

## Calendar Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbCalGreg</b>	0	Indicates that the Gregorian calendar is used.
<b>vbCalHijri</b>	1	Indicates that the Hijri calendar is used.

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbBlack</b>	0x0	Black
<b>vbRed</b>	0xFF	Red
<b>vbGreen</b>	0xFF00	Green
<b>vbYellow</b>	0xFFFF	Yellow
<b>vbBlue</b>	0xFF0000	Blue
<b>vbMagenta</b>	0xFF00FF	Magenta
<b>vbCyan</b>	0xFFFF00	Cyan
<b>vbWhite</b>	0xFFFFFFFF	White

## Comparison Constants

The following [constants](#) are defined in the Visual Basic for Applications [type library](#) and can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	For Microsoft Access (Windows only), performs a comparison based on information contained in your database.

## Compiler Constants

Visual Basic for Applications defines [constants](#) for exclusive use with the **#If...Then...#Else** directive. These constants are functionally equivalent to constants defined with the **#If...Then...#Else** directive except that they are global in [scope](#); that is, they apply everywhere in a [project](#).

On 16-bit development platforms, the compiler constants are defined as follows:

Constant	Value	Description
<b>Win16</b>	<b>True</b>	Indicates development environment is 16-bit.
<b>Win32</b>	<b>False</b>	Indicates that the development environment is not 32-bit.

On 32-bit development platforms, the compiler constants are defined as follows:

Constant	Value	Description
----------	-------	-------------

<b>Vba6</b>	<b>True</b>	Indicates that the development environment is Visual Basic for Applications, version 6.0.
<b>Vba6</b>	<b>False</b>	Indicates that the development environment is not Visual Basic for Applications, version 6.0.
<b>Win16</b>	<b>False</b>	Indicates that the development environment is not 16-bit.
<b>Win32</b>	<b>True</b>	Indicates that the development environment is 32-bit.
<b>Mac</b>	<b>False</b>	Indicates that the development environment is not Macintosh.
<b>Win16</b>	<b>False</b>	Indicates that the development environment is not 16-bit.
<b>Win32</b>	<b>False</b>	Indicates that the development environment is 32-bit Windows.
<b>Mac</b>	<b>True</b>	Indicates that the development environment is Macintosh.

**Note** These constants are provided by Visual Basic, so you cannot define your own constants with these same names at any level.

Date

Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Argument Values

The *firstdayofweek* [argument](#) has the following values:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use NLS API setting.
<b>vbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

The *firstdayofyear* argument has the following values:

Constant	Value	Description
----------	-------	-------------

<b>vbUseSystem</b>	0	Use NLS API setting.
<b>VbUseSystem</b>	0	Use the day of the week specified in your system settings for the first day of the week.
<b>DayOfWeek</b>		
<b>VbFirstJan1</b>	1	Start with week in which January 1 occurs (default).
<b>vbFirstFourDays</b>	2	Start with the first week that has at least four days in the new year.
<b>vbFirstFullWeek</b>	3	Start with the first full week of the year.

#### Return Values

Constant	Value	Description
<b>vbSunday</b>	1	Sunday
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>vbGeneralDate</b>	0	Display a date and/or time. For real numbers, display a data and time. If there is no fractional part, display only a date. If there is no integer part, display time only. Date and time display is determined by your system settings.
<b>vbLongDate</b>	1	Display a date using the long date format specified in your computer's regional settings.
<b>vbShortDate</b>	2	Display a date using the short date format specified in your computer's regional settings.
<b>vbLongTime</b>	3	Display a time using the long time format specified in your computer's regional settings.
<b>vbShortTime</b>	4	Display a time using the short time format specified in your computer's regional settings.

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbNormal</b>	0	Normal (default for <b>Dir</b> and <b>SetAttr</b> )
<b>vbReadOnly</b>	1	Read-only
<b>vbHidden</b>	2	Hidden
<b>vbSystem</b>	4	System file
<b>vbVolume</b>	8	Volume label
<b>vbDirectory</b>	16	Directory or folder
<b>vbArchive</b>	32	File has changed since last backup
<b>vbAlias</b>	64	On the Macintosh, identifier is an alias.

Only **VbNormal**, **vbReadOnly**, **vbHidden**, and **vbAlias** are available on the Macintosh.

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>Unknown</b>	0	Drive type can't be determined.
<b>Removable</b>	1	Drive has removable media. This includes all floppy drives and many other varieties of storage devices.
<b>Fixed</b>	2	Drive has fixed (nonremovable) media. This includes all hard drives, including hard drives that are removable.
<b>Remote</b>	3	Network drives. This includes drives shared anywhere on a network.
<b>CDROM</b>	4	Drive is a CD-ROM. No distinction is made between read-only and read/write CD-ROM drives.
<b>RAMDisk</b>	5	Drive is a block of Random Access Memory (RAM) on the local computer that behaves like a disk drive.

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>Normal</b>	0	Normal file. No attributes are set.
<b>ReadOnly</b>	1	Read-only file. Attribute is read/write.
<b>Hidden</b>	2	Hidden file. Attribute is read/write.
<b>System</b>	4	System file. Attribute is read/write.
<b>Volume</b>	8	Disk drive volume label. Attribute is read-only.
<b>Directory</b>	16	Folder or directory. Attribute is read-only.
<b>Archive</b>	32	File has changed since last backup. Attribute is read/write.
<b>Alias</b>	64	Link or shortcut. Attribute is read-only.
<b>Compressed</b>	128	Compressed file. Attribute is read-only.

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>ForReading</b>	1	Open a file for reading only. You can't write to this file.
<b>ForWriting</b>	2	Open a file for writing. If a file with the same name exists, its previous contents are overwritten.
<b>ForAppending</b>	8	Open a file and write to the end of the file.

## IMEStatus Constants

The following [constants](#) can be used anywhere in your code in place of the actual values.

The constants for the Japanese [locale](#) are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME (default)
<b>vbIMEModeOn</b>	1	IME on
<b>vbIMEModeOff</b>	2	IME off
<b>vbIMEModeDisable</b>	3	IME disabled
<b>vbIMEModeHiragana</b>	4	Full-width Hiragana mode
<b>vbIMEModeKatakana</b>	5	Full-width Katakana mode
<b>vbIMEModeKatakanaHalf</b>	6	Half-width Katakana mode
<b>vbIMEModeAlphaFull</b>	7	Full-width Alphanumeric mode
<b>vbIMEModeAlpha</b>	8	Half-width Alphanumeric

mode

The constant values for the Korean locale are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME(default)
<b>vbIMEModeAlphaFull</b>	7	Full-width Alphanumeric mode
<b>vbIMEModeAlpha</b>	8	Half-width Alphanumeric mode
<b>vbIMEModeHangulFull</b>	9	Full-width Hangul mode
<b>vbIMEModeHangul</b>	10	Half-width Hangul mode

The constant values for the Chinese locale are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME (default)
<b>vbIMEModeOn</b>	1	IME on
<b>vbIMEModeOff</b>	2	IME off

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbKeyLButton</b>	0x1	Left mouse button
<b>vbKeyRButton</b>	0x2	Right mouse button
<b>vbKeyCancel</b>	0x3	CANCEL key
<b>vbKeyMButton</b>	0x4	Middle mouse button
<b>vbKeyBack</b>	0x8	BACKSPACE key
<b>vbKeyTab</b>	0x9	TAB key
<b>vbKeyClear</b>	0xC	CLEAR key
<b>vbKeyReturn</b>	0xD	ENTER key
<b>vbKeyShift</b>	0x10	SHIFT key
<b>vbKeyControl</b>	0x11	CTRL key
<b>vbKeyMenu</b>	0x12	MENU key
<b>vbKeyPause</b>	0x13	PAUSE key
<b>vbKeyCapital</b>	0x14	CAPS LOCK key
<b>vbKeyEscape</b>	0x1B	ESC key
<b>vbKeySpace</b>	0x20	SPACEBAR key

<b>vbKeyPageUp</b>	0x21	PAGE UP key
<b>vbKeyPageDown</b>	0x22	PAGE DOWN key
<b>vbKeyEnd</b>	0x23	END key
<b>vbKeyHome</b>	0x24	HOME key
<b>vbKeyLeft</b>	0x25	LEFT ARROW key
<b>vbKeyUp</b>	0x26	UP ARROW key
<b>vbKeyRight</b>	0x27	RIGHT ARROW key
<b>vbKeyDown</b>	0x28	DOWN ARROW key
<b>vbKeySelect</b>	0x29	SELECT key
<b>vbKeyPrint</b>	0x2A	PRINT SCREEN key
<b>vbKeyExecute</b>	0x2B	EXECUTE key
<b>vbKeySnapshot</b>	0x2C	SNAPSHOT key
<b>vbKeyInsert</b>	0x2D	INSERT key
<b>vbKeyDelete</b>	0x2E	DELETE key
<b>vbKeyHelp</b>	0x2F	HELP key
<b>vbKeyNumlock</b>	0x90	NUM LOCK key

The A key through the Z key are the same as the ASCII equivalents A – Z:

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<b>vbKeyA</b>	65	A key
<b>vbKeyB</b>	66	B key
<b>vbKeyC</b>	67	C key
<b>vbKeyD</b>	68	D key
<b>vbKeyE</b>	69	E key
<b>vbKeyF</b>	70	F key
<b>vbKeyG</b>	71	G key
<b>vbKeyH</b>	72	H key
<b>vbKeyI</b>	73	I key
<b>vbKeyJ</b>	74	J key
<b>vbKeyK</b>	75	K key
<b>vbKeyL</b>	76	L key

<b>vbKeyM</b>	77	M key
<b>vbKeyN</b>	78	N key
<b>vbKeyO</b>	79	O key
<b>vbKeyP</b>	80	P key
<b>vbKeyQ</b>	81	Q key
<b>vbKeyR</b>	82	R key
<b>vbKeyS</b>	83	S key
<b>vbKeyT</b>	84	T key
<b>vbKeyU</b>	85	U key
<b>vbKeyV</b>	86	V key
<b>vbKeyW</b>	87	W key
<b>vbKeyX</b>	88	X key
<b>vbKeyY</b>	89	Y key
<b>vbKeyZ</b>	90	Z key

The 0 key through 9 key are the same as their ASCII equivalents 0 – 9:

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<b>vbKey0</b>	48	0 key
<b>vbKey1</b>	49	1 key
<b>vbKey2</b>	50	2 key
<b>vbKey3</b>	51	3 key
<b>vbKey4</b>	52	4 key
<b>vbKey5</b>	53	5 key
<b>vbKey6</b>	54	6 key
<b>vbKey7</b>	55	7 key
<b>vbKey8</b>	56	8 key
<b>vbKey9</b>	57	9 key

The following constants represent keys on the numeric keypad:

---

Constant	Value	Description
<b>vbKeyNumpad0</b>	0x60	0 key
<b>vbKeyNumpad1</b>	0x61	1 key
<b>vbKeyNumpad2</b>	0x62	2 key
<b>vbKeyNumpad3</b>	0x63	3 key
<b>vbKeyNumpad4</b>	0x64	4 key
<b>vbKeyNumpad5</b>	0x65	5 key
<b>vbKeyNumpad6</b>	0x66	6 key
<b>vbKeyNumpad7</b>	0x67	7 key
<b>vbKeyNumpad8</b>	0x68	8 key
<b>vbKeyNumpad9</b>	0x69	9 key
<b>vbKeyMultiply</b>	0x6A	MULTIPLICATION SIGN (*) key
<b>vbKeyAdd</b>	0x6B	PLUS SIGN (+) key
<b>vbKeySeparator</b>	0x6C	ENTER key
<b>vbKeySubtract</b>	0x6D	MINUS SIGN (–) key
<b>vbKeyDecimal</b>	0x6E	DECIMAL POINT (.) key
<b>vbKeyDivide</b>	0x6F	DIVISION SIGN (/) key

The following constants represent function keys:

Constant	Value	Description
<b>vbKeyF1</b>	0x70	F1 key
<b>vbKeyF2</b>	0x71	F2 key
<b>vbKeyF3</b>	0x72	F3 key
<b>vbKeyF4</b>	0x73	F4 key
<b>vbKeyF5</b>	0x74	F5 key
<b>vbKeyF6</b>	0x75	F6 key
<b>vbKeyF7</b>	0x76	F7 key
<b>vbKeyF8</b>	0x77	F8 key
<b>vbKeyF9</b>	0x78	F9 key

<b>vbKeyF10</b>	0x79	F10 key
<b>vbKeyF11</b>	0x7A	F11 key
<b>vbKeyF12</b>	0x7B	F12 key
<b>vbKeyF13</b>	0x7C	F13 key
<b>vbKeyF14</b>	0x7D	F14 key
<b>vbKeyF15</b>	0x7E	F15 key
<b>vbKeyF16</b>	0x7F	F16 key

## Miscellaneous Constants

The following [constants](#) are defined in the Visual Basic for Applications [type library](#) and can be used anywhere in your code in place of the actual values:

Constant	Equivalent	Description
<b>vbCrLf</b>	<b>Chr(13) + Chr(10)</b>	Carriage return–linefeed combination
<b>vbCr</b>	<b>Chr(13)</b>	Carriage return character
<b>vbLf</b>	<b>Chr(10)</b>	Linefeed character
<b>vbNewLine</b>	<b>Chr(13) + Chr(10)</b> or, on the Macintosh, <b>Chr(13)</b>	Platform-specific new line character; whichever is appropriate for current platform
<b>vbNullChar</b>	<b>Chr(0)</b>	Character having value 0
<b>vbNullString</b>	String having value 0	Not the same as a zero-length string (""); used for calling external procedures
<b>vbObjectError</b>	-2147221504	User-defined error numbers should be greater than this value. For example: Err.Raise Number = vbObjectError + 1000

<b>vbTab</b>	<b>Chr(9)</b>	Tab character
<b>vbBack</b>	<b>Chr(8)</b>	Backspace character
<b>vbFormFeed</b>	<b>Chr(12)</b>	Not useful in Microsoft Windows or on the Macintosh
<b>vbVerticalTab</b>	<b>Chr(11)</b>	Not useful in Microsoft Windows or on the Macintosh

The following [constants](#) can be used anywhere in your code in place of the actual values:

#### MsgBox Arguments

Constant	Value	Description
<b>vbOKOnly</b>	0	<b>OK</b> button only (default)
<b>vbOKCancel</b>	1	<b>OK</b> and <b>Cancel</b> buttons
<b>vbAbortRetryIgnore</b>	2	<b>Abort</b> , <b>Retry</b> , and <b>Ignore</b> buttons
<b>vbYesNoCancel</b>	3	<b>Yes</b> , <b>No</b> , and <b>Cancel</b> buttons
<b>vbYesNo</b>	4	<b>Yes</b> and <b>No</b> buttons
<b>vbRetryCancel</b>	5	<b>Retry</b> and <b>Cancel</b> buttons
<b>vbCritical</b>	16	Critical message
<b>vbQuestion</b>	32	Warning query
<b>vbExclamation</b>	48	Warning message
<b>vbInformation</b>	64	Information message
<b>vbDefaultButton1</b>	0	First button is default (default)
<b>vbDefaultButton2</b>	256	Second button is default
<b>vbDefaultButton3</b>	512	Third button is default
<b>vbDefaultButton4</b>	768	Fourth button is default

<b>vbApplicationModal</b>	0	Application modal message box (default)
<b>vbSystemModal</b>	4096	System modal message box
<b>vbMsgBoxHelpButton</b>	16384	Adds Help button to the message box
<b>VbMsgBoxSetForeground</b>	65536	Specifies the message box window as the foreground window
<b>vbMsgBoxRight</b>	524288	Text is right aligned
<b>vbMsgBoxRtlReading</b>	1048576	Specifies text should appear as right-to-left reading on Hebrew and Arabic systems

#### MsgBox Return Values

Constant	Value	Description
<b>vbOK</b>	1	<b>OK</b> button pressed
<b>vbCancel</b>	2	<b>Cancel</b> button pressed
<b>vbAbort</b>	3	<b>Abort</b> button pressed
<b>vbRetry</b>	4	<b>Retry</b> button pressed
<b>vbIgnore</b>	5	<b>Ignore</b> button pressed
<b>vbYes</b>	6	<b>Yes</b> button pressed
<b>vbNo</b>	7	<b>No</b> button pressed

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbFormControlMenu</b>	0	The user chose the <b>Close</b> command from the <b>Control</b> menu on the form.
<b>vbFormCode</b>	1	The <b>Unload</b> statement is invoked from code.
<b>vbAppWindows</b>	2	The current Microsoft Windows operating environment session is ending.
<b>vbAppTaskManager</b>	3	The Windows <b>Task Manager</b> is closing the application.

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbHide</b>	0	Window is hidden and focus is passed to the hidden window.
<b>vbNormalFocus</b>	1	Window has focus and is restored to its original size and position.
<b>vbMinimizedFocus</b>	2	Window is displayed as an icon with focus.
<b>vbMaximizedFocus</b>	3	Window is maximized with focus.
<b>vbNormalNoFocus</b>	4	Window is restored to its most recent size and position. The currently active window remains active.
<b>vbMinimizedNoFocus</b>	6	Window is displayed as an icon. The currently active window remains active.

On the Macintosh, **vbNormalFocus**, **vbMinimizedFocus**, and **vbMaximizedFocus** all place the application in the foreground; **vbHide**, **vbNoFocus**, **vbMinimizedFocus** all place the application in the background.

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>WindowsFolder</b>	0	The Windows folder contains files installed by the Windows operating system.
<b>SystemFolder</b>	1	The System folder contains libraries, fonts, and device drivers.
<b>TemporaryFolder</b>	2	The Temp folder is used to store temporary files. Its path is found in the TMP environment variable.

#### StrConv Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbUpperCase</b>	1	Converts the string to uppercase characters.
<b>vbLowerCase</b>	2	Converts the string to lowercase characters.
<b>vbProperCase</b>	3	Converts the first letter of every word in string to uppercase.
<b>vbWide</b>	4	Converts narrow (single-byte) characters in string to wide (double-byte) characters. Applies to Far East <a href="#">locales</a> .
<b>vbNarrow</b>	8	Converts wide (double-byte) characters in string to narrow (single-byte) characters. Applies to Far East locales.

<b>vbKatakana</b>	16	Converts Hiragana characters in string to Katakana characters. Applies to Japan only.
<b>vbHiragana</b>	32	Converts Katakana characters in string to Hiragana characters. Applies to Japan only.
<b>vbUnicode</b>	64	Converts the string to <a href="#">Unicode</a> using the default code page of the system. (Not available on the Macintosh.)
<b>vbFromUnicode</b>	128	Converts the string from Unicode to the default code page of the system. (Not available on the Macintosh.)

## System Color Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbScrollBars</b>	0x80000000	Scroll bar color
<b>vbDesktop</b>	0x80000001	Desktop color
<b>vbActiveTitleBar</b>	0x80000002	Color of the title bar for the active window
<b>vbInactiveTitleBar</b>	0x80000003	Color of the title bar for the inactive window
<b>vbMenuBar</b>	0x80000004	Menu background color
<b>vbWindowBackground</b>	0x80000005	Window background color
<b>vbWindowFrame</b>	0x80000006	Window frame color
<b>vbMenuText</b>	0x80000007	Color of text on menus
<b>vbWindowText</b>	0x80000008	Color of text in windows
<b>vbTitleBarText</b>	0x80000009	Color of text in caption, size box, and scroll arrow
<b>vbActiveBorder</b>	0x8000000A	Border color of active window
<b>vbInactiveBorder</b>	0x8000000B	Border color of inactive

<b>vbApplicationWorkspace</b>	0x8000000C	Background color of multiple-document interface (MDI) applications
<b>vbHighlight</b>	0x8000000D	Background color of items selected in a control
<b>vbHighlightText</b>	0x8000000E	Text color of items selected in a control
<b>vbButtonFace</b>	0x8000000F	Color of shading on the face of command buttons
<b>vbButtonShadow</b>	0x80000010	Color of shading on the edge of command buttons
<b>vbGrayText</b>	0x80000011	Grayed (disabled) text
<b>vbButtonText</b>	0x80000012	Text color on push buttons
<b>vbInactiveCaptionText</b>	0x80000013	Color of text in an inactive caption
<b>vb3DHighlight</b>	0x80000014	Highlight color for 3-D display elements
<b>vb3DDKShadow</b>	0x80000015	Darkest shadow color for 3-D display elements
<b>vb3DLight</b>	0x80000016	Second lightest 3-D color after <b>vb3DHighlight</b>
<b>vbInfoText</b>	0x80000017	Color of text in ToolTips
<b>vbInfoBackground</b>	0x80000018	Background color of ToolTips

These constants are only available when your project has an explicit reference to the appropriate [type library](#) containing these constant definitions.

Constant	Value	Description
<b>vbTrue</b>	-1	True
<b>vbFalse</b>	0	False
<b>vbUseDefault</b>	-2	Use default setting

VarType Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Description
<b>vbEmpty</b>	0	Uninitialized (default)
<b>vbNull</b>	1	Contains no valid data
<b>vbInteger</b>	2	<a href="#">Integer</a>
<b>vbLong</b>	3	Long integer
<b>vbSingle</b>	4	Single-precision floating-point number
<b>vbDouble</b>	5	Double-precision floating-point number
<b>vbCurrency</b>	6	<a href="#">Currency</a>
<b>vbDate</b>	7	<a href="#">Date</a>
<b>vbString</b>	8	<a href="#">String</a>
<b>vbObject</b>	9	Object
<b>vbError</b>	10	Error
<b>vbBoolean</b>	11	<a href="#">Boolean</a>
<b>vbVariant</b>	12	<a href="#">Variant</a> (used only for <a href="#">arrays</a> of variants)
<b>vbDataObject</b>	13	Data access object
<b>vbDecimal</b>	14	<a href="#">Decimal</a>
<b>vbByte</b>	17	<a href="#">Byte</a>
<b>vbUserDefinedType</b>	36	Variants that contain user-defined types
<b>vbArray</b>	8192	Array

## Visual Basic Constants

Visual Basic for Applications defines [constants](#) to simplify your programming. The following constants can be used anywhere in your code in place of the actual values:

[Calendar Constants](#)

[CallType Constants](#)

[Color Constants](#)

[Comparison Constants](#)

[Compiler Constants](#)

[Date Constants](#)

[Date Format Constants](#)

[Dir, GetAttr, and SetAttr Constants](#)

[DriveType Constants](#)

[File Attribute Constants](#)

[File Input/Output Constants](#)

[Form Constants](#)

[IMEStatus Constants](#)

[Keycode Constants](#)

[Miscellaneous Constants](#)

[MsgBox Constants](#)

[QueryClose Constants](#)

[Shell Constants](#)

[SpecialFolder Constants](#)

[StrConv Constants](#)

[System Color Constants](#)

[Tristate Constants](#)

[VarType Constants](#)

[Visual Basic Constants](#)

## Boolean Data Type

[Boolean variables](#) are stored as 16-bit (2-byte) numbers, but they can only be **True** or **False**. **Boolean** variables display as either `True` or `False` (when **Print** is used) or `#TRUE#` or `#FALSE#` (when **Write #** is used). Use the [keywords](#) **True** and **False** to assign one of the two states to **Boolean** variables.

When other [numeric types](#) are converted to **Boolean** values, 0 becomes **False** and all other values become **True**. When **Boolean** values are converted to other [data types](#), **False** becomes 0 and **True** becomes -1.

## Byte Data Type

[Byte variables](#) are stored as single, unsigned, 8-bit (1-byte) numbers ranging in value from 0–255.

The **Byte** [data type](#) is useful for containing binary data.

## Currency Data Type

[Currency variables](#) are stored as 64-bit (8-byte) numbers in an integer format, scaled by 10,000 to give a fixed-point number with 15 digits to the left of the decimal point and 4 digits to the right. This representation provides a range of -922,337,203,685,477.5808 to 922,337,203,685,477.5807. The [type-declaration character](#) for **Currency** is the at sign (@).

The **Currency** [data type](#) is useful for calculations involving money and for fixed-point calculations in which accuracy is particularly important.

## Date Data Type

[Date variables](#) are stored as IEEE 64-bit (8-byte) floating-point numbers that represent dates ranging from 1 January 100 to 31 December 9999 and times from 0:00:00 to 23:59:59. Any recognizable literal date values can be assigned to **Date** variables. [Date literals](#) must be enclosed within number signs (#), for example, #January 1, 1993# or #1 Jan 93#.

**Date** variables display dates according to the short date format recognized by your computer. Times display according to the time format (either 12-hour or 24-hour) recognized by your computer.

When other [numeric types](#) are converted to **Date**, values to the left of the decimal represent date information while values to the right of the decimal represent time. Midnight is 0 and midday is 0.5. Negative whole numbers represent dates before 30 December 1899.

## Decimal Data Type

[Decimal variables](#) are stored as 96-bit (12-byte) signed integers scaled by a variable power of 10. The power of 10 scaling factor specifies the number of digits to the right of the decimal point, and ranges from 0 to 28. With a scale of 0 (no decimal places), the largest possible value is +/-79,228,162,514,264,337,593,543,950,335. With a 28 decimal places, the largest value is +/-7.9228162514264337593543950335 and the smallest, non-zero value is +/-0.00000000000000000000000000000001.

**Note** At this time the **Decimal** data type can only be used within a [Variant](#), that is, you cannot declare a variable to be of type **Decimal**. You can, however, create a **Variant** whose subtype is **Decimal** using the **CDec** function.

## Double Data Type

[Double \(double-precision floating-point\) variables](#) are stored as IEEE 64-bit (8-byte) floating-point numbers ranging in value from -1.79769313486231E308 to -4.94065645841247E-324 for negative values and from 4.94065645841247E-324 to 1.79769313486232E308 for positive values. The [type-declaration character](#) for **Double** is the number sign (#).

## Integer Data Type

[Integer variables](#) are stored as 16-bit (2-byte) numbers ranging in value from -32,768 to 32,767. The [type-declaration character](#) for **Integer** is the percent sign (%).

You can also use **Integer** variables to represent enumerated values. An enumerated value can contain a finite set of unique whole numbers, each of which has special meaning in the context in which it is used. Enumerated values provide a convenient way to select among a known number of choices, for example, black = 0, white = 1, and so on. It is good programming practice to

define [constants](#) using the **Const** statement for each enumerated value.

Long Data Type

Long (long integer) variables are stored as signed 32-bit (4-byte) numbers ranging in value from -2,147,483,648 to 2,147,483,647. The type-declaration character for **Long** is the ampersand (&).

Object Data Type

[Object variables](#) are stored as 32-bit (4-byte) addresses that refer to objects. Using the **Set** statement, a variable declared as an **Object** can have any object reference assigned to it.

**Note** Although a variable declared with **Object** type is flexible enough to contain a reference to any object, binding to the object referenced by that variable is always late ([run-time](#) binding). To force early binding ([compile-time](#) binding), assign the object reference to a variable declared with a specific [class](#) name.

## Single Data Type

[Single \(single-precision floating-point\) variables](#) are stored as IEEE 32-bit (4-byte) floating-point numbers, ranging in value from -3.402823E38 to -1.401298E-45 for negative values and from 1.401298E-45 to 3.402823E38 for positive values. The [type-declaration character](#) for **Single** is the exclamation point (!).

## String Data Type

There are two kinds of strings: variable-length and fixed-length strings.

A variable-length string can contain up to approximately 2 billion ( $2^{31}$ )

characters.

A fixed-length string can contain 1 to approximately 64K ( $2^{16}$ ) characters.

**Note** A [Public](#) fixed-length string can't be used in a [class module](#).

The codes for [String](#) characters range from 0–255. The first 128 characters (0–127) of the character set correspond to the letters and symbols on a standard U.S. keyboard. These first 128 characters are the same as those defined by the [ASCII](#) character set. The second 128 characters (128–255) represent special characters, such as letters in international alphabets, accents, currency symbols, and fractions. The [type-declaration character](#) for **String** is the dollar sign (\$).

## User-Defined Data Type

Any [data type](#) you define using the **Type** statement. User-defined data types can contain one or more elements of a data type, an [array](#), or a previously defined user-defined type. For example:

```
Type MyType
    MyName As String      ' String variable store
    MyBirthDate As Date   ' Date variable stor
    MySex As Integer      ' Integer variable stor
End Type                  ' female, 1 for male).
```

Variant Data Type

The **Variant** data type is the [data type](#) for all [variables](#) that are not explicitly declared as some other type (using [statements](#) such as **Dim**, **Private**, **Public**, or **Static**). The **Variant** data type has no [type-declaration character](#).

A **Variant** is a special data type that can contain any kind of data except fixed-length [String](#) data. (**Variant** types now support [user-defined types](#).) A **Variant** can also contain the special values [Empty](#), **Error**, **Nothing**, and [Null](#). You can determine how the data in a **Variant** is treated using the **VarType** function or **TypeName** function.

Numeric data can be any integer or real number value ranging from -1.797693134862315E308 to -4.94066E-324 for negative values and from 4.94066E-324 to 1.797693134862315E308 for positive values. Generally, numeric **Variant** data is maintained in its original data type within the **Variant**. For example, if you assign an [Integer](#) to a **Variant**, subsequent operations treat the **Variant** as an **Integer**. However, if an arithmetic operation is performed on a **Variant** containing a [Byte](#), an **Integer**, a [Long](#), or a [Single](#), and the result exceeds the normal range for the original data type, the result is promoted within the **Variant** to the next larger data type. A **Byte** is promoted to an **Integer**, an **Integer** is promoted to a **Long**, and a **Long** and a **Single** are promoted to a [Double](#). An error occurs when **Variant** variables containing [Currency](#), [Decimal](#), and **Double** values exceed their respective ranges.

You can use the **Variant** data type in place of any data type to work with data in

a more flexible way. If the contents of a **Variant** variable are digits, they may be either the string representation of the digits or their actual value, depending on the context. For example:

```
Dim MyVar As Variant  
MyVar = 98052
```

In the preceding example, `MyVar` contains a numeric representation—the actual value 98052. Arithmetic operators work as expected on **Variant** variables that contain numeric values or string data that can be interpreted as numbers. If you use the `+` operator to add `MyVar` to another **Variant** containing a number or to a variable of a [numeric type](#), the result is an arithmetic sum.

The value [Empty](#) denotes a **Variant** variable that hasn't been initialized (assigned an initial value). A **Variant** containing **Empty** is 0 if it is used in a numeric context and a zero-length string ("" ) if it is used in a string context.

Don't confuse **Empty** with [Null](#). **Null** indicates that the **Variant** variable intentionally contains no valid data.

In a **Variant**, **Error** is a special value used to indicate that an error condition has occurred in a [procedure](#). However, unlike for other kinds of errors, normal application-level error handling does not occur. This allows you, or the application itself, to take some alternative action based on the error value. **Error** values are created by converting real numbers to error values using the **CVErr** function.

#Const Directive

Used to define [conditional compiler constants](#) for Visual Basic.

## Syntax

**#Const** *constname* = *expression*

The **#Const** compiler directive syntax has these parts:

Part	Description
<i>constname</i>	Required; <b>Variant (String)</b> . Name of the <a href="#">constant</a> ; follows standard <a href="#">variable</a> naming conventions.
<i>expression</i>	Required. Literal, other conditional compiler constant, or any combination that includes any or all arithmetic or logical operators except <b>Is</b> .

## Remarks

Conditional compiler constants are always [Private](#) to the [module](#) in which they appear. It is not possible to create [Public](#) compiler constants using the **#Const** directive. **Public** compiler constants can only be created in the user interface.

Only conditional compiler constants and literals can be used in *expression*. Using a standard constant defined with **Const**, or using a constant that is undefined, causes an error to occur. Conversely, constants defined using the **#Const** [keyword](#) can only be used for conditional compilation.

Conditional compiler constants are always evaluated at the [module level](#), regardless of their placement in code.

#If...Then...#Else Directive

Conditionally compiles selected blocks of Visual Basic code.

### **Syntax**

**#If** *expression* **Then**

*statements*

**[#ElseIf** *expression-n* **Then**

[*elseifstatements*]]

[**#Else**

[*elsestatements*]]

**#End If**

The **#If...Then...#Else** directive syntax has these parts:

Part	Description
<i>expression</i>	Required. Any <a href="#">expression</a> , consisting exclusively of one or more <a href="#">conditional compiler constants</a> , literals, and operators, that evaluates to <b>True</b> or <b>False</b> .
<i>statements</i>	Required. Visual Basic program lines or compiler directives that are evaluated if the associated expression is <b>True</b> .
<i>expression-n</i>	Optional. Any expression, consisting exclusively of one or more conditional compiler constants, literals, and operators, that evaluates to <b>True</b> or <b>False</b> .
<i>elseifstatements</i>	Optional. One or more program lines or compiler directives that are evaluated if <i>expression-n</i> is <b>True</b> .
<i>elsestatements</i>	Optional. One or more program lines or compiler directives that are evaluated if no previous <i>expression</i> or <i>expression-n</i> is <b>True</b> .

## Remarks

The behavior of the **#If...Then...#Else** directive is the same as the **If...Then...Else** statement, except that there is no single-line form of the **#If**, **#Else**, **#ElseIf**, and **#End If** directives; that is, no other code can appear on the same line as any of the directives. Conditional compilation is typically used to compile the same program for different platforms. It is also used to prevent debugging code from appearing in an executable file. Code excluded during conditional compilation is completely omitted from the final executable file, so it has no size or performance effect.

Regardless of the outcome of any evaluation, all expressions are evaluated.

Therefore, all [constants](#) used in expressions must be defined — any undefined constant evaluates as [Empty](#).

**Note** The **Option Compare** statement does not affect expressions in **#If** and **#ElseIf** statements. Expressions in a conditional-compiler directive are always evaluated with **Option Compare Text**.

## Activate, Deactivate Events

The Activate event occurs when an object becomes the active window. The Deactivate event occurs when an object is no longer the active window.

### Syntax

**Private Sub** *object\_Activate*()

**Private Sub** *object\_Deactivate*()

The *object* placeholder represents an [object expression](#) that evaluates to an object in the Applies To list.

### Remarks

An object can become active by using the **Show** method in code.

The Activate event can occur only when an object is visible. A **UserForm** loaded with **Load** isn't visible unless you use the **Show** method.

The Activate and Deactivate events occur only when you move the [focus](#) within an application. Moving the focus to or from an object in another application doesn't trigger either event.

The Deactivate event doesn't occur when unloading an object.

## Initialize Event

Occurs after an object is loaded, but before it's shown.

### Syntax

**Private Sub** *object*\_**Initialize()**

The *object* placeholder represents an [object expression](#) that evaluates to an object in the Applies To list.

### Remarks

The Initialize event is typically used to prepare an application or **UserForm** for use. [Variables](#) are assigned initial values, and controls may be moved or resized to accommodate initialization data.

Resize Event

Occurs when a user form is resized.

