarshal
Object o = u.unmarshal( source );

// check for events
if( vec.hasEvents() ) {
    // iterate over events
}

Unmarshalling from a StAX XMLStreamReader:

JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
Unmarshaller u = jc.createUnmarshaller();

javax.xml.stream.XMLStreamReader xmlStreamReader =
    javax.xml.stream.XMLInputFactory().newInstance().createXMLStreamReader();

Object o = u.unmarshal( xmlStreamReader );

Unmarshalling from a StAX XMLEventReader:

JAXBContext jc = JAXBContext.newInstance( "com.acme.foo" );
Unmarshaller u = jc.createUnmarshaller();

javax.xml.stream.XMLEventReader xmlEventReader =
    javax.xml.stream.XMLInputFactory().newInstance().createXMLEventReader();
Object o = u.unmarshal( xmlEventReader );

Unmarshalling XML Data

Unmarshalling can deserialize XML data that represents either an entire XML document or a subtree of an XML document. Typically, it is sufficient to use the unmarshalling methods described by Unmarshal root element that is declared globally. These unmarshal methods utilize JAXBContext’s mapping of global XML element declarations and type definitions to JAXB mapped classes to initiate the unmarshalling of the root element of XML data. When the JAXBContext’s mappings are not sufficient to unmarshal the root element of XML data, the application can assist the unmarshalling process by using the unmarshal by declaredType methods. These methods are useful for unmarshalling XML data where the root element corresponds to a local element declaration in the schema.

An unmarshal method never returns null. If the unmarshal process is unable to unmarshal the root of XML content to a JAXB mapped object, a fatal error is reported that terminates processing by throwing JAXBException.

Unmarshal a root element that is globally declared

The unmarshal methods that do not have an declaredType parameter use JAXBContext to unmarshal the root element of an XML data. The JAXBContext instance is the one that was used to create this Unmarshaller. The JAXBContext instance maintains a mapping of globally declared XML element and type definition names to JAXB mapped classes. The unmarshal method checks if JAXBContext has a mapping from the root element’s XML name and/or @xsi:type to a JAXB mapped class. If it does, it umarshalls the XML data using the appropriate JAXB mapped class. Note that when the root element name is unknown and the root element has an @xsi:type, the XML data is unmarshalled using that JAXB mapped class as the value of a JAXBElement. When the JAXBContext object does not have a mapping for the root element’s name nor its @xsi:type, if it exists, then the unmarshal operation will abort immediately by throwing a UnmarshalException. This exception scenario can be worked around
by using the unmarshal by declaredType methods described in the next subsection.

Unmarshal by Declared Type

The unmarshal methods with a declaredType parameter enable an application to deserialize a root element of XML data, even when there is no mapping in JAXBContext of the root element's XML name. The unmarshaller unmarshals the root element using the application provided mapping specified as the declaredType parameter. Note that even when the root element's element name is mapped by JAXBContext, the declaredType parameter overrides that mapping for deserializing the root element when using these unmarshal methods. Additionally, when the root element of XML data has an xsi:type attribute and that attribute's value references a type definition that is mapped to a JAXB mapped class by JAXBContext, that the root element's xsi:type attribute takes precedence over the unmarshal methods declaredType parameter. These methods always return a JAXBElement<declaredType> instance. The table below shows how the properties of the returned JAXBElement instance are set.

<table>
<thead>
<tr>
<th>Unmarshal By Declared Type returned JAXBElement</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>JAXBElemnt Property</td>
<td>Value</td>
</tr>
<tr>
<td>name</td>
<td>xml element name</td>
</tr>
<tr>
<td>value</td>
<td>instanceof declaredType</td>
</tr>
<tr>
<td>declaredType</td>
<td>unmarshal method declaredType parameter</td>
</tr>
<tr>
<td>scope</td>
<td>null (actual scope is unknown)</td>
</tr>
</tbody>
</table>

The following is an example of unmarshal by declaredType method.

Unmarshal by declaredType from a org.w3c.dom.Node:

```xml
<xs:schema>
  <xs:complexType name="FooType">...
  </xs:complexType>
<!-- global element declaration "PurchaseOrder" -->
<xs:element name="PurchaseOrder">
  <xs:complexType>
    <xs:sequence>
```
<xs:element name="foo" type="FooType"/>
...
</xs:sequence>
</xs:complexType>
</xs:element>
</xs:schema>

JAXBContext jc = JAXBContext.newInstance("com.acme.foo");
Unmarshaller u = jc.createUnmarshaller();

DocumentBuilderFactory dbf = DocumentBuilderFactory.newInstance();
dbf.setNamespaceAware(true);
DocumentBuilder db = dbf.newDocumentBuilder();
Document doc = db.parse(new File("nosferatu.xml"));
Element fooSubtree = ...; // traverse DOM till reach xml e
// local element declaration in

// FooType is the JAXB mapping of the type of local element
JAXBElement<FooType> foo = u.unmarshal(fooSubtree, FooType

**Support for SAX2.0 Compliant Parsers**

A client application has the ability to select the SAX2.0 compliant parser of their choice. If a SAX parser is not selected, then the JAXB Provider's default parser will be used. Even though the JAXB Provider's default parser is not required to be SAX2.0 compliant, all providers are required to allow a client application to specify their own SAX2.0 parser. Some providers may require the client application to specify the SAX2.0 parser at schema compile time. See [unmarshal(Source)](#) for more detail.

**Validation and Well-Formedness**

A client application can enable or disable JAXP 1.3 validation mechanism via the `setSchema(javax.xml.validation.Schema)` API. Sophisticated clients can specify their own validating SAX 2.0 compliant parser and bypass the JAXP 1.3 validation mechanism using the [unmarshal(Source)](#) API.

Since unmarshalling invalid XML content is defined in JAXB 2.0, the Unmarshaller default validation event handler was made more lenient than in JAXB 1.0. When schema-derived code generated by
JAXB 1.0 binding compiler is registered with JAXBContext, the default unmarshal validation handler is DefaultValidationEventHandler and it terminates the marshal operation after encountering either a fatal error or an error. For a JAXB 2.0 client application, there is no explicitly defined default validation handler and the default event handling only terminates the marshal operation after encountering a fatal error.

**Supported Properties**

There currently are not any properties required to be supported by all JAXB Providers on Unmarshaller. However, some providers may support their own set of provider specific properties.

**Unmarshal Event Callbacks**

The Unmarshaller provides two styles of callback mechanisms that allow application specific processing during key points in the unmarshalling process. In 'class defined' event callbacks, application specific code placed in JAXB mapped classes is triggered during unmarshalling. 'External listeners' allow for centralized processing of unmarshal events in one callback method rather than by type event callbacks.

'Class defined' event callback methods allow any JAXB mapped class to specify its own specific callback methods by defining methods with the following method signature:

```java
// This method is called immediately after the object is created.
// object begins. The callback provides an opportunity to initialize JavaBean properties prior to unmarshalling.
void beforeUnmarshal(Unmarshaller, Object parent);

// This method is called after all the properties (except IDREF) are unmarshalled for this object,
// but before this object is set to the parent object.
void afterUnmarshal(Unmarshaller, Object parent);
```

The class defined callback methods should be used when the callback method requires access to non-public methods and/or fields of the class.
The external listener callback mechanism enables the registration of a `Unmarshaller.Listener` instance with an `Unmarshaller.Listener.setListener(Listener)`. The external listener receives all callback events, allowing for more centralized processing than per class defined callback methods. The external listener receives events when unmarshalling process is marshalling to a JAXB element or to JAXB mapped class.

The 'class defined' and external listener event callback methods are independent of each other, both can be called for one event. The invocation ordering when both listener callback methods exist is defined in `Unmarshaller.Listener.beforeUnmarshal(Object, Object)` and `Unmarshaller.Listener.afterUnmarshal(Object, Object)`. An event callback method throwing an exception terminates the current unmarshal process.

### Nested Class Summary

<table>
<thead>
<tr>
<th>static class</th>
<th>Unmarshaller.Listener</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Register an instance of an implementation of this class with <code>Unmarshaller</code> to externally listen for unmarshal events.</td>
</tr>
</tbody>
</table>

### Method Summary
**getAdapter(Class type)**

Gets the adapter associated with the specified type.

**AttachmentUnmarshaller getAttachmentUnmarshaller()**

Return the current event handler or the default event handler if one hasn't been set.

**Unmarshaller.Listener getListener()**

Return `Unmarshaller.Listener` registered with this `Unmarshaller`.

**setAdapter(Class type, A adapter)**

Associates a configured instance of `XmlAdapter` with this unmarshaller.

**setAdapter(XmlAdapter adapter)**

Associates a configured instance of `XmlAdapter` with this unmarshaller.

**setAttachmentUnmarshaller(AttachmentUnmarshaller au)**

Associate a context that resolves cid's, content-id URIs, to binary data passed as attachments.

**setEventHandler(ValidationEventHandler handler)**

Allow an application to register a `ValidationEventHandler`.  

**setListener(Unmarshaller.Listener listener)**

Register unmarshal event callback `Unmarshaller.Listener` with this `Unmarshaller`.  

**setProperty(String name, Object value)**

Set the particular property in the underlying implementation of Unmarshaller.

**setSchema(Schema schema)**

Specify the JAXP 1.3 `Schema` object that should be used to validate subsequent unmarshal operations against.

**setValidating(boolean validating)**

Deprecated. since JAXB2.0, please see `setSchema()`
Unmarshal XML data from the specified file and return the resulting content tree.  
`object unmarshal(InputSource source)`
Unmarshal XML data from the specified SAX InputSource and return the resulting content tree.  
`object unmarshal(InputStream is)`
Unmarshal XML data from the specified InputStream and return the resulting content tree.  
`object unmarshal(Node node)`
Unmarshal global XML data from the specified DOM tree and return the resulting content tree.

<T>  
`JAXBElement<T> unmarshal(Node node, Class<T> declaredType)`
Unmarshal XML data by JAXB mapped declaredType and return the resulting content tree.  
`Object unmarshal(Reader reader)`
Unmarshal XML data from the specified Reader and return the resulting content tree.  
`Object unmarshal(Source source)`
Unmarshal XML data from the specified XML Source and return the resulting content tree.

<T>  
`JAXBElement<T> unmarshal(Source source, Class<T> declaredType)`
Unmarshal XML data from the specified XML Source by declaredType and return the resulting content tree.  
`Object unmarshal(URL url)`
Unmarshal XML data from the specified URL and return the resulting content tree.  
`Object unmarshal(XMLEventReader reader)`
Unmarshal XML data from the specified pull parser and return the resulting content tree.

<T>  
`JAXBElement<T> unmarshal(XMLEventReader reader, Class<T> declaredType)`
Unmarshal root element to JAXB mapped declaredType and return the resulting content tree.  
`Object unmarshal(XMLStreamReader reader)`
Unmarshal XML data from the specified pull parser and return the resulting content tree.

<T>  
`JAXBElement<T> unmarshal(XMLStreamReader reader, Class<T> declaredType)`
Unmarshal root element to JAXB mapped declaredType and return the resulting content tree.

throws JAXBException

Unmarshal XML data from the specified file and return the resulting content tree.

Implements Unmarshal Global Root Element.

Parameters:
  f - the file to unmarshal XML data from

Returns:
  the newly created root object of the java content tree

Throws:
  JAXBException - If any unexpected errors occur while unmarshalling
  UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
  IllegalArgumentException - If the file parameter is null

public Object unmarshal(java.io.InputStream is) throws
**JAXBException**

**InputStream XML unmarshal API**

```
is XML InputStream
return java

Throws JAXBException:

Throws UnmarshalException: ValidationEventHandler handleEvent
false Unmarshaller XML Java XML

Throws IllegalArgumentException: InputStream null
```

**unmarshal**

```
Object unmarshal(InputStream is)
throws JAXBException
```

Unmarshal XML data from the specified InputStream and return the resulting content tree. Validation event location information may be incomplete when using this form of the unmarshal API.

Implements **Unmarshal Global Root Element**.

**Parameters:**

- is - the InputStream to unmarshal XML data from

**Returns:**

- the newly created root object of the java content tree

**Throws:**

- JAXBException - If any unexpected errors occur while unmarshalling
- UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
- IllegalArgumentException - If the InputStream parameter is null

```
public Object unmarshal(java.io.Reader reader) throws
```
JAXBException
Reader XML unmarshal API Reader ID

```
  reader       XML Reader
  return      java
Throws    JAXBException:
  UnmarshalException: ValidationEventHandler handleEvent
  false Unmarshaller XML Java XML
  IllegalArgumentException: InputStream null
  since     JAXB2.0
```

unmarshal

```
  Object unmarshal(Reader reader)
  throws JAXBException
```

Unmarshal XML data from the specified Reader and return the resulting content tree. Validation event location information may be incomplete when using this form of the unmarshal API, because a Reader does not provide the system ID.

Implements Unmarshal Global Root Element.

Parameters:
  reader - the Reader to unmarshal XML data from

Returns:
  the newly created root object of the java content tree

Throws:
  JAXBException - If any unexpected errors occur while unmarshalling
  UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
  IllegalArgumentException - If the InputStream parameter is null
public Object unmarshal(java.net.URL url) throws JAXBException

Parameters:
url - the url to unmarshal XML data from

Returns:
the newly created root object of the java content tree

Throws:
JAXBException - If any unexpected errors occur while unmarshalling
UnmarshalingException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
public Object unmarshal(org.xml.sax.InputSource source) throws JAXBException

SAX InputSource  XML

unmarshal

Object unmarshal(InputSource source)

throws JAXBException

Unmarshal XML data from the specified SAX InputSource and return the resulting content tree.

Implements Unmarshal Global Root Element.

Parameters:

- source - the input source to unmarshal XML data from

Returns:

the newly created root object of the java content tree

Throws:

- JAXBException - If any unexpected errors occur while unmarshalling
- UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
- IllegalArgumentException - If the InputSource parameter is null
public Object unmarshal(org.w3c.dom.Node node) throws JAXBException
DOM XML

return java
Throws JAXBException:
UnmarshalException: Unmarshaller XML Java XML

Throws ValidationEventHandler handleEvent
false

Throws IllegalArgumentException: Node null
See also unmarshal(org.w3c.dom.Node, Class)

unmarshal

Object unmarshal(Node node)
throws JAXBException

Unmarshal global XML data from the specified DOM tree and return the resulting content tree.

Implements Unmarshal Global Root Element.

Parameters:
node - the document/element to unmarshal XML data from. The caller must support at least Document and Element.

Returns:
the newly created root object of the java content tree

Throws:
JAXBException - If any unexpected errors occur while unmarshalling
UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
IllegalArgumentException - If the Node parameter is null

See Also:
unmarshal(org.w3c.dom.Node, Class)

unmarshal

<T> JAXBEElement<T> unmarshal(Node node, Class<T> declaredType) throws JAXBException

Unmarshal XML data by JAXB mapped declaredType and return the resulting content tree.

Implements Unmarshal by Declared Type

Parameters:
node - the document/element to unmarshal XML data from. The caller must support at least Document and Element.
declaredType - appropriate JAXB mapped class to hold node's XML data.

Returns:
JAXB Element representation of node

Throws:
JAXBException - If any unexpected errors occur while unmarshalling
UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
IllegalArgumentException - If any parameter is null

Since:
JAXB2.0

unmarshal

Object unmarshal(Source source)
throws JAXBException

Unmarshal XML data from the specified XML Source and return the resulting content tree.
Implements **Unmarshal Global Root Element**.

**SAX 2.0 Parser Pluggability**

A client application can choose not to use the default parser mechanism supplied with their JAXB provider. Any SAX 2.0 compliant parser can be substituted for the JAXB provider's default mechanism. To do so, the client application must properly configure a SAXSource containing an XMLReader implemented by the SAX 2.0 parser provider. If the XMLReader has an org.xml.sax.ErrorHandler registered on it, it will be replaced by the JAXB Provider so that validation errors can be reported via the ValidationEventHandler mechanism of JAXB. If the SAXSource does not contain an XMLReader, then the JAXB provider's default parser mechanism will be used.

This parser replacement mechanism can also be used to replace the JAXB provider's unmarshal-time validation engine. The client application must properly configure their SAX 2.0 compliant parser to perform validation (as shown in the example above). Any SAXParserExceptions encountered by the parser during the unmarshal operation will be processed by the JAXB provider and converted into JAXB ValidationEvent objects which will be reported back to the client via the ValidationEventHandler registered with the Unmarshaller. *Note:* specifying a substitute validating SAX 2.0 parser for unmarshalling does not necessarily replace the validation engine used by the JAXB provider for performing on-demand validation.

The only way for a client application to specify an alternate parser mechanism to be used during unmarshal is via the unmarshal(SAXSource) API. All other forms of the unmarshal method (File, URL, Node, etc) will use the JAXB provider's default parser and validator mechanisms.

**Parameters:**

- **source** - the XML Source to unmarshal XML data from (providers are only required to support SAXSource, DOMSource, and StreamSource)

**Returns:**

- the newly created root object of the java content tree
Throws:

- **JAXBException** - If any unexpected errors occur while unmarshalling.
- **UnmarshalException** - If the `ValidationEventHandler` returns false from its `handleEvent` method or the Unmarshaller is unable to perform the XML to Java binding. See [Unmarshalling XML Data](#).

See Also:

- `unmarshal(javax.xml.transform.Source, Class)`

---

```java
<T> JAXBElement<T> unmarshal(Source source, Class<T> declaredType) throws JAXBException
```

Unmarshal XML data from the specified XML Source by declaredType and return the resulting content tree.

Implements [Unmarshal by Declared Type](#)

See [SAX 2.0 Parser Pluggability](#)

**Parameters:**

- `source` - the XML Source to unmarshal XML data from (providers are only required to support SAXSource, DOMSource, and StreamSource).
- `declaredType` - appropriate JAXB mapped class to hold `source`'s xml root element.

**Returns:**

Java content rooted by [JAXB Element](#)

**Throws:**

- **JAXBException** - If any unexpected errors occur while unmarshalling.
- **UnmarshalException** - If the `ValidationEventHandler` returns false from its `handleEvent` method or the Unmarshaller is unable to perform the XML to Java binding. See [Unmarshalling XML Data](#).
IllegalArgumentException - If any parameter is null

Since:
JAXB2.0

public Object unmarshal(XMLStreamReader reader) throws JAXBException
pull XML

START_DOCUMENT START_ELEMENT
reader
reader
return java
Throws JAXBException:
throws UnmarshalException: ValidationEventHandler handleEvent
false Unmarshaller XML Java XML
Throws IllegalStateException: reader null
Throws IllegalArgumentException: reader null
since JAXB2.0
See also unmarshal(javax.xml.stream.XMLStreamReader, Class)

unmarshal

Object unmarshal(XMLStreamReader reader)
throws JAXBException

Unmarshal XML data from the specified pull parser and return the resulting content tree.

Implements Unmarshal Global Root Element.

This method assumes that the parser is on a START_DOCUMENT
or START_ELEMENT event. Unmarshalling will be done from this start event to the corresponding end event. If this method returns successfully, the reader will be pointing at the token right after the end event.

**Parameters:**
reader - The parser to be read.

**Returns:**
the newly created root object of the java content tree.

**Throws:**
- **JAXBException** - If any unexpected errors occur while unmarshalling
- **UnmarshallerException** - If the ValidationEventHandle returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See [Unmarshalling XML Data](Unmarshalling_XML_Data)
- **IllegalArgumentException** - If the reader parameter is null
- **IllegalStateException** - If reader is not pointing to a START_DOCUMENT or START_ELEMENT event.

**Since:**
JAXB2.0

**See Also:**
unmarshal(javax.xml.stream.XMLStreamReader, Class)

---

unmarshal

<T> JAXBElement<T> unmarshal(XMLStreamReader reader, Class<T> declaredType)

throws JAXBException

Unmarshal root element to JAXB mapped declaredType and return the resulting content tree.

This method implements **unmarshal by declaredType**.

This method assumes that the parser is on a START_DOCUMENT or START_ELEMENT event. Unmarshalling will be done from this start event to the corresponding end event. If this method returns
successfully, the reader will be pointing at the token right after the end event.

**Parameters:**
- reader - The parser to be read.
- declaredType - appropriate JAXB mapped class to hold reader's START_ELEMENT XML data.

**Returns:**
- content tree rooted by JAXB Element representation

**Throws:**
- JAXBException - If any unexpected errors occur while unmarshalling
- UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
- IllegalArgumentException - If any parameter is null

**Since:**
- JAXB2.0

---

```java
public Object unmarshal(XMLEventReader reader) throws JAXBException
{
    pull XML

    START_DOCUMENT  START_ELEMENT
    reader
    reader
    return  java
    Throws  JAXBException:
    Throws  UnmarshalException: ValidationEventHandler handleEvent
    false Unmarshaller XML Java XML
    Throws  IllegalArgumentException: reader null
    Throws  IllegalStateException: reader null
    since  JAXB2.0
}
unmarshal

Object unmarshal(XMLEventReader reader) throws JAXBException

Unmarshal XML data from the specified pull parser and return the resulting content tree.

This method is an Unmarshal Global Root method.

This method assumes that the parser is on a START_DOCUMENT or START_ELEMENT event. Unmarshalling will be done from this start event to the corresponding end event. If this method returns successfully, the reader will be pointing at the token right after the end event.

Parameters:
    reader - The parser to be read.

Returns:
the newly created root object of the java content tree.

Throws:
    JAXBException - If any unexpected errors occur while unmarshalling
    UnmarshalException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
    IllegalArgumentException - If the reader parameter is null
    IllegalStateException - If reader is not pointing to a START_DOCUMENT or START_ELEMENT event.

Since:
    JAXB2.0

See Also:
    unmarshal(javax.xml.stream.XMLEventReader, Class)
unmarshal

<T> JAXBElement<T> unmarshal(XMLEventReader reader, Class<T> declaredType) throws JAXBException

Unmarshal root element to JAXB mapped declaredType and return the resulting content tree.

This method implements unmarshal by declaredType.

This method assumes that the parser is on a START_DOCUMENT or START_ELEMENT event. Unmarshalling will be done from this start event to the corresponding end event. If this method returns successfully, the reader will be pointing at the token right after the end event.

Parameters:
reader - The parser to be read.
declaredType - appropriate JAXB mapped class to hold reader's START_ELEMENT XML data.

Returns:
content tree rooted by JAXB Element representation

Throws:
JAXBException - If any unexpected errors occur while unmarshalling
UnmarshallingException - If the ValidationEventHandler returns false from its handleEvent method or the Unmarshaller is unable to perform the XML to Java binding. See Unmarshalling XML Data
IllegalArgumentException - If any parameter is null

Since:
JAXB2.0

public UnmarshallerHandler getUnmarshallerHandler() XML unmarshaller
getUnmarshallerHandler

Get an unmarshaller handler object that can be used as a component in an XML pipeline.

The JAXB Provider can return the same handler object for multiple invocations of this method. In other words, this method does not necessarily create a new instance of UnmarshallerHandler. If the application needs to use more than one UnmarshallerHandler, it should create more than one Unmarshaller.

Returns:
the unmarshaller handler object

See Also:
UnmarshallerHandler

public void setValidating(boolean validating) throws JAXBException

unmarshal

JAXB SAX 2.0 API JAXB ""

JAXB 2.0 API

setSchema(javax.xml.val
setValidating

void setValidating(boolean validating)
    throws JAXBException

Deprecated. since JAXB2.0, please see
setSchema(javax.xml.validation.Schema)

Specifies whether or not the default validation mechanism of the
Unmarshaller should validate during unmarshal operations. By
default, the Unmarshaller does not validate.

This method may only be invoked before or after calling one of the
unmarshal methods.

This method only controls the JAXB Provider's default unmarshal-
time validation mechanism - it has no impact on clients that specify
their own validating SAX 2.0 compliant parser. Clients that specify
their own unmarshal-time validation mechanism may wish to turn off
the JAXB Provider's default validation mechanism via this API to avoid "double validation".

This method is deprecated as of JAXB 2.0 - please use the new
setSchema(javax.xml.validation.Schema) API.

Parameters:
    validating - true if the Unmarshaller should validate during
unmarshal, false otherwise

Throws:
    JAXBException - if an error occurred while enabling or disabling
validation at unmarshal time
    UnsupportedOperationException - could be thrown if this method
is invoked on an Unmarshaller created from a JAXBContext referencing JAXB 2.0 mapped classes

public boolean isValidating() throws JAXBException
Unmarshaller

API JAXB

JAXB 2.0

getSchema() API

return Unmarshaller true false
Throws JAXBException:
Throws UnsupportedOperationException: JAXB 2.0
JAXBContext Unmarshaller
deprecated JAXB 2.0 getSchema()

isValidating

boolean isValidating() throws JAXBException

Deprecated. since JAXB2.0, please see getSchema()

Indicates whether or not the Unmarshaller is configured to validate during unmarshal operations.

This API returns the state of the JAXB Provider's default unmarshal-time validation mechanism.

This method is deprecated as of JAXB 2.0 - please use the new getSchema() API.

Returns:
true if the Unmarshaller is configured to validate during unmarshal operations, false otherwise

Throws:
public void setEventHandler(ValidationEventHandler handler) throws JAXBException

ValidationEventHandler

unmarshal ValidationEventHandler
unmarshal ValidationEventHandler

null Unmarshaller
handler

Unmarshaller

void setEventHandler(ValidationEventHandler handler)

throws JAXBException

Allow an application to register a ValidationEventHandler.

The ValidationEventHandler will be called by the JAXB Provider if any validation errors are encountered during calls to any of the unmarshal methods. If the client application does not register a ValidationEventHandler before invoking the unmarshal methods, then ValidationEvents will be handled by the default event handler which will terminate the unmarshal operation after the first error or fatal error is encountered.

Calling this method with a null parameter will cause the Unmarshaller to revert back to the default event handler.
Parameters:
  handler - the validation event handler

Throws:
  JAXBException - if an error was encountered while setting the event handler

public ValidationEventHandler getEventHandler() throws JAXBException

  return ValidationEventHandler
  Throws JAXBException:

getEventHandler

ValidationEventHandler getEventHandler() throws JAXBException

  Return the current event handler or the default event handler if one hasn't been set.

Returns:
  the current ValidationEventHandler or the default event handler if it hasn't been set

Throws:
  JAXBException - if an error was encountered while getting the current event handler

public void setProperty(String name, Object value) throws PropertyException

UnmarshalException JAXB PropertyException

  name
  value
  Throws PropertyException:
  Throws IllegalArgumentException: name null
**setProperty**

```java
void setProperty(String name, 
                Object value) 
    throws PropertyException
```

Set the particular property in the underlying implementation of Unmarshaller. This method can only be used to set one of the standard JAXB defined properties above or a provider specific property. Attempting to set an undefined property will result in a PropertyException being thrown. See [Supported Properties](#).

**Parameters:**
- `name` - the name of the property to be set. This value can either be specified using one of the constant fields or a user supplied string.
- `value` - the value of the property to be set

**Throws:**
- `PropertyException` - when there is an error processing the given property or value
- `IllegalArgumentException` - If the name parameter is null

---

**public Object getProperty(String name) throws PropertyException**

```java
Unmarshaller JAXB PropertyException
    name
    return
    Throws PropertyException:
    Throws IllegalArgumentException: name null
```

---

**getProperty**

```java
Object getProperty(String name) 
    throws PropertyException
```
Get the particular property in the underlying implementation of Unmarshaller. This method can only be used to get one of the standard JAXB defined properties above or a provider specific property. Attempting to get an undefined property will result in a PropertyException being thrown. See Supported Properties.

**Parameters:**

- `name` - the name of the property to retrieve

**Returns:**

the value of the requested property

**Throws:**

- `PropertyException` - when there is an error retrieving the given property or value property name
- `IllegalArgumentException` - If the name parameter is null

```java
public void setSchema(javax.xml.validation.Schema schema)
```

**JAXP 1.3**

Set the JAXP 1.3 Schema object that should be used to validate subsequent unmarshal operations against. Passing null into this method will disable validation.

```java
public void setValidating(boolean)
```

**API**

Set whether the Unmarshaller should validate during unmarshaling. Null indicates the default, which is to not validate.

```java
setSchema(Schema schema)
```

Throws

- `UnsupportedOperationException`: JAXB 1.0 JAXBContext Unmarshaller

**since**

JAXB2.0
This method replaces the deprecated `setValidating(boolean)` API.

Initially this property is set to `null`.

**Parameters:**

- `schema` - Schema object to validate unmarshal operations against or `null` to disable validation

**Throws:**

- `UnsupportedOperationException` - could be thrown if this method is invoked on an Unmarshaller created from a JAXBContext referencing JAXB 1.0 mapped classes

**Since:**

JAXB2.0

---

```java
public javax.xml.validation.Schema getSchema()
JAXP 1.3
null

#isValidating() API
null

boolean isValidating = u.getSchema()!=null;
return Schema null

Throws
UnsupportedOperationException: JAXB 1.0 JAXBContext Unmarshaller
since JAXB2.0
```

**getSchema**

```java
Schema getSchema()
```

Get the JAXP 1.3 `Schema` object being used to perform unmarshal-time validation. If there is no Schema set on the unmarshaller, then this method will return null indicating that unmarshal-time validation will not be performed.
This method provides replacement functionality for the deprecated `isValidating()` API as well as access to the Schema object. To determine if the Unmarshaller has validation enabled, simply test the return type for null:

```java
boolean isValidating = u.getSchema()!=null;
```

**Returns:**
the Schema object being used to perform unmarshal-time validation or null if not present

**Throws:**
`UnsupportedOperationException` - could be thrown if this method is invoked on an Unmarshaller created from a JAXBContext referencing JAXB 1.0 mapped classes

**Since:**
JAXB2.0

---

**public void setAdapter("XmlAdapter adapter)\**

```java
XmlAdapter unmarshaller

setAdapter(adapter.getClass(),adapter);
```

**Throws**
`IllegalArgumentException`: adapter null

**Throws**
`UnsupportedOperationException`: JAXB 1.0 since JAXB2.0

**See also**
`setAdapter(Class,XmlAdapter)`

---

**setAdapter**

```java
void setAdapter(XmlAdapter adapter)
```

Associates a configured instance of `XmlAdapter` with this unmarshaller.

This is a convenience method that invokes `setAdapter(adapter.getClass(),adapter);`.
Throws:
   IllegalArgumentException - if the adapter parameter is null.
   UnsupportedOperationException - if invoked against a JAXB 1.0 implementation.

Since:
   JAXB2.0

See Also:
   setAdapter(Class,XmlAdapter)

setAdapter

<A extends XmlAdapter> void setAdapter(Class<A> type, A adapter)

Associates a configured instance of XmlAdapter with this unmarshaller.

Every unmarshaller internally maintains a Map<Class,XmlAdapter>, which it uses for unmarshalling classes whose fields/methods are annotated with XmlJavaTypeAdapter.

This method allows applications to use a configured instance of XmlAdapter. When an instance of an adapter is not given, an unmarshaller will create one by invoking its default constructor.

Parameters:
   type - The type of the adapter. The specified instance will be used when XmlJavaTypeAdapter.value() refers to this type.
   adapter - The instance of the adapter to be used. If null, it will un-register the current adapter set for this type.

Throws:
   IllegalArgumentException - if the type parameter is null.
   UnsupportedOperationException - if invoked against a JAXB 1.0 implementation.

Since:
   JAXB2.0
getAdapter

<A extends XmAdapter> A getAdapter(Class<A> type)

 Gets the adapter associated with the specified type. This is the reverse operation of the setAdapter(javax.xml.bind.annotation.adapters.XmlAdapter) method.

 **Throws:**  
  * IllegalArgumentException - if the type parameter is null.  
  * UnsupportedOperationException - if invoked agains a JAXB 1.0 implementation.

 **Since:**  
  JAXB2.0

---

public void setAttachmentUnmarshaller(AttachmentUnmarshaller au)

cid id URI

 #setSchema(Schema) unmarshaller XOP

 **Throws**  
  * IllegalStateException:

---

setAttachmentUnmarshaller

void setAttachmentUnmarshaller(AttachmentUnmarshaller au)

 Associate a context that resolves cid's, content-id URIs, to binary data passed as attachments.

 Unmarshal time validation, enabled via setSchema(Schema), must be supported even when unmarshaller is performing XOP processing.
Throws:

IllegalArgumentException - if attempt to concurrently call this method during a unmarshal operation.

```java
public AttachmentUnmarshaller getAttachmentUnmarshaller()
```

```java
AttachmentUnmarshaller getAttachmentUnmarshaller()
```

```java
public void setListener(Unmarshaller.Listener listener)
```

```java
Unmarshaller Listener Listener Listener Listener listener null Listener
```

**setListener**

```java
void setListener(Unmarshaller.Listener listener)
```

Register unmarshal event callback Unmarshaller.Listener with this Unmarshaller.

There is only one Listener per Unmarshaller. Setting a Listener replaces the previous set Listener. One can unregister current Listener by setting listener to null.

**Parameters:**

- listener - provides unmarshal event callbacks for this
public Unmarshaller.Listener getListener()

Returns:
registered Unmarshaller.Listener or null if no Listener is registered with this Unmarshaller.

Since:
JAXB2.0
javax.xml.bind  **Class Unmarshaller.Listener**

**java.lang.Object**

| javax.xml.bind.Unmarshaller.Listener |

**Enclosing interface:**

**Unmarshaller**

---

```java
public abstract static class Unmarshaller.Listener
edinstanted by Object

**Contained within:** Unmarshaller

Unmarshaller

XML JAXB JAXB XML JAXBElement JAXB Java

Unmarshal Event Callback

(@link #setListener(Listener)) (@link #getListener() since JAXB2.0

Register an instance of an implementation of this class with Unmarshaller
to externally listen for unmarshal events.

This class enables pre and post processing of an instance of a JAXB
mapped class as XML data is unmarshalled into it. The event callbacks
are called when unmarshalling XML content into a JAXBElement
instance or a JAXB mapped class that represents a complex type
definition. The event callbacks are not called when unmarshalling to an
instance of a Java datatype that represents a simple type definition.

External listener is one of two different mechanisms for defining
unmarshal event callbacks. See Unmarshal Event Callbacks for an overview.

(@link #setListener(Listener)} (@link #getListener{})

**Since:**
JAXB2.0

### Constructor Detail

**public Unmarshaller.Listener()**
### Unmarshaller.Listener

**public Unmarshaller.Listener()**

#### Method Detail

**public void beforeUnmarshal(Object target, Object parent)**

```java
public void beforeUnmarshal(Object target, Object parent)
```

**target**

<table>
<thead>
<tr>
<th>target</th>
<th>target</th>
<th>beforeUnmarshal</th>
</tr>
</thead>
<tbody>
<tr>
<td>target</td>
<td>JAXB</td>
<td>null</td>
</tr>
<tr>
<td>parent</td>
<td>target</td>
<td>JAXB</td>
</tr>
<tr>
<td></td>
<td>target</td>
<td>null</td>
</tr>
</tbody>
</table>

**beforeUnmarshal**

Public void **beforeUnmarshal(Object target, Object parent)**

Callback method invoked before unmarshalling into target.

This method is invoked immediately after target was created and before the unmarshalling of this object begins. Note that if the class of target defines its own beforeUnmarshal method, the class specific callback method is invoked before this method is invoked.

**Parameters:**

- **target** - non-null instance of JAXB mapped class prior to unmarshalling into it.
- **parent** - instance of JAXB mapped class that will eventually reference target. null when target is root element.

**public void afterUnmarshal(Object target, Object parent)**

```java
public void afterUnmarshal(Object target, Object parent)
```
afterUnmarshal

```java
public void afterUnmarshal(Object target, Object parent)
```

Callback method invoked after unmarshalling XML data into `target`.

This method is invoked after all the properties (except IDREF) are unmarshalled into `target`, but before `target` is set into its parent object. Note that if the class of `target` defines its own `afterUnmarshal` method, the class specific callback method is invoked before this method is invoked.

**Parameters:**
- `target` - non-null instance of JAXB mapped class prior to unmarshalling into it.
- `parent` - instance of JAXB mapped class that will reference `target`. `null` when `target` is root element.
PS:
javax.xml.bind Interface UnmarshallerHandler

All Superinterfaces:

ContentHandler

public interface UnmarshallerHandler
extends ContentHandler

Implements: org.xml.sax.ContentHandler

SAX ContentHandler Unmarshaller

JAXB XML

JAXBContext context = JAXBContext.newInstance( "org.acme.foo" );
Unmarshaller unmarshaller = context.createUnmarshaller();
UnmarshallerHandler unmarshallerHandler = unmarshaller.getUnmarshaller();

SAXParserFactory spf = SAXParserFactory.newInstance();
spf.setNamespaceAware( true );

XMLReader xmlReader = spf.newSAXParser().getXMLReader();
xmlReader.setContentHandler( unmarshallerHandler );
xmlReader.parse( new InputSource( new FileInputStream( XML_FILE ) ) );

MyObject myObject= (MyObject)unmarshallerHandler.getResult();

/

version '$Revision: 1.2 $ $Date: 2006/03/08 16:55:17 $'

since JAXB1.0

See also getUnmarshallerHandler()

Unmarshaller implemented as SAX ContentHandler.
Applications can use this interface to use their JAXB provider as a component in an XML pipeline. For example:

```java
JAXBContext context = JAXBContext.newInstance( "org.acme.foo"
Unmarshaller unmarshaller = context.createUnmarshaller();
UnmarshallerHandler unmarshallerHandler = unmarshaller.getUnmarshallerHandler();
SAXParserFactory spf = SAXParserFactory.newInstance();
spf.setNamespaceAware( true );
XMLReader xmlReader = spf.newSAXParser().getXMLReader();
xmlReader.setContentHandler( unmarshallerHandler );
xmlReader.parse(new InputSource( new FileInputStream( XML_FILE )
MyObject myObject= (MyObject)unmarshallerHandler.getResult();
```

This interface is reusable: even if the user fails to unmarshal an object, s/he can still start a new round of unmarshalling.

Since:
JAXB1.0

gResultado

Object  getResult()
throws  JAXBException, IllegalStateException

Obtains the unmarshalled result. This method can be called only after this handler receives the endDocument SAX event.

Returns:
always return a non-null valid object which was unmarshalled.

Throws:
IllegalStateException - if this method is called before this handler receives the endDocument event.
JAXBException - if there is any unmarshalling error. Note that the implementation is allowed to throw SAXException during the parsing when it finds an error.

public UnsupportedCapabilityException()
    Throwable JAXRException

UnsupportedCapabilityException

public UnsupportedCapabilityException()

    Constructs a JAXRException object with no reason or embedded Throwable.

public UnsupportedCapabilityException(String reason)
    JAXRException String reason

UnsupportedCapabilityException

public UnsupportedCapabilityException(String reason)

    Constructs a JAXRException object with the given String as the reason for the exception being thrown.

    Parameters:
        reason - a description of what caused the exception

public UnsupportedCapabilityException(String reason, Throwable cause)
    JAXRException String Throwable
    Throwable
        reason
        cause
        JAXRException Throwable
UnsupportedCapabilityException

public UnsupportedCapabilityException(String reason, Throwable cause)

Constructs a JAXRException object with the given String as the reason for the exception being thrown and the given Throwable object as an embedded Throwable.

Parameters:
reason - a description of what caused the exception
cause - a Throwable object that is to be embedded in this JAXRException object

public UnsupportedCapabilityException(Throwable cause)

Throws:
JAXRException

cause - the Throwable that caused this Exception
to license terms.

PS:
javax.xml.registry.infomodel Interface URIValidator

All Known Subinterfaces:
   ExternalLink, ServiceBinding

public interface URIValidator

Implemented by: ExternalLink, ServiceBinding

URI

Defines common behavior expected of any class that validates URIs.

Author:
   Farrukh S. Najmi

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>boolean validateURI()</td>
</tr>
<tr>
<td>void setValidateURI(boolean validate)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>public void setValidateURI(boolean validate) throws JAXRException</td>
</tr>
</tbody>
</table>

validate true JAXR URI URI false
Throws: **JAXRException**: JAXR

**setValidateURI**

```java
void setValidateURI(boolean validate)
throws JAXRException
```

Sets whether to do URI validation for this object. Default is true.

**Capability Level: 0**

**Parameters:**
- `validate` - true implies JAXR provider must perform validation of URIs when they are set; false implies validation is turned off

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

**public boolean getValidateURI() throws JAXRException**

```java
URI
```

0

```java
return true JAXR URI URI false
```

**Throws:** **JAXRException**: JAXR

**getValidateURI**

```java
boolean getValidateURI()
throws JAXRException
```

Gets whether to do URI validation for this object.

**Capability Level: 0**

**Returns:**
true implies JAXR provider must perform validation of URIs when they are set; false implies validation is turned off

Throws:

JAXRException - If the JAXR provider encounters an internal error

PS:
javax.activation Class URLDataSource

java.lang.Object
   javax.activation.URLDataSource

All Implemented Interfaces:
   DataSource

Public class URLDataSource

extends Object
implements DataSource

Implements: DataSource

URLDataSource URL DataSource URLDataSource
JavaBeans Activation Framework URL DataHandler
URL DataHandler DataHandler URLDataSource

See also javax.activation.DataSource,
also javax.activation.DataHandler

The URLDataSource class provides an object that wraps a URL object in a
DataSource interface. URLDataSource simplifies the handling of data
described by URLs within the JavaBeans Activation Framework because
this class can be used to create new DataHandlers. NOTE: The
DataHandler object creates a URLDataSource internally, when it is
constructed with a URL.

See Also:
   DataSource, DataHandler

Constructor Summary

### Methods inherited from class java.lang.Object

- `clone`, `equals`, `finalize`, `getClass`, `hashCode`, `notify`, `notifyAll`, `toString`, `wait`, `wait`, `wait`<br>

### Constructor Detail

**public URLDataSource(java.net.URL url)**

**URLDataSource**

- `URL url`<br>

**URLDataSource**

**public URLDataSource(URL url)**

URLDataSource constructor. The URLDataSource class will not open a connection to the URL until a method requiring it to do so is called.
Parameters:

url - The URL to be encapsulated in this object.

### Method Detail

**public String getContentType()**

```java
URL - (content-type) URLConnection
URLConnection.openConnection
URLConnection.getContentType
"application/octet-stream"
return
```

**getContentType**

**public String getContentType()**

Returns the value of the URL content-type header field. It calls the URL's `URLConnection.getContentType` method after retrieving a `URLConnection` object. **Note: this method attempts to call the openConnection method on the URL. If this method fails, or if a content type is not returned from the URLConnection, getContentType returns "application/octet-stream" as the content type.**

**Specified by:**  
`getContentType` in interface `DataSource`

**Returns:**  
the content type.

**public String getName()**

```java
URL    return
getFile  URL    getFile
```
**getName**

```java
public String getName()
```

Calls the `getFile` method on the URL used to instantiate the object.

**Specified by:**
`getName` in interface `DataSource`

**Returns:**
the result of calling the URL's `getFile` method.

---

**public java.io.InputStream getInputStream() throws java.io.IOException**

```java
URL getInputStream URL
return InputStream
```

The `getInputStream` method from the URL. Calls the `openStream` method on the URL.

**Specified by:**
`getInputStream` in interface `DataSource`

**Returns:**
the InputStream.

**Throws:**
`IOException`

---

**public java.io.OutputStream getOutputStream() throws java.io.IOException**

```java
URL getOutputStream URL URLConnection
URLConnection getOutputStream URL
```

---
getOutputStream

public OutputStream getOutputStream()
throws IOException

The getOutputStream method from the URL. First an attempt is made to get the URLConnection object for the URL. If that succeeds, the getOutputStream method on the URLConnection is returned.

Specified by:
getOutputStream in interface DataSource

Returns:
the OutputStream.

Throws:
IOException

public java.net.URL getURL()

DataSource URL

return URL

getURL

public URL getURL()

Return the URL used to create this DataSource.

Returns:
The URL.
javax.mail  Class URLName

java.lang.Object
   _javax.mail.URLName

public class URLName
extends Object

URL URL Internet URL

   java.net.URL URL URL
   version 1.19, 07/05/04

The name of a URL. This class represents a URL name and also provides the basic parsing functionality to parse most internet standard URL schemes.

Note that this class differs from java.net.URL in that this class just represents the name of a URL, it does not model the connection to a URL.