### **Syntax**

**Private Sub UserForm\_Resize()**

### **Remarks**

Use a Resize event [procedure](#) to move or resize [controls](#) when the parent

**UserForm** is resized. You can also use this event procedure to recalculate [variables](#) or [properties](#).

Terminate Event

Occurs when all references to an instance of an object are removed from memory by setting all [variables](#) that refer to the object to **Nothing** or when the last reference to the object goes out of [scope](#).

### Syntax

**Private Sub** *object*\_Terminate( )

The *object* placeholder represents an [object expression](#) that evaluates to an

object in the Applies To list.

### **Remarks**

The Terminate event occurs after the object is unloaded. The Terminate event isn't triggered if the instances of the **UserForm** or [class](#) are removed from memory because the application terminated abnormally. For example, if your application invokes the **End** statement before removing all existing instances of the class or **UserForm** from memory, the Terminate event isn't triggered for that class or **UserForm**.

Abs Function

Returns a value of the same type that is passed to it specifying the absolute value of a number.

### **Syntax**

**Abs**(*number*)

The required *number* [argument](#) can be any valid [numeric expression](#). If *number* contains [Null](#), **Null** is returned; if it is an uninitialized [variable](#), zero is returned.

**Remarks**

The absolute value of a number is its unsigned magnitude. For example, `ABS(-1)` and `ABS(1)` both return 1.

Array Function

Returns a [Variant](#) containing an [array](#).

## Syntax

### **Array**(*arglist*)

The required *arglist* [argument](#) is a comma-delimited list of values that are assigned to the elements of the array contained within the **Variant**. If no arguments are specified, an array of zero length is created.

### Remarks

The notation used to refer to an element of an array consists of the [variable](#) name followed by parentheses containing an index number indicating the desired element. In the following example, the first [statement](#) creates a variable named A as a **Variant**. The second statement assigns an array to variable A. The last statement assigns the value contained in the second array element to another variable.

```
Dim A As Variant  
A = Array(10, 20, 30)  
B = A(2)
```

The lower bound of an array created using the **Array** function is determined by the lower bound specified with the **Option Base** statement, unless **Array** is qualified with the name of the type library (for example **VBA.Array**). If qualified with the type-library name, **Array** is unaffected by **Option Base**.

**Note** A **Variant** that is not declared as an array can still contain an array. A **Variant** variable can contain an array of any type, except fixed-length strings and [user-defined types](#). Although a **Variant** containing an array is conceptually different from an array whose elements are of type **Variant**, the array elements are accessed in the same way.

Asc Function

Returns an [Integer](#) representing the [character code](#) corresponding to the first letter in a string.

## Syntax

**Asc**(*string*)

The required *string* [argument](#) is any valid [string expression](#). If the *string* contains no characters, a [run-time error](#) occurs.

## Remarks

The range for returns is 0 – 255 on non-DBCS systems, but –32768 – 32767 on [DBCS](#) systems.

**Note** The **AscB** function is used with byte data contained in a string. Instead of returning the character code for the first character, **AscB** returns the first byte. The **AscW** function returns the [Unicode](#) character code except on platforms where Unicode is not supported, in which case, the behavior is identical to the **Asc** function.

**Note** Visual Basic for the Macintosh does not support Unicode strings. Therefore, **AscW**(*n*) cannot return all Unicode characters for *n* values in the range of 128 – 65,535, as it does in the Windows environment. Instead, **AscW**(*n*) attempts a "best guess" for Unicode values *n* greater than 127. Therefore, you should not use **AscW** in the Macintosh environment.

## Atn Function

Returns a **Double** specifying the arctangent of a number.

### Syntax

**Atn**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#).

### Remarks

The **Atn** function takes the ratio of two sides of a right triangle (*number*) and returns the corresponding angle in radians. The ratio is the length of the side opposite the angle divided by the length of the side adjacent to the angle.

The range of the result is  $-\pi/2$  to  $\pi/2$  radians.

To convert degrees to radians, multiply degrees by  $\pi/180$ . To convert radians to degrees, multiply radians by  $180/\pi$ .

**Note** **Atn** is the inverse trigonometric function of **Tan**, which takes an angle as its argument and returns the ratio of two sides of a right triangle. Do not confuse **Atn** with the cotangent, which is the simple inverse of a tangent ( $1/\text{tangent}$ ).

Choose Function

Selects and returns a value from a list of [arguments](#).

**Syntax**

**Choose**(*index*, *choice-1*[, *choice-2*, ... [, *choice-n*]])

The **Choose** function syntax has these parts:

Part	Description
<i>index</i>	Required. <a href="#">Numeric expression</a> or field that results in a value between 1 and the number of available choices.
<i>choice</i>	Required. <a href="#">Variant expression</a> containing one of the possible choices.

## Remarks

**Choose** returns a value from the list of choices based on the value of *index*. If *index* is 1, **Choose** returns the first choice in the list; if *index* is 2, it returns the second choice, and so on.

You can use **Choose** to look up a value in a list of possibilities. For example, if *index* evaluates to 3 and *choice-1* = "one", *choice-2* = "two", and *choice-3* = "three", **Choose** returns "three". This capability is particularly useful if *index* represents the value in an option group.

**Choose** evaluates every choice in the list, even though it returns only one. For this reason, you should watch for undesirable side effects. For example, if you use the **MsgBox** function as part of an [expression](#) in all the choices, a message box will be displayed for each choice as it is evaluated, even though **Choose** returns the value of only one of them.

The **Choose** function returns a [Null](#) if *index* is less than 1 or greater than the number of choices listed.

If *index* is not a whole number, it is rounded to the nearest whole number before being evaluated.

Chr Function

Returns a [String](#) containing the character associated with the specified [character code](#).

## Syntax

**Chr**(*charcode*)

The required *charcode* [argument](#) is a [Long](#) that identifies a character.

## Remarks

Numbers from 0 – 31 are the same as standard, nonprintable [ASCII](#) codes. For example, **Chr**(10) returns a linefeed character. The normal range for *charcode* is 0 – 255. However, on [DBCS](#) systems, the actual range for *charcode* is -32768 to 65535.

**Note** The **ChrB** function is used with byte data contained in a **String**. Instead of returning a character, which may be one or two bytes, **ChrB** always returns a single byte. The **ChrW** function returns a **String** containing the [Unicode](#) character except on platforms where Unicode is not supported, in which case, the behavior is identical to the **Chr** function.

**Note** Visual Basic for the Macintosh does not support Unicode strings. Therefore, **ChrW**(*n*) cannot return all Unicode characters for *n* values in the range of 128 – 65,535, as it does in the Windows environment. Instead, **ChrW**(*n*) attempts a "best guess" for Unicode values *n* greater than 127. Therefore, you should not use **ChrW** in the Macintosh environment.

## Command Function

Returns the [argument](#) portion of the [command line](#) used to launch Microsoft Visual Basic or an executable program developed with Visual Basic. The Visual Basic **Command** function is not available in Microsoft Office applications.

### Syntax

### Command

### Remarks

When Visual Basic is launched from the command line, any portion of the command line that follows /cmd is passed to the program as the command-line argument. In the following example, cmdlineargs represents the argument information returned by the **Command** function.

```
VB /cmd cmdlineargs
```

For applications developed with Visual Basic and compiled to an .exe file, **Command** returns any arguments that appear after the name of the application on the command line. For example:

```
MyApp cmdlineargs
```

To find how command line arguments can be changed in the user interface of the application you're using, search Help for "command line arguments."

Cos Function

Returns a **Double** specifying the cosine of an angle.

### Syntax

**Cos**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#) that expresses an angle in radians.

## Remarks

The **Cos** function takes an angle and returns the ratio of two sides of a right triangle. The ratio is the length of the side adjacent to the angle divided by the length of the hypotenuse.

The result lies in the range -1 to 1.

To convert degrees to radians, multiply degrees by  $\pi/180$ . To convert radians to degrees, multiply radians by  $180/\pi$ .

CreateObject Function

Creates and returns a reference to an [ActiveX object](#).

## Syntax

**CreateObject**(*class*,[*servername*])

The **CreateObject** function syntax has these parts:

Part	Description
<i>class</i>	Required; <b>Variant (String)</b> . The application name and class of the object to create.
<i>servername</i>	Optional; <b>Variant (String)</b> . The name of the network server where the object will be created. If <i>servername</i> is an empty string (""), the local machine is used.

The *class* [argument](#) uses the syntax *appname.objecttype* and has these parts:

Part	Description
<i>appname</i>	Required; <b>Variant (String)</b> . The name of the application providing the object.
<i>objecttype</i>	Required; <b>Variant (String)</b> . The type or <a href="#">class</a> of object to create.

## Remarks

Every application that supports Automation provides at least one type of object. For example, a word processing application may provide an **Application** object, a **Document** object, and a **Toolbar** object.

To create an ActiveX object, assign the object returned by **CreateObject** to an

[object variable](#):

```
' Declare an object variable to hold the object  
' reference. Dim as Object causes late binding.  
Dim ExcelSheet As Object  
Set ExcelSheet = CreateObject("Excel.Sheet")
```

This code starts the application creating the object, in this case, a Microsoft Excel spreadsheet. Once an object is created, you reference it in code using the object variable you defined. In the following example, you access [properties](#) and [methods](#) of the new object using the object variable, ExcelSheet, and other Microsoft Excel objects, including the Application object and the Cells collection.

```
' Make Excel visible through the Application ob  
ExcelSheet.Application.Visible = True  
' Place some text in the first cell of the shee  
ExcelSheet.Application.Cells(1, 1).Value = "Thi  
' Save the sheet to C:\test.xls directory.  
ExcelSheet.SaveAs "C:\TEST.XLS"  
' Close Excel with the Quit method on the Appli  
ExcelSheet.Application.Quit  
' Release the object variable.  
Set ExcelSheet = Nothing
```

Declaring an object variable with the As object clause creates a variable that can contain a reference to any type of object. However, access to the object through that variable is late bound; that is, the binding occurs when your program is run. To create an object variable that results in early binding, that is, binding when the program is compiled, declare the object variable with a specific class ID. For example, you can declare and create the following Microsoft Excel references:

```
Dim xlApp As Excel.Application  
Dim xlBook As Excel.Workbook  
Dim xlSheet As Excel.WorkSheet  
Set xlApp = CreateObject("Excel.Application")
```

```
Set xlBook = xlApp.Workbooks.Add  
Set xlSheet = xlBook.Worksheets(1)
```

The reference through an early-bound variable can give better performance, but can only contain a reference to the [class](#) specified in the [declaration](#).

You can pass an object returned by the **CreateObject** function to a function expecting an object as an argument. For example, the following code creates and passes a reference to a Excel.Application object:

```
Call MySub (CreateObject("Excel.Application"))
```

You can create an object on a remote networked computer by passing the name of the computer to the *servername* argument of **CreateObject**. That name is the same as the Machine Name portion of a share name: for a share named "\\MyServer\Public," *servername* is "MyServer."

**Note** Refer to COM documentation (see *Microsoft Developer Network*) for additional information on making an application visible on a remote networked computer. You may have to add a registry key for your application.

The following code returns the version number of an instance of Excel running on a remote computer named MyServer:

```
Dim xlApp As Object  
Set xlApp = CreateObject("Excel.Application", "  
Debug.Print xlApp.Version
```

If the remote server doesn't exist or is unavailable, a run-time error occurs.

**Note** Use **CreateObject** when there is no current instance of the object. If an instance of the object is already running, a new instance is started, and an object of the specified type is created. To use the current instance, or to start the application and have it load a file, use the **GetObject** function.

If an object has registered itself as a single-instance object, only one instance of the object is created, no matter how many times **CreateObject** is executed.

## CurDir Function

Returns a **Variant (String)** representing the current path.

### Syntax

**CurDir**[(*drive*)]

The optional *drive* [argument](#) is a [string expression](#) that specifies an existing drive. If no drive is specified or if *drive* is a zero-length string (""), **CurDir** returns the path for the current drive. On the Macintosh, **CurDir** ignores any *drive* specified and simply returns the path for the current drive.

CVErr Function

Returns a [Variant](#) of subtype **Error** containing an [error number](#) specified by the user.

## Syntax

**CVErr**(*errornumber*)

The required *errornumber* [argument](#) is any valid error number.

## Remarks

Use the **CVErr** function to create user-defined errors in user-created [procedures](#). For example, if you create a function that accepts several arguments and normally returns a string, you can have your function evaluate the input arguments to ensure they are within acceptable range. If they are not, it is likely your function will not return what you expect. In this event, **CVErr** allows you to return an error number that tells you what action to take.

Note that implicit conversion of an **Error** is not allowed. For example, you can't directly assign the return value of **CVErr** to a [variable](#) that is not a **Variant**. However, you can perform an explicit conversion (using **CInt**, **CDBl**, and so on) of the value returned by **CVErr** and assign that to a variable of the appropriate [data type](#).

Returns a **Variant (Date)** containing the current system date.

### Syntax

### Date

### Remarks

To set the system date, use the **Date** statement.

**Date**, and if the calendar is Gregorian, **Date\$** behavior is unchanged by the **Calendar** property setting. If the calendar is Hijri, **Date\$** returns a 10-character string of the form *mm-dd-yyyy*, where *mm* (01-12), *dd* (01-30) and *yyyy* (1400-1523) are the Hijri month, day and year. The equivalent Gregorian range is Jan 1, 1980 through Dec 31, 2099.

DateAdd Function

Returns a **Variant (Date)** containing a date to which a specified time interval has been added.

## Syntax

**DateAdd**(*interval*, *number*, *date*)

The **DateAdd** function syntax has these [named arguments](#):

Part	Description
<i>interval</i>	Required. <a href="#">String expression</a> that is the interval of time you want to add.
<i>number</i>	Required. <a href="#">Numeric expression</a> that is the number of intervals you want to add. It can be positive (to get dates in the future) or negative (to get dates in the past).
<i>date</i>	Required. <b>Variant (Date)</b> or literal representing date to which the interval is added.

## Settings

The *interval* [argument](#) has these settings:

Setting	Description
yyyy	Year
q	Quarter
m	Month
y	Day of year
d	Day
w	Weekday
ww	Week
h	Hour
n	Minute
s	Second

## Remarks

You can use the **DateAdd** function to add or subtract a specified time interval

from a date. For example, you can use **DateAdd** to calculate a date 30 days from today or a time 45 minutes from now.

To add days to *date*, you can use Day of Year ("y"), Day ("d"), or Weekday ("w").

The **DateAdd** function won't return an invalid date. The following example adds one month to January 31:

```
DateAdd("m", 1, "31-Jan-95")
```

In this case, **DateAdd** returns 28-Feb-95, not 31-Feb-95. If *date* is 31-Jan-96, it returns 29-Feb-96 because 1996 is a leap year.

If the calculated date would precede the year 100 (that is, you subtract more years than are in *date*), an error occurs.

If *number* isn't a [Long](#) value, it is rounded to the nearest whole number before being evaluated.

**Note** The format of the return value for **DateAdd** is determined by **Control Panel** settings, not by the format that is passed in *date* argument.

**Note** For *date*, if the **Calendar** property setting is Gregorian, the supplied date must be Gregorian. If the calendar is Hijri, the supplied date must be Hijri. If month values are names, the name must be consistent with the current **Calendar** property setting. To minimize the possibility of month names conflicting with the current **Calendar** property setting, enter numeric month values (Short Date format).

DateDiff Function

Returns a **Variant (Long)** specifying the number of time intervals between two specified dates.

## Syntax

**DateDiff**(*interval*, *date1*, *date2*[, *firstdayofweek*[, *firstweekofyear*]])

The **DateDiff** function syntax has these [named arguments](#):

Part	Description
<i>interval</i>	Required. <a href="#">String expression</a> that is the interval of time you use to calculate the difference between <i>date1</i> and <i>date2</i> .
<i>date1</i> , <i>date2</i>	Required; <b>Variant (Date)</b> . Two dates you want to use in the calculation.
<i>firstdayofweek</i>	Optional. A <a href="#">constant</a> that specifies the first day of the week. If not specified, Sunday is assumed.
<i>firstweekofyear</i>	Optional. A constant that specifies the first week of the year. If not specified, the first week is assumed to be the week in which January 1 occurs.

## Settings

The *interval* [argument](#) has these settings:

Setting	Description
yyyy	Year
q	Quarter
m	Month
y	Day of year
d	Day
w	Weekday
ww	Week
h	Hour
n	Minute
s	Second

The *firstdayofweek* argument has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use the NLS API setting.
<b>vbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

Constant	Value	Description
<b>vbUseSystem</b>	0	Use the NLS API setting.
<b>vbFirstJan1</b>	1	Start with week in which January 1 occurs (default).
<b>vbFirstFourDays</b>	2	Start with the first week that has at least four days in the new year.
<b>vbFirstFullWeek</b>	3	Start with first full week of the year.

## Remarks

You can use the **DateDiff** function to determine how many specified time intervals exist between two dates. For example, you might use **DateDiff** to calculate the number of days between two dates, or the number of weeks between today and the end of the year.

To calculate the number of days between *date1* and *date2*, you can use either Day of year ("y") or Day ("d"). When *interval* is Weekday ("w"), **DateDiff** returns the number of weeks between the two dates. If *date1* falls on a Monday,

**DateDiff** counts the number of Mondays until *date2*. It counts *date2* but not *date1*. If *interval* is Week ("ww"), however, the **DateDiff** function returns the number of calendar weeks between the two dates. It counts the number of Sundays between *date1* and *date2*. **DateDiff** counts *date2* if it falls on a Sunday; but it doesn't count *date1*, even if it does fall on a Sunday.

If *date1* refers to a later point in time than *date2*, the **DateDiff** function returns a negative number.

The *firstdayofweek* argument affects calculations that use the "w" and "ww" interval symbols.

If *date1* or *date2* is a [date literal](#), the specified year becomes a permanent part of that date. However, if *date1* or *date2* is enclosed in double quotation marks (" "), and you omit the year, the current year is inserted in your code each time the *date1* or *date2* expression is evaluated. This makes it possible to write code that can be used in different years.

When comparing December 31 to January 1 of the immediately succeeding year, **DateDiff** for Year ("yyyy") returns 1 even though only a day has elapsed.

**Note** For *date1* and *date2*, if the **Calendar** property setting is Gregorian, the supplied date must be Gregorian. If the calendar is Hijri, the supplied date must be Hijri.

DatePart Function

Returns a **Variant (Integer)** containing the specified part of a given date.

**Syntax**

**DatePart(interval, date[,firstdayofweek[, firstweekofyear]])**

The **DatePart** function syntax has these [named arguments](#):

Part	Description
<i>interval</i>	Required. <a href="#">String expression</a> that is the interval of time you want to return.
<i>date</i>	Required. <b>Variant (Date)</b> value that you want to evaluate.
<i>firstdayofweek</i>	Optional. A <a href="#">constant</a> that specifies the first day of the week. If not specified, Sunday is assumed.
<i>firstweekofyear</i>	Optional. A constant that specifies the first week of the year. If not specified, the first week is assumed to be the week in which January 1 occurs.

## Settings

The *interval* [argument](#) has these settings:

Setting	Description
yyyy	Year
q	Quarter
m	Month
y	Day of year
d	Day
w	Weekday
ww	Week
h	Hour
n	Minute
s	Second

The *firstdayofweek* argument has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use the NLS API setting.

<b>vbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

The *firstweekofyear* argument has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use the NLS API setting.
<b>vbFirstJan1</b>	1	Start with week in which January 1 occurs (default).
<b>vbFirstFourDays</b>	2	Start with the first week that has at least four days in the new year.
<b>vbFirstFullWeek</b>	3	Start with first full week of the year.

## Remarks

You can use the **DatePart** function to evaluate a date and return a specific interval of time. For example, you might use **DatePart** to calculate the day of the week or the current hour.

The *firstdayofweek* argument affects calculations that use the "w" and "ww" interval symbols.

If *date* is a [date literal](#), the specified year becomes a permanent part of that date. However, if *date* is enclosed in double quotation marks (" "), and you omit the year, the current year is inserted in your code each time the *date* expression is evaluated. This makes it possible to write code that can be used in different

years.

**Note** For *date*, if the **Calendar** property setting is Gregorian, the supplied date must be Gregorian. If the calendar is Hijri, the supplied date must be Hijri.

The returned date part is in the time period units of the current Arabic calendar. For example, if the current calendar is Hijri and the date part to be returned is the year, the year value is a Hijri year.

## DateSerial Function

Returns a **Variant (Date)** for a specified year, month, and day.

### Syntax

**DateSerial**(*year, month, day*)

The **DateSerial** function syntax has these [named arguments](#):

Part	Description
------	-------------

<b><i>year</i></b>	Required; <b>Integer</b> . Number between 100 and 9999, inclusive, or a <a href="#">numeric expression</a> .
<b><i>month</i></b>	Required; <b>Integer</b> . Any numeric expression.
<b><i>day</i></b>	Required; <b>Integer</b> . Any numeric expression.

## Remarks

To specify a date, such as December 31, 1991, the range of numbers for each **DateSerial** [argument](#) should be in the accepted range for the unit; that is, 1–31 for days and 1–12 for months. However, you can also specify relative dates for each argument using any numeric expression that represents some number of days, months, or years before or after a certain date.

The following example uses numeric expressions instead of absolute date numbers. Here the **DateSerial** function returns a date that is the day before the first day (1 - 1), two months before August (8 - 2), 10 years before 1990 (1990 - 10); in other words, May 31, 1980.

**DateSerial(1990 - 10, 8 - 2, 1 - 1)**

Under Windows 98 or Windows 2000, two digit years for the ***year*** argument are interpreted based on user-defined machine settings. The default settings are that values between 0 and 29, inclusive, are interpreted as the years 2000–2029. The default values between 30 and 99 are interpreted as the years 1930–1999. For all other ***year*** arguments, use a four-digit year (for example, 1800).

Earlier versions of Windows interpret two-digit years based on the defaults described above. To be sure the function returns the proper value, use a four-digit year.

When any argument exceeds the accepted range for that argument, it increments to the next larger unit as appropriate. For example, if you specify 35 days, it is evaluated as one month and some number of days, depending on where in the year it is applied. If any single argument is outside the range -32,768 to 32,767, an error occurs. If the date specified by the three arguments falls outside the acceptable range of dates, an error occurs.

**Note** For ***year***, ***month***, and ***day***, if the **Calendar** property setting is Gregorian,

the supplied value is assumed to be Gregorian. If the **Calendar** property setting is Hijri, the supplied value is assumed to be Hijri.

The returned date part is in the time period units of the current Visual Basic calendar. For example, if the current calendar is Hijri and the date part to be returned is the year, the year value is a Hijri year. For the argument *year*, values between 0 and 99, inclusive, are interpreted as the years 1400-1499. For all other *year* values, use the complete four-digit year (for example, 1520).

DateValue Function

Returns a **Variant (Date)**.

### **Syntax**

**DateValue**(*date*)

The required *date* [argument](#) is normally a [string expression](#) representing a date from January 1, 100 through December 31, 9999. However, *date* can also be any [expression](#) that can represent a date, a time, or both a date and time, in that

range.

## Remarks

If *date* is a string that includes only numbers separated by valid [date separators](#), **DateValue** recognizes the order for month, day, and year according to the Short Date format you specified for your system. **DateValue** also recognizes unambiguous dates that contain month names, either in long or abbreviated form. For example, in addition to recognizing 12/30/1991 and 12/30/91, **DateValue** also recognizes December 30, 1991 and Dec 30, 1991.

If the year part of *date* is omitted, **DateValue** uses the current year from your computer's system date.

If the *date* argument includes time information, **DateValue** doesn't return it. However, if *date* includes invalid time information (such as "89:98"), an error occurs.

**Note** For *date*, if the **Calendar** property setting is Gregorian, the supplied date must be Gregorian. If the calendar is Hijri, the supplied date must be Hijri. If the supplied date is Hijri, the argument *date* is a **String** representing a date from 1/1/100 (Gregorian Aug 2, 718) through 4/3/9666 (Gregorian Dec 31, 9999).

Day Function

Returns a **Variant (Integer)** specifying a whole number between 1 and 31, inclusive, representing the day of the month.

## Syntax

### **Day**(*date*)

The required *date* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a date. If *date* contains [Null](#), **Null** is returned.

**Note** If the **Calendar** property setting is Gregorian, the returned integer represents the Gregorian day of the month for the date argument. If the calendar is Hijri, the returned integer represents the Hijri day of the month for the date argument.

## DDB Function

Returns a [Double](#) specifying the depreciation of an asset for a specific time period using the double-declining balance method or some other method you specify.

### Syntax

**DDB(*cost, salvage, life, period*[, *factor*])**

The **DDB** function has these [named arguments](#):

Part	Description
<i>cost</i>	Required. <b>Double</b> specifying initial cost of the asset.
<i>salvage</i>	Required. <b>Double</b> specifying value of the asset at the end of its useful life.
<i>life</i>	Required. <b>Double</b> specifying length of useful life of the asset.
<i>period</i>	Required. <b>Double</b> specifying period for which asset depreciation is calculated.
<i>factor</i>	Optional. <a href="#">Variant</a> specifying rate at which the balance declines. If omitted, 2 (double-declining method) is assumed.

## Remarks

The double-declining balance method computes depreciation at an accelerated rate. Depreciation is highest in the first period and decreases in successive periods.

The *life* and *period* [arguments](#) must be expressed in the same units. For example, if *life* is given in months, *period* must also be given in months. All arguments must be positive numbers.

The **DDB** function uses the following formula to calculate depreciation for a given period:

$$\text{Depreciation} / \textit{period} = ((\textit{cost} - \textit{salvage}) * \textit{factor}) / \textit{life}$$

Dir Function

Returns a **String** representing the name of a file, directory, or folder that matches a specified pattern or file attribute, or the volume label of a drive.

## Syntax

**Dir**[(*pathname*[, *attributes*])]

The **Dir** function syntax has these parts:

Part	Description
<i>pathname</i>	Optional. <a href="#">String expression</a> that specifies a file name — may include directory or folder, and drive. A zero-length string ("") is returned if <i>pathname</i> is not found.
<i>attributes</i>	Optional. <a href="#">Constant</a> or <a href="#">numeric expression</a> , whose sum specifies file attributes. If omitted, returns files that match <i>pathname</i> but have no attributes.

## Settings

The *attributes* [argument](#) settings are:

Constant	Value	Description
<b>vbNormal</b>	0	(Default) Specifies files with no attributes.
<b>vbReadOnly</b>	1	Specifies read-only files in addition to files with no attributes.
<b>vbHidden</b>	2	Specifies hidden files in addition to files with no attributes.
<b>VbSystem</b>	4	Specifies system files in addition to files with no attributes. Not available on the Macintosh.
<b>vbVolume</b>	8	Specifies volume label; if any other attributed is specified, <b>vbVolume</b> is ignored. Not available on the Macintosh.
<b>vbDirectory</b>	16	Specifies directories or folders in addition to files with no attributes.
<b>vbAlias</b>	64	Specified file name is an alias. Available only on the Macintosh.

**Note** These constants are specified by Visual Basic for Applications and can be used anywhere in your code in place of the actual values.

## Remarks

In Microsoft Windows, **Dir** supports the use of multiple character (\*) and single character (?) wildcards to specify multiple files. On the Macintosh, these characters are treated as valid file name characters and can't be used as wildcards to specify multiple files.

Since the Macintosh doesn't support the wildcards, use the file type to identify groups of files. You can use the **MacID** function to specify file type instead of using the file names. For example, the following statement returns the name of the first TEXT file in the current folder:

```
Dir("SomePath", MacID("TEXT"))
```

To iterate over all files in a folder, specify an empty string:

```
Dir("")
```

If you use the **MacID** function with **Dir** in Microsoft Windows, an error occurs.

Any *attribute* value greater than 256 is considered a **MacID** value.

You must specify *pathname* the first time you call the **Dir** function, or an error occurs. If you also specify file attributes, *pathname* must be included.

**Dir** returns the first file name that matches *pathname*. To get any additional file names that match *pathname*, call **Dir** again with no arguments. When no more file names match, **Dir** returns a zero-length string (""). Once a zero-length string is returned, you must specify *pathname* in subsequent calls or an error occurs. You can change to a new *pathname* without retrieving all of the file names that match the current *pathname*. However, you can't call the **Dir** function recursively. Calling **Dir** with the **vbDirectory** attribute does not continually return subdirectories.

**Tip** Because file names are retrieved in no particular order, you may want to store returned file names in an [array](#), and then sort the array.

## DoEvents Function

Yields execution so that the operating system can process other events.

### Syntax

**DoEvents( )**

### Remarks

The **DoEvents** function returns an [Integer](#) representing the number of open forms in stand-alone versions of Visual Basic, such as Visual Basic, Professional Edition. **DoEvents** returns zero in all other applications.

**DoEvents** passes control to the operating system. Control is returned after the operating system has finished processing the events in its queue and all keys in the **SendKeys** queue have been sent.

**DoEvents** is most useful for simple things like allowing a user to cancel a process after it has started, for example a search for a file. For long-running processes, yielding the processor is better accomplished by using a Timer or delegating the task to an ActiveX EXE component.. In the latter case, the task can continue completely independent of your application, and the operating system takes care of multitasking and time slicing.

**Caution** Any time you temporarily yield the processor within an event procedure, make sure the [procedure](#) is not executed again from a different part of your code before the first call returns; this could cause unpredictable results. In addition, do not use **DoEvents** if other applications could possibly interact with your procedure in unforeseen ways during the time you have yielded control.

Environ Function

Returns the **String** associated with an operating system environment variable.  
Not available on the Macintosh

### Syntax

**Environ**({*envstring* | *number*})

The **Environ** function syntax has these [named arguments](#):

Part	Description
<i>envstring</i>	Optional. <a href="#">String expression</a> containing the name of an environment variable.
<i>number</i>	Optional. <a href="#">Numeric expression</a> corresponding to the numeric order of the environment string in the environment-string table. The <i>number argument</i> can be any numeric expression, but is rounded to a whole number before it is evaluated.

## Remarks

If *envstring* can't be found in the environment-string table, a zero-length string ("" ) is returned. Otherwise, **Environ** returns the text assigned to the specified *envstring*; that is, the text following the equal sign (=) in the environment-string table for that environment variable.

If you specify *number*, the string occupying that numeric position in the environment-string table is returned. In this case, **Environ** returns all of the text, including *envstring*. If there is no environment string in the specified position, **Environ** returns a zero-length string.

EOF Function

Returns an [Integer](#) containing the [Boolean](#) value **True** when the end of a file opened for **Random** or sequential **Input** has been reached.

### Syntax

**EOF**(*filenumber*)

The required *filenumber* [argument](#) is an **Integer** containing any valid [file number](#).

## Remarks

Use **EOF** to avoid the error generated by attempting to get input past the end of a file.

The **EOF** function returns **False** until the end of the file has been reached. With files opened for **Random** or **Binary** access, **EOF** returns **False** until the last executed **Get** statement is unable to read an entire record.

With files opened for **Binary** access, an attempt to read through the file using the **Input** function until **EOF** returns **True** generates an error. Use the **LOF** and **Loc** functions instead of **EOF** when reading binary files with **Input**, or use **Get** when using the **EOF** function. With files opened for **Output**, **EOF** always returns **True**.

## Error Function

Returns the error message that corresponds to a given [error number](#).

### Syntax

**Error**[(*errornumber*)]

The optional *errornumber* [argument](#) can be any valid error number. If *errornumber* is a valid error number, but is not defined, **Error** returns the string "Application-defined or object-defined error." If *errornumber* is not valid, an

error occurs. If *errornumber* is omitted, the message corresponding to the most recent [run-time error](#) is returned. If no run-time error has occurred, or *errornumber* is 0, **Error** returns a zero-length string ("").

## Remarks

Examine the [property](#) settings of the **Err** object to identify the most recent run-time error. The return value of the **Error** function corresponds to the **Description** property of the **Err** object.

Exp Function

Returns a **Double** specifying  $e$  (the base of natural logarithms) raised to a power.

### Syntax

**Exp**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#).

### Remarks

If the value of *number* exceeds 709.782712893, an error occurs. The [constant](#) *e* is approximately 2.718282.

**Note** The **Exp** function complements the action of the **Log** function and is sometimes referred to as the antilogarithm.

FileAttr Function

Returns a [Long](#) representing the file mode for files opened using the **Open** statement.

## Syntax

### **FileAttr**(*filenumber*, *returntype*)

The **FileAttr** function syntax has these [named arguments](#):

Part	Description
<i>filenumber</i>	Required; <a href="#">Integer</a> . Any valid <a href="#">file number</a> .
<i>returntype</i>	Required; <b>Integer</b> . Number indicating the type of information to return. Specify 1 to return a value indicating the file mode. On 16-bit systems only, specify 2 to retrieve an operating system file handle. <b>Returntype</b> 2 is not supported in 32-bit systems and causes an error.

## Return Values

When the **returntype** [argument](#) is 1, the following return values indicate the file access mode:

Mode	Value
<b>Input</b>	1
<b>Output</b>	2
<b>Random</b>	4
<b>Append</b>	8
<b>Binary</b>	32

## FileDateTime Function

Returns a **Variant (Date)** that indicates the date and time when a file was created or last modified.

### Syntax

**FileDateTime**(*pathname*)

The required *pathname* [argument](#) is a [string expression](#) that specifies a file name. The *pathname* may include the directory or folder, and the drive.

FileLen Function

Returns a [Long](#) specifying the length of a file in bytes.

### Syntax

**FileLen**(*pathname*)

The required *pathname* [argument](#) is a [string expression](#) that specifies a file. The *pathname* may include the directory or folder, and the drive.

### Remarks

If the specified file is open when the **FileLen** function is called, the value returned represents the size of the file immediately before it was opened.

**Note** To obtain the length of an open file, use the **LOF** function.

## Description

Returns a zero-based array containing subset of a string array based on a specified filter criteria.

## Syntax

**Filter**(*sourcearray*, *match*[, *include*[, *compare*]])

The **Filter** function syntax has these [named argument](#):

Part	Description
<i>sourcearray</i>	Required. One-dimensional array of strings to be searched.
<i>match</i>	Required. String to search for.
<i>include</i>	Optional. <b>Boolean</b> value indicating whether to return substrings that include or exclude <i>match</i> . If <i>include</i> is <b>True</b> , <b>Filter</b> returns the subset of the array that contains <i>match</i> as a substring. If <i>include</i> is <b>False</b> , <b>Filter</b> returns the subset of the array that does not contain <i>match</i> as a substring.
<i>compare</i>	Optional. Numeric value indicating the kind of string

comparison to use. See Settings section for values.

## Settings

The ***compare*** argument can have the following values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Remarks

If no matches of ***match*** are found within ***sourcearray***, **Filter** returns an empty array. An error occurs if ***sourcearray*** is **Null** or is not a one-dimensional array.