Version:
   1.19, 07/05/04

Author:
   Christopher Cotton, Bill Shannon

**Field Detail**

**fullURL**

protected **String** fullURL

The full version of the URL

---

**Constructor Detail**

public **URLName**(String protocol, String host, int port, String file, String username, String password)

**URLName** -1 URL

**URLName**

public **URLName**(String protocol,

    String host,

    int port,

    String file,

    String username,

    String password)

Creates a URLName object from the specified protocol, host, port number, file, username, and password. Specifying a port number of -1 indicates that the URL should use the default port for the protocol.

public **URLName**(java.net.URL url)
java.net.URL  URLName

URLName

public URLName(URL url)

Construct a URLName from a java.net.URL object.

public URLName(String url)

Construct a URLName from the string. Parses out all the possible information (protocol, host, port, file, username, password).

Method Detail

public String toString()

toString

public String toString()

Constructs a string representation of this URLName.

Overrides:

toString in class Object
protected void parseString(String url)

parseString

protected void parseString(String url)

Method which does all of the work of parsing the string.

public int getPort()
URLName -1

getPort

public int getPort()

Returns the port number of this URLName. Returns -1 if the port is not set.

public String getProtocol()
URLName URLName null

getProtocol

public String getProtocol()

Returns the protocol of this URLName. Returns null if this URLName has no protocol.

public String getFile()
URLName URLName null
**getFileName**

```java
public String getFile()
```

Returns the file name of this URLName. Returns null if this URLName has no file name.

**getRef**

```java
public String getRef()
```

Returns the reference of this URLName. Returns null if this URLName has no reference.

**getHost**

```java
public String getHost()
```

Returns the host of this URLName. Returns null if this URLName has no host.
**getUsername**

```java
public String getUsername()

    Returns the user name of this URLName. Returns null if this
    URLName has no user name.
```

**public String getPassword()**

```java
URLName  URLName  null
```

**getPassword**

```java
public String getPassword()

    Returns the password of this URLName. Returns null if this
    URLName has no password.
```

**public java.net.URL getURL() throws java.net.MalformedURLException**

```java
URLName URLException  URL
```

**getURL**

```java
public URL getURL()

    Constructs a URL from the URLName.

    **Throws:**
    java.net.MalformedURLException
```

**public boolean equals(Object obj)**

```java
URLName null URLName  URLName  true
```
equals

public boolean equals(Object obj)

Compares two URLNames. The result is true if and only if the argument is not null and is a URLName object that represents the same URLName as this object. Two URLName objects are equal if they have the same protocol and the same host, the same port number on the host, the same username, and the same file on the host. The fields (host, username, file) are also considered the same if they are both null.

Hosts are considered equal if the names are equal (case independent) or if host name lookups for them both succeed and they both reference the same IP address.

Note that URLName has no knowledge of default port numbers for particular protocols, so "imap://host" and "imap://host:143" would not compare as equal.

Note also that the password field is not included in the comparison, nor is any reference field appended to the filename.

Overrides:

equals in class Object
public int hashCode()
URLName

hashCode

public int hashCode()

Compute the hash code for this URLName.

Overrides:
hashCode in class Object
public interface URLStats

extends Stats

Implements: Stats

URL

Specifies the statistics provided by a URL resource.

Method Detail

public Organization getOrganization() throws JAXRException
User Organization

0

getOrganization

Organization getOrganization()
throws JAXRException

Gets the Organization that this User is affiliated with.

Capability Level: 0

Returns:
the Organization that this User is affiliated with

Throws:
JAXRException - If the JAXR provider encounters an internal error
public PersonName getPersonName() throws JAXRException
User

Returns the name of this User.

Capability Level: 0

Returns: the name of this User

Throws: JAXRException - If the JAXR provider encounters an internal error

public void setPersonName(PersonName personName) throws JAXRException
User

Throws JAXRException: JAXR
setPersonName

void setPersonName(PersonName personName)
    throws JAXRException

    Sets the name of this User.

    Capability Level: 0

    Parameters:
        personName - the name of this User

    Throws:
        JAXRException - If the JAXR provider encounters an internal error

public java.util.Collection<E> getPostalAddresses() throws JAXRException
User

    return PostalAddress CollectionCollection null

    Throws
        JAXRException: JAXR

    supplierCardinality

    associates

    directed

    supplierRole

    clientCardinality

    See also
    javax.xml.registry.infomodel.PostalAddress

getPostalAddresses

Collection getPostalAddresses() throws JAXRException
Gets the postal address for this User.

**Capability Level: 0**

**Returns:**
Collection of PostalAddress instances. The Collection may be empty but not null.

**Throws:**
- [JAXRException](#) - If the JAXR provider encounters an internal error

**See Also:**
PostalAddress

```java
public void setPostalAddresses(java.util.Collection<? extends PostalAddress> addresses) throws JAXRException

User
0

addresses PostAddress Collection
Throws JAXRException: JAXR
```

**setPostalAddresses**

```java
void setPostalAddresses(Collection<PostalAddress> addresses) throws JAXRException

Sets the addresses for this User.

**Capability Level: 0**

**Parameters:**
addresses - Is a Collection of PostAddress instances.

**Throws:**
- [JAXRException](#) - If the JAXR provider encounters an internal error
public java.net.URL getUrl() throws JAXRException
User Web URL

1

    return User URL
    Throws JAXRException: JAXR

getUrl

URL getUrl() throws JAXRException

Gets the URL to the web page for this User.

Capability Level: 1

Returns:
the URL for this User's home page

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setUrl(java.net.URL url) throws JAXRException
User Web URL

1

    url User URL
    Throws JAXRException: JAXR

setUrl

void setUrl(URL url) throws JAXRException
Sets the URL to the web page for this User.

**Capability Level: 1**

**Parameters:**
- `url` - the URL for this User's home page

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

```java
public java.util.Collection<E> getTelephoneNumbers(String phoneType) throws JAXRException
User
```

```java
return null
```

**Throws**
- `JAXRException`: JAXR
- `supplierCardinality`: 1
- `associates`: `(){TelephoneNumber}
- `supplierRole`: `phones`
- `clientCardinality`: `1..*`

**See also**
- `javax.xml.registry.infomodel.TelephoneNumber`

**getTelephoneNumbers**

```java
Collection getTelephoneNumbers(String phoneType)
```

`throws JAXRException`

Gets the telephone numbers for this User that match the specified telephone number type.
Capability Level: 0

Parameters:
    phoneType - specifies the type of phone numbers to be returned. If phoneType is null, return all telephoneNumbers

Returns:
    Collection of TelephoneNumber instances. The Collection may be empty but not null.

Throws:
    JAXRException - If the JAXR provider encounters an internal error

See Also:
    TelephoneNumber

```
public void setTelephoneNumbers(java.util.Collection<E> phoneNumbers) throws JAXRException
```

0

```
phoneNumbers  TelephoneNumber  Collection
Throws         JAXRException: JAXR
```

setTelephoneNumbers

```
void setTelephoneNumbers(Collection phoneNumbers) throws JAXRException
```

Sets the various telephone numbers for this user.

Capability Level: 0

Parameters:
    phoneNumbers - the Collection of TelephoneNumbers to be set

Throws:
    JAXRException - If the JAXR provider encounters an internal error
public java.util.Collection<E> getEmailAddresses() throws JAXRException

User

0

return EmailAddress CollectionCollection null

Throws JAXRException: JAXR

supplierCardinality 1

associates <EmailAddress>

directed

supplierRole emailAddresses

clientCardinality 0..*

See also javax.xml.registry.infomodel.EmailAddress

getEmailAddresses

Collection getEmailAddresses() throws JAXRException

Gets the email addresses for this User.

Capability Level: 0

Returns:
Collection of EmailAddress instances. The Collection may be empty but not null.

Throws:
JAXRException - If the JAXR provider encounters an internal error

See Also:
EmailAddress
public void setEmailAddresses(java.util.Collection<E> emailAddresses) throws JAXRException
User EmailAddress Collection

void setEmailAddresses(Collection emailAddresses)
throws JAXRException

Sets the Collection of EmailAddress instances for this User.

Capability Level: 0

Parameters:
   emailAddresses - the Collection of EmailAddresses to be set

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public String getType() throws JAXRException
User NULL

String getType

return User String

Throws JAXRException: JAXR
String getType() throws JAXRException

Gets the type for this User. Default is a NULL String.

Capability Level: 0

Returns:
the type for this User, which is an arbitrary String

Throws:
JAXRException - If the JAXR provider encounters an internal error

public void setType(String type) throws JAXRException

User

0

type User String

Throws JAXRException: JAXR

setType

void setType(String type)
throws JAXRException

Sets the type for this User.

Capability Level: 0

Parameters:
  type - the type for this User, which is an arbitrary String

Throws:
  JAXRException - If the JAXR provider encounters an internal error

<tr>
<td>void setRollbackOnly()</td>
<td>Modify the transaction associated with the current thread such that the only possible outcome of the transaction is to rollback the transaction.</td>
</tr>
<tr>
<td>void setTransactionTimeout(int seconds)</td>
<td>Modify the timeout value that is associated with transactions started by the current thread with the begin method.</td>
</tr>
</tbody>
</table>
public void begin() throws NotSupportedException, SystemException

Throws NotSupportedException: TransactionManager
Throws SystemException:

begin

void begin() throws NotSupportedException, SystemException

Create a new transaction and associate it with the current thread.

Throws:
- NotSupportedException - Thrown if the thread is already associated with a transaction and the Transaction Manager implementation does not support nested transactions.
- SystemException - Thrown if the transaction manager encounters an unexpected error condition.

public void commit() throws RollbackException, HeuristicMixedException, HeuristicRollbackException, SecurityException, IllegalStateException, SystemException

Throws RollbackException:
Throws HeuristicMixedException:
Throws HeuristicRollbackException:
Throws SecurityException:
Throws IllegalStateException:
Throws SystemException:

commit
void commit()
    throws RollbackException,
            HeuristicMixedException,
            HeuristicRollbackException,
            SecurityException,
            IllegalStateException,
            SystemException

Complete the transaction associated with the current thread. When
this method completes, the thread is no longer associated with a
transaction.

Throws:
    RollbackException - Thrown to indicate that the transaction has
been rolled back rather than committed.
    HeuristicMixedException - Thrown to indicate that a heuristic
decision was made and that some relevant updates have been
committed while others have been rolled back.
    HeuristicRollbackException - Thrown to indicate that a heuristic
decision was made and that all relevant updates have been
rolled back.
    SecurityException - Thrown to indicate that the thread is not
allowed to commit the transaction.
    IllegalStateException - Thrown if the current thread is not
associated with a transaction.
    SystemException - Thrown if the transaction manager encounters
an unexpected error condition.

public void rollback() throws IllegalStateException,
            SecurityException, SystemException

    Throws SecurityException: 
    Throws IllegalStateException: 
    Throws SystemException: 

rollback
void rollback() throws IllegalStateException, SecurityException, SystemException

Roll back the transaction associated with the current thread. When this method completes, the thread is no longer associated with a transaction.

Throws:
SecurityException - Thrown to indicate that the thread is not allowed to roll back the transaction.
IllegalStateException - Thrown if the current thread is not associated with a transaction.
SystemException - Thrown if the transaction manager encounters an unexpected error condition.

public void setRollbackOnly() throws IllegalStateException, SystemException

Throws
IllegalStateException:
SystemException:

setRollbackOnly

void setRollbackOnly() throws IllegalStateException, SystemException

Modify the transaction associated with the current thread such that the only possible outcome of the transaction is to roll back the transaction.

Throws:
IllegalStateException - Thrown if the current thread is not associated with a transaction.
SystemException - Thrown if the transaction manager encounters an unexpected error condition.
public int getStatus() throws SystemException

    return Status.NoTransaction

Throws SystemException:

getStatus

int getStatus() throws SystemException

    Obtain the status of the transaction associated with the current thread.

    Returns:
    The transaction status. If no transaction is associated with the current thread, this method returns the Status.NoTransaction value.

    Throws:
    SystemException - Thrown if the transaction manager encounters an unexpected error condition.

public void setTransactionTimeout(int seconds) throws SystemException

begin

    seconds 0 SystemException

Throws SystemException:

setTransactionTimeout

void setTransactionTimeout(int seconds)
throws SystemException

Modify the timeout value that is associated with transactions started by the current thread with the begin method.

If an application has not called this method, the transaction service uses some default value for the transaction timeout.

Parameters:
seconds - The value of the timeout in seconds. If the value is zero, the transaction service restores the default value. If the value is negative a SystemException is thrown.

Throws:
SystemException - Thrown if the transaction manager encounters an unexpected error condition.
public interface ValidatingManagedConnectionFactory

ManagedConnection ManagedConnectionFactory

ManagedConnection

version 1.0

This interface is implemented by a ManagedConnectionFactory instance that supports the ability to validate ManagedConnection objects.

This may be used by the application server to prune invalid ManagedConnection objects from its connection pool.

Version: 1.0
Author: Ram Jeyaraman

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Set getInvalidConnections(Set connectionSet)</td>
</tr>
</tbody>
</table>

This method returns a set of invalid ManagedConnection objects chosen from a specified set of ManagedConnection objects.

Method Detail

public java.util.Set<E>
getInvalidConnections(java.util.Set<E> connectionSet)
throws ResourceException

ManagedConnection connectionSet
return

Throws

getInvalidConnections

Set getInvalidConnections(Set connectionSet)
throws ResourceException

This method returns a set of invalid ManagedConnection objects chosen from a specified set of ManagedConnection objects.

Parameters:
connectionSet - a set of ManagedConnection objects that need to be validated.

Returns:
a set of invalid ManagedConnection objects.

Throws:
ResourceException - generic exception.
javax.xml.bind Interface ValidationEvent

All Known Subinterfaces:
   NotIdentifiableEvent, ParseConversionEvent, PrintConversionEvent

All Known Implementing Classes:
   NotIdentifiableEventImpl, ParseConversionEventImpl, PrintConversionEventImpl, ValidationEventImpl

public interface ValidationEvent

Implemented by: NotIdentifiableEvent, ParseConversionEvent, PrintConversionEvent, ValidationEventImpl

This event indicates that a problem was encountered while validating the incoming XML data during an unmarshal operation, while performing on-demand validation of the Java content tree, or while marshalling the Java content tree back to XML data.

Since:
   JAXB1.0

Method Detail

public int getSeverity()
/

ValidationError.WARNINGValidationError.ERROR
getSeverity

```java
int getSeverity()

Retrieve the severity code for this warning/error.

Must be one of ValidationError.WARNING, ValidationError.ERROR, or ValidationError.FATAL_ERROR.

Returns:
the severity code for this warning/error
```

public String getMessage()
/

```java
return / null
```

getMessage

```java
String getMessage()

Retrieve the text message for this warning/error.

Returns:
the text message for this warning/error or null if one wasn't set
```

public Throwable getLinkedException()
/

```java
return / null
```
getLinkedException

Throwable getLinkedException()

Retrieve the linked exception for this warning/error.

Returns:
the linked exception for this warning/error or null if one wasn't set

public ValidationEventLocator getLocator()
/

    return /

getLocator

ValidationEventLocator getLocator()

Retrieve the locator for this warning/error.

Returns:
the locator that indicates where the warning/error occurred

**Constructor Detail**

public ValidationEventCollector()

**Method Detail**

public ValidationEvent[] getEvents()

return getEvents

getEvents

public ValidationEvent[] getEvents()

Return an array of ValidationEvent objects containing a copy of each of the collected errors and warnings.

**Returns:**

a copy of all the collected errors and warnings or an empty array if there weren't any

public void reset()

reset

public void reset()
Clear all collected errors and warnings.

```java
public boolean hasEvents()
    ValidationEvent true
    return ValidationEvent true false
```

### hasEvents

```java
public boolean hasEvents()
```

Returns `true` if this event collector contains at least one `ValidationEvent`.

**Returns:**

- `true` if this event collector contains at least one `ValidationEvent`,
- `false` otherwise

```java
public boolean handleEvent(ValidationEvent event)
```

### handleEvent

```java
public boolean handleEvent(ValidationEvent event)
```

**Description copied from interface:** `ValidationEventHandler`  
Receive notification of a validation warning or error. The `ValidationEvent` will have a `ValidationEventLocator` embedded in it that indicates where the error or warning occurred.

If an unchecked runtime exception is thrown from this method, the JAXB provider will treat it as if the method returned false and interrupt the current unmarshal, validate, or marshal operation.

**Specified by:**

- `handleEvent` in interface `ValidationEventHandler`
Parameters:

- **event** - the encapsulated validation event information. It is a provider error if this parameter is null.

Returns:

- true if the JAXB Provider should attempt to continue the current unmarshal, validate, or marshal operation after handling this warning/error, false if the provider should terminate the current operation with the appropriate UnmarshalException, ValidationException, or MarshalException.

javax.xml.bind Interface ValidationEventHandler

All Known Implementing Classes:
  _DefaultValidationEventHandler, _ValidationEventCollector

public interface ValidationEventHandler

Implemented by: _DefaultValidationEventHandler,
_ValidationEventCollector

handleEvent JAXB false

Java

handleEvent false

Validator javadocs

version $Revision: 1.1 $ en
since JAXB1.0

javax.xml.bind.Unmarshaller, javax.xml.bind.Validator,
javax.xml.bind.Marshaller,
javax.xml.bind.ValidationEvent,
javax.xml.bind.util.ValidationEventCollector

A basic event handler interface for validation errors.

If an application needs to implement customized event handling, it must
implement this interface and then register it with either the Unmarshaller,
the Validator, or the Marshaller. The JAXB Provider will then report
validation errors and warnings encountered during the unmarshal, marshal, and validate operations to these event handlers.

If the `handleEvent` method throws an unchecked runtime exception, the JAXB Provider must treat that as if the method returned false, effectively terminating whatever operation was in progress at the time (unmarshal, validate, or marshal).

Modifying the Java content tree within your event handler is undefined by the specification and may result in unexpected behaviour.

Failing to return false from the `handleEvent` method after encountering a fatal error is undefined by the specification and may result in unexpected behavior.

**Default Event Handler**

See: [Validator javadocs](#)

**Since:**

JAXB1.0

return UnmarshalExceptionValidationException MarshalException false

Throws IllegalArgumentException: null

handleEvent

boolean handleEvent(ValidationEvent event)

Receive notification of a validation warning or error. The ValidationEvent will have a ValidationEventLocator embedded in it that indicates where the error or warning occurred.

If an unchecked runtime exception is thrown from this method, the JAXB provider will treat it as if the method returned false and interrupt the current unmarshal, validate, or marshal operation.

Parameters:

  event - the encapsulated validation event information. It is a provider error if this parameter is null.

Returns:

  true if the JAXB Provider should attempt to continue the current unmarshal, validate, or marshal operation after handling this warning/error, false if the provider should terminate the current operation with the appropriate UnmarshalException, ValidationException, or MarshalException.

Throws:

  IllegalArgumentException - if the event object is null.

**public int getSeverity()**

**getSeverity**

**public int getSeverity()**

*Description copied from interface: ValidationEvent*
Retrieve the severity code for this warning/error.

Must be one of ValidationEvent.WARNING, ValidationEvent.ERROR, or ValidationEvent.FATAL_ERROR.

*Specified by:*
setSeverity in interface ValidationEvent

**Returns:**
the severity code for this warning/error

**public void setSeverity(int _severity)**

**severity**

_severity  ValidationEvent.WARNING
ValidationEvent.ERROR
ValidationEvent.FATAL_ERROR

**Throws**
IllegalArgumentException: severity

**setSeverity**
public void setSeverity(int _severity)

Set the severity field of this event.

**Parameters:**

_severity - Must be one of ValidationEvent.WARNING, ValidationEvent.ERROR, or ValidationEvent.FATAL_ERROR.

**Throws:**

IllegalArgumentException - if an illegal severity field is supplied

---

public String getMessage()

**getMessage**

public String getMessage()

Description copied from interface: ValidationEvent
Retrieve the text message for this warning/error.

**Specified by:**

getMessage in interface ValidationEvent

**Returns:**

the text message for this warning/error or null if one wasn't set

---

public void setMessage(String _message)

setMessage

public void setMessage(String _message)

Set the message field of this event.

**Parameters:**
_message - String message - may be null.

public Throwable getLinkedException()

getLinkedException

public Throwable getLinkedException()

Description copied from interface: ValidationEvent
Retrieve the linked exception for this warning/error.

Specified by:
getLinkedException in interface ValidationEvent

Returns:
the linked exception for this warning/error or null if one wasn't set

public void setLinkedException(Throwable _linkedException)

_setLinkedException

_setLinkedException

null

setLinkedException

public void setLinkedException(Throwable _linkedException)

Set the linked exception field of this event.

Parameters:
_linkedException - Optional linked exception - may be null.

public ValidationEventLocator getLocator()
getLocator

public ValidationEventLocator getLocator()

Description copied from interface: ValidationEvent
Retrieve the locator for this warning/error.

Specified by:
   getLocator in interface ValidationEvent

Returns:
   the locator that indicates where the warning/error occurred

public void setLocator(ValidationEventLocator _locator)

   _locator null

setLocator

public void setLocator(ValidationEventLocator _locator)

   Set the locator object for this event.

   Parameters:
   _locator - The locator - may be null.

public String toString()

   See also            equals(Object)

toString

public String toString()

   Returns a string representation of this object in a format helpful to
debugging.

Overrides:

`toString` in class `Object`

See Also:

`Object.equals(Object)`
**javax.xml.bind** Interface **ValidationEventLocator**

All Known Implementing Classes:
  
  [ValidationEventLocatorImpl](#)

---

```java
public interface ValidationEventLocator

Implemented by: [ValidationEventLocatorImpl](#)

ValidationEvent

  ValidationEventLocator ValidationEvent on-demand validation Java unmarshal-time validation XML url Node

  **version** $Revision: 1.1 $**

  **since** JAXB1.0

See also [javax.xml.bind.Validator](#), [javax.xml.bind.ValidationEvent](#)
```

Encapsulate the location of a ValidationEvent.

The ValidationEventLocator indicates where the ValidationEvent occurred. Different fields will be set depending on the type of validation that was being performed when the error or warning was detected. For example, on-demand validation would produce locators that contained references to objects in the Java content tree while unmarshal-time validation would produce locators containing information appropriate to the source of the XML data (file, url, Node, etc).

Constructor Detail

public ValidationEventLocatorImpl()
**ValidationEventLocatorImpl**

```java
public ValidationEventLocatorImpl(Locator loc)

Constructs an object from an org.xml.sax.Locator. The object's ColumnNumber, LineNumber, and URL become available from the values returned by the locator's getColumnNumber(), getLineNumber(), and getSystemId() methods respectively. Node, Object, and Offset are not available.

**Parameters:**
- **loc** - the SAX Locator object that will be used to populate this event locator.

**Throws:**
- **IllegalArgumentException** - if the Locator is null

public ValidationEventLocatorImpl(org.xml.sax.SAXParseException e)

SAXParseException ColumnNumber
LineNumber URL Locator getColumnNumber() getLineNumber() getSystemId() NodeObject Offset
e SAXParseException

**Throws**
- **IllegalArgumentException** - SAXParseException null
ValidationEventLocatorImpl

public ValidationEventLocatorImpl(SAXParseException e)

Constructs an object from the location information of a SAXParseException. The object's ColumnNumber, LineNumber, and URL become available from the values returned by the locator's getColumnNumber(), getLineNumber(), and getSystemId() methods respectively. Node, Object, and Offset are not available.

Parameters:
e - the SAXParseException object that will be used to populate this event locator.

Throws:
IllegalArgumentException - if the SAXParseException is null

public ValidationEventLocatorImpl(org.w3c.dom.Node _node)

DOM Node ColumnNumber
LineNumber ObjectOffset URL
_node DOM Node

Throws
IllegalArgumentException: Node null

ValidationEventLocatorImpl

public ValidationEventLocatorImpl(Node _node)

Constructs an object that points to a DOM Node. The object's Node becomes available. ColumnNumber, LineNumber, Object, Offset, and URL are not available.

Parameters:
_node - the DOM Node object that will be used to populate this event locator.

Throws:
IllegalArgumentException - if the Node is null
ValidationEventLocatorImpl

public ValidationEventLocatorImpl(Object _object)

Constructs an object that points to a JAXB content object. The object's Object becomes available. ColumnNumber, LineNumber, Node, Offset, and URL are not available.

Parameters:
   _object - the Object that will be used to populate this event locator.

Throws:
   IllegalArgumentException - if the Object is null

Method Detail

getURL

public java.net.URL getURL()

See also getURL()
Returns:
the name of the XML source as a URL or null if unavailable

See Also:
ValidationEventLocator.getURL()

---

class ValidationEventLocator {
    public void setURL(java.net.URL _url) {
        URL _url;
    }

    public void setURL(URL _url) {
        Set the URL field on this event locator. Null values are allowed.
        Parameters:
        _url - the url
    }

    public int getOffset() {
        See also
        getOffset()
    }

    public int getOffset() {
        Description copied from interface: ValidationEventLocator
        Return the byte offset if available
        Specified by:
        getOffset in interface ValidationEventLocator
        Returns:
        the byte offset into the input source or -1 if unavailable
        See Also:
        ValidationEventLocator.getOffset()
    }
}
public void setOffset(int _offset)
  
  offset
  
  _offset

setOffset

public void setOffset(int _offset)

  Set the offset field on this event locator.

  Parameters:
  
  _offset - the offset

public int getLineNumber()

  See also

  getLineNumber()

getLineNumber

public int getLineNumber()

  Description copied from interface: ValidationEventLocator
  Return the line number if available

  Specified by:
  
  getLineNumber in interface ValidationEventLocator

  Returns:
  
  the line number or -1 if unavailable

  See Also:
  
  ValidationEventLocator.getLineNumber()

public void setLineNumber(int _lineNumber)

  lineNumber
  
  _lineNumber
**setLineNumber**

```java
public void setLineNumber(int _lineNumber)
```

Set the lineNumber field on this event locator.

**Parameters:**

_`lineNumber` - the line number

---

**public int getColumnNumber()**

See also

getColumnNumber()

**getColumnNumber**

```java
public int getColumnNumber()
```

**Description copied from interface:** `ValidationEventLocator`

Return the column number if available

**Specified by:**

`getColumnNumber` in interface `ValidationEventLocator`

**Returns:**

the column number or -1 if unavailable

See Also:

`ValidationEventLocator.getColumnNumber()`

---

**public void setColumnNumber(int _columnNumber)**

```java
_columnNumber
```

**setColumnNumber**
public void setColumnNumber(int _columnNumber)

Set the columnNumber field on this event locator.

Parameters:
_columnNumber - the column number

---

public Object getObject()

See also

getObject()

gGetObject

public Object getObject()

Description copied from interface: ValidationEventLocator
Return a reference to the object in the Java content tree if available

Specified by:

gGetObject in interface ValidationEventLocator

Returns:
a reference to the object in the Java content tree or null if unavailable

See Also:

ValidationEventLocator.getObject()

---

public void setObject(Object _object)

Object null

_setObject

java

setObject

public void setObject(Object _object)

Set the Object field on this event locator. Null values are allowed.
Parameters:
_object - the java content object

public org.w3c.dom.Node getNode()

See also
getNode()

getNode

public Node getNode()

Description copied from interface: ValidationEventLocator
Return a reference to the DOM Node if available

Specified by:
getNode in interface ValidationEventLocator

Returns:
a reference to the DOM Node or null if unavailable

See Also:
ValidationEventLocator.getNode()

public void setNode(org.w3c.dom.Node _node)
Node null

_setNode

setNode

public void setNode(Node node)

Set the Node field on this event locator. Null values are allowed.

Parameters:
_node - the Node
public String toString()

See also

equals(Object)

toString

public String toString()

Returns a string representation of this object in a format helpful to debugging.

Overrides:

toString in class Object

See Also:

Object.equals(Object)

Constructor Detail

```java
public ValidationException(String message)
```

ValidatesException errorCode linkedException null

```java
message
```

### ValidationException

```java
public ValidationException(String message)
```

Construct an ValidationException with the specified detail message. The errorCode and linkedException will default to null.

**Parameters:**

- `message` - a description of the exception

```java
public ValidationException(String message, String errorCode)
```

```java
errorCode ValidationException linkedException null
```

```java
message
```

```java
errorCode
```

### ValidationException

```java
public ValidationException(String message, String errorCode)
```

Construct an ValidationException with the specified detail message
and vendor specific errorCode. The linkedException will default to null.

**Parameters:**
- `message` - a description of the exception
- `errorCode` - a string specifying the vendor specific error code

---

```java
default constructor

public ValidationException(Throwable exception)
linkedException = ValidationException errorCode = null

exception
```

---

```java
ValidationException constructor

public ValidationException(Throwable exception)

Construct an ValidationException with a linkedException. The detail message and vendor specific errorCode will default to null.

**Parameters:**
- `exception` - the linked exception

---

```java
public ValidationException(String message, Throwable exception)
linkedException = ValidationException errorCode = null

message

exception
```

---

```java
ValidationException constructor

public ValidationException(String message, Throwable exception)

```
Construct an ValidationException with the specified detail message and linkedException. The errorCode will default to null.

**Parameters:**
- `message` - a description of the exception
- `exception` - the linked exception

```java
public ValidationException(String message, String errorCode, Throwable exception)
```

**ValidationException**

```java
public ValidationException(String message, String errorCode, Throwable exception)
```

Construct an ValidationException with the specified detail message, vendor specific errorCode, and linkedException.

**Parameters:**
- `message` - a description of the exception
- `errorCode` - a string specifying the vendor specific error code
- `exception` - the linked exception
PS:
javax.servlet.jsp.tagext  

Class **ValidationMessage**

java.lang.Object  
  ↓  javax.servlet.jsp.tagext.ValidationMessage

public class **ValidationMessage**
extends **Object**

TagLibraryValidator  TagExtraInfo

JSP 2.0 JSP  jsp:id  JSP  "id"  id  jsp:id
XML  XML  TagLibraryValidator  ValidationMessage

<table>
<thead>
<tr>
<th>id</th>
<th>jsp</th>
<th><a href="http://java.sun.com/JSP/Page">http://java.sun.com/JSP/Page</a></th>
</tr>
</thead>
<tbody>
<tr>
<td>uri</td>
<td>TagLibraryValidator</td>
<td>id</td>
</tr>
</tbody>
</table>

A validation message from either TagLibraryValidator or TagExtraInfo.

As of JSP 2.0, a JSP container must support a jsp:id attribute to provide higher quality validation errors. The container will track the JSP pages as passed to the container, and will assign to each element a unique "id", which is passed as the value of the jsp:id attribute. Each XML element in the XML view available will be extended with this attribute. The TagLibraryValidator can then use the attribute in one or more ValidationMessage objects. The container then, in turn, can use these values to provide more precise information on the location of an error.

The actual prefix of the id attribute may or may not be jsp but it will always map to the namespace http://java.sun.com/JSP/Page. A TagLibraryValidator implementation must rely on the uri, not the prefix, of the id attribute.

**Constructor Detail**

public ValidationMessage(String id, String message)  
ValidationMessage String null XML  
jsp:id id null id null id validate()  
PageData jsp:id  
    id null jsp:id  
message

**ValidationMessage**

public ValidationMessage(String id,  
String message)  
Create a ValidationMessage. The message String should be non-null. The value of id may be null, if the message is not specific to any XML element, or if no jsp:id attributes were passed on. If non-null, the value of id must be the value of a jsp:id attribute for the
PageData passed into the validate() method.

**Parameters:**
- id - Either null, or the value of a jsp:id attribute.
- message - A localized validation message.

### Method Detail

**public String getId()**
```java
jsp:idnull
    return jsp:id
```

**getId**

**public String getId()**
```
    Get the jsp:id. Null means that there is no information available.
```

**Returns:**
- The jsp:id information.

**public String getMessage()**
```java
return
```

**getMessage**

**public String getMessage()**
```
    Get the localized validation message.
```

**Returns:**
- A validation message

javax.faces.validator Interface Validator

All Superinterfaces:
   EventListener

All Known Implementing Classes:
   DoubleRangeValidator, LengthValidator, LongRangeValidator, MethodExpressionValidator

public interface Validator
extends EventListener

Implements: java.util.EventListener
Implemented by: DoubleRangeValidator, LengthValidator, LongRangeValidator, MethodExpressionValidator

A Validator implementation is a class that can perform validation (correctness checks) on a EditableValueHolder. Zero or more Validators can be associated with each EditableValueHolder in the view, and are called during the Process Validations phase of the request processing lifecycle.

Individual Validators should examine the value and component that they are passed, and throw a ValidatorException containing a FacesMessage,
documenting any failures to conform to the required rules.

For maximum generality, Validator instances may be configurable based on properties of the Validator implementation class. For example, a range check Validator might support configuration of the minimum and maximum values to be used.

Validator implementations must have a zero-arguments public constructor. In addition, if the Validator class wishes to have configuration property values saved and restored with the view, the implementation must also implement StateHolder.

---

**Field Summary**

<table>
<thead>
<tr>
<th>static String NOT_IN_RANGE_MESSAGE_ID</th>
<th>Deprecated. Use DoubleRangeValidator.NOT_IN_RANGE_MESSAGE_ID or LongRangeValidator.NOT_IN_RANGE_MESSAGE_ID instead.</th>
</tr>
</thead>
</table>

**Method Summary**

```java
void validate(FacesContext context, UIComponent component, Object value)
```

Perform the correctness checks implemented by this Validator against the specified UIComponent.

**Field Detail**

**NOT_IN_RANGE_MESSAGE_ID**

static final String NOT_IN_RANGE_MESSAGE_ID

**Deprecated. Use DoubleRangeValidator.NOT_IN_RANGE_MESSAGE_ID or LongRangeValidator.NOT_IN_RANGE_MESSAGE_ID instead.**
The message identifier of the FacesMessage to be created if the maximum or minimum value check fails, and both the maximum and minimum values for this validator have been set. The message format string for this message may optionally include a \{0\} placeholder, which will be replaced by the configured minimum value, and a \{1\} placeholder, which will be replaced by the configured maximum value.

- **value**

**Throws**

- ValidatorException:

**Throws**

- NullPointerException: context component null

validate

```java
void validate(FacesContext context, UIComponent component, Object value) throws ValidatorException
```

Perform the correctness checks implemented by this Validator against the specified UIComponent. If any violations are found, a ValidatorException will be thrown containing the FacesMessage describing the failure.
Parameters:

- context - FacesContext for the request we are processing
- component - UIComponent we are checking for correctness
- value - the value to validate

Throws:

- ValidatorException - if validation fails
- NullPointerException - if context or component is null

Marshaller

validateunmarshal  marshal
Vali

setEventHandler  API  ValidatorUnmarshaller  Marshaller

Unmarshaller  /  Validator
As of JAXB 2.0, this class is deprecated and optional.

The `Validator` class is responsible for controlling the validation of content trees during runtime.

**Three Forms of Validation**

**Unmarshal-Time Validation**

This form of validation enables a client application to receive information about validation errors and warnings detected while unmarshalling XML data into a Java content tree and is completely orthogonal to the other types of validation. To enable or disable it, see the javadoc for `Unmarshaller.setValidating`. All JAXB 1.0 Providers are required to support this operation.
On-Demand Validation

This form of validation enables a client application to receive information about validation errors and warnings detected in the Java content tree. At any point, client applications can call the `Validator.validate` method on the Java content tree (or any sub-tree of it). All JAXB 1.0 Providers are required to support this operation.

Fail-Fast Validation

This form of validation enables a client application to receive immediate feedback about modifications to the Java content tree that violate type constraints on Java Properties as defined in the specification. JAXB Providers are not required support this type of validation. Of the JAXB Providers that do support this type of validation, some may require you to decide at schema compile time whether or not a client application will be allowed to request fail-fast validation at runtime.

The `Validator` class is responsible for managing On-Demand Validation. The `Unmarshaller` class is responsible for managing Unmarshal-Time Validation during the unmarshal operations. Although there is no formal method of enabling validation during the marshal operations, the `Marshaller` may detect errors, which will be reported to the `ValidationEventHandler` registered on it.

Using the Default EventHandler

If the client application does not set an event handler on their `Validator`, `Unmarshaller`, or `Marshaller` prior to calling the `validate`, `unmarshal`, or `marshal` methods, then a default event handler will receive notification of any errors or warnings encountered. The default event handler will cause the current operation to halt after encountering the first error or fatal error (but will attempt to continue after receiving warnings).

Handling Validation Events

There are three ways to handle events encountered during the unmarshal, validate, and marshal operations:
Use the default event handler
The default event handler will be used if you do not specify one via the setEventHandler API's on Validator, Unmarshaller, or Marshaller.

Implement and register a custom event handler
Client applications that require sophisticated event processing can implement the ValidationEventHandler interface and register it with the Unmarshaller and/or Validator.

Use the ValidationEventCollector utility
For convenience, a specialized event handler is provided that simply collects any ValidationEvent objects created during the unmarshal, validate, and marshal operations and returns them to the client application as a java.util.Collection.

Validation and Well-Formedness

Validation events are handled differently depending on how the client application is configured to process them as described in the previous section. However, there are certain cases where a JAXB Provider indicates that it is no longer able to reliably detect and report errors. In these cases, the JAXB Provider will set the severity of the ValidationEvent to FATAL_ERROR to indicate that the unmarshal, validate, or marshal operations should be terminated. The default event handler and ValidationEventCollector utility class must terminate processing after being notified of a fatal error. Client applications that supply their own ValidationEventHandler should also terminate processing after being notified of a fatal error. If not, unexpected behaviour may occur.

Supported Properties

There currently are not any properties required to be supported by all JAXB Providers on Validator. However, some providers may support their own set of provider specific properties.

</tr>
</tbody>
</table>

## Method Detail

```java
public void setEventHandler(ValidationEventHandler handler) throws JAXBException
```

```java
validate JAXB
null Validator
handler
```
setEvent.Handler

void setEvent.Handler(ValidationEventHandler handler)
throws JAXBException

Deprecated. since JAXB2.0

Allow an application to register a validation event handler.

The validation event handler will be called by the JAXB Provider if any validation errors are encountered during calls to validate. If the client application does not register a validation event handler before invoking the validate method, then validation events will be handled by the default event handler which will terminate the validate operation after the first error or fatal error is encountered.

Calling this method with a null parameter will cause the Validator to revert back to the default default event handler.

Parameters:
handler - the validation event handler

Throws:
JAXBException - if an error was encountered while setting the event handler

public ValidationEventHandler getEvent.Handler() throws JAXBException

return ValidationEventHandler

Throws JAXBException:

deprecated JAXB 2.0
getEventHandler

ValidationEventHandler getEventHandler() throws JAXBException

Deprecated. since JAXB2.0

Return the current event handler or the default event handler if one hasn't been set.

Returns:
the current ValidationEventHandler or the default event handler if it hasn't been set

Throws:
JAXBException - if an error was encountered while getting the current event handler

public boolean validate(Object subrootObj) throws JAXBException

subrootObj Java

Java subrootObj

Throws JAXBException:

Throws ValidationException:

Throws ValidationEventHandler
handleEvent false Validator subrootObj

Throws IllegalArgumentException:
return subrootObj null
return subrootObj true false
deprecated JAXB 2.0

validate

boolean validate(Object subrootObj) throws JAXBException
**Deprecated. since JAXB2.0**

Validate the Java content tree starting at `subrootObj`.

Client applications can use this method to validate Java content trees on-demand at runtime. This method can be used to validate any arbitrary subtree of the Java content tree. Global constraint checking **will not** be performed as part of this operation (i.e. ID/IDREF constraints).

**Parameters:**
- `subrootObj` - the obj to begin validation at

**Returns:**
- true if the subtree rooted at `subrootObj` is valid, false otherwise

**Throws:**
- `JAXBException` - if any unexpected problem occurs during validation
- `ValidationException` - If the `ValidationEventHandler` returns false from its `handleEvent` method or the `Validator` is unable to validate the content tree rooted at `subrootObj`
- `IllegalArgumentException` - If the `subrootObj` parameter is null

```
public boolean validateRoot(Object rootObj) throws 
JAXBException
  
rootObj   Java
```

```java
Java
  
rootObj
Throws  JAXBException:
  
Throws  ValidationException:  
  
Throws  IllegalArgumentException:  rootObj null
  
return  rootObj true false
deprecated  JAXB 2.0
```
**validateRoot**

```java
boolean validateRoot(Object rootObj)
    throws JAXBException
```

**Deprecated. since JAXB2.0**

Validate the Java content tree rooted at `rootObj`.

Client applications can use this method to validate Java content trees on-demand at runtime. This method is used to validate an entire Java content tree. Global constraint checking will be performed as part of this operation (i.e. ID/IDREF constraints).

**Parameters:**
- `rootObj` - the root obj to begin validation at

**Returns:**
- true if the tree rooted at `rootObj` is valid, false otherwise

**Throws:**
- `JAXBException` - if any unexpected problem occurs during validation
- `ValidationException` - If the `ValidationEventHandler` returns false from its `handleEvent` method or the `Validator` is unable to validate the content tree rooted at `rootObj`
- `IllegalArgumentException` - If the `rootObj` parameter is null

---

**public void setProperty(String name, Object value) throws PropertyException**

- **Validator**
  - JAXB
  - PropertyException

- **Throws**
  - PropertyException:
  - `IllegalArgumentException`: name null
  - `deprecated` JAXB 2.0

**setProperty**
void setProperty(String name, Object value) throws PropertyException

*Deprecated. since JAXB2.0*

Set the particular property in the underlying implementation of Validator. This method can only be used to set one of the standard JAXB defined properties above or a provider specific property. Attempting to set an undefined property will result in a PropertyException being thrown. See [Supported Properties](#).

**Parameters:**
- name - the name of the property to be set. This value can either be specified using one of the constant fields or a user supplied string.
- value - the value of the property to be set

**Throws:**
- PropertyException - when there is an error processing the given property or value
- IllegalArgumentException - If the name parameter is null

```java
public Object getProperty(String name) throws PropertyException

*Deprecated. since JAXB2.0*
```
Get the particular property in the underlying implementation of `Validator`. This method can only be used to get one of the standard JAXB defined properties above or a provider specific property. Attempting to get an undefined property will result in a `PropertyException` being thrown. See [Supported Properties](#).

**Parameters:**
- `name` - the name of the property to retrieve

**Returns:**
- the value of the requested property

**Throws:**
- `PropertyException` - when there is an error retrieving the given property or value property name
- `IllegalArgumentException` - If the name parameter is null

Extends: TagSupport

ValidatorELTag JSP  UICOMPONENTTag
EditableValueHolder  Validator  UICOMPONENTTagBase
UICOMPONENT  Validator

Validator

cREATEVALIDATOR()  Validator  Validator
createVALIDATOR()

ValidatorELTag is a base class for all JSP custom actions that create and register a Validator instance on the EditableValueHolder associated with our most immediate surrounding instance of a tag whose implementation class is a subclass of UICOMPONENTTag. To avoid creating duplicate instances when a page is redisplayed, creation and registration of a Validator occurs only if the corresponding UICOMPONENT was created (by the owning UICOMPONENTTagBase) during the execution of the current page.
This class must be used as a base class for tag instances that support specific `Validator` subclasses.

Subclasses of this class must implement the `createValidator()` method, which creates and returns a `Validator` instance. Any configuration properties that specify the limits to be enforced by this `Validator` must have been set by the `createValidator()` method. Generally, this occurs by copying corresponding attribute values on the tag instance.

This tag creates no output to the page currently being created. It is used solely for the side effect of `Validator` creation.

Throws JspException: JSP
doStartTag

public int doStartTag() throws JspException

Create a new instance of the specified Validator class, and register it with the UICOMPONENT instance associated with our most immediately surrounding UICOMPONENT instance, if the UICOMPONENT instance was created by this execution of the containing JSP page.

Specified by: 
doStartTag in interface Tag
Overrides: 
doStartTag in class TagSupport
Returns: 
SKIP_BODY
Throws: 
JspException - if a JSP error occurs
See Also: 
Tag.doStartTag()

abstract protected Validator createValidator() throws JspException

Validator UICOMPONENT

Throws JspException:

createValidator

protected abstract Validator createValidator() throws JspException

Create and return a new Validator to be registered on our
surrounding UIComponent.

Throws:

```
JspException - if a new instance cannot be created
```

createValidator()  Validator  Validator
createValidator()

**deprecated**

ValidatorELTag  #createValidator

**public class**  **ValidatorTag**

extends TagSupport

**ValidatorTag** is a base class for all JSP custom actions that create and register a Validator instance on the EditableValueHolder associated with
our most immediate surrounding instance of a tag whose implementation class is a subclass of \texttt{UIComponentTag}. To avoid creating duplicate instances when a page is redisplayed, creation and registration of a \texttt{Validator} occurs \textbf{only} if the corresponding \texttt{UIComponent} was created (by the owning \texttt{UIComponentTag}) during the execution of the current page.

This class may be used directly to implement a generic validator registration tag (based on the validator-id specified by the \texttt{id} attribute), or as a base class for tag instances that support specific \texttt{Validator} subclasses. This \texttt{id} attribute must refer to one of the well known validator-ids, or a custom validator-id as defined in a \texttt{faces-config.xml} file.

Subclasses of this class must implement the \texttt{createValidator()} method, which creates and returns a \texttt{Validator} instance. Any configuration properties that specify the limits to be enforced by this \texttt{Validator} must have been set by the \texttt{createValidator()} method. Generally, this occurs by copying corresponding attribute values on the tag instance.

This tag creates no output to the page currently being created. It is used solely for the side effect of \texttt{Validator} creation.

PS:
**Class ValueBinding**

```
javax.faces.el
  Object
   javax.faces.el.ValueBinding
```

**Deprecated. This has been replaced by ValueExpression.**

The `ValueBinding` class is an object that can be used to access the property represented by an action or value binding expression. An immutable `ValueBinding` for a particular value binding can be acquired by calling the `createValueBinding()` method of the `Application` instance for this web application.

**Constructor Summary**

**ValueBinding**

**public ValueBinding()**

*Deprecated.*

### Method Detail

**abstract public Object getValue** (`FacesContext context`)  
**throws** `EvaluationException`, `PropertyNotFoundException`
**FacesContext**  
**ValueBinding**

```
class ValueBinding
{
    public abstract Object getValue(FacesContext context)
        throws EvaluationException, PropertyNotFoundException;

    abstract public void setValue(FacesContext context, Object value)
        throws EvaluationException, PropertyNotFoundException;
}
```
Throws `EvaluationException`:
Throws `NullPointerException`: context null
Throws `PropertyNotFoundException`:

**setValue**

```java
public abstract void setValue(FacesContext context,
                              Object value)
throws EvaluationException,
       PropertyNotFoundException
```

*Deprecated.*

Set the value of the property represented by this `ValueBinding`, relative to the specified `FacesContext`.

**Parameters:**
- context - `FacesContext` for the current request
- value - The new value to be set

**Throws:**
- `EvaluationException` - if an exception is thrown while setting the value (the thrown exception must be included as the `cause` property of this exception)
- `NullPointerException` - if `context` is null
- `PropertyNotFoundException` - if a specified property name does not exist, or is not writeable

---

```java
abstract public boolean isReadOnly(FacesContext context)
throws EvaluationException, PropertyNotFoundException
```

true  false

```java
context FacesContext
Throws EvaluationException:
Throws NullPointerException: context null
Throws PropertyNotFoundException:
```
isReadOnly

```java
public abstract boolean isReadOnly(FacesContext context)
throws EvaluationException, PropertyNotFoundException
```

**Deprecated.**

Return `true` if the specified property of the specified property is known to be immutable; otherwise, return `false`.

**Parameters:**
- `context` - `FacesContext` for the current request

**Throws:**
- `EvaluationException` - if an exception is thrown while getting the description of the property (the thrown exception must be included as the `cause` property of this exception)
- `NullPointerException` - if `context` is null
- `PropertyNotFoundException` - if a specified property name does not exist

---

getType

```java
abstract public Class<T> getType(FacesContext context)
throws EvaluationException, PropertyNotFoundException
```

```java
context ValueBinding

<table>
<thead>
<tr>
<th>context</th>
<th>FacesContext</th>
</tr>
</thead>
<tbody>
<tr>
<td>Throws</td>
<td><code>EvaluationException</code>:</td>
</tr>
<tr>
<td>Throws</td>
<td><code>NullPointerException</code>: context null</td>
</tr>
<tr>
<td>Throws</td>
<td><code>PropertyNotFoundException</code>:</td>
</tr>
</tbody>
</table>
```

getType

```java
public abstract Class getType(FacesContext context)
throws EvaluationException,
```
PropertyNotFoundException

Deprecated.

Return the type of the property represented by this ValueBinding, relative to the specified FacesContext.

Parameters:

context - FacesContext for the current request

Throws:

EvaluationException - if an exception is thrown while getting the description of the property (the thrown exception must be included as the cause property of this exception)

NullPointerException - if context is null

PropertyNotFoundException - if a specified property name does not exist

public String getExpressionString()

    ValueBinding String null

getExpressionString

public String getExpressionString()

    Deprecated.

    Return the (possibly null) expression String, including the delimiters, from which this ValueBinding was built.

**Constructor Detail**

public ValueChangeEvent(**UIComponent** component, Object oldValue, Object newValue)
ValueChangeEvent

public ValueChangeEvent(UIComponent component, Object oldValue, Object newValue)

Construct a new event object from the specified source component, old value, and new value.

The default PhaseId for this event is PhaseId.ANY_PHASE.

Parameters:
- component - Source UIComponent for this event
- oldValue - The previous local value of this UIComponent
- newValue - The new local value of this UIComponent

Throws:
- IllegalArgumentException - if component is null

Method Detail

public Object getOldValue()

UIComponent

ggetOldValue

public Object getOldValue()
public Object getNewValue()

    UICOMPONENT

getNewValue

public Object getNewValue()

    Return the current local value of the source UICOMPONENT.

public boolean isAppropriateListener(FacesListener listener)

isAppropriateListener

public boolean isAppropriateListener(FacesListener listener)

Description copied from class: FacesEvent

Return true if this FacesListener is an instance of a listener class that this event supports. Typically, this will be accomplished by an "instanceof" check on the listener class.

Specified by:
    isAppropriateListener in class FacesEvent

Parameters:
    listener - FacesListener to evaluate

public void processListener(FacesListener listener)

    AbortProcessingException: NullPointerException
    JavaServer
public void processListener(FacesListener listener)

Description copied from class: FacesEvent

Broadcast this FacesEvent to the specified FacesListener, by whatever mechanism is appropriate. Typically, this will be accomplished by calling an event processing method, and passing this FacesEvent as a parameter.

Specified by:

processListener in class FacesEvent

Parameters:

listener - FacesListener to send this FacesEvent to

Throws:

AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed

Submit a bug or feature

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.
javax.faces.event Interface ValueChangeListener

All Superinterfaces: 
EventListener, FacesListener

All Known Implementing Classes: 
MethodExpressionValueChangeListener

public interface ValueChangeListener 
extends FacesListener

Implements: FacesListener
Implemented by: MethodExpressionValueChangeListener

ValueChangeEvent addValueChangeListener()
UIComponent

A listener interface for receiving ValueChangeEvent s. A class that is interested in receiving such events implements this interface, and then registers itself with the source UIComponent of interest, by calling addValueChangeListener().

Method Summary

<table>
<thead>
<tr>
<th>Method Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void processValueChange(ValueChangeEvent event)</td>
<td>Invoked when the value change described by the specified ValueChangeEvent occurs.</td>
</tr>
</tbody>
</table>

Method Detail
public void processValueChange(ValueChangeEvent event) throws AbortProcessingException

Throws
AbortProcessingException: JavaServer Faces

Invoked when the value change described by the specified ValueChangeEvent occurs.

Parameters:
  event - The ValueChangeEvent that has occurred

Throws:
AbortProcessingException - Signal the JavaServer Faces implementation that no further processing on the current event should be performed

API     ValueExpression  l-value  r-value  r-value  l-value
EL      l-value          "$\{1+1\}$"   "$\{firstName\} \$\{lastName\}"

ExpressionFactory#createValueExpression       ValueExpression
   FunctionMapper
   ELContext

   #getValue#setValue#isReadOnly #getType   ELContext
ELResolver . [ ] 4       ELResolver#getValue
base     ValueExpression
ELResolver#getValueELResolver#setValueELResolver#isReadOnly
ELResolver#getType     ValueExpression

Expression javadoc
since JSP 2.1
See javax.el.ELResolver, javax.el.Expression,
also javax.el.ExpressionFactory

An Expression that can get or set a value.
In previous incarnations of this API, expressions could only be read. ValueExpression objects can now be used both to retrieve a value and to set a value. Expressions that can have a value set on them are referred to as l-value expressions. Those that cannot are referred to as r-value expressions. Not all r-value expressions can be used as l-value expressions (e.g. "${1+1}" or "${firstName} ${lastName}"). See the EL Specification for details. Expressions that cannot be used as l-values must always return true from isReadOnly().

The ExpressionFactory.createValueExpression(javax.el.ELContext, java.lang.String, java.lang.Class) method can be used to parse an expression string and return a concrete instance of ValueExpression that encapsulates the parsed expression. The FunctionMapper is used at parse time, not evaluation time, so one is not needed to evaluate an expression using this class. However, the ELContext is needed at evaluation time.

The getValue(javax.el.ELContext), setValue(javax.el.ELContext, java.lang.Object), isReadOnly(javax.el.ELContext) and getType(javax.el.ELContext) methods will evaluate the expression each time they are called. The ELResolver in the ELContext is used to resolve the top-level variables and to determine the behavior of the . and [] operators. For any of the four methods, the ELResolver.getValue(javax.el.ELContext, java.lang.Object, java.lang.Object) method is used to resolve all properties up to but excluding the last one. This provides the base object. At the last resolution, the ValueExpression will call the corresponding ELResolver.getValue(javax.el.ELContext, java.lang.Object, java.lang.Object), ELResolver.setValue(javax.el.ELContext, java.lang.Object, java.lang.Object, java.lang.Object), ELResolver.isReadOnly(javax.el.ELContext, java.lang.Object, java.lang.Object) or ELResolver.getType(javax.el.ELContext, java.lang.Object, java.lang.Object) method, depending on which was called on the ValueExpression.

See the notes about comparison, serialization and immutability in the Expression javadocs.

Since:
    JSP 2.1

### Constructor Detail

```java
class ValueExpression {
    public ValueExpression() {
    }
}
```

### Method Detail

#### abstract public Object getValue(ELContext context)

```java
public abstract Object getValue(ELContext context)
```

- Evaluates the expression relative to the provided context, and returns the resulting value.
- The resulting value is automatically coerced to the type returned by `getExpectedType()`, which was provided to the `ExpressionFactory` when this expression was created.

```java
ExpressionFactory getExpectedType()
```

- `context`:
- `return`:
- `Throws`:
  - `NullPointerException`: context null
  - `PropertyNotFoundException`: 
  - `ELException`: cause
Parameters:
   context - The context of this evaluation.

Returns:
   The result of the expression evaluation.

 Throws:
   NullPointerException - if context is null.
   PropertyNotFoundException - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.
   ELException - if an exception was thrown while performing property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

abstract public void setValue(ELContext context, Object value)

   context
   value

   Throws
   NullPointerException: context null
   PropertyNotFoundException:
   PropertyNotWritableException:
   ELException: cause

setValue

public abstract void setValue(ELContext context, Object value)

   Evaluates the expression relative to the provided context, and sets the result to the provided value.

Parameters:
   context - The context of this evaluation.
   value - The new value to be set.

 Throws:
   NullPointerException - if context is null.
**PropertyNotFoundException** - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.

**PropertyNotWritableException** - if the final variable or property resolution failed because the specified variable or property is not writable.

**ELException** - if an exception was thrown while attempting to set the property or variable. The thrown exception must be included as the cause property of this exception, if available.

---

abstract public boolean **isReadOnly**(ELContext context)  

    #setValue    true

    context

    return true false

    Throws NullPointerException: context null

    Throws PropertyNotFoundException:

    Throws ELException: cause

        NullPointerException context null

**isReadOnly**

public abstract boolean **isReadOnly**(ELContext context)

    Evaluates the expression relative to the provided context, and returns true if a call to setValue(javax.el.ELContext, java.lang.Object) will always fail.

**Parameters:**

    context - The context of this evaluation.

**Returns:**

    true if the expression is read-only or false if not.

**Throws:**

    NullPointerException - if context is null.

    PropertyNotFoundException - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.
**ELException** - if an exception was thrown while performing property or variable resolution. The thrown exception must be included as the cause property of this exception, if available. * @throws NullPointerException if context is null

```java
abstract public Class<T> getType(ELContext context)
```

```java
getValue().getClass() getType
```

**Throws**
- NullPointerException: context null
- PropertyNotFoundException:
- ELException: cause

```
public abstract <T> Class<T> getType(ELContext context)
```

Evaluates the expression relative to the provided context, and returns the most general type that is acceptable for an object to be passed as the value parameter in a future call to the setValue(javax.el.ELContext, java.lang.Object) method.

This is not always the same as getValue().getClass(). For example, in the case of an expression that references an array element, the getType method will return the element type of the array, which might be a superclass of the type of the actual element that is currently in the specified array element.

**Parameters:**
- context: The context of this evaluation.

**Returns:**
- the most general acceptable type; otherwise undefined.

**Throws:**
NullPointerException - if context is null.
PropertyNotFoundException - if one of the property resolutions failed because a specified variable or property does not exist or is not readable.
ELException - if an exception was thrown while performing property or variable resolution. The thrown exception must be included as the cause property of this exception, if available.

abstract public Class<T> getExpectedType()

    return ValueExpression ExpressionFactory.createValueExpression(expectedType)

getExpectedType

public abstract Class<?<> getExpectedType()

    Returns the type the result of the expression will be coerced to after evaluation.

    Returns:
    the expectedType passed to the
    ExpressionFactory.createValueExpression method that created this ValueExpression.

PS :
javax.faces.component Interface ValueHolder

All Known Subinterfaces:
   EditableValueHolder

All Known Implementing Classes:

public interface ValueHolder

Implemented by: EditableValueHolder, UOutput

ValueHolder String UComponent

ValueHolder is an interface that may be implemented by any concrete UComponent that wishes to support a local value, as well as access data in the model tier via a value expression, and support conversion between String and the model tier data’s native data type.

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getConverter()</td>
<td>Return the Converter (if any) that is registered for this UComponent.</td>
</tr>
<tr>
<td>getLocalValue()</td>
<td>Return the local value of this UComponent (if any), without evaluating any associated ValueExpression.</td>
</tr>
</tbody>
</table>
### Method Detail

#### public Object getLocalValue()

This method returns the local value of this UIComponent (if any), without evaluating any associated ValueExpression.

#### public Object getValue()

This method gets the value of this UIComponent.
Gets the value of this `UIComponent`. First, consult the local value property of this component. If non-null return it. If null, see if we have a `ValueExpression` for the `value` property. If so, return the result of evaluating the property, otherwise return null. Note that because the specification for `UIComponent.setValueBinding(java.lang.String, javax.faces.el.ValueBinding)` requires a call through to `UIComponent.setValueExpression(java.lang.String, javax.el.ValueExpression)`, legacy tags will continue to work.

```
public void setValue(Object value)

   UIComponent

   value

setValue

void setValue(Object value)

   Set the value of this `UIComponent` (if any).

   Parameters:
      value - The new local value
```

```
public Converter getConverter()

   UIComponent   Converter

getConverter

   Converter getConverter()

   Return the `Converter` (if any) that is registered for this `UIComponent`.
```
public void setConverter(Converter converter)

setConverter

void setConverter(Converter converter)

Set the Converter (if any) that is registered for this UIComponent.

Parameters:

converter - New Converter (or null)

¹ EVAL_BODY_INCLUDE  

doStartTag()  
doInitBody()

TLD

<tag>  <variable>  JSP

Information on the scripting variables that are created/modified by a tag (at run-time). This information is provided by TagExtraInfo classes and it is used by the translation phase of JSP.

Scripting variables generated by a custom action have an associated scope of either AT_BEGIN, NESTED, or AT_END.

The class name (VariableInfo.getClassName) in the returned objects is used to determine the types of the scripting variables. Note that because scripting variables are assigned their values from scoped attributes which cannot be of primitive types, "boxed" types such as java.lang.Integer must be used instead of primitives.

The class name may be a Fully Qualified Class Name, or a short class
name.

If a Fully Qualified Class Name is provided, it should refer to a class that should be in the CLASSPATH for the Web Application (see Servlet 2.4 specification - essentially it is WEB-INF/lib and WEB-INF/classes). Failure to be so will lead to a translation-time error.

If a short class name is given in the VariableInfo objects, then the class name must be that of a public class in the context of the import directives of the page where the custom action appears. The class must also be in the CLASSPATH for the Web Application (see Servlet 2.4 specification - essentially it is WEB-INF/lib and WEB-INF/classes). Failure to be so will lead to a translation-time error.

**Usage Comments**

Frequently a fully qualified class name will refer to a class that is known to the tag library and thus, delivered in the same JAR file as the tag handlers. In most other remaining cases it will refer to a class that is in the platform on which the JSP processor is built (like Java EE). Using fully qualified class names in this manner makes the usage relatively resistant to configuration errors.

A short name is usually generated by the tag library based on some attributes passed through from the custom action user (the author), and it is thus less robust: for instance a missing import directive in the referring JSP page will lead to an invalid short name class and a translation error.

**Synchronization Protocol**

The result of the invocation on getVariableInfo is an array of VariableInfo objects. Each such object describes a scripting variable by providing its name, its type, whether the variable is new or not, and what its scope is. Scope is best described through a picture:

The JSP 2.0 specification defines the interpretation of 3 values:

- NESTED, if the scripting variable is available between the start tag
and the end tag of the action that defines it.

- **AT_BEGIN**, if the scripting variable is available from the start tag of
  the action that defines it until the end of the scope.
- **AT_END**, if the scripting variable is available after the end tag of the
  action that defines it until the end of the scope.

The scope value for a variable implies what methods may affect its value and
thus where synchronization is needed as illustrated by the table below. **Note:** the synchronization of the variable(s) will occur *after* the respective method has been called.

<table>
<thead>
<tr>
<th>Variable Synchronization Points</th>
<th>doStartTag()</th>
<th>doInitBody()</th>
<th>doAfterBody()</th>
<th>doEndTag()</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Tag</strong></td>
<td>AT_BEGIN, NESTED</td>
<td></td>
<td>AT_BEGIN, AT_END</td>
<td></td>
</tr>
<tr>
<td><strong>IterationTag</strong></td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, AT_END</td>
<td></td>
</tr>
<tr>
<td><strong>BodyTag</strong></td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, AT_END</td>
</tr>
<tr>
<td><strong>SimpleTag</strong></td>
<td>AT_BEGIN, NESTED</td>
<td>AT_BEGIN, NESTED</td>
<td></td>
<td>AT_BEGIN, AT_END</td>
</tr>
</tbody>
</table>

1 Called after doStartTag() if EVAL_BODY_INCLUDE is returned, or after doInitBody() otherwise.

**Variable Information in the TLD**

Scripting variable information can also be encoded directly for most cases into the Tag Library Descriptor using the `<variable>` subelement of the `<tag>` element. See the JSP specification.

**Constructor Summary**

```java
VariableInfo(String varName, String className, boolean declare, int scope)
```

Constructor

These objects can be created (at translation time) by the TagExtraInfo instances.

**Method Summary**

- `String getClassName()`
  - Returns the type of this variable.

- `boolean getDeclare()`
  - Returns whether this is a new variable.

- `int getScope()`
  - Returns the lexical scope of the variable.

- `String getVarName()`
  - Returns the name of the scripting variable.

**Methods inherited from class java.lang.Object**

- `clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait`

**Field Detail**

**NESTED**

```java
public static final int NESTED
```
Scope information that scripting variable is visible only within the start/end tags.

See Also:
Constant Field Values

AT_BEGIN

public static final int AT_BEGIN

Scope information that scripting variable is visible after start tag.

See Also:
Constant Field Values

AT_END

public static final int AT_END

Scope information that scripting variable is visible after end tag.

See Also:
Constant Field Values

Constructor Detail

public VariableInfo(String varName, String className, boolean declare, int scope)

TagExtraInfo

varName
className
VariableInfo

public VariableInfo(String varName, String className, boolean declare, int scope)

Constructor These objects can be created (at translation time) by the TagExtraInfo instances.

Parameters:
- varName - The name of the scripting variable
- className - The type of this variable
- declare - If true, it is a new variable (in some languages this will require a declaration)
- scope - Indication on the lexical scope of the variable

Method Detail

public String getVarName()

    return

getVarName

public String getVarName()

    Returns the name of the scripting variable.

    Returns:
    the name of the scripting variable
public String getClassName()

    return

getClassName

public String getClassName()

    Returns the type of this variable.

    Returns:
    the type of this variable

public boolean getDeclare()

    return

getDeclare

public boolean getDeclare()

    Returns whether this is a new variable. If so, in some languages this will require a declaration.

    Returns:
    whether this is a new variable.

public int getScope()

    return

    See also

    AT_BEGIN, AT_END, NESTED
getScope

public int getScope()

Returns the lexical scope of the variable.

Returns: the lexical scope of the variable, either AT_BEGIN, AT_END, or NESTED.

See Also: AT_BEGIN, AT_END, NESTED
javax.el  **Class VariableMapper**

`java.lang.Object`  
└ `javax.el.VariableMapper`  

```java
public abstract class VariableMapper
    extends Object
```

**EL**  

```
since JSP 2.1
```

The interface to a map between EL variables and the EL expressions they are associated with.

**Since:**  
JSP 2.1

</tr>
</tbody>
</table>
| `abstract ValueExpression setVariable(String variable, ValueExpression expression)`  
Assign a ValueExpression to an EL variable, replacing any previously assignment to the same variable. |

**Methods inherited from class java.lang.Object**
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

## Constructor Detail

public VariableMapper()

VariableMapper

public VariableMapper()

## Method Detail

abstract public ValueExpression resolveVariable(String variable)

    variable
    return ValueExpression null

resolveVariable

public abstract ValueExpression resolveVariable(String variable)

    Parameters:
    variable - The variable name

    Returns:
    the ValueExpression assigned to the variable, null if there is no previous assignment to this variable.

abstract public ValueExpression setVariable(String variable, ValueExpression expression)

ValueExpression EL
setVariable

public abstract ValueExpression setVariable(String variable, ValueExpression expression)

Assign a ValueExpression to an EL variable, replacing any previously assignment to the same variable. The assignment for the variable is removed if the expression is null.

Parameters:
- variable - The variable name
- expression - The ValueExpression to be assigned to the variable.

Returns:
The previous ValueExpression assigned to this variable, null if there is no previous assignment to this variable.
javax.faces.el  Class VariableResolver

java.lang.Object  
  javax.faces.el.VariableResolver

Deprecated. This has been replaced by ELResolver when operating with a null base argument.

VariableResolver

deprecated  null base  javax.el.ELResolver

public abstract class VariableResolver
extends Object

VariableResolver represents a pluggable mechanism for resolving a top-level variable reference at evaluation time.

Constructor Summary

<table>
<thead>

Constructor Detail

public VariableResolver()

VariableResolver

public VariableResolver()

Deprecated.

Method Detail

abstract public Object resolveVariable(FacesContext context, String name) throws EvaluationException

null

context
name

Throws EvaluationException:

Throws NullPointerException: context name null

resolveVariable

public abstract Object resolveVariable(FacesContext context, String name)

throws EvaluationException

Deprecated.

Resolve the specified variable name, and return the corresponding object, if any; otherwise, return null.
Parameters:
  context - FacesContext against which to resolve this variable name
  name - Name of the variable to be resolved

Throws:
  EvaluationException - if an exception is thrown while resolving the variable name (the thrown exception must be included as the cause property of this exception)
  NullPointerException - if context or name is null

Interface VariableResolver

Deprecated. As of JSP 2.1, replaced by ELResolver

ExpressionEvaluator ""

since 2.0

public interface VariableResolver

This class is used to customize the way an ExpressionEvaluator resolves variable references at evaluation time. For example, instances of this class can implement their own variable lookup mechanisms, or introduce the notion of "implicit variables" which override any other variables. An instance of this class should be passed when evaluating an expression.

An instance of this class includes the context against which resolution will happen.

Since:
JSP 2.0

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>resolveVariable(String pName)</td>
</tr>
<tr>
<td>Deprecated. Resolves the specified variable.</td>
</tr>
</tbody>
</table>

| Method Detail |
public Object resolveVariable(String pName) throws ELException
null

  pName
  return
  Throws

resolvéVariable

Object resolveVariable(String pName)

throws ELException

Deprecated.
Resolves the specified variable. Returns null if the variable is not found.

Parameters:
  pName - the name of the variable to resolve

Returns:
  the result of the variable resolution

Throws:
  ELException - if a failure occurred while trying to resolve the given variable
This annotation specifies the version field or property of an entity class that serves as its optimistic lock value. The version is used to ensure integrity when performing the merge operation and for optimistic concurrency control.

Only a single `Version` property or field should be used per class; applications that use more than one `Version` property or field will not be portable.

The `Version` property should be mapped to the primary table for the entity
class; applications that map the Version property to a table other than the primary table will not be portable.

The following types are supported for version properties: int, Integer, short, Short, long, Long, Timestamp.

Example:

```java
@Version
@Column(name="OPTLOCK")
protected int getVersionNum() { return versionNum; }
```

Since:
Java Persistence 1.0

Versionable

```

1

```java
return

Throws JAXRException: JAXR

**getMajorVersion**

```java
int getMajorVersion() throws JAXRException

```

Gets the major revision number for this version of the Versionable object.

**Capability Level: 1**

**Returns:**

the major version for this object

**Throws:**

JAXRException - If the JAXR provider encounters an internal error
public void setMajorVersion(int majorVersion) throws JAXRException
Versionable

1

majorVersion

Throws JAXRException: JAXR

setMajorVersion

void setMajorVersion(int majorVersion)
throws JAXRException

Sets the major revision number for this version of the Versionable object.

Capability Level: 1

Parameters:
   majorVersion - the major version number

Throws:
   JAXRException - If the JAXR provider encounters an internal error

public int getMinorVersion() throws JAXRException
Versionable

1

return

Throws JAXRException: JAXR
getMinorVersion

```java
int getMinorVersion() throws JAXRException
```

Gets the minor revision number for this version of the Versionable object.

**Capability Level: 1**

**Returns:**
- the minor version for this object

**Throws:**
- `JAXRException` - If the JAXR provider encounters an internal error

---

**public void setMinorVersion(int minorVersion) throws JAXRException**

**Versionable**

1

```java
minorVersion
```

**Throws**
- `JAXRException`: JAXR

---

setMinorVersion

```java
void setMinorVersion(int minorVersion) throws JAXRException
```

Sets the minor revision number for this version of the Versionable object.

**Capability Level: 1**

**Parameters:**
- `minorVersion` - the minor version number
Throws:
JAXRException - If the JAXR provider encounters an internal error

public String getUserVersion() throws JAXRException
Versionable

1

return
Throws JAXRException: JAXR

getUserVersion

String getUserVersion() throws JAXRException

Gets the user-specified revision number for this version of the Versionable object.

Capability Level: 1

Returns: the user-defined version number

Throws: JAXRException - If the JAXR provider encounters an internal error

public void setUserVersion(String userVersion) throws JAXRException
Versionable

1

userVersion
Throws: **JAXRException**: JAXR

### setUserVersion

```java
void setUserVersion(String userVersion)
throws JAXRException
```

Sets the user specified revision number for this version of the Versionable object.

**Capability Level: 1**

**Parameters:**
- `userVersion` - the user-defined version number

**Throws:**
- **JAXRException** - If the JAXR provider encounters an internal error

public ViewExpiredException()

ViewExpiredException

public ViewExpiredException()

Construct a new exception with no detail message or root cause.

public ViewExpiredException(String viewId)

viewId

ViewExpiredException

public ViewExpiredException(String viewId)

Construct a new exception with the specified view identifier.

Parameters:

    viewId - The view identifier for this exception

public ViewExpiredException(String message, String viewId)
ViewExpiredException

public ViewExpiredException(String message, String viewId)

Construct a new exception with the specified detail message and no root cause.

Parameters:
message - The detail message for this exception
viewId - The view identifier for this exception

public ViewExpiredException(Throwable cause, String viewId)

(cause == null ? null : cause.toString())

cause
viewId

ViewExpiredException

public ViewExpiredException(Throwable cause, String viewId)

Construct a new exception with the specified root cause. The detail message will be set to (cause == null ? null : cause.toString())

Parameters:
cause - The root cause for this exception
viewId - The view identifier for this exception
public ViewExpiredException(String message, Throwable cause, String viewId)

Construct a new exception with the specified detail message and root cause.

Parameters:
message - The detail message for this exception
cause - The root cause for this exception
viewId - The view identifier for this exception

Method Detail

public String getViewId()

null

ggetViewId

public String getViewId()

Return the view identifier of this exception, or null if the view
identifier is nonexistent or unknown.

public String getMessage()

null

getMessage

public String getMessage()

    Return the message for this exception prepended with the view identifier if the view identifier is not null, otherwise, return the message.

    Overrides:
        getMessage in class Throwable
javax.faces.application  **Class ViewHandler**

### Field Detail

**CHARACTER_ENCODING_KEY**

```java
public static final String CHARACTER_ENCODING_KEY
```

The key, in the session's attribute set, under which the response character encoding may be stored and retrieved.

**See Also:**
- [Constant Field Values](#)
**DEFAULT SUFFIX PARAM_NAME**

`public static final String DEFAULT_SUFFIX_PARAM_NAME`

Allow the web application to define an alternate suffix for pages containing JSF content. If this init parameter is not specified, the default value is taken from the value of the constant `DEFAULT_SUFFIX`.

**See Also:**
- [Constant Field Values](#)

---

**DEFAULT SUFFIX**

`public static final String DEFAULT_SUFFIX`

The value to use for the default extension if the webapp is using url extension mapping.

**See Also:**
- [Constant Field Values](#)

---

### Constructor Detail

**public ViewHandler()**

**ViewHandler**

**public ViewHandler()**

### Method Detail

`abstract public java.util.Locale calculateLocale(FacesContext context)`
Locale

context

Throws

FacesContext

NullPointerException: context null

calculateLocale

public abstract Locale calculateLocale(FacesContext context)

Returns an appropriate Locale to use for this and subsequent requests for the current client.

Parameters:

context - FacesContext for the current request

Throws:

NullPointerException - if context is null

calculateCharacterEncoding

public String calculateCharacterEncoding(FacesContext context)

- Content-Type charset

- charset getSession(boolean) false

ture ExternalContext#getSessionMap Map

ViewHandler#CHARACTER_ENCODING_KEY String

- null
**calculateCharacterEncoding**

```java
public String calculateCharacterEncoding(FacesContext context)
```

Returns the correct character encoding to be used for this request.

The following algorithm is employed.

- Examine the `Content-Type` request header. If it has a `charset` parameter, extract it and return that as the encoding.

- If no `charset` parameter was found, check for the existence of a session by calling `ExternalContext.getSession(boolean)` passing `false` as the argument. If that method returns `true`, get the session Map by calling `ExternalContext.getSessionMap()` and look for a value under the key given by the value of the symbolic constant `CHARACTER_ENCODING_KEY`. If present, return the value, converted to String.

- Otherwise, return `null`

**abstract public String calculateRenderKitId(FacesContext context)**

```java
renderKitId null
default javax.faces.render.RenderKitFactory#HTML_BASIC_RENDER_KIT
```

Throws `NullPointerException: context null`

**calculateRenderKitId**

```java
public abstract String calculateRenderKitId(FacesContext context)
```

Return an appropriate `renderKitId` for this and subsequent requests
from the current client. It is an error for this method to return null.

The default return value is RenderKitFactory.HTML_BASIC_RENDER_KIT.

Parameters:
  context - FacesContext for the current request

Throws:
  NullPointerException - if context is null

abstract public UIViewRoot createView(FacesContext context, String viewId)

FacesContext  viewId  UIViewRoot

FacesContext  ViewRoot  locale  renderKitId
#calculateLocale  #calculateRenderKitId  UIViewRoot
locale  renderKitId

Throws  NullPointerException:  context  null

createView

public abstract UIViewRoot createView(FacesContext context, String viewId)

Create and return a new UIViewRoot instance initialized with information from the argument FacesContext and viewId.

If there is an existing ViewRoot available on the FacesContext, this method must copy its locale and renderKitId to this new view root. If not, this method must call calculateLocale(javax.faces.context.FacesContext) and calculateRenderKitId(javax.faces.context.FacesContext), and store the results as the values of the locale and renderKitId, properties, respectively, of the newly created UIViewRoot.
**Throws:**

*NullPointerException* - if context is null

**abstract public String getActionURL(FacesContext context, String viewId)**

**URL**

*Web*  
*ExternalContext*  
*encodeActionURL()*

**Parameters:**

- **context** - *FacesContext* for this request
- **viewId** - View identifier of the desired view

**Throws:**

*IllegalArgumentException* - if viewId is not valid for this ViewHandler.

*NullPointerException* - if context or viewId is null.

**abstract public String getResourceURL(FacesContext context, String path)**

**URL**

*Web*  
*ExternalContext*  
*encodeResourceURL()*
getResourceURL

public abstract String getResourceURL(FacesContext context, String path)

Return a URL suitable for rendering (after optional encoding performed by the encodeResourceURL() method of ExternalContext) that selects the specified web application resource. If the specified path starts with a slash, it must be treated as context relative; otherwise, it must be treated as relative to the action URL of the current view.

Parameters:
context - FacesContext for the current request
path - Resource path to convert to a URL

Throws:
IllegalArgumentException - if viewId is not valid for this ViewHandler.
NullPointerException - if context or path is null.

public void initView(FacesContext context) throws FacesException

#calculateCharacterEncoding null
**initView**

public void **initView**(FacesContext context) throws FacesException

Initialize the view for the request processing lifecycle.

This method must be called at the beginning of the Restore View Phase of the Request Processing Lifecycle. It is responsible for performing any per-request initialization necessary to the operation of the lifecycle.

The default implementation calls calculateCharacterEncoding(javax.faces.context.FacesContext) and passes the result, if non-null into the ExternalContext.setRequestCharacterEncoding(java.lang.String) method.

**Throws:**

FacesException - if a problem occurs setting the encoding, such as the UnsupportedEncodingException thrown by the underlying Servlet or Portlet technology when the encoding is not supported.

---

**abstract public void renderView**(FacesContext context, UIViewRoot viewToRender) throws java.io.IOException, FacesException

FacesContext context

viewToRender
Throws: java.io.IOException: /
Throws: NullPointerException: context viewToRender null
Throws: FacesException: servlet

renderView

public abstract void renderView(FacesContext context, UIViewRoot viewToRender)
throws IOException, FacesException

Perform whatever actions are required to render the response view to the response object associated with the current FacesContext.

Parameters:
context - FacesContext for the current request
viewToRender - the view to render

Throws:
IOException - if an input/output error occurs
NullPointerException - if context or viewToRender is null
FacesException - if a servlet error occurs

abstract public UIViewRoot restoreView(FacesContext context, String viewId)

FacesContext viewId StateManager restoreView
viewId null

context FacesContext
viewId

Throws: NullPointerException: context null
Throws: FacesException: servlet

restoreView
public abstract UIViewRoot restoreView(FacesContext context, String viewId)

Perform whatever actions are required to restore the view associated with the specified FacesContext and viewId. It may delegate to the restoreView of the associatedStateManager to do the actual work of restoring the view. If there is no available state for the specified viewId, return null.

Parameters:
- context - FacesContext for the current request
- viewId - the view identifier for the current request

Throws:
- NullPointerException - if context is null
- FacesException - if a servlet error occurs

abstract public void writeState(FacesContext context) throws java.io.IOException

StateManager#writeState

context - FacesContext

Throws java.io.IOException: /

Throws NullPointerException: context null

writeState

public abstract void writeState(FacesContext context) throws IOException

Take any appropriate action to either immediately write out the current state information (by callingStateManager.writeState(javax.faces.context.FacesContext, java.lang.Object), or noting where state information should later be written.

Parameters:
context - FacesContext for the current request

Throws:

IOException - if an input/output error occurs

NullPointerException - if context is null
public abstract class `ViewHandlerWrapper` extends `ViewHandler`

Extends: `ViewHandler`

Provides a simple implementation of `ViewHandler` that can be subclassed by developers wishing to provide specialized behavior to an existing `ViewHandler` instance. The default implementation of all methods is to call through to the wrapped `ViewHandler`.

Usage: extend this class and override `getWrapped()` to return the instance we are wrapping.

Since: 1.2

Method Detail

abstract protected ViewHandler getWrapped()
   return getWrapped
protected abstract ViewHandler getWrapped()

    Returns:
    the instance that we are wrapping.

public String calculateCharacterEncoding(FacesContext context)

    ViewHandler calculateCharacterEncoding(javax.faces.context.FacesContext)

    since 1.2
    See also calculateCharacterEncoding(javax.faces.context.FacesContext)

calculateCharacterEncoding

public String calculateCharacterEncoding(FacesContext context)

    The default behavior of this method is to call
    ViewHandler.calculateCharacterEncoding(javax.faces.context.FacesContext)
on the wrapped ViewHandler object.

    Overrides: calculateCharacterEncoding in class ViewHandler
    Since: 1.2
    See Also: ViewHandler.calculateCharacterEncoding(javax.faces.context.FacesContext)

public java.util.Locale calculateLocale(FacesContext context)

    ViewHandler calculateLocale(javax.faces.context.FacesContext)
**calculateLocale**

```java
public Locale calculateLocale(FacesContext context)
```

The default behavior of this method is to call `ViewHandler.calculateLocale(javax.faces.context.FacesContext)` on the wrapped `ViewHandler` object.

**Specified by:**
- `calculateLocale` in class `ViewHandler`

**Parameters:**
- `context` - `FacesContext` for the current request

**Since:**
- 1.2

**See Also:**
- `ViewHandler.calculateLocale(javax.faces.context.FacesContext)`

---

**public String calculateRenderKitId(FacesContext context)**

```java
ViewHandler calculateRenderKitId(javax.faces.context.FacesContext)
```

**since**
- 1.2

**See also**
- `calculateRenderKitId(javax.faces.context.FacesContext)`

---

**calculateRenderKitId**

```java
public String calculateRenderKitId(FacesContext context)
```

The default behavior of this method is to call `ViewHandler.calculateRenderKitId(javax.faces.context.FacesContext)` on the wrapped `ViewHandler` object.
public UIViewRoot createView(FacesContext context, String viewId)

ViewHandler createView(javax.faces.context.FacesContext, String)

Since: 1.2
See also createView(javax.faces.context.FacesContext, String)

cREATEVIEW

public UIViewRoot createView(FacesContext context, String viewId)

The default behavior of this method is to call ViewHandler.createView(javax.faces.context.FacesContext, String) on the wrapped ViewHandler object.

Specified by:
createView in class ViewHandler

Since: 1.2
See Also: ViewHandler.createView(javax.faces.context.FacesContext, String)

public String getActionURL(FacesContext context, String
public String getResourceURL(FacesContext context, String path)

ViewHandler
getResourceURL(javax.faces.context.FacesContext, String)

since 1.2
See also getResourceURL(javax.faces.context.FacesContext, String)
getResourceURL

public String getResourceURL(FacesContext context, String path)

The default behavior of this method is to call ViewHandler.getResourceURL(javax.faces.context.FacesContext, String) on the wrapped ViewHandler object.

Specified by: getResourceURL in class ViewHandler

Parameters:
- context - FacesContext for the current request
- path - Resource path to convert to a URL

Since: 1.2

See Also: ViewHandler.getResourceURL(javax.faces.context.FacesContext, String)

public void initView(FacesContext context) throws FacesException

ViewHandler initView

since 1.2

See also initView

initView

public void initView(FacesContext context) throws FacesException

The default behavior of this method is to call ViewHandler.initView(javax.faces.context.FacesContext) on the
wrapped ViewHandler object.

Overrides:
initView in class ViewHandler

Throws:
FacesException - if a problem occurs setting the encoding, such as the UnsupportedEncodingException thrown by the underlying Servlet or Portlet technology when the encoding is not supported.

Since:
1.2

See Also:
ViewHandler.initView(javax.faces.context.FacesContext)

public void renderView(FacesContext context, UIViewRoot viewToRender) throws java.io.IOException, FacesException

ViewHandler renderView(javax.faces.context.FacesContext, javax.faces.component.UIViewRoot)

since 1.2

See also renderView(javax.faces.context.FacesContext, java.util.FacesContext, javax.faces.component.UIViewRoot)

renderView

public void renderView(FacesContext context, UIViewRoot viewToRender) throws IOException, FacesException

The default behavior of this method is to call ViewHandler.renderView(javax.faces.context.FacesContext, javax.faces.component.UIViewRoot) on the wrapped ViewHandler object.
Specified by:
   renderView in class ViewHandler

Parameters:
   context - FacesContext for the current request
   viewToRender - the view to render

Throws:
   IOException - if an input/output error occurs
   FacesException - if a servlet error occurs

Since:
   1.2

See Also:
   ViewHandler.renderView(javax.faces.context.FacesContext,
                           javax.faces.componentUIViewRoot)

---

class UIViewRoot

publicUIViewRoot restoreView(FacesContext context, String viewId)

   ViewHandler
   restoreView(javax.faces.context.FacesContext,FacesContext,String)

since 1.2

See also restoreView(javax.faces.context.FacesContext, String)

---

_restoreView_

public UIViewRoot _restoreView_(FacesContext context, String viewId)

The default behavior of this method is to call
ViewHandler._restoreView_(javax.faces.context.FacesContext,
String) on the wrapped ViewHandler object.

Specified by:
   _restoreView_ in class ViewHandler

Parameters:
   context - FacesContext for the current request
   viewId - the view identifier for the current request
public void writeState(FacesContext context) throws java.io.IOException

ViewHandler
writeState(java.faces.context.FacesContext)

since 1.2
See also writeState(java.faces.context.FacesContext)

writeState

public void writeState(FacesContext context)
throws IOException

The default behavior of this method is to call
ViewHandler.writeState(java.faces.context.FacesContext) on the
wrapped ViewHandler object.

Specified by:
writeState in class ViewHandler

Parameters:
context - FacesContext for the current request

Throws:
IOException - if an input/output error occurs

Since: 1.2
See Also:
ViewHandler.writeState(java.faces.context.FacesContext)

PS:
javax.xml.bind.annotation  

Class W3CDomHandler

java.lang.Object  
  javax.xml.bind.annotation.W3CDomHandler

All Implemented Interfaces:
  DomHandler<Element,DOMResult>

public class W3CDomHandler
  extends Object
  implements DomHandler<Element,DOMResult>

Implements: ">DomHandler

W3C DOM  org.w3c.dom  DomHandler
  since  JAXB2.0

DomHandler implementation for W3C DOM (org.w3c.dom package.)

Since:  JAXB2.0
Author:  Kohsuke Kawaguchi

Constructor Summary

<table>
<thead>
<tr>
<th>Constructor</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W3CDomHandler()</td>
<td>Default constructor.</td>
</tr>
<tr>
<td>W3CDomHandler(DocumentBuilder builder)</td>
<td>Constructor that allows applications to specify which DOM implementation to be used.</td>
</tr>
</tbody>
</table>

Method Summary
When a JAXB provider needs to unmarshal a part of a document into an infoset representation, it first calls this method to create a Result object.

Once the portion is sent to the Result.

This method is called when a JAXB provider needs to marshal an element to XML.

Default constructor. It is up to a JAXB provider to decide which DOM implementation to use or how that is configured.
W3CDomHandler

public W3CDomHandler(DocumentBuilder builder)

Constructor that allows applications to specify which DOM implementation to be used.

Parameters:
  builder - must not be null. JAXB uses this DocumentBuilder to create a new element.

Method Detail

public javax.xml.parsers.DocumentBuilder getBuilder()

getBuilder

public DocumentBuilder getBuilder()

public void setBuilder(javax.xml.parsers.DocumentBuilder builder)

setBuilder

public void setBuilder(DocumentBuilder builder)

public javax.xml.transform.dom.DOMResult
createUnmarshaller(ValidationEventHandler errorHandler)

createUnmarshaller

public DOMResult createUnmarshaller(ValidationEventHandler errorHandler)

Description copied from interface: DomHandler
When a JAXB provider needs to unmarshal a part of a document into an infoset representation, it first calls this method to create a Result object.

A JAXB provider will then send a portion of the XML into the given result. Such a portion always form a subtree of the whole XML document rooted at an element.

Specified by:
createUnmarshaller in interface DomHandler<Element, DOMResult>

Parameters:
errorHandler - if any error happens between the invocation of this method and the invocation of DomHandler.getElement(Result), they must be reported to this handler. The caller must provide a non-null error handler. The Result object created from this method may hold a reference to this error handler.

Returns:
null if the operation fails. The error must have been reported to the error handler.

public org.w3c.dom.Element
getElement(javax.xml.transform.dom.DOMResult r)

g getElement

public Element getElement(DOMResult r)
Description copied from interface: **DomHandler**
Once the portion is sent to the **Result**. This method is called by a JAXB provider to obtain the unmarshalled element representation.

Multiple invocations of this method may return different objects. This method can be invoked only when the whole sub-tree are fed to the **Result** object.

**Specified by:**  
**getElement** in interface DomHandler\<Element, DOMResult\>

**Parameters:**
- r - The **Result** object created by  
  DomHandler.createUnmarshaller(ValidationEventHandler).

**Returns:**
null if the operation fails. The error must have been reported to the error handler.