The array returned by the **Filter** function contains only enough elements to contain the number of matched items.

Int, Fix Functions

Returns the integer portion of a number.

### **Syntax**

**Int**(*number*)

**Fix**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#). If

*number* contains [Null](#), **Null** is returned.

## Remarks

Both **Int** and **Fix** remove the fractional part of *number* and return the resulting integer value.

The difference between **Int** and **Fix** is that if *number* is negative, **Int** returns the first negative integer less than or equal to *number*, whereas **Fix** returns the first negative integer greater than or equal to *number*. For example, **Int** converts -8.4 to -9, and **Fix** converts -8.4 to -8.

**Fix**(*number*) is equivalent to:

$$\text{Sgn}(\textit{number}) * \text{Int}(\text{Abs}(\textit{number}))$$

## Format Function

Returns a **Variant (String)** containing an [expression](#) formatted according to instructions contained in a format expression.

### Syntax

**Format**(*expression*[, *format*[, *firstdayofweek*[, *firstweekofyear*]]])

The **Format** function syntax has these parts:

Part	Description
------	-------------

<i>expression</i>	Required. Any valid expression.
<i>format</i>	Optional. A valid named or user-defined format expression.
<i>firstdayofweek</i>	Optional. A <a href="#">constant</a> that specifies the first day of the week.
<i>firstweekofyear</i>	Optional. A constant that specifies the first week of the year.

## Settings

The *firstdayofweek* [argument](#) has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use NLS API setting.
<b>VbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

The *firstweekofyear* argument has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use NLS API setting.
<b>vbFirstJan1</b>	1	Start with week in which January 1 occurs (default).
<b>vbFirstFourDays</b>	2	Start with the first week that has at least four days in the year.
<b>vbFirstFullWeek</b>	3	Start with the first full week of the year.

## Remarks

To Format	Do This
Numbers	Use predefined named numeric formats or create user-defined numeric formats.
Dates and times	Use predefined named date/time formats or create user-defined date/time formats.
Date and time serial numbers	Use date and time formats or numeric formats.
Strings	Create your own user-defined string formats.

If you try to format a number without specifying *format*, **Format** provides functionality similar to the **Str** function, although it is internationally aware. However, positive numbers formatted as strings using **Format** don't include a leading space reserved for the sign of the value; those converted using **Str** retain the leading space.

If you are formatting a non-localized numeric string, you should use a user-defined numeric format to ensure that you get the look you want.

**Note** If the **Calendar** property setting is Gregorian and *format* specifies date formatting, the supplied *expression* must be Gregorian. If the Visual Basic **Calendar** property setting is Hijri, the supplied *expression* must be Hijri.

If the calendar is Gregorian, the meaning of *format* expression symbols is unchanged. If the calendar is Hijri, all date format symbols (for example, *dddd*, *mmmm*, *yyyy*) have the same meaning but apply to the Hijri calendar. Format symbols remain in English; symbols that result in text display (for example, AM and PM) display the string (English or Arabic) associated with that symbol. The range of certain symbols changes when the calendar is Hijri.

Symbol	Range
<i>d</i>	1-30
<i>dd</i>	1-30
<i>ww</i>	1-51

*mmm*

Displays full month names (Hijri  
month names have no abbreviations).

*y*

1-355

*yyyy*

100-9666

## Description

Returns an expression formatted as a currency value using the currency symbol defined in the system control panel.

## Syntax

**FormatCurrency**(*Expression* [, *NumDigitsAfterDecimal* [, *IncludeLeadingDigit* [, *UseParensForNegativeNumbers* [, *GroupDigits*]]]])

The **FormatCurrency** function syntax has these parts:

Part	Description
<i>Expression</i>	Required. Expression to be formatted.
<i>NumDigitsAfterDecimal</i>	Optional. Numeric value indicating how many places to the right of the decimal are displayed. Default value is –1, which indicates that the computer's regional settings are used.
<i>IncludeLeadingDigit</i>	Optional. Tristate constant that indicates whether or not a leading zero is displayed for fractional values. See Settings section

for values.

*UseParensForNegativeNumbers*

Optional. Tristate constant that indicates whether or not to place negative values within parentheses. See Settings section for values.

*GroupDigits*

Optional. Tristate constant that indicates whether or not numbers are grouped using the group delimiter specified in the computer's regional settings. See Settings section for values.

## Settings

The *IncludeLeadingDigit*, *UseParensForNegativeNumbers*, and *GroupDigits* arguments have the following settings:

Constant	Value	Description
<b>vbTrue</b>	-1	True
<b>vbFalse</b>	0	False
<b>vbUseDefault</b>	-2	Use the setting from the computer's regional settings.

## Remarks

When one or more optional arguments are omitted, the values for omitted arguments are provided by the computer's regional settings.

The position of the currency symbol relative to the currency value is determined by the system's regional settings.

**Note** All settings information comes from the **Regional Settings Currency** tab, except leading zero which comes from the **Number** tab.

## Description

Returns an expression formatted as a date or time.

## Syntax

**FormatDateTime**(*Date*[,*NamedFormat*])

The **FormatDateTime** function syntax has these parts:

Part	Description
<i>Date</i>	Required. Date expression to be formatted.
<i>NamedFormat</i>	Optional. Numeric value that indicates the date/time format used. If omitted, <b>vbGeneralDate</b> is used.

## Settings

The *NamedFormat* argument has the following settings:

Constant	Value	Description
<b>vbGeneralDate</b>	0	Display a date and/or time. If there is a date part, display it as a short date. If there is a time

part, display it as a long time. If present, both parts are displayed.

<b>vbLongDate</b>	1	Display a date using the long date format specified in your computer's regional settings.
<b>vbShortDate</b>	2	Display a date using the short date format specified in your computer's regional settings.
<b>vbLongTime</b>	3	Display a time using the time format specified in your computer's regional settings.
<b>vbShortTime</b>	4	Display a time using the 24-hour format (hh:mm).

## Description

Returns an expression formatted as a number.

## Syntax

**FormatNumber**(*Expression* [, *NumDigitsAfterDecimal* [, *IncludeLeadingDigit* [, *UseParensForNegativeNumbers* [, *GroupDigits*]]]])

The **FormatNumber** function syntax has these parts:

Part	Description
<i>Expression</i>	Required. Expression to be formatted.
<i>NumDigitsAfterDecimal</i>	Optional. Numeric value indicating how many places to the right of the decimal are displayed. Default value is –1, which indicates that the computer's regional settings are used.
<i>IncludeLeadingDigit</i>	Optional. Tristate constant that indicates whether or not a leading zero is displayed for fractional values. See Settings section for values.

*UseParensForNegativeNumbers* Optional. Tristate constant that indicates whether or not to place negative values within parentheses. See Settings section for values.

*GroupDigits* Optional. Tristate constant that indicates whether or not numbers are grouped using the group delimiter specified in the computer's regional settings. See Settings section for values.

## Settings

The *IncludeLeadingDigit*, *UseParensForNegativeNumbers*, and *GroupDigits* arguments have the following settings:

Constant	Value	Description
<b>vbTrue</b>	–1	True
<b>vbFalse</b>	0	False
<b>vbUseDefault</b>	–2	Use the setting from the computer's regional settings.

## Remarks

When one or more optional arguments are omitted, the values for omitted arguments are provided by the computer's regional settings.

**Note** All settings information comes from the **Regional Settings Number** tab.

## Description

Returns an expression formatted as a percentage (multiplied by 100) with a trailing % character.

## Syntax

**FormatPercent**(*Expression* [, *NumDigitsAfterDecimal* [, *IncludeLeadingDigit* [, *UseParensForNegativeNumbers* [, *GroupDigits*]]]])

The **FormatPercent** function syntax has these parts:

Part	Description
<i>Expression</i>	Required. Expression to be formatted.
<i>NumDigitsAfterDecimal</i>	Optional. Numeric value indicating how many places to the right of the decimal are displayed. Default value is -1, which indicates that the computer's regional settings are used.
<i>IncludeLeadingDigit</i>	Optional. Tristate constant that indicates whether or not a leading zero is displayed for fractional values. See Settings section

for values.

*UseParensForNegativeNumbers*

Optional. Tristate constant that indicates whether or not to place negative values within parentheses. See Settings section for values.

*GroupDigits*

Optional. Tristate constant that indicates whether or not numbers are grouped using the group delimiter specified in the computer's regional settings. See Settings section for values.

## Settings

The *IncludeLeadingDigit*, *UseParensForNegativeNumbers*, and *GroupDigits* arguments have the following settings:

Constant	Value	Description
<b>vbTrue</b>	-1	True
<b>vbFalse</b>	0	False
<b>vbUseDefault</b>	-2	Use the setting from the computer's regional settings.

## Remarks

When one or more optional arguments are omitted, the values for omitted arguments are provided by the computer's regional settings.

**Note** All settings information comes from the **Regional Settings Number** tab.

#### FreeFile Function

Returns an [Integer](#) representing the next [file number](#) available for use by the **Open** statement.

#### Syntax

**FreeFile**[(*rangenum*)]

The optional *rangenum* argument is a [Variant](#) that specifies the range from which the next free file number is to be returned. Specify a 0 (default) to return a

file number in the range 1 – 255, inclusive. Specify a 1 to return a file number in the range 256 – 511.

### **Remarks**

Use **FreeFile** to supply a file number that is not already in use.

FV Function

Returns a [Double](#) specifying the future value of an annuity based on periodic, fixed payments and a fixed interest rate.

## Syntax

**FV**(*rate*, *nper*, *pmt*[, *pv*[, *type*]])

The **FV** function has these [named arguments](#):

Part	Description
<b>rate</b>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<b>nper</b>	Required. <a href="#">Integer</a> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of 4 * 12 (or 48) payment periods.
<b>pmt</b>	Required. <b>Double</b> specifying payment to be made each period. Payments usually contain principal and interest that doesn't change over the life of the annuity.
<b>pv</b>	Optional. <a href="#">Variant</a> specifying present value (or lump sum) of a series of future payments. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make. If omitted, 0 is assumed.
<b>type</b>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

The **rate** and **nper** [arguments](#) must be calculated using payment periods expressed in the same units. For example, if **rate** is calculated using months, **nper** must also be calculated using months.

For all arguments, cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by positive numbers.

GetAllSettings Function

Returns a list of key settings and their respective values (originally created with **SaveSetting**) from an application's entry in the Windows [registry](#) or (on the

Macintosh) information in the application's initialization file.

## Syntax

### **GetAllSettings(*appname*, *section*)**

The **GetAllSettings** function syntax has these [named arguments](#):

Part	Description
<b><i>appname</i></b>	Required. <a href="#">String expression</a> containing the name of the application or <a href="#">project</a> whose key settings are requested. On the Macintosh, this is the filename of the initialization file in the Preferences folder in the System folder.
<b><i>section</i></b>	Required. String <b>expression</b> containing the name of the section whose key settings are requested. <b>GetAllSettings</b> returns a <a href="#">Variant</a> whose contents is a two-dimensional <a href="#">array</a> of strings containing all the key settings in the specified section and their corresponding values.

## Remarks

**GetAllSettings** returns an uninitialized **Variant** if either ***appname*** or ***section*** does not exist.

## GetAttr Function

Returns an **Integer** representing the attributes of a file, directory, or folder.

### Syntax

**GetAttr**(*pathname*)

The required *pathname* [argument](#) is a [string expression](#) that specifies a file name. The *pathname* may include the directory or folder, and the drive.

### Return Values

The value returned by **GetAttr** is the sum of the following attribute values:

Constant	Value	Description
<b>vbNormal</b>	0	Normal.
<b>vbReadOnly</b>	1	Read-only.
<b>vbHidden</b>	2	Hidden.
<b>vbSystem</b>	4	System file. Not available on the Macintosh.
<b>vbDirectory</b>	16	Directory or folder.
<b>vbArchive</b>	32	File has changed since last backup. Not available on the Macintosh.
<b>vbAlias</b>	64	Specified file name is an alias. Available only on the Macintosh.

**Note** These [constants](#) are specified by Visual Basic for Applications. The names can be used anywhere in your code in place of the actual values.

### Remarks

To determine which attributes are set, use the **And** operator to perform a [bitwise comparison](#) of the value returned by the **GetAttr** function and the value of the individual file attribute you want. If the result is not zero, that attribute is set for the named file. For example, the return value of the following **And** expression is zero if the Archive attribute is not set:

```
Result = GetAttr(FName) And vbArchive
```

A nonzero value is returned if the Archive attribute is set.

GetObject Function

Returns a reference to an object provided by an ActiveX component.

**Syntax**

## **GetObject**([*pathname*] [, *class*])

The **GetObject** function syntax has these [named arguments](#):

Part	Description
<i>pathname</i>	Optional; <b>Variant (String)</b> . The full path and name of the file containing the object to retrieve. If <i>pathname</i> is omitted, <i>class</i> is required.
<i>class</i>	Optional; <b>Variant (String)</b> . A string representing the <a href="#">class</a> of the object.

The *class* [argument](#) uses the syntax *appname.objecttype* and has these parts:

Part	Description
<i>appname</i>	Required; <b>Variant (String)</b> . The name of the application providing the object.
<i>objecttype</i>	Required; <b>Variant (String)</b> . The type or class of object to create.

## Remarks

Use the **GetObject** function to access an ActiveX object from a file and assign the object to an [object variable](#). Use the **Set** statement to assign the object returned by **GetObject** to the object variable. For example:

```
Dim CADObject As Object
Set CADObject = GetObject("C:\CAD\SCHEMA.CAD")
```

When this code is executed, the application associated with the specified *pathname* is started and the object in the specified file is activated.

If *pathname* is a zero-length string (""), **GetObject** returns a new object instance of the specified type. If the *pathname* argument is omitted, **GetObject** returns a currently active object of the specified type. If no object of the specified type exists, an error occurs.

Some applications allow you to activate part of a file. Add an exclamation point

(!) to the end of the file name and follow it with a string that identifies the part of the file you want to activate. For information on how to create this string, see the documentation for the application that created the object.

For example, in a drawing application you might have multiple layers to a drawing stored in a file. You could use the following code to activate a layer within a drawing called `SCHEMA.CAD`:

```
Set LayerObject = GetObject("C:\CAD\SCHEMA.CAD!
```

If you don't specify the object's **class**, Automation determines the application to start and the object to activate, based on the file name you provide. Some files, however, may support more than one class of object. For example, a drawing might support three different types of objects: an **Application** object, a **Drawing** object, and a **Toolbar** object, all of which are part of the same file. To specify which object in a file you want to activate, use the optional **class** argument. For example:

```
Dim MyObject As Object  
Set MyObject = GetObject("C:\DRAWINGS\SAMPLE.DR
```

In the example, `FIGMENT` is the name of a drawing application and `DRAWING` is one of the object types it supports.

Once an object is activated, you reference it in code using the object variable you defined. In the preceding example, you access [properties](#) and [methods](#) of the new object using the object variable `MyObject`. For example:

```
MyObject.Line 9, 90  
MyObject.InsertText 9, 100, "Hello, world."  
MyObject.SaveAs "C:\DRAWINGS\SAMPLE.DRW"
```

**Note** Use the **GetObject** function when there is a current instance of the object or if you want to create the object with a file already loaded. If there is no current instance, and you don't want the object started with a file loaded, use the **CreateObject** function.

If an object has registered itself as a single-instance object, only one instance of

the object is created, no matter how many times **CreateObject** is executed. With a single-instance object, **GetObject** always returns the same instance when called with the zero-length string ("" ) syntax, and it causes an error if the *pathname* argument is omitted. You can't use **GetObject** to obtain a reference to a class created with Visual Basic.

## GetSetting Function

Returns a key setting value from an application's entry in the Windows [registry](#) or (on the Macintosh) information in the application's initialization file.

### Syntax

**GetSetting**(*appname*, *section*, *key*[, *default*])

The **GetSetting** function syntax has these [named arguments](#):

Part	Description
<b><i>appname</i></b>	Required. <a href="#">String expression</a> containing the name of the application or project whose key setting is requested. On the Macintosh, this is the filename of the initialization file in the Preferences folder in the System folder.
<b><i>section</i></b>	Required. String expression containing the name of the section where the key setting is found.
<b><i>key</i></b>	Required. String expression containing the name of the key setting to return.
<b><i>default</i></b>	Optional. <a href="#">Expression</a> containing the value to return if no value is set in the key setting. If omitted, <b><i>default</i></b> is assumed to be a zero-length string ("").

## Remarks

If any of the items named in the **GetSetting** arguments do not exist, **GetSetting** returns the value of ***default***.

Hex Function

Returns a [String](#) representing the hexadecimal value of a number.

**Syntax**

## Hex(*number*)

The required *number* [argument](#) is any valid [numeric expression](#) or [string expression](#).

### Remarks

If *number* is not already a whole number, it is rounded to the nearest whole number before being evaluated.

If <i>number</i> is	Hex returns
<a href="#">Null</a>	Null
<a href="#">Empty</a>	Zero (0)
Any other number	Up to eight hexadecimal characters

You can represent hexadecimal numbers directly by preceding numbers in the proper range with &H. For example, &H10 represents decimal 16 in hexadecimal notation.

Hour Function

Returns a **Variant (Integer)** specifying a whole number between 0 and 23, inclusive, representing the hour of the day.

## Syntax

### **Hour**(*time*)

The required *time* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a time. If *time* contains [Null](#), **Null** is returned.

IIf

Function

Returns one of two parts, depending on the evaluation of an [expression](#).

## Syntax

**IIf(*expr*, *truepart*, *falsepart*)**

The **IIf** function syntax has these [named arguments](#):

Part	Description
<i>expr</i>	Required. Expression you want to evaluate.
<i>truepart</i>	Required. Value or expression returned if <i>expr</i> is <b>True</b> .
<i>falsepart</i>	Required. Value or expression returned if <i>expr</i> is <b>False</b> .

## Remarks

**IIf** always evaluates both *truepart* and *falsepart*, even though it returns only one

of them. Because of this, you should watch for undesirable side effects. For example, if evaluating ***falsepart*** results in a division by zero error, an error occurs even if ***expr*** is **True**.

## IMEStatus Function

Returns an [Integer](#) specifying the current Input Method Editor (IME) mode of Microsoft Windows; available in East Asian versions only.

### Syntax

### IMEStatus

### Return Values

The return values for the Japanese [locale](#) are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME (default)
<b>vbIMEModeOn</b>	1	IME on
<b>vbIMEModeOff</b>	2	IME off

<b>vbIMEModeDisable</b>	3	IME disabled
<b>vbIMEModeHiragana</b>	4	Full-width Hiragana mode
<b>vbIMEModeKatakana</b>	5	Full-width Katakana mode
<b>vbIMEModeKatakanaHalf</b>	6	Half-width Katakana mode
<b>vbIMEModeAlphaFull</b>	7	Full-width Alphanumeric mode
<b>vbIMEModeAlpha</b>	8	Half-width Alphanumeric mode

The return values for the Korean locale are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME(default)
<b>vbIMEModeAlphaFull</b>	7	Full-width Alphanumeric mode
<b>vbIMEModeAlpha</b>	8	Half-width Alphanumeric mode
<b>vbIMEModeHangulFull</b>	9	Full-width Hangul mode
<b>vbIMEModeHangul</b>	10	Half-width Hangul mode

The return values for the Chinese locale are as follows:

Constant	Value	Description
<b>vbIMEModeNoControl</b>	0	Don't control IME (default)
<b>vbIMEModeOn</b>	1	IME on
<b>vbIMEModeOff</b>	2	IME off

## Input Function

Returns [String](#) containing characters from a file opened in **Input** or **Binary** mode.

### Syntax

**Input**(*number*, [#]*filenumber*)

The **Input** function syntax has these parts:

Part	Description
------	-------------

*number* Required. Any valid [numeric expression](#) specifying the number of characters to return.

*filenumber* Required. Any valid [file number](#).

## Remarks

Data read with the **Input** function is usually written to a file with **Print #** or **Put**. Use this function only with files opened in **Input** or **Binary** mode.

Unlike the **Input #** statement, the **Input** function returns all of the characters it reads, including commas, carriage returns, linefeeds, quotation marks, and leading spaces.

With files opened for **Binary** access, an attempt to read through the file using the **Input** function until **EOF** returns **True** generates an error. Use the **LOF** and **Loc** functions instead of **EOF** when reading binary files with **Input**, or use **Get** when using the **EOF** function.

**Note** Use the **InputB** function for byte data contained within text files. With **InputB**, *number* specifies the number of bytes to return rather than the number of characters to return.

InputBox Function

Displays a prompt in a dialog box, waits for the user to input text or click a button, and returns a [String](#) containing the contents of the text box.

## Syntax

**InputBox(prompt[, title] [, default] [, xpos] [, ypos] [, helpfile, context])**

The **InputBox** function syntax has these [named arguments](#):

Part	Description
<b>prompt</b>	Required. <a href="#">String expression</a> displayed as the message in the dialog box. The maximum length of <b>prompt</b> is approximately 1024 characters, depending on the width of the characters used. If <b>prompt</b> consists of more than one line, you can separate the lines using a carriage return character ( <b>Chr(13)</b> ), a linefeed character ( <b>Chr(10)</b> ), or carriage return–linefeed character combination ( <b>Chr(13) &amp; Chr(10)</b> ) between each line.
<b>title</b>	Optional. String expression displayed in the title bar of the dialog box. If you omit <b>title</b> , the application name is placed in the title bar.
<b>default</b>	Optional. String expression displayed in the text box as the default response if no other input is provided. If you omit <b>default</b> , the text box is displayed empty.
<b>xpos</b>	Optional. <a href="#">Numeric expression</a> that specifies, in twips, the horizontal distance of the left edge of the dialog box from the left edge of the screen. If <b>xpos</b> is omitted, the dialog box is horizontally centered.
<b>ypos</b>	Optional. Numeric expression that specifies, in twips, the vertical distance of the upper edge of the dialog box from the top of the screen. If <b>ypos</b> is omitted, the dialog box is vertically

	positioned approximately one-third of the way down the screen.
<b><i>helpfile</i></b>	Optional. String expression that identifies the Help file to use to provide context-sensitive Help for the dialog box. If <b><i>helpfile</i></b> is provided, <b><i>context</i></b> must also be provided.
<b><i>context</i></b>	Optional. Numeric expression that is the Help context number assigned to the appropriate Help topic by the Help author. If <b><i>context</i></b> is provided, <b><i>helpfile</i></b> must also be provided.

## Remarks

When both ***helpfile*** and ***context*** are provided, the user can press F1 (Windows) or HELP (Macintosh) to view the Help topic corresponding to the ***context***. Some [host applications](#), for example, Microsoft Excel, also automatically add a **Help** button to the dialog box. If the user clicks **OK** or presses ENTER, the **InputBox** function returns whatever is in the text box. If the user clicks **Cancel**, the function returns a zero-length string ("").

**Note** To specify more than the first named argument, you must use **InputBox** in an [expression](#). To omit some positional [arguments](#), you must include the corresponding comma delimiter.

InStr Function

Returns a **Variant (Long)** specifying the position of the first occurrence of one string within another.

## Syntax

**InStr**(*[start, ]string1, string2[, compare]*)

The **InStr** function syntax has these [arguments](#):

Part	Description
<i>start</i>	Optional. <a href="#">Numeric expression</a> that sets the starting position for each search. If omitted, search begins at the first character position. If <b>start</b> contains <a href="#">Null</a> , an error occurs. The <b>start</b> argument is required if <b>compare</b> is specified.
<i>string1</i>	Required. <a href="#">String expression</a> being searched.
<i>string2</i>	Required. String expression sought.
<i>compare</i>	Optional. Specifies the type of <a href="#">string comparison</a> . If <b>compare</b> is Null, an error occurs. If <b>compare</b> is omitted, the <b>Option Compare</b> setting determines the type of comparison. Specify a valid LCID (LocaleID) to use locale-specific rules in the comparison.

## Settings

The *compare* argument settings are:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Return Values

If	InStr returns
----	---------------

<i>string1</i> is zero-length	0
<i>string1</i> is <b>Null</b>	Null
<i>string2</i> is zero-length	<i>start</i>
<i>string2</i> is <b>Null</b>	Null
<i>string2</i> is not found	0
<i>string2</i> is found within <i>string1</i>	Position at which match is found
<i>start</i> > <i>string2</i>	0

## Remarks

The **InStrB** function is used with byte data contained in a string. Instead of returning the character position of the first occurrence of one string within another, **InStrB** returns the byte position.

InStrRev Function

## Description

Returns the position of an occurrence of one string within another, from the end of string.

## Syntax

**InstrRev**(*stringcheck*, *stringmatch*[, *start*[, *compare*]])

The **InstrRev** function syntax has these [named arguments](#):

Part	Description
<i>stringcheck</i>	Required. <a href="#">String expression</a> being searched.
<i>stringmatch</i>	Required. String expression being searched for.
<i>start</i>	Optional. <a href="#">Numeric expression</a> that sets the starting position for each search. If omitted, -1 is used, which means that the search begins at the last character position. If <i>start</i> contains <a href="#">Null</a> , an error occurs.
<i>compare</i>	Optional. Numeric value indicating the kind of comparison to use when evaluating substrings. If omitted, a binary comparison is performed. See Settings section for values.

## Settings

The *compare* argument can have the following values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Return Values

**InStrRev** returns the following values:

If	InStrRev returns
<i>stringcheck</i> is zero-length	0
<i>stringcheck</i> is <b>Null</b>	<b>Null</b>

<i>stringmatch</i> is zero-length	<i>start</i>
<i>stringmatch</i> is <b>Null</b>	<b>Null</b>
<i>stringmatch</i> is not found	0
<i>stringmatch</i> is found within <i>stringcheck</i>	Position at which match is found
<i>start</i> > <b>Len(stringmatch)</b>	0

## Remarks

Note that the syntax for the **InstrRev** function is not the same as the syntax for the **Instr** function.

## IPmt Function

Returns a [Double](#) specifying the interest payment for a given period of an annuity based on periodic, fixed payments and a fixed interest rate.

### Syntax

**IPmt**(*rate*, *per*, *nper*, *pv*[, *fv*[, *type*]])

The **IPmt** function has these [named arguments](#):

Part	Description
<b>rate</b>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<b>per</b>	Required. <b>Double</b> specifying payment period in the range 1 through <b>nper</b> .
<b>nper</b>	Required. <b>Double</b> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of 4 * 12 (or 48) payment periods.
<b>pv</b>	Required. <b>Double</b> specifying present value, or value today, of a series of future payments or receipts. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make.
<b>fv</b>	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you've made the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<b>type</b>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

The **rate** and **nper** [arguments](#) must be calculated using payment periods expressed in the same units. For example, if **rate** is calculated using months, **nper** must also be calculated using months.

For all arguments, cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by positive numbers.

## IRR Function

Returns a [Double](#) specifying the internal rate of return for a series of periodic cash flows (payments and receipts).

### Syntax

**IRR**(*values*()[, *guess*])

The **IRR** function has these [named arguments](#):

Part	Description
<b>values()</b>	Required. <a href="#">Array</a> of <b>Double</b> specifying cash flow values. The array must contain at least one negative value (a payment) and one positive value (a receipt).
<b>guess</b>	Optional. <a href="#">Variant</a> specifying value you estimate will be returned by <b>IRR</b> . If omitted, <b>guess</b> is 0.1 (10 percent).

## Remarks

The internal rate of return is the interest rate received for an investment consisting of payments and receipts that occur at regular intervals.

The **IRR** function uses the order of values within the array to interpret the order of payments and receipts. Be sure to enter your payment and receipt values in the correct sequence. The cash flow for each period doesn't have to be fixed, as it is for an annuity.

**IRR** is calculated by iteration. Starting with the value of **guess**, **IRR** cycles through the calculation until the result is accurate to within 0.00001 percent. If **IRR** can't find a result after 20 tries, it fails.

IsArray Function

Returns a **Boolean** value indicating whether a [variable](#) is an [array](#).

**Syntax**

## **IsArray**(*varname*)

The required *varname* [argument](#) is an [identifier](#) specifying a variable.

### **Remarks**

**IsArray** returns **True** if the variable is an array; otherwise, it returns **False**.

**IsArray** is especially useful with [variants](#) containing arrays.

IsDate Function

Returns a **Boolean** value indicating whether an [expression](#) can be converted to a date.

## Syntax

**IsDate**(*expression*)

The required *expression* [argument](#) is a [Variant](#) containing a [date expression](#) or [string expression](#) recognizable as a date or time.

## Remarks

**IsDate** returns **True** if the expression is a date or is recognizable as a valid date; otherwise, it returns **False**. In Microsoft Windows, the range of valid dates is January 1, 100 A.D. through December 31, 9999 A.D.; the ranges vary among operating systems.

IsEmpty Function

Returns a **Boolean** value indicating whether a [variable](#) has been initialized.

## Syntax

**IsEmpty**(*expression*)

The required *expression* [argument](#) is a [Variant](#) containing a [numeric](#) or [string expression](#). However, because **IsEmpty** is used to determine if individual variables are initialized, the *expression* argument is most often a single variable name.

## Remarks

**IsEmpty** returns **True** if the variable is uninitialized, or is explicitly set to [Empty](#); otherwise, it returns **False**. **False** is always returned if *expression* contains more than one variable. **IsEmpty** only returns meaningful information for [variants](#).

IsError Function

Returns a **Boolean** value indicating whether an [expression](#) is an error value.

### Syntax

**IsError**(*expression*)

The required *expression* [argument](#) can be any valid expression.

### Remarks

Error values are created by converting real numbers to error values using the **CVErr** function. The **IsError** function is used to determine if a [numeric expression](#) represents an error. **IsError** returns **True** if the *expression* argument indicates an error; otherwise, it returns **False**.

IsMissing Function

Returns a **Boolean** value indicating whether an optional **Variant** [argument](#) has been passed to a [procedure](#).

### Syntax

**IsMissing**(*argname*)

The required *argname* argument contains the name of an optional **Variant** procedure argument.

## Remarks

Use the **IsMissing** function to detect whether or not optional **Variant** arguments have been provided in calling a procedure. **IsMissing** returns **True** if no value has been passed for the specified argument; otherwise, it returns **False**. If **IsMissing** returns **True** for an argument, use of the missing argument in other code may cause a user-defined error. If **IsMissing** is used on a **ParamArray** argument, it always returns **False**. To detect an empty **ParamArray**, test to see if the [array's](#) upper bound is less than its lower bound.

**Note** **IsMissing** does not work on simple data types (such as **Integer** or **Double**) because, unlike **Variants**, they don't have a provision for a "missing" flag bit. Because of this, the syntax for typed optional arguments allows you to specify a default value. If the argument is omitted when the procedure is called, then the argument will have this default value, as in the example below:

```
Sub MySub(Optional MyVar As String = "specialva
    If MyVar = "specialvalue" Then
        ' MyVar was omitted.
    Else
        . . .
End Sub
```

In many cases you can omit the `If MyVar` test entirely by making the default value equal to the value you want `MyVar` to contain if the user omits it from the function call. This makes your code more concise and efficient.

IsNull Function

Returns a **Boolean** value that indicates whether an [expression](#) contains no valid data ([Null](#)).

## Syntax

**IsNull**(*expression*)

The required *expression* [argument](#) is a [Variant](#) containing a [numeric expression](#) or [string expression](#).

## Remarks

**IsNull** returns **True** if *expression* is **Null**; otherwise, **IsNull** returns **False**. If *expression* consists of more than one [variable](#), **Null** in any constituent variable causes **True** to be returned for the entire expression.

The **Null** value indicates that the **Variant** contains no valid data. **Null** is not the same as [Empty](#), which indicates that a variable has not yet been initialized. It is also not the same as a zero-length string (""), which is sometimes referred to as a null string.

**Important** Use the **IsNull** function to determine whether an expression contains a **Null** value. Expressions that you might expect to evaluate to **True** under some circumstances, such as `If Var = Null` and `If Var <> Null`, are always **False**. This is because any expression containing a **Null** is itself **Null** and, therefore, **False**.

IsNumeric Function

Returns a **Boolean** value indicating whether an [expression](#) can be evaluated as a number.

## Syntax

**IsNumeric**(*expression*)

The required *expression* [argument](#) is a [Variant](#) containing a [numeric expression](#) or [string expression](#).

## Remarks

**IsNumeric** returns **True** if the entire *expression* is recognized as a number; otherwise, it returns **False**.

**IsNumeric** returns **False** if *expression* is a [date expression](#).

IsObject Function

Returns a **Boolean** value indicating whether an [identifier](#) represents an object [variable](#).

## Syntax

**IsObject**(*identifier*)

The required *identifier* [argument](#) is a variable name.

## Remarks

**IsObject** is useful only in determining whether a [Variant](#) is of **VarType vbObject**. This could occur if the **Variant** actually references (or once referenced) an object, or if it contains **Nothing**.

**IsObject** returns **True** if *identifier* is a variable declared with [Object](#) type or any valid [class](#) type, or if *identifier* is a **Variant** of **VarType vbObject**, or a user-defined object; otherwise, it returns **False**. **IsObject** returns **True** even if the variable has been set to **Nothing**.

Use error trapping to be sure that an object reference is valid.

Join

Function

## Description

Returns a string created by joining a number of substrings contained in an [array](#).

## Syntax

**Join**(*sourcearray*[, *delimiter*])

The **Join** function syntax has these [named arguments](#):

Part	Description
<i>sourcearray</i>	Required. One-dimensional array containing substrings to be joined.
<i>delimiter</i>	Optional. String character used to separate the substrings in the returned string. If omitted, the space character (" ") is used. If <i>delimiter</i> is a zero-length string (""), all items in the list are

concatenated with no delimiters.

## LBound Function

Returns a [Long](#) containing the smallest available subscript for the indicated dimension of an [array](#).

### Syntax

**LBound**(*arrayname*[, *dimension*])

The **LBound** function syntax has these parts:

Part	Description
------	-------------

<i>arrayname</i>	Required. Name of the array <a href="#">variable</a> ; follows standard variable naming conventions.
<i>dimension</i>	Optional; <b>Variant (Long)</b> . Whole number indicating which dimension's lower bound is returned. Use 1 for the first dimension, 2 for the second, and so on. If <i>dimension</i> is omitted, 1 is assumed.

## Remarks

The **LBound** function is used with the **UBound** function to determine the size of an array. Use the **UBound** function to find the upper limit of an array dimension.

**LBound** returns the values in the following table for an array with the following dimensions:

```
Dim A(1 To 100, 0 To 3, -3 To 4)
```

Statement	Return Value
LBound(A, 1)	1
LBound(A, 2)	0
LBound(A, 3)	-3

The default lower bound for any dimension is either 0 or 1, depending on the setting of the **Option Base** statement. The base of an array created with the **Array** function is zero; it is unaffected by **Option Base**.

Arrays for which dimensions are set using the **To** clause in a **Dim**, **Private**, **Public**, **ReDim**, or **Static** statement can have any integer value as a lower bound.