```
public javax.xml.transform.Source marshal(org.w3c.dom.Element element,  
  ValidationEventHandler errorHandler)
```

**marshal**

```
public Source marshal(Element element,  
  ValidationEventHandler errorHandler)
```

Description copied from interface: **DomHandler**
This method is called when a JAXB provider needs to marshal an element to XML.

If non-null, the returned **Source** must contain a whole document rooted at one element, which will then be weaved into a bigger document that the JAXB provider is marshalling.

**Specified by:**  
**marshal** in interface DomHandler\<Element, DOMResult\>
errorHandler - Receives any errors happened during the
process of converting an element into a Source. The caller must provide a non-null error handler.

**Returns:**
null if there was an error. The error should have been reported to the handler.

PS:
javax.xml.ws Annotation Type WebEndpoint

```java
@Target(value=METHOD)
@Retention(value=RUNTIME)
@Documented
public @interface WebEndpoint
```

**Implements:** Annotation
@Target(value=METHOD)
@Retention(value=RUNTIME)
@Documented

```java
getPortName()
```

wsdl:service    wsdl:port    WebServiceClient
since           JAX-WS 2.0
See also        javax.xml.ws.WebServiceClient

Used to annotate the `getPortName()` methods of a generated service interface.

The information specified in this annotation is sufficient to uniquely identify a `wsdl:port` element inside a `wsdl:service`. The latter is determined based on the value of the `WebServiceClient` annotation on the generated service interface itself.

**Since:**
JAX-WS 2.0

**See Also:**

Enum Constant Detail

IN
public static final WebParam.Mode IN

OUT
public static final WebParam.Mode OUT

INOUT
public static final WebParam.Mode INOUT
**Method Detail**

**final** public static [WebParam.Mode][] values()  

**values**  

public static final WebParam.Mode[] values()  

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(WebParam.Mode c : WebParam.Mode.values())
    System.out.println(c);
```

**Returns:**

an array containing the constants of this enum type, in the order they're declared

---

**public static WebParam.Mode valueOf(String name)**  

**valueOf**  

public static WebParam.Mode valueOf(String name)  

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**

name - the name of the enum constant to be returned.

**Returns:**

the enum constant with the specified name

**Throws:**
IllegalArgumentException - if this enum type has no constant with the specified name

actions HTTP null HTTP

WebResourcePermission

public WebResourcePermission(String name, String actions)

Creates a new WebResourcePermission with the specified name and actions.

The name contains a URLPatternSpec that identifies the web resources to which the permissions applies. The syntax of a
URLPatternSpec is as follows:

\[
\text{URLPatternList} ::= \text{URLPattern} \mid \text{URLPatternList colon } \text{URLPattern}
\]
\[
\text{URLPatternSpec} ::= \text{null} \mid \text{URLPattern} \mid \text{URLPattern colc}
\]

A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor. The empty string is an exact URLPattern, and may occur anywhere in a URLPatternSpec that an exact URLPattern may occur. The first URLPattern in a URLPatternSpec may be any of the pattern types, exact, path-prefix, extension, or default as defined in the Java Servlet Specification. When a URLPatternSpec includes a URLPatternList, the patterns of the URLPatternList identify the resources to which the permission does NOT apply and depend on the pattern type and value of the first pattern as follows:

- No pattern may exist in the URLPatternList that matches the first pattern.
- If the first pattern is a path-prefix pattern, only exact patterns matched by the first pattern and path-prefix patterns matched by, but different from, the first pattern may occur in the URLPatternList.
- If the first pattern is an extension pattern, only exact patterns that are matched by the first pattern and path-prefix patterns may occur in the URLPatternList.
- If the first pattern is the default pattern, "/", any pattern except the default pattern may occur in the URLPatternList.
- If the first pattern is an exact pattern a URLPatternList must not be present in the URLPatternSpec.

The actions parameter contains a comma seperated list of HTTP methods. The syntax of the actions parameter is defined as follows:

\[
\text{ExtensionMethod ::= any token as defined by RFC 2616 (that is, 1*[any CHAR except CTLs or separat}
\]
\[
\text{HTTPMethod ::= "GET" | "POST" | "PUT" | "DELETE" | "HE "OPTIONS" | "TRACE" | ExtensionMethod}
\]
If duplicates occur in the HTTPMethodSpec they must be eliminated by the permission constructor.

A null or empty string HTTPMethodSpec indicates that the permission applies to all HTTP methods at the resources identified by the URL pattern.

If the HTTPMethodSpec contains an HTTPMethodExceptionList (i.e., it begins with an exclamationPoint), the permission pertains to all methods except those occurring in the exception list.

**Parameters:**
- **name** - the URLPatternSpec that identifies the application specific web resources to which the permission pertains. All URLPatterns in the URLPatternSpec are relative to the context path of the deployed web application module, and the same URLPattern must not occur more than once in a URLPatternSpec. A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor.

- **actions** - identifies the HTTP methods to which the permission pertains. If the value passed through this parameter is null or the empty string, then the permission pertains to all the possible HTTP methods.

```java
public WebResourcePermission(String urlPatternSpec, String[] HTTPMethods)
WebResourcePermission URLPatternSpec HTTP
```
WebResourcePermission

public WebResourcePermission(String urlPatternSpec, String[] HTTPMethods)

Creates a new WebResourcePermission with name corresponding to the URLPatternSpec, and actions composed from the array of HTTP methods.

Parameters:
urlPatternSpec - the URLPatternSpec that identifies the application specific web resources to which the permission pertains. All URLPatterns in the URLPatternSpec are relative to the context path of the deployed web application module, and the same URLPattern must not occur more than once in a URLPatternSpec. A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor.

HTTPMethods - an array of strings each element of which contains the value of an HTTP method. If the value passed through this parameter is null or is an array with no elements, then the permission pertains to all the possible HTTP methods.

public WebResourcePermission(HttpServletRequest request)

HttpServletRequest WebResourcePermission

Servlet HttpServletRequest contextPath
(HttpServletRequest.getContextPath()) requestURI
request (HttpServletRequest.getRequestURI()) "/"
WebResourcePermission

public WebResourcePermission(HttpServletRequest request)

Creates a new WebResourcePermission from the HttpServletRequest object.

Parameters:
request - the HttpServletRequest object corresponding to the Servlet operation to which the permission pertains. The permission name is the substring of the requestURI (HttpServletRequest.getRequestURI()) that begins after the contextPath (HttpServletRequest.getContextPath()). When the substring operation yields the string "/", the permission is constructed with the empty string as its name. The permission's actions field is obtained from HttpServletRequest.getMethod().

Method Detail

public boolean equals(Object o)
WebResourcePermission WebResourcePermission
URLPatternSpec URLPatternSpec
URLPatternSpec URLPatternSpec
URLPatternList URLPatternList

P1.implies(P2) && P2.implies(P1)  Permission P1 P2

o  WebResourcePermission WebResourcePermission
return WebResourcePermission WebResourcePermission true
equals

public boolean equals(Object o)

Checks two WebResourcePermission objects for equality. WebResourcePermission objects are equivalent if their URLPatternSpec and (canonicalized) actions values are equivalent. The URLPatternSpec of a reference permission is equivalent to that of an argument permission if their first patterns are equivalent, and the patterns of the URLPatternList of the reference permission collectively match exactly the same set of patterns as are matched by the patterns of the URLPatternList of the argument permission.

Two Permission objects, P1 and P2, are equivalent if and only if P1.implies(P2) && P2.implies(P1).

Specified by:
equals in class Permission

Parameters:
o - the WebResourcePermission object being tested for equality with this WebResourcePermission.

Returns:
true if the argument WebResourcePermission object is equivalent to this WebResourcePermission.

public String getActions()
WebResourcePermission HTTP
HTTP null

return WebResourcePermission null

getActions
public String getActions()

Returns a canonical String representation of the actions of this WebResourcePermission. In the canonical form, predefined methods precede extension methods, and within each method classification the corresponding methods occur in ascending lexical order. There may be no duplicate HTTP methods in the canonical form, and the canonical form of the set of all HTTP methods is the value null.

Specified by: getActions in class Permission

Returns: a String containing the canonicalized actions of this WebResourcePermission (or the null value).

public int hashCode()

WebResourcePermission

- Java WebResourcePermission hashCode
  WebResourcePermission hashCode
- equals WebResourcePermission
  Permission hashCode
  return

hashCode

public int hashCode()

Returns the hash code value for this WebResourcePermission. The properties of the returned hash code must be as follows:

- During the lifetime of a Java application, the hashCode method must return the same integer value, every time it is called on a WebResourcePermission object. The value returned by
hashCode for a particular WebResourcePermission need not remain consistent from one execution of an application to another.

- If two WebResourcePermission objects are equal according to the equals method, then calling the hashCode method on each of the two Permission objects must produce the same integer result (within an application).

Specified by:

hashCode in class Permission

Returns:

the integer hash code value for this object.

---

public boolean implies(java.security.Permission
permission)
WebResourcePermission "" Permission
true

- WebResourcePermission
- permission URLPattern URLPattern
- permission URLPattern URLPatternSpec
  URLPatternList URLPattern
- permission URLPattern URLPatternSpec
  URLPattern URLPatternSpec URLPatternList
  URLPattern permission URLPatternList
  URLPattern
- permission HTTP HTTP

URLPattern Servlet URL

- String
- path-prefix "/*"
- path-prefix "/" "/*" 2
  "/"
- extension "*."
**implies**

```java
public boolean implies(Permission permission)
```

Determines if the argument Permission is "implied by" this WebResourcePermission. For this to be the case, all of the following must be true:

- The argument is an instanceof WebResourcePermission
- The first URLPattern in the name of the argument permission is matched by the first URLPattern in the name of this permission.
- The first URLPattern in the name of the argument permission is NOT matched by any URLPattern in the URLPatternList of the URLPatternSpec of this permission.
- If the first URLPattern in the name of the argument permission matches the first URLPattern in the URLPatternSpec of this permission, then every URLPattern in the URLPatternList of the URLPatternSpec of this permission is matched by a URLPattern in the URLPatternList of the argument permission.
- The HTTP methods represented by the actions of the argument permission are a subset of the HTTP methods represented by the actions of this permission.

URLPattern matching is performed using the *Servlet matching rules* where two URL patterns match if they are related as follows:

- their pattern values are String equivalent, or
- this pattern is the path-prefix pattern "/*/", or
- this pattern is a path-prefix pattern (that is, it starts with "/" and
ends with "/*/" and the argument pattern starts with the substring of this pattern, minus its last 2 characters, and the next character of the argument pattern, if there is one, is "/", or

- this pattern is an extension pattern (that is, it starts with "*.") and the argument pattern ends with this pattern, or
- the reference pattern is the special default pattern, "/", which matches all argument patterns.

All of the comparisons described above are case sensitive.

**Specified by:**

`implies` in class `Permission`

**Parameters:**

`permission` - "this" WebResourcePermission is checked to see if it implies the argument permission.

**Returns:**

true if the specified permission is implied by this object, false if not.
javax.jws Annotation Type WebResult

</table>

**abstract public String name()**
public abstract String name

Name of return value.

If the operation is rpc style and @WebResult.partName has not been specified, this is the name of the wsdl:part representing the return value.
If the operation is document style or the return value maps to a header, this is the local name of the XML element representing the return value.

Default: ""

abstract public String partName()

wsdl:part

rpc BARE

specdefault since {@code

partName

public abstract String partName

The name of the wsdl:part representing this return value.
This is only used if the operation is rpc style, or if the operation is document style and the parameter style is BARE.

**Since:**
2.0

**Default:**
""

```java
abstract public String targetNamespace()
XML
```

**targetNamespace**

```java
public abstract String targetNamespace
```

The XML namespace for the return value.

Only used if the operation is document style or the return value maps to a header. If the target namespace is set to `??`, this represents the empty namespace.

**Default:**
""

```java
abstract public boolean header()
true
```

**header**

```java
since 2.0
```
public abstract boolean header

If true, the result is pulled from a message header rather than the message body.

WebRoleRefPermission servlet Web servlet
.isUserInRole (String reference)

WebRoleRefPermission WebRoleRefPermission

newPermissionCollection

See also java.security.Permission

Class for Servlet isUserInRole (String reference) permissions. A WebRoleRefPermission is a named permission and has actions.

The name of an WebRoleRefPermission (also referred to as the target name) identifies a Web resource by the servlet name (in the deployment descriptor corresponding to the component from which the call to isUserInRole (String reference) is being made.
The actions of a WebRoleRefPermission identifies the role reference to which the permission applies. A WebRoleRefPermission is checked to determine if the subject is a member of the role identified by the reference.

Implementations of this class MAY implement newPermissionCollection or inherit its implementation from the super class.

**Constructor Detail**

public **WebRoleRefPermission**(String name, String actions)

WebRoleRefPermission

**Parameters:**
- **name** - the servlet-name that identifies the application specific web resource in whose context the role references are to be evaluated.

- **actions** - identifies the role reference to which the permission pertains. The role reference is scoped to the Web resource identified in the name parameter. The value of the role reference must not be null or the empty string.

**Method Detail**

public boolean equals(Object o)
WebRoleRefPermission  WebRoleRefPermission

P1.implies(P2) && P2.implies(P1)  Permission P1
P2

o  WebRoleRefPermission  WebRoleRefPermission
return  EJBRoleRefPermission  EJBRoleRefPermission
true

equals

public boolean equals(Object o)

Checks two WebRoleRefPermission objects for equality. WebRoleRefPermission objects are equivalent if they have case equivalent name and actions values.

Two Permission objects, P1 and P2, are equivalent if and only if P1.implies(P2) && P2.implies(P1).

The name and actions comparisons described above are case sensitive.

Specified by:  
equals in class Permission

Parameters:
  o - the WebRoleRefPermission object being tested for equality with this WebRoleRefPermission.

Returns:
  true if the argument WebRoleRefPermission object is equivalent to this WebRoleRefPermission.
public String getActions()
WebRoleRefPermission

return WebRoleRefPermission

getActions

public String getActions()

Returns a canonical String representation of the actions of this WebRoleRefPermission.

Specified by:
getActions in class Permission

Returns:
a String containing the canonicalized actions of this WebRoleRefPermission.

public int hashCode()
WebRoleRefPermission

• Java WebRoleRefPermission hashCode
WebRoleRefPermission hashCode
• equals WebRoleRefPermission Permission hashCode

return

hashCode

public int hashCode()
Returns the hash code value for this WebRoleRefPermission. The properties of the returned hash code must be as follows:

- During the lifetime of a Java application, the hashCode method must return the same integer value, every time it is called on a WebRoleRefPermission object. The value returned by hashCode for a particular WebRoleRefPermission need not remain consistent from one execution of an application to another.
- If two WebRoleRefPermission objects are equal according to the equals method, then calling the hashCode method on each of the two Permission objects must produce the same integer result (within an application).

Specified by:
hashCode in class Permission

Returns:
the integer hash code value for this object.

public boolean implies(java.security.Permission permission)
WebRoleRefPermission “” Permission

- WebRoleRefPermission
- WebRoleRefPermission
- WebRoleRefPermission

permission "this" WebRoleRefPermission
return true false

implies
public boolean implies(Permission permission)

Determines if the argument Permission is "implied by" this WebRoleRefPermission. For this to be the case,

- The argument must be an instance of WebRoleRefPermission
- with name equivalent to this WebRoleRefPermission, and
- with role reference equivalent to this WebRoleRefPermission (as defined in their actions).

The comparisons described above are case sensitive.

Specified by:
implies in class Permission

Parameters:
permission - "this" WebRoleRefPermission is checked to see if it implies the argument permission.

Returns:
true if the specified permission is implied by this object, false if not.

</thead>
<tbody>
<tr>
<td></td>
<td>If the @WebService.targetNamespace annotation is on a service endpoint interface, the targetNamespace is used for the namespace for the wsdl:portType (and associated XML elements).</td>
</tr>
</tbody>
</table>
String wsdlLocation

The location of a pre-defined WSDL describing the service.

abstract public String name()

Web Service

WSDL 1.1  wsdl:portType

specdefault  Java

name

public abstract String name

The name of the Web Service.

Used as the name of the wsdl:portType when mapped to WSDL 1.1.

Default:

abstract public String targetNamespace()

@WebService.targetNamespace  targetNamespace

wsdl:portType  XML

endpointInterface

bean  targetNamespace  wsdl:portType

wsdl:service  XML

@WebService.targetNamespace  endpointInterface

bean  targetNamespace  wsdl:service

XML

specdefault  JAX-WS 2.0 [5]  3.2
targetNamespace

public abstract String targetNamespace

If the @WebService.targetNamespace annotation is on a service endpoint interface, the targetNamespace is used for the namespace for the wsdl:portType (and associated XML elements).

If the @WebService.targetNamespace annotation is on a service implementation bean that does NOT reference a service endpoint interface (through the endpointInterface attribute), the targetNamespace is used for both the wsdl:portType and the wsdl:service (and associated XML elements).

If the @WebService.targetNamespace annotation is on a service implementation bean that does reference a service endpoint interface (through the endpointInterface attribute), the targetNamespace is used for only the wsdl:service (and associated XML elements).

Default:

""

abstract public String serviceName()

Web Service

WSDL 1.1 wsdl:service

specdefault Java class + Service

serviceName
public abstract String serviceName

The service name of the Web Service.
Used as the name of the wsdl:service when mapped to WSDL 1.1.

*This member-value is not allowed on endpoint interfaces.*

**Default:**

```
""
```

---

abstract public String portName()

**Web Service**

**WSDL 1.1  wsdl:port**

specdefault @WebService.name+?Port?.

since 2.0

**portName**

public abstract String portName

The port name of the Web Service.
Used as the name of the wsdl:port when mapped to WSDL 1.1.

*This member-value is not allowed on endpoint interfaces.*

**Since:**

2.0

**Default:**

```
""
```
abstract public String wsdlLocation()
WSDL

wsdlLocation WSDL URLwsdlLocation
bean WSDL bean WSDL portType
JSR-181 WSDL portType bean Web
Service portType

wsdlLocation

public abstract String wsdlLocation

The location of a pre-defined WSDL describing the service.

The wsdlLocation is a URL (relative or absolute) that refers to a pre-existing WSDL file. The presence of a wsdlLocation value indicates that the service implementation bean is implementing a pre-defined WSDL contract. The JSR-181 tool MUST provide feedback if the service implementation bean is inconsistent with the portType and bindings declared in this WSDL. Note that a single WSDL file might contain multiple portTypes and multiple bindings. The annotations on the service implementation bean determine the specific portType and bindings that correspond to the Web Service.

Default: 

""

abstract public String endpointInterface()
Web

WSDL portType Java WSDL JSR-181
Bean
Web Bean
endpointInterface

```java
public abstract String endpointInterface
```

The complete name of the service endpoint interface defining the service's abstract Web Service contract.

This annotation allows the developer to separate the interface contract from the implementation. If this annotation is present, the service endpoint interface is used to determine the abstract WSDL contract (portType and bindings). The service endpoint interface MAY include JSR-181 annotations to customize the mapping from Java to WSDL.

The service implementation bean MAY implement the service endpoint interface, but is not REQUIRED to do so.

If this member-value is not present, the Web Service contract is generated from annotations on the service implementation bean. If a service endpoint interface is required by the target environment, it will be generated into an implementation-defined package with an implementation-defined name.

*This member-value is not allowed on endpoint interfaces.*

**Default:**

```
PS:
javax.xml.ws Annotation Type WebServiceClient

@Target(value=TYPE)
@Retention(value=RUNTIME)
@Documented
public @interface WebServiceClient

**Implements:** Annotation
@Target(value=TYPE)
@Retention(value=RUNTIME)
@Documented

WSDL  wsdl:service  wsdl:service Web
      since        JAX-WS 2.0

Used to annotate a generated service interface.

The information specified in this annotation is sufficient to uniquely identify a `wsdl:service` element inside a WSDL document. This `wsdl:service` element represents the Web service for which the generated service interface provides a client view.

**Since:**
JAX-WS 2.0

wsdlLocation

public abstract String wsdlLocation
The location of the WSDL document for the service (a URL).

**Default:**

"""
javax.xml.ws Interface WebServiceContext

public interface WebServiceContext

WebServiceContext Web

since JAX-WS 2.0
See also javax.annotation.Resource

A WebServiceContext makes it possible for a web service endpoint implementation class to access message context and security information relative to a request being served. Typically a WebServiceContext is injected into an endpoint implementation class using the Resource annotation.

Since: JAX-WS 2.0
See Also: Resource

### Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>getMessageContext()</td>
<td>Returns the MessageContext for the request being served at the time this method is called.</td>
</tr>
<tr>
<td>getUserPrincipal()</td>
<td>Returns the Principal that identifies the sender of the request currently being serviced.</td>
</tr>
<tr>
<td>boolean isUserInRole(String role)</td>
<td>Returns a boolean indicating whether the authenticated user is included in the specified logical role.</td>
</tr>
</tbody>
</table>
public MessageContext getMessageContext()
MessageContext APPLICATION

    return MessageContext

    Throws IllegalStateException:

See also javax.xml.ws.handler.MessageContext,
javax.xml.ws.handler.MessageContext.Scope,
java.lang.IllegalStateException

getMessageContext

    MessageContext getMessageContext()

    Returns the MessageContext for the request being served at the
time this method is called. Only properties with APPLICATION scope
will be visible to the application.

    Returns: MessageContext The message context.

    Throws: IllegalStateException - This exception is thrown if the method
is called while no request is being serviced.

See Also: MessageContext, MessageContext.Scope, IllegalStateException

public java.security.Principal getUserPrincipal()
Principal

    return Principal

    Throws IllegalStateException:

See also java.security.Principal, java.lang.IllegalStateException

getUserPrincipal
**Principal** `getUserPrincipal()`

Returns the Principal that identifies the sender of the request currently being serviced. If the sender has not been authenticated, the method returns `null`.

**Returns:**
Principal The principal object.

**Throws:**
`IllegalStateException` - This exception is thrown if the method is called while no request is being serviced.

**See Also:**
Principal, `IllegalStateException`

---

**public boolean isUserInRole(String role)**

`false`

```java
role String
return boolean
Throws IllegalArgumentException: IllegalStateException:
```

**isUserInRole**

boolean `isUserInRole(String role)`

Returns a boolean indicating whether the authenticated user is included in the specified logical role. If the user has not been authenticated, the method returns false.

**Parameters:**
role - A String specifying the name of the role

**>Returns:**
a boolean indicating whether the sender of the request belongs to a given role

**Throws:**
`IllegalStateException` - This exception is thrown if the method is called while no request is being serviced.

<td><code>WebServiceException()</code></td>
<td>Constructs a new exception with <code>null</code> as its detail message.</td>
</tr>
</tbody>
</table>
### Constructor Detail

**public WebServiceException()**

nullcause

**WebServiceException**

**public WebServiceException()**

Constructs a new exception with null as its detail message. The cause is not initialized.
public WebServiceException(String message)

Constructs a new exception with the specified detail message. The cause is not initialized.

Parameters:
message - The detail message which is later retrieved using the getMessage method

public WebServiceException(String message, Throwable cause)

Constructs a new exception with the specified detail message and cause.

Parameters:
message - The detail message which is later retrieved using the getMessage method
cause - The cause which is saved for the later retrieval throw by the getCause method
public WebServiceException(Throwable cause)

cause (cause==null ? null : cause.toString)

WebServiceException

cause WebServiceException

cause cause getCause

WebServiceException

public WebServiceException((Throwable cause)

Constructs a new WebServiceException with the specified cause and a detail message of (cause==null ? null : cause.toString()) (which typically contains the class and detail message of cause).

Parameters:

cause - The cause which is saved for the later retrieval throw by the getCause method. (A null value is permitted, and indicates that the cause is nonexistent or unknown.)

javax.xml.ws  **Class WebServicePermission**

`java.lang.Object`  
  `java.security.Permission`  
    `java.security.BasicPermission`  
      `javax.xml.ws.WebServicePermission`

**All Implemented Interfaces:**  
  Serializable, Guard

```java
public final class WebServicePermission
extends BasicPermission

Extends: java.security.Permission > java.security.BasicPermission

Web
Web ""

publishEndpoint

publishEndpoint    javax.xml.ws.Endpoint    publish Web

See also    javax.xml.ws.Endpoint, java.security.BasicPermission,  
            java.security.Permission, java.security.Permissions,  
            java.lang.SecurityManager
```

This class defines web service permissions.

Web service Permissions are identified by name (also referred to as a  
"target name") alone. There are no actions associated with them.

The following permission target name is defined:

publishEndpoint
The `publishEndpoint` permission allows publishing a web service endpoint using the `publish` methods defined by the `javax.xml.ws.Endpoint` class.

See Also:

- `Endpoint`, `BasicPermission`, `Permission`, `Permissions`, `SecurityManager`, `Serialized Form`
WebServicePermission

public WebServicePermission(String name)

Creates a new permission with the specified name.

Parameters:
name - the name of the WebServicePermission

public WebServicePermission(String name, String actions)

name - WebServicePermission
actions - null

WebServicePermission

public WebServicePermission(String name, String actions)

Creates a new permission with the specified name and actions. The actions parameter is currently unused and it should be null.

Parameters:
name - the name of the WebServicePermission
actions - should be null

</tr>
</tbody>
</table>

```java
abstract public String name()
JNDI  JavaBean

name
```

```java
public abstract String name

The JNDI name of the resource. For field annotations, the default is the field name. For method annotations, the default is the JavaBeans property name corresponding to the method. For class annotations, there is no default and this must be specified.

**Default:**
""
```

```java
abstract public Class<T> type()
Java  JavaBean

type
```

```java
public abstract Class type

The Java type of the resource. For field annotations, the default is the type of the field. For method annotations, the default is the type of the JavaBeans property. For class annotations, there is no default and this must be specified.

**Default:**
java.lang.Object.class
```
A product specific name that this resource should be mapped to. The name of this resource, as defined by the `name` element or defaulted, is a name that is local to the application component using the resource. (It's a name in the JNDI `java:comp/env` namespace.) Many application servers provide a way to map these local names to names of resources known to the application server. This mapped name is often a *global* JNDI name, but may be a name of any form.

Application servers are not required to support any particular form or type of mapped name, nor the ability to use mapped names. The mapped name is product-dependent and often installation-dependent. No use of a mapped name is portable.

**Default:**

```
"
```
The service class, always a type extending javax.xml.ws.Service. This element must be specified whenever the type of the reference is a service endpoint interface.

Default:
java.lang.Object.class

abstract public String wsdlLocation()
Web WSDL URL WSDL

wsdlLocation

public abstract String wsdlLocation

A URL pointing to the WSDL document for the web service. If not specified, the WSDL location specified by annotations on the resource type is used instead.

Default:

Web URLPatternSpecURLPatternSpec URLPattern
Web URLPatternSpec NULLPatternnull
URLPatternSpec URLPattern("/")

name actions HTTP null HTTP transportType "NONE"

WebUserDataPermission

public WebUserDataPermission(String name,
 String actions)

Creates a new WebUserDataPermission with the specified name and actions.
The name contains a URLPatternSpec that identifies the web resources to which the permissions applies. The syntax of a URLPatternSpec is as follows:

\[
\begin{align*}
\text{URLPatternList} & ::= \text{URLPattern} \mid \text{URLPatternList} \colon \text{URLPattern} \\
\text{URLPatternSpec} & ::= \text{null} \mid \text{URLPattern} \mid \text{URLPattern colc}
\end{align*}
\]

A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor. The empty string is an exact URLPattern, and may occur anywhere in a URLPatternSpec that an exact URLPattern may occur. The first URLPattern in a URLPatternSpec may be any of the pattern types, exact, path-prefix, extension, or default as defined in the Java Servlet Specification. When a URLPatternSpec includes a URLPatternList, the patterns of the URLPatternList identify the resources to which the permission does NOT apply and depend on the pattern type and value of the first pattern as follows:

- No pattern may exist in the URLPatternList that matches the first pattern.
- If the first pattern is a path-prefix pattern, only exact patterns matched by the first pattern and path-prefix patterns matched by, but different from, the first pattern may occur in the URLPatternList.
- If the first pattern is an extension pattern, only exact patterns that are matched by the first pattern and path-prefix patterns may occur in the URLPatternList.
- If the first pattern is the default pattern, "/", any pattern except the default pattern may occur in the URLPatternList.
- If the first pattern is an exact pattern a URLPatternList must not be present in the URLPatternSpec.

The actions parameter contains a comma separated list of HTTP methods that may be followed by a transportType separated from the HTTP method by a colon.

\[
\text{ExtensionMethod} ::= \text{any token as defined by RFC 2616} \\
\quad \text{(that is, } 1^*\text{[any CHAR except CTLs or separator}}
\]
HTTPMethod ::= "Get" | "POST" | "PUT" | "DELETE" | "HEAD" | "OPTIONS" | "TRACE" | ExtensionMethod

HTTPMethodList ::= HTTPMethod | HTTPMethodList comma HTTPMethod

HTTPMethodExceptionList ::= exclamationPoint HTTPMethodList

HTTPMethodSpec ::= emptyString | HTTPMethodExceptionList | HTTPMethodList

transportType ::= "INTEGRAL" | "CONFIDENTIAL" | "NONE"

actions ::= null | HTTPMethodSpec | HTTPMethodSpec colon transportType

If duplicates occur in the HTTPMethodSpec they must be eliminated by the permission constructor.

An empty string HTTPMethodSpec is a shorthand for a List containing all the possible HTTP methods.

If the HTTPMethodSpec contains an HTTPMethodExceptionList (i.e., it begins with an exclamationPoint), the permission pertains to all methods except those occurring in the exception list.

An actions string without a transportType is a shorthand for a actions string with the value "NONE" as its TransportType.

A granted permission representing a transportType of "NONE", indicates that the associated resources may be accessed using any conection type.

Parameters:
name - the URLPatternSpec that identifies the application specific web resources to which the permission pertains. All URLPatterns in the URLPatternSpec are relative to the context path of the deployed web application module, and the same URLPattern must not occur more than once in a URLPatternSpec. A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor.
actions - identifies the HTTP methods and transport type to which the permission pertains. If the value passed through this parameter is null or the empty string, then the permission is constructed with actions corresponding to all the possible HTTP methods and transportType "NONE".

```
public WebUserDataPermission(String urlPatternSpec, String[] HTTPMethods, String transportType)
WebUserDataPermission URLPatternSpec HTTP
```

```
urlPatternSpec
Web URLPatternSpec
URLPattern Spec
URLPatternnull
URLPatternSpec
URLPattern ("/")
```

```
HTTPMethods
HTTP null HTTP
```

```
transportType
transportType String null transportType
"NONE"
```

**WebUserDataPermission**

```
public WebUserDataPermission(String urlPatternSpec,
String[] HTTPMethods,
String transportType)
```

Creates a new WebUserDataPermission with name corresponding to the URLPatternSpec, and actions composed from the array of HTTP methods and the transport type.

**Parameters:**

- **urlPatternSpec** - the URLPatternSpec that identifies the application specific web resources to which the permission pertains. All URLPatterns in the URLPatternSpec are relative to the context path of the deployed web application module, and the same URLPattern must not occur more than once in a
URLPatternSpec. A null URLPatternSpec is translated to the default URLPattern, "/", by the permission constructor.

HTTPMethods - an array of strings each element of which contains the value of an HTTP method. If the value passed through this parameter is null or is an array with no elements, then the permission is constructed with actions corresponding to all the possible HTTP methods.

transportType - a String whose value is a transportType. If the value passed through this parameter is null, then the permission is constructed with actions corresponding to transportType "NONE".

```java
public WebUserDataPermission(HttpServletRequest request) {
    HttpServletRequest request = (HttpServletRequest) request;
    Servlet contextPath = request.getContextPath();
    String requestURI = request.getRequestURI();
    String[] HTTPMethods = request.getMethod().split(\s+);
    String transportType = request.isSecure() ? "SECURED" : "NONE";
    // Create WebUserDataPermission
}
```

WebUserDataPermission

```java
public WebUserDataPermission(HttpServletRequest request) {
    // Create WebUserDataPermission
}
```

Creates a new WebUserDataPermission from the HttpServletRequest object.

Parameters:

request - the HttpServletRequest object corresponding to the Servlet operation to which the permission pertains. The permission name is the substring of the requestURI (HttpServletRequest.getRequestURI()) that begins after the
contextPath (HttpServletRequest.getContextPath()). When the substring operation yields the string "/", the permission is constructed with the empty string as its name. The HTTP method component of the permission's actions is as obtained from HttpServletRequest.getMethod(). The TransportType component of the permission's actions is determined by calling HttpServletRequest.isSecure().

**Method Detail**

```java
class WebUserDataPermission

public boolean equals(Object o)

WebUserDataPermission
WebUserDataPermission URLPatternSpec
URLPatternSpec URLPatternSpec
URLPatternList URLPatternList

P1.implies(P2) && P2.implies(P1) Permission P1
P2

    o  WebUserDataPermission WebUserDataPermission

    return WebUserDataPermission WebUserDataPermission
    true

equals

class WebUserDataPermission

public boolean equals(Object o)

Checks two WebUserDataPermission objects for equality. WebUserDataPermission objects are equivalent if their URLPatternSpec and (canonicalized) actions values are equivalent. The URLPatternSpec of a reference permission is equivalent to that of an argument permission if their first patterns are equivalent, and the patterns of the URLPatternList of the reference permission collectively match exactly the same set of patterns as are matched
by the patterns of the URLPatternList of the argument permission.

Two Permission objects, P1 and P2, are equivalent if and only if 
P1.implies(P2) && P2.implies(P1).

**Specified by:**
equals in class Permission

**Parameters:**
- the WebUserDataPermission object being tested for equality with this WebUserDataPermission.

**Returns:**
true if the argument WebUserDataPermission object is 
equivalent to this WebUserDataPermission.

```java
public String getActions()
WebUserDataPermission
WebUserDataPermission

ExtensionMethod ::= any token as defined by RFC 2616
  1*[ CTL ]

HTTPMethod ::= "GET" | "POST" | "PUT" | "DELETE" | "HEAD" | "OPTIONS" | "TRACE" | ExtensionMethod

HTTPMethodList ::= HTTPMethod | HTTPMethodList comma HTTPMethod

HTTPMethodExceptionList ::= exclamationPoint HTTPMethodList

HTTPMethodSpec ::= emptyString | HTTPMethodExceptionList | HTTPMethodList

transportType ::= "INTEGRAL" | "CONFIDENTIAL" | "NONE"

actions ::= null | HTTPMethodList | HTTPMethodSpec colon transportType
```
getActions

public String getActions()

Returns a canonical String representation of the actions of this WebUserDataPermission. The canonical form of the actions of a WebUserDataPermission is described by the following syntax description.

```
ExtensionMethod ::= any token as defined by RFC 2616
                 (that is, 1*[any CHAR except CTLs or separatec

HTTPMethod ::= "GET" | "POST" | "PUT" | "DELETE" | "HE
             "OPTIONS" | "TRACE" | ExtensionMethod

HTTPMethodList ::= HTTPMethod | HTTPMethodList comma HTTPMethod

HTTPMethodExceptionList ::= exclamationPoint HTTPMethodList

HTTPMethodSpec ::= emptyString | HTTPMethodExceptionList
                 HTTPMethodList

transportType ::= "INTEGRAL" | "CONFIDENTIAL" | "NONE"

actions ::= null | HTTPMethodList |
           HTTPMethodSpec colon transportType
```
If the permission's HTTP methods correspond to the entire HTTP method set and the permission's transport type is "INTEGRAL" or "CONFIDENTIAL", the HTTP methods shall be represented in the canonical form by an emptyString HTTPMethodSpec. If the permission's HTTP methods correspond to the entire HTTP method set, and the permission's transport type is not "INTEGRAL" or "CONFIDENTIAL", the canonical actions value shall be the null value.

If the permission's methods do not correspond to the entire HTTP method set, duplicates must be eliminated and the remaining elements must be ordered such that the predefined methods precede the extension methods, and such that within each method classification the corresponding methods occur in ascending lexical order. The resulting (non-emptyString) HTTPMethodSpec must be included in the canonical form, and if the permission's transport type is not "INTEGRAL" or "CONFIDENTIAL", the canonical actions value must be exactly the resulting HTTPMethodSpec.

**Specified by:**

`getActions` in class `Permission`

**Returns:**

a String containing the canonicalized actions of this WebUserDataPermission (or the null value).

```java
public int hashCode()

WebUserDataPermission

- Java WebUserDataPermission hashCode
  EJBMethode hashCode
- equals WebUserDataPermission
  Permission hashCode

  return
```
**hashCode**

```
public int hashCode()
```

Returns the hash code value for this WebUserDataPermission. The properties of the returned hash code must be as follows:

- During the lifetime of a Java application, the hashCode method shall return the same integer value every time it is called on a WebUserDataPermission object. The value returned by hashCode for a particular EJBMeth permission need not remain consistent from one execution of an application to another.
- If two WebUserDataPermission objects are equal according to the equals method, then calling the hashCode method on each of the two Permission objects must produce the same integer result (within an application).

**Specified by:**

hashCode in class Permission

**Returns:**

the integer hash code value for this object.

---

**public boolean implies(java.security.Permission permission)**

```
WebUserDataPermission "" Permission
```

true

- WebUserDataPermission
- permission URLPattern URLPattern
- permission URLPattern URLPatternSpec
  URLPatternList URLPattern
- permission URLPattern URLPatternSpec
  URLPattern URLPatternSpec URLPatternSpec URLPatternList
URLPattern  permission URLPatternList
URLPattern
URLPattern
permission HTTP HTTP
transportType "NONE" permission
transportType

URLPattern Servlet URL

- String
- path-prefix "/*"
- path-prefix "/*" 2
- extension "."
- "/*"

permission "this" WebUserDataPermission
return true false

implies

public boolean implies(Permission permission)

Determines if the argument Permission is "implied by" this WebUserDataPermission. For this to be the case all of the following must be true:

- The argument is an instance of WebUserDataPermission.
- The first URLPattern in the name of the argument permission is matched by the first URLPattern in the name of this permission.
- The first URLPattern in the name of the argument permission is NOT matched by any URLPattern in the URLPatternList of the URLPatternSpec of this permission.
- If the first URLPattern in the name of the argument permission matches the first URLPattern in the URLPatternSpec of this
permission, then every URLPattern in the URLPatternList of the
URLPatternSpec of this permission is matched by a URLPattern
in the URLPatternList of the argument permission.

- The HTTP methods represented by the actions of the argument
  permission are a subset of the HTTP methods represented by
  the actions of this permission.
- The transportType in the actions of this permission either
  corresponds to the value "NONE", or equals the transportType
  in the actions of the argument permission.

URLPattern matching is performed using theServlet matching rules
where two URL patterns match if they are related as follows:

- their pattern values are String equivalent, or
- this pattern is the path-prefix pattern "/*", or
- this pattern is a path-prefix pattern (that is, it starts with "/" and
  ends with "/*") and the argument pattern starts with the substring
  of this pattern, minus its last 2 characters, and the next
  character of the argument pattern, if there is one, is "/", or
- this pattern is an extension pattern (that is, it starts with "*."
  and the argument pattern ends with this pattern, or
- the reference pattern is the special default pattern, "/", which
  matches all argument patterns.

All of the comparisons described above are case sensitive.

**Specified by:**
implies in class Permission

**Parameters:**
permission - "this" WebUserDataPermission is checked to see if
it implies the argument permission.

**Returns:**
true if the specified permission is implied by this object, false if
not.

Method Detail
public void release()

release

void release()

The WorkManager might call this method to hint the active Work instance to complete execution as soon as possible. This would be called on a separate thread other than the one currently executing the Work instance.
public class WorkAdapter

extends Object
implements WorkListener

Implements: WorkListener

Version: 1.0
Author: Ram Jeyaraman

This class is provided as a convenience for easily creating WorkListener instances by extending this class and overriding only those methods of interest.

Constructor Summary

workAccepted(WorkEvent e)

Method Summary

workAccepted(WorkEvent e)
void Invoked when a work instance has been accepted.

void workCompleted(WorkEvent e)
Invoked when a work instance has completed execution.

void workRejected(WorkEvent e)
Invoked when a work instance has been rejected.

void workStarted(WorkEvent e)
Invoked when a work instance has started execution.

Methods inherited from class java.lang.Object
clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait

Constructor Detail

public WorkAdapter()

WorkAdapter

public WorkAdapter()

Method Detail

public void workAccepted(WorkEvent e)
  Work

workAccepted

public void workAccepted(WorkEvent e)
  Invoked when a work instance has been accepted.
public void workRejected(WorkEvent e)

Invoked when a Work instance has been rejected.

Specified by:
workRejected in interface WorkListener

public void workStarted(WorkEvent e)

Invoked when a Work instance has started execution. This only means that a thread has been allocated.

Specified by:
workStarted in interface WorkListener

public void workCompleted(WorkEvent e)

workCompleted
public void workCompleted(WorkEvent e)

Invoked when a Work instance has completed execution.

**Specified by:**
workCompleted in interface WorkListener

public class WorkCompletedException
   extends WorkException

Extends: Throwable > Exception > ResourceException > WorkException

WorkManager Work
Work Work
Work.run()
Work.run()

WorkException.TX_RECREATE_FAILED
WorkException.TX_CONCURRENT_WORK_DISALLOWED
WorkException.UNDEFINED

version 1.0

This exception is thrown by a WorkManager to indicate that a submitted Work instance has completed with an exception.

This could be thrown only after the execution of a Work instance has started (that is, after a thread has been allocated for Work execution). The allocated thread sets up an execution context (if it has been specified), and then calls Work.run().
Any exception thrown during execution context setup or during `Work` execution (that is, during `Work.run()`) is chained within this exception.

An associated error code indicates the nature of the error condition. Possible error codes are `WorkException.TX_RECREATE_FAILED`, `WorkException.TX_CONCURRENT_WORK_DISALLOWED` or `WorkException.UNDEFINED`.

WorkCompletedException

public WorkCompletedException(String message)

Constructs a new instance with the specified detail message.

Parameters:
message - the detail message.

public WorkCompletedException(Throwables cause)

cause throwable

cause Throwable

WorkCompletedException

public WorkCompletedException(Throwables cause)

Constructs a new throwable with the specified cause.

Parameters:
cause - a chained exception of type Throwable.

public WorkCompletedException(String message, Throwable cause)

cause throwable

message

cause Throwable

WorkCompletedException

public WorkCompletedException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and
cause.

**Parameters:**
- `message` - the detail message.
- `cause` - a chained exception of type Throwable.

```java
public WorkCompletedException(String message, String errorCode)
```

`throwable`

```java
message
errorCode
```

## WorkCompletedException

**public WorkCompletedException(String message, String errorCode)**

Constructs a new throwable with the specified detail message and an error code.

**Parameters:**
- `message` - a description of the exception.
- `errorCode` - a string specifying the vendor specific error code.

Constructor Detail

public WorkEvent(Object source, int type, Work work, WorkException exc)

source  
  type  
  work  Work
  exc  Work

WorkEvent

public WorkEvent(Object source, 
  int type, 
  Work work, 
  WorkException exc)

Constructor.

Parameters:
    source - The object on which the event initially occurred.
    type - The event type.
    work - The Work object on which the event occurred.
    exc - The exception that occurred during Work processing.

public WorkEvent(Object source, int type, Work work, 
  WorkException exc, long startDuration)
WorkEvent

public WorkEvent(Object source, int type, Work work, WorkException exc, long startDuration)

Constructor.

Parameters:
- source - The object on which the event initially occurred.
- type - The event type.
- work - The Work object on which the event occurred.
- exc - The exception that occurred during Work processing.
- startDuration - The start delay duration (in milliseconds).

Method Detail

public int getType()

    return

getType

public int getType()

    Return the type of this event.
Returns:
the event type.

public Work getWork()
Work work
return work

getWork

public Work getWork()

Return the work instance which is the cause of the event.

Returns:
the work instance.

public long getStartDuration()
return Work work -1

getStartDuration

public long getStartDuration()

Return the start interval duration.

Returns:
the time elapsed (in milliseconds) since the work was accepted, until the work execution started. Note, this does not offer real-time guarantees. It is valid to return -1, if the actual start interval duration is unknown.

public WorkException getException()
public WorkException getException()

Return the WorkException. The actual WorkException subtype returned depends on the type of the event.