LCASE Function

Returns a [String](#) that has been converted to lowercase.

### **Syntax**

**LCASE**(*string*)

The required *string* [argument](#) is any valid [string expression](#). If *string* contains [Null](#), Null is returned.

**Remarks**

Only uppercase letters are converted to lowercase; all lowercase letters and nonletter characters remain unchanged.

Left Function

Returns a **Variant (String)** containing a specified number of characters from the left side of a string.

### Syntax

**Left**(*string*, *length*)

The **Left** function syntax has these [named arguments](#):

Part	Description
<i>string</i>	Required. <a href="#">String expression</a> from which the leftmost characters are returned. If <i>string</i> contains <a href="#">Null</a> , Null is returned.
<i>length</i>	Required; <b>Variant (Long)</b> . <a href="#">Numeric expression</a> indicating how many characters to return. If 0, a zero-length string ("" ) is returned. If greater than or equal to the number of characters in <i>string</i> , the entire string is returned.

## Remarks

To determine the number of characters in *string*, use the **Len** function.

**Note** Use the **LeftB** function with byte data contained in a string. Instead of specifying the number of characters to return, *length* specifies the number of bytes.

Len Function

Returns a [Long](#) containing the number of characters in a string or the number of bytes required to store a [variable](#).

## Syntax

**Len**(*string* | *varname*)

The **Len** function syntax has these parts:

Part	Description
<i>string</i>	Any valid <a href="#">string expression</a> . If <i>string</i> contains <a href="#">Null</a> , Null is returned.
<i>Varname</i>	Any valid <a href="#">variable</a> name. If <i>varname</i> contains <b>Null</b> , <b>Null</b> is returned. If <i>varname</i> is a <a href="#">Variant</a> , <b>Len</b> treats it the same as a <b>String</b> and always returns the number of characters it contains.

## Remarks

One (and only one) of the two possible [arguments](#) must be specified. With [user-defined types](#), **Len** returns the size as it will be written to the file.

**Note** Use the **LenB** function with byte data contained in a string, as in double-byte character set (DBCS) languages. Instead of returning the number of characters in a string, **LenB** returns the number of bytes used to represent that

string. With user-defined types, **LenB** returns the in-memory size, including any padding between elements. For sample code that uses **LenB**, see the second example in the example topic.

**Note** **Len** may not be able to determine the actual number of storage bytes required when used with variable-length strings in user-defined [data types](#).

Loc Function

Returns a [Long](#) specifying the current read/write position within an open file.

### **Syntax**

**Loc**(*filenumber*)

The required *filenumber* [argument](#) is any valid [Integer file number](#).

### **Remarks**

The following describes the return value for each file access mode:

Mode	Return Value
<b>Random</b>	Number of the last record read from or written to the file.
<b>Sequential</b>	Current byte position in the file divided by 128. However, information returned by <b>Loc</b> for sequential files is neither used nor required.
<b>Binary</b>	Position of the last byte read or written.

LOF Function

Returns a [Long](#) representing the size, in bytes, of a file opened using the **Open** statement.

### **Syntax**

**LOF**(*filename*)

The required *filename* [argument](#) is an [Integer](#) containing a valid [file number](#).

**Note** Use the **FileLen** function to obtain the length of a file that is not open.

## Log Function

Returns a **Double** specifying the natural logarithm of a number.

### Syntax

**Log**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#) greater than zero.

## Remarks

The natural logarithm is the logarithm to the base  $e$ . The [constant](#)  $e$  is approximately 2.718282.

You can calculate base- $n$  logarithms for any number  $x$  by dividing the natural logarithm of  $x$  by the natural logarithm of  $n$  as follows:

$$\text{Log}_n(x) = \mathbf{Log}(x) / \mathbf{Log}(n)$$

The following example illustrates a custom **Function** that calculates base-10 logarithms:

```
Static Function Log10(X)
    Log10 = Log(X) / Log(10#)
End Function
```

LTrim, RTrim, and Trim Functions

Returns a **Variant (String)** containing a copy of a specified string without leading spaces (**LTrim**), trailing spaces (**RTrim**), or both leading and trailing spaces (**Trim**).

### **Syntax**

**LTrim**(*string*)

**RTrim**(*string*)

**Trim**(*string*)

The required *string* [argument](#) is any valid [string expression](#). If *string* contains [Null](#), **Null** is returned.

Mid Function

Returns a **Variant (String)** containing a specified number of characters from a string.

## Syntax

**Mid**(*string*, *start*[, *length*])

The **Mid** function syntax has these [named arguments](#):

Part	Description
<i>string</i>	Required. <a href="#">String expression</a> from which characters are returned. If <i>string</i> contains <a href="#">Null</a> , <b>Null</b> is returned.
<i>start</i>	Required; <a href="#">Long</a> . Character position in <i>string</i> at which the part to be taken begins. If <i>start</i> is greater than the number of characters in <i>string</i> , <b>Mid</b> returns a zero-length string ("").
<i>length</i>	Optional; <b>Variant (Long)</b> . Number of characters to return. If omitted or if there are fewer than <i>length</i> characters in the text (including the character at <i>start</i> ), all characters from the <i>start</i> position to the end of the string are returned.

## Remarks

To determine the number of characters in *string*, use the **Len** function.

**Note** Use the **MidB** function with byte data contained in a string, as in double-byte character set languages. Instead of specifying the number of characters, the [arguments](#) specify numbers of bytes. For sample code that uses **MidB**, see the second example in the example topic.

Minute Function

Returns a **Variant (Integer)** specifying a whole number between 0 and 59, inclusive, representing the minute of the hour.

## Syntax

### **Minute**(*time*)

The required *time* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a time. If *time* contains [Null](#), **Null** is returned.

## MIRR Function

Returns a [Double](#) specifying the modified internal rate of return for a series of periodic cash flows (payments and receipts).

### Syntax

**MIRR**(*values*()), *finance\_rate*, *reinvest\_rate*)

The **MIRR** function has these [named arguments](#):

--	--

Part	Description
<b>values()</b>	Required. <a href="#">Array</a> of <b>Double</b> specifying cash flow values. The array must contain at least one negative value (a payment) and one positive value (a receipt).
<b>finance_rate</b>	Required. <b>Double</b> specifying interest rate paid as the cost of financing.
<b>reinvest_rate</b>	Required. <b>Double</b> specifying interest rate received on gains from cash reinvestment.

## Remarks

The modified internal rate of return is the internal rate of return when payments and receipts are financed at different rates. The **MIRR** function takes into account both the cost of the investment (**finance\_rate**) and the interest rate received on reinvestment of cash (**reinvest\_rate**).

The **finance\_rate** and **reinvest\_rate** [arguments](#) are percentages expressed as decimal values. For example, 12 percent is expressed as 0.12.

The **MIRR** function uses the order of values within the array to interpret the order of payments and receipts. Be sure to enter your payment and receipt values in the correct sequence.

Month Function

Returns a **Variant (Integer)** specifying a whole number between 1 and 12, inclusive, representing the month of the year.

## Syntax

### **Month**(*date*)

The required *date* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a date. If *date* contains [Null](#), **Null** is returned.

**Note** If the **Calendar** property setting is Gregorian, the returned integer represents the Gregorian day of the week for the date argument. If the calendar is Hijri, the returned integer represents the Hijri day of the week for the date argument. For Hijri dates, the argument number is any numeric expression that can represent a date and/or time from 1/1/100 (Gregorian Aug 2, 718) through 4/3/9666 (Gregorian Dec 31, 9999).

## Description

Returns a string indicating the specified month.

## Syntax

**MonthName**(*month*[, *abbreviate*])

The **MonthName** function syntax has these parts:

Part	Description
<i>month</i>	Required. The numeric designation of the month. For example, January is 1, February is 2, and so on.
<i>abbreviate</i>	Optional. <b>Boolean</b> value that indicates if the month name is to be abbreviated. If omitted, the default is <b>False</b> , which means that the month name is not abbreviated.

MsgBox Function

Displays a message in a dialog box, waits for the user to click a button, and returns an **Integer** indicating which button the user clicked.

## Syntax

**MsgBox**(*prompt*[, *buttons*] [, *title*] [, *helpfile*, *context*])

The **MsgBox** function syntax has these [named arguments](#):

Part	Description
<b><i>prompt</i></b>	Required. <a href="#">String expression</a> displayed as the message in the dialog box. The maximum length of <b><i>prompt</i></b> is approximately 1024 characters, depending on the width of the characters used. If <b><i>prompt</i></b> consists of more than one line, you can separate the lines using a carriage return character ( <b>Chr(13)</b> ), a linefeed character ( <b>Chr(10)</b> ), or carriage return – linefeed character combination ( <b>Chr(13) &amp; Chr(10)</b> ) between each line.
<b><i>buttons</i></b>	Optional. <a href="#">Numeric expression</a> that is the sum of values specifying the number and type of buttons to display, the icon style to use, the identity of the default button, and the modality of the message box. If omitted, the default value for <b><i>buttons</i></b> is 0.
<b><i>title</i></b>	Optional. String expression displayed in the title bar of the dialog box. If you omit <b><i>title</i></b> , the application name is placed in the title bar.
<b><i>helpfile</i></b>	Optional. String expression that identifies the Help file to use to provide context-sensitive Help for the dialog box. If <b><i>helpfile</i></b> is provided, <b><i>context</i></b> must also be provided.
<b><i>context</i></b>	Optional. Numeric expression that is the Help context number assigned to the appropriate Help topic by the Help author. If <b><i>context</i></b> is provided, <b><i>helpfile</i></b> must also be provided.

## Settings

The *buttons* [argument](#) settings are:

Constant	Value	Description
<b>vbOKOnly</b>	0	Display <b>OK</b> button only.
<b>vbOKCancel</b>	1	Display <b>OK</b> and <b>Cancel</b> buttons.
<b>vbAbortRetryIgnore</b>	2	Display <b>Abort</b> , <b>Retry</b> , and <b>Ignore</b> buttons.
<b>vbYesNoCancel</b>	3	Display <b>Yes</b> , <b>No</b> , and <b>Cancel</b> buttons.
<b>vbYesNo</b>	4	Display <b>Yes</b> and <b>No</b> buttons.
<b>vbRetryCancel</b>	5	Display <b>Retry</b> and <b>Cancel</b> buttons.
<b>vbCritical</b>	16	Display <b>Critical Message</b> icon.
<b>vbQuestion</b>	32	Display <b>Warning Query</b> icon.
<b>vbExclamation</b>	48	Display <b>Warning Message</b> icon.
<b>vbInformation</b>	64	Display <b>Information Message</b> icon.
<b>vbDefaultButton1</b>	0	First button is default.
<b>vbDefaultButton2</b>	256	Second button is default.
<b>vbDefaultButton3</b>	512	Third button is default.
<b>vbDefaultButton4</b>	768	Fourth button is default.
<b>vbApplicationModal</b>	0	Application modal; the user must respond to the message box before continuing work in the current application.
<b>vbSystemModal</b>	4096	System modal; all applications are suspended until the user responds to the message box.
<b>vbMsgBoxHelpButton</b>	16384	Adds Help button to the message box
<b>VbMsgBoxSetForeground</b>	65536	Specifies the message box window as the foreground window
<b>vbMsgBoxRight</b>	524288	Text is right aligned
<b>vbMsgBoxRtlReading</b>	1048576	Specifies text should appear as right-to-left reading on Hebrew and Arabic systems

The first group of values (0–5) describes the number and type of buttons displayed in the dialog box; the second group (16, 32, 48, 64) describes the icon style; the third group (0, 256, 512) determines which button is the default; and the fourth group (0, 4096) determines the modality of the message box. When adding numbers to create a final value for the **buttons** argument, use only one number from each group.

**Note** These [constants](#) are specified by Visual Basic for Applications. As a result, the names can be used anywhere in your code in place of the actual values.

### Return Values

Constant	Value	Description
<b>vbOK</b>	1	<b>OK</b>
<b>vbCancel</b>	2	<b>Cancel</b>
<b>vbAbort</b>	3	<b>Abort</b>
<b>vbRetry</b>	4	<b>Retry</b>
<b>vbIgnore</b>	5	<b>Ignore</b>
<b>vbYes</b>	6	<b>Yes</b>
<b>vbNo</b>	7	<b>No</b>

### Remarks

When both **helpfile** and **context** are provided, the user can press F1 (Windows) or HELP (Macintosh) to view the Help topic corresponding to the **context**. Some [host applications](#), for example, Microsoft Excel, also automatically add a **Help** button to the dialog box.

If the dialog box displays a **Cancel** button, pressing the ESC key has the same effect as clicking **Cancel**. If the dialog box contains a **Help** button, context-sensitive Help is provided for the dialog box. However, no value is returned until one of the other buttons is clicked.

**Note** To specify more than the first named argument, you must use **MsgBox** in an [expression](#). To omit some positional [arguments](#), you must include the corresponding comma delimiter.

## Now Function

Returns a **Variant (Date)** specifying the current date and time according your computer's system date and time.

### Syntax

#### Now

## NPer Function

Returns a [Double](#) specifying the number of periods for an annuity based on periodic, fixed payments and a fixed interest rate.

### Syntax

**NPer**(*rate*, *pmt*, *pv*[, *fv*[, *type*]])

The **NPer** function has these [named arguments](#):

Part	Description
<b>rate</b>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<b>pmt</b>	Required. <b>Double</b> specifying payment to be made each period. Payments usually contain principal and interest that doesn't change over the life of the annuity.
<b>pv</b>	Required. <b>Double</b> specifying present value, or value today, of a series of future payments or receipts. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make.
<b>fv</b>	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you've made the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<b>type</b>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

For all [arguments](#), cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by positive numbers.

## NPV Function

Returns a [Double](#) specifying the net present value of an investment based on a series of periodic cash flows (payments and receipts) and a discount rate.

### Syntax

**NPV**(*rate*, *values*())

The **NPV** function has these [named arguments](#):

Part	Description
------	-------------

- rate** Required. **Double** specifying discount rate over the length of the period, expressed as a decimal.
- values()** Required. [Array](#) of **Double** specifying cash flow values. The array must contain at least one negative value (a payment) and one positive value (a receipt).

## Remarks

The net present value of an investment is the current value of a future series of payments and receipts.

The **NPV** function uses the order of values within the array to interpret the order of payments and receipts. Be sure to enter your payment and receipt values in the correct sequence.

The **NPV** investment begins one period before the date of the first cash flow value and ends with the last cash flow value in the array.

The net present value calculation is based on future cash flows. If your first cash flow occurs at the beginning of the first period, the first value must be added to the value returned by **NPV** and must not be included in the cash flow values of **values()**.

The **NPV** function is similar to the **PV** function (present value) except that the **PV** function allows cash flows to begin either at the end or the beginning of a period. Unlike the variable **NPV** cash flow values, **PV** cash flows must be fixed throughout the investment.

Oct Function

Returns a **Variant (String)** representing the octal value of a number.

**Syntax**

## Oct(*number*)

The required *number* [argument](#) is any valid [numeric expression](#) or [string expression](#).

### Remarks

If *number* is not already a whole number, it is rounded to the nearest whole number before being evaluated.

If <i>number</i> is	Oct returns
<a href="#">Null</a>	<b>Null</b>
<a href="#">Empty</a>	Zero (0)
Any other number	Up to 11 octal characters

You can represent octal numbers directly by preceding numbers in the proper range with &0. For example, &010 is the octal notation for decimal 8.

## Partition Function

Returns a **Variant (String)** indicating where a number occurs within a calculated series of ranges.

### Syntax

**Partition**(*number, start, stop, interval*)

The **Partition** function syntax has these [named arguments](#):

Part	Description
<i>number</i>	Required. Whole number that you want to evaluate against the ranges.
<i>start</i>	Required. Whole number that is the start of the overall range of numbers. The number can't be less than 0.
<i>stop</i>	Required. Whole number that is the end of the overall range

of numbers. The number can't be equal to or less than **start**.

## Remarks

The **Partition** function identifies the particular range in which **number** falls and returns a **Variant (String)** describing that range. The **Partition** function is most useful in queries. You can create a select query that shows how many orders fall within various ranges, for example, order values from 1 to 1000, 1001 to 2000, and so on.

The following table shows how the ranges are determined using three sets of **start**, **stop**, and **interval** parts. The First Range and Last Range columns show what **Partition** returns. The ranges are represented by *lowervalue:uppervalue*, where the low end (*lowervalue*) of the range is separated from the high end (*uppervalue*) of the range with a colon (:).

<b>start</b>	<b>stop</b>	<b>interval</b>	<b>Before First</b>	<b>First Range</b>	<b>Last Range</b>	<b>After Last</b>
0	99	5	" :-1"	" 0: 4"	" 95: 99"	" 100: "
20	199	10	" : 19"	" 20: 29"	" 190: 199"	" 200: "
100	1010	20	" : 99"	" 100: 119"	" 1000: 1010"	" 1011: "

In the table shown above, the third line shows the result when **start** and **stop** define a set of numbers that can't be evenly divided by **interval**. The last range extends to **stop** (11 numbers) even though **interval** is 20.

If necessary, **Partition** returns a range with enough leading spaces so that there are the same number of characters to the left and right of the colon as there are characters in **stop**, plus one. This ensures that if you use **Partition** with other numbers, the resulting text will be handled properly during any subsequent sort operation.

If **interval** is 1, the range is **number:number**, regardless of the **start** and **stop** arguments. For example, if **interval** is 1, **number** is 100 and **stop** is 1000, **Partition** returns " 100: 100".

If any of the parts is [Null](#), **Partition** returns a **Null**.

Pmt Function

Returns a [Double](#) specifying the payment for an annuity based on periodic, fixed payments and a fixed interest rate.

## Syntax

**Pmt**(*rate*, *nper*, *pv*[, *fv*[, *type*]])

The **Pmt** function has these [named arguments](#):

Part	Description
<b>rate</b>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<b>nper</b>	Required. <a href="#">Integer</a> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of 4 * 12 (or 48) payment periods.
<b>pv</b>	Required. <b>Double</b> specifying present value (or lump sum) that a series of payments to be paid in the future is worth now. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make.
<b>fv</b>	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you've made the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<b>type</b>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

The **rate** and **nper** [arguments](#) must be calculated using payment periods expressed in the same units. For example, if **rate** is calculated using months, **nper** must also be calculated using months.

For all arguments, cash paid out (such as deposits to savings) is represented by

negative numbers; cash received (such as dividend checks) is represented by positive numbers.

PPmt Function

Returns a [Double](#) specifying the principal payment for a given period of an annuity based on periodic, fixed payments and a fixed interest rate.

## Syntax

**PPmt**(*rate*, *per*, *nper*, *p*v[, *f*v[, *type*]])

The **PPmt** function has these [named arguments](#):

Part	Description
<i>rate</i>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<i>per</i>	Required. <a href="#">Integer</a> specifying payment period in the range 1 through <i>nper</i> .
<i>nper</i>	Required. <b>Integer</b> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of 4 * 12 (or 48) payment periods.
<i>p</i> v	Required. <b>Double</b> specifying present value, or value today, of a series of future payments or receipts. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make.
<i>f</i> v	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you've made the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<i>type</i>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

The *rate* and *nper* [arguments](#) must be calculated using payment periods expressed in the same units. For example, if *rate* is calculated using months, *nper* must also be calculated using months.

For all arguments, cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by positive numbers.

PV Function

Returns a [Double](#) specifying the present value of an annuity based on periodic, fixed payments to be paid in the future and a fixed interest rate.

## Syntax

**PV**(*rate*, *nper*, *pmt*[, *fv*[, *type*]])

The **PV** function has these [named arguments](#):

Part	Description
<b>rate</b>	Required. <b>Double</b> specifying interest rate per period. For example, if you get a car loan at an annual percentage rate (APR) of 10 percent and make monthly payments, the rate per period is 0.1/12, or 0.0083.
<b>nper</b>	Required. <a href="#">Integer</a> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of 4 * 12 (or 48) payment periods.
<b>pmt</b>	Required. <b>Double</b> specifying payment to be made each period. Payments usually contain principal and interest that doesn't change over the life of the annuity.
<b>fv</b>	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you've made the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<b>type</b>	Optional. <b>Variant</b> specifying when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

The **rate** and **nper** [arguments](#) must be calculated using payment periods expressed in the same units. For example, if **rate** is calculated using months, **nper** must also be calculated using months.

For all arguments, cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by

positive numbers.

## QBColor Function

Returns a [Long](#) representing the RGB color code corresponding to the specified color number.

### Syntax

**QBColor**(*color*)

The required *color* [argument](#) is a whole number in the range 0–15.

### Settings

The *color* argument has these settings:

Number	Color	Number	Color
0	Black	8	Gray
1	Blue	9	Light Blue

2	Green	10	Light Green
3	Cyan	11	Light Cyan
4	Red	12	Light Red
5	Magenta	13	Light Magenta
6	Yellow	14	Light Yellow
7	White	15	Bright White

### **Remarks**

The *color* argument represents color values used by earlier versions of Basic (such as Microsoft Visual Basic for MS-DOS and the Basic Compiler). Starting with the least-significant byte, the returned value specifies the red, green, and blue values used to set the appropriate color in the RGB system used by Visual Basic for Applications.

Rate Function

Returns a [Double](#) specifying the interest rate per period for an annuity.

### Syntax

**Rate**(*nper*, *pmt*, *pv*[, *fv*[, *type*[, *guess*]]])

The **Rate** function has these [named arguments](#):

Part	Description
------	-------------

<b><i>nper</i></b>	Required. <b>Double</b> specifying total number of payment periods in the annuity. For example, if you make monthly payments on a four-year car loan, your loan has a total of $4 * 12$ (or 48) payment periods.
<b><i>pmt</i></b>	Required. <b>Double</b> specifying payment to be made each period. Payments usually contain principal and interest that doesn't change over the life of the annuity.
<b><i>pv</i></b>	Required. <b>Double</b> specifying present value, or value today, of a series of future payments or receipts. For example, when you borrow money to buy a car, the loan amount is the present value to the lender of the monthly car payments you will make.
<b><i>fv</i></b>	Optional. <a href="#">Variant</a> specifying future value or cash balance you want after you make the final payment. For example, the future value of a loan is \$0 because that's its value after the final payment. However, if you want to save \$50,000 over 18 years for your child's education, then \$50,000 is the future value. If omitted, 0 is assumed.
<b><i>type</i></b>	Optional. <b>Variant</b> specifying a number indicating when payments are due. Use 0 if payments are due at the end of the payment period, or use 1 if payments are due at the beginning of the period. If omitted, 0 is assumed.
<b><i>guess</i></b>	Optional. <b>Variant</b> specifying value you estimate will be returned by <b>Rate</b> . If omitted, <b>guess</b> is 0.1 (10 percent).

## Remarks

An annuity is a series of fixed cash payments made over a period of time. An annuity can be a loan (such as a home mortgage) or an investment (such as a monthly savings plan).

For all [arguments](#), cash paid out (such as deposits to savings) is represented by negative numbers; cash received (such as dividend checks) is represented by positive numbers.

**Rate** is calculated by iteration. Starting with the value of **guess**, **Rate** cycles through the calculation until the result is accurate to within 0.00001 percent. If **Rate** can't find a result after 20 tries, it fails. If your guess is 10 percent and **Rate** fails, try a different value for **guess**.

Replace

Function

## Description

Returns a string in which a specified substring has been replaced with another substring a specified number of times.

## Syntax

**Replace**(*expression*, *find*, *replace*[, *start*[, *count*[, *compare*]]])

The **Replace** function syntax has these [named arguments](#):

Part	Description
<i>expression</i>	Required. <a href="#">String expression</a> containing substring to replace.
<i>find</i>	Required. Substring being searched for.
<i>replace</i>	Required. Replacement substring.

<b><i>start</i></b>	Optional. Position within <b><i>expression</i></b> where substring search is to begin. If omitted, 1 is assumed.
<b><i>count</i></b>	Optional. Number of substring substitutions to perform. If omitted, the default value is -1, which means make all possible substitutions.
<b><i>compare</i></b>	Optional. Numeric value indicating the kind of comparison to use when evaluating substrings. See Settings section for values.

## Settings

The ***compare*** argument can have the following values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Return Values

**Replace** returns the following values:

If	Replace returns
<b><i>expression</i></b> is zero-length	Zero-length string ("")
<b><i>expression</i></b> is Null	An error.
<b><i>find</i></b> is zero-length	Copy of <b><i>expression</i></b> .
<b><i>replace</i></b> is zero-length	Copy of <b><i>expression</i></b> with all occurrences of <b><i>find</i></b> removed.
<b><i>start</i> &gt; Len(<i>expression</i>)</b>	Zero-length string.
<b><i>count</i></b> is 0	Copy of <b><i>expression</i></b> .

## Remarks

The return value of the **Replace** function is a string, with substitutions made, that begins at the position specified by *start* and concludes at the end of the *expression* string. It is not a copy of the original string from start to finish.

RGB Function

Returns a [Long](#) whole number representing an RGB color value.

**Syntax**

## RGB(*red*, *green*, *blue*)

The **RGB** function syntax has these [named arguments](#):

Part	Description
<i>red</i>	Required; <b>Variant (Integer)</b> . Number in the range 0–255, inclusive, that represents the red component of the color.
<i>green</i>	Required; <b>Variant (Integer)</b> . Number in the range 0–255, inclusive, that represents the green component of the color.
<i>blue</i>	Required; <b>Variant (Integer)</b> . Number in the range 0–255, inclusive, that represents the blue component of the color.

### Remarks

Application [methods](#) and [properties](#) that accept a color specification expect that specification to be a number representing an RGB color value. An RGB color value specifies the relative intensity of red, green, and blue to cause a specific color to be displayed.

The value for any [argument](#) to **RGB** that exceeds 255 is assumed to be 255.

The following table lists some standard colors and the red, green, and blue values they include:

Color	Red Value	Green Value	Blue Value
Black	0	0	0
Blue	0	0	255
Green	0	255	0
Cyan	0	255	255
Red	255	0	0
Magenta	255	0	255
Yellow	255	255	0
White	255	255	255

The RGB color values returned by this function are incompatible with those used

by the Macintosh operating system. They may be used within the context of Microsoft applications for the Macintosh, but should not be used when communicating color changes directly to the Macintosh operating system.

Right Function

Returns a **Variant (String)** containing a specified number of characters from the right side of a string.

### Syntax

**Right**(*string*, *length*)

The **Right** function syntax has these [named arguments](#):

Part	Description
<b><i>string</i></b>	Required. <a href="#">String expression</a> from which the rightmost characters are returned. If <b><i>string</i></b> contains <a href="#">Null</a> , <b>Null</b> is returned.
<b><i>length</i></b>	Required; <b>Variant (Long)</b> . <a href="#">Numeric expression</a> indicating how many characters to return. If 0, a zero-length string ("" ) is returned. If greater than or equal to the number of characters in <b><i>string</i></b> , the entire string is returned.

## Remarks

To determine the number of characters in ***string***, use the **Len** function.

**Note** Use the **RightB** function with byte data contained in a string. Instead of specifying the number of characters to return, ***length*** specifies the number of bytes.

Rnd Function

Returns a **Single** containing a random number.

### Syntax

**Rnd**[(*number*)]

The optional *number* [argument](#) is a [Single](#) or any valid [numeric expression](#).

### Return Values

---

If <i>number</i> is	Rnd generates
Less than zero	The same number every time, using <i>number</i> as the <a href="#">seed</a> .
Greater than zero	The next random number in the sequence.
Equal to zero	The most recently generated number.
Not supplied	The next random number in the sequence.

## Remarks

The **Rnd** function returns a value less than 1 but greater than or equal to zero.

The value of *number* determines how **Rnd** generates a random number:

For any given initial seed, the same number sequence is generated because each successive call to the **Rnd** function uses the previous number as a seed for the next number in the sequence.

Before calling **Rnd**, use the **Randomize** statement without an argument to initialize the random-number generator with a seed based on the system timer.

To produce random integers in a given range, use this formula:

$$\text{Int}((\text{upperbound} - \text{lowerbound} + 1) * \text{Rnd} + \text{lowerbound})$$

Here, *upperbound* is the highest number in the range, and *lowerbound* is the lowest number in the range.

**Note** To repeat sequences of random numbers, call **Rnd** with a negative argument immediately before using **Randomize** with a numeric argument. Using **Randomize** with the same value for *number* does not repeat the previous sequence.

## Description

Returns a number rounded to a specified number of decimal places.

## Syntax

**Round**(*expression* [,*numdecimalplaces*])

The **Round** function syntax has these parts:

Part	Description
<i>expression</i>	Required. <a href="#">Numeric expression</a> being rounded.
<i>numdecimalplaces</i>	Optional. Number indicating how many places to the right of the decimal are included in the rounding. If omitted, integers are returned by the <b>Round</b> function.

Second Function

Returns a **Variant (Integer)** specifying a whole number between 0 and 59, inclusive, representing the second of the minute.

## Syntax

### **Second**(*time*)

The required *time* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a time. If *time* contains [Null](#), **Null** is returned.

## Seek Function

Returns a [Long](#) specifying the current read/write position within a file opened using the **Open** statement.

### Syntax

**Seek**(*filenumber*)

The required *filenumber* [argument](#) is an [Integer](#) containing a valid [file number](#).

### Remarks

**Seek** returns a value between 1 and 2,147,483,647 (equivalent to  $2^{31} - 1$ ), inclusive.

The following describes the return values for each file access mode.

Mode	Return Value
<b>Random</b>	Number of the next record read or written
<b>Binary, Output, Append, Input</b>	Byte position at which the next operation takes place. The first byte in a file is at position 1, the second byte is at position 2, and so on.

Sgn

Function

Returns a **Variant (Integer)** indicating the sign of a number.

### Syntax

**Sgn**(*number*)

The required *number* [argument](#) can be any valid [numeric expression](#).

### Return Values

If <i>number</i> is	Sgn returns
Greater than zero	1
Equal to zero	0
Less than zero	-1

### Remarks

The sign of the *number* argument determines the return value of the **Sgn** function.

## Shell Function

Runs an executable program and returns a **Variant (Double)** representing the program's task ID if successful, otherwise it returns zero.

### Syntax

**Shell**(*pathname*[,*windowstyle*])

The **Shell** function syntax has these [named arguments](#):

Part	Description
------	-------------

<b><i>pathname</i></b>	Required; <b>Variant (String)</b> . Name of the program to execute and any required <a href="#">arguments</a> or <a href="#">command-line switches</a> ; may include directory or folder and drive. On the Macintosh, you can use the <b>MacID</b> function to specify an application's signature instead of its name. The following example uses the signature for Microsoft Word: <code>Shell MacID("MSWD")</code>
<b><i>windowstyle</i></b>	Optional. <b>Variant (Integer)</b> corresponding to the style of the window in which the program is to be run. If <b><i>windowstyle</i></b> is omitted, the program is started minimized with focus. On the Macintosh (System 7.0 or later), <b><i>windowstyle</i></b> only determines whether or not the application gets the focus when it is run.

The ***windowstyle*** named argument has these values:

Constant	Value	Description
<b>vbHide</b>	0	Window is hidden and focus is passed to the hidden window. The <b>vbHide</b> constant is not applicable on Macintosh platforms.
<b>vbNormalFocus</b>	1	Window has focus and is restored to its original size and position.
<b>vbMinimizedFocus</b>	2	Window is displayed as an icon with focus.
<b>vbMaximizedFocus</b>	3	Window is maximized with focus.
<b>vbNormalNoFocus</b>	4	Window is restored to its most recent size and position. The currently active window remains active.
<b>vbMinimizedNoFocus</b>	6	Window is displayed as an icon. The currently active window remains active.

## Remarks

If the **Shell** function successfully executes the named file, it returns the task ID

of the started program. The task ID is a unique number that identifies the running program. If the **Shell** function can't start the named program, an error occurs.

On the Macintosh, **vbNormalFocus**, **vbMinimizedFocus**, and **vbMaximizedFocus** all place the application in the foreground; **vbHide**, **vbNoFocus**, **vbMinimizeFocus** all place the application in the background.

**Note** By default, the **Shell** function runs other programs asynchronously. This means that a program started with **Shell** might not finish executing before the statements following the **Shell** function are executed.

## Sin Function

Returns a **Double** specifying the sine of an angle.

### Syntax

**Sin**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#) that expresses an angle in radians.

## Remarks

The **Sin** function takes an angle and returns the ratio of two sides of a right triangle. The ratio is the length of the side opposite the angle divided by the length of the hypotenuse.

The result lies in the range -1 to 1.

To convert degrees to radians, multiply degrees by  $\pi/180$ . To convert radians to degrees, multiply radians by  $180/\pi$ .

## SLN Function

Returns a [Double](#) specifying the straight-line depreciation of an asset for a single period.

### Syntax

**SLN(*cost*, *salvage*, *life*)**

The **SLN** function has these [named arguments](#):

Part	Description
------	-------------

***cost*** Required. **Double** specifying initial cost of the asset.

***salvage*** Required. **Double** specifying value of the asset at the end of its useful life.

***life*** Required. **Double** specifying length of the useful life of the asset.

### **Remarks**

The depreciation period must be expressed in the same unit as the ***life*** [argument](#). All arguments must be positive numbers.

## Space Function

Returns a **Variant (String)** consisting of the specified number of spaces.

### Syntax

**Space**(*number*)

The required *number* [argument](#) is the number of spaces you want in the string.

### Remarks

The **Space** function is useful for formatting output and clearing data in fixed-length strings.

## Spc Function

Used with the **Print #** statement or the **Print** method to position output.

### Syntax

#### **Spc(*n*)**

The required *n* [argument](#) is the number of spaces to insert before displaying or printing the next [expression](#) in a list.

### Remarks

If *n* is less than the output line width, the next print position immediately follows the number of spaces printed. If *n* is greater than the output line width, **Spc** calculates the next print position using the formula:

*currentprintposition* + (*n* **Mod** *width*)

For example, if the current print position is 24, the output line width is 80, and you specify **Spc**(90), the next print will start at position 34 (current print position + the remainder of 90/80). If the difference between the current print position and the output line width is less than  $n$  (or  $n \bmod width$ ), the **Spc** function skips to the beginning of the next line and generates spaces equal to  $n - (width - currentprintposition)$ .

**Note** Make sure your tabular columns are wide enough to accommodate wide letters.

When you use the **Print** method with a proportionally spaced font, the width of space characters printed using the **Spc** function is always an average of the width of all characters in the point size for the chosen font. However, there is no correlation between the number of characters printed and the number of fixed-width columns those characters occupy. For example, the uppercase letter W occupies more than one fixed-width column and the lowercase letter i occupies less than one fixed-width column.

## Split Function

### Description

Returns a zero-based, one-dimensional [array](#) containing a specified number of substrings.