Returns:
  a WorkRejectedException or a WorkCompletedException, if any.

**Constructor Detail**

public WorkException()

null
**WorkException**

```java
public WorkException()

    Constructs a new instance with null as its detail message.
```

```java
public WorkException(String message)

    message
```

**WorkException**

```java
public WorkException(String message)

    Constructs a new instance with the specified detail message.

    Parameters:
        message - the detail message.
```

```java
public WorkException(Throwable cause)

    cause throwable
```

**WorkException**

```java
public WorkException(Throwable cause)

    Constructs a new throwable with the specified cause.

    Parameters:
        cause - a chained exception of type Throwable.
```

```java
public WorkException(String message, Throwable cause)
```
public WorkException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.

public WorkException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.

PS:
javax.resource.spi.work Interface WorkListener

All Superinterfaces:
   EventListener

All Known Implementing Classes:
   WorkAdapter

public interface WorkListener
   extends EventListener

Implements: java.util.EventListener
Implemented by: WorkAdapter

<table>
<thead>
<tr>
<th>WorkListener</th>
<th>Work</th>
<th>WorkManager</th>
</tr>
</thead>
<tbody>
<tr>
<td>WorkListener</td>
<td></td>
<td>version 1.0</td>
</tr>
</tbody>
</table>

This models a WorkListener instance which would be notified by the WorkManager when the various Work processing events (work accepted, work rejected, work started, work completed) occur. The WorkListener instance must not make any thread assumptions and must be thread-safe ie., a notification could occur from any arbitrary thread. Further, it must not make any assumptions on the ordering of notifications.

### Method Detail

**public void workAccepted(WorkEvent e)**

Work

**workAccepted**

```java
void workAccepted(WorkEvent e)
```

Invoked when a work instance has been accepted.

**public void workRejected(WorkEvent e)**

Work

**workRejected**

```java
void workRejected(WorkEvent e)
```

Invoked when a work instance has been rejected.

**public void workStarted(WorkEvent e)**

Work
workStarted

void workStarted(WorkEvent e)

Invoked when a Work instance has started execution. This only means that a thread has been allocated.

workCompleted

public void workCompleted(WorkEvent e)

Invoked when a Work instance has completed execution.
public interface WorkManager

WorkManager Work Java

* Work Work WorkRejectedException
* Work Work WorkRejectedException
  WorkWorkRejectedException
* Work Work Work Work WorkRejectedException
  Work.run()
  Work.run()
* Work WorkManager Work
  WorkCompletedException

version 1.0

This interface models a WorkManager which provides a facility to submit Work instances for execution. This frees the user from having to create Java threads directly to do work. Further, this allows efficient pooling of thread resources and more control over thread usage. The various stages in Work processing are:

- **work submit**: A Work instance is being submitted for execution. The Work instance could either be accepted or rejected with a WorkRejectedException set to an appropriate error code.
- **work accepted**: The submitted Work instance has been accepted. The accepted Work instance could either start execution or could be rejected again with a WorkRejectedException set to an appropriate error code. There is no guarantee on when the execution would start unless a start timeout duration is specified. When a start timeout is specified, the Work execution must be started within the specified duration (not a real-time guarantee), failing which a
WorkRejectedException set to an error code (WorkRejected.TIMED_OUT) is thrown.

- **work rejected**: The Work instance has been rejected. The Work instance could be rejected during Work submittal or after the Work instance has been accepted (but before Work instance starts execution). The rejection could be due to internal factors or start timeout expiration. A WorkRejectedException with an appropriate error code (indicates the reason) is thrown in both cases.

- **work started**: The execution of the Work instance has started. This means that a thread has been allocated for its execution. But this does not guarantee that the allocated thread has been scheduled to run on a CPU resource. Once execution is started, the allocated thread sets up an appropriate execution context (transaction, security, etc) and calls Work.run(). Note, any exception thrown during execution context setup or Work.run() leads to completion of processing.

- **work completed**: The execution of the Work has been completed. The execution could complete with or without an exception. The WorkManager catches any exception thrown during Work processing (which includes execution context setup), and wraps it with a WorkCompletedException.

Method Detail

public void doWork(Work work) throws WorkException

<table>
<thead>
<tr>
<th>Work</th>
<th>Work</th>
<th>Work</th>
</tr>
</thead>
<tbody>
<tr>
<td>work</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Throws

WorkRejectedException: Work

Throws

WorkCompletedException: Work

doWork

void doWork(Work work)

throws WorkException

Accepts a Work instance for processing. This call blocks until the Work instance completes execution. There is no guarantee on when the
accepted work instance would start execution i.e., there is no time constraint to start execution.

**Parameters:**
- **work** - The unit of work to be done. Could be long or short-lived.

**Throws:**
- **WorkRejectedException** - indicates that a work instance has been rejected from further processing. This can occur due to internal factors.
- **WorkCompletedException** - indicates that a work instance has completed execution with an exception.
- **WorkException**

```java
public void doWork(Work work, long startTimeout, ExecutionContext execContext, WorkListener workListener) throws WorkException
    work
    startTimeout (WorkRejectedException.TIMED_OUT)  WorkRejectedException
    execContext
    workListener 
    Throws  WorkRejectedException:  Work
    Throws  WorkCompletedException:  Work
```

doWork

```java
void doWork(Work work,
            long startTimeout,
            ExecutionContext execContext,
            WorkListener workListener)
    throws WorkException
```

Accepts a work instance for processing. This call blocks until the work instance completes execution.
Parameters:
- **work**: The unit of work to be done. Could be long or short-lived.
- **startTimeTimeout**: A time duration (in milliseconds) within which the execution of the **Work** instance must start. Otherwise, the **Work** instance is rejected with a **WorkRejectedException** set to an appropriate error code (**WorkRejectedException.TIMED_OUT**).
  
  Note, this does not offer real-time guarantees.
- **execContext**: An object containing the execution context with which the submitted **Work** instance must be executed.
- **workListener**: An object which would be notified when the various **Work** processing events (work accepted, work rejected, work started, work completed) occur.

Throws:
- **WorkRejectedException** - indicates that a **Work** instance has been rejected from further processing. This can occur due to internal factors or start timeout expiration.
- **WorkCompletedException** - indicates that a **Work** instance has completed execution with an exception.
- **WorkException**

```java
public long startWork(Work work) throws WorkException {
    Work work
    return Work -1
    Throws WorkRejectedException:
}
```

### startWork

```java
long startWork(Work work) throws WorkException {
    Accepts a **Work** instance for processing. This call blocks until the **Work** instance starts execution but not until its completion. There is no guarantee on when the accepted **Work** instance would start execution i.e., there is no time constraint to start execution.

    Parameters:
```
work - The unit of work to be done. Could be long or short-lived.

Returns:
the time elapsed (in milliseconds) from work acceptance until start of execution. Note, this does not offer real-time guarantees. It is valid to return -1, if the actual start delay duration is unknown.

Throws:
WorkRejectedException - indicates that a work instance has been rejected from further processing. This can occur due to internal factors.
WorkException

```java
public long startWork(Work work, long startTimeout, ExecutionContext execContext, WorkListener workListener) throws WorkException {
    Work startWork(Work work, long startTimeout, ExecutionContext execContext, WorkListener workListener)
    
    return Work -1
    
    Throws WorkRejectedException:

    startWork

    long startWork(Work work,
    long startTimeout,
    ExecutionContext execContext,
    WorkListener workListener)
    throws WorkException
```

Accepts a Work instance for processing. This call blocks until the Work instance starts execution but not until its completion. There is no guarantee on when the accepted Work instance would start execution i.e., there is no time constraint to start execution.
Parameters:

- **work** - The unit of work to be done. Could be long or short-lived.
- **startTimeout** - a time duration (in milliseconds) within which the execution of the **Work** instance must start. Otherwise, the **Work** instance is rejected with a **WorkRejectedException** set to an appropriate error code (**WorkRejectedException.TIMED_OUT**).
  
  Note, this does not offer real-time guarantees.
- **execContext** - an object containing the execution context with which the submitted **Work** instance must be executed.
- **workListener** - an object which would be notified when the various **Work** processing events (work accepted, work rejected, work started, work completed) occur.

Returns:

- the time elapsed (in milliseconds) from **Work** acceptance until start of execution. Note, this does not offer real-time guarantees. It is valid to return -1, if the actual start delay duration is unknown.

Throws:

- **WorkRejectedException** - indicates that a **Work** instance has been rejected from further processing. This can occur due to internal factors or start timeout expiration.
- **WorkException**

---

```java
public void scheduleWork(Work work) throws WorkException
```

**Throws**  
**WorkRejectedException**

```java
void scheduleWork(Work work)
```

**Throws**  
**WorkException**

Accepts a **Work** instance for processing. This call does not block and returns immediately once a **Work** instance has been accepted for
There is no guarantee on when the submitted Work instance would start execution i.e., there is no time constraint to start execution.

**Parameters:**
- work - The unit of work to be done. Could be long or short-lived.

**Throws:**
- WorkRejectedException - indicates that a Work instance has been rejected from further processing. This can occur due to internal factors.
- WorkException

```
public void scheduleWork(Work work, long startTimeout, ExecutionContext execContext,WorkListener workListener) throws WorkException
```

**scheduleWork**

```
void scheduleWork(Work work, long startTimeout, ExecutionContext execContext, WorkListener workListener)
throws WorkException
```

Accepts a Work instance for processing. This call does not block and returns immediately once a Work instance has been accepted for processing.

**Parameters:**
work - The unit of work to be done. Could be long or short-lived.

startTime - a time duration (in milliseconds) within which the execution of the Work instance must start. Otherwise, the Work instance is rejected with a WorkRejectedException set to an appropriate error code (WorkRejectedException.TIMED_OUT). Note, this does not offer real-time guarantees.

execContext - an object containing the execution context with which the submitted Work instance must be executed.

workListener - an object which would be notified when the various Work processing events (work accepted, work rejected, work started, work completed) occur.

Throws:

WorkRejectedException - indicates that a Work instance has been rejected from further processing. This can occur due to internal factors.

javax.resource.spi.work  Class WorkRejectedException

java.lang.Object
   ↓ java.lang.Throwable
      ↓ java.lang.Exception
         ↓ javax.resource.ResourceException
            ↓ javax.resource.spi.work.WorkException
                ↓ javax.resource.spi.work.WorkRejectedException

All Implemented Interfaces:
   Serializable

public class WorkRejectedException
   extends WorkException

Extends: Throwable > Exception > ResourceException > WorkException

WorkManager  Work

Work  Work

WorkException.START_TIMED_OUT  WorkException.INTERNAL
WorkException.UNDEFINED

version  1.0

This exception is thrown by a WorkManager to indicate that a submitted Work instance has been rejected. The rejection could be due to internal factors or start timeout expiration.

This could be thrown only before the execution of a Work instance starts (that is, before a thread has been allocated for Work execution).

An associated error code indicates the nature of the error condition. Possible error codes are WorkException.START_TIMED_OUT, WorkException.INTERNAL OR WorkException.UNDEFINED.
Field Summary

Fields inherited from class javax.resource.spi.work.WorkException
INTERNAL, START_TIMED_OUT, TX_CONCURRENT_WORK_DISALLOWED,
TX_RECREATE_FAILED, UNDEFINED

Constructor Summary

WorkRejectedException()
Constructs a new instance with null as its detail message.

WorkRejectedException(String message)
Constructs a new instance with the specified detail message.

WorkRejectedException(String message, String errorCode)
Constructs a new throwable with the specified detail message
and an error code.

WorkRejectedException(String message, Throwable cause)
Constructs a new throwable with the specified detail message
and cause.

WorkRejectedException(Throwable cause)
Constructs a new throwable with the specified cause.

WorkRejectedException

public WorkRejectedException()

Constructs a new instance with null as its detail message.

public WorkRejectedException(String message)

message

WorkRejectedException

public WorkRejectedException(String message)

Constructs a new instance with the specified detail message.

Parameters:
message - the detail message.
public WorkRejectedException(Throwable cause)

Constructs a new throwable with the specified cause.

Parameters:
cause - a chained exception of type Throwable.

public WorkRejectedException(String message, Throwable cause)

Constructs a new throwable with the specified detail message and cause.

Parameters:
message - the detail message.
cause - a chained exception of type Throwable.
WorkRejectedException

public WorkRejectedException(String message, String errorCode)

Constructs a new throwable with the specified detail message and an error code.

Parameters:
message - a description of the exception.
errorCode - a string specifying the vendor specific error code.
javax.jms Interface XAConnection

All Superinterfaces:  
  Connection

All Known Subinterfaces:  
  XAQueueConnection, XATopicConnection

The XAConnection interface extends the capability of Connection by providing an XASession (optional).

The XAConnection interface is optional. JMS providers are not required to support this interface. This interface is for use by JMS providers to support transactional environments. Client programs are strongly encouraged to use the transactional support available in their environment, rather than use these XA interfaces directly.

Version:  
  1.1 February 2, 2002

<tr>
<td>XASession createXASession</td>
<td>Creates an XASession object.</td>
</tr>
</tbody>
</table>

## Methods inherited from interface javax.jms.Connection

- close, createConnectionConsumer, createDurableConnectionConsumer, getClientID, getExceptionListener, getMetaData, setClientID, setExceptionListener, start, stop

## Method Detail

```java
public XASession createXASession() throws JMSException
```

XASession

```
return XASession
```

Throws: JMSException: XAConnection XASession

since

1.1

createXASession

```
XASession createXASession() throws JMSException
```

Creates an XASession object.

**Returns:**
- a newly created XASession

**Throws:**
- JMSException - if the XAConnection object fails to create an
XASession due to some internal error.

Since:
   1.1

---

public Session createSession(boolean transacted, int acknowledgeMode) throws JMSException

Session
    transacted
    acknowledgeMode

return Session

Throws JMSException: XAConnection Session
since 1.1

createSession

Session createSession(boolean transacted, int acknowledgeMode) throws JMSException

Creates an Session object.

Specified by:
   createSession in interface Connection

Parameters:
    transacted - usage undefined
    acknowledgeMode - usage undefined

Returns:
    a Session object

Throws:
    JMSException - if the XAConnection object fails to create an Session due to some internal error.

Since:
    1.1

PS :
javax.jms  **Interface XAConnectionFactory**

**All Known Subinterfaces:**

`XAQueueConnectionFactory`, `XATopicConnectionFactory`

```java
public interface XAConnectionFactory
```

**Implemented by:** `XAQueueConnectionFactory`, `XATopicConnectionFactory`

The `XAConnectionFactory` interface is a base interface for the `XAQueueConnectionFactory` and `XATopicConnectionFactory` interfaces.

Some application servers provide support for grouping JTS capable resource use into a distributed transaction (optional). To include JMS API transactions in a JTS transaction, an application server requires a JTS aware JMS provider. A JMS provider exposes its JTS support using an `XAConnectionFactory` object, which an application server uses to create `XAConnection` objects.

`XAConnectionFactory` objects are JMS administered objects, just like
ConnectionFactory objects. It is expected that application servers will find them using the Java Naming and Directory Interface (JNDI) API.

The XAConnectionFactory interface is optional. JMS providers are not required to support this interface. This interface is for use by JMS providers to support transactional environments. Client programs are strongly encouraged to use the transactional support available in their environment, rather than use these XA interfaces directly.

Version:
   1.1 April 4, 2002

</tbody>
</table>

### Method Detail

```java
public XAConnection createXAConnection() throws JMSException

   return XAConnection

   Throws JMSException: JMS XA
   Throws JMSSecurityException: since 1.1
```
createXAConnection

**XAC**
createXAConnection() throws JMSException

Creates an XAConnection with the default user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

**Returns:**
- a newly created XAConnection

**Throws:**
- JMSException - if the JMS provider fails to create an XA connection due to some internal error.
- JMSSecurityException - if client authentication fails due to an invalid user name or password.

**Since:**
1.1

---

public XAC createXAConnection(String userName, String password) throws JMSException

**userName**

**password**

**return**

**XAC**

**Throws**
- JMSException: JMS XA
- JMSSecurityException: since 1.1

createXAConnection

**XAC** createXAConnection(String userName, String password) throws JMSException

Creates an XA connection with the specified user identity. The connection is created in stopped mode. No messages will be
delivered until the `Connection.start` method is explicitly called.

**Parameters:**
- `userName` - the caller's user name
- `password` - the caller's password

**Returns:**
a newly created XA connection

**Throws:**
- `JMSException` - if the JMS provider fails to create an XA connection due to some internal error.
- `JMSSecurityException` - if client authentication fails due to an invalid user name or password.

**Since:**
1.1
javax.transaction.xa  Class XAException

java.lang.Object  
   ↓ java.lang.Throwable  
      ↓ java.lang.Exception  
         ↓ javax.transaction.xa.XAException

All Implemented Interfaces:
   Serializable

public class XAException

extends Exception

Extends: Throwable > Exception

(RM)  XAException

The XAException is thrown by the Resource Manager (RM) to inform the Transaction Manager of an error encountered by the involved transaction.

Field Detail

errorCode

public int errorCode

The error code with which to create the SystemException.

XA_RBBASE

public static final int XA_RBBASE

The inclusive lower bound of the rollback codes.

See Also:
Constant Field Values

XA_RBROLLBACK

public static final int XA_RBROLLBACK

Indicates that the rollback was caused by an unspecified reason.
See Also:  
Constant Field Values

XA_RBCOMMFAIL

public static final int XA_RBCOMMFAIL

Indicates that the rollback was caused by a communication failure.

See Also:  
Constant Field Values

XA_RBDEADLOCK

public static final int XA_RBDEADLOCK

A deadlock was detected.

See Also:  
Constant Field Values

XA_RBINTEGRITY

public static final int XA_RBINTEGRITY

A condition that violates the integrity of the resource was detected.

See Also:  
Constant Field Values
XA_RBOTHER

public static final int XA_RBOTHER

The resource manager rolled back the transaction branch for a reason not on this list.

See Also:
Constant Field Values

XA_RBPROTO

public static final int XA_RBPROTO

A protocol error occurred in the resource manager.

See Also:
Constant Field Values

XA_RBTIMEOUT

public static final int XA_RBTIMEOUT

A transaction branch took too long.

See Also:
Constant Field Values

XA_RBTRANSIENT
public static final int XA_RBTRANSIENT

May retry the transaction branch.

See Also:
Constant Field Values

XA_RBEND

public static final int XA_RBEND

The inclusive upper bound of the rollback error code.

See Also:
Constant Field Values

XA_NOMIGRATE

public static final int XA_NOMIGRATE

Resumption must occur where the suspension occurred.

See Also:
Constant Field Values

XA_HEURHAZ

public static final int XA_HEURHAZ

The transaction branch may have been heuristically completed.
XA_HEURCOM

public static final int XA_HEURCOM

The transaction branch has been heuristically committed.

See Also:
Constant Field Values

XA_HEURRB

public static final int XA_HEURRB

The transaction branch has been heuristically rolled back.

See Also:
Constant Field Values

XA_HEURMIX

public static final int XA_HEURMIX

The transaction branch has been heuristically committed and rolled back.

See Also:
Constant Field Values
XA_RETRY

public static final int XA_RETRY

    Routine returned with no effect and may be reissued.

    See Also:
    Constant Field Values

XA_RDONLY

public static final int XA_RDONLY

    The transaction branch was read-only and has been committed.

    See Also:
    Constant Field Values

XAER_ASYNC

public static final int XAER_ASYNC

    There is an asynchronous operation already outstanding.

    See Also:
    Constant Field Values

XAER_RMERR
public static final int XAER_RMERR

A resource manager error has occurred in the transaction branch.

See Also:
   Constant Field Values

XAER_NOTA

public static final int XAER_NOTA

The XID is not valid.

See Also:
   Constant Field Values

XAER_INVAL

public static final int XAER_INVAL

Invalid arguments were given.

See Also:
   Constant Field Values

XAER_PROTO

public static final int XAER_PROTO

Routine was invoked in an improper context.
See Also:  
Constant Field Values

XAER_RMFFAIL

public static final int XAER_RMFFAIL

Resource manager is unavailable.

See Also:  
Constant Field Values

XAER_DUPID

public static final int XAER_DUPID

The XID already exists.

See Also:  
Constant Field Values

XAER_OUTSIDE

public static final int XAER_OUTSIDE

The resource manager is doing work outside a global transaction.

See Also:  
Constant Field Values
public XAException()
XAException

XAException

public XAException()

Create an XAException.

public XAException(String s)
XAException

s
String

XAException

public XAException(String s)

Create an XAException with a given string.

Parameters:
s - The String object containing the exception message.

public XAException(int errcode)
XAException

errcode

XAException

public XAException(int errcode)
Create an XAException with a given error code.

**Parameters:**

errcode - The error code identifying the exception.

javax.jms Interface XAQueueConnection

All Superinterfaces:
   Connection, QueueConnection, XAConnection

public interface XAQueueConnection
   extends XAConnection, QueueConnection

Implements: XAConnection, QueueConnection

XAQueueConnection    QueueConnection    XAConnection

XAQueueConnection    JMS    JMS    XA

version            1.1 February 2 - 2002
See also            javax.jms.XAConnection

An XAQueueConnection provides the same create options as
QueueConnection (optional). The only difference is that an XAConnection is
by definition transacted.

The XAQueueConnection interface is optional. JMS providers are not
required to support this interface. This interface is for use by JMS
providers to support transactional environments. Client programs are
strongly encouraged to use the transactional support available in their
environment, rather than use these XA interfaces directly.

Method Detail

```
public XAQueueSession createXAQueueSession() throws JMSException

    XAQueueSession
    return XAQueueSession

    Throws JMSException: XAQueueConnection XA
```

createXAQueueSession
**createXAQueueSession()**

 Throws: *JMSException*

 Creates an XAQueueSession object.

 **Returns:**
 a newly created XAQueueSession

 **Throws:**
 *JMSException* - if the XAQueueConnection object fails to create an XA queue session due to some internal error.

---

**createQueueSession**

 **public QueueSession createQueueSession(boolean transacted, int acknowledgeMode)**

 Throws: *JMSException*

 Creates an XAQueueSession object.

 **Specified by:**
 *createQueueSession* in interface *QueueConnection*

 **Parameters:**
 - transacted - usage undefined
 - acknowledgeMode - usage undefined

 **Returns:**
 a newly created XAQueueSession

 **Throws:**
 *JMSException* - if the XAQueueConnection object fails to create an XA queue session due to some internal error.

### Method Detail

```java
public XAQueueConnection createXAQueueConnection() throws JMSException
    XA
return

throws JMSException: JMS XA
Throws JMSException: JMSException:

createXAQueueConnection

XAQueueConnection createXAQueueConnection() throws JMSException
```
Creates an XA queue connection with the default user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

**Returns:**
- a newly created XA queue connection

**Throws:**
- `JMSException` - if the JMS provider fails to create an XA queue connection due to some internal error.
- `JMSSecurityException` - if client authentication fails due to an invalid user name or password.

```java
public XAQueueConnection createXAQueueConnection(String userName, String password) throws JMSException, JMSSecurityException {
    return XAConnection.start(userName, password);
}
```

Creates an XA queue connection with the specified user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

**Parameters:**
- `userName` - the caller's user name
- `password` - the caller's password

**Returns:**
a newly created XA queue connection

**Throws:**

- `JMSException` - if the JMS provider fails to create an XA queue connection due to some internal error.
- `JMSSecurityException` - if client authentication fails due to an invalid user name or password.

PS:
The XAResource interface is a Java mapping of the industry standard XA interface based on the X/Open CAE Specification (Distributed Transaction Processing: The XA Specification).

The XA interface defines the contract between a Resource Manager and a Transaction Manager in a distributed transaction processing (DTP) environment. A JDBC driver or a JMS provider implements this interface to support the association between a global transaction and a database or message service connection.

The XAResource interface can be supported by any transactional resource that is intended to be used by application programs in an environment where transactions are controlled by an external transaction manager. An example of such a resource is a database management system. An application may access data through multiple database connections. Each database connection is enlisted with the transaction manager as a transactional resource. The transaction manager obtains an XAResource for each connection participating in a global transaction. The transaction manager uses the start method to associate the global transaction with the resource, and it uses the end method to disassociate
the transaction from the resource. The resource manager is responsible for associating the global transaction to all work performed on its data between the start and end method invocations.

At transaction commit time, the resource managers are informed by the transaction manager to prepare, commit, or rollback a transaction according to the two-phase commit protocol.

void commit(Xid xid,
            boolean onePhase)
        throws XAException
Commits the global transaction specified by xid.

**Parameters:**
- xid - A global transaction identifier
- onePhase - If true, the resource manager should use a one-phase commit protocol to commit the work done on behalf of xid.

**Throws:**
- XAException - An error has occurred. Possible XAExceptions are XA_HEURHAZ, XA_HEURCOM, XA_HEURRB, XA_HEURMIX, XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

If the resource manager did not commit the transaction and the parameter onePhase is set to true, the resource manager may throw one of the XA_RB* exceptions. Upon return, the resource manager has rolled back the branch's work and has released all held resources.

```
public void end(Xid xid, int flags) throws XAException
{
    XA
    TMSUSPEND
    start
    TMRESUME
    TMFAIL
    TMSUCCESS
}
```

**Throws**
- XAException: XAException XAER_RMERR

```
        xid
    flags
         start
         TMSUCCESTMFAIL TMSUSPEND
    XAException: XAER_RMFAILXAER_NOTAXAER_INVALXAER_PROTO
```

```
end
```
void end(Xid xid,  
    int flags)  
throws XAException

Ends the work performed on behalf of a transaction branch. The resource manager disassociates the XA resource from the transaction branch specified and lets the transaction complete.

If TMSUSPEND is specified in the flags, the transaction branch is temporarily suspended in an incomplete state. The transaction context is in a suspended state and must be resumed via the start method with TMRESUME specified.

If TMFAIL is specified, the portion of work has failed. The resource manager may mark the transaction as rollback-only.

If TMSUCCESS is specified, the portion of work has completed successfully.

Parameters:
  xid - A global transaction identifier that is the same as the identifier used previously in the start method.
  flags - One of TMSUCCESS, TMFAIL, or TMSUSPEND.

Throws:
  XAException - An error has occurred. Possible XAException values are XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, XAERPROTO, or XA_RB*.

public void forget(Xid xid) throws XAException

xid

Throws XAException: XAER_RMERRXAER_RMFAIL  
XAER_NOTAXAER_INVAL XAER_PROTO

forget

void forget(Xid xid)  
throws XAException
Tells the resource manager to forget about a heuristically completed transaction branch.

**Parameters:**
- `xid` - A global transaction identifier.

**Throws:**
- `XAException` - An error has occurred. Possible exception values are XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAERPROTO.

```java
public int getTransactionTimeout() throws XAException
```

**getTransactionTimeout**

```java
public boolean isSameRM(XAResource xares) throws XAException
```
xares

xares XAResource
return RM true false
Throws XAException: XAER_RMERR XAER_RMFAIL

isSameRM

boolean isSameRM(XAResource xares)
throws XAException

This method is called to determine if the resource manager instance represented by the target object is the same as the resource manager instance represented by the parameter xares.

Parameters:
  xares - An XAResource object whose resource manager instance is to be compared with the resource manager instance of the target object.

Returns:
  true if it's the same RM instance; otherwise false.

Throws:
  XAException - An error has occurred. Possible exception values are XAER_RMERR and XAER_RMFAIL.

public int prepare(Xid xid) throws XAException

xid

throws XAException: XA_RB*XAER_RMERR

Throws XAER_RMFAIL XAER_NOTAXAER_INVAL XAER_PROTO

return XA_RDONLY XA_OK prepare XAException

prepare
int prepare(Xid xid)
    throws XAException

Ask the resource manager to prepare for a transaction commit of the transaction specified in xid.

Parameters:
    xid - A global transaction identifier.

Returns:
    A value indicating the resource manager's vote on the outcome of the transaction. The possible values are: XA_RDONLY or XA_OK. If the resource manager wants to roll back the transaction, it should do so by raising an appropriate XAException in the prepare method.

Throws:
    XAException - An error has occurred. Possible exception values are: XA_RB*, XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

public Xid[] recover(int flag) throws XAException

flag:
    TMSTARTRSCANMENDRSCANMNOFLAGS
    MNOFLAGS

Throws:
    XAException: XAER_RMERR XAER_RMFAIL
    XAER_INVAL XAER_PROTO

return 0 XID XAException

recover

Xid[] recover(int flag)
    throws XAException

Obtains a list of prepared transaction branches from a resource manager. The transaction manager calls this method during recovery to obtain the list of transaction branches that are currently in prepared or heuristically completed states.
Parameters:
flag - One of TMSTARTRSCAN, TMENDRSCAN, TMNOFLAGS. TMNOFLAGS must be used when no other flags are set in the parameter.

Returns:
The resource manager returns zero or more XIDs of the transaction branches that are currently in a prepared or heuristically completed state. If an error occurs during the operation, the resource manager should throw the appropriate XAException.

Throws:
XAException - An error has occurred. Possible values are XAER_RMERR, XAER_RMFAIL, XAER_INVAL, and XAER_PROTO.

```java
public void rollback(Xid xid) throws XAException
```

**xid**

XAException: XAExceptions XA_HEURHAZ
XA_HEURCOMXAXA_HEURRBXAXA_HEURMIX
XAER_RMERRXAXAER_RMFAILXAXAER_NOTAXAER_INVAL
XAER_PROTO

Throws
XA_RB*

rollback

```java
void rollback(Xid xid)
```

throws XAException

Informs the resource manager to roll back work done on behalf of a transaction branch.

Parameters:

- **xid** - A global transaction identifier.

Throws:
XAException - An error has occurred. Possible XAExceptions are XA_HEURHAZ, XA_HEURCOM, XA_HEURRB, XA_HEURMIX, XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

If the transaction branch is already marked rollback-only the resource manager may throw one of the XA_RB* exceptions. Upon return, the resource manager has rolled back the branch's work and has released all held resources.

### public boolean setTransactionTimeout(int seconds) throws XAException

<table>
<thead>
<tr>
<th>XAResource</th>
<th>setTransactionTimeout</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>true  false false</td>
</tr>
</tbody>
</table>

*seconds*

*return*

*Throws* XAException: XAER_RMERR XAER_RMFAIL XAER_INVAL

### setTransactionTimeout

boolean setTransactionTimeout(int seconds) throws XAException

Sets the current transaction timeout value for this XAResource instance. Once set, this timeout value is effective until setTransactionTimeout is invoked again with a different value. To reset the timeout value to the default value used by the resource manager, set the value to zero. If the timeout operation is performed successfully, the method returns true; otherwise false. If a resource manager does not support explicitly setting the transaction timeout value, this method returns false.

**Parameters:**
seconds - The transaction timeout value in seconds.

**Returns:**

- *true* if the transaction timeout value is set successfully;
- *false* otherwise.

**Throws:**

- `XAException` - An error has occurred. Possible exception values are XAER_RMERR, XAER_RMFAIL, or XAER_INVAL.

```java
public void start(Xid xid, int flags) throws XAException

xid
TMJOIN TMRESUME
XAException

xid
flags
TMJOIN TMRESUME
XAException: XA_RB*XAER_RMERR

Throws
XAER_RMFAILXAER_DUPIDXAER_OUTSIDE
XAER_NOTAXAER_INVAL XAER_PROTO
```

**start**

```java
void start(Xid xid,
            int flags)
            throws XAException
```

Starts work on behalf of a transaction branch specified in `xid`. If TMJOIN is specified, the start applies to joining a transaction previously seen by the resource manager. If TMRESUME is specified, the start applies to resuming a suspended transaction specified in the parameter `xid`. If neither TMJOIN nor TMRESUME is specified and the transaction specified by `xid` has previously been seen by the resource manager, the resource manager throws the XAException exception with XAER_DUPIP error code.

**Parameters:**

- `xid` - A global transaction identifier to be associated with the resource.
flags - One of TMNOFLAGS, TMJOIN, or TMRESUME.

**Throws:**

XAException - An error has occurred. Possible exceptions are XA_RB*, XAER_RMERR, XAER_RMFAIL, XAER_DUPID, XAER_OUTSIDE, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

PS :
The XASession interface extends the capability of Session by adding access to a JMS provider's support for the Java Transaction API (JTA) (optional). This support takes the form of a javax.transaction.xa.XAResource object. The functionality of this object closely resembles that defined by the standard X/Open XA Resource interface.
An application server controls the transactional assignment of an XASession by obtaining its XAResource. It uses the XAResource to assign the session to a transaction, prepare and commit work on the transaction, and so on.

An XAResource provides some fairly sophisticated facilities for interleaving work on multiple transactions, recovering a list of transactions in progress, and so on. A JTA aware JMS provider must fully implement this functionality. This could be done by using the services of a database that supports XA, or a JMS provider may choose to implement this functionality from scratch.

A client of the application server is given what it thinks is a regular JMS Session. Behind the scenes, the application server controls the transaction management of the underlying XASession.

The XASession interface is optional. JMS providers are not required to support this interface. This interface is for use by JMS providers to support transactional environments. Client programs are strongly encouraged to use the transactional support available in their environment, rather than use these XA interfaces directly.

Method Detail

public Session getSession() throws JMSException

    XASession
    return

    Throws JMSException: since 1.1

getSession

Session getSession()
Gets the session associated with this XASession.

**Returns:**
the session object

**Throws:**
`JMSException` - if an internal error occurs.

**Since:**
1.1

```java
public XAResource getXAResource()
```

Returns an XA resource to the caller.

**Returns:**
an XA resource to the caller

---

```java
public boolean getTransacted() throws JMSException
```

**Returns:**
true

**Throws**
`JMSException`: JMS

---

**getTransacted**

```java
boolean getTransacted()
```
Indicates whether the session is in transacted mode.

Specified by:
   getTransacted in interface Session

Returns: true

Throws:
   JMSException - if the JMS provider fails to return the transaction mode due to some internal error.

---

**public void commit() throws JMSException**

TransactionInProgressException XASession

Throws TransactionInProgressException: XASession

**commit**

void commit()
   throws JMSException

Throws a TransactionInProgressException, since it should not be called for an XASession object.

Specified by:
   commit in interface Session

Throws:
   TransactionInProgressException - if the method is called on an XASession.
   JMSException - if the JMS provider fails to commit the transaction due to some internal error.
   TransactionRolledBackException - if the transaction is rolled back due to some internal error during commit.
   IllegalStateException - if the method is not called by a transacted session.

---

**public void rollback() throws JMSException**
rollback

void rollback() throws JMSException

Throws a TransactionInProgressException, since it should not be called for an XASession object.

Specified by:
rollback in interface Session

Throws:
TransactionInProgressException - if the method is called on an XASession.
JMSException - if the JMS provider fails to roll back the transaction due to some internal error.
IllegalStateException - if the method is not called by a transacted session.
The XATerminator interface is used for transaction completion and crash recovery flows.

<tr>
<td><strong>void</strong></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
public void commit(Xid xid, boolean onePhase) throws XAException

Commits the global transaction specified by xid.

Parameters:
- xid: A global transaction identifier
- onePhase: If true, the resource manager should use a one-phase commit protocol to commit the work done on behalf of xid.

Throws:
- XAException: An error has occurred. Possible XAExceptions are XA_HEURHAZ, XA_HEURCOM, XA_HEURRB, XA_HEURMIX, XAER_RMERR, XAER_RMFIAL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

If the resource manager did not commit the transaction and the
parameter onePhase is set to true, the resource manager may throw one of the XA_RB* exceptions. Upon return, the resource manager has rolled back the branch’s work and has released all held resources.

**public void forget(Xid xid) throws XAException**

  *xid*

  **Throws**

  XAException: XAER_RMERR XAER_RMFAIL XAER_NOTA XAER_INVAL XAER_PROTO

**forget**

void forget(Xid xid)
  throws XAException

  Tells the resource manager to forget about a heuristically completed transaction branch.

  **Parameters:**

  xid - A global transaction identifier.

  **Throws:**

  XAException - An error has occurred. Possible exception values are XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

**public int prepare(Xid xid) throws XAException**

  *xid*

  **Throws**

  XAException: XA_RB* XAER_RMERR

  XAER_RMFAIL XAER_NOTA XAER_INVAL XAER_PROTO

  return javax.transaction.xa.XAResource prepare
    throws XAException
prepare

```java
int prepare(Xid xid)
    throws XAException
```

Ask the resource manager to prepare for a transaction commit of the transaction specified in xid.

**Parameters:**
- `xid` - A global transaction identifier.

**Returns:**
A value indicating the resource manager's vote on the outcome of the transaction. The possible values are: XA_RDONLY or XA_OK. These constants are defined in `javax.transaction.xa.XAResource` interface. If the resource manager wants to roll back the transaction, it should do so by raising an appropriate XAException in the prepare method.

**Throws:**
- `XAException` - An error has occurred. Possible exception values are: XA_RB*, XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAER_INVAL, or XAER_PROTO.

---

public `Xid[]` recover(int flag) throws `XAException`

```java
flag TMSTARTRSCANMENDRSCANMNOFLAGS
     MNOFLAGS javax.transaction.xa.XAResource
Throws XAException: XAER_RMERR XAER_RMFAIL
             XAER_INVAL XAER_PROTO
return 0 XID XAException
```

recover

```java
Xid[] recover(int flag)
    throws XAException
```
Obtains a list of prepared transaction branches from a resource manager. The transaction manager calls this method during recovery to obtain the list of transaction branches that are currently in prepared or heuristically completed states.

**Parameters:**
flag - One of TMSTARTRSCAN, TMENDRSCAN, TMNOFLAGS. TMNOFLAGS must be used when no other flags are set in the parameter. These constants are defined in javax.transaction.xa.XAResource interface.

**Returns:**
The resource manager returns zero or more XIDs of the transaction branches that are currently in a prepared or heuristically completed state. If an error occurs during the operation, the resource manager should throw the appropriate XAException.

**Throws:**
- XAException - An error has occurred. Possible values are XAER_RMERR, XAER_RMFAIL, XAER_INVAL, and XAER_PROTO.

```java
public void rollback(Xid xid) throws XAException
```

### Throws
- XAException: XAExceptions XA_HEURHAZ
  - XA_HEURCOM
  - XA_HEURRB
  - XA_HEURMIX
  - XAER_RMERR
  - XAER_RMFAIL
  - XAER_NOTAX
  - XAER_INVAL
  - XAER_PROTO

### XA_RB*

```java
void rollback(Xid xid)
```

throws XAException
Informs the resource manager to roll back work done on behalf of a transaction branch.

**Parameters:**
- `xid` - A global transaction identifier.

**Throws:**
- `XAException` - An error has occurred. Possible XAExceptions are XA_HEURHAZ, XA_HEURCOM, XA_HEURRB, XA_HEURMIX, XAER_RMERR, XAER_RMFAIL, XAER_NOTA, XAERINVAL, or XAER_PROTO.

If the transaction branch is already marked rollback-only the resource manager may throw one of the XA_RB* exceptions. Upon return, the resource manager has rolled back the branch's work and has released all held resources.

Methods inherited from interface javax.jms.ConnectionFactory
createConnection, createConnection

Method Detail

```java
public XATopicConnection createXATopicConnection() throws JMSException
```

```
return XAConnec

Throws JMSException: JMS XA
Throws JMSSecurityException:
```

createXATopicConnection

```java
XATopicConnection createXATopicConnection() throws JMSException
```
Creates an XA topic connection with the default user identity. The connection is created in stopped mode. No messages will be delivered until the Connection.start method is explicitly called.

Returns:
- a newly created XA topic connection

Throws:
- JMSException - if the JMS provider fails to create an XA topic connection due to some internal error.
- JMSSecurityException - if client authentication fails due to an invalid user name or password.

```java
public XATopicConnection createXATopicConnection(String userName, String password) throws JMSException
```

Parameters:
- `userName` - the caller's user name
- `password` - the caller's password

Returns:
a newly created XA topic connection

**Throws:**

*JMSException* - if the JMS provider fails to create an XA topic connection due to some internal error.

*JMSSecurityException* - if client authentication fails due to an invalid user name or password.

```

XATopicSession

```java
return
```

**Throws**

```java
JMSException:
```
getTopicSession

**TopicSession** getTopicSession()

**Throws: JMSException**

Gets the topic session associated with this XATopicSession.

**Returns:**

the topic session object

**Throws:**

JMSException - if an internal error occurs.
public interface Xid

Xid X/Open XID Java ID ID Xid

The Xid interface is a Java mapping of the X/Open transaction identifier XID structure. This interface specifies three accessor methods to retrieve a global transaction's format ID, global transaction ID, and branch qualifier. The Xid interface is used by the transaction manager and the resource managers. This interface is not visible to the application programs.

### Field Summary

### Method Detail

**public int getFormatId()**

```
XID
    return O OSI CCR
```

**getFormatId**

```
int getFormatId()
    Obtain the format identifier part of the XID.
```
Returns:
Format identifier. O means the OSI CCR format.

```java
public byte[] getGlobalTransactionId()
XID
    return

getGlobalTransactionId

byte[] getGlobalTransactionId()

    Obtain the global transaction identifier part of XID as an array of bytes.

    Returns:
    Global transaction identifier.

public byte[] getBranchQualifier()
XID
    return

getBranchQualifier

byte[] getBranchQualifier()

    Obtain the transaction branch identifier part of XID as an array of bytes.

    Returns:
    Global transaction identifier.

**Methods inherited from class java.lang.Object**

- finalize, getClass, notify, notifyAll, wait, wait, wait

**Enum Constant Detail**

**UNDEFINED**

public static final XmlAccessOrder UNDEFINED

The ordering of fields and properties in a class is undefined.
The ordering of fields and properties in a class is in alphabetical order as determined by the method java.lang.String.compareTo(String anotherString).

### Method Detail

**final public static XmlAccessOrder[] values()**

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(XmlAccessOrder c : XmlAccessOrder.values())
    System.out.println(c);
```

**Returns:**
- an array containing the constants of this enum type, in the order they're declared

**public static XmlAccessOrder valueOf(String name)**

Returns the enum constant of this type with the specified name. The string must match *exactly* an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not...
permitted.)

**Parameters:**
- `name` - the name of the enum constant to be returned.

**Returns:**
- the enum constant with the specified name

**Throws:**
- `IllegalArgumentException` - if this enum type has no constant with the specified name

@XmlAccessorType(XmlAccessOrder.UNDEFINED)

package a top level class

The annotation @XmlAccessorType on a package applies to all classes in a package. The following inheritance semantics apply:

• If there is a @XmlAccessorType on a class, then it is used.
• Otherwise, if a @XmlAccessorType exists on one of its super classes, then it is inherited.
• Otherwise, the @XmlAccessorType on a package is inherited.

Defaulting Rules:

By default, if @XmlAccessorType on a package is absent, then the following package level annotation is assumed.

@XmlElement(XmlAccessOrder.UNDEFINED)
By default, if @XmlAccessorOrder on a class is absent and none of super classes is annotated with XmlAccessorOrder, then the following default on the class is assumed:

@XmlAccessorType(XmlAccessOrder.UNDEFINED)

This annotation can be used with the following annotations: XmlType, XmlRootElement, XmlAccessorType, XmlSchema, XmlSchemaType, XmlSchemaTypes, XmlJavaTypeAdapter. It can also be used with the following annotations at the package level: XmlJavaTypeAdapter.

javax.xml.bind.annotation.XmlAccessorType
```

Controls whether fields or Javabean properties are serialized by default.

**Usage**

@XmlAccessorType annotation can be used with the following program elements:

- package
- a top level class

This annotation provides control over the default serialization of properties and fields in a class.

The annotation @XmlAccessorType on a package applies to all classes in the package. The following inheritance semantics apply:

- If there is a @XmlAccessorType on a class, then it is used.
- Otherwise, if a @XmlAccessorType exists on one of its super classes, then it is inherited.
- Otherwise, the @XmlAccessorType on a package is inherited.

**Defaulting Rules:**

By default, if @XmlAccessorType on a package is absent, then the
following package level annotation is assumed.

```java
@XmlAccessorType(XmlAccessType.PUBLIC_MEMBER)
```

By default, if `@XmlAccessorType` on a class is absent, and none of its super classes is annotated with `@XmlAccessorType`, then the following default on the class is assumed:

```java
@XmlAccessorType(XmlAccessType.PUBLIC_MEMBER)
```

This annotation can be used with the following annotations: `XmlType`, `XmlRootElement`, `XmlAccessorType`, `XmlSchema`, `XmlSchemaType`, `XmlSchemaTypes`, `XmlJavaTypeAdapter`. It can also be used with the following annotations at the package level: `XmlJavaTypeAdapter`.

### Enum Constant Detail

**PROPERTY**

```java
public static final XmlAccessType PROPERTY
```
Every getter/setter pair in a JAXB-bound class will be automatically bound to XML, unless annotated by `XmlTransient`. Fields are bound to XML only when they are explicitly annotated by some of the JAXB annotations.

---

**FIELD**

```java
public static final XmlAccessType FIELD
```

Every non static, non transient field in a JAXB-bound class will be automatically bound to XML, unless annotated by `XmlTransient`. Getter/setter pairs are bound to XML only when they are explicitly annotated by some of the JAXB annotations.

---

**PUBLIC_MEMBER**

```java
public static final XmlAccessType PUBLIC_MEMBER
```

Every public getter/setter pair and every public field will be automatically bound to XML, unless annotated by `XmlTransient`. Fields or getter/setter pairs that are private, protected, or defaulted to package-only access are bound to XML only when they are explicitly annotated by the appropriate JAXB annotations.

---

**NONE**

```java
public static final XmlAccessType NONE
```

None of the fields or properties is bound to XML unless they are specifically annotated with some of the JAXB annotations.
Method Detail

final public static XmlAccessType[] values()

values

public static final XmlAccessType[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

```java
for(XmlAccessType c : XmlAccessType.values())
    System.out.println(c);
```

**Returns:**

an array containing the constants of this enum type, in the order they're declared

---

public static XmlAccessType valueOf(String name)

valueOf

public static XmlAccessType valueOf(String name)

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

**Parameters:**

name - the name of the enum constant to be returned.

**Returns:**

the enum constant with the specified name

**Throws:**
IllegalArgumentException - if this enum type has no constant with the specified name

BoundType JAXB

ValueType JAXB

since JAXB 2.0

See also javax.xml.bind.annotation.adapters.XmlJavaTypeAdapter

Adapts a Java type for custom marshaling.

Usage:

Some Java types do not map naturally to a XML representation, for
example HashMap or other non JavaBean classes. Conversely, a XML representation may map to a Java type but an application may choose to access the XML representation using another Java type. For example, the schema to Java binding rules bind xs:DateTime by default to XmlGregorianCalendar. But an application may desire to bind xs:DateTime to a custom type, MyXmlGregorianCalendar, for example. In both cases, there is a mismatch between bound type, used by an application to access XML content and the value type, that is mapped to an XML representation.

This abstract class defines methods for adapting a bound type to a value type or vice versa. The methods are invoked by the JAXB binding framework during marshaling and unmarshalling:

- **XmlAdapter.marshal(...):** During marshalling, JAXB binding framework invokes XmlAdapter.marshal(..) to adapt a bound type to value type, which is then marshaled to XML representation.
- **XmlAdapter.unmarshal(...):** During unmarshalling, JAXB binding framework first unmarshals XML representation to a value type and then invokes XmlAdapter.unmarshal(..) to adapt the value type to a bound type.

Writing an adapter therefore involves the following steps:

- Write an adapter that implements this abstract class.
- Install the adapter using the annotation `@XmlJavaTypeAdapter`

**Example:** Customized mapping of HashMap

The following example illustrates the use of `@XmlAdapter` and `@XmlJavaTypeAdapter` to customize the mapping of a HashMap.

**Step 1:** Determine the desired XML representation for HashMap.

```xml
<hashmap>
  <entry key="id123">this is a value</entry>
  <entry key="id312">this is another value</entry>
  ...
</hashmap>
```
Step 2: Determine the schema definition that the desired XML representation shown above should follow.

```xml
<xs:complexType name="myHashMapType">
  <xs:sequence>
    <xs:element name="entry" type="myHashMapEntryType" minOccurs="0" maxOccurs="unbounded"/>
  </xs:sequence>
</xs:complexType>
<xs:complexType name="myHashMapEntryType">
  <xs:simpleContent>
    <xs:extension base="xs:string">
      <xs:attribute name="key" type="xs:int"/>
    </xs:extension>
  </xs:simpleContent>
</xs:complexType>
```

Step 3: Write value types that can generate the above schema definition.

```java
public class MyHashMapType {
    List<MyHashMapEntryType> entry;
}

public class MyHashMapEntryType {
    @XmlAttribute
    public Integer key;

    @XmlValue
    public String value;
}
```

Step 4: Write the adapter that adapts the value type, MyHashMapType to a bound type, HashMap, used by the application.

```java
public final class MyHashMapAdapter extends XmlAdapter<HashMap, MyHashMapType> {
    ...
}
```

Step 5: Use the adapter.

```java
public class Foo {
```
@XmlJavaTypeAdapter(MyHashMapAdapter.class)
HashMap hashmap;
...
}

The above code fragment will map to the following schema:

```xml
<xs:complexType name="Foo">
  <xs:sequence>
    <xs:element name="hashmap" type="myHashMapType"/>
  </xs:sequence>
</xs:complexType>
```

Since:

### Method Summary

| abstract ValueType | marshal(BoundType v) | Convert a bound type to a value type. |
| abstract BoundType  | unmarshal(ValueType v) | Convert a value type to a bound type. |

Methods inherited from class java.lang.Object:
- clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait, wait
Constructor Detail

protected XmlAdapter()

XmlAdapter

protected XmlAdapter()

Do-nothing constructor for the derived classes.

Method Detail

unmarshal

public abstract BoundType unmarshal(ValueType v)

throws Exception

Convert a value type to a bound type.

Parameters:
  v - The value to be converted. Can be null.

Throws:
  Exception - if there's an error during the conversion. The caller is responsible for reporting the error to the user through ValidationEventHandler.

marshal

public abstract ValueType marshal(BoundType v)

throws Exception
Convert a bound type to a value type.

**Parameters:**

- `v` - The value to be converted. Can be null.

**Throws:**

- `Exception` - if there's an error during the conversion. The caller is responsible for reporting the error to the user through `ValidationEventHandler`.

### javax.xml.bind.annotation Annotation Type XmlAnyAttribute

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})

public @interface XmlAnyAttribute

**Implements:** Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})

JavaBean

@XmlAnyAttribute

- JavaBean
- static transient

Maps a JavaBean property to a map of wildcard attributes.

**Usage**

The @XmlAnyAttribute annotation can be used with the following program elements:
JavaBean property
non static, non transient field

The usage is subject to the following constraints:

- At most one field or property in a class can be annotated with @XmlAnyAttribute.
- The type of the property or the field must java.util.Map

While processing attributes to be unmarshalled into a value class, each attribute that is not statically associated with another JavaBean property, viaXmlAttribute, is entered into the wildcard attribute map represented by Map<QName, Object>. The attribute QName is the map's key. The key's value is the String value of the attribute.

class Foo {
    @XmlAnyElement(lax=true)
    public Object[] others;
}
```

```xml
<foo>
    <unknown/>
</unknown></foo><foo>
</foo>
```

Foo foo = unmarshal();
// 1 for 'unknown', another for 'foo'
assert foo.others.length==2;
// 'unknown' unmarshals to a DOM element
assert foo.others[0] instanceof Element;
// because of lax=true, the 'foo' element eagerly
// unmarshals to a Foo object.
assert foo.others[1] instanceof Foo;

since JAXB2.0

Maps a JavaBean property to XML infoset representation and/or JAXB element.

This annotation serves as a "catch-all" property while unmarshalling xml content into a instance of a JAXB annotated class. It typically annotates a multi-valued JavaBean property, but it can occur on single value JavaBean property. During unmarshalling, each xml element that does not match a static @XmlElement or @XmlElementRef annotation for the other JavaBean properties on the class, is added to this "catch-all" property.
Usages:

```java
@XmlElement
public Element[] others;

// Collection of Element or JAXB elements.
@XmlElement(lax="true")
public Object[] others;

@XmlElement
private List<Element> nodes;

@XmlElement
private Element node;
```
Restriction usage constraints

This annotation is mutually exclusive with `XmlElement`, `XmlAttribute`, `XmlValue`, `XmlElements`, `XmlID`, and `XmlIDREF`.

There can be only one `XmlAnyElement` annotated JavaBean property in a class and its super classes.
Relationship to other annotations

This annotation can be used with `XmlJavaTypeAdapter`, so that users can map their own data structure to DOM, which in turn can be composed into XML.

This annotation can be used with `XmlMixed` like this:

```java
// List of java.lang.String or DOM nodes.
@XmlElement @XmlMixed
List<Object> others;
```
Schema To Java example

The following schema would produce the following Java class:

```xml
&lt;xs:complextype name="foo"&gt;
    &lt;xs:sequence&gt;
        &lt;xs:element name="a" type="xs:int"/&gt;
        &lt;xs:element name="b" type="xs:int"&gt;
            &lt;xsi:namespace prefix="#other" processContents="lax" minOccurs="0" maxOccurs="unbounded" /&gt;
        &lt;/xs:element&gt;
    &lt;/xs:sequence&gt;
&lt;/xs:complextype&gt;

class Foo {
    int a;
    int b;
    @XmlAnyElement
    List&lt;Element&gt; any;
}
```

It can unmarshal instances like

```xml
&lt;foo xmlns:e="extra"&gt;
    &lt;a&gt;1&lt;/a&gt;
    &lt;e:other&gt; // this will be bound to DOM, because unmarshalling is orderless
    &lt;b&gt;3&lt;/b&gt;
    &lt;/e:other&gt;
    &lt;/e:other&gt;
    &lt;e:other&gt;
    &lt;c&gt;5&lt;/c&gt; // this will be bound to DOM, because the annotation doesn't remember namespaces.
    &lt;/e:other&gt;
&lt;/foo&gt;
```

The following schema would produce the following Java class:

```xml
&lt;xs:complextype name="bar"&gt;
    &lt;xs:complexContent&gt;
        &lt;xs:extension base="foo"&gt;
            &lt;xs:sequence&gt;
                &lt;xs:element name="c" type="xs:int"/&gt;
                &lt;xsi:namespace prefix="#other" processContents="lax" minOccurs="0" maxOccurs="unbounded" /&gt;
            &lt;/xs:sequence&gt;
        &lt;/xs:extension&gt;
    &lt;/xs:complexContent&gt;
&lt;/xs:complextype&gt;
```
class Bar extends Foo {
    int c;
    // Foo.getAny() also represents wildcard content for type definit
}

It can unmarshal instances like

&lt;bar xmlns:e="extra"&gt;
    &lt;a&gt;1&lt;/a&gt;
    &lt;/e:other&gt;  // this will be bound to DOM, because unmarshal
    &lt;b&gt;3&lt;/b&gt;  
    &lt;/e:other&gt;&lt;/e:other&gt;  // this now goes to Bar.c
    &lt;c&gt;5&lt;/c&gt;  // this will go to Foo.any
&lt;/e:other&gt;&lt;/bar&gt;
Using `XmlAnyElement` with `XmlElementRef`

The `XmlAnyElement` annotation can be used with `XmlElementRefs` to designate additional elements that can participate in the content tree.

The following schema would produce the following Java class:

```xml
<xs:complexType name="foo">
  <xs:choice maxOccurs="unbounded" minOccurs="0">  
    <xs:element name="a" type="xs:int"></xs:element>
    <xs:element name="b" type="xs:int"></xs:element>
    <xs:any namespace="##other" processContents="lax"></xs:any>
  </xs:choice>
</xs:complexType>

class Foo {
  @XmlAnyElement(lax="true")
  @XmlElementRefs({
    @XmlElementRef(name="a", type=JAXBElement.class)
    @XmlElementRef(name="b", type=JAXBElement.class)
  })
  List<Object> others;
}

@XmlRegistry
class ObjectFactory {
...
  @XmlElementDecl(name = "a", namespace = ",", scope = Foo.class)
  JAXBElement<Integer> createFooA(Integer i) { ... }

  @XmlElementDecl(name = "b", namespace = ",", scope = Foo.class)
  JAXBElement<Integer> createFooB(Integer i) { ... }
}

It can unmarshal instances like

```xml
&lt;foo xmlns:e="extra"&gt;
  &lt;a&gt;1&lt;/a&gt;  // this will unmarshal to a &lt;a href="
  &lt;e:other&gt; // this will unmarshal to a DOM &lt;a href="http
  &lt;b&gt;3&lt;/b&gt;  // this will unmarshal to a &lt;a href="
  &lt;/e:other&gt;&lt;/foo&gt;
```
W3C XML Schema "lax" wildcard emulation

The lax element of the annotation enables the emulation of the "lax" wildcard semantics. For example, when the Java source code is annotated like this:

```java
@XmlRootElement
class Foo {
    @XmlAnyElement(lax=true)
    public Object[] others;
}
```

then the following document will unmarshal like this:

```xml
<foo>
    <unknown/>
    <unknown/>
</foo>
<foo>
</foo>
```

Foo foo = unmarshal();
// 1 for 'unknown', another for 'foo'
assert foo.others.length==2;
// 'unknown' unmarshals to a DOM element
assert foo.others[0] instanceof Element;
// because of lax=true, the 'foo' element eagerly
// unmarshals to a Foo object.
assert foo.others[1] instanceof Foo;

Since:
   JAXB2.0

true JAXBContext XmlAnyElement XmlRootElement

XmlElementDecl unmarshaller JAXB DOM xsi:type xsi:type JAXB JAXBElem entraller

JAXBElem elem

DOM JAXB

W3C XML "lax"

lax

public abstract boolean lax

Controls the unmarshaller behavior when it sees elements known to the current JAXBContext.

When false

If false, all the elements that match the property will be unmarshalled to DOM, and the property will only contain DOM elements.

When true
If true, when an element matches a property marked with 
XmlAnyElement is known to JAXBContext (for example, there's a class 
with XmlRootElement that has the same tag name, or there's 
XmlElementDecl that has the same tag name), the unmarshaller will 
eagerly unmarshal this element to the JAXB object, instead of 
unmarshalling it to DOM. Additionally, if the element is unknown but 
it has a known xsi:type, the unmarshaller eagerly unmarshals the 
element to a JAXBElement, with the unknown element name and the 
JAXBElement value is set to an instance of the JAXB mapping of the 
known xsi:type.

As a result, after the unmarshalling, the property can become 
heterogeneous; it can have both DOM nodes and some JAXB 
objects at the same time.

This can be used to emulate the "lax" wildcard semantics of the W3C 
XML Schema.

**Default:**
false

---

abstract public Class<T> value()

**DomHandler** XML  DOM

value

public abstract Class<? extends DomHandler> value

Specifies the DomHandler which is responsible for actually converting 
XML from/to a DOM-like data structure.

**Default:**
javax.xml.bind.annotation.W3CDomHandler.class
Submit a bug or feature

Copyright 2007 Sun Microsystems, Inc. All rights reserved. Use is subject to license terms.

PS:
javax.xml.bind.annotation  Annotation Type
XmlAttachmentRef

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PARAMETER})
public @interface XmlAttachmentRef

**Implements:** Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PARAMETER})

/ XML  MIME  URI  MIME out-of-line
DataHandler
since JAXB2.0

Marks a field/property that its XML form is a uri reference to mime
The mime content is optimally stored out-of-line as an attachment.

A field/property must always map to the DataHandler class.
Usage

```java
@XmlElement
class Foo {
    @XmlAttribute
    @XmlAttachmentRef
    DataHandler data;

    @XmlAttachmentRef
    @XmlElement
    DataHandler body;
}
```

The above code maps to the following XML:

```xml
<xs:element name="foo" xmlns:ref="http://ws-i.org/profiles/basic">
    <xs:complexType>
        <xs:sequence>
        </xs:sequence></xs:complexType></xs:element><xs:element name="body" type="ref:swaRef" minOccurs="0">
    <xs:attribute name="data" type="ref:swaRef" use="optional">
    </xs:attribute></xs:element>
```

The above binding supports WS-I AP 1.0 [WS-I Attachments Profile Version 1.0](https://www.ws-i.org). Since:

JAXB 2.0

            <xs:list itemType="xs:int"/>
        </xs:simpleType>
    </xs:complexType>
</xs:complexType>
See also [javax.xml.bind.annotation.XmlType](https://docs.oracle.com/javadocs/api/java/beans/property/javax/xml/bind/annotation/XmlType.html)

Maps a JavaBean property to a XML attribute.

**Usage**

The `@XmlAttribute` annotation can be used with the following program elements:

- JavaBean property
- field

A static final field is mapped to a XML fixed attribute.

The usage is subject to the following constraints:

- If type of the field or the property is a collection type, then the collection item type must be mapped to schema simple type.

  // Examples
  @XmlAttribute List<Integer> items; //legal
  @XmlAttribute List<Bar> foo; // illegal if Bar does not map

- If the type of the field or the property is a non collection type, then the type of the property or field must map to a simple schema type.

  // Examples
  @XmlAttribute int foo; // legal
  @XmlAttribute Foo foo; // illegal if Foo does not map to a

- This annotation can be used with the following annotations: `XmlID`, `XmlIDREF`, `XmlList`, `XmlSchemaType`, `XmlValue`, `XmlAttachmentRef`, `XmlMimeType`, `XmlInlineBinaryData`, `XmlJavaTypeAdapter`.

**Example 1:** Map a JavaBean property to an XML attribute.
//Example: Code fragment
public class USPrice {
    @XmlAttribute
    public java.math.BigDecimal getPrice() {...};
    public void setPrice(java.math.BigDecimal ) {...};
}
<!-- Example: XML Schema fragment -->
<xs:complexType name="USPrice">
    <xs:sequence>
        <xs:attribute name="price" type="xs:decimal"/>
    </xs:sequence>
</xs:complexType>

Example 2: Map a JavaBean property to an XML attribute with anonymous type.

See Example 7 in @XmlType.

Example 3: Map a JavaBean collection property to an XML attribute.

    // Example: Code fragment
    class Foo {
        ...
        @XmlAttribute List<Integer> items;
    }

    <!-- Example: XML Schema fragment -->
    <xs:complexType name="foo">
        ...
        <xs:attribute name="items">
            <xs:simpleType>
                <xs:list itemType="xs:int"/>
            </xs:simpleType>
        </xs:attribute>
    </xs:complexType>

</xs:complexType>

4 JavaBean XML

@  

since  JAXB2.0

version  $Revision: 1.19 $
Maps a JavaBean property to a XML element derived from property name.

Usage

@XmlElement annotation can be used with the following program elements:

- a JavaBean property
- non static, non transient field
- within XmlElements

The usage is subject to the following constraints:

- This annotation can be used with following annotations: XmlID, XmlIDREF, XmlList, XmlSchemaType, XmlValue, XmlAttachmentRef, XmlMimeType, XmlInlineBinaryData, XmlElementWrapper, XmlJavaTypeAdapter
- if the type of JavaBean property is a collection type of array, an indexed property, or a parameterized list, and this annotation is used with XmlElements then, @XmlElement.type() must be DEFAULT.class since the collection item type is already known.

A JavaBean property, when annotated with @XmlElement annotation is mapped to a local element in the XML Schema complex type to which the containing class is mapped.

**Example 1:** Map a public non static non final field to local element

```java
//Example: Code fragment
class USPrice {
    @XmlElement(name="itemprice")
    public java.math.BigDecimal price;
}

<!-- Example: Local XML Schema element -->
<xs:complexType name="USPrice"/>
<xs:sequence>
    <xs:element name="itemprice" type="xs:decimal" minOccurs="0"
</sequence>
```
Example 2: Map a field to a nillable element.

```
//Example: Code fragment
public class USPrice {
    @XmlElement(nillable=true)
    public java.math.BigDecimal price;
}
```

<!-- Example: Local XML Schema element -->
```
<xs:complexType name="USPrice">
    <xs:sequence>
        <xs:element name="price" type="xs:decimal" nillable="true"/>
    </sequence>
</xs:complexType>
```

Example 3: Map a field to a nillable, required element.

```
//Example: Code fragment
public class USPrice {
    @XmlElement(nillable=true, required=true)
    public java.math.BigDecimal price;
}
```

<!-- Example: Local XML Schema element -->
```
<xs:complexType name="USPrice">
    <xs:sequence>
        <xs:element name="price" type="xs:decimal" nillable="true"/>
    </sequence>
</xs:complexType>
```

Example 4: Map a JavaBean property to an XML element with anonymous type.

See Example 6 in @XmlType.

</tbody>
</table>

abstract public String name()
XML

"##default" JavaBean

**name**

public abstract String name

    Name of the XML Schema element.

    If the value is "##default", then element name is derived from the JavaBean property name.

**Default:**

"##default"
abstract public boolean nillable()
nillable()
	nillable()  true  JavaBean  XML  nillable

nillable

public abstract boolean nillable

    Customize the element declaration to be nillable.
    
    If nillable() is true, then the JavaBean property is mapped to a XML Schema nillable element declaration.

    Default:
    false

abstract public boolean required()

required()  true  JavaBean  minOccurs="1"  XML
maxOccurs  "1"  maxOccurs  "unbounded"

required()  false  JavaBean  minOccurs="0"
XML  maxOccurs  "1"  maxOccurs
"unbounded"

required

public abstract boolean required

    Customize the element declaration to be required.
If required() is true, then JavaBean property is mapped to an XML schema element declaration with minOccurs="1". maxOccurs is "1" for a single valued property and "unbounded" for a multivalued property.

If required() is false, then the JavaBean property is mapped to XML Schema element declaration with minOccurs="0". maxOccurs is "1" for a single valued property and "unbounded" for a multivalued property.

Default: false

abstract public String namespace()
XML  XML

"##default"

1. XmlSchema  elementFormDefault  QUALIFIED
2. ""

namespace

public abstract String namespace

XML target namespace of the XML Schema element.

If the value is "##default", then the namespace is determined as follows:

1. If the enclosing package has XmlSchema annotation, and its elementFormDefault is QUALIFIED, then the namespace of the enclosing class.
2. Otherwise "" (which produces unqualified element in the default namespace.)
Abstract public String defaultValue()

" null 'no default value'

defaultValue

Public abstract String defaultValue

Default value of this element.

The " value specified as a default of this annotation element is used as a poor-man's substitute for null to allow implementations to recognize the 'no default value' state.

Default:

"\u0000"

Abstract public Class<T> type()

javadoc

&lt;!-- Example: XML schema definition --&gt;
&lt;xs:schema&gt;
&lt;xs:complexType name="pea">
 &lt;xs:choice maxOccurs="unbounded">
    &lt;xs:element name="foo" type="xs:string"&gt;
    &lt;/xs:element&gt;
    &lt;xs:element name="bar" type="xs:string"&gt;
    &lt;/xs:element&gt;
 &lt;/xs:choice&gt;
 &lt;/xs:complexType&gt;
 &lt;xs:element name="foo" type="xs:int"&gt;
 &lt;/xs:element&gt;&lt;/xs:schema&gt;

// Example: expected default binding
class Pea {
    @XmlElementRefs({
        @XmlElementRef(name="foo",type=JAXBElement.class)
        @XmlElementRef(name="bar",type=JAXBElement.class)
    })
    List<JAXBElement<String>> fooOrBar;
}

@XmlRegistry
class ObjectFactory {
    @XmlElementDecl(scope=Pea.class,name="foo")
    JAXBElement createPeaFoo(String s);

    @XmlElementDecl(scope=Pea.class,name="bar")
    JAXBElement createPeaBar(String s);

    @XmlElementDecl(name="foo")
    JAXBElement createFoo(Integer i);
}

createFoo createPeaFoo "foo" XML
Maps a factory method to a XML element.

Usage

The annotation creates a mapping between an XML schema element declaration and a *element factory method* that returns a JAXBElemnt instance representing the element declaration. Typically, the element factory method is generated (and annotated) from a schema into the ObjectFactory class in a Java package that represents the binding of the element declaration's target namespace. Thus, while the annotation syntax allows `@XmlElementDecl` to be used on any method, semantically its use is restricted to annotation of element factory method. The usage is subject to the following constraints:

- The class containing the element factory method annotated with `@XmlElementDecl` must be marked with `XmlRegistry`.
- The element factory method must take one parameter assignable to `Object`.

**Example 1: Annotation on a factory method**

```java
// Example: code fragment
@XmlRegistry
class ObjectFactory {
    @XmlElementDecl(name="foo")
    JAXBElement<String> createFoo(String s) { ... }
}

&lt;!-- XML input --&gt;
    &lt;foo&gt;string&lt;/foo&gt;

// Example: code fragment corresponding to XML input
JAXBElement&lt;String&gt; o =
    (JAXBElement&lt;/string&gt;&lt;string&gt;)unmarshaller.unmarshal(aboveDocument);
// print JAXBElement instance to show values
System.out.println(o.getName()); // prints "{}foo"
System.out.println(o.getValue()); // prints "string"
```
System.out.println(o.getValue().getClass()); // prints "java.lang.String"

<!-- Example: XML schema definition --&gt;
&lt;xs:element name="foo" type="xs:string"&gt;
&lt;/xs:element&gt;&lt;/string&gt;

**Example 2: Element declaration with non local scope**

The following example illustrates the use of scope annotation parameter in binding of element declaration in schema derived code.

The following example may be replaced in a future revision of this javadoc.

```xml
&lt;xs:element name="foo" type="xs:int"&gt;
&lt;/xs:element&gt;

&lt;xs:element name="foo" type="xs:string"&gt;
&lt;/xs:element&gt;

&lt;xs:complexType name="pea">
  &lt;xs:choice maxOccurs="unbounded">
    &lt;xs:element name="foo" type="xs:string"&gt;
    &lt;/xs:element&gt;
    &lt;xs:element name="bar" type="xs:string"&gt;
    &lt;/xs:element&gt;
  &lt;/xs:choice&gt;
&lt;/xs:complexType&gt;

// Example: expected default binding
class Pea {
  @XmlElementRefs(
    @XmlElementRef(name="foo",type=JAXBElement.class)
    @XmlElementRef(name="bar",type=JAXBElement.class)
  )
  List<JAXBElement<String>> fooOrBar;
}

@XmlRegistry
class ObjectFactory {
  @XmlElementDecl(scope=Pea.class,name="foo")
  JAXBElement createPeaFoo(String s);

  @XmlElementDecl(scope=Pea.class,name="bar")
  JAXBElement createPeaBar(String s);

  @XmlElementDecl(name="foo")
  JAXBElement createFoo(Integer i);
}
Without scope createFoo and createPeaFoo would become ambiguous since both of them map to an XML schema element with the same local name "foo".

Since:
JAXB 2.0

### Required Element Summary

| String name | local name of the XML element. |

### Optional Element Summary

| String defaultValue | Default value of this element. |
| String namespace | namespace name of the XML element. |
| Class scope | scope of the mapping. |
| String substitutionHeadName | XML local name of a substitution group's head element. |
| String substitutionHeadNamespace | namespace name of a substitution group's head XML element. |

### Element Detail

abstract public String name()
XML
See also

name

public abstract String name

local name of the XML element.

**Note to reviewers:** There is no default name; since the annotation is on a factory method, it is not clear that the method name can be derived from the factory method name.

See Also:

namespace()

abstract public Class<T> scope()

**XmlElementDecl.GLOBAL**

scope

public abstract Class scope

scope of the mapping.

If this is not XmlElementDecl.GLOBAL, then this element declaration mapping is only active within the specified class.

**Default:**

javax.xml.bind.annotation.XmlElementDecl.GLOBAL.class
abstract public String namespace()

"##default"

See also name()

namespace

public abstract String namespace

namespace name of the XML element.

If the value is "##default", then the value is the namespace name for the package of the class containing this factory method.

See Also:

name()

Default:

"##default"

-------------------------------

abstract public String substitutionHeadNamespace()

XML

substitutionHeadName() XML

substitutionHeadName() "" "##default"

substitutionHeadName() ""

substitutionHeadName() "" "##default"

XmlRegistry

substitutionHeadName() "" "##default"

See also substitutionHeadName()
substitutionHeadNamespace

public abstract String substitutionHeadNamespace

namespace name of a substitution group's head XML element.

This specifies the namespace name of the XML element whose local name is specified by substitutionHeadName().

If substitutionHeadName() is "", then this value can only be "##default". But the value is ignored since this element is not part of substitution group when the value of substitutionHeadName() is "".

If substitutionHeadName() is not "" and the value is "##default", then the namespace name is the namespace name to which the package of the containing class, marked with XmlRegistry, is mapped.

If substitutionHeadName() is not "" and the value is not "##default", then the value is the namespace name.

See Also:
substitutionHeadName()

Default:
"##default"

abstract public String substitutionHeadName()

XML

See also
substitutionHeadNamespace()
public abstract String substitutionHeadName

XML local name of a substitution group's head element.

If the value is "", then this element is not part of any substitution group.

See Also:
  substitutionHeadNamespace()

Default:
  ""

abstract public String defaultValue()

" null 'no default value'

defaultValue

public abstract String defaultValue

Default value of this element.

The " value specified as a default of this annotation element is used as a poor-man's substitute for null to allow implementations to recognize the 'no default value' state.

m.term = new ObjectFactory().createAdd(new Operator());
marshal(m);

XML

<math>
<add>...</add>
</math>

since JAXB2.0

See also javax.xml.bind.annotation.XmlElementRefs

Maps a JavaBean property to a XML element derived from property's type.

Usage

@XmlElementRef annotation can be used with a JavaBean property or from within XmlElementRefs

This annotation dynamically associates an XML element name with the JavaBean property. When a JavaBean property is annotated with
XmlElement, the XML element name is statically derived from the JavaBean property name. However, when this annotation is used, the XML element name is derived from the instance of the type of the JavaBean property at runtime.

**XML Schema substitution group support**

XML Schema allows a XML document author to use XML element names that were not statically specified in the content model of a schema using substitution groups. Schema derived code provides support for substitution groups using an *element property*, (section 5.5.5, "Element Property" of JAXB 2.0 specification). An element property method signature is of the form:

```java
public void setTerm(JAXBElement<? extends Operator?>);
public JAXBElement<? extends Operator?> getTerm();
```

An element factory method annotated with `XmlElementDecl` is used to create a `JAXBElement` instance, containing an XML element name. The presence of `@XmlElementRef` annotation on an element property indicates that the element name from `JAXBElement` instance be used instead of deriving an XML element name from the JavaBean property name.

The usage is subject to the following constraints:

- If the collection item type (for collection property) or property type (for single valued property) is `JAXBElement`, then `@XmlElementRef`.name() and `@XmlElementRef.namespace()` must point to an element factory method with an `@XmlElementDecl` annotation in a class annotated with `@XmlRegistry` (usually ObjectFactory class generated by the schema compiler):
  - `@XmlElementDecl.name()` must equal `@XmlElementRef.name()`
  - `@XmlElementDecl.namespace()` must equal `@XmlElementRef.namespace()`.
- If the collection item type (for collection property) or property type (for single valued property) is not `JAXBElement`, then the type...
referenced by the property or field must be annotated with
\texttt{XmlRootElement}.

- This annotation can be used with the following annotations:
  \texttt{XmlElementWrapper, XmlJavaTypeAdapter}.

See "Package Specification" in \texttt{javax.xml.bind.package javadoc} for additional common information.

\textbf{Example 1: Ant Task Example}

The following Java class hierarchy models an Ant build script. An Ant task corresponds to a class in the class hierarchy. The XML element name of an Ant task is indicated by the \texttt{@XmlRootElement} annotation on its corresponding class.

```java
@XmlElement(name="target")
class Target {
    // The presence of @XmlElementRef indicates that the XML
    // element name will be derived from the @XmlRootElement
    // annotation on the type (for e.g. "jar" for JarTask).
    @XmlElementRef
    List<Task> tasks;
}

abstract class Task {
}

@XmlElement(name="jar")
class JarTask extends Task {
    ...
}

@XmlElement(name="javac")
class JavacTask extends Task {
    ...
}

<xs:element name="target" type="Target">
    <xs:complexType name="Target">
        <xs:sequence>
            <xs:choice maxOccurs="unbounded">
                <xs:element ref="jar">
                <xs:element ref="javac">
            </xs:choice>
        </xs:sequence>
    </xs:complexType>
</xs:element>
```
Thus the following code fragment:

```java
Target target = new Target();
target.tasks.add(new JarTask());
target.tasks.add(new JavacTask());
marshal(target);
```

will produce the following XML output:

```xml
&lt;target&gt;
  &lt;jar&gt;
    ....
  &lt;/jar&gt;
  &lt;javac&gt;
    ....
  &lt;/javac&gt;
&lt;/target&gt;
```

It is not an error to have a class that extends `Task` that doesn't have `XmlRootElement`. But they can't show up in an XML instance (because they don't have XML element names).

**Example 2: XML Schema Substitution group support**

The following example shows the annotations for XML Schema substitution groups. The annotations and the ObjectFactory are derived from the schema.

```java
@XmlElement
class Math {
    // The value of `type()` is
    // JAXBElement.class, which indicates the XML
    // element name ObjectFactory - in general a class marked
    // with @XmlRegistry. (See ObjectFactory below)
    //
    // The `name()` is "operator", a pointer to a
    // factory method annotated with a
    // `XmlElementDecl` with the name "operator". Since
    // "operator" is the head of a substitution group that
    // contains elements "add" and "sub" elements, "operator"
```
// element can be substituted in an instance document by
// elements "add" or "sub". At runtime, JAXBElement
// instance contains the element name that has been
// substituted in the XML document.

@XmlElementRef(type=JAXBElement.class,name="operator")
JAXBElement<? extends Operator> term;

@XmlRegistry
class ObjectFactory {
    @XmlElementDecl(name="operator")
    JAXBElement<Operator> createOperator(Operator o) {...}
    @XmlElementDecl(name="add",substitutionHeadName="operator")
    JAXBElement<Operator> createAdd(Operator o) {...}
    @XmlElementDecl(name="sub",substitutionHeadName="operator")
    JAXBElement<Operator> createSub(Operator o) {...}
}

class Operator {
    ...
}

Thus, the following code fragment

Math m = new Math();
m.term = new ObjectFactory().createAdd(new Operator());
marshal(m);

will produce the following XML output:

<math>
    <add>...</add>
</math>

</tr>
</thead>
<tbody>
<tr>
<td>String namespace</td>
<td></td>
</tr>
<tr>
<td>Class type</td>
<td>The Java type being referenced.</td>
</tr>
</tbody>
</table>

abstract public Class<T> type()
Java

DEFAULT.class JavaBean

type

public abstract Class type

The Java type being referenced.

If the value is DEFAULT.class, the type is inferred from the the type of the JavaBean property.

Default:
javax.xml.bind.annotation.XmlElementRef.DEFAULT.class

abstract public String namespace()

#name() JavaBean XML

type() JAXBElement.class namespace() name() XmlElementDecl XML XML XmlElementDecl
XmlElementDecl
namespace

public abstract String namespace

This parameter and name() are used to determine the XML element for the JavaBean property.

If type() is JAXBElement.class, then namespace() and name() point to a factory method with XmlElementDecl. The XML element name is the element name from the factory method's XmlElementDecl annotation or if an element from its substitution group (of which it is a head element) has been substituted in the XML document, then the element name is from the XmlElementDecl on the substituted element.

If type() is not JAXBElement.class, then the XML element name is the XML element name statically associated with the type using the annotation XmlRootElement on the type. If the type is not annotated with an XmlElementDecl, then it is an error.

If type() is not JAXBElement.class, then this value must be "".

Default: ""

abstract public String name()

XmlElement JAXBElement

XmlElement @xsi:type

XmlJavaTypeAdapter XmlElementWrapper

since JAXB2.0

See javax.xml.bind.annotation.XmlElementWrapper,
also javax.xml.bind.annotation.XmlElementRef

Marks a property that refers to classes with XmlElement or JAXBElement.

Compared to an element property (property with XmlElement annotation),
a reference property has a different substitution semantics. When a sub-class
is assigned to a property, an element property produces the same
tag name with @xsi:type, whereas a reference property produces a
different tag name (the tag name that's on the the sub-class.)

This annotation can be used with the following annotations:
XmlJavaTypeAdapter, XmlElementWrapper.

        </xs:element>
    </xs:sequence>
</xs:complexType>

since JAXB2.0

javax.xml.bind.annotation.XmlElement,
See javax.xml.bind.annotation.XmlElementRef,
also javax.xml.bind.annotation.XmlElementRefs,
javax.xml.bind.annotation.adapters.XmlJavaTypeAdapter

A container for multiple @XmlElement annotations. Multiple annotations of
the same type are not allowed on a program element. This annotation
therefore serves as a container annotation for multiple @XmlElements as
follows:
The `@XmlElements` annotation can be used with the following program elements:

- a JavaBean property
- non static, non transient field

This annotation is intended for annotation a JavaBean collection property (e.g. List).

**Usage**

The usage is subject to the following constraints:

- This annotation can be used with the following annotations: `@XmlIDREF, @XmlElementWrapper`.
- If `@XmlIDREF` is also specified on the JavaBean property, then each `@XmlElement.type()` must contain a JavaBean property annotated with `@XmlID`.

---

**Example 1:** Map to a list of elements

```java
// Mapped code fragment
public class Foo {
    @XmlElements(
        @XmlElement(name="A", type=Integer.class),
        @XmlElement(name="B", type=Float.class)
    )
    public List items;
}
```

XML output is not wrapped using another element -->

```
... 1 2.5 ...
```
Example 2: Map to a list of elements wrapped with another element

```java
// Mapped code fragment
public class Foo {
    @XmlElementWrapper(name="bar")
    @XmlElements(
        @XmlElement(name="A", type=Integer.class),
        @XmlElement(name="B", type=Float.class)
    )
    public List items;
}
```

Example 3: Change element name based on type using an adapter.

class Foo {
    @XmlJavaTypeAdapter(QtoPAdapter.class)
    @XmlElements({
        @XmlElement(name="A", type=PX.class),
        @XmlElement(name="B", type=PY.class)
    })
}
Q bar;
}

@XmlType abstract class P {...}
@XmlType(name="PX") class PX extends P {...}
@XmlType(name="PY") class PY extends P {...}

<xs:complexType name="Foo">
  <xs:sequence>
    <xs:element name="bar">
      <xs:complexType>
        <xs:choice minOccurs="0" maxOccurs="unbounded">
          <xs:element name="A" type="PX"/>
          <xs:element name="B" type="PY"/>
        </xs:choice>
      </xs:complexType>
    </xs:element>
  </xs:sequence>
</xs:complexType>

abstract public XElement[] value()
@XmlElement
public abstract XmlElement[] value

Collection of @XmlElement annotations
javax.xml.bind.annotation  Annotation Type
XmlElementWrapper

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})
public @interface XmlElementWrapper

**Implements:** Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})

```
XML
//Example:code fragment
int[] names;

// XML Serialization Form 1 (Unwrapped collection)
<names> ...</names>
<names> ...</names>

// XML Serialization Form 2 (Wrapped collection)
<wrapperElement>
<names> value-of-item </names>
<names> value-of-item </names>
....
</wrapperElement>
```

nillable XML null

@XmlElementWrapper

- JavaBean
- static transient
Generates a wrapper element around XML representation. This is primarily intended to be used to produce a wrapper XML element around collections. The annotation therefore supports two forms of serialization shown below.

```java
//Example: code fragment
int[] names;

// XML Serialization Form 1 (Unwrapped collection)
<names> ... </names>
<names> ... </names>

// XML Serialization Form 2 (Wrapped collection )
<wrapperElement>
    <names> value-of-item </names>
    <names> value-of-item </names>
    ....
</wrapperElement>
```

The two serialized XML forms allow a null collection to be represented either by absence or presence of an element with a nillable attribute.

**Usage**

The `@XmlElementWrapper` annotation can be used with the following program elements:

- JavaBean property
- non static, non transient field
The usage is subject to the following constraints:

- The property must be a collection property
- This annotation can be used with the following annotations:
  - `XmlElement`, `XmlElements`, `XmlElementRef`, `XmlElementRefs`, `XmlJavaTypeAdapter`

Since:
- JAXB2.0

Author:
- Kohsuke Kawaguchi, Sun Microsystems, Inc.
- Sekhar Vajjhala, Sun Microsystems, Inc.

<td>nillable</td>
<td>If true, the absence of the collection is represented by using xsi:nil='true'.</td>
</tr>
</tbody>
</table>

abstract public String name()

XML XML JavaBean

name

public abstract String name
Name of the XML wrapper element. By default, the XML wrapper element name is derived from the JavaBean property name.

Default:
"##default"

---

abstract public String namespace()

XML namespace

"##default"

1. XmlSchema elementFormDefault QUALIFIED
2. ""

---

namespace

public abstract String namespace

XML target namespace of the XML wrapper element.

If the value is "##default", then the namespace is determined as follows:

1. If the enclosing package has XmlSchema annotation, and its elementFormDefault is QUALIFIED, then the namespace of the enclosing class.
2. Otherwise "" (which produces unqualified element in the default namespace.

Default:
"##default"

---

abstract public boolean nillable()

true xsi:nil='true'
nillable

public abstract boolean nillable

If true, the absence of the collection is represented by using xsi:nil='true'. Otherwise, it is represented by the absence of the element.

Default:
false

   <xs:restriction base="xs:int">
      <xs:enumeration value="1"/>
      <xs:enumeration value="2"/>
   </xs:restriction>
</xs:simpleType>

since JAXB 2.0

Maps an enum constant in Enum type to XML representation.
Usage

The `@XmlEnumValue` annotation can be used with the following program elements:

- enum constant

This annotation, together with `XmlEnum` provides a mapping of enum type to XML representation.

An enum type is mapped to a schema simple type with enumeration facets. The schema type is derived from the Java type specified in `@XmlEnum.value()`. Each enum constant `@XmlEnumValue` must have a valid lexical representation for the type `@XmlEnum.value()`.

In the absence of this annotation, `Enum.name()` is used as the XML representation.

**Example 1:** Map enum constant name -> enumeration facet

```java
//Example: Code fragment
@XmlEnum(String.class)
public enum Card { CLUBS, DIAMONDS, HEARTS, SPADES }

<!-- Example: XML Schema fragment -->
<x:simpleType name="Card">
    <x:restriction base="xs:string"/>
    <x:enumeration value="CLUBS"/>
    <x:enumeration value="DIAMONDS"/>
    <x:enumeration value="HEARTS"/>
    <x:enumeration value="SPADES"/>
</xs:simpleType>
```

**Example 2:** Map enum constant name(value) -> enumeration facet

```java
//Example: code fragment
@XmlType
@XmlEnum(Integer.class)
public enum Coin {
    @XmlEnumValue("1") PENNY(1),
```
Example 3: Map enum constant name -> enumeration facet

```java
//Code fragment
@XmlType
@XmlEnum(Integer.class)
public enum Code {
    @XmlEnumValue("1") ONE,
    @XmlEnumValue("2") TWO;
}

<!-- Example: XML Schema fragment -->
<xs:simpleType name="Coin">
    <xs:restriction base="xs:int">
        <xs:enumeration value="1"/>
        <xs:enumeration value="5"/>
        <xs:enumeration value="10"/>
        <xs:enumeration value="25"/>
    </xs:restriction>
</xs:simpleType>
```

## Method Detail

**public int getEventType()**
getEventType

int getEventType()

Returns an integer code for this event.

See Also:
XMLStreamConstants.START_ELEMENT,
XMLStreamConstants.END_ELEMENT,
XMLStreamConstants.CHARACTERS,
XMLStreamConstantsATTRIBUTE,
XMLStreamConstants.NAMESPACE,
XMLStreamConstants.PROCESSING_INSTRUCTION,

XMLStreamConstants.START_DOCUMENT,
XMLStreamConstants.END_DOCUMENT,
XMLStreamConstants.DTD

public Location getLocation()

Location

See also
javax.xml.stream.Location

getAddress

Location getSocketAddress()

Return the location of this event. The Location returned from this method is non-volatile and will retain its information.

See Also:
Location
public boolean isStartElement()

See also javax.xml.stream.events.StartElement

isStartElement

boolean isStartElement()

A utility function to check if this event is a StartElement.

See Also: StartElement

public boolean isAttribute()

See also javax.xml.stream.events.Attribute

isAttribute

boolean isAttribute()

A utility function to check if this event is an Attribute.

See Also: Attribute

public boolean isNamespace()

See also javax.xml.stream.events.Namespace

isNamespace

boolean isNamespace()
A utility function to check if this event is a Namespace.

See Also:
Namespace

```java
public boolean isEndElement()
EndElement
See also javax.xml.stream.events.EndElement
```

isEndElement

```java
boolean isEndElement()
```

A utility function to check if this event is a EndElement.

See Also:
EndElement

```java
public boolean isEntityReference()
EntityReference
See also javax.xml.stream.events.EntityReference
```

isEntityReference

```java
boolean isEntityReference()
```

A utility function to check if this event is an EntityReference.

See Also:
EntityReference

```java
public boolean isProcessingInstruction()
ProcessingInstruction
```
See also [javax.xml.stream.events.ProcessingInstruction](https://docs.oracle.com/javaee/8/javase-ref-guide/xml/stream-events.html#JAVJAA-1E3612471)

### isProcessingInstruction

```java
boolean isProcessingInstruction()
```

A utility function to check if this event is a ProcessingInstruction.

**See Also:** [ProcessingInstruction](https://docs.oracle.com/javaee/8/javase-ref-guide/xml/stream-events.html#JAVJAA-1E3612471)

---

### public boolean isCharacters()

**Characters**

See also [javax.xml.stream.events.Characters](https://docs.oracle.com/javaee/8/javase-ref-guide/xml/stream-events.html#JAVJAA-1E3612471)

### isCharacters

```java
boolean isCharacters()
```

A utility function to check if this event is Characters.

**See Also:** [Characters](https://docs.oracle.com/javaee/8/javase-ref-guide/xml/stream-events.html#JAVJAA-1E3612471)

---

### public boolean isStartDocument()

**StartDocument**

See also [javax.xml.stream.events.StartDocument](https://docs.oracle.com/javaee/8/javase-ref-guide/xml/stream-events.html#JAVJAA-1E3612471)

### isStartDocument

```java
boolean isStartDocument()
```

A utility function to check if this event is a StartDocument.
public boolean isEndDocument()

EndDocument

See also javax.xml.stream.events.EndDocument

isEndDocument

boolean isEndDocument()

A utility function to check if this event is an EndDocument.

See Also: EndDocument

public StartElement asStartElement()

asStartElement

StartElement asStartElement()

Returns this event as a start element event, may result in a class cast exception if this event is not a start element.

publicEndElement asEndElement()

asEndElement

EndElement asEndElement()
Returns this event as an end element event, may result in a class cast exception if this event is not a end element.