### Syntax

**Split**(*expression*[, *delimiter*[, *limit*[, *compare*]]])

The **Split** function syntax has these [named arguments](#):

Part	Description
<i>expression</i>	Required. <a href="#">String expression</a> containing substrings and delimiters. If <i>expression</i> is a zero-length string(""), <b>Split</b> returns an empty array, that is, an array with no elements and no data.
<i>delimiter</i>	Optional. String character used to identify substring limits. If omitted, the space character (" ") is assumed to be the delimiter. If <i>delimiter</i> is a zero-length string, a single-element array containing the entire <i>expression</i> string is returned.
<i>limit</i>	Optional. Number of substrings to be returned; -1 indicates that all substrings are returned.
<i>compare</i>	Optional. Numeric value indicating the kind of comparison to use when evaluating substrings. See Settings section for values.

## Settings

The *compare* argument can have the following values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

Sqr Function

Returns a **Double** specifying the square root of a number.

### Syntax

**Sqr**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#) greater than or equal to zero.

Str Function

Returns a **Variant (String)** representation of a number.

### Syntax

**Str**(*number*)

The required *number* [argument](#) is a [Long](#) containing any valid [numeric expression](#).

### Remarks

When numbers are converted to strings, a leading space is always reserved for the sign of *number*. If *number* is positive, the returned string contains a leading space and the plus sign is implied.

Use the **Format** function to convert numeric values you want formatted as dates, times, or currency or in other user-defined formats. Unlike **Str**, the **Format** function doesn't include a leading space for the sign of *number*.

**Note** The **Str** function recognizes only the period (.) as a valid decimal separator. When different decimal separators may be used (for example, in international applications), use **CStr** to convert a number to a string.

StrComp Function

Returns a **Variant (Integer)** indicating the result of a [string comparison](#).

**Syntax**

**StrComp**(*string1*, *string2*[, *compare*])

The **StrComp** function syntax has these [named arguments](#):

Part	Description
<i>string1</i>	Required. Any valid <a href="#">string expression</a> .
<i>string2</i>	Required. Any valid string expression.
<i>compare</i>	Optional. Specifies the type of string comparison. If the <i>compare</i> <a href="#">argument</a> is <a href="#">Null</a> , an error occurs. If <i>compare</i> is omitted, the <b>Option Compare</b> setting determines the type of comparison.

## Settings

The **compare** argument settings are:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Return Values

The **StrComp** function has the following return values:

If	StrComp returns
<i>string1</i> is less than <i>string2</i>	-1
<i>string1</i> is equal to <i>string2</i>	0
<i>string1</i> is greater than <i>string2</i>	1
<i>string1</i> or <i>string2</i> is Null	Null

StrConv Function

Returns a **Variant (String)** converted as specified.

## Syntax

**StrConv**(*string*, *conversion*, *LCID*)

The **StrConv** function syntax has these [named arguments](#):

Part	Description
<i>string</i>	Required. <a href="#">String expression</a> to be converted.
<i>conversion</i>	Required. <a href="#">Integer</a> . The sum of values specifying the type of conversion to perform.
<i>LCID</i>	Optional. The LocaleID, if different than the system LocaleID. (The system LocaleID is the default.)

## Settings

The *conversion* [argument](#) settings are:

Constant	Value	Description
<b>vbUpperCase</b>	1	Converts the string to uppercase characters.
<b>vbLowerCase</b>	2	Converts the string to lowercase characters.
<b>vbProperCase</b>	3	Converts the first letter of every word in string to

		uppercase.
<b>vbWide*</b>	4*	Converts narrow (single-byte) characters in string to wide (double-byte) characters.
<b>vbNarrow*</b>	8*	Converts wide (double-byte) characters in string to narrow (single-byte) characters.
<b>vbKatakana**</b>	16**	Converts Hiragana characters in string to Katakana characters.
<b>vbHiragana**</b>	32**	Converts Katakana characters in string to Hiragana characters.
<b>vbUnicode</b>	64	Converts the string to <a href="#">Unicode</a> using the default code page of the system. (Not available on the Macintosh.)
<b>vbFromUnicode</b>	128	Converts the string from Unicode to the default code page of the system. (Not available on the Macintosh.)

\*Applies to Far East locales.

\*\*Applies to Japan only.

**Note** These [constants](#) are specified by Visual Basic for Applications. As a result, they may be used anywhere in your code in place of the actual values. Most can be combined, for example, **vbUpperCase** + **vbWide**, except when they are mutually exclusive, for example, **vbUnicode** + **vbFromUnicode**. The constants **vbWide**, **vbNarrow**, **vbKatakana**, and **vbHiragana** cause [run-time errors](#) when used in [locales](#) where they do not apply.

The following are valid word separators for proper casing: [Null](#) (**Chr\$(0)**), horizontal tab (**Chr\$(9)**), linefeed (**Chr\$(10)**), vertical tab (**Chr\$(11)**), form feed (**Chr\$(12)**), carriage return (**Chr\$(13)**), space (SBCS) (**Chr\$(32)**). The actual value for a space varies by country for [DBCS](#).

## Remarks

When you're converting from a **Byte** array in ANSI format to a string, you should use the **StrConv** function. When you're converting from such an array in

Unicode format, use an assignment statement.

## Description

Returns a string in which the character order of a specified string is reversed.

## Syntax

### **StrReverse(*expression*)**

The ***expression*** argument is the string whose characters are to be reversed. If ***expression*** is a zero-length string (""), a zero-length string is returned. If ***expression*** is **Null**, an error occurs.

String Function

Returns a **Variant (String)** containing a repeating character string of the length specified.

## Syntax

**String**(*number*, *character*)

The **String** function syntax has these [named arguments](#):

Part	Description
<i>number</i>	Required; <a href="#">Long</a> . Length of the returned string. If <i>number</i> contains <a href="#">Null</a> , <b>Null</b> is returned.
<i>character</i>	Required; <a href="#">Variant</a> . <a href="#">Character code</a> specifying the character or <a href="#">string expression</a> whose first character is used to build the return string. If <i>character</i> contains <b>Null</b> , <b>Null</b> is returned.

## Remarks

If you specify a number for *character* greater than 255, **String** converts the number to a valid character code using the formula:

*character* Mod 256

Switch Function

Evaluates a list of [expressions](#) and returns a **Variant** value or an expression associated with the first expression in the list that is **True**.

## Syntax

**Switch**(*expr-1*, *value-1*[, *expr-2*, *value-2* ... [, *expr-n*,*value-n*]])

The **Switch** function syntax has these parts:

Part	Description
<i>expr</i>	Required. <a href="#">Variant expression</a> you want to evaluate.
<i>value</i>	Required. Value or expression to be returned if the corresponding expression is <b>True</b> .

## Remarks

The **Switch** function [argument](#) list consists of pairs of expressions and values. The expressions are evaluated from left to right, and the value associated with the first expression to evaluate to **True** is returned. If the parts aren't properly paired, a [run-time error](#) occurs. For example, if *expr-1* is **True**, **Switch** returns *value-1*. If *expr-1* is **False**, but *expr-2* is **True**, **Switch** returns *value-2*, and so on.

**Switch** returns a [Null](#) value if:

None of the expressions is **True**.

The first **True** expression has a corresponding value that is **Null**.

**Switch** evaluates all of the expressions, even though it returns only one of them. For this reason, you should watch for undesirable side effects. For example, if the evaluation of any expression results in a division by zero error, an error occurs.

## SYD Function

Returns a [Double](#) specifying the sum-of-years' digits depreciation of an asset for a specified period.

### Syntax

**SYD**(*cost, salvage, life, period*)

The **SYD** function has these [named arguments](#):

Part	Description
------	-------------

<b><i>cost</i></b>	Required. <b>Double</b> specifying initial cost of the asset.
<b><i>salvage</i></b>	Required. <b>Double</b> specifying value of the asset at the end of its useful life.
<b><i>life</i></b>	Required. <b>Double</b> specifying length of the useful life of the asset.
<b><i>period</i></b>	Required. <b>Double</b> specifying period for which asset depreciation is calculated.

## Remarks

The ***life*** and ***period*** [arguments](#) must be expressed in the same units. For example, if ***life*** is given in months, ***period*** must also be given in months. All arguments must be positive numbers.

Tab Function

Used with the **Print** # statement or the **Print** method to position output.

### Syntax

**Tab**[(*n*)]

The optional *n* [argument](#) is the column number moved to before displaying or printing the next [expression](#) in a list. If omitted, **Tab** moves the insertion point to the beginning of the next [print zone](#). This allows **Tab** to be used instead of a

comma in [locales](#) where the comma is used as a decimal separator.

## Remarks

If the current print position on the current line is greater than  $n$ , **Tab** skips to the  $n$ th column on the next output line. If  $n$  is less than 1, **Tab** moves the print position to column 1. If  $n$  is greater than the output line width, **Tab** calculates the next print position using the formula:

$n \bmod \text{width}$

For example, if *width* is 80 and you specify **Tab**(90), the next print will start at column 10 (the remainder of 90/80). If  $n$  is less than the current print position, printing begins on the next line at the calculated print position. If the calculated print position is greater than the current print position, printing begins at the calculated print position on the same line.

The leftmost print position on an output line is always 1. When you use the **Print #** statement to print to files, the rightmost print position is the current width of the output file, which you can set using the **Width #** statement.

**Note** Make sure your tabular columns are wide enough to accommodate wide letters.

When you use the **Tab** function with the **Print** method, the print surface is divided into uniform, fixed-width columns. The width of each column is an average of the width of all characters in the point size for the chosen font. However, there is no correlation between the number of characters printed and the number of fixed-width columns those characters occupy. For example, the uppercase letter W occupies more than one fixed-width column and the lowercase letter i occupies less than one fixed-width column.

## Tan Function

Returns a **Double** specifying the tangent of an angle.

### Syntax

**Tan**(*number*)

The required *number* [argument](#) is a [Double](#) or any valid [numeric expression](#) that expresses an angle in radians.

## Remarks

**Tan** takes an angle and returns the ratio of two sides of a right triangle. The ratio is the length of the side opposite the angle divided by the length of the side adjacent to the angle.

To convert degrees to radians, multiply degrees by  $\pi/180$ . To convert radians to degrees, multiply radians by  $180/\pi$ .

## Time Function

Returns a **Variant (Date)** indicating the current system time.

### Syntax

### Time

### Remarks

To set the system time, use the **Time** statement.

## Timer Function

Returns a **Single** representing the number of seconds elapsed since midnight.

### Syntax

### Timer

### Remarks

In Microsoft Windows the **Timer** function returns fractional portions of a second. On the Macintosh, timer resolution is one second.

## TimeSerial Function

Returns a **Variant (Date)** containing the time for a specific hour, minute, and second.

### Syntax

**TimeSerial**(*hour, minute, second*)

The **TimeSerial** function syntax has these [named arguments](#):

Part	Description
<i>hour</i>	Required; <b>Variant (Integer)</b> . Number between 0 (12:00 A.M.) and 23 (11:00 P.M.), inclusive, or a <a href="#">numeric expression</a> .
<i>minute</i>	Required; <b>Variant (Integer)</b> . Any numeric expression.
<i>second</i>	Required; <b>Variant (Integer)</b> . Any numeric expression.

## Remarks

To specify a time, such as 11:59:59, the range of numbers for each **TimeSerial** argument should be in the normal range for the unit; that is, 0–23 for hours and 0–59 for minutes and seconds. However, you can also specify relative times for each [argument](#) using any numeric expression that represents some number of hours, minutes, or seconds before or after a certain time. The following example uses [expressions](#) instead of absolute time numbers. The **TimeSerial** function returns a time for 15 minutes before (-15) six hours before noon (12 - 6), or 5:45:00 A.M.

**TimeSerial(12 - 6, -15, 0)**

When any argument exceeds the normal range for that argument, it increments to the next larger unit as appropriate. For example, if you specify 75 minutes, it is evaluated as one hour and 15 minutes. If any single argument is outside the range -32,768 to 32,767, an error occurs. If the time specified by the three arguments causes the date to fall outside the acceptable range of dates, an error occurs.

TimeValue Function

Returns a **Variant (Date)** containing the time.

### Syntax

**TimeValue**(*time*)

The required *time* [argument](#) is normally a [string expression](#) representing a time from 0:00:00 (12:00:00 A.M.) to 23:59:59 (11:59:59 P.M.), inclusive. However, *time* can also be any [expression](#) that represents a time in that range. If *time*

contains [Null](#), **Null** is returned.

## Remarks

You can enter valid times using a 12-hour or 24-hour clock. For example, "2:24PM" and "14:24" are both valid *time* arguments.

If the *time* argument contains date information, **TimeValue** doesn't return it. However, if *time* includes invalid date information, an error occurs.

Type Conversion Functions

Each function coerces an [expression](#) to a specific [data type](#).

### **Syntax**

**CBool**(*expression*)

**CByte**(*expression*)

**CCur**(*expression*)

**CDate**(*expression*)

**CDBl**(*expression*)

**CDec**(*expression*)

**CInt**(*expression*)

**CLng**(*expression*)

**CSng**(*expression*)

**CStr**(*expression*)

**CVar**(*expression*)

The required *expression* [argument](#) is any [string expression](#) or [numeric expression](#).

## Return Types

The function name determines the return type as shown in the following:

Function	Return Type	Range for <i>expression</i> argument
CBool	<a href="#">Boolean</a>	Any valid <b>string</b> or numeric expression.
CByte	<a href="#">Byte</a>	0 to 255.
CCur	<a href="#">Currency</a>	-922,337,203,685,477.5808 to 922,337,203,685,477.5807.
CDate	<a href="#">Date</a>	Any valid <a href="#">date expression</a> .
Cdbl	<a href="#">Double</a>	-1.79769313486231E308 to -4.94065645841247E-324 for negative values; 4.94065645841247E-324 to 1.79769313486232E308 for positive values.
CDec	<a href="#">Decimal</a>	+/-79,228,162,514,264,337,593,543,950,335 for zero-scaled numbers, that is, numbers with no decimal places. For numbers with 28 decimal places, the range is +/-7.9228162514264337593543950335. The smallest possible non-zero number is 0.000000000000000000000000000001.
CInt	<a href="#">Integer</a>	-32,768 to 32,767; fractions are rounded.
CLng	<a href="#">Long</a>	-2,147,483,648 to 2,147,483,647; fractions are rounded.
CSng	<a href="#">Single</a>	-3.402823E38 to -1.401298E-45 for negative values; 1.401298E-45 to 3.402823E38 for positive values.
CStr	<a href="#">String</a>	<a href="#">Returns for CStr</a> depend on the <i>expression</i> argument.
CVar	<a href="#">Variant</a>	Same range as <b>Double</b> for numerics. Same range as <b>String</b> for non-numerics.

## Remarks

If the *expression* passed to the function is outside the range of the data type being converted to, an error occurs.

In general, you can document your code using the data-type conversion functions to show that the result of some operation should be expressed as a particular data type rather than the default data type. For example, use **CCur** to force currency arithmetic in cases where single-precision, double-precision, or integer arithmetic normally would occur.

You should use the data-type conversion functions instead of **Val** to provide internationally aware conversions from one data type to another. For example, when you use **CCur**, different decimal separators, different thousand separators, and various currency options are properly recognized depending on the [locale](#) setting of your computer.

When the fractional part is exactly 0.5, **CInt** and **CLng** always round it to the nearest even number. For example, 0.5 rounds to 0, and 1.5 rounds to 2. **CInt** and **CLng** differ from the **Fix** and **Int** functions, which truncate, rather than round, the fractional part of a number. Also, **Fix** and **Int** always return a value of the same type as is passed in.

Use the **IsDate** function to determine if *date* can be converted to a date or time. **CDate** recognizes [date literals](#) and time literals as well as some numbers that fall within the range of acceptable dates. When converting a number to a date, the whole number portion is converted to a date. Any fractional part of the number is converted to a time of day, starting at midnight.

**CDate** recognizes date formats according to the locale setting of your system. The correct order of day, month, and year may not be determined if it is provided in a format other than one of the recognized date settings. In addition, a long date format is not recognized if it also contains the day-of-the-week string.

A **CVDate** function is also provided for compatibility with previous versions of Visual Basic. The syntax of the **CVDate** function is identical to the **CDate** function, however, **CVDate** returns a **Variant** whose subtype is **Date** instead of an actual **Date** type. Since there is now an intrinsic **Date** type, there is no further

need for **CVDate**. The same effect can be achieved by converting an expression to a **Date**, and then assigning it to a **Variant**. This technique is consistent with the conversion of all other intrinsic types to their equivalent **Variant** subtypes.

**Note** The **CDec** function does not return a discrete data type; instead, it always returns a **Variant** whose value has been converted to a **Decimal** subtype.

TypeName Function

Returns a **String** that provides information about a [variable](#).

## Syntax

**TypeName**(*varname*)

The required *varname* [argument](#) is a [Variant](#) containing any variable except a variable of a [user-defined type](#).

## Remarks

The string returned by **TypeName** can be any one of the following:

String returned	Variable
<a href="#">object type</a>	An object whose type is <i>objecttype</i>
<a href="#">Byte</a>	Byte value
<a href="#">Integer</a>	Integer
<a href="#">Long</a>	Long integer
<a href="#">Single</a>	Single-precision floating-point number
<a href="#">Double</a>	Double-precision floating-point number
<a href="#">Currency</a>	Currency value
<a href="#">Decimal</a>	Decimal value
<a href="#">Date</a>	Date value

<a href="#"><u>String</u></a>	String
<a href="#"><u>Boolean</u></a>	Boolean value
<b>Error</b>	An error value
<a href="#"><u>Empty</u></a>	Uninitialized
<a href="#"><u>Null</u></a>	No valid data
<a href="#"><u>Object</u></a>	An object
Unknown	An object whose type is unknown
<b>Nothing</b>	Object variable that doesn't refer to an object

If *varname* is an [array](#), the returned string can be any one of the possible returned strings (or **Variant**) with empty parentheses appended. For example, if *varname* is an array of integers, **TypeName** returns "Integer()".

## UBound Function

Returns a [Long](#) containing the largest available subscript for the indicated dimension of an [array](#).

### Syntax

**UBound**(*arrayname*[, *dimension*])

The **UBound** function syntax has these parts:

Part	Description
------	-------------

*arrayname* Required. Name of the array [variable](#); follows standard variable naming conventions.

*dimension* Optional; **Variant (Long)**. Whole number indicating which dimension's upper bound is returned. Use 1 for the first dimension, 2 for the second, and so on. If *dimension* is omitted, 1 is assumed.

## Remarks

The **UBound** function is used with the **LBound** function to determine the size of an array. Use the **LBound** function to find the lower limit of an array dimension.

**UBound** returns the following values for an array with these dimensions:

```
Dim A(1 To 100, 0 To 3, -3 To 4)
```

Statement	Return Value
UBound(A, 1)	100
UBound(A, 2)	3
UBound(A, 3)	4

## UCase Function

Returns a **Variant (String)** containing the specified string, converted to uppercase.

### Syntax

**UCase**(*string*)

The required *string* [argument](#) is any valid [string expression](#). If *string* contains [Null](#), **Null** is returned.

**Remarks**

Only lowercase letters are converted to uppercase; all uppercase letters and nonletter characters remain unchanged.

## Val Function

Returns the numbers contained in a string as a numeric value of appropriate type.

### Syntax

**Val**(*string*)

The required *string* [argument](#) is any valid [string expression](#).

### Remarks

The **Val** function stops reading the string at the first character it can't recognize as part of a number. Symbols and characters that are often considered parts of numeric values, such as dollar signs and commas, are not recognized. However, the function recognizes the radix prefixes &o (for octal) and &h (for hexadecimal). Blanks, tabs, and linefeed characters are stripped from the argument.

The following returns the value 1615198:

```
Val("    1615 198th Street N.E.")
```

In the code below, **Val** returns the decimal value -1 for the hexadecimal value shown:

```
Val("&HFFFF")
```

**Note** The **Val** function recognizes only the period (.) as a valid decimal separator. When different decimal separators are used, as in international applications, use **Cdbl** instead to convert a string to a number.

VarType Function

Returns an **Integer** indicating the subtype of a [variable](#).

## Syntax

**VarType**(*varname*)

The required *varname* [argument](#) is a [Variant](#) containing any variable except a variable of a [user-defined type](#).

## Return Values

Constant	Value	Description
<b>vbEmpty</b>	0	<a href="#">Empty</a> (uninitialized)
<b>vbNull</b>	1	<a href="#">Null</a> (no valid data)
<b>vbInteger</b>	2	Integer
<b>vbLong</b>	3	Long integer
<b>vbSingle</b>	4	Single-precision floating-point number
<b>vbDouble</b>	5	Double-precision floating-point number
<b>vbCurrency</b>	6	Currency value
<b>vbDate</b>	7	Date value
<b>vbString</b>	8	String
<b>vbObject</b>	9	Object

<b>vbError</b>	10	Error value
<b>vbBoolean</b>	11	Boolean value
<b>vbVariant</b>	12	<b>Variant</b> (used only with <a href="#">arrays</a> of variants)
<b>vbDataObject</b>	13	A data access object
<b>vbDecimal</b>	14	Decimal value
<b>vbByte</b>	17	Byte value
<b>vbUserDefinedType</b>	36	Variants that contain user-defined types
<b>vbArray</b>	8192	Array

**Note** These [constants](#) are specified by Visual Basic for Applications. The names can be used anywhere in your code in place of the actual values.

## Remarks

The **VarType** function never returns the value for **vbArray** by itself. It is always added to some other value to indicate an array of a particular type. The constant **vbVariant** is only returned in conjunction with **vbArray** to indicate that the argument to the **VarType** function is an array of type **Variant**. For example, the value returned for an array of integers is calculated as **vbInteger** + **vbArray**, or 8194. If an object has a default [property](#), **VarType (object)** returns the type of the object's default property.

Weekday Function

Returns a **Variant (Integer)** containing a whole number representing the day of the week.

## Syntax

**Weekday**(*date*, [*firstdayofweek*])

The **Weekday** function syntax has these [named arguments](#):

Part	Description
<i>date</i>	Required. <a href="#">Variant</a> , <a href="#">numeric expression</a> , <a href="#">string expression</a> , or any combination, that can represent a date. If <i>date</i> contains <a href="#">Null</a> , <b>Null</b> is returned.
<i>firstdayofweek</i>	Optional. A <a href="#">constant</a> that specifies the first day of the week. If not specified, <b>vbSunday</b> is assumed.

## Settings

The *firstdayofweek* argument has these settings:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use the NLS API setting.
<b>vbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

## Return Values

The **Weekday** function can return any of these values:

Constant	Value	Description
<b>vbSunday</b>	1	Sunday
<b>vbMonday</b>	2	Monday

<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

## Remarks

If the **Calendar** property setting is Gregorian, the returned integer represents the Gregorian day of the week for the date argument. If the calendar is Hijri, the returned integer represents the Hijri day of the week for the date argument. For Hijri dates, the argument number is any numeric expression that can represent a date and/or time from 1/1/100 (Gregorian Aug 2, 718) through 4/3/9666 (Gregorian Dec 31, 9999).

## Description

Returns a string indicating the specified day of the week.

## Syntax

**WeekdayName**(*weekday*, *abbreviate*, *firstdayofweek*)

The **WeekdayName** function syntax has these parts:

Part	Description
<i>weekday</i>	Required. The numeric designation for the day of the week. Numeric value of each day depends on setting of the <i>firstdayofweek</i> setting.
<i>abbreviate</i>	Optional. <b>Boolean</b> value that indicates if the weekday name is to be abbreviated. If omitted, the default is <b>False</b> , which means that the weekday name is not abbreviated.
<i>firstdayofweek</i>	Optional. Numeric value indicating the first day of the week. See Settings section for values.

## Settings

The *firstdayofweek* argument can have the following values:

Constant	Value	Description
<b>vbUseSystem</b>	0	Use National Language Support (NLS) API setting.
<b>vbSunday</b>	1	Sunday (default)
<b>vbMonday</b>	2	Monday
<b>vbTuesday</b>	3	Tuesday
<b>vbWednesday</b>	4	Wednesday
<b>vbThursday</b>	5	Thursday
<b>vbFriday</b>	6	Friday
<b>vbSaturday</b>	7	Saturday

Year Function

Returns a **Variant (Integer)** containing a whole number representing the year.

**Syntax**

## **Year(*date*)**

The required *date* [argument](#) is any [Variant](#), [numeric expression](#), [string expression](#), or any combination, that can represent a date. If *date* contains [Null](#), **Null** is returned.

**Note** If the **Calendar** property setting is Gregorian, the returned integer represents the Gregorian year for the date argument. If the calendar is Hijri, the returned integer represents the Hijri year for the date argument. For Hijri dates, the argument number is any numeric expression that can represent a date and/or time from 1/1/100 (Gregorian Aug 2, 718) through 4/3/9666 (Gregorian Dec 31, 9999).

Data  
Type

Summary

The following table shows the supported [data types](#), including storage sizes and ranges.

Data type	Storage size	Range
<b>Byte</b>	1 byte	0 to 255
<b>Boolean</b>	2 bytes	<b>True</b> or <b>False</b>
<b>Integer</b>	2 bytes	-32,768 to 32,767
<b>Long</b> (long integer)	4 bytes	-2,147,483,648 to 2,147,483,647
<b>Single</b> (single-precision floating-point)	4 bytes	-3.402823E38 to -1.401298E-45 for negative values; 1.401298E-45 to 3.402823E38 for positive values
<b>Double</b> (double-precision floating-point)	8 bytes	-1.79769313486231E308 to -4.94065645841247E-324 for negative values; 4.94065645841247E-324 to 1.79769313486232E308 for positive values
<b>Currency</b> (scaled integer)	8 bytes	-922,337,203,685,477.5808 to 922,337,203,685,477.5807
<b>Decimal</b>	14 bytes	+/-79,228,162,514,264,337,593,543,950,335 with no decimal point;

		+/-7.9228162514264337593543950335 with 28 places to the right of the decimal; smallest non-zero number is +/-0.00000000000000000000000000000001
<b>Date</b>	8 bytes	January 1, 100 to December 31, 9999
<b>Object</b>	4 bytes	Any <b>Object</b> reference
<b>String</b> (variable-length)	10 bytes + string length	0 to approximately 2 billion
<b>String</b> (fixed-length)	Length of string	1 to approximately 65,400
<b>Variant</b> (with numbers)	16 bytes	Any numeric value up to the range of a <b>Double</b>
<b>Variant</b> (with characters)	22 bytes + string length	Same range as for variable-length <b>String</b>
User-defined (using <b>Type</b> )	Number required by elements	The range of each element is the same as the range of its data type.

**Note** [Arrays](#) of any data type require 20 bytes of memory plus 4 bytes for each array dimension plus the number of bytes occupied by the data itself. The memory occupied by the data can be calculated by multiplying the number of data elements by the size of each element. For example, the data in a single-dimension array consisting of 4 **Integer** data elements of 2 bytes each occupies 8 bytes. The 8 bytes required for the data plus the 24 bytes of overhead brings the total memory requirement for the array to 32 bytes.

A **Variant** containing an array requires 12 bytes more than the array alone.

**Note** Use the **StrConv** function to convert one type of string data to another.

The following is a list of nonintrinsic math functions that can be derived from the intrinsic math functions:

Function	Derived equivalents
Secant	$\text{Sec}(X) = 1 / \text{Cos}(X)$
Cosecant	$\text{Cosec}(X) = 1 / \text{Sin}(X)$
Cotangent	$\text{Cotan}(X) = 1 / \text{Tan}(X)$
Inverse Sine	$\text{Arcsin}(X) = \text{Atn}(X / \text{Sqr}(-X * X + 1))$
Inverse Cosine	$\text{Arccos}(X) = \text{Atn}(-X / \text{Sqr}(-X * X + 1)) + 2 * \text{Atn}(1)$
Inverse Secant	$\text{Arcsec}(X) = \text{Atn}(X / \text{Sqr}(X * X - 1)) + \text{Sgn}((X) - 1) * (2 * \text{Atn}(1))$
Inverse Cosecant	$\text{Arccosec}(X) = \text{Atn}(X / \text{Sqr}(X * X - 1)) + (\text{Sgn}(X) - 1) * (2 * \text{Atn}(1))$
Inverse Cotangent	$\text{Arccotan}(X) = \text{Atn}(X) + 2 * \text{Atn}(1)$
Hyperbolic Sine	$\text{HSin}(X) = (\text{Exp}(X) - \text{Exp}(-X)) / 2$
Hyperbolic Cosine	$\text{HCos}(X) = (\text{Exp}(X) + \text{Exp}(-X)) / 2$
Hyperbolic Tangent	$\text{HTan}(X) = (\text{Exp}(X) - \text{Exp}(-X)) / (\text{Exp}(X) + \text{Exp}(-X))$
Hyperbolic Secant	$\text{HSec}(X) = 2 / (\text{Exp}(X) + \text{Exp}(-X))$
Hyperbolic Cosecant	$\text{HCosec}(X) = 2 / (\text{Exp}(X) - \text{Exp}(-X))$
Hyperbolic Cotangent	$\text{HCotan}(X) = (\text{Exp}(X) + \text{Exp}(-X)) / (\text{Exp}(X) - \text{Exp}(-X))$
Inverse Hyperbolic Sine	$\text{HArcsin}(X) = \text{Log}(X + \text{Sqr}(X * X + 1))$
Inverse Hyperbolic Cosine	$\text{HArccos}(X) = \text{Log}(X + \text{Sqr}(X * X - 1))$
Inverse Hyperbolic	$\text{HArctan}(X) = \text{Log}((1 + X) / (1 - X)) / 2$

Tangent

Inverse Hyperbolic Secant       $\text{HArcsec}(X) = \text{Log}((\text{Sqr}(-X * X + 1) + 1) / X)$

Inverse Hyperbolic Cosecant       $\text{HArccosec}(X) = \text{Log}((\text{Sgn}(X) * \text{Sqr}(X * X + 1) + 1) / X)$

Inverse Hyperbolic Cotangent       $\text{HArccotan}(X) = \text{Log}((X + 1) / (X - 1)) / 2$

Logarithm to base N       $\text{LogN}(X) = \text{Log}(X) / \text{Log}(N)$

## Operator Precedence

When several operations occur in an [expression](#), each part is evaluated and resolved in a predetermined order called operator precedence.

When expressions contain operators from more than one category, arithmetic operators are evaluated first, [comparison operators](#) are evaluated next, and logical operators are evaluated last. Comparison operators all have equal precedence; that is, they are evaluated in the left-to-right order in which they appear. Arithmetic and logical operators are evaluated in the following order of precedence:

Arithmetic	Comparison	Logical
Exponentiation (^)	Equality (=)	<b>Not</b>
Negation (−)	Inequality (<>)	<b>And</b>
Multiplication and division (*, /)	Less than (<)	<b>Or</b>

Integer division (\)	Greater than (>)	<b>Xor</b>
Modulus arithmetic ( <b>Mod</b> )	Less than or equal to (<=)	<b>Eqv</b>
Addition and subtraction (+, -)	Greater than or equal to (>=)	<b>Imp</b>
String concatenation ( <b>&amp;</b> )	<b>Like</b>	<b>Is</b>

When multiplication and division occur together in an expression, each operation is evaluated as it occurs from left to right. When addition and subtraction occur together in an expression, each operation is evaluated in order of appearance from left to right. Parentheses can be used to override the order of precedence and force some parts of an expression to be evaluated before others. Operations within parentheses are always performed before those outside. Within parentheses, however, operator precedence is maintained.

The string concatenation operator (**&**) is not an arithmetic operator, but in precedence, it does follow all arithmetic operators and precede all comparison operators.

The **Like** operator is equal in precedence to all comparison operators, but is actually a pattern-matching operator.

The **Is** operator is an object reference comparison operator. It does not compare objects or their values; it checks only to determine if two object references refer to the same object.

## Operator Summary

Operators	Description
<a href="#">Arithmetic Operators</a>	Operators used to perform mathematical calculations.
<a href="#">Comparison Operators</a>	Operators used to perform comparisons.
<a href="#">Concatenation Operators</a>	Operators used to combine strings.
<a href="#">Logical Operators</a>	Operators used to perform logical operations.