```java
public Characters asCharacters()

Characters

asCharacters

Characters asCharacters()

Returns this event as Characters, may result in a class cast exception if this event is not Characters.

```

```java
public javax.xml.namespace.QName getSchemaType()

null

getSchemaType

QName getSchemaType()

This method is provided for implementations to provide optional type information about the associated event. It is optional and will return null if no information is available.

```

```java
public void writeAsEncodedUnicode(java.io.Writer writer)

throws XMLStreamException

XML 1.0 XMLEvent Unicode Event Event

writer

Throws XMLStreamException:

```
writeAsEncodedUnicode

void writeAsEncodedUnicode(Writer writer)
    throws XMLStreamException

This method will write the XMLEvent as per the XML 1.0 specification as Unicode characters. No indentation or whitespace should be outputted. Any user defined event type SHALL have this method called when being written to on an output stream. Built in Event types MUST implement this method, but implementations MAY choose not call these methods for optimizations reasons when writing out built in Events to an output stream. The output generated MUST be equivalent in terms of the infoset expressed.

Parameters:
    writer - The writer that will output the data

Throws:
    XMLStreamException - if there is a fatal error writing the event

public interface XMLEventAllocator

This interface defines a class that allows a user to register a way to allocate events given an XMLStreamReader. An implementation is not required to use the XMLEventFactory implementation but this is recommended. The XMLEventAllocator can be set on an XMLInputFactory using the property "javax.xml.stream.allocator"

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>XMLEvent allocate(XMLStreamReader reader)</td>
<td>This method allocates an event given the current state of the XMLStreamReader.</td>
</tr>
<tr>
<td>void allocate(XMLStreamReader reader, XMLEventConsumer consumer)</td>
<td>This method allocates an event or set of events given the current state of the XMLStreamReader and adds the event or set of events to the consumer that was</td>
</tr>
</tbody>
</table>
This method creates an instance of the XMLEventAllocator.

Method Detail

```java
public XMLEventAllocator newInstance()
XMLEventAllocator XMLInputFactory reader
```

newInstance

```java
XMLEventAllocator newInstance()
```

This method creates an instance of the XMLEventAllocator. This allows the XMLInputFactory to allocate a new instance per reader.

```java
public XMLEvent allocate(XMLStreamReader reader)
throws XMLStreamException
XMLStreamReader XMLEventAllocator reader
null XMLStreamReader
```

allocate

```java
XMLEvent allocate(XMLStreamReader reader)
throws XMLStreamException
```

This method allocates an event given the current state of the XMLStreamReader. If this XMLEventAllocator does not have a one-
to-one mapping between reader states and events this method will return null. This method must not modify the state of the XMLStreamReader.

**Parameters:**
- `reader` - The XMLStreamReader to allocate from

**Returns:**
- the event corresponding to the current reader state

**Throws:**
- [XMLStreamException](#)

```java
public void allocate(XMLStreamReader reader, XMLEventConsumer consumer) throws XMLStreamException
```

This method allocates an event or set of events given the current state of the XMLStreamReader and adds the event or set of events to the consumer that was passed in. This method can be used to expand or contract reader states into event states. This method may modify the state of the XMLStreamReader.

**Parameters:**
- `reader` - The XMLStreamReader to allocate from
- `consumer` - The XMLEventConsumer to add to.

**Throws:**
- [XMLStreamException](#)

PS:
javax.xml.stream.util  Interface XMLEventConsumer

All Known Subinterfaces:
   XMLEventWriter

public interface XMLEventConsumer

Implemented by: XMLEventWriter

add

   version 1.0

This interface defines an event consumer interface. The contract of the consumer is to accept the event. This interface can be used to mark an object as able to receive events. Add may be called several times in immediate succession so a consumer must be able to cache events it hasn't processed yet.

Version: 1.0

<table>
<thead>
<tr>
<th>Method Summary</th>
</tr>
</thead>
<tbody>
<tr>
<td>void add(XMLEvent event)</td>
</tr>
<tr>
<td>This method adds an event to the consumer.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Method Detail</th>
</tr>
</thead>
<tbody>
<tr>
<td>public void add(XMLEvent event) throws XMLStreamException</td>
</tr>
</tbody>
</table>
This method adds an event to the consumer. Calling this method invalidates the event parameter. The client application should discard all references to this event upon calling add. The behavior of an application that continues to use such references is undefined.

**Parameters:**
- event - the event to add, may not be null

**Throws:**
- XMLStreamException

abstract StartElement(String namespaceUri, String localName, Iterator attributes, Iterator namespaces)

Create a new StartElement.

abstract StartElement createStartElement(String prefix, String namespaceUri, String localName, Iterator attributes, Iterator namespaces, NamespaceContext context)

Create a new StartElement.

static XMLEventFactory newInstance()

Create a new instance of the factory

static XMLEventFactory newInstance(String factoryId, ClassLoader classLoader)

Create a new instance of the factory

abstract void setLocation(Location location)

This method allows setting of the Location on each event that is created by this factory.

Methods inherited from class java.lang.Object

clone, equals, finalize, getClass, hashCode, notify, notifyAll, toString, wait, wait

Constructor Detail

protected XMLEventFactory()

XMLEventFactory

protected XMLEventFactory()

Method Detail

public static XMLEventFactory newInstance() throws FactoryConfigurationError
Throws: FactoryConfigurationException

newInstance

public static XMLEventFactory newInstance() throws FactoryConfigurationException

Create a new instance of the factory

Throws:
FactoryConfigurationException - if an instance of this factory cannot be loaded

newInstance

public static XMLEventFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationException

factoryId
classLoader
return

Throws: FactoryConfigurationException

newInstance

public static XMLEventFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationException

Parameters:
factoryId - Name of the factory to find, same as a property name
classLoader - classLoader to use
Returns:
   the factory implementation

Throws:
   FactoryConfigurationError - if an instance of this factory cannot be loaded

abstract public void setLocation(Location location)
   Location location null

   location

setLocation

public abstract void setLocation(Location location)

   This method allows setting of the Location on each event that is created by this factory. The values are copied by value into the events created by this factory. To reset the location information set the location to null.

   Parameters:
   location - the location to set on each event created

abstract public Attribute createAttribute(String prefix, String namespaceURI, String localName, String value)

   Attribute

   prefix null
   namespaceURI null
   localName XML localName null
   value unll
   return Attribute

createAttribute
public abstract Attribute createAttribute(String prefix,
String namespaceURI,
String localName,
String value)

Create a new Attribute

Parameters:
prefix - the prefix of this attribute, may not be null
namespaceURI - the attribute value is set to this value, may not be null
localName - the local name of the XML name of the attribute,
localName cannot be null
value - the attribute value to set, may not be null

Returns:
the Attribute with specified values

abstract public Attribute createAttribute(String localName,
String value)

Attribute

localName  XML localName  null
value      unll
return     Attribute

createAttribute

public abstract Attribute createAttribute(String localName,
String value)

Create a new Attribute

Parameters:
localName - the local name of the XML name of the attribute,
localName cannot be null
value - the attribute value to set, may not be null

Returns:
the Attribute with specified values
abstract public Attribute createAttribute(javax.xml.namespace.QName name, String value)

Attribute

<table>
<thead>
<tr>
<th>name</th>
<th>null</th>
</tr>
</thead>
<tbody>
<tr>
<td>value</td>
<td>null</td>
</tr>
<tr>
<td>return</td>
<td>Attribute</td>
</tr>
</tbody>
</table>

createAttribute

public abstract Attribute createAttribute(QName name, String value)

Create a new Attribute

Parameters:
- name - the qualified name of the attribute, may not be null
- value - the attribute value to set, may not be null

Returns: the Attribute with specified values

abstract public Namespace createNamespace(String namespaceURI)

Namespace

<table>
<thead>
<tr>
<th>namespaceURI</th>
<th>URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>Namespace</td>
</tr>
</tbody>
</table>

createNamespace

public abstract Namespace createNamespace(String namespaceURI)

Create a new default Namespace
abstract public Namespace createNamespace(String prefix, String namespaceUri)

Create a new Namespace

Parameters:
  prefix - the prefix of this namespace, may not be null
  namespaceUri - the attribute value is set to this value, may not be null

Returns:
  the Namespace with the specified values

abstract public StartElement createStartElement(javax.xml.namespace.QName name, java.util.Iterator<E> attributes, java.util.Iterator<E> namespaces)

StartElement Namespace Iterator StartElement Attribute Iterator StartElement

Parameters:
  name - null
  attributes - StartElement Attribute null
namespaces

return

createStartElement

public abstract **StartElement** createStartElement(**QName** name,
**Iterator** attributes,
**Iterator** namespaces)

Create a new StartElement. Namespaces can be added to this StartElement by passing in an Iterator that walks over a set of Namespace interfaces. Attributes can be added to this StartElement by passing an iterator that walks over a set of Attribute interfaces.

**Parameters:**
- **name** - the qualified name of the attribute, may not be null
- **attributes** - an optional unordered set of objects that implement Attribute to add to the new StartElement, may be null
- **namespaces** - an optional unordered set of objects that implement Namespace to add to the new StartElement, may be null

**Returns:**
- an instance of the requested StartElement

---

abstract public **StartElement** createStartElement(**String** prefix,
**String** namespaceUri,
**String** localName)

**StartElement** **NamespaceContext**

**NamespaceContext**
- **namespaceUri**
- **localName**
- **prefix**
- **return**

createStartElement

public abstract **StartElement** createStartElement(**String** prefix,
Create a new StartElement. This defaults the NamespaceContext to an empty NamespaceContext. Querying this event for its namespaces or attributes will result in an empty iterator being returned.

**Parameters:**
- `namespaceUri` - the uri of the QName of the new StartElement
- `localName` - the local name of the QName of the new StartElement
- `prefix` - the prefix of the QName of the new StartElement

**Returns:**
an instance of the requested StartElement

```java
abstract public StartElement createStartElement(String prefix, String namespaceUri, String localName, java.util.Iterator<E> attributes, java.util.Iterator<E> namespaces)
```

### CreateStartElement

```java
public abstract StartElement createStartElement(String prefix, String namespaceUri, String localName, Iterator attributes, Iterator namespaces)
```
Create a new StartElement. Namespaces can be added to this StartElement by passing in an Iterator that walks over a set of Namespace interfaces. Attributes can be added to this StartElement by passing an iterator that walks over a set of Attribute interfaces.

Parameters:
- namespaceUri - the uri of the QName of the new StartElement
- localName - the local name of the QName of the new StartElement
- prefix - the prefix of the QName of the new StartElement
- attributes - an unordered set of objects that implement Attribute to add to the new StartElement
- namespaces - an unordered set of objects that implement Namespace to add to the new StartElement

Returns:
an instance of the requested StartElement

abstract public StartElement createStartElement(String prefix, String namespaceUri, String localName, java.util.Iterator<E> attributes, java.util.Iterator<E> namespaces, javax.xml.namespace.NamespaceContext context)

StartElement Namespace Iterator StartElement
StartElement Attribute Iterator StartElement
namespaceUri StartElement QName URI
localName StartElement QName
prefix StartElemente QName
attributes StartElement Attribute null
namespaces StartElement Namespace null
context startElement
return StartElement

createStartElement

public abstract StartElement createStartElement(String prefix, String namespaceUri, String localName, java.util.Iterator<E> attributes, java.util.Iterator<E> namespaces, javax.xml.namespace.NamespaceContext context)
Create a new StartElement. Namespaces can be added to this StartElement by passing in an Iterator that walks over a set of Namespace interfaces. Attributes can be added to this StartElement by passing an iterator that walks over a set of Attribute interfaces.

Parameters:
- `namespaceUri` - the uri of the QName of the new StartElement
- `localName` - the local name of the QName of the new StartElement
- `prefix` - the prefix of the QName of the new StartElement
- `attributes` - an unordered set of objects that implement Attribute to add to the new StartElement, may be null
- `namespaces` - an unordered set of objects that implement Namespace to add to the new StartElement, may be null
- `context` - the namespace context of this element

Returns:
- an instance of the requested StartElement

abstract public **EndElement**
createEndElement( javax.xml.namespace.QName name, java.util.Iterator<E> namespaces)

**EndElement**
- `name`
- `namespaces`
- `return`

createEndElement

public abstract **EndElement** createEndElement( QName name, Iterator namespaces)
Create a new EndElement

**Parameters:**
- name - the qualified name of the EndElement
- namespaces - an optional unordered set of objects that implement Namespace that have gone out of scope, may be null

**Returns:**
an instance of the requested EndElement

```java
abstract public EndElement createEndElement(String prefix, String namespaceUri, String localName)
```

## createEndElement

Create a new EndElement

**Parameters:**
- namespaceUri - the uri of the QName of the new StartElement
- localName - the local name of the QName of the new StartElement
- prefix - the prefix of the QName of the new StartElement

**Returns:**
an instance of the requested EndElement

```java
abstract public EndElement createEndElement(String prefix, String namespaceUri, String localName, String qName)
```
java.util.Iterator<E> namespaces)

EndElement

<table>
<thead>
<tr>
<th>namespaceUri</th>
<th>StartElement QName</th>
<th>URI</th>
</tr>
</thead>
<tbody>
<tr>
<td>localName</td>
<td>StartElement QName</td>
<td></td>
</tr>
<tr>
<td>prefix</td>
<td>StartElement QName</td>
<td></td>
</tr>
<tr>
<td>namespaces</td>
<td>Namespace null</td>
<td></td>
</tr>
<tr>
<td>return</td>
<td>EndElement</td>
<td></td>
</tr>
</tbody>
</table>

createEndElement

public abstract EndElement createEndElement(String prefix,
                                          String namespaceUri,
                                          String localName,
                                          Iterator namespaces)

Create a new EndElement

Parameters:
- namespaceUri - the uri of the QName of the new StartElement
- localName - the local name of the QName of the new StartElement
- prefix - the prefix of the QName of the new StartElement
- namespaces - an unordered set of objects that implement Namespace that have gone out of scope, may be null

Returns:
- an instance of the requested EndElement

abstract public Characters createCharacters(String content)

Character #createSpace(String)

Creates a new EndElement

Parameters:
- namespaceUri - the uri of the QName of the new StartElement
- localName - the local name of the QName of the new StartElement
- prefix - the prefix of the QName of the new StartElement
- namespaces - an unordered set of objects that implement Namespace that have gone out of scope, may be null

Returns:
- an instance of the requested EndElement

abstract public Characters createCharacters(String content)

Character #createSpace(String)
public abstract Characters createCharacters(String content)

Create a Characters event, this method does not check if the content is all whitespace. To create a space event use #createSpace(String)

Parameters:
  content - the string to create
Returns:
a Characters event

abstract public Characters createCData(String content)
CData true Character

createCData

public abstract Characters createCData(String content)

Create a Characters event with the CData flag set to true

Parameters:
  content - the string to create
Returns:
a Characters event

abstract public Characters createSpace(String content)
isSpace true Character

createSpace

public abstract Characters createSpace(String content)
Create a Characters event with the isSpace flag set to true

**Parameters:**
- content - the content of the space to create

**Returns:**
a Characters event

---

abstract public Characters createIgnorableSpace(String content)

```
calendar
    content
    return

Character
```

**createIgnorableSpace**

public abstract Characters createIgnorableSpace(String content)

Create an ignorable space

**Parameters:**
- content - the space to create

**Returns:**
a Characters event

---

abstract public StartDocument createStartDocument()

**StartDocument**

```
    return

StartDocument
```

**createStartDocument**

public abstract StartDocument createStartDocument()

Creates a new instance of a StartDocument event
abstract public StartDocument createStartDocument(String encoding, String version, boolean standalone)
StartDocument
  encoding
  version
  standalone
  return
return StartDocument

createStartDocument

public abstract StartDocument createStartDocument(String encoding, String version, boolean standalone)

Creates a new instance of a StartDocument event

Parameters:
  encoding - the encoding style
  version - the XML version
  standalone - the status of standalone may be set to "true" or "false"

Returns:
a StartDocument event

abstract public StartDocument createStartDocument(String encoding, String version)
StartDocument
  encoding
  version
  return
return StartDocument
createStartDocument

public abstract StartDocument createStartDocument(String encoding, String version)

Creates a new instance of a StartDocument event

Parameters:
   encoding - the encoding style
   version - the XML version

Returns:
   a StartDocument event

----------------------------------------

abstract public StartDocument createStartDocument(String encoding)
StartDocument
   encoding
   return
   StartDocument

createStartDocument

public abstract StartDocument createStartDocument(String encoding)

Creates a new instance of a StartDocument event

Parameters:
   encoding - the encoding style

Returns:
   a StartDocument event

----------------------------------------

abstract public EndDocument createEndDocument()
EndDocument
   return
   EndDocument
createEndDocument

public abstract EndDocument createEndDocument()

    Creates a new instance of an EndDocument event

    Returns:
    an EndDocument event

abstract public EntityReference createEntityReference(String name, EntityDeclaration declaration)

    EntityReference
        name
        declaration
        return EntityReference

createEntityReference

public abstract EntityReference createEntityReference(String name, EntityDeclaration declaration)

    Creates a new instance of a EntityReference event

    Parameters:
    name - The name of the reference
    declaration - the declaration for the event

    Returns:
    an EntityReference event

abstract public Comment createComment(String text)

text Comment
createComment

public abstract Comment createComment(String text)

Create a comment

Parameters:

text - The text of the comment a Comment event

abstract public ProcessingInstruction
createProcessingInstruction(String target, String data)

target
data
return ProcessingInstruction

createProcessingInstruction

public abstract ProcessingInstruction createProcessingInstruction(String target, String data)

Create a processing instruction

Parameters:

target - The target of the processing instruction
data - The text of the processing instruction

Returns:
a ProcessingInstruction event

abstract public DTD createDTD(String dtd)

XML 1.0 doctypedecl
dtd
return DTD
createDTD

public abstract DTD createDTD(String dtd)

Create a document type definition event This string contains the entire document type declaration that matches the doctypedcl in the XML 1.0 specification

Parameters:

dtd - the text of the document type definition

Returns:

a DTD event
public interface XMLEventReader

extends Iterator

Implements: java.util.Iterator<E>
Implemented by: EventReaderDelegate

This is the top level interface for parsing XML Events. It provides the ability to peek at the next event and returns configuration information through the property interface.

Method Summary

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>close()</td>
<td>Frees any resources associated with this Reader.</td>
</tr>

<td>Check the next XMLEvent without reading it from the stream.</td>
</tr>
</tbody>
</table>

Methods inherited from interface `java.util.Iterator`:
- `next`, `remove`

### Method Detail

**public XMLEvent nextEvent() throws XMLStreamException**

**XMLEvent**

- Throws `XMLStreamException`: XML
- Throws `NoSuchElementException`: 
- See also [javax.xml.stream.events.XMLEvent](#)

**nextEvent**

**XMLEvent nextEvent()**

- throws `XMLStreamException`

Get the next XMLEvent
Throws:

XMLStreamException - if there is an error with the underlying XML.
NoSuchElementException - iteration has no more elements.

See Also:
XMLEvent

public boolean hasNext()
true false
    return reader true false

hasNext

boolean hasNext()

Check if there are more events. Returns true if there are more events and false otherwise.

Specified by:
hasNext in interface Iterator

Returns:
true if the event reader has more events, false otherwise

public XMLEvent peek() throws XMLStreamException
XMLEvent EOF  XMLEvent null peek()
next()

Throws
XMLStreamException:
See also
javax.xml.stream.events.XMLEvent

peek

XMLEvent peek()
    throws XMLStreamException
Check the next XMLEvent without reading it from the stream. Returns null if the stream is at EOF or has no more XMLEvents. A call to peek() will be equal to the next return of next().

Throws:

XMLStreamException

See Also:

XMLEvent

```java
public String getElementText() throws XMLStreamException
```

START_ELEMENT END_ELEMENT

Throws XMLStreamException: START_ELEMENT

getElementText

```java
String getElementText() throws XMLStreamException
```

Reads the content of a text-only element. Precondition: the current event is START_ELEMENT. Postcondition: The current event is the corresponding END_ELEMENT.

Throws:

XMLStreamException - if the current event is not a START_ELEMENT or if a non text element is encountered

```java
public XMLEvent nextTag() throws XMLStreamException
```

START_ELEMENT END_ELEMENT

DTD

Throws XMLStreamException:
**nextTag()**

Skips any insignificant space events until a START_ELEMENT or END_ELEMENT is reached. If anything other than space characters are encountered, an exception is thrown. This method should be used when processing element-only content because the parser is not able to recognize ignorable whitespace if the DTD is missing or not interpreted.

**Throws:**

- **XMLStreamException** - if anything other than space characters are encountered

---

**getProperty(String name) throws IllegalArgumentException**

Get the value of a feature/property from the underlying implementation

**Parameters:**

- **name** - The name of the property

**Returns:**

- The value of the property

**Throws:**

- **IllegalArgumentException** - if the property is not supported
public void close() throws XMLStreamException

Reader

Throws XMLStreamException:

close

void close()
throws XMLStreamException

Frees any resources associated with this Reader. This method does not close the underlying input source.

Throws:

XMLStreamException - if there are errors freeing associated resources

public void add(XMLEventReader reader) throws XMLStreamException
hasNext() false inputStream next()
reader add
   reader
   Throws XMLStreamException:

add

void add(XMLEventReader reader)
   throws XMLStreamException

   Adds an entire stream to an output stream, calls next() on the
   inputStream argument until hasNext() returns false. This should be
   treated as a convenience method that will perform the following loop
   over all the events in an event reader and call add on each event.

   Parameters:
   reader - the event stream to add to the output

   Throws:
   XMLStreamException

public String getPrefix(String uri) throws XMLStreamException

   URI

   uri
   Throws URI
   XMLStreamException:

getPrefix

String getPrefix(String uri)
   throws XMLStreamException

   Gets the prefix the uri is bound to

   Parameters:
   uri - the uri to look up

   Throws:
   XMLStreamException
public void setPrefix(String prefix, String uri) throws XMLStreamException

Sets the prefix the uri is bound to. This prefix is bound in the scope of the current START_ELEMENT / END_ELEMENT pair. If this method is called before a START_ELEMENT has been written the prefix is bound in the root scope.

Parameters:
prefix - the prefix to bind to the uri
uri - the uri to bind to the prefix

Throws: XMLStreamException

public void setDefaultNamespace(String uri) throws XMLStreamException

Sets the default namespace for the current scope. If this method is called before a START_ELEMENT has been written the default namespace is bound in the root scope.

Parameters:
uri - the uri to bind to the default namespace

Throws: XMLStreamException
void setDefaultCloseOperation(String uri)
    throws XMLStreamException

Binds a URI to the default namespace. This URI is bound in the scope of the current START_ELEMENT / END_ELEMENT pair. If this method is called before a START_ELEMENT has been written the uri is bound in the root scope.

Parameters:
    uri - the uri to bind to the default namespace

Throws:
    XMLStreamException

public void setNamespaceContext(javax.xml.namespace.NamespaceContext context) throws XMLStreamException

Sets the current namespace context for prefix and uri bindings. This context becomes the root namespace context for writing and will replace the current root namespace context. Subsequent calls to setPrefix and setDefaultCloseOperation will bind namespaces using the context passed to the method as the root context for resolving namespaces.

Parameters:
    context - the namespace context to use for this writer

Throws:
    XMLStreamException
public javax.xml.namespace.NamespaceContext
getNamespaceContext() {
    return getNamespaceContext();
}

getNamespaceContext

NamespaceContext getNamespaceContext() {

    Returns the current namespace context.

    Returns: the current namespace context

PS:
javax.xml.bind.annotation  Annotation Type XmlID

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})
public @interface XmlID

Implements: Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})

JavaBean XML ID

XML

@XmlID
- JavaBean
- static transient

javax.xml.bind.package javadoc ""

- @XmlID
- JavaBean java.lang.String
- @XmlID @XmlElement @XmlAttribute

JavaBean xs:ID

// Example: code fragment
public class Customer {
    @XmlAttribute
    @XmlID
    public String getCustomerID();
    public void setCustomerID(String id);
    .... other properties not shown
}
Maps a JavaBean property to XML ID.

To preserve referential integrity of an object graph across XML serialization followed by a XML deserialization, requires an object reference to be marshalled by reference or containment appropriately. Annotations @XmlID and @XmlIDREF together allow a customized mapping of a JavaBean property's type by containment or reference.

Usage

The @XmlID annotation can be used with the following program elements:

- a JavaBean property
- non static, non transient field

The usage is subject to the following constraints:

- At most one field or property in a class can be annotated with @XmlID.
- The JavaBean property's type must be java.lang.String.
- The only other mapping annotations that can be used with @XmlID are: @XmlElement and @XmlAttribute.
Example: Map a JavaBean property's type to xs:ID

    // Example: code fragment
    public class Customer {
        @XmlAttribute
        @XmlID
        public String getCustomerID();
        public void setCustomerID(String id);
        .... other properties not shown
    }

    <!-- Example: XML Schema fragment -->
    <xs:complexType name="Customer">
        <xs:complexContent>
            <xs:sequence>
            ....
             </xs:sequence>
            <xs:attribute name="customerID" type="xs:ID"/>
        </xs:complexContent>
    </xs:complexType>

      ....
    </xs:sequence>
  </xs:complexContent>
</xs:complexType>

<xs:complexType name="Customer">
  <xs:complexContent>
    <xs:sequence>
      ....
    </xs:sequence>
    <xs:attribute name="CustomerID" type="xs:ID"/>
  </xs:complexContent>
</xs:complexType>

<xs:complexType name="CustomerData">
  <xs:complexContent>
    <xs:sequence>
      <xs:element name="customer" type="xs:Customer"/>
      <xs:element name="shipping" type="xs:Shipping"/>
      <xs:element name="invoice" type="xs:Invoice"/>
    </xs:sequence>
  </xs:complexContent>
</xs:complexType>

<xs:element name="customerData" type="xs:CustomerData"/>
<customerData>
    <customer customerID="Alice">
        ....
    </customer>

    <shipping customer="Alice">
        ....
    </shipping>

    <invoice customer="Alice">
        ....
    </invoice>
</customerData>

3  IDREF

    // Code fragment
    public class Shipping {
        @XmlIDREF
        @XmlElement(name="Alice")
            public List customers;
    }

</xs:complexType name="Shipping">
</xs:sequence>
</xs:complexType>

4  IDREF

    // Code fragment
    public class Shipping {
        @XmlIDREF
        @XmlElements(
            @XmlElement(name="Alice", type="Customer.class")
            @XmlElement(name="John", type="InternationalCustomer.c"
        public List customers;
    }

</!-- XML Schema fragment -->
Maps a JavaBean property to XML IDREF.

To preserve referential integrity of an object graph across XML serialization followed by a XML deserialization, requires an object reference to be marshalled by reference or containment appropriately. Annotations @XmlID and @XmlIDREF together allow a customized mapping of a JavaBean property's type by containment or reference.

Usage

The @XmlIDREF annotation can be used with the following program elements:

- a JavaBean property
- non static, non transient field

The usage is subject to the following constraints:

- If the type of the field or property is a collection type, then the collection item type must contain a property or field annotated with @XmlID.
- If the field or property is single valued, then the type of the property or field must contain a property or field annotated with @XmlID.
Note: If the collection item type or the type of the property (for non collection type) is java.lang.Object, then the instance must contain a property/field annotated with @XmlID attribute.

- This annotation can be used with the following annotations: XmlElement, XmlAttribute, XmlList, and XmlElements.

Example: Map a JavaBean property to xs:IDREF (i.e. by reference rather than by containment)

```java
//EXAMPLE: Code fragment
public class Shipping {
    @XmlIDREF public Customer getCustomer();
    public void setCustomer(Customer customer);
    ....
}

<!-- Example: XML Schema fragment -->
<xs:complexType name="Shipping">
    <xs:complexContent>
        <xs:sequence>
            <xs:element name="customer" type="xs:IDREF"/>
            ....
        </xs:sequence>
    </xs:complexContent>
</xs:complexType>
```

Example 2: The following is a complete example of containment versus reference.

```java
// By default, Customer maps to complex type xs:Customer
public class Customer {
    // map JavaBean property type to xs:ID
    @XmlID public String getCustomerID();
    public void setCustomerID(String id);
    // .... other properties not shown
}

// By default, Invoice maps to a complex type xs:Invoice
public class Invoice {
```
// map by reference
@XmlIDREF public Customer getCustomer();
public void setCustomer(Customer customer);

// .... other properties not shown here
}

// By default, Shipping maps to complex type xs:Shipping
public class Shipping {

    // map by reference
    @XmlIDREF public Customer getCustomer();
    public void setCustomer(Customer customer);
}

// at least one class must reference Customer by containment;
// Customer instances won't be marshalled.
@XmlElement(name="CustomerData")
public class CustomerData {

    // map reference to Customer by containment by default.
    public Customer getCustomer();

    // maps reference to Shipping by containment by default.
    public Shipping getShipping();

    // maps reference to Invoice by containment by default.
    public Invoice getInvoice();
}

<!-- XML Schema mapping for above code fragment -->

<xs:complexType name="Invoice">
    <xs:complexContent>
        <xs:sequence>
            <xs:element name="customer" type="xs:IDREF"/>
            ....
        </xs:sequence>
    </xs:complexContent>
</xs:complexType>

<xs:complexType name="Shipping">
    <xs:complexContent>
        <xs:sequence>
            <xs:element name="customer" type="xs:IDREF"/>
            ....
        </xs:sequence>
    </xs:complexContent>
</xs:complexType>

<xs:complexType name="Customer"/>
Example 3: Mapping List to repeating element of type IDREF

    // Code fragment
    public class Shipping {
        @XmlIDREF
        @XmlElement(name="Alice")
        public List customers;
    }

    <!-- XML schema fragment -->
    <xs:complexType name="Shipping">
        <xs:sequence>
Example 4: Mapping a List to a list of elements of type IDREF.

//Code fragment
public class Shipping {
    @XmlIDREF
    @XmlElements(
        @XmlElement(name="Alice", type="Customer.class")
        @XmlElement(name="John", type="InternationalCustomer.class")
    public List customers;
}

<!-- XML Schema fragment -->
<xs:complexType name="Shipping">
    <xs:sequence>
        <xs:choice minOccurs="0" maxOccurs="unbounded">
            <xs:element name="Alice" type="xs:IDREF"/>
            <xs:element name="John" type="xs:IDREF"/>
        </xs:choice>
    </xs:sequence>
</xs:complexType>

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, TYPE})
public @interface XmlInlineBinaryData

Implements: Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, TYPE})

XML base64-encoded XOP

XOP isXOPPackage() base64-encoded ImageSource
byte[] XOP JAXB JAXB
addMtomAttachment(DataHandler, String, String)
addMtomAttachment(byte[], int, int, String, String, String)
since JAXB2.0

Disable consideration of XOP encoding for datatypes that are bound to base64-encoded binary data in XML.

When XOP encoding is enabled as described in AttachmentMarshaller.isXOPPackage(), this annotation disables datatypes such as Image or Source or byte[] that are bound to base64-encoded binary from being considered for XOP encoding. If a JAXB property is annotated with this annotation or if the JAXB property's base type is annotated with this annotation, neither AttachmentMarshaller.addMtomAttachment(DataHandler, String, String) nor AttachmentMarshaller.addMtomAttachment(byte[], int, int, String, String, String) is ever called for the property. The binary data will always be inlined.

Since: JAXB2.0

IS_NAMESPACE_AWARE

public static final String IS_NAMESPACE_AWARE

The property used to turn on/off namespace support, this is to support XML 1.0 documents, only the true setting must be supported

See Also:
Constant Field Values

IS_VALIDATING

public static final String IS_VALIDATING

The property used to turn on/off implementation specific validation

See Also:
Constant Field Values

IS_COALESCING

public static final String IS_COALESCING

The property that requires the parser to coalesce adjacent character data sections

See Also:
### Constant Field Values

**IS_REPLACING_ENTITY_REFERENCES**

```java
public static final String IS_REPLACING_ENTITY_REFERENCES
```

Requires the parser to replace internal entity references with their replacement text and report them as characters.

**See Also:**
- [Constant Field Values](#)

---

**IS_SUPPORTING_EXTERNAL_ENTITIES**

```java
public static final String IS_SUPPORTING_EXTERNAL_ENTITIES
```

The property that requires the parser to resolve external parsed entities.

**See Also:**
- [Constant Field Values](#)

---

**SUPPORT_DTD**

```java
public static final String SUPPORT_DTD
```

The property that requires the parser to support DTDs.

**See Also:**
- [Constant Field Values](#)
REPORTER

public static final String REPORTER

    The property used to set/get the implementation of the XMLReporter interface

    See Also:
    Constant Field Values

RESOLVER

public static final String RESOLVER

    The property used to set/get the implementation of the XMLResolver

    See Also:
    Constant Field Values

ALLOCATOR

public static final String ALLOCATOR

    The property used to set/get the implementation of the allocator

    See Also:
    Constant Field Values

Constructor Detail

protected XMLInputFactory()
public static XMLInputFactory newInstance() throws FactoryConfigurationError

Create a new instance of the factory. This static method creates a new factory instance. This method uses the following ordered lookup procedure to determine the XMLInputFactory implementation class to load: Use the javax.xml.stream.XMLInputFactory system property. Use the properties file "lib/stax.properties" in the JRE directory. This configuration file is in standard java.util.Properties format and contains the fully qualified name of the implementation class with the key being the system property defined above. Use the Services API (as detailed in the JAR specification), if available, to determine the classname. The Services API will look for a classname in the file META-INF/services(javax.xml.stream.XMLInputFactory) in jars available to the runtime. Platform default XMLInputFactory instance.
Once an application has obtained a reference to a XMLInputFactory it can use the factory to configure and obtain stream instances.

Throws:

- `FactoryConfigurationError` - if an instance of this factory cannot be loaded

```java
public static XMLInputFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationError

factoryId
classLoader
return
```

Throws `FactoryConfigurationError`:

```java
newInstance
public static XMLInputFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationError

factoryId - Name of the factory to find, same as a property name
classLoader - classLoader to use

Returns:
the factory implementation

Throws:
- `FactoryConfigurationError` - if an instance of this factory cannot be loaded

abstract public XMLStreamReader
```
createXMLStreamReader(java.io.Reader reader) throws XMLStreamException

reader  XMLStreamReader

Create a new XMLStreamReader from a reader

Parameters:
reader - the XML data to read from

Throws:
XMLStreamException

createXMLStreamReader(javax.xml.transform.Source source) throws XMLStreamException

JAXP  XMLStreamReader

source  XMLEventReader

Create a new XMLStreamReader from a JAXP source. This method is optional.

Parameters:
source - the source to read from

Throws:
UnsupportedOperationException - if this method is not supported by this XMLInputFactory
XMLStreamException

abstract public XMLStreamReader createXMLStreamReader(java.io.InputStream stream)
throws XMLStreamException

java.io.InputStream  XMLStreamReader
stream

Throws
XMLStreamException:

createXMLStreamReader

public abstract XMLStreamReader createXMLStreamReader(InputStream stream)
throws XMLStreamException

Create a new XMLStreamReader from a java.io.InputStream

Parameters:
stream - the InputStream to read from

Throws:
XMLStreamException

abstract public XMLStreamReader createXMLStreamReader(java.io.InputStream stream, String encoding) throws XMLStreamException

java.io.InputStream  XMLStreamReader
stream  encoding

Throws
XMLStreamException:
createXMLStreamReader

```java
public abstract XMLStreamReader createXMLStreamReader(InputStream stream,
String encoding)
throws XMLStreamException
```

Create a new XMLStreamReader from a java.io.InputStream

**Parameters:**
- `stream` - the InputStream to read from
- `encoding` - the character encoding of the stream

**Throws:**
- XMLStreamException

---

abstract public XMLStreamReader
createXMLStreamReader(String systemId,
java.io.InputStream stream) throws XMLStreamException
java.io.InputStream XMLStreamReader

```java
    systemId ID
    stream XMLEventReader InputStream
```

createXMLStreamReader

```java
public abstract XMLStreamReader createXMLStreamReader(String systemId,
InputStream stream)
throws XMLStreamException
```

Create a new XMLStreamReader from a java.io.InputStream

**Parameters:**
- `systemId` - the system ID of the stream
- `stream` - the InputStream to read from

**Throws:**
- XMLStreamException

---

abstract public XMLStreamReader
createXMLStreamReader(String systemId, java.io.Reader reader) throws XMLStreamException
java.io.InputStream XMLStreamReader

Create a new XMLStreamReader from a java.io.InputStream

Parameters:
- systemId - the system ID of the stream
- reader - the InputStream to read from

Throws:
XMLStreamException

abstract public XMLEventReader createXMLEventReader(java.io.Reader reader) throws XMLStreamException

Create a new XMLEventReader from a reader

Parameters:
abstract public XMLEventReader createXMLEventReader(String systemId, java.io.Reader reader) throws XMLStreamException
reader XMLEventReader

Create a new XMLEventReader from a reader

Parameters:
  systemId - the system ID of the input
  reader - the XML data to read from

Throws:
  XMLStreamException

abstract public XMLEventReader createXMLEventReader(XMLStreamReader reader) throws XMLStreamException

Create a new XMLEventReader from a reader

Parameters:
  reader - the XML data to read from

Throws:
  XMLStreamException
createXMLEventReader

```java
public abstract XMLEventReader createXMLEventReader(XMLStreamReader reader) throws XMLStreamException

Create a new XMLEventReader from an XMLStreamReader. After being used to construct the XMLEventReader instance returned from this method the XMLStreamReader must not be used.

Parameters:
  reader - the XMLStreamReader to read from (may not be modified)

Returns:
  a new XMLEventReader

Throws:
  XMLStreamException
```

abstract public XMLEventReader createXMLEventReader(javax.xml.transform.Source source) throws XMLStreamException

JAXP XMLEventReader
```java
  source XMLEventReader
  Throws UnsupportedOperationException: XMLInputFactory
```

createXMLEventReader

```java
public abstract XMLEventReader createXMLEventReader(Source source) throws XMLStreamException

Create a new XMLEventReader from a JAXP source. Support of this method is optional.

Parameters:
  source - the source to read from

Throws:
UnsupportedOperationException - if this method is not supported by this XMLInputFactory

XMLStreamException

abstract public XMLEventReader createXMLEventReader(java.io.InputStream stream) throws XMLStreamException

java.io.InputStream XMLEventReader

Create a new XMLEventReader from a java.io.InputStream

Parameters:
stream - the InputStream to read from

Throws:
XMLStreamException

abstract public XMLEventReader createXMLEventReader(java.io.InputStream stream, String encoding) throws XMLStreamException

java.io.InputStream XMLEventReader

Create a new XMLEventReader from a java.io.InputStream

Parameters:
stream - the InputStream to read from
encoding - the encoding to use

Throws:
XMLStreamException

createXMLEventReader
public abstract XMLEventReader createXMLEventReader(InputStream stream, String encoding) throws XMLStreamException

Create a new XMLEventReader from a java.io.InputStream

Parameters:
- stream - the InputStream to read from
- encoding - the character encoding of the stream

Throws:
- XMLStreamException

abstract public XMLEventReader createXMLEventReader(String systemId, java.io.InputStream stream) throws XMLStreamException
java.io.InputStream XMLEventReader

Create a new XMLEventReader from a java.io.InputStream

Parameters:
- systemId - the system ID of the stream
- stream - the InputStream to read from

Throws:
- XMLStreamException

abstract public XMLStreamReader createFilteredReader(XMLStreamReader reader,
StreamFilter filter) throws XMLStreamException
reader reader

Throws

createFilteredReader

public abstract XMLStreamReader createFilteredReader(StreamFilter filter)
throws XMLStreamException:

Create a filtered reader that wraps the filter around the reader

Parameters:
reader - the reader to filter
filter - the filter to apply to the reader

Throws:
XMLStreamException

abstract public XMLEventReader createFilteredReader(XMLEventReader reader, EventFilter filter)
throws XMLStreamException
reader reader

Throws

createFilteredReader

public abstract XMLEventReader createFilteredReader(XMLEventReader reader, EventFilter filter)
throws XMLStreamException:

Create a filtered event reader that wraps the filter around the event

---
Parameters:
reader - the event reader to wrap
filter - the filter to apply to the event reader

Throws:
XMLStreamException

abstract public XMLResolver getXMLResolver()
XMLStreamReader  XMLEventReader

getXMLResolver

public abstract XMLResolver getXMLResolver()

The resolver that will be set on any XMLStreamReader or XMLEventReader created by this factory instance.

abstract public void setXMLResolver(XMLResolver resolver)
XMLStreamReader  XMLEventReader
resolver

setXMLResolver

public abstract void setXMLResolver(XMLResolver resolver)

The resolver that will be set on any XMLStreamReader or XMLEventReader created by this factory instance.

Parameters:
resolver - the resolver to use to resolve references
abstract public XMLReporter getXMLReporter()
XMLStreamReader  XMLEventReader

getXMLReporter

public abstract XMLReporter getXMLReporter()

The reporter that will be set on any XMLStreamReader or XMLEventReader created by this factory instance.

abstract public void setXMLReporter(XMLReporter reporter)
XMLStreamReader  XMLEventReader

setXMLReporter

public abstract void setXMLReporter(XMLReporter reporter)

The reporter that will be set on any XMLStreamReader or XMLEventReader created by this factory instance.

Parameters:

reporter - the resolver to use to report non fatal errors

abstract public void setProperty(String name, Object value)
throws IllegalArgumentException
/ IllegalArgumentException

name null
value

Throws IllegalArgumentException:

IllegalArgumentOutOfRangeException:
setProperty

```java
public abstract void setProperty(String name, Object value)
    throws IllegalArgumentException
```

Allows the user to set specific feature/property on the underlying implementation. The underlying implementation is not required to support every setting of every property in the specification and may use IllegalArgumentException to signal that an unsupported property may not be set with the specified value.

**Parameters:**
- `name` - The name of the property (may not be null)
- `value` - The value of the property

**Throws:**
- `IllegalArgumentException` - if the property is not supported

---

abstract public Object getProperty(String name) throws IllegalArgumentException

```java
Object getProperty(String name)
```

Get the value of a feature/property from the underlying implementation

**Parameters:**
- `name` - The name of the property (may not be null)

**Returns:**
- The value of the property

---

getProperty

```java
public abstract Object getProperty(String name)
    throws IllegalArgumentException
```

Get the value of a feature/property from the underlying implementation

**Parameters:**
- `name` - The name of the property (may not be null)

**Returns:**
- The value of the property
abstract public boolean isPropertySupported(String name)

    name null
    return true false

isPropertySupported

public abstract boolean isPropertySupported(String name)

    Query the set of properties that this factory supports.

    Parameters:
        name - The name of the property (may not be null)

    Returns:
        true if the property is supported and false otherwise

abstract public void setEventAllocator(XMLEventAllocator allocator)

    allocator

setEventAllocator

public abstract void setEventAllocator(XMLEventAllocator allocator)

    Set a user defined event allocator for events

    Parameters:
        allocator - the user defined allocator
abstract public XMLEventAllocator getEventAllocator()
javax.xml.bind.annotation.adapters  Annotation Type

XmlJavaTypeAdapter

@Retention(value=RUNTIME)
@Target(value={PACKAGE, FIELD, METHOD, TYPE, PARAMETER})
public @interface XmlJavaTypeAdapter

Implements: Annotation
Inner classes: XmlJavaTypeAdapter.DEFAULT

@Retention(value=RUNTIME)
@Target(value={PACKAGE, FIELD, METHOD, TYPE, PARAMETER})

 XmlAdapter

@XmlJavaTypeAdapter

- JavaBean
- XmlAccessorType
- XmlSchema
- XmlSchemaType
- XmlSchemaTypes

XmlElement
XmlAttribute
XmlElementRef
XmlElementRefs
XmlAnyElement

XmlElement.XmlAttribute.XmlElementRef.XmlElementRefs.XmlAnyElement.XmlAccessorType.XmlSchema.XmlSchemaType.XmlSchemaTypes

XmlAdapter
Use an adapter that implements XMLAdapter for custom marshaling.

Usage:

The @XmlJavaTypeAdapter annotation can be used with the following program elements:

- a JavaBean property
- field
- parameter
- package
- from within XmlJavaTypeAdapters

When @XmlJavaTypeAdapter annotation is defined on a class, it applies to all references to the class.

When @XmlJavaTypeAdapter annotation is defined at the package level it applies to all references from within the package to @XmlJavaTypeAdapter.type().

When @XmlJavaTypeAdapter annotation is defined on the field, property or parameter, then the annotation applies to the field, property or the parameter only.

A @XmlJavaTypeAdapter annotation on a field, property or parameter overrides the @XmlJavaTypeAdapter annotation associated with the class being referenced by the field, property or parameter.

A @XmlJavaTypeAdapter annotation on a class overrides the @XmlJavaTypeAdapter annotation specified at the package level for that class.

This annotation can be used with the following other annotations:
**Required Element Summary**

<table>

PS:
javax.xml.bind.annotation Annotation Type XmlList

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PARAMETER})
public @interface XmlList

Implements: Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PARAMETER})

@XmlList

- JavaBean

@XmlElement

@XmlElement
@XmlRootElement
class Foo {
    @XmlElement
    List<String> data;
}

XML

&lt;foo&gt;
&lt;data&gt;abc&lt;/data&gt;
&lt;data&gt;def&lt;/data&gt;
&lt;/foo&gt;

@XmlList

@XmlRootElement
class Foo {
    @XmlElement
    @XmlList
List<String> data;
}

XML

&lt;foo&gt;
 &lt;data&gt;abc def&lt;/data&gt;
 &lt;/foo&gt;

XmlElement XmlAttribute XmlValue XmlIDREF

- @XmlList XmlValue XmlList XmlValue
- @XmlList XmlAttribute XmlList XmlAttribute

since JAXB2.0

Used to map a property to a list simple type.

Usage

The @XmlList annotation can be used with the following program elements:

- JavaBean property
- field

When a collection property is annotated just with @XmlElement, each item in the collection will be wrapped by an element. For example,

@XmlRootElement
class Foo {
    @XmlElement
    List<String> data;
}

would produce XML like this:
@XmlList annotation, on the other hand, allows multiple values to be represented as whitespace-separated tokens in a single element. For example,

```java
@XmlElement
@XmlList
List<String> data;
```

the above code will produce XML like this:

```xml
<foo>
  <data>abc def</data>
</foo>
```

This annotation can be used with the following annotations: `XmlElement`, `XmlAttribute`, `XmlValue`, `XmlIDREF`.

- The use of `@XmlList` with `XmlValue` while allowed, is redundant since `XmlList` maps a collection type to a simple schema type that derives by list just as `XmlValue` would.
- The use of `@XmlList` with `XmlAttribute` while allowed, is redundant since `XmlList` maps a collection type to a simple schema type that derives by list just as `XmlAttribute` would.

@Target(value={FIELD, METHOD, PARAMETER})

XML MIME

XML base64-encoded  

xmime:contentType  
since  

JAXB2.0

Associates the MIME type that controls the XML representation of the property.

This annotation is used in conjunction with datatypes such as Image or Source that are bound to base64-encoded binary in XML.

If a property that has this annotation has a sibling property bound to the xmime:contentType attribute, and if in the instance the property has a value, the value of the attribute takes precedence and that will control the marshalling.

Since:  
JAXB2.0

Author:  
Kohsuke Kawaguchi

---

Required Element Summary
The textual representation of the MIME type, such as "image/jpeg" "image/*", "text/xml; charset=iso-8859-1" and so on.

### Element Detail

**abstract public String value()**

```java
MIME "image/jpeg" "image/*" "text/xml; charset=iso-8859-1"
```

**value**

```java
public abstract String value
```

The textual representation of the MIME type, such as "image/jpeg" "image/*", "text/xml; charset=iso-8859-1" and so on.

javax.xml.bind.annotation Annotation Type XmlMixed

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})
public @interface XmlMixed

Implements: Annotation
@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD})

JavaBean

- @XmlElementRef @XmlElementRefs @XmlAnyElement

@XmlMixed

- XML java.lang.String
- JAXB @XmlRootElement
- JAXB Element @XmlAnyElement

&lt;!-- schema fragment having mixed content --&gt;
&lt;xs:complexType name="letterBody" mixed="true"&gt;
  &lt;xs:sequence&gt;
    &lt;xs:element name="name" type="xs:string"&gt;
      &lt;/xs:element&gt;&lt;xs:element name="quantity" type="xs:positiveInteger"&gt;
      &lt;/xs:element&gt;&lt;xs:element name="productName" type="xs:string"&gt;
      &lt;/xs:element&gt;&lt;!-- etc. --&gt;
  &lt;/xs:sequence&gt;
&lt;/xs:complexType&gt;

// Schema-derived Java code:
// (Only annotations relevant to mixed content are shown below, others are omitted.)
import java.math.BigInteger;
public class ObjectFactory {
// element instance factories
JAXBElement<letterbody> createLetterBody(LetterBody va
JAXBElement&lt;string&gt; createLetterBodyName(String va
JAXBElement&lt;biginteger&gt; createLetterBodyQuantity(BigInteger	value);
JAXBElement&lt;/biginteger&gt;&lt;/string&gt;&lt;/string&gt; createLetterBodyProductName(String	value);
// type instance factory
LetterBody&}; createLetterBody();
}

public class LetterBody {
    // Mixed content can contain instances of Element classes
    // Name, Quantity and ProductName. Text data is represented
    // java.util.String for text.
    @XmlMixed
    @XmlElementRefs({
        @XmlElementRef(name="productName", type=JAXBElement.class),
        @XmlElementRef(name="quantity", type=JAXBElement.class),
        @XmlElementRef(name="name", type=JAXBElement.class)
    })
    List getContent(){...}
}

XML

&lt;letterbody&gt;
Dear Mr.&lt;name&gt;Robert Smith&lt;/name&gt;
Your order of &lt;quantity&gt;1&lt;/quantity&gt; &lt;productname&gt;Baby Monitor&lt;/productname&gt; shipped from our warehouse. ....
&lt;/letterbody&gt;

JAXB API

LetterBody lb = ObjectFactory.createLetterBody();
JAXBElement&lt;letterbody&gt; lbe = ObjectFactory.createLetterBody(lb); List gcl = lb.getContent(); //add mixed content to general content
gcl.add(&amp;quot;Dear Mr.&amp;quot;); // add text information item

// add child element information item
    gcl.add(ObjectFactory.createLetterBodyName(&amp;quot;Robert Smith&amp;quot;));
gcl.add(&amp;quot;Your order of &amp;quot;); // add text information

// add children element information items
    gcl.add(ObjectFactory.
        createLetterBodyQuantity(new BigInteger(&amp;
    gcl.add(ObjectFactory.createLetterBodyProductName(&amp;quot;Baby Monitor&amp;quot;)); // add text
Annotate a JavaBean multi-valued property to support mixed content.

The usage is subject to the following constraints:

- can be used with @XmlElementRef, @XmlElementRefs or @XmlAnyElement

The following can be inserted into @XmlMixed annotated multi-valued property

- XML text information items are added as values of java.lang.String.
- Children element information items are added as instances of JAXBElement or instances with a class that is annotated with @XmlRootElement.
- Unknown content that is not be bound to a JAXB mapped class is inserted as Element. (Assumes property annotated with @XmlAnyElement)

Below is an example of binding and creation of mixed content.

```xml
&lt;!-- schema fragment having mixed content --&gt;
&lt;xs:complexType name="letterBody" mixed="true"><
  &lt;xs:sequence&
    &lt;xs:element name="name" type="xs:string"&
    &lt;/xs:element>&
    &lt;xs:element name="quantity" type="xs:positiveInteger"&
    &lt;/xs:element>&
    &lt;!-- etc. --&gt;
  &lt;/xs:sequence&
&lt;/xs:complexType&

// Schema-derived Java code:
// (Only annotations relevant to mixed content are shown below,
// others are ommitted.)
import java.math.BigInteger;
public class ObjectFactory {
```
The following is an XML instance document with mixed content

```xml
<letterbody>
  Dear Mr.<name>Robert Smith</name>
  Your order of <quantity>1</quantity> <productname>Baby Monitor</productname> shipped from our warehouse. ....
</letterbody>
```

that can be constructed using following JAXB API calls.

```java
LetterBody lb = ObjectFactory.createLetterBody();
JAXBElement<letterbody> lbe = ObjectFactory.createLetterBody(lb);
List gcl = lb.getContent();  //add mixed content to general content
  gcl.add("Dear Mr.");  // add text information item as a String.
  // add child element information item
  gcl.add(ObjectFactory.createLetterBodyName("Robert Smith"));
  gcl.add("Your order of ");  // add text information item as a String
  // add children element information items
  gcl.add(ObjectFactory.createLetterBodyQuantity(new BigInteger("1")));
  gcl.add(ObjectFactory.createLetterBodyProductName("Baby Monitor"));
  gcl.add("shipped from our warehouse");  // add text information item
```

**Enum Constant Detail**

**UNQUALIFIED**

public static final `XmlNsForm` UNQUALIFIED

**QUALIFIED**

public static final `XmlNsForm` QUALIFIED

**UNSET**

public static final `XmlNsForm` UNSET

**Method Detail**

final public static `XmlNsForm[]` values()
values

public static final XmlNsForm[] values()

Returns an array containing the constants of this enum type, in the order they're declared. This method may be used to iterate over the constants as follows:

for(XmlNsForm c : XmlNsForm.values())
    System.out.println(c);

Returns:
an array containing the constants of this enum type, in the order they're declared

valueOf

public static XmlNsForm valueOf(String name)

valueOf

Returns the enum constant of this type with the specified name. The string must match exactly an identifier used to declare an enum constant in this type. (Extraneous whitespace characters are not permitted.)

Parameters:
   name - the name of the enum constant to be returned.

Returns:
   the enum constant with the specified name

Throws:
   IllegalArgumentException - if this enum type has no constant with the specified name

javax.xml.stream  **Class XMLOutputFactory**

java.lang.Object
   \javax.xml.stream.XMLOutputFactory

public abstract class XMLOutputFactory
   extends Object

   XMLEventWriter  XMLStreamWriter ""

t javax.xml.stream.isRepairingNamespaces
   Boolean False

   setProperty("javax.xml.stream.isRepairingNamespaces",new
   Boolean(true|false));

   writer false

   writer  RepairingNamespaces StartElement
   StartElement URI StartElement StartElement
   defaultNamespace URI StartElement QName

   URI

   / URI URI

   URI  URI

   URI  URI

   version  1.0

   See also  javax.xml.stream.XMLInputFactory,
   javax.xml.stream.XMLEventWriter,
   javax.xml.stream.XMLStreamWriter
Defines an abstract implementation of a factory for getting XMLEventWriters and XMLStreamWriters. The following table defines the standard properties of this specification. Each property varies in the level of support required by each implementation. The level of support required is described in the 'Required' column.

<table>
<thead>
<tr>
<th>Property Name</th>
<th>Behavior</th>
<th>Return type</th>
<th>Default Value</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>javax.xml.stream.isRepairingNamespaces</td>
<td>defaults prefixes on the output side</td>
<td>Boolean</td>
<td>False</td>
<td>Yes</td>
</tr>
</tbody>
</table>

The following paragraphs describe the namespace and prefix repair algorithm:

The property can be set with the following code line:

```java
setProperty("javax.xml.stream.isRepairingNamespaces", new Boolean(true|false));
```

This property specifies that the writer default namespace prefix declarations. The default value is false.

If a writer isRepairingNamespaces it will create a namespace declaration on the current StartElement for any attribute that does not currently have a namespace declaration in scope. If the StartElement has a uri but no prefix specified a prefix will be assigned, if the prefix has not been declared in a parent of the current StartElement it will be declared on the current StartElement. If the defaultNamespace is bound and in scope and the default namespace matches the URI of the attribute or StartElement QName no prefix will be assigned.

If an element or attribute name has a prefix, but is not bound to any namespace URI, then the prefix will be removed during serialization.

If element and/or attribute names in the same start or empty-element tag
are bound to different namespace URIs and are using the same prefix then the element or the first occurring attribute retains the original prefix and the following attributes have their prefixes replaced with a new prefix that is bound to the namespace URIs of those attributes.

If an element or attribute name uses a prefix that is bound to a different URI than that inherited from the namespace context of the parent of that element and there is no namespace declaration in the context of the current element then such a namespace declaration is added.

If an element or attribute name is bound to a prefix and there is a namespace declaration that binds that prefix to a different URI then that namespace declaration is either removed if the correct mapping is inherited from the parent context of that element, or changed to the namespace URI of the element or attribute using that prefix.

**protected XMLOutputFactory()**

Method Detail

`public static XMLOutputFactory newInstance() throws`
**FactoryConfigurationError**

Throws FactoryConfigurationError:

newInstance

public static XMLOutputFactory newInstance() throws FactoryConfigurationError

Create a new instance of the factory.

Throws:

FactoryConfigurationError - if an instance of this factory cannot be loaded

public static XMLInputFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationError

factoryId
classLoader
return

Throws FactoryConfigurationError:

newInstance

public static XMLInputFactory newInstance(String factoryId, ClassLoader classLoader) throws FactoryConfigurationError

Create a new instance of the factory

Parameters:

factoryId - Name of the factory to find, same as a property name
classLoader - classLoader to use

Returns:
the factory implementation

Throws:
FactoryConfigurationException - if an instance of this factory cannot be loaded

abstract public XMLStreamWriter createXMLStreamWriter(java.io.Writer stream) throws XMLStreamException
writer XMLStreamWriter
stream XMLStreamWriter writer

Create a new XMLStreamWriter that writes to a writer

Parameters:
stream - the writer to write to

Throws:
XMLStreamException

abstract public XMLStreamWriter createXMLStreamWriter(java.io.OutputStream stream) throws XMLStreamException

Create a new XMLStreamWriter that writes to a writer

Parameters:
stream - the writer to write to

Throws:
XMLStreamException
createXMLStreamWriter

public abstract XMLStreamWriter createXMLStreamWriter(OutputStream stream) throws XMLStreamException

Create a new XMLStreamWriter that writes to a stream

Parameters:
  stream - the stream to write to

Throws:
  XMLStreamException

abstract public XMLStreamWriter createXMLStreamWriter(java.io.OutputStream stream, String encoding) throws XMLStreamException

XMLStreamWriter
  stream
  encoding

Throws
  XMLStreamException:

createXMLStreamWriter

public abstract XMLStreamWriter createXMLStreamWriter(OutputStream stream, String encoding) throws XMLStreamException

Create a new XMLStreamWriter that writes to a stream

Parameters:
  stream - the stream to write to
  encoding - the encoding to use

Throws:
  XMLStreamException

abstract public XMLStreamWriter createXMLStreamWriter(javax.xml.transform.Result result)
createXMLStreamWriter

public abstract XMLStreamWriter createXMLStreamWriter(Result result)
throws XMLStreamException

Create a new XMLStreamWriter that writes to a JAXP result. This method is optional.

Parameters:
result - the result to write to

Throws:
UnsupportedOperationException - if this method is not supported by this XMLOutputFactory
XMLStreamException

abstract public XMLEventWriter createXMLEventWriter(java.xml.transform.Result result)
throws XMLStreamException

Create a new XMLEventWriter that writes to a JAXP result. This
method is optional.

**Parameters:**
- `result` - the result to write to

**Throws:**
- `UnsupportedOperationException` - if this method is not supported by this XMLOutputFactory
- `XMLStreamException`

```java
abstract public XMLEventWriter createXMLEventWriter(java.io.OutputStream stream)
throws XMLStreamException
```

Create a new XMLEventWriter that writes to a stream

**Parameters:**
- `stream` - the stream to write to

**Throws:**
- `XMLStreamException`

```java
public abstract XMLEventWriter createXMLEventWriter(java.io.OutputStream stream,
String encoding)
throws XMLStreamException
```

abstract public XMLEventWriter createXMLEventWriter(java.io.OutputStream stream,
String encoding) throws XMLStreamException

**Parameters:**
- `stream`
- `encoding`

**Throws:**
- `XMLStreamException`
createXMLEventWriter

public abstract XMLEventWriter createXMLEventWriter(OutputStream stream, String encoding) throws XMLStreamException

Create a new XMLEventWriter that writes to a stream

Parameters:
stream - the stream to write to
encoding - the encoding to use

Throws:
XMLStreamException

abstract public XMLEventWriter createXMLEventWriter(java.io.Writer stream) throws XMLStreamException

writer XMLEventWriter stream

throws XMLStreamException:

createXMLEventWriter

public abstract XMLEventWriter createXMLEventWriter(Writer stream) throws XMLStreamException

Create a new XMLEventWriter that writes to a writer

Parameters:
stream - the stream to write to

Throws:
XMLStreamException

abstract public void setProperty(String name, Object value)
Throws IllegalArgumentException
/

name
value
Throws IllegalArgumentExpection:

setProperty

public abstract void `setProperty`(String name,
Object value)
throws IllegalArgumentExpection

Allows the user to set specific features/properties on the underlying implementation.

Parameters:
name - The name of the property
value - The value of the property

Throws:
IllegalArgumentExpection - if the property is not supported

getPropert

abstract public Object `getProperty`(String name) throws
IllegalArgumentExpection
/

name
return
Throws IllegalArgumentExpection:

getPropert

public abstract Object `getProperty`(String name)
throws IllegalArgumentExpection

Get a feature/property on the underlying implementation
Parameters:

name - The name of the property

Returns:

The value of the property

Throws:

IllegalArgumentException - if the property is not supported

abstract public boolean isPropertySupported(String name)

name null

return true false

isPropertySupported

public abstract boolean isPropertySupported(String name)

Query the set of properties that this factory supports.

Parameters:

name - The name of the property (may not be null)

Returns:

ture if the property is supported and false otherwise

```

message

errorType

relatedInformation
void report(String message,
String errorType,
Object relatedInformation,
Location location)
throws XMLStreamException

Report the desired message in an application specific format. Only warnings and non-fatal errors should be reported through this interface. Fatal errors should be thrown as XMLStreamException.

Parameters:
message - the error message
errorType - an implementation defined error type
relatedInformation - information related to the error, if available
location - the location of the error, if available

Throws:
XMLStreamException

resolveEntity

Object resolveEntity(String publicID, String systemID, String baseURI, String namespace) throws XMLStreamException

Retrieves a resource. This resource can be of the following three return types: (1) java.io.InputStream (2) javax.xml.stream.XMLStreamReader (3) java.xml.stream.XMLEventReader. If this method returns null the processor will attempt to resolve the entity using its default mechanism.

Parameters:
- publicID - The public identifier of the external entity being referenced, or null if none was supplied.
- systemID - The system identifier of the external entity being referenced.
- baseURI - Absolute base URI associated with systemId.
- namespace - The namespace of the entity to resolve.

Returns:
The resource requested or null.

Throws:
- XMLStreamException - if there was a failure attempting to resolve the resource.

class Point3D extends Point {
    int z;
    Point3D(int _x, int _y, int _z) {super(_x,_y);z=_z;}
}

// Example: Code fragment corresponding to XML output *
marshal( new Point3D(3,5,0), System.out );

&lt;x&gt;3&lt;/x&gt;
&lt;y&gt;5&lt;/y&gt;
&lt;z&gt;0&lt;/z&gt;
&lt;/point3D&gt;

<!-- Example: XML schema definition --&gt;
&lt;xs:element name="point3D" type="point3D"&gt;
&lt;xs:complexType name="point3D"&gt;
  &lt;xs:complexContent&gt;
    &lt;xs:extension base="point"&gt;
      &lt;xs:sequence&gt;
        &lt;xs:element name="z" type="xs:int"/&gt;
      &lt;/xs:sequence&gt;
    &lt;/xs:extension&gt;
  &lt;/xs:complexContent&gt;
&lt;/xs:complexType&gt;&lt;/xs:element&gt;
Maps a class or an enum type to an XML element.

Usage

The @XmlRootElement annotation can be used with the following program elements:

- a top level class
- an enum type

When a top level class or an enum type is annotated with the @XmlRootElement annotation, then its value is represented as XML element in an XML document.

This annotation can be used with the following annotations: XmlType,
Example 1: Associate an element with XML Schema type

```java
@XmlRootElement
class Point {
    int x;
    int y;
    Point(int _x, int _y) {x=_x; y=_y;}
}
```

```xml
<point>
    <x>3</x>
    <y>5</y>
</point>
```

The annotation causes an global element declaration to be produced in the schema. The global element declaration is associated with the XML schema type to which the class is mapped.

Example 2: Orthogonality to type inheritance

An element declaration annotated on a type is not inherited by its derived types. The following example shows this.

```java
@XmlRootElement
class Point {
    int x;
    int y;
    Point(int _x, int _y) {x=_x; y=_y;}
}
```

```xml
<point>
    <x>3</x>
    <y>5</y>
</point>
```
class Point3D extends Point {
    int z;
    Point3D(int _x, int _y, int _z) {super(_x, _y); z=_z;}
}

//Example: Code fragment corresponding to XML output *
marshal( new Point3D(3,5,0), System.out );

<!-- Example: XML output -->
<!-- The element name is point3D not point -->
<point3D>
    <x>3</x>
    <y>5</y>
    <z>0</z>
</point3D>

<!-- Example: XML schema definition -->
<xs:element name="point3D" type="point3D"/>
<xs:complexType name="point3D">
    <xs:complexContent>
        <xs:extension base="point">
            <xs:sequence>
                <xs:element name="z" type="xs:int"/>
            </xs:sequence>
        </xs:extension>
    </xs:complexContent>
</xs:complexType>

Example 3: Associate a global element with XML Schema type to which
the class is mapped.

//Example: Code fragment
@XmlElement(name="PriceElement")
public class USPrice {
    @XmlElement
    public java.math.BigDecimal price;
}

<!-- Example: XML schema definition -->
<xs:element name="PriceElement" type="USPrice"/>
<xs:complexType name="USPrice">
    <xs:sequence>
        <xs:element name="price" type="xs:decimal"/>
    </xs:sequence>
</xs:complexType>

Optional Element Summary

<table>
<thead>
<tr>
<th>String name</th>
<th>local name of the XML element.</th>
</tr>
</thead>
<tbody>
<tr>
<td>String namespace</td>
<td>namespace name of the XML element.</td>
</tr>
</tbody>
</table>

abstract public String namespace()

XML

"##default" XML ( XmlSchema) XML

namespace

public abstract String namespace

namespace name of the XML element.

If the value is "##default", then the XML namespace name is derived from the package of the class (XmlSchema). If the package is unnamed, then the XML namespace is the default empty namespace.

Default:

"##default"

abstract public String name()

XML
"##default"

**name**

```java
public abstract String name
```

local name of the XML element.

If the value is "##default", then the name is derived from the class name.

**Default:**

"##default"

    since JAXB2.0

    version $Revision: 1.9 $  

Maps a package name to a XML namespace.

Usage

The XmlSchema annotation can be used with the following program elements:

- package
This is a package level annotation and follows the recommendations and restrictions contained in JSR 175, section III, "Annotations". Thus the usage is subject to the following constraints and recommendations.

- There can only be one package declaration as noted in JSR 175, section III, "Annotations".
- JSR 175 recommends package-info.java for package level annotations. JAXB Providers that follow this recommendation will allow the package level annotations to be defined in package-info.java.

**Example 1:** Customize name of XML namespace to which package is mapped.

```java
@javax.xml.bind.annotation.XmlSchema (  
   namespace = "http://www.example.com/MYP01"
)

<!-- XML Schema fragment -->
<schema  
   xmlns=...  
   xmlns:po=...  
   targetNamespace="http://www.example.com/MYP01"
  >
  <!-- prefixes generated by default are implementation depenedent -->
</schema>
```

**Example 2:** Customize namespace prefix, namespace URI mapping

```java
// Package level annotation  
@javax.xml.bind.annotation.XmlSchema (  
   xmlns = {  
      @javax.xml.bind.annotation.XmlNs(prefix = "po",  
         namespaceURI="http://www.example.com/myPO1"),

      @javax.xml.bind.annotation.XmlNs(prefix="xs",  
         namespaceURI="http://www.w3.org/2001/XMLSchema")  
   }
)

<!-- XML Schema fragment -->
<schema  
   xmlns:xs="http://www.w3.org/2001/XMLSchema"  
   xmlns:po="http://www.example.com/P01"  
   targetNamespace="http://www.example.com/P01">
```
Example 3: Customize elementFormDefault

```java
@javax.xml.bind.annotation.XmlSchema (elementFormDefault=XmlNsForm.UNQUALIFIED ... )

<schema xmlns="http://www.w3.org/2001/XMLSchema"
    xmlns:po="http://www.example.com/PO1"
    elementFormDefault="unqualified">
```

abstract public `XmlNs[]` `xmlns()`

URI XML JAXB
xmlNs

public abstract XmlNs[] xmlns

Customize the namespace URI, prefix associations. By default, the namespace prefixes for a XML namespace are generated by a JAXB Provider in an implementation dependent way.

Default:

{}

abstract public String namespace()
XML

namespace

public abstract String namespace

Name of the XML namespace.

Default:

""

abstract public XmlNsForm elementFormDefault()
XML

elementFormDefault

public abstract XmlNsForm elementFormDefault

Namespace qualification for elements. By default, element default attribute will be absent from the XML Schema fragment.
abstract public XmlNsForm attributeFormDefault()
attributesFormDefault XML

attributeFormDefault

public abstract XmlNsForm attributeFormDefault

Namespace qualification for attributes. By default, attributesFormDefault will be absent from the XML Schema fragment.

Default:
UNSET
javax.xml.bind.annotation  Annotation Type XmlSchemaType

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PACKAGE})
public @interface XmlSchemaType

**Implements:** Annotation

**Inner classes:** XmlSchemaType.DEFAULT

@Retention(value=RUNTIME)
@Target(value={FIELD, METHOD, PACKAGE})

Java

```java
@XmlSchemaType
JavaBean
```

Java

```java
@XmlSchemaType
```

**XmlElement**

**XmlAttribute**

1 XMLGregorianCalendar

//Example: Code fragment
public class USPrice {
    @XmlElement
    @XmlSchemaType(name="date")
    public XMLGregorianCalendar date;
}

<!--[-- Example: Local XML Schema element -->
<x:s:complexType name="USPrice="/>
    <x:s:sequence>
        <x:s:element name="date" type="x:s:date"/>
    </sequence>
</x:s:complexType>
Maps a Java type to a simple schema built-in type.

**Usage**

@XmlSchemaType annotation can be used with the following program elements:

- a JavaBean property
- field
- package

@XmlSchemaType annotation defined for Java type applies to all references to the Java type from a property/field. A @XmlSchemaType annotation specified on the property/field overrides the @XmlSchemaType annotation specified at the package level.

This annotation can be used with the following annotations: `XmlElement`, `XmlAttribute`.

**Example 1:** Customize mapping of XMLGregorianCalendar on the field.

```java
//Example: Code fragment
public class USPrice {
    @XmlElement
    @XmlSchemaType(name="date")
    public XMLGregorianCalendar date;
}

<!-- Example: Local XML Schema element -->
<xs:complexType name="USPrice"/>
```
Example 2: Customize mapping of XMLGregorianCalendar at package level

```java
package foo;
@javax.xml.bind.annotation.XmlSchemaType(
    name="date", type=javax.xml.datatype.XMLGregorianCalendar.
)}
```

javax.xml.bind.package javadoc "" since JAXB2.0
See also  javax.xml.bind.annotation.XmlSchemaType

A container for multiple @XmlSchemaType annotations.

Multiple annotations of the same type are not allowed on a program element. This annotation therefore serves as a container annotation for multiple @XmlSchemaType annotations as follows:

@XmlSchemaTypes({ @XmlSchemaType(...), @XmlSchemaType(...) })

The @XmlSchemaTypes annotation can be used to define XmlSchemaType for different types at the package level.

</table>
The XMLStreamReader interface allows forward, read-only access to XML. It is designed to be the lowest level and most efficient way to read XML data.

The XMLStreamReader is designed to iterate over XML using next() and hasNext(). The data can be accessed using methods such as getEventType(), getNamespaceURI(), getLocalName() and getText();

The `next()` method causes the reader to read the next parse event. The `next()` method returns an integer which identifies the type of event just read.

The event type can be determined using `getEventType()`.

Parsing events are defined as the XML Declaration, a DTD, start tag, character data, white space, end tag, comment, or processing instruction. An attribute or namespace event may be encountered at the root level of a document as the result of a query operation.

For XML 1.0 compliance an XML processor must pass the identifiers of declared unparsed entities, notation declarations and their associated identifiers to the application. This information is provided through the property API on this interface. The following two properties allow access to this information: `javax.xml.stream.notations` and `javax.xml.stream.entities`. When the current event is a DTD the following call will return a list of Notations:

```java
List l = (List) getProperty("javax.xml.stream.notations");
```

The following call will return a list of entity declarations:

```java
List l = (List) getProperty("javax.xml.stream.entities");
```

These properties can only be accessed during a DTD event and are defined to return null if the information is not available.

The following table describes which methods are valid in what state. If a method is called in an invalid state the method will throw a java.lang.IllegalStateException.

<td>Returns the prefix of the current event or null if the event does not have a prefix.</td>
</tr>
<tr>
<td>Object getProperty(String name)</td>
<td>Get the value of a feature/property from the underlying implementation.</td>
</tr>
<tr>
<td>String getText()</td>
<td>Returns the current value of the parse event as a string, this returns the string value of a CHARACTERS event, returns the value of a COMMENT, the replacement value for an ENTITY_REFERENCE, the string value of a CDATA section, the string value for a SPACE event, or the String value of the internal subset of the DTD.</td>
</tr>
<tr>
<td>char[] getTextCharacters()</td>
<td>Returns an array which contains the characters from this event.</td>
</tr>
</tbody>
</table>
**getTextCharacters(int sourceStart, char[] target, int targetStart, int length)**

Gets the text associated with a CHARACTERS, SPACE or CDATA event.

**getTextLength()**

Returns the length of the sequence of characters for this Text event within the text character array.

**getTextStart()**

Returns the offset into the text character array where the first character (of this text event) is stored.

**getVersion()**

Get the xml version declared on the xml declaration. Returns null if none was declared.

**hasName()**

Returns true if the current event has a name (is a START_ELEMENT or END_ELEMENT) returns false otherwise

**hasNext()**

Returns true if there are more parsing events and false if there are no more events.

**hasText()**

Return true if the current event has text, false otherwise. The following events have text: CHARACTERS, DTD, ENTITY_REFERENCE, COMMENT, SPACE

**isAttributeSpecified(int index)**

Returns a boolean which indicates if this attribute was created by default.

**isCharacters()**

Returns true if the cursor points to a character data event.

**isEndElement()**

Returns true if the cursor points to an end tag (otherwise false)

**isStandalone()**

**Method Detail**

```java
public Object getProperty(String name) throws IllegalArgumentException
/
```

**name**
null

**return**

**Throws**
IllegalArgumentException: name null
getProperty

`Object getProperty(String name)`

throws `IllegalArgumentException`

Get the value of a feature/property from the underlying implementation.

**Parameters:**
- `name` - The name of the property, may not be null

**Returns:**
- The value of the property

**Throws:**
- `IllegalArgumentException` - if name is null

---

```java
public int next() throws XMLStreamException
    —— javax.xml.stream.isCoalescing true
    CDATA CHARACTERS
    "" CHARACTERS

    XML
    <foo>!--description--><!
    [CDATA[<greeting>Hello</greeting>]]></foo>
    foo next()
    1- (COMMENT)
    2- (CHARACTERS)
    3- CDATA CHARACTERS
    4- CHARACTERS
    5- END_ELEMENT

    <tag/>START_ELEMENT END_ELEMENT
    —— <tag></tag> hasNext() false
IllegalStateException
    return
    Throws NoSuchElementException: hasNext() false
```
next

`int next()`

Throws `XMLStreamException`: XML

Get next parsing event - a processor may return all contiguous character data in a single chunk, or it may split it into several chunks. If the property `javax.xml.stream.isCoalescing` is set to true element content must be coalesced and only one `CHARACTERS` event must be returned for contiguous element content or CDATA Sections. By default entity references must be expanded and reported transparently to the application. An exception will be thrown if an entity reference cannot be expanded. If element content is empty (i.e. content is "") then no `CHARACTERS` event will be reported.

Given the following XML:
```
<foo><!--description-->content text<![CDATA[<greeting>Hello</greeting>]]>other content</foo>
```
The behavior of calling `next()` when being on `foo` will be:
1. the comment (COMMENT)
2. then the characters section (CHARACTERS)
3. then the CDATA section (another CHARACTERS)
4. then the next characters section (another CHARACTERS)
5. then the END_ELEMENT

**NOTE:** empty element (such as `<tag/>`) will be reported with two separate events: `START_ELEMENT`, `END_ELEMENT` - This preserves parsing equivalency of empty element to `<tag></tag>`. This method will throw an `IllegalStateException` if it is called after `hasNext()` returns false.

**Returns:**
the integer code corresponding to the current parse event

**Throws:**
NoSuchElementException - if this is called when hasNext() returns false

XMLStreamException - if there is an error processing the underlying XML source

XMLEvent

---

```java
public void require(int type, String namespaceURI, String localName) throws XMLStreamException
namespaceURI null localName

    type
namespaceURI URI null
    localName localName null

    Throws XMLStreamException:
```

### require

```java
void require(int type,
    String namespaceURI,
    String localName)
throws XMLStreamException
```

Test if the current event is of the given type and if the namespace and name match the current namespace and name of the current event. If the namespaceURI is null it is not checked for equality, if the localName is null it is not checked for equality.

**Parameters:**

- `type` - the event type
- `namespaceURI` - the uri of the event, may be null
- `localName` - the localName of the event, may be null

**Throws:**

- `XMLStreamException` - if the required values are not matched.

---

```java
public String getElementText() throws
```

---
if(getEventType() != XMLStreamConstants.START_ELEMENT) {
    throw new XMLStreamException("parser must be on START_ELEMENT to read next text", getLocation());
}
int eventType = next();
StringBuffer content = new StringBuffer();
while(eventType != XMLStreamConstants.END_ELEMENT) {
    if(eventType == XMLStreamConstants.CHARACTERS ||
        eventType == XMLStreamConstants.CDATA ||
        eventType == XMLStreamConstants.SPACE ||
        eventType == XMLStreamConstants.ENTITY_REFERENCE) {
        buf.append(getText());
    } else if(eventType == XMLStreamConstants.PROCESSING_INSTRUCTION ||
        eventType == XMLStreamConstants.COMMENT) {
        // skipping
    } else if(eventType == XMLStreamConstants.END_DOCUMENT) {
        throw new XMLStreamException("unexpected end of document when reading element text content", getLocation());
    } else if(eventType == XMLStreamConstants.START_ELEMENT) {
        throw new XMLStreamException("element text content may not contain START_ELEMENT", getLocation());
    } else {
        throw new XMLStreamException("Unexpected event type "+eventType, getLocation());
    }
    eventType = next();
} return buf.toString();

Throws XMLStreamException: START_ELEMENT

g getElementText
String getElementText() throws XMLStreamException

Reads the content of a text-only element, an exception is thrown if this is not a text-only element. Regardless of value of javax.xml.stream.isCoalescing this method always returns coalesced content.
Precondition: the current event is START_ELEMENT.
Postcondition: the current event is the corresponding END_ELEMENT.
The method does the following (implementations are free to optimized but must do equivalent processing):

    if(getEventType() != XMLStreamConstants.START_ELEMENT) {
        throw new XMLStreamException("parser must be on START_ELEMENT to read next text", getLocation());
        int eventType = next();
        StringBuffer content = new StringBuffer();
        while(eventType != XMLStreamConstants.END_ELEMENT) {
            if(eventType == XMLStreamConstants.CHARACTERS || eventType == XMLStreamConstants.CDATA || eventType == XMLStreamConstants.SPACE || eventType == XMLStreamConstants.ENTITY_REFERENCE) {
                buf.append(getText());
            } else if(eventType == XMLStreamConstants.PROCESSING_INSTRUCTION || eventType == XMLStreamConstants.COMMENT) {
                // skipping
            } else if(eventType == XMLStreamConstants.END_DOCUMENT) {
                throw new XMLStreamException("unexpected end of document when reading element text content", getLocation());
            } else if(eventType == XMLStreamConstants.START_ELEMENT) {
                throw new XMLStreamException("element text content may not contain START_ELEMENT", getLocation());
            } else {
                throw new XMLStreamException("Unexpected event type "+eventType, getLocation());
            }
            eventType = next();
        }
        return buf.toString();
    }

Throws:
    XMLStreamException - if the current event is not a START_ELEMENT or if a non text element is encountered
public int nextTag() throws XMLStreamException

START_ELEMENT END_ELEMENT

isWhiteSpace() true

COMMENT

PROCESSING_INSTRUCTION

COMMENT

PROCESSING_INSTRUCTION

START_ELEMENT

END_ELEMENT

START_ELEMENT END_ELEMENT

int eventType = next();
while((eventType == XMLStreamConstants.CHARACTERS && isWhiteSpace())
|| (eventType == XMLStreamConstants.CDATA && isWhiteSpace())
// skip whitespace
|| eventType == XMLStreamConstants.SPACE
|| eventType == XMLStreamConstants.PROCESSING_INSTRUCTION
|| eventType == XMLStreamConstants.COMMENT
)
{
    eventType = next();
}
if (eventType != XMLStreamConstants.START_ELEMENT && eventType != XMLStreamConstants.END_ELEMENT)
throw new String XMLStreamException("expected start or end tag", getLocation());
return eventType;

return START_ELEMENT END_ELEMENT

Throws XMLStreamException: PROCESSING_INSTRUCTION

START_ELEMENT END_ELEMENT

Throws NoSuchElementException: hasNext() false

nextTag

int nextTag()
    throws XMLStreamException

Skips any white space (isWhiteSpace() returns true), COMMENT, or
PROCESSING_INSTRUCTION, until a START_ELEMENT or END_ELEMENT is reached. If other than white space characters, COMMENT, PROCESSING_INSTRUCTION, START_ELEMENT, END_ELEMENT are encountered, an exception is thrown. This method should be used when processing element-only content separated by white space.

Precondition: none
Postcondition: the current event is START_ELEMENT or END_ELEMENT and cursor may have moved over any whitespace event.

Essentially it does the following (implementations are free to optimized but must do equivalent processing):

```java
int eventType = next();
while((eventType == XMLStreamConstants.CHARACTERS && isWhiteSpace())
     || (eventType == XMLStreamConstants.CDATA && isWhiteSpace())
     // skip whitespace
     || eventType == XMLStreamConstants.SPACE
     || eventType == XMLStreamConstants.PROCESSING_INSTRUCTION
     || eventType == XMLStreamConstants.COMMENT
     ) {
    eventType = next();
}
if (eventType != XMLStreamConstants.START_ELEMENT && eventType != XMLStreamConstants.END_ELEMENT)
    throw new StringXMLStreamException("expected start or end tag"
}
return eventType;
```

**Returns:**
the event type of the element read (START_ELEMENT or END_ELEMENT)

**Throws:**

- XMLStreamException - if the current event is not white space, PROCESSING_INSTRUCTION, START_ELEMENT or END_ELEMENT
- NoSuchElementException - if this is called when hasNext() returns false

---

public boolean hasNext() throws XMLStreamException
true false XMLStreamReader
hasNext

boolean hasNext() throws XMLStreamException

Returns true if there are more parsing events and false if there are no more events. This method will return false if the current state of the XMLStreamReader is END_DOCUMENT

Returns:
true if there are more events, false otherwise

Throws:
XMLStreamException - if there is a fatal error detecting the next state

public void close() throws XMLStreamException

Frees any resources associated with this Reader. This method does not close the underlying input source.

Throws:
XMLStreamException - if there are errors freeing associated resources
public String getNamespaceURI(String prefix)
URI URI

**Namespaces in XML** 'xml'
"http://www.w3.org/XML/1998/namespace"

'xmlns'  
http://www.w3.org/2000/xmlns/
  
prefix  null
return  URI null
Throws  IllegalArgumentException: null

getNamespaceURI

String getNamespaceURI(String prefix)

Return the uri for the given prefix. The uri returned depends on the current state of the processor.

**NOTE:** The 'xml' prefix is bound as defined in **Namespaces in XML** specification to "http://www.w3.org/XML/1998/namespace".

**NOTE:** The 'xmlns' prefix must be resolved to following namespace http://www.w3.org/2000/xmlns/

Parameters:
- prefix - The prefix to lookup, may not be null

Returns:
- the uri bound to the given prefix or null if it is not bound

Throws:
- IllegalArgumentException - if the prefix is null

public boolean isStartElement()
true false
  
return  true false
isStartElement

boolean isStartElement()

Returns true if the cursor points to a start tag (otherwise false)

Returns:
true if the cursor points to a start tag, false otherwise

public boolean isEndElement()
true false
return true false

isEndElement

boolean isEndElement()

Returns true if the cursor points to an end tag (otherwise false)

Returns:
true if the cursor points to an end tag, false otherwise

public boolean isCharacters()
true
return true false

isCharacters

boolean isCharacters()

Returns true if the cursor points to a character data event
public boolean isWhiteSpace()
true
return true false

isWhiteSpace

boolean isWhiteSpace()

Returns true if the cursor points to a character data event that consists of all whitespace

Returns:
true if the cursor points to all whitespace, false otherwise

public String getAttributeValue(String namespaceURI,
String localName)
localName namespaceURI null
namespaceURI

namespaceURI

localName
null

return null

Throws
IllegalStateException: START_ELEMENT ATTRIBUTE

getAttributeValue

String getAttributeValue(String namespaceURI,
String localName)

Returns the normalized attribute value of the attribute with the namespace and localName If the namespaceURI is null the namespace is not checked for equality
Parameters:
namespaceURI - the namespace of the attribute
localName - the local name of the attribute, cannot be null

Returns:
returns the value of the attribute, returns null if not found

Throws:
IllegalStateException - if this is not a START_ELEMENT or ATTRIBUTE

public int getAttributeCount()
START_ELEMENT START_ELEMENT
ATTRIBUTE
return
Throws IllegalStateException: START_ELEMENT ATTRIBUTE

getAttributeCount

int getAttributeCount()

Returns the count of attributes on this START_ELEMENT, this method is only valid on a START_ELEMENT or ATTRIBUTE. This count excludes namespace definitions. Attribute indices are zero-based.

Returns:
returns the number of attributes

Throws:
IllegalStateException - if this is not a START_ELEMENT or ATTRIBUTE

public javax.xml.namespace.QName getAttributeName(int index)
qname
index

getAttributeName

```java
QName getAttributeName(int index)
```

Returns the qname of the attribute at the provided index

**Parameters:**
- index - the position of the attribute

**Returns:**
- the QName of the attribute

**Throws:**
- `IllegalStateException` - if this is not a START_ELEMENT or ATTRIBUTE

---

getAttributeNamespace

```java
public String getAttributeNamespace(int index)
```

```java
index
return URI null
Throws IllegalStateException: START_ELEMENT ATTRIBUTE
```

getattributeNamespace

```java
String getAttributeNamespace(int index)
```

Returns the namespace of the attribute at the provided index

**Parameters:**
- index - the position of the attribute

**Returns:**
- the namespace URI (can be null)

**Throws:**