Action	Keywords
Verify an array.	<a href="#">IsArray</a>
Create an array.	<a href="#">Array</a>
Change default lower limit.	<a href="#">Option Base</a>
Declare and initialize an array.	<a href="#">Dim</a> , <a href="#">Private</a> , <a href="#">Public</a> , <a href="#">ReDim</a> , <a href="#">Static</a>
Find the limits of an array.	<a href="#">LBound</a> , <a href="#">UBound</a>
Reinitialize an array.	<a href="#">Erase</a> , <a href="#">ReDim</a>

## Collection Object Keyword Summary

Action	Keywords
Create a <b>Collection</b> object.	<a href="#">Collection</a>
Add an object to a collection.	<a href="#">Add</a>
Remove an object from a collection.	<a href="#">Remove</a>
Reference an item in a collection.	<a href="#">Item</a>

## Compiler Directive Keyword Summary

Action	Keywords
Define compiler constant.	<a href="#"><u>#Const</u></a>
Compile selected blocks of code.	<a href="#"><u>#If...Then...#Else</u></a>

## Control Flow Keyword Summary

Action	Keywords
Branch.	<a href="#">GoSub...Return</a> , <a href="#">GoTo</a> , <a href="#">On Error</a> , <a href="#">On...GoSub</a> , <a href="#">On...GoTo</a>

Loop.	<a href="#">Do...Loop</a> , <a href="#">For...Next</a> , <a href="#">For Each...Next</a> , <a href="#">While...Wend</a> , <a href="#">With</a>
Make decisions.	<a href="#">Choose</a> , <a href="#">If...Then...Else</a> , <a href="#">Select Case</a> , <a href="#">Switch</a>
Use procedures.	<a href="#">Call</a> , <a href="#">Function</a> , <a href="#">Property Get</a> , <a href="#">Property Let</a> , <a href="#">Property Set</a> , <a href="#">Sub</a>

Action	Keywords
ANSI value to string.	<a href="#">Chr</a>
String to lowercase or uppercase.	<a href="#">Format</a> , <a href="#">LCase</a> , <a href="#">Ucase</a>
Date to serial number.	<a href="#">DateSerial</a> , <a href="#">DateValue</a>
Decimal number to other bases.	<a href="#">Hex</a> , <a href="#">Oct</a>
Number to string.	<a href="#">Format</a> , <a href="#">Str</a>
One data type to another.	<a href="#">CBool</a> , <a href="#">CByte</a> , <a href="#">CCur</a> , <a href="#">CDate</a> , <a href="#">CDBl</a> , <a href="#">CDec</a> , <a href="#">CInt</a> , <a href="#">CLng</a> , <a href="#">CSng</a> , <a href="#">CStr</a> , <a href="#">CVar</a> , <a href="#">CVer</a> , <a href="#">Fix</a> , <a href="#">Int</a>
Date to day, month, weekday, or year.	<a href="#">Day</a> , <a href="#">Month</a> , <a href="#">Weekday</a> , <a href="#">Year</a>
Time to hour, minute, or second.	<a href="#">Hour</a> , <a href="#">Minute</a> , <a href="#">Second</a>
String to ASCII value.	<a href="#">Asc</a>
String to number.	<a href="#">Val</a>
Time to serial number.	<a href="#">TimeSerial</a> , <a href="#">TimeValue</a>

Action	Keywords
Convert between data types.	<a href="#">CBool</a> , <a href="#">CByte</a> , <a href="#">CCur</a> , <a href="#">CDate</a> , <a href="#">CDBl</a> , <a href="#">CDec</a> , <a href="#">CInt</a> , <a href="#">CLng</a> , <a href="#">CSng</a> , <a href="#">CStr</a> , <a href="#">CVar</a> , <a href="#">CVer</a> , <a href="#">Fix</a> , <a href="#">Int</a>
Set intrinsic data types.	<a href="#">Boolean</a> , <a href="#">Byte</a> , <a href="#">Currency</a> , <a href="#">Date</a> , <a href="#">Double</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Object</a> , <a href="#">Single</a> , <a href="#">String</a> , <a href="#">Variant (default)</a>
Verify data types.	<a href="#">IsArray</a> , <a href="#">IsDate</a> , <a href="#">IsEmpty</a> , <a href="#">IsError</a> , <a href="#">IsMissing</a> , <a href="#">IsNull</a> , <a href="#">IsNumeric</a> , <a href="#">IsObject</a>

## Dates and Times Keyword Summary

Action	Keywords
Get the current date or time.	<a href="#">Date</a> , <a href="#">Now</a> , <a href="#">Time</a>
Perform date calculations.	<a href="#">DateAdd</a> , <a href="#">DateDiff</a> , <a href="#">DatePart</a>
Return a date.	<a href="#">DateSerial</a> , <a href="#">DateValue</a>
Return a time.	<a href="#">TimeSerial</a> , <a href="#">TimeValue</a>
Set the date or time.	<a href="#">Date</a> , <a href="#">Time</a>
Time a process.	<a href="#">Timer</a>

Action	Keywords
Change directory or folder.	<a href="#"><u>ChDir</u></a>
Change the drive.	<a href="#"><u>ChDrive</u></a>
Copy a file.	<a href="#"><u>FileCopy</u></a>
Make directory or folder.	<a href="#"><u>MkDir</u></a>
Remove directory or folder.	<a href="#"><u>RmDir</u></a>
Rename a file, directory, or folder.	<a href="#"><u>Name</u></a>
Return current path.	<a href="#"><u>CurDir</u></a>
Return file date/time stamp.	<a href="#"><u>FileDateTime</u></a>
Return file, directory, label attributes.	<a href="#"><u>GetAttr</u></a>
Return file length.	<a href="#"><u>FileLen</u></a>
Return file name or volume label.	<a href="#"><u>Dir</u></a>
Set attribute information for a file.	<a href="#"><u>SetAttr</u></a>

Action	Keywords
Generate run-time errors.	<a href="#">Clear</a> , <a href="#">Error</a> , <a href="#">Raise</a>
Get error messages.	<a href="#">Error</a>
Provide error information.	<a href="#">Err</a>
Return <b>Error</b> variant.	<a href="#">CVer</a>
Trap errors during run time.	<a href="#">On Error</a> , <a href="#">Resume</a>
Type verification.	<a href="#">IsError</a>

## Financial Keyword Summary

Action	Keywords
Calculate depreciation.	<a href="#">DDB</a> , <a href="#">SLN</a> , <a href="#">SYD</a>
Calculate future value.	<a href="#">FV</a>
Calculate interest rate.	<a href="#">Rate</a>
Calculate internal rate of return.	<a href="#">IRR</a> , <a href="#">MIRR</a>
Calculate number of periods.	<a href="#">NPer</a>
Calculate payments.	<a href="#">IPmt</a> , <a href="#">Pmt</a> , <a href="#">PPmt</a>
Calculate present value.	<a href="#">NPV</a> , <a href="#">PV</a>

Action	Keywords
Access or create a file.	<a href="#">Open</a>
Close files.	<a href="#">Close</a> , <a href="#">Reset</a>
Control output appearance.	<a href="#">Format</a> , <a href="#">Print</a> , <a href="#">Print #</a> , <a href="#">Spc</a> , <a href="#">Tab</a> , <a href="#">Width #</a>
Copy a file.	<a href="#">FileCopy</a>
Get information about a file.	<a href="#">EOF</a> , <a href="#">FileAttr</a> , <a href="#">FileDateTime</a> , <a href="#">FileLen</a> , <a href="#">FreeFile</a> , <a href="#">GetAttr</a> , <a href="#">Loc</a> , <a href="#">LOF</a> , <a href="#">Seek</a>
Manage files.	<a href="#">Dir</a> , <a href="#">Kill</a> , <a href="#">Lock</a> , <a href="#">Unlock</a> , <a href="#">Name</a>
Read from a file.	<a href="#">Get</a> , <a href="#">Input</a> , <a href="#">Input #</a> , <a href="#">Line Input #</a>
Return length of a file.	<a href="#">FileLen</a>
Set or get file attributes.	<a href="#">FileAttr</a> , <a href="#">GetAttr</a> , <a href="#">SetAttr</a>
Set read-write position in a file.	<a href="#">Seek</a>
Write to a file.	<a href="#">Print #</a> , <a href="#">Put</a> , <a href="#">Write #</a>

Category	Description
<a href="#">Arrays</a>	Creating, defining, and using arrays.
<a href="#">Compiler Directives</a>	Controlling compiler behavior.
<a href="#">Control Flow</a>	Looping and controlling procedure flow.
<a href="#">Conversion</a>	Converting numbers and data types.
<a href="#">Data Types</a>	Data types and variant subtypes.
<a href="#">Dates and Times</a>	Converting and using date and time expressions.
<a href="#">Directories and Files</a>	Controlling the file system and processing files.
<a href="#">Errors</a>	Trapping and returning error values.
<a href="#">Financial</a>	Performing financial calculations.
<a href="#">Input and Output</a>	Receiving input and displaying or printing output.
<a href="#">Math</a>	Performing trigonometric and other mathematical calculations.
<a href="#">Miscellaneous</a>	Starting other applications and processing events.
<a href="#">Operators</a>	Comparing expressions and other operations.
<a href="#">String Manipulation</a>	Manipulating strings and string type data.
<a href="#">Variables and Constants</a>	Declaring and defining variables and constants.

Action	Keywords
Derive trigonometric functions.	<a href="#">Atn</a> , <a href="#">Cos</a> , <a href="#">Sin</a> , <a href="#">Tan</a>
General calculations.	<a href="#">Exp</a> , <a href="#">Log</a> , <a href="#">Sqr</a>
Generate random numbers.	<a href="#">Randomize</a> , <a href="#">Rnd</a>
Get absolute value.	<a href="#">Abs</a>
Get the sign of an expression.	<a href="#">Sgn</a>
Perform numeric conversions.	<a href="#">Fix</a> , <a href="#">Int</a>

Action	Keywords
Process pending events.	<a href="#">DoEvents</a>
Run other programs.	<a href="#">AppActivate</a> , <a href="#">Shell</a>
Send keystrokes to an application.	<a href="#">SendKeys</a>
Sound a beep from computer.	<a href="#">Beep</a>
System.	<a href="#">Environ</a>
Provide a command-line string.	<a href="#">Command</a>
Automation.	<a href="#">CreateObject</a> , <a href="#">GetObject</a>
Color.	<a href="#">QBColor</a> , <a href="#">RGB</a>

## Operators Keyword Summary

Action	Keywords
Arithmetic.	<u>^</u> , =, <u>_</u> , /, \, <u>Mod</u> , +, <u>&amp;</u> , <u>=</u>
Comparison.	<u>=</u> , <u>&lt;&gt;</u> , ≤, ≥, <u>≤</u> , <u>≥</u> , <u>Like</u> , <u>Is</u>
Logical operations.	<u>Not</u> , <u>And</u> , <u>Or</u> , <u>Xor</u> , <u>Eqv</u> , <u>Imp</u>

## Registry Keyword Summary

Action	Keywords
Delete program settings.	<a href="#">DeleteSetting</a>
Read program settings.	<a href="#">GetSetting</a> , <a href="#">GetAllSettings</a>
Save program settings.	<a href="#">SaveSetting</a>

Action	Keywords
Compare two strings.	<a href="#">StrComp</a>
Convert strings.	<a href="#">StrConv</a>
Convert to lowercase or uppercase.	<a href="#">Format</a> , <a href="#">Lcase</a> , <a href="#">Ucase</a>
Create string of repeating character.	<a href="#">Space</a> , <a href="#">String</a>
Find length of a string.	<a href="#">Len</a>
Format a string.	<a href="#">Format</a>
Justify a string.	<a href="#">LSet</a> , <a href="#">Rset</a>
Manipulate strings.	<a href="#">InStr</a> , <a href="#">Left</a> , <a href="#">LTrim</a> , <a href="#">Mid</a> , <a href="#">Right</a> , <a href="#">RTrim</a> , <a href="#">Trim</a>
Set string comparison rules.	<a href="#">Option Compare</a>
Work with ASCII and ANSI values.	<a href="#">Asc</a> , <a href="#">Chr</a>

Action	Keywords
Assign value.	<a href="#">Let</a>
Declare variables or constants.	<a href="#">Const</a> , <a href="#">Dim</a> , <a href="#">Private</a> , <a href="#">Public</a> , <a href="#">New</a> , <a href="#">Static</a>
Declare module as private.	<a href="#">Option Private Module</a>
Get information about a variant.	<a href="#">IsArray</a> , <a href="#">IsDate</a> , <a href="#">IsEmpty</a> , <a href="#">IsError</a> , <a href="#">IsMissing</a> , <a href="#">IsNull</a> , <a href="#">IsNumeric</a> , <a href="#">IsObject</a> , <a href="#">TypeName</a> , <a href="#">VarType</a>
Refer to current object.	<a href="#">Me</a>
Require explicit variable declarations.	<a href="#">Option Explicit</a>
Set default data type.	<a href="#">Deftype</a>

As

The **As** keyword is used in these contexts:

[Const Statement](#)

[Declare Statement](#)

[Dim Statement](#)

[Function Statement](#)

[Name Statement](#)

[Open Statement](#)

[Private Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Public Statement](#)

[ReDim Statement](#)

[Static Statement](#)

[Sub Statement](#)

[Type Statement](#)

Binary

The **Binary** keyword is used in these contexts:

[Open Statement](#)

[Option Compare Statement](#)

ByRef

The **ByRef** keyword is used in these contexts:

[Call Statement](#)

[Declare Statement](#)

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Sub Statement](#)

ByVal

The **ByVal** keyword is used in these contexts:

[Call Statement](#)

[Declare Statement](#)

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Sub Statement](#)

Date

The **Date** keyword is used in these contexts:

[Date Data Type](#)

[Date Function](#)

[Date Statement](#)

Else

The **Else** keyword is used in these contexts:

[If...Then...Else Statement](#)

[Select Case Statement](#)

Empty

The **Empty** [keyword](#) is used as a [Variant](#) subtype. It indicates an uninitialized [variable](#) value.

Error

The **Error** keyword is used in these contexts:

[Error Function](#)

[Error Statement](#)

[On Error Statement](#)

False

The **False** [keyword](#) has a value equal to 0.

For

The **For** keyword is used in these contexts:

[For...Next Statement](#)

[For Each...Next Statement](#)

[Open Statement](#)

Get

The **Get** keyword is used in these contexts:

[Get Statement](#)

[Property Get Statement](#)

Input

The **Input** keyword is used in these contexts:

[Input Function](#)

[Input # Statement](#)

[Line Input # Statement](#)

[Open Statement](#)

Is

The **Is** keyword is used in these contexts:

[If...Then...Else Statement](#)

[Is Operator](#)

[Select Case Statement](#)

Len

The **Len** keyword is used in these contexts:

[Len Function](#)

[Open Statement](#)

Let

The **Let** keyword is used in these contexts:

[Let Statement](#)

[Property Let Statement](#)

Lock

The **Lock** keyword is used in these contexts:

[Lock, Unlock Statements](#)

[Open Statement](#)

Me

The **Me** [keyword](#) behaves like an implicitly declared [variable](#). It is automatically available to every [procedure](#) in a [class module](#). When a [class](#) can have more than

one instance, **Me** provides a way to refer to the specific instance of the class where the code is executing. Using **Me** is particularly useful for passing information about the currently executing instance of a class to a procedure in another [module](#). For example, suppose you have the following procedure in a module:

```
Sub ChangeFormColor(FormName As Form)
    FormName.BackColor = RGB(Rnd * 256, Rnd * 2
End Sub
```

You can call this procedure and pass the current instance of the Form class as an [argument](#) using the following [statement](#):

```
ChangeFormColor Me
```

Mid

The **Mid** keyword is used in these contexts:

[Mid Function](#)

[Mid Statement](#)

New

The **New** keyword is used in these contexts:

[Dim Statement](#)

[Private Statement](#)

[Public Statement](#)

[Set Statement](#)

[Static Statement](#)

Next

The **Next** keyword is used in these contexts:

[For...Next Statement](#)

[For Each...Next Statement](#)

[On Error Statement](#)

[Resume Statement](#)

Nothing

The **Nothing** [keyword](#) is used to disassociate an object [variable](#) from an actual object. Use the **Set** statement to assign **Nothing** to an object variable. For example:

```
Set MyObject = Nothing
```

Several object variables can refer to the same actual object. When **Nothing** is assigned to an object variable, that variable no longer refers to an actual object. When several object variables refer to the same object, memory and system resources associated with the object to which the variables refer are released only after all of them have been set to **Nothing**, either explicitly using **Set**, or implicitly after the last object variable set to **Nothing** goes out of [scope](#).

Null

The [Null keyword](#) is used as a [Variant](#) subtype. It indicates that a [variable](#) contains no valid data.

On

The **On** keyword is used in these contexts:

[On Error Statement](#)

[On...GoSub Statement](#)

[On...GoTo Statement](#)

Option

The **Option** keyword is used in these contexts:

[Option Base Statement](#)

[Option Compare Statement](#)

[Option Explicit Statement](#)

[Option Private Statement](#)

Optional

The **Optional** keyword is used in these contexts:

[Declare Statement](#)

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Sub Statement](#)

ParamArray

The **ParamArray** keyword is used in these contexts:

[Declare Statement](#)

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Sub Statement](#)

Print

The **Print** keyword is used in these contexts:

[Print Method](#)

[Print # Statement](#)

Private

The **Private** keyword is used in these contexts:

[Const Statement](#)

[Declare Statement](#)

[Enum Statement](#)

[Function Statement](#)

[Option Private Statement](#)

[Private Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Sub Statement](#)

[Type Statement](#)

Property

The **Property** keyword is used in these contexts:

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

Public

The **Public** keyword is used in these contexts:

[Const Statement](#)

[Declare Statement](#)

[Enum Statement](#)

[Event Statement](#)

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Public Statement](#)

[Sub Statement](#)

[Type Statement](#)

Resume

The **Resume** keyword is used in these contexts:

[On Error Statement](#)

[Resume Statement](#)

Seek

The **Seek** keyword is used in these contexts:

[Seek Function](#)

[Seek Statement](#)

Set

The **Set** keyword is used in these contexts:

[Set Statement](#)

[Property Set Statement](#)

Static

The **Static** keyword is used in these contexts:

[Function Statement](#)

[Property Get Statement](#)

[Property Let Statement](#)

[Property Set Statement](#)

[Static Statement](#)

[Sub Statement](#)

Step

The **Step** keyword is used in these contexts:

[For...Next Statement](#)

[For Each...Next Statement](#)

String

The **String** keyword is used in these contexts:

[String Data Type](#)

[String Function](#)

Then

The **Then** keyword is used in these contexts:

[#If...Then...#Else Directive](#)

[If...Then...Else Statement](#)

Time

The **Time** keyword is used in these contexts:

[Time Function](#)

[Time Statement](#)

To

The **To** keyword is used in these contexts:

[Dim Statement](#)

[For...Next Statement](#)

[Lock, Unlock Statements](#)

[Private Statement](#)

[Public Statement](#)

[ReDim Statement](#)

[Select Case Statement](#)

[Static Statement](#)

[Type Statement](#)

True

The **True** [keyword](#) has a value equal to -1.

WithEvents

The **WithEvents** keyword is used in these contexts:

[Dim Statement](#)

[Private Statement](#)

[Public Statement](#)

Add Method

Adds a [member](#) to a **Collection** object.

## Syntax

*object*.**Add** *item, key, before, after*

The **Add** method syntax has the following object qualifier and [named arguments](#):

Part	Description
<i>object</i>	Required. An <a href="#">object expression</a> that evaluates to an object in the Applies To list.
<i>item</i>	Required. An <a href="#">expression</a> of any type that specifies the member to add to the <a href="#">collection</a> .
<i>key</i>	Optional. A unique <a href="#">string expression</a> that specifies a key string that can be used, instead of a positional index, to access a member of the collection.
<i>before</i>	Optional. An expression that specifies a relative position in the collection. The member to be added is placed in the collection before the member identified by the <i>before</i> <a href="#">argument</a> . If a <a href="#">numeric expression</a> , <i>before</i> must be a number from 1 to the value of the collection's <b>Count</b> property. If a string expression, <i>before</i> must correspond to the <i>key</i> specified when the member being referred to was added to the collection. You can specify a <i>before</i> position or an <i>after</i> position, but not both.
<i>after</i>	Optional. An expression that specifies a relative position in the collection. The member to be added is placed in the collection after the member identified by the <i>after</i> argument. If numeric, <i>after</i> must be a number from 1 to the value of the collection's <b>Count</b> property. If

a string, *after* must correspond to the *key* specified when the member referred to was added to the collection. You can specify a *before* position or an *after* position, but not both.

## Remarks

Whether the *before* or *after* argument is a string expression or numeric expression, it must refer to an existing member of the collection, or an error occurs.

An error also occurs if a specified *key* duplicates the *key* for an existing member of the collection.

## Description

Adds a key and item pair to a **Dictionary** object.

## Syntax

*object*.**Add** *key*, *item*

The **Add** method has the following parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Dictionary</b> object.
<i>key</i>	Required. The key associated with the item being added.
<i>item</i>	Required. The item associated with the key being added.

## Remarks

An error occurs if the *key* already exists.

## Description

Adds a new **Folder** to a **Folders** collection.

## Syntax

*object*.**Add** *folderName*

The **Add** method has the following parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Folders</b> collection.
<i>folderName</i>	Required. The name of the new <b>Folder</b> being added.

## Remarks

An error occurs if the *folderName* already exists.

## Description

Appends a name to an existing path.

## Syntax

*object*.**BuildPath**(*path*, *name*)

The **BuildPath** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>path</i>	Required. Existing path to which <i>name</i> is appended. Path can be absolute or relative and need not specify an existing folder.
<i>name</i>	Required. Name being appended to the existing <i>path</i> .

## Remarks

The **BuildPath** method inserts an additional path separator between the existing path and the name, only if necessary.

## Clear Method

Clears all [property](#) settings of the **Err** object.

### Syntax

*object*.**Clear**

The *object* is always the **Err** object.

### Remarks

Use **Clear** to explicitly clear the **Err** object after an error has been handled, for example, when you use deferred error handling with **On Error Resume Next**. The **Clear** method is called automatically whenever any of the following [statements](#) is executed:

Any type of **Resume** statement

## Exit Sub, Exit Function, Exit Property

### Any **On Error** statement

**Note** The **On Error Resume Next** construct may be preferable to **On Error GoTo** when handling errors generated during access to other objects. Checking **Err** after each interaction with an object removes ambiguity about which object was accessed by the code. You can be sure which object placed the error code in **Err.Number**, as well as which object originally generated the error (the object specified in **Err.Source**).

Close Method

## Description

Closes an open **TextStream** file.

## Syntax

*object*.**Close**

The *object* is always the name of a **TextStream** object.

## Description

Copies a specified file or folder from one location to another.

## Syntax

*object*.**Copy** *destination*[, *overwrite*]

The **Copy** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> or <b>Folder</b> object.
<i>destination</i>	Required. Destination where the file or folder is to be copied. Wildcard characters are not allowed.
<i>overwrite</i>	Optional. <b>Boolean</b> value that is <b>True</b> (default) if existing files or folders are to be overwritten; <b>False</b> if they are not.

## Remarks

The results of the **Copy** method on a **File** or **Folder** are identical to operations performed using **FileSystemObject.CopyFile** or **FileSystemObject.CopyFolder** where the file or folder referred to by *object* is

passed as an argument. You should note, however, that the alternative methods are capable of copying multiple files or folders.

## Description

Copies one or more files from one location to another.

## Syntax

*object*.**CopyFile** *source*, *destination*[, *overwrite*]

The **CopyFile** method syntax has these parts:

Part	Description
<i>object</i>	Required. The <i>object</i> is always the name of a <b>FileSystemObject</b> .
<i>source</i>	Required. Character string file specification, which can include wildcard characters, for one or more files to be copied.
<i>destination</i>	Required. Character string destination where the file or files from <i>source</i> are to be copied. Wildcard characters are not allowed.
<i>overwrite</i>	Optional. <b>Boolean</b> value that indicates if existing files are to be overwritten. If <b>True</b> , files are overwritten; if <b>False</b> , they are not. The default is <b>True</b> . Note that <b>CopyFile</b> will

fail if *destination* has the read-only attribute set, regardless of the value of *overwrite*.

## Remarks

Wildcard characters can only be used in the last path component of the *source* argument. For example, you can use:

```
FileSystemObject.CopyFile "c:\mydocuments\lette
```

But you can't use:

```
FileSystemObject.CopyFile "c:\mydocuments\*\R1?
```

If *source* contains wildcard characters or *destination* ends with a path separator (\), it is assumed that *destination* is an existing folder in which to copy matching files. Otherwise, *destination* is assumed to be the name of a file to create. In either case, three things can happen when an individual file is copied.

If *destination* does not exist, *source* gets copied. This is the usual case.

If *destination* is an existing file, an error occurs if *overwrite* is **False**. Otherwise, an attempt is made to copy *source* over the existing file.

If *destination* is a directory, an error occurs.

An error also occurs if a *source* using wildcard characters doesn't match any files. The **CopyFile** method stops on the first error it encounters. No attempt is made to roll back or undo any changes made before an error occurs.

## Description

Recursively copies a folder from one location to another.

## Syntax

*object*.**CopyFolder** *source*, *destination*[, *overwrite*]

The **CopyFolder** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>source</i>	Required. Character string folder specification, which can include wildcard characters, for one or more folders to be copied.
<i>destination</i>	Required. Character string destination where the folder and subfolders from <i>source</i> are to be copied. Wildcard characters are not allowed.
<i>overwrite</i>	Optional. <b>Boolean</b> value that indicates if existing folders are to be overwritten. If <b>True</b> , files are overwritten; if <b>False</b> , they are not. The default is <b>True</b> .

## Remarks

Wildcard characters can only be used in the last path component of the *source* argument. For example, you can use:

```
FileSystemObject.CopyFolder "c:\mydocuments\let
```

But you can't use:

```
FileSystemObject.CopyFolder "c:\mydocuments\*\*
```

If *source* contains wildcard characters or *destination* ends with a path separator (\), it is assumed that *destination* is an existing folder in which to copy matching folders and subfolders. Otherwise, *destination* is assumed to be the name of a folder to create. In either case, four things can happen when an individual folder is copied.

If *destination* does not exist, the *source* folder and all its contents gets copied. This is the usual case.

If *destination* is an existing file, an error occurs.

If *destination* is a directory, an attempt is made to copy the folder and all its contents. If a file contained in *source* already exists in *destination*, an error occurs if *overwrite* is **False**. Otherwise, it will attempt to copy the file over the existing file.

If *destination* is a read-only directory, an error occurs if an attempt is made to copy an existing read-only file into that directory and *overwrite* is **False**.

An error also occurs if a *source* using wildcard characters doesn't match any folders.

The **CopyFolder** method stops on the first error it encounters. No attempt is made to roll back any changes made before an error occurs.

## Description

Creates a folder.

## Syntax

*object*.**CreateFolder**(*foldername*)

The **CreateFolder** method has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>foldername</i>	Required. <a href="#">String expression</a> that identifies the folder to create.

## Remarks

An error occurs if the specified folder already exists.

## Description

Creates a specified file name and returns a **TextStream** object that can be used to read from or write to the file.

## Syntax

*object*.**CreateTextFile**(*filename*[, *overwrite*[, *unicode*]])

The **CreateTextFile** method has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> or <b>Folder</b> object.
<i>filename</i>	Required. <a href="#">String expression</a> that identifies the file to create.

<i>overwrite</i>	Optional. <b>Boolean</b> value that indicates if an existing file can be overwritten. The value is <b>True</b> if the file can be overwritten; <b>False</b> if it can't be overwritten. If omitted, existing files are not overwritten.
<i>unicode</i>	Optional. <b>Boolean</b> value that indicates whether the file is created as a Unicode or ASCII file. The value is <b>True</b> if the file is created as a Unicode file; <b>False</b> if it's created as an ASCII file. If omitted, an ASCII file is assumed.

## Remarks

The following code illustrates how to use the **CreateTextFile** method to create and open a text file:

```
Sub CreateAfile
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set a = fs.CreateTextFile("c:\testfile.txt")
    a.WriteLine("This is a test.")
    a.Close
End Sub
```

If the *overwrite* argument is **False**, or is not provided, for a *filename* that already exists, an error occurs.

## Description

Deletes a specified file or folder.

## Syntax

*object*.**Delete** *force*

The **Delete** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> or <b>Folder</b> object.
<i>force</i>	Optional. <b>Boolean</b> value that is <b>True</b> if files or folders with the read-only attribute set are to be deleted; <b>False</b> (default) if they are not.

## Remarks

An error occurs if the specified file or folder does not exist.

The results of the **Delete** method on a **File** or **Folder** are identical to operations performed using **FileSystemObject.DeleteFile** or

## **FileSystemObject.DeleteFolder.**

The **Delete** method does not distinguish between folders that have contents and those that do not. The specified folder is deleted regardless of whether or not it has contents.

## Description

Deletes a specified file.

## Syntax

*object*.**DeleteFile** *filespec*[, *force*]

The **DeleteFile** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>filespec</i>	Required. The name of the file to delete. The <i>filespec</i> can contain wildcard characters in the last path component.
<i>force</i>	Optional. <b>Boolean</b> value that is <b>True</b> if files with the read-only attribute set are to be deleted; <b>False</b> (default) if they are not.

## Remarks

An error occurs if no matching files are found. The **DeleteFile** method stops on the first error it encounters. No attempt is made to roll back or undo any changes that were made before an error occurred.

## Description

Deletes a specified folder and its contents.

## Syntax

*object*.**DeleteFolder** *folderspec*[, *force*]

The **DeleteFolder** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>folderspec</i>	Required. The name of the folder to delete. The <i>folderspec</i> can contain wildcard characters in the last path component.
<i>force</i>	Optional. <b>Boolean</b> value that is <b>True</b> if folders with the read-only attribute set are to be deleted; <b>False</b> (default) if they are not.

## Remarks

The **DeleteFolder** method does not distinguish between folders that have contents and those that do not. The specified folder is deleted regardless of whether or not it has contents.

An error occurs if no matching folders are found. The **DeleteFolder** method stops on the first error it encounters. No attempt is made to roll back or undo any changes that were made before an error occurred.

## Description

Returns **True** if the specified drive exists; **False** if it does not.

## Syntax

*object*.**DriveExists**(*drivespec*)

The **DriveExists** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>drivespec</i>	Required. A drive letter or a complete path specification.

## Remarks

For drives with removable media, the **DriveExists** method returns **True** even if there are no media present. Use the **IsReady** property of the **Drive** object to determine if a drive is ready.

## Description

Returns **True** if a specified key exists in the **Dictionary** object; **False** if it does not.

## Syntax

*object*.**Exists**(*key*)

The **Exists** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Dictionary</b> object.
<i>key</i>	Required. <i>Key</i> value being searched for in the <b>Dictionary</b> object.

## Description

Returns **True** if a specified file exists; **False** if it does not.

## Syntax

*object*.**FileExists**(*filespec*)

The **FileExists** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>filespec</i>	Required. The name of the file whose existence is to be determined. A complete path specification (either absolute or relative) must be provided if the file isn't expected to exist in the current folder.

## Description

Returns **True** if a specified folder exists; **False** if it does not.

## Syntax

*object*.**FolderExists**(*folderspec*)

The **FolderExists** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>folderspec</i>	Required. The name of the folder whose existence is to be determined. A complete path specification (either absolute or relative) must be provided if the folder isn't expected to exist in the current folder.

## Description

Returns a complete and unambiguous path from a provided path specification.

## Syntax

*object*.**GetAbsolutePathName**(*pathspec*)

The **GetAbsolutePathName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>pathspec</i>	Required. Path specification to change to a complete and unambiguous path.

## Remarks

A path is complete and unambiguous if it provides a complete reference from the root of the specified drive. A complete path can only end with a path separator character (\) if it specifies the root folder of a mapped drive.

Assuming the current directory is c:\mydocuments\reports, the following table

illustrates the behavior of the **GetAbsolutePathName** method.

<i><b>pathspec</b></i>	<b>Returned path</b>
"c:"	"c:\mydocuments\reports"
"c:.."	"c:\mydocuments"
"c:\\\"	"c:\"
"c:*. *\may97"	"c:\mydocuments\reports\*. *\may97"
"region1"	"c:\mydocuments\reports\region1"
"c:\..\..\mydocuments"	"c:\mydocuments"

## Description

Returns a string containing the base name of the last component, less any file extension, in a path.

## Syntax

*object*.**GetBaseName**(*path*)

The **GetBaseName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>path</i>	Required. The path specification for the component whose base name is to be returned.

## Remarks

The **GetBaseName** method returns a zero-length string ("") if no component matches the *path* argument.

**Note** The **GetBaseName** method works only on the provided *path* string. It

does not attempt to resolve the path, nor does it check for the existence of the specified path.

## Description

Returns a **Drive** object corresponding to the drive in a specified path.

## Syntax

*object*.**GetDrive** *drivespec*

The **GetDrive** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>drivespec</i>	Required. The <i>drivespec</i> argument can be a drive letter (c), a drive letter with a colon appended (c:), a drive letter with a colon and path separator appended (c:\), or any network share specification (\\computer2\share1).

## Remarks

For network shares, a check is made to ensure that the share exists.

An error occurs if *drivespec* does not conform to one of the accepted forms or

does not exist.

To call the **GetDrive** method on a normal path string, use the following sequence to get a string that is suitable for use as *drivespec*:

```
DriveSpec = GetDriveName(GetAbsolutePathName(Pa
```

## Description

Returns a string containing the name of the drive for a specified path.

## Syntax

*object*.**GetDriveName**(*path*)

The **GetDriveName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>path</i>	Required. The path specification for the component whose drive name is to be returned.

## Remarks

The **GetDriveName** method returns a zero-length string ("") if the drive can't be determined.

**Note** The **GetDriveName** method works only on the provided *path* string. It does not attempt to resolve the path, nor does it check for the existence of the

specified path.

## Description

Returns a string containing the extension name for the last component in a path.

## Syntax

*object*.**GetExtensionName**(*path*)

The **GetExtensionName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>path</i>	Required. The path specification for the component whose extension name is to be returned.

## Remarks

For network drives, the root directory (\) is considered to be a component.

The **GetExtensionName** method returns a zero-length string ("" ) if no component matches the *path* argument.

## Description

Returns a **File** object corresponding to the file in a specified path.

## Syntax

*object*.**GetFile**(*filespec*)

The **GetFile** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>filespec</i>	Required. The <i>filespec</i> is the path (absolute or relative) to a specific file.

## Remarks

An error occurs if the specified file does not exist.

## Description

Returns the last component of specified path that is not part of the drive specification.

## Syntax

*object*.**GetFileName**(*pathspec*)

The **GetFileName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>pathspec</i>	Required. The path (absolute or relative) to a specific file.

## Remarks

The **GetFileName** method returns a zero-length string ("" ) if *pathspec* does not end with the named component.

**Note** The **GetFileName** method works only on the provided path string. It does

not attempt to resolve the path, nor does it check for the existence of the specified path.

## Description

Returns a **Folder** object corresponding to the folder in a specified path.

## Syntax

*object*.**GetFolder**(*folderspec*)

The **GetFolder** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>folderspec</i>	Required. The <i>folderspec</i> is the path (absolute or relative) to a specific folder.

## Remarks

An error occurs if the specified folder does not exist.

## Description

Returns a string containing the name of the parent folder of the last component in a specified path.

## Syntax

*object*.**GetParentFolderName**(*path*)

The **GetParentFolderName** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>path</i>	Required. The path specification for the component whose parent folder name is to be returned.

## Remarks

The **GetParentFolderName** method returns a zero-length string ("" ) if there is no parent folder for the component specified in the *path* argument.

**Note** The **GetParentFolderName** method works only on the provided *path*

string. It does not attempt to resolve the path, nor does it check for the existence of the specified path.

## Description

Returns the special folder specified.

## Syntax

*object*.**GetSpecialFolder**(*folderspec*)

The **GetSpecialFolder** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>folderspec</i>	Required. The name of the special folder to be returned. Can be any of the constants shown in the Settings section.

## Settings

The *folderspec* argument can have any of the following values:

Constant	Value	Description
<b>WindowsFolder</b>	0	The Windows folder contains files installed by the Windows operating system.

<b>SystemFolder</b>	1	The System folder contains libraries, fonts, and device drivers.
<b>TemporaryFolder</b>	2	The Temp folder is used to store temporary files. Its path is found in the TMP environment variable.

## Description

Returns a randomly generated temporary file or folder name that is useful for performing operations that require a temporary file or folder.

## Syntax

*object*.**GetTempName**

The optional *object* is always the name of a **FileSystemObject**.

## Remarks

The **GetTempName** method does not create a file. It provides only a temporary file name that can be used with **CreateTextFile** to create a file.

Item Method

Returns a specific [member](#) of a **Collection** object either by position or by key.

## Syntax

*object*.**Item**(*index*)

The **Item** method syntax has the following object qualifier and part:

Part	Description
<i>object</i>	Required. An <a href="#">object expression</a> that evaluates to an object in the Applies To list.
<i>index</i>	Required. An <a href="#">expression</a> that specifies the position of a member of the <a href="#">collection</a> . If a <a href="#">numeric expression</a> , <i>index</i> must be a number from 1 to the value of the collection's <b>Count</b> property. If a <a href="#">string expression</a> , <i>index</i> must correspond to the <b>key argument</b> specified when the member referred to was added to the collection.

## Remarks

If the value provided as *index* doesn't match any existing member of the collection, an error occurs.

The **Item** method is the default method for a collection. Therefore, the following lines of code are equivalent:

```
Print MyCollection(1)
Print MyCollection.Item(1)
```

## Description

Returns an array containing all the items in a **Dictionary** object.

## Syntax

*object*.**Items**

The *object* is always the name of a **Dictionary** object.

## Remarks

The following code illustrates use of the **Items** method:

```
Dim a, d, i                'Create some variables
Set d = CreateObject("Scripting.Dictionary")
d.Add "a", "Athens"        'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
a = d.Items                'Get the items
For i = 0 To d.Count -1    'Iterate the array
    Print a(i)              'Print item
```

Next

...

## Description

Returns an array containing all existing keys in a **Dictionary** object.

## Syntax

*object*.**Keys**

The *object* is always the name of a **Dictionary** object.

## Remarks

The following code illustrates use of the **Keys** method:

```
Dim a, d, i                'Create some variables
Set d = CreateObject("Scripting.Dictionary")
d.Add "a", "Athens"        'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
a = d.keys                'Get the keys
For i = 0 To d.Count -1    'Iterate the array
    Print a(i)             'Print key
```

Next

...

## Description

Moves a specified file or folder from one location to another.

## Syntax

*object*.**Move** *destination*

The **Move** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> or <b>Folder</b> object.
<i>destination</i>	Required. Destination where the file or folder is to be moved. Wildcard characters are not allowed.

## Remarks

The results of the **Move** method on a **File** or **Folder** are identical to operations performed using **FileSystemObject.MoveFile** or **FileSystemObject.MoveFolder**. You should note, however, that the alternative methods are capable of moving multiple files or folders.

## Description

Moves one or more files from one location to another.

## Syntax

*object*.**MoveFile** *source*, *destination*

The **MoveFile** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>source</i>	Required. The path to the file or files to be moved. The <i>source</i> argument string can contain wildcard characters in the last path component only.
<i>destination</i>	Required. The path where the file or files are to be moved. The <i>destination</i> argument can't contain wildcard characters.

## Remarks

If *source* contains wildcards or *destination* ends with a path separator (\), it is assumed that *destination* specifies an existing folder in which to move the

matching files. Otherwise, *destination* is assumed to be the name of a destination file to create. In either case, three things can happen when an individual file is moved:

If *destination* does not exist, the file gets moved. This is the usual case.

If *destination* is an existing file, an error occurs.

If *destination* is a directory, an error occurs.

An error also occurs if a wildcard character that is used in *source* doesn't match any files. The **MoveFile** method stops on the first error it encounters. No attempt is made to roll back any changes made before the error occurs.

**Important** This method allows moving files between volumes only if supported by the operating system.

## Description

Moves one or more folders from one location to another.

## Syntax

*object*.**MoveFolder** *source*, *destination*

The **MoveFolder** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>source</i>	Required. The path to the folder or folders to be moved. The <i>source</i> argument string can contain wildcard characters in the last path component only.
<i>destination</i>	Required. The path where the folder or folders are to be moved. The <i>destination</i> argument can't contain wildcard characters.

## Remarks

If *source* contains wildcards or *destination* ends with a path separator (\), it is assumed that *destination* specifies an existing folder in which to move the

matching files. Otherwise, *destination* is assumed to be the name of a destination folder to create. In either case, three things can happen when an individual folder is moved:

If *destination* does not exist, the folder gets moved. This is the usual case.

If *destination* is an existing file, an error occurs.

If *destination* is a directory, an error occurs.

An error also occurs if a wildcard character that is used in *source* doesn't match any folders. The **MoveFolder** method stops on the first error it encounters. No attempt is made to roll back any changes made before the error occurs.

**Important** This method allows moving folders between volumes only if supported by the operating system.

## Description

Opens a specified file and returns a **TextStream** object that can be used to read from, write to, or append to the file.

## Syntax

*object*.**OpenAsTextStream**([*iomode*, [*format*]])

The **OpenAsTextStream** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> object.
<i>iomode</i>	Optional. Indicates input/output mode. Can be one of three constants: <b>ForReading</b> , <b>ForWriting</b> , or <b>ForAppending</b> .
<i>format</i>	Optional. One of three <b>Tristate</b> values used to indicate the format of the opened file. If omitted, the file is opened as ASCII.

## Settings

The *iomode* argument can have any of the following settings:

Constant	Value	Description
<b>ForReading</b>	1	Open a file for reading only. You can't write to this file.
<b>ForWriting</b>	2	Open a file for writing. If a file with the same name exists, its previous contents are overwritten.
<b>ForAppending</b>	8	Open a file and write to the end of the file.

The *format* argument can have any of the following settings:

Constant	Value	Description
<b>TristateUseDefault</b>	-2	Opens the file using the system default.
<b>TristateTrue</b>	-1	Opens the file as Unicode.
<b>TristateFalse</b>	0	Opens the file as ASCII.

## Remarks

The **OpenAsTextStream** method provides the same functionality as the **OpenTextFile** method of the **FileSystemObject**. In addition, the **OpenAsTextStream** method can be used to write to a file.

The following code illustrates the use of the **OpenAsTextStream** method:

```
Sub TextStreamTest
    Const ForReading = 1, ForWriting = 2, ForAp
    Const TristateUseDefault = -2, TristateTrue
    Dim fs, f, ts, s
    Set fs = CreateObject("Scripting.FileSystem
    fs.CreateTextFile "test1.txt"           'C
    Set f = fs.GetFile("test1.txt")
    Set ts = f.OpenAsTextStream(ForWriting, Tri
```

```
ts.Write "Hello World"  
ts.Close  
Set ts = f.OpenAsTextStream(ForReading, Tri  
s = ts.ReadLine  
MsgBox s  
ts.Close  
End Sub
```

## Description

Opens a specified file and returns a **TextStream** object that can be used to read from or append to the file.

## Syntax

*object*.**OpenTextFile**(*filename*[, *iomode*[, *create*[, *format*]]])

The **OpenTextFile** method has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>FileSystemObject</b> .
<i>filename</i>	Required. <a href="#">String expression</a> that identifies the file to open.

<i>iomode</i>	Optional. Indicates input/output mode. Can be one of two constants, either <b>ForReading</b> or <b>ForAppending</b> .
<i>create</i>	Optional. <b>Boolean</b> value that indicates whether a new file can be created if the specified <i>filename</i> doesn't exist. The value is <b>True</b> if a new file is created; <b>False</b> if it isn't created. The default is <b>False</b> .
<i>format</i>	Optional. One of three <b>Tristate</b> values used to indicate the format of the opened file. If omitted, the file is opened as ASCII.

## Settings

The *iomode* argument can have either of the following settings:

Constant	Value	Description
<b>ForReading</b>	1	Open a file for reading only. You can't write to this file.
<b>ForAppending</b>	8	Open a file and write to the end of the file.

The *format* argument can have any of the following settings:

Constant	Value	Description
<b>TristateUseDefault</b>	-2	Opens the file using the system default.
<b>TristateTrue</b>	-1	Opens the file as Unicode.
<b>TristateFalse</b>	0	Opens the file as ASCII.

## Remarks

The following code illustrates the use of the **OpenTextFile** method to open a file for appending text:

```
Sub OpenTextFileTest
    Const ForReading = 1, ForWriting = 2, ForAp
```

```
    Dim fs, f
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.OpenTextFile("c:\testfile.txt",
    f.Write "Hello world!"
    f.Close
End Sub
```

Print Method

Prints text in the **Immediate** window.

**Syntax**

*object*.**Print** [*outputlist*]

The **Print** method syntax has the following object qualifier and part:

Part	Description
<i>object</i>	Optional. An <a href="#">object expression</a> that evaluates to an object in the Applies To list.
<i>outputlist</i>	Optional. <a href="#">Expression</a> or list of expressions to print. If omitted, a blank line is printed.

The *outputlist* [argument](#) has the following syntax and parts:

{**Spc**(*n*) | **Tab**(*n*)} *expression charpos*

Part	Description
<b>Spc</b> ( <i>n</i> )	Optional. Used to insert space characters in the output, where <i>n</i> is the number of space characters to insert.
<b>Tab</b> ( <i>n</i> )	Optional. Used to position the insertion point at an absolute column number where <i>n</i> is the column number. Use <b>Tab</b> with no argument to position the insertion point at the beginning of the next <a href="#">print zone</a> .
<i>expression</i>	Optional. <a href="#">Numeric expression</a> or <a href="#">string expression</a> to print.
<i>charpos</i>	Optional. Specifies the insertion point for the next character. Use a semicolon (;) to position the insertion point immediately following the last character displayed. Use <b>Tab</b> ( <i>n</i> ) to position the insertion point at an absolute column number. Use <b>Tab</b> with no argument to position the insertion point at the beginning of the next print zone. If <i>charpos</i> is omitted, the next character is printed on the next line.

## Remarks

Multiple expressions can be separated with either a space or a semicolon.

All data printed to the **Immediate** window is properly formatted using the

decimal separator for the [locale](#) settings specified for your system. The [keywords](#) are output in the appropriate language for the [host application](#).

For [Boolean](#) data, either `True` or `False` is printed. The **True** and **False** keywords are translated according to the locale setting for the host application.

[Date](#) data is written using the standard short date format recognized by your system. When either the date or the time component is missing or zero, only the data provided is written.

Nothing is written if *outputlist* data is [Empty](#). However, if *outputlist* data is [Null](#), `Null` is output. The **Null** keyword is appropriately translated when it is output.

For error data, the output is written as `Error errorcode`. The **Error** keyword is appropriately translated when it is output.

The *object* is required if the method is used outside a [module](#) having a default display space. For example an error occurs if the method is called in a [standard module](#) without specifying an *object*, but if called in a form module, *outputlist* is displayed on the form.

**Note** Because the **Print** method typically prints with proportionally-spaced characters, there is no correlation between the number of characters printed and the number of fixed-width columns those characters occupy. For example, a wide letter, such as a "W", occupies more than one fixed-width column, and a narrow letter, such as an "i", occupies less. To allow for cases where wider than average characters are used, your tabular columns must be positioned far enough apart. Alternatively, you can print using a fixed-pitch font (such as Courier) to ensure that each character uses only one column.

Raise Method

Generates a [run-time error](#).

## Syntax

*object*.**Raise** *number*, *source*, *description*, *helpfile*, *helpcontext*

The **Raise** method has the following object qualifier and [named arguments](#):

Argument	Description
<i>object</i>	Required. Always the <b>Error</b> object.
<i>number</i>	Required. <a href="#">Long</a> integer that identifies the nature of the error. Visual Basic errors (both Visual Basic-defined and user-defined errors) are in the range 0–65535. The range 0–512 is reserved for system errors; the range 513–65535 is available for user-defined errors. When setting the <b>Number</b> property to your own error code in a class module, you add your error code number to the <b>vbObjectError</b> <a href="#">constant</a> . For example, to generate the <a href="#">error number</a> 513, assign <b>vbObjectError</b> + 513 to the <b>Number</b> property.
<i>source</i>	Optional. <a href="#">String expression</a> naming the object or application that generated the error. When setting this <a href="#">property</a> for an object, use the form <i>project.class</i> . If <i>source</i> is not specified, the programmatic ID of the current Visual Basic <a href="#">project</a> is used.

<b><i>description</i></b>	Optional. String expression describing the error. If unspecified, the value in <b>Number</b> is examined. If it can be mapped to a Visual Basic run-time error code, the string that would be returned by the <b>Error</b> function is used as <b>Description</b> . If there is no Visual Basic error corresponding to <b>Number</b> , the "Application-defined or object-defined error" message is used.
<b><i>helpfile</i></b>	Optional. The fully qualified path to the Help file in which help on this error can be found. If unspecified, Visual Basic uses the fully qualified drive, path, and file name of the Visual Basic Help file.
<b><i>helpcontext</i></b>	Optional. The context ID identifying a topic within <b>helpfile</b> that provides help for the error. If omitted, the Visual Basic Help file context ID for the error corresponding to the <b>Number</b> property is used, if it exists.

## Remarks

All of the [arguments](#) are optional except **number**. If you use **Raise** without specifying some arguments, and the property settings of the **Err** object contain values that have not been cleared, those values serve as the values for your error.

**Raise** is used for generating run-time errors and can be used instead of the **Error** statement. **Raise** is useful for generating errors when writing class modules, because the **Err** object gives richer information than is possible if you generate errors with the **Error** statement. For example, with the **Raise** method, the source that generated the error can be specified in the **Source** property, online Help for the error can be referenced, and so on.

## Description

Reads a specified number of characters from a **TextStream** file and returns the resulting string.

## Syntax

*object*.**Read**(*characters*)

The **Read** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>TextStream</b> object.
<i>characters</i>	Required. Number of characters you want to read from the file.

## Description

Reads an entire **TextStream** file and returns the resulting string.

## Syntax

*object*.**ReadAll**

The *object* is always the name of a **TextStream** object.

## Remarks

For large files, using the **ReadAll** method wastes memory resources. Other techniques should be used to input a file, such as reading a file line by line.

## Description

Reads an entire line (up to, but not including, the newline character) from a **TextStream** file and returns the resulting string.

## Syntax

*object*.**ReadLine**

The *object* argument is always the name of a **TextStream** object.

Remove Method

Removes a [member](#) from a **Collection** object.

## Syntax

*object*.**Remove** *index*

The **Remove** method syntax has the following object qualifier and part:

Part	Description
<i>object</i>	Required. An <a href="#">object expression</a> that evaluates to an object in the Applies To list.
<i>index</i>	Required. An <a href="#">expression</a> that specifies the position of a member of the <a href="#">collection</a> . If a <a href="#">numeric expression</a> , <i>index</i> must be a number from 1 to the value of the collection's <b>Count</b> <a href="#">property</a> . If a <a href="#">string expression</a> , <i>index</i> must correspond to the <b>key</b> <a href="#">argument</a> specified when the member referred to was added to the collection.

## Remarks

If the value provided as *index* doesn't match an existing member of the collection, an error occurs.

## Description

Removes a key, item pair from a **Dictionary** object.

## Syntax

*object*.**Remove**(*key*)

The **Remove** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Dictionary</b> object.
<i>key</i>	Required. Key associated with the key, item pair you want to remove from the <b>Dictionary</b> object.

## Remarks

An error occurs if the specified key, item pair does not exist.

The following code illustrates use of the **Remove** method:

```
Dim a, d, i                                'Create some variables
```

```
Set d = CreateObject("Scripting.Dictionary")
d.Add "a", "Athens"      'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
'''
a = d.Remove()          'Remove second pair
```

## Description

The **RemoveAll** method removes all key, item pairs from a **Dictionary** object.

## Syntax

*object*.**RemoveAll**

The *object* is always the name of a **Dictionary** object.

## Remarks

The following code illustrates use of the **RemoveAll** method:

```
Dim a, d, i           'Create some variables
Set d = CreateObject("Scripting.Dictionary")
d.Add "a", "Athens"    'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
...
a = d.RemoveAll      'Clear the dictionary
```

## Description

Skips a specified number of characters when reading a **TextStream** file.

## Syntax

*object*.**Skip**(*characters*)

The **Skip** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>TextStream</b> object.
<i>characters</i>	Required. Number of characters to skip when reading a file.

## Remarks

Skipped characters are discarded.

## Description

Skips the next line when reading a **TextStream** file.

## Syntax

*object*.**SkipLine**

The *object* is always the name of a **TextStream** object.

## Remarks

Skipping a line means reading and discarding all characters in a line up to and including the next newline character.

An error occurs if the file is not open for reading.

## Description

Writes a specified string to a **TextStream** file.

## Syntax

*object*.**Write**(*string*)

The **Write** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>TextStream</b> object.
<i>string</i>	Required. The text you want to write to the file.

## Remarks

Specified strings are written to the file with no intervening spaces or characters between each string. Use the **WriteLine** method to write a newline character or a string that ends with a newline character.

## Description

Writes a specified number of newline characters to a **TextStream** file.

## Syntax

*object*.**WriteBlankLines**(*lines*)

The **WriteBlankLines** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>TextStream</b> object.
<i>lines</i>	Required. Number of newline characters you want to write to the file.

## Description

Writes a specified string and newline character to a **TextStream** file.

## Syntax

*object*.**WriteLine**([*string*])

The **WriteLine** method syntax has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>TextStream</b> object.
<i>string</i>	Optional. The text you want to write to the file. If omitted, a newline character is written to the file.

Character Set (0 – 127)

0	32	[space]	64	@	96	`

157 €	189	½	221 Ý	253 ý
158 €	190	¾	222 Þ	254 þ
159 €	191	¿	223 ß	255 ÿ

€These characters aren't supported by Microsoft Windows.

The values in the table are the Windows default. However, values in the ANSI character set above 127 are determined by the code page specific to your operating system.

Visual Basic documentation uses the following typographic conventions.

Convention	Description
<b>Sub, If, ChDir, Print, True, Debug</b>	Words in bold with initial letter capitalized indicate language-specific keywords.
<b>Setup</b>	Words you are instructed to type appear in bold.
<i>object, varname, arglist</i>	Italic, lowercase letters indicate placeholders for information you supply.
<b><i>pathname, filename</i></b>	Bold, italic, and lowercase letters indicate placeholders for arguments where you can use either positional or <a href="#">named-argument</a> syntax.
[ <i>expressionlist</i> ]	In syntax, items inside brackets are optional.
{ <b>While</b>   <b>Until</b> }	In syntax, braces and a vertical bar indicate a mandatory choice between two or more items. You

must choose one of the items unless all of the items are also enclosed in brackets. For example:

[{**This** | **OrThat**}]

ESC, ENTER	Words in capital letters indicate key names and key sequences.
ALT+F1, CTRL+R	A plus sign (+) between key names indicates a combination of keys. For example, ALT+F1 means hold down the ALT key while pressing the F1 key.

## Code Conventions

The following code conventions are used:

Sample Code	Description
MyString = "Hello, world!"	This font is used for code, variables, and error message text.
' This is a comment.	An apostrophe (') introduces code comments.
MyVar = "This is an " _ & "example" _ & " of how to continue code."	A space and an underscore ( _ ) continue a line of code.

Collection Object

A **Collection** object is an ordered set of items that can be referred to as a unit.

## Remarks

The **Collection** object provides a convenient way to refer to a related group of items as a single object. The items, or [members](#), in a collection need only be related by the fact that they exist in the [collection](#). Members of a collection don't have to share the same [data type](#).

A collection can be created the same way other objects are created. For example:

```
Dim X As New Collection
```

Once a collection is created, members can be added using the **Add** method and removed using the **Remove** method. Specific members can be returned from the collection using the **Item** method, while the entire collection can be iterated using the **For Each...Next** statement.

Debug Object

The **Debug** object sends output to the **Immediate** window at [run time](#).

## Description

Object that stores data key, item pairs.

## Syntax

## Scripting.Dictionary

## Remarks

A **Dictionary** object is the equivalent of a PERL associative array. Items, which can be any form of data, are stored in the array. Each item is associated with a unique key. The key is used to retrieve an individual item and is usually a integer or a string, but can be anything except an array.

The following code illustrates how to create a **Dictionary** object:

```
Dim d                                'Create a variable
Set d = CreateObject(Scripting.Dictionary)
d.Add "a", "Athens"                 'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
...
```

## Description

Provides access to the properties of a particular disk drive or network share.

## Remarks

The following code illustrates the use of the **Drive** object to access drive properties:

```
Sub ShowFreeSpace(drvPath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(fs.GetDriveName(drvPath))
    s = "Drive " & UCase(drvPath) & " - "
    s = s & d.VolumeName & vbCrLf
End Sub
```

```
s = s & "Free Space: " & FormatNumber(d.Fre  
s = s & " Kbytes"  
MsgBox s  
End Sub
```

## Description

Read-only collection of all available drives.

## Remarks

Removable-media drives need not have media inserted for them to appear in the **Drives** collection.

The following code illustrates how to get the **Drives** collection and iterate the collection using the **For Each...Next** statement:

```
Sub ShowDriveList
    Dim fs, d, dc, s, n
    Set fs = CreateObject("Scripting.FileSystem
```

```
Set dc = fs.Drives
For Each d in dc
    s = s & d.DriveLetter & " - "
    If d.DriveType = Remote Then
        n = d.ShareName
    Else
        n = d.VolumeName
    End If
    s = s & n & vbCrLf
Next
MsgBox s
End Sub
```

Err Object

Contains information about [run-time errors](#).

## Remarks

The [properties](#) of the **Err** object are set by the generator of an error — Visual Basic, an object, or the programmer.

The default property of the **Err** object is **Number**. Because the default property can be represented by the object name **Err**, earlier code written using the **Err** function or **Err** statement doesn't have to be modified.

When a run-time error occurs, the properties of the **Err** object are filled with information that uniquely identifies the error and information that can be used to handle it. To generate a run-time error in your code, use the **Raise** method.

The **Err** object's properties are reset to zero or zero-length strings ("" ) after an **Exit Sub**, **Exit Function**, **Exit Property** or **Resume Next** statement within an error-handling routine. Using any form of the **Resume** statement outside of an error-handling routine will not reset the **Err** object's properties. The **Clear** method can be used to explicitly reset **Err**.

Use the **Raise** method, rather than the **Error** statement, to generate run-time errors for system errors and class modules. Using the **Raise** method in other code depends on the richness of the information you want to return.

The **Err** object is an intrinsic object with global [scope](#). There is no need to create an instance of it in your code.

## Description

Provides access to all the properties of a file.

## Remarks

The following code illustrates how to obtain a **File** object and how to view one of its properties.

```
Sub ShowFileInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = f.DateCreated
    MsgBox s
```

End Sub

## Description

Collection of all **File** objects within a folder.

## Remarks

The following code illustrates how to get a **Files** collection and iterate the collection using the **For Each...Next** statement:

```
Sub ShowFolderList(folderspec)
    Dim fs, f, f1, fc, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(folderspec)
    Set fc = f.Files
    For Each f1 in fc
```

```
        s = s & f1.name
        s = s & vbCrLf
    Next
    MsgBox s
End Sub
```

## Description

Provides access to a computer's file system.

## Syntax

### **Scripting.FileSystemObject**

## Remarks

The following code illustrates how the **FileSystemObject** is used to return a **TextStream** object that can be read from or written to:

```
Set fs = CreateObject("Scripting.FileSystemObject")
Set a = fs.CreateTextFile("c:\testfile.txt", True)
a.WriteLine("This is a test.")
```

`a.Close`

In the code shown above, the **CreateObject** function returns the **FileSystemObject** (fs). The **CreateTextFile** method then creates the file as a **TextStream** object (a), and the **WriteLine** method writes a line of text to the created text file. The **Close** method flushes the buffer and closes the file.

## Description

Provides access to all the properties of a folder.

## Remarks

The following code illustrates how to obtain a **Folder** object and how to return one of its properties:

```
Sub ShowFolderInfo(folderspec)
    Dim fs, f, s,
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(folderspec)
    s = f.DateCreated
    MsgBox s
```

End Sub

## Description

Collection of all **Folder** objects contained within a **Folder** object.

## Remarks

The following code illustrates how to get a **Folders** collection and how to iterate the collection using the **For Each...Next** statement:

```
Sub ShowFolderList(folderspec)
    Dim fs, f, f1, fc, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(folderspec)
    Set fc = f.SubFolders
    For Each f1 in fc
```

```
        s = s & f1.name
        s = s & vbCrLf
    Next
    MsgBox s
End Sub
```

## Description

Facilitates sequential access to file.

## Syntax

**TextStream.**{*property* | *method*}

The *property* and *method* arguments can be any of the properties and methods associated with the **TextStream** object. Note that in actual usage **TextStream** is replaced by a variable placeholder representing the **TextStream** object returned from the **FileSystemObject**.

## Remarks

In the following code, a is the **TextStream** object returned by the

**CreateTextFile** method on the **FileSystemObject**:

```
Set fs = CreateObject("Scripting.FileSystemObject")
Set a = fs.CreateTextFile("c:\testfile.txt", True)
a.WriteLine("This is a test.")
a.Close
```

**WriteLine** and **Close** are two methods of the **TextStream** Object.

& Operator

Used to force string concatenation of two [expressions](#).

## Syntax

*result* = *expression1* & *expression2*

The & operator syntax has these parts:

Part	Description
<i>result</i>	Required; any <a href="#">String</a> or <a href="#">Variant variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

## Remarks

If an *expression* is not a string, it is converted to a **String** variant. The [data type](#) of *result* is **String** if both expressions are [string expressions](#); otherwise, *result* is a **String** variant. If both expressions are [Null](#), *result* is **Null**. However, if only one *expression* is **Null**, that expression is treated as a zero-length string ("") when concatenated with the other expression. Any expression that is [Empty](#) is also treated as a zero-length string.

\* Operator

Used to multiply two numbers.

### **Syntax**

*result = number1\*number2*

The \* operator syntax has these parts:

Part	Description
------	-------------

*result* Required; any numeric [variable](#).  
*number1* Required; any [numeric expression](#).  
*number2* Required; any numeric expression.

## Remarks

The [data type](#) of *result* is usually the same as that of the most precise [expression](#). The order of precision, from least to most precise, is [Byte](#), [Integer](#), [Long](#), [Single](#), [Currency](#), [Double](#), and [Decimal](#). The following are exceptions to this order:

If	Then <i>result</i> is
Multiplication involves a <b>Single</b> and a <b>Long</b> ,	converted to a <b>Double</b> .
The data type of <i>result</i> is a <b>Long</b> , <b>Single</b> , or <b>Date</b> variant that overflows its legal range,	converted to a <b>Variant</b> containing a <b>Double</b> .
The data type of <i>result</i> is a <b>Byte</b> variant that overflows its legal range,	converted to an <b>Integer</b> variant.
the data type of <i>result</i> is an <b>Integer</b> variant that overflows its legal range,	converted to a <b>Long</b> variant.

If one or both expressions are [Null](#) expressions, *result* is **Null**. If an expression is [Empty](#), it is treated as 0.

**Note** The order of precision used by multiplication is not the same as the order of precision used by addition and subtraction.

+ Operator

Used to sum two numbers.

## Syntax

*result* = *expression1* + *expression2*

The + operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any <a href="#">expression</a> .
<i>expression2</i>	Required; any expression.

## Remarks

When you use the + operator, you may not be able to determine whether addition or string concatenation will occur. Use the & operator for concatenation to eliminate ambiguity and provide self-documenting code.

If at least one expression is not a [Variant](#), the following rules apply:

If	Then
Both expressions are <a href="#">numeric data types</a> ( <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Date</a> , <a href="#">Currency</a> , or <a href="#">Decimal</a> )	Add.
Both expressions are <a href="#">String</a>	Concatenate.
One expression is a numeric data type and the other is any <b>Variant</b> except <a href="#">Null</a>	Add.
One expression is a <b>String</b> and the other is any <b>Variant</b> except <b>Null</b>	Concatenate.

One expression is an <a href="#">Empty Variant</a>	Return the remaining expression unchanged as <i>result</i> .
One expression is a numeric data type and the other is a <b>String</b>	A Type mismatch error occurs.
Either expression is <b>Null</b>	<i>result</i> is <b>Null</b> .

If both expressions are **Variant** expressions, the following rules apply:

If	Then
Both <b>Variant</b> expressions are numeric	Add.
Both <b>Variant</b> expressions are strings	Concatenate.
One <b>Variant</b> expression is numeric and the other is a string	Add.

For simple arithmetic addition involving only expressions of numeric data types, the [data type](#) of *result* is usually the same as that of the most precise expression. The order of precision, from least to most precise, is **Byte**, **Integer**, **Long**, **Single**, **Double**, **Currency**, and **Decimal**. The following are exceptions to this order:

If	Then <i>result</i> is
A <b>Single</b> and a <b>Long</b> are added,	a <b>Double</b> .
The data type of <i>result</i> is a <b>Long</b> , <b>Single</b> , or <b>Date</b> variant that overflows its legal range,	converted to a <b>Double</b> variant.
The data type of <i>result</i> is a <b>Byte</b> variant that overflows its legal range,	converted to an <b>Integer</b> variant.
The data type of <i>result</i> is an <b>Integer</b> variant that overflows its legal range,	converted to a <b>Long</b> variant.
A <b>Date</b> is added to any data type,	a <b>Date</b> .

If one or both expressions are **Null** expressions, *result* is **Null**. If both expressions are **Empty**, *result* is an **Integer**. However, if only one expression is **Empty**, the other expression is returned unchanged as *result*.

**Note** The order of precision used by addition and subtraction is not the same as the order of precision used by multiplication.

- Operator

Used to find the difference between two numbers or to indicate the negative value of a [numeric expression](#).

## Syntax 1

*result* = *number1*–*number2*

## Syntax 2

–*number*

The – operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>number</i>	Required; any numeric expression.
<i>number1</i>	Required; any numeric expression.
<i>number2</i>	Required; any numeric expression.

## Remarks

In Syntax 1, the – operator is the arithmetic subtraction operator used to find the difference between two numbers. In Syntax 2, the – operator is used as the unary negation operator to indicate the negative value of an expression.

The [data type](#) of *result* is usually the same as that of the most precise [expression](#). The order of precision, from least to most precise, is [Byte](#), [Integer](#), [Long](#), [Single](#), [Double](#), [Currency](#), and [Decimal](#). The following are exceptions to this order:

If	Then <i>result</i> is
Subtraction involves a <b>Single</b> and a <b>Long</b> ,	converted to a <b>Double</b> .
The data type of <i>result</i> is a <b>Long</b> , <b>Single</b> , or <a href="#">Date</a> variant that overflows its legal range,	converted to a <a href="#">Variant</a> containing a <b>Double</b> .
The data type of <i>result</i> is a <b>Byte</b> variant that overflows its legal range,	converted to an <b>Integer</b> variant.
The data type of <i>result</i> is an <b>Integer</b> variant that overflows its legal range,	converted to a <b>Long</b> variant.
Subtraction involves a <b>Date</b> and any	a <b>Date</b> .

other data type,

Subtraction involves two **Date** expressions, a **Double**.

One or both expressions are [Null](#) expressions, *result* is **Null**. If an expression is [Empty](#), it is treated as 0.

**Note** The order of precision used by addition and subtraction is not the same as the order of precision used by multiplication.

/ Operator

Used to divide two numbers and return a floating-point result.

## Syntax

*result* = *number1*/*number2*

The / operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>number1</i>	Required; any <a href="#">numeric expression</a> .
<i>number2</i>	Required; any numeric expression.

## Remarks

The [data type](#) of *result* is usually a [Double](#) or a **Double** variant. The following

are exceptions to this rule:

If	Then <i>result</i> is
Both <a href="#">expressions</a> are <a href="#">Byte</a> , <a href="#">Integer</a> , or <a href="#">Single</a> expressions,	a <b>Single</b> unless it overflows its legal range; in which case, an error occurs.
Both expressions are <b>Byte</b> , <b>Integer</b> , or <b>Single</b> variants,	a <b>Single</b> variant unless it overflows its legal range; in which case, <i>result</i> is a <a href="#">Variant</a> containing a <b>Double</b> .
Division involves a <a href="#">Decimal</a> and any other data type,	a <b>Decimal</b> data type.

One or both expressions are [Null](#) expressions, *result* is **Null**. Any expression that is [Empty](#) is treated as 0.

\ Operator

Used to divide two numbers and return an integer result.

## Syntax

*result* = *number1* \ *number2*

The \ operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>number1</i>	Required; any <a href="#">numeric expression</a> .
<i>number2</i>	Required; any numeric expression.

## Remarks

Before division is performed, the numeric expressions are rounded to [Byte](#), [Integer](#), or [Long](#) expressions.

Usually, the [data type](#) of *result* is a **Byte**, **Byte** variant, **Integer**, **Integer** variant, **Long**, or **Long** variant, regardless of whether *result* is a whole number. Any fractional portion is truncated. However, if any [expression](#) is [Null](#), *result* is **Null**. Any expression that is [Empty](#) is treated as 0.

<sup>^</sup>Operator

Used to raise a number to the power of an exponent.

## Syntax

*result* = *number*^*exponent*

The ^ operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>number</i>	Required; any <a href="#">numeric expression</a> .
<i>exponent</i>	Required; any numeric expression.

## Remarks

A *number* can be negative only if *exponent* is an integer value. When more than one exponentiation is performed in a single [expression](#), the ^ operator is evaluated as it is encountered from left to right.

Usually, the [data type](#) of *result* is a [Double](#) or a [Variant](#) containing a **Double**. However, if either *number* or *exponent* is a [Null](#) expression, *result* is **Null**.

= Operator

## Description

Used to assign a value to a [variable](#) or [property](#).

## Syntax

*variable* = *value*

The = operator syntax has these parts:

Part	Description
<i>variable</i>	Any variable or any writable property.
<i>value</i>	Any numeric or string literal, <a href="#">constant</a> , or <a href="#">expression</a> .

## Remarks

The name on the left side of the equal sign can be a simple scalar variable or an element of an [array](#). Properties on the left side of the equal sign can only be those properties that are writable at [run time](#).

And Operator

Used to perform a logical conjunction on two [expressions](#).

**Syntax**

*result* = *expression1* **And** *expression2*

The **And** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

### Remarks

If both expressions evaluate to **True**, *result* is **True**. If either expression evaluates to **False**, *result* is **False**. The following table illustrates how *result* is determined:

If <i>expression1</i> is	And <i>expression2</i> is	The <i>result</i> is
<b>True</b>	<b>True</b>	<b>True</b>
<b>True</b>	<b>False</b>	<b>False</b>
<b>True</b>	<a href="#">Null</a>	<b>Null</b>
<b>False</b>	<b>True</b>	<b>False</b>
<b>False</b>	<b>False</b>	<b>False</b>
<b>False</b>	<b>Null</b>	<b>False</b>
<b>Null</b>	<b>True</b>	<b>Null</b>
<b>Null</b>	<b>False</b>	<b>False</b>
<b>Null</b>	<b>Null</b>	<b>Null</b>

The **And** operator also performs a [bitwise comparison](#) of identically positioned bits in two [numeric expressions](#) and sets the corresponding bit in *result* according to the following table:

If bit in <i>expression1</i> is	And bit in <i>expression2</i> is	The <i>result</i> is
0	0	0
0	1	0

1

0

0

1

1

1

Comparison Operators

Used to compare [expressions](#).

## Syntax

*result = expression1 comparisonoperator expression2*

*result = object1 **Is** object2*

*result = string **Like** pattern*

[Comparison operators](#) have these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression</i>	Required; any expression.
<i>comparisonoperator</i>	Required; any comparison operator.
<i>object</i>	Required; any object name.
<i>string</i>	Required; any <a href="#">string expression</a> .
<i>pattern</i>	Required; any string expression or range of characters.

## Remarks

The following table contains a list of the comparison operators and the

conditions that determine whether *result* is **True**, **False**, or [Null](#):

Operator	True if	False if	Null if
< (Less than)	<i>expression1</i> < <i>expression2</i>	<i>expression1</i> >= <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>
<= (Less than or equal to)	<i>expression1</i> <= <i>expression2</i>	<i>expression1</i> > <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>
> (Greater than)	<i>expression1</i> > <i>expression2</i>	<i>expression1</i> <= <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>
>= (Greater than or equal to)	<i>expression1</i> >= <i>expression2</i>	<i>expression1</i> < <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>
= (Equal to)	<i>expression1</i> = <i>expression2</i>	<i>expression1</i> <> <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>
<> (Not equal to)	<i>expression1</i> <> <i>expression2</i>	<i>expression1</i> = <i>expression2</i>	<i>expression1</i> or <i>expression2</i> = <b>Null</b>

**Note** The **Is** and **Like** operators have specific comparison functionality that differs from the operators in the table.

When comparing two expressions, you may not be able to easily determine whether the expressions are being compared as numbers or as strings. The following table shows how the expressions are compared or the result when either expression is not a [Variant](#):

If	Then
Both expressions are <a href="#">numeric data types</a> ( <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Date</a> , <a href="#">Currency</a> , or <a href="#">Decimal</a> )	Perform a numeric comparison.
Both expressions are <a href="#">String</a>	Perform a <a href="#">string comparison</a> .
One expression is a numeric data type and the other is a <b>Variant</b> that is, or can be, a number	Perform a numeric comparison.
One expression is a numeric data type and the other is a string <b>Variant</b> that	A Type Mismatch error occurs.

can't be converted to a number

One expression is a **String** and the other is any **Variant** except a **Null** Perform a string comparison.

One expression is **Empty** and the other is a numeric data type Perform a numeric comparison, using 0 as the **Empty** expression.

One expression is **Empty** and the other is a **String** Perform a string comparison, using a zero-length string ("" ) as the **Empty** expression.

If *expression1* and *expression2* are both **Variant** expressions, their underlying type determines how they are compared. The following table shows how the expressions are compared or the result from the comparison, depending on the underlying type of the **Variant**:

If	Then
Both <b>Variant</b> expressions are numeric	Perform a numeric comparison.
Both <b>Variant</b> expressions are strings	Perform a string comparison.
One <b>Variant</b> expression is numeric and the other is a string	The numeric expression is less than the string expression.
One <b>Variant</b> expression is <b>Empty</b> and the other is numeric	Perform a numeric comparison, using 0 as the <b>Empty</b> expression.
One <b>Variant</b> expression is <b>Empty</b> and the other is a string	Perform a string comparison, using a zero-length string ("" ) as the <b>Empty</b> expression.
Both <b>Variant</b> expressions are <b>Empty</b>	The expressions are equal.

When a **Single** is compared to a **Double**, the **Double** is rounded to the precision of the **Single**.

If a **Currency** is compared with a **Single** or **Double**, the **Single** or **Double** is converted to a **Currency**. Similarly, when a **Decimal** is compared with a **Single** or **Double**, the **Single** or **Double** is converted to a **Decimal**. For **Currency**, any fractional value less than .0001 may be lost; for **Decimal**, any fractional value

less than  $1\text{E-}28$  may be lost, or an overflow error can occur. Such fractional value loss may cause two values to compare as equal when they are not.

Eqv Operator

Used to perform a logical equivalence on two [expressions](#).

**Syntax**

*result* = *expression1* **Eqv** *expression2*

The **Eqv** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

### Remarks

If either expression is [Null](#), *result* is also **Null**. When neither expression is **Null**, *result* is determined according to the following table:

If <i>expression1</i> is	And <i>expression2</i> is	The <i>result</i> is
True	True	True
True	False	False
False	True	False
False	False	True

The **Eqv** operator performs a [bitwise comparison](#) of identically positioned bits in two [numeric expressions](#) and sets the corresponding bit in *result* according to the following table:

If bit in <i>expression1</i> is	And bit in <i>expression2</i> is	The <i>result</i> is
0	0	1
0	1	0
1	0	0
1	1	1

Imp Operator

Used to perform a logical implication on two [expressions](#).

**Syntax**

*result* = *expression1* **Imp** *expression2*

The **Imp** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

### Remarks

The following table illustrates how *result* is determined:

If <i>expression1</i> is	And <i>expression2</i> is	The <i>result</i> is
True	True	True
True	False	False
True	<a href="#">Null</a>	Null
False	True	True
False	False	True
False	Null	True
Null	True	True
Null	False	Null
Null	Null	Null

The **Imp** operator performs a [bitwise comparison](#) of identically positioned bits in two [numeric expressions](#) and sets the corresponding bit in *result* according to the following table:

If bit in <i>expression1</i> is	And bit in <i>expression2</i> is	The <i>result</i> is
0	0	1
0	1	1
1	0	0
1	1	1

Used to compare two object reference [variables](#).

## Syntax

*result* = *object1* **Is** *object2*

The **Is** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric variable.
<i>object1</i>	Required; any object name.
<i>object2</i>	Required; any object name.

## Remarks

If *object1* and *object2* both refer to the same object, *result* is **True**; if they do not, *result* is **False**. Two variables can be made to refer to the same object in several ways.

In the following example, A has been set to refer to the same object as B:

Set A = B

The following example makes A and B refer to the same object as C:

Set A = C

Set B = C

Like Operator

Used to compare two strings.

## Syntax

*result* = *string* **Like** *pattern*

The **Like** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>string</i>	Required; any <a href="#">string expression</a> .
<i>pattern</i>	Required; any string expression conforming to the pattern-matching conventions described in Remarks.

## Remarks

If *string* matches *pattern*, *result* is **True**; if there is no match, *result* is **False**. If either *string* or *pattern* is [Null](#), *result* is **Null**.

The behavior of the **Like** operator depends on the **Option Compare** statement. The default [string-comparison](#) method for each [module](#) is **Option Compare Binary**.

**Option Compare Binary** results in string comparisons based on a [sort order](#)

derived from the internal binary representations of the characters. Sort order is determined by the code page. In the following example, a typical binary sort order is shown:

A < B < E < Z < a < b < e < z < À < Ê < Ø < à < ê < ø

**Option Compare Text** results in string comparisons based on a case-insensitive, textual sort order determined by your system's [locale](#). When you sort the same characters using **Option Compare Text**, the following text sort order is produced:

(A=a) < (À=à) < (B=b) < (E=e) < (Ê=ê) < (Z=z) < (Ø=ø)

Built-in pattern matching provides a versatile tool for string comparisons. The pattern-matching features allow you to use wildcard characters, character lists, or character ranges, in any combination, to match strings. The following table shows the characters allowed in *pattern* and what they match:

Characters in <i>pattern</i>	Matches in <i>string</i>
?	Any single character.
*	Zero or more characters.
#	Any single digit (0–9).
[ <i>charlist</i> ]	Any single character in <i>charlist</i> .
[! <i>charlist</i> ]	Any single character not in <i>charlist</i> .

A group of one or more characters (*charlist*) enclosed in brackets ([ ]) can be used to match any single character in *string* and can include almost any [character code](#), including digits.

**Note** To match the special characters left bracket ([), question mark (?), number sign (#), and asterisk (\*), enclose them in brackets. The right bracket (]) can't be used within a group to match itself, but it can be used outside a group as an individual character.

By using a hyphen (–) to separate the upper and lower bounds of the range,

*charlist* can specify a range of characters. For example, [A-Z] results in a match if the corresponding character position in *string* contains any uppercase letters in the range A–Z. Multiple ranges are included within the brackets without delimiters.

The meaning of a specified range depends on the character ordering valid at [run time](#) (as determined by **Option Compare** and the [locale](#) setting of the system the code is running on). Using the **Option Compare Binary** example, the range [A–E] matches A, B and E. With **Option Compare Text**, [A–E] matches A, a, Å, à, B, b, E, e. The range does not match Ê or ê because accented characters fall after unaccented characters in the sort order.

Other important rules for pattern matching include the following:

An exclamation point (!) at the beginning of *charlist* means that a match is made if any character except the characters in *charlist* is found in *string*. When used outside brackets, the exclamation point matches itself.

A hyphen (–) can appear either at the beginning (after an exclamation point if one is used) or at the end of *charlist* to match itself. In any other location, the hyphen is used to identify a range of characters.

When a range of characters is specified, they must appear in ascending sort order (from lowest to highest). [A-Z] is a valid pattern, but [Z-A] is not.

The character sequence [] is considered a zero-length string ("").

In some languages, there are special characters in the alphabet that represent two separate characters. For example, several languages use the character "æ" to represent the characters "a" and "e" when they appear together. The **Like** operator recognizes that the single special character and the two individual characters are equivalent.

When a language that uses a special character is specified in the system locale settings, an occurrence of the single special character in either *pattern* or *string*

matches the equivalent 2-character sequence in the other string. Similarly, a single special character in *pattern* enclosed in brackets (by itself, in a list, or in a range) matches the equivalent 2-character sequence in *string*.

Mod Operator

Used to divide two numbers and return only the remainder.

## Syntax

*result* = *number1* **Mod** *number2*

The **Mod** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>number1</i>	Required; any <a href="#">numeric expression</a> .
<i>number2</i>	Required; any numeric expression.

## Remarks

The modulus, or remainder, operator divides *number1* by *number2* (rounding floating-point numbers to integers) and returns only the remainder as *result*. For example, in the following [expression](#), A (*result*) equals 5.

A = 19 Mod 6.7

Usually, the [data type](#) of *result* is a [Byte](#), **Byte** variant, [Integer](#), **Integer** variant, [Long](#), or [Variant](#) containing a **Long**, regardless of whether or not *result* is a whole number. Any fractional portion is truncated. However, if any expression is

Null, *result* is **Null**. Any expression that is Empty is treated as 0.

Not Operator

Used to perform logical negation on an [expression](#).

### Syntax

*result* = **Not** *expression*

The **Not** operator syntax has these parts:

Part	Description
------	-------------

*result* Required; any numeric [variable](#).

*expression* Required; any expression.

## Remarks

The following table illustrates how *result* is determined:

If <i>expression</i> is	Then <i>result</i> is
True	False
False	True
<a href="#">Null</a>	Null

In addition, the **Not** operator inverts the bit values of any variable and sets the corresponding bit in *result* according to the following table:

If bit in <i>expression</i> is	Then bit in <i>result</i> is
0	1
1	0

Or Operator

Used to perform a logical disjunction on two [expressions](#).

**Syntax**

*result* = *expression1* **Or** *expression2*

The **Or** operator syntax has these parts:

Part	Description
<i>result</i>	Required; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

### Remarks

If either or both expressions evaluate to **True**, *result* is **True**. The following table illustrates how *result* is determined:

If <i>expression1</i> is	And <i>expression2</i> is	Then <i>result</i> is
<b>True</b>	<b>True</b>	<b>True</b>
<b>True</b>	<b>False</b>	<b>True</b>
<b>True</b>	<a href="#">Null</a>	<b>True</b>
<b>False</b>	<b>True</b>	<b>True</b>
<b>False</b>	<b>False</b>	<b>False</b>
<b>False</b>	<b>Null</b>	<b>Null</b>
<b>Null</b>	<b>True</b>	<b>True</b>
<b>Null</b>	<b>False</b>	<b>Null</b>
<b>Null</b>	<b>Null</b>	<b>Null</b>

The **Or** operator also performs a [bitwise comparison](#) of identically positioned bits in two [numeric expressions](#) and sets the corresponding bit in *result* according to the following table:

If bit in <i>expression1</i> is	And bit in <i>expression2</i> is	Then <i>result</i> is
0	0	0
0	1	1
1	0	1
1	1	1

Xor Operator

Used to perform a logical exclusion on two [expressions](#).

**Syntax**

[*result* =] *expression1* **Xor** *expression2*

The **Xor** operator syntax has these parts:

Part	Description
<i>result</i>	Optional; any numeric <a href="#">variable</a> .
<i>expression1</i>	Required; any expression.
<i>expression2</i>	Required; any expression.

### Remarks

If one, and only one, of the expressions evaluates to **True**, *result* is **True**. However, if either expression is [Null](#), *result* is also **Null**. When neither expression is **Null**, *result* is determined according to the following table:

If <i>expression1</i> is	And <i>expression2</i> is	Then <i>result</i> is
<b>True</b>	<b>True</b>	<b>False</b>
<b>True</b>	<b>False</b>	<b>True</b>
<b>False</b>	<b>True</b>	<b>True</b>
<b>False</b>	<b>False</b>	<b>False</b>

The **Xor** operator performs as both a logical and bitwise operator. A [bit-wise comparison](#) of two [expressions](#) using exclusive-or logic to form the result, as shown in the following table:

If bit in <i>expression1</i> is	And bit in <i>expression2</i> is	Then <i>result</i> is
0	0	0
0	1	1
1	0	1
1	1	0

## Description

Read-only property that returns **True** if the file pointer immediately precedes the end-of-line marker in a **TextStream** file; **False** if it does not.

## Syntax

*object*.**AtEndOfLine**

The *object* is always the name of a **TextStream** object.

## Remarks

The **AtEndOfLine** property applies only to **TextStream** files that are open for reading; otherwise, an error occurs.

The following code illustrates the use of the **AtEndOfLine** property:

```
Dim fs, a, retstring
Set fs = CreateObject("Scripting.FileSystemObject")
Set a = fs.OpenTextFile("c:\testfile.txt", ForReading)
Do While a.AtEndOfLine <> True
```

```
        retstring = a.Read(1)
    ...
Loop
a.Close
```

## Description

Read-only property that returns **True** if the file pointer is at the end of a **TextStream** file; **False** if it is not.

## Syntax

*object*.**AtEndOfStream**

The *object* is always the name of a **TextStream** object.

## Remarks

The **AtEndOfStream** property applies only to **TextStream** files that are open for reading; otherwise, an error occurs.

The following code illustrates the use of the **AtEndOfStream** property:

```
Dim fs, a, retstring
Set fs = CreateObject("Scripting.FileSystemObject")
Set a = fs.OpenTextFile("c:\testfile.txt", ForReading)
Do While a.AtEndOfStream <> True
```

```
        retstring = a.ReadLine
    ...
Loop
a.Close
```

## Description

Sets or returns the attributes of files or folders. Read/write or read-only, depending on the attribute.

## Syntax

*object*.**Attributes** [= *newattributes*]

The **Attributes** property has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> or <b>Folder</b> object.
<i>newattributes</i>	Optional. If provided, <i>newattributes</i> is the new value for the attributes of the specified <i>object</i> .

## Settings

The *newattributes* argument can have any of the following values or any logical combination of the following values:

Constant	Value	Description
----------	-------	-------------

<b>Normal</b>	0	Normal file. No attributes are set.
<b>ReadOnly</b>	1	Read-only file. Attribute is read/write.
<b>Hidden</b>	2	Hidden file. Attribute is read/write.
<b>System</b>	4	System file. Attribute is read/write.
<b>Volume</b>	8	Disk drive volume label. Attribute is read-only.
<b>Directory</b>	16	Folder or directory. Attribute is read-only.
<b>Archive</b>	32	File has changed since last backup. Attribute is read/write.
<b>Alias</b>	64	Link or shortcut. Attribute is read-only.
<b>Compressed</b>	128	Compressed file. Attribute is read-only.

## Remarks

The following code illustrates the use of the **Attributes** property with a file:

```
Sub SetClearArchiveBit(filespec)
    Dim fs, f, r
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(fs.GetFileName(filespec))
    If f.attributes and 32 Then
        r = MsgBox("The Archive bit is set, do you want to clear it?", vbYesNo)
        If r = vbYes Then
            f.attributes = f.attributes - 32
            MsgBox "Archive bit is cleared."
        Else
            MsgBox "Archive bit remains set."
        End If
    Else
        r = MsgBox("The Archive bit is not set, do you want to set it?", vbYesNo)
        If r = vbYes Then
            f.attributes = f.attributes + 32
            MsgBox "Archive bit is set."
        End If
    End If
End Sub
```

```
        Else
            MsgBox "Archive bit remains clear."
        End If
    End If
End Sub
```

## Description

Returns the amount of space available to a user on the specified drive or network share.

## Syntax

*object*.**AvailableSpace**

The *object* is always a **Drive** object.

## Remarks

The value returned by the **AvailableSpace** property is typically the same as that returned by the **FreeSpace** property. Differences may occur between the two values for computer systems that support quotas.

The following code illustrates the use of the **AvailableSpace** property:

```
Sub ShowAvailableSpace(drvPath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystem
```

```
Set d = fs.GetDrive(fs.GetDriveName(drvPath)
s = "Drive " & UCase(drvPath) & " - "
s = s & d.VolumeName & vbCrLf
s = s & "Available Space: " & FormatNumber(
s = s & " Kbytes"
MsgBox s
End Sub
```

Returns or sets a value specifying the type of calendar to use with your [project](#).

You can use one of two settings for **Calendar**:

Setting	Value	Description
<b>vbCalGreg</b>	0	Use Gregorian calendar (default).
<b>vbCalHijri</b>	1	Use Hijri calendar.

### Remarks

You can only set the **Calendar** property programmatically. For example, to use the Hijri calendar, use:

```
Calendar = vbCalHijri
```

## Description

Read-only property that returns the column number of the current character position in a **TextStream** file.

## Syntax

*object*.**Column**

The *object* is always the name of a **TextStream** object.

## Remarks

After a newline character has been written, but before any other character is written, **Column** is equal to 1.

## Description

Sets and returns the comparison mode for comparing string keys in a **Dictionary** object.

## Syntax

*object*.**CompareMode**[ = *compare*]

The **CompareMode** property has the following parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Dictionary</b> object.
<i>compare</i>	Optional. If provided, <i>compare</i> is a value representing the comparison mode used by functions such as <b>StrComp</b> .

## Settings

The *compare* argument can have the following values:

Constant	Value	Description
<b>vbUseCompareOption</b>	-1	Performs a comparison using the setting of

		the <b>Option Compare</b> statement.
<b>vbBinaryCompare</b>	0	Performs a binary comparison.
<b>vbTextCompare</b>	1	Performs a textual comparison.
<b>vbDatabaseCompare</b>	2	Microsoft Access only. Performs a comparison based on information in your database.

## Remarks

An error occurs if you try to change the comparison mode of a **Dictionary** object that already contains data.

The **CompareMode** property uses the same values as the *compare* argument for the **StrComp** function. Values greater than 2 can be used to refer to comparisons using specific Locale IDs (LCID).

Count Property

Returns a [Long](#) (long integer) containing the number of objects in a [collection](#).  
Read-only.

## Description

Returns the number of items in a collection or **Dictionary** object. Read-only.

## Syntax

*object*.**Count**

The *object* is always the name of one of the items in the Applies To list.

## Remarks

The following code illustrates use of the **Count** property:

```
Dim a, d, i                'Create some variables
Set d = CreateObject("Scripting.Dictionary")
d.Add "a", "Athens"        'Add some keys and item
d.Add "b", "Belgrade"
d.Add "c", "Cairo"
a = d.Keys                 'Get the keys
For i = 0 To d.Count -1   'Iterate the array
    Print a(i)             'Print key
```

Next

...

## Description

Returns the date and time that the specified file or folder was created. Read-only.

## Syntax

*object*.**DateCreated**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **DateCreated** property with a file:

```
Sub ShowFileInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = "Created: " & f.DateCreated
    MsgBox s
End Sub
```

## Description

Returns the date and time that the specified file or folder was last accessed.  
Read-only.

## Syntax

*object*.**DateLastAccessed**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **DateLastAccessed** property with a file:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = UCase(filespec) & vbCrLf
    s = s & "Created: " & f.DateCreated & vbCrLf
End Sub
```

```
s = s & "Last Accessed: " & f.DateLastAccessed  
s = s & "Last Modified: " & f.DateLastModified  
MsgBox s, 0, "File Access Info"  
End Sub
```

**Important** This method depends on the underlying operating system for its behavior. If the operating system does not support providing time information, none will be returned.

## Description

Returns the date and time that the specified file or folder was last modified.  
Read-only.

## Syntax

*object*.**DateLastModified**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **DateLastModified** property with a file:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = UCase(filespec) & vbCrLf
    s = s & "Created: " & f.DateCreated & vbCrLf
```

```
s = s & "Last Accessed: " & f.DateLastAccessed  
s = s & "Last Modified: " & f.DateLastModified  
MsgBox s, 0, "File Access Info"  
End Sub
```

Description Property

Returns or sets a [string expression](#) containing a descriptive string associated with an object. Read/write.

For the **Error** object, returns or sets a descriptive string associated with an error.

## Remarks

The **Description** property setting consists of a short description of the error. Use this [property](#) to alert the user to an error that you either can't or don't want to

handle. When generating a user-defined error, assign a short description of your error to the **Description** property. If **Description** isn't filled in, and the value of **Number** corresponds to a Visual Basic [run-time error](#), the string returned by the **Error** function is placed in **Description** when the error is generated.

## Description

Returns the drive letter of the drive on which the specified file or folder resides.  
Read-only.

## Syntax

*object*.**Drive**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **Drive** property:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = f.Name & " on Drive " & UCase(f.Drive) & vbCrLf
    s = s & "Created: " & f.DateCreated & vbCrLf
    s = s & "Last Accessed: " & f.DateLastAccessed & vbCrLf
    Print s
End Sub
```

```
s = s & "Last Modified: " & f.DateLastModif  
MsgBox s, 0, "File Access Info"  
End Sub
```

## Description

Returns the drive letter of a physical local drive or a network share. Read-only.

## Syntax

*object*.**DriveLetter**

The *object* is always a **Drive** object.

## Remarks

The **DriveLetter** property returns a zero-length string ("") if the specified drive is not associated with a drive letter, for example, a network share that has not been mapped to a drive letter.

The following code illustrates the use of the **DriveLetter** property:

```
Sub ShowDriveLetter(drvPath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(fs.GetDriveName(drvPath))
```

```
s = "Drive " & d.DriveLetter & ": - "  
s = s & d.VolumeName & vbCrLf  
s = s & "Free Space: " & FormatNumber(d.Fre  
s = s & " Kbytes"  
MsgBox s  
End Sub
```

## Description

Returns a **Drives** collection consisting of all **Drive** objects available on the local machine.

## Syntax

*object*.**Drives**

The *object* is always a **FileSystemObject**.

## Remarks

Removable-media drives need not have media inserted for them to appear in the **Drives** collection.

You can iterate the members of the **Drives** collection using a **For Each...Next** construct as illustrated in the following code:

```
Sub ShowDriveList
    Dim fs, d, dc, s, n
    Set fs = CreateObject("Scripting.FileSystemObject")
```

```
Set dc = fs.Drives
For Each d in dc
    s = s & d.DriveLetter & " - "
    If d.DriveType = 3 Then
        n = d.ShareName
    Else
        n = d.VolumeName
    End If
    s = s & n & vbCrLf
Next
MsgBox s
End Sub
```

## Description

Returns a value indicating the type of a specified drive.

## Syntax

*object*.**DriveType**

The *object* is always a **Drive** object.

## Remarks

The following code illustrates the use of the **DriveType** property:

```
Sub ShowDriveType(drvpath)
    Dim fs, d, s, t
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(drvpath)
    Select Case d.DriveType
        Case 0: t = "Unknown"
        Case 1: t = "Removable"
        Case 2: t = "Fixed"
```

```
        Case 3: t = "Network"
        Case 4: t = "CD-ROM"
        Case 5: t = "RAM Disk"
    End Select
    s = "Drive " & d.DriveLetter & ": - " & t
    MsgBox s
End Sub
```

## Description

Returns a **Files** collection consisting of all **File** objects contained in the specified folder, including those with hidden and system file attributes set.

## Syntax

*object*.**Files**

The *object* is always a **Folder** object.

## Remarks

The following code illustrates the use of the **Files** property:

```
Sub ShowFileList(folderspec)
    Dim fs, f, f1, fc, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(folderspec)
    Set fc = f.Files
    For Each f1 in fc
        s = s & f1.name
    
```

```
        s = s & vbCrLf
    Next
    MsgBox s
End Sub
```

## Description

Returns the type of file system in use for the specified drive.

## Syntax

*object*.**FileSystem**

The *object* is always a **Drive** object.

## Remarks

Available return types include FAT, NTFS, and CDFS.

The following code illustrates the use of the **FileSystem** property:

```
Sub ShowFileSystemType
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive("e:")
    s = d.FileSystem
    MsgBox s
```

End Sub

## Description

Returns the amount of free space available to a user on the specified drive or network share. Read-only.

## Syntax

*object*.**FreeSpace**

The *object* is always a **Drive** object.

## Remarks

The value returned by the **FreeSpace** property is typically the same as that returned by the **AvailableSpace** property. Differences may occur between the two for computer systems that support quotas.

The following code illustrates the use of the **FreeSpace** property:

```
Sub ShowFreeSpace(drvPath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystem
```

```
Set d = fs.GetDrive(fs.GetDriveName(drvPath)
s = "Drive " & UCase(drvPath) & " - "
s = s & d.VolumeName & vbCrLf
s = s & "Free Space: " & FormatNumber(d.Free
s = s & " Kbytes"
MsgBox s
End Sub
```

HelpContext Property

Returns or sets a [string expression](#) containing the context ID for a topic in a Help file. Read/write.

### Remarks

The **HelpContext** [property](#) is used to automatically display the Help topic specified in the **HelpFile** property. If both **HelpFile** and **HelpContext** are empty, the value of **Number** is checked. If **Number** corresponds to a Visual Basic [run-time error](#) value, then the Visual Basic Help context ID for the error is used. If

the **Number** value doesn't correspond to a Visual Basic error, the contents screen for the Visual Basic Help file is displayed.

**Note** You should write routines in your application to handle typical errors. When programming with an object, you can use the object's Help file to improve the quality of your error handling, or to display a meaningful message to your user if the error isn't recoverable.

## HelpFile Property

Returns or sets a [string expression](#) the fully qualified path to a Help file.  
Read/write.

### Remarks

If a Help file is specified in **HelpFile**, it is automatically called when the user presses the **Help** button (or the F1 KEY in Windows or the HELP key on the Macintosh) in the error message dialog box. If the **HelpContext** property contains a valid context ID for the specified file, that topic is automatically displayed. If no **HelpFile** is specified, the Visual Basic Help file is displayed.

**Note** You should write routines in your application to handle typical errors. When programming with an object, you can use the object's Help file to improve the quality of your error handling, or to display a meaningful message to your user if the error isn't recoverable.

## Description

Returns **True** if the specified drive is ready; **False** if it is not.

## Syntax

object.**IsReady**

The object is always a **Drive** object.

## Remarks

For removable-media drives and CD-ROM drives, **IsReady** returns **True** only when the appropriate media is inserted and ready for access.

The following code illustrates the use of the **IsReady** property:

```
Sub ShowDriveInfo(drvpath)
    Dim fs, d, s, t
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(drvpath)
    Select Case d.DriveType
```

```
        Case 0: t = "Unknown"
        Case 1: t = "Removable"
        Case 2: t = "Fixed"
        Case 3: t = "Network"
        Case 4: t = "CD-ROM"
        Case 5: t = "RAM Disk"
    End Select
    s = "Drive " & d.DriveLetter & ": - " & t
    If d.IsReady Then
        s = s & vbCrLf & "Drive is Ready."
    Else
        s = s & vbCrLf & "Drive is not Ready."
    End If
    MsgBox s
End Sub
```

## Description

Returns **True** if the specified folder is the root folder; **False** if it is not.

## Syntax

*object*.**IsRootFolder**

The *object* is always a **Folder** object.

## Remarks

The following code illustrates the use of the **IsRootFolder** property:

```
Dim fs
Set fs = CreateObject("Scripting.FileSystemObjec
Sub DisplayLevelDepth(pathspec)
    Dim f, n
    Set f = fs.GetFolder(pathspec)
    If f.IsRootFolder Then
        MsgBox "The specified folder is the roo
    Else
```

```
        Do Until f.IsRootFolder
            Set f = f.ParentFolder
            n = n + 1
        Loop
        MsgBox "The specified folder is nested"
    End If
End Sub
```

## Description

Sets or returns an *item* for a specified *key* in a **Dictionary** object. For collections, returns an *item* based on the specified *key*. Read/write.

## Syntax

*object*.**Item**(*key*) [= *newitem*]

The **Item** property has the following parts:

Part	Description
<i>object</i>	Required. Always the name of a collection or <b>Dictionary</b> object.
<i>key</i>	Required. <i>Key</i> associated with the item being retrieved or added.
<i>newitem</i>	Optional. Used for <b>Dictionary</b> object only; no application for collections. If provided, <i>newitem</i> is the new value associated with the specified <i>key</i> .

## Remarks

If *key* is not found when changing an *item*, a new *key* is created with the specified *newitem*. If *key* is not found when attempting to return an existing item,

a new *key* is created and its corresponding item is left empty.

## Description

Sets a *key* in a **Dictionary** object.

## Syntax

*object*.**Key**(*key*) = *newkey*

The **Key** property has the following parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Dictionary</b> object.
<i>key</i>	Required. <i>Key</i> value being changed.
<i>newkey</i>	Required. New value that replaces the specified <i>key</i> .

## Remarks

If *key* is not found when changing a *key*, a [run-time error](#) will occur.

#### LastDLLError Property

Returns a system error code produced by a call to a [dynamic-link library](#) (DLL). Read-only. LastDLLError always returns zero on the Macintosh.

#### Remarks

The **LastDLLError** [property](#) applies only to DLL calls made from Visual Basic code. When such a call is made, the called function usually returns a code indicating success or failure, and the **LastDLLError** property is filled. Check the documentation for the DLL's functions to determine the return values that indicate success or failure. Whenever the failure code is returned, the Visual Basic application should immediately check the **LastDLLError** property. No exception is raised when the **LastDLLError** property is set.

Line Property

## Description

Read-only property that returns the current line number in a **TextStream** file.

## Syntax

*object*.**Line**

The *object* is always the name of a **TextStream** object.

## Remarks

After a file is initially opened and before anything is written, **Line** is equal to 1.

## Description

Sets or returns the name of a specified file or folder. Read/write.

## Syntax

*object*.**Name** [= *newname*]

The **Name** property has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>File</b> or <b>Folder</b> object.
<i>newname</i>	Optional. If provided, <i>newname</i> is the new name of the specified <i>object</i> .

## Remarks

The following code illustrates the use of the **Name** property:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystem
```

```
Set f = fs.GetFile(filespec)
s = f.Name & " on Drive " & UCase(f.Drive)
s = s & "Created: " & f.DateCreated & vbCrLf
s = s & "Last Accessed: " & f.DateLastAccessed & vbCrLf
s = s & "Last Modified: " & f.DateLastModified & vbCrLf
MsgBox s, 0, "File Access Info"
End Sub
```

## Number Property

Returns or sets a numeric value specifying an error. **Number** is the **Err** object's default property. Read/write.

### Remarks

When returning a user-defined error from an object, set **Err.Number** by adding the number you selected as an error code to the **vbObjectError** [constant](#). For example, you use the following code to return the number 1051 as an error code:

```
Err.Raise Number := vbObjectError + 1051, Sourc
```

## Description

Returns the folder object for the parent of the specified file or folder. Read-only.

## Syntax

*object*.**ParentFolder**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **ParentFolder** property with a file:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = UCase(f.Name) & " in " & UCase(f.ParentFolder.Name)
    s = s & "Created: " & f.DateCreated & vbCrLf
    s = s & "Last Accessed: " & f.DateLastAccessed & vbCrLf
    s = s & "Last Modified: " & f.DateLastModified & vbCrLf
    Print s
End Sub
```

```
        MsgBox s, 0, "File Access Info"  
End Sub
```

## Description

Returns the path for a specified file, folder, or drive.

## Syntax

*object*.**Path**

The *object* is always a **File**, **Folder**, or **Drive** object.

## Remarks

For drive letters, the root drive is not included. For example, the path for the C drive is C:, not C:\.

The following code illustrates the use of the **Path** property with a **File** object:

```
Sub ShowFileAccessInfo(filespec)
    Dim fs, d, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = UCase(f.Path) & vbCrLf
End Sub
```

```
s = s & "Created: " & f.DateCreated & vbCrL
s = s & "Last Accessed: " & f.DateLastAcces
s = s & "Last Modified: " & f.DateLastModif
MsgBox s, 0, "File Access Info"
End Sub
```

## Description

Returns a **Folder** object representing the root folder of a specified drive. Read-only.

## Syntax

*object*.**RootFolder**

The *object* is always a **Drive** object.

## Remarks

All the files and folders contained on the drive can be accessed using the returned **Folder** object.

## Description

Returns the decimal serial number used to uniquely identify a disk volume.

## Syntax

*object*.**SerialNumber**

The *object* is always a **Drive** object.

## Remarks

You can use the **SerialNumber** property to ensure that the correct disk is inserted in a drive with removable media.

The following code illustrates the use of the **SerialNumber** property:

```
Sub ShowDriveInfo(drvpath)
    Dim fs, d, s, t
    Set fs = CreateObject("Scripting.FileSystem
    Set d = fs.GetDrive(fs.GetDriveName(fs.GetA
    Select Case d.DriveType
```

```
        Case 0: t = "Unknown"
        Case 1: t = "Removable"
        Case 2: t = "Fixed"
        Case 3: t = "Network"
        Case 4: t = "CD-ROM"
        Case 5: t = "RAM Disk"
    End Select
    s = "Drive " & d.DriveLetter & ": - " & t
    s = s & vbCrLf & "SN: " & d.SerialNumber
    MsgBox s
End Sub
```

## Description

Returns the network share name for a specified drive.

## Syntax

*object*.**ShareName**

The *object* is always a **Drive** object.

## Remarks

If *object* is not a network drive, the **ShareName** property returns a zero-length string ("").

The following code illustrates the use of the **ShareName** property:

```
Sub ShowDriveInfo(drvpath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(fs.GetDriveName(fs.GetAbsolutePathName(drvpath)))
    s = "Drive " & d.DriveLetter & ": - " & d.ShareName
End Sub
```

```
        MsgBox s  
End Sub
```

## Description

Returns the short name used by programs that require the earlier 8.3 naming convention.

## Syntax

*object*.**ShortName**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **ShortName** property with a **File** object:

```
Sub ShowShortName(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = "The short name for " & f.Name & " is " & f.ShortName & vbCrLf
    Print s
```

```
    s = s & "is: " & "" & f.ShortName & ""  
    MsgBox s, 0, "Short Name Info"  
End Sub
```

## Description

Returns the short path used by programs that require the earlier 8.3 file naming convention.

## Syntax

*object*.**ShortPath**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **ShortName** property with a **File** object:

```
Sub ShowShortPath(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFile(filespec)
    s = "The short path for " & "" & UCase(f.Name) & " is "
    s = s & "" & vbCrLf
```

```
s = s & "is: " & "" & f.ShortPath & ""  
MsgBox s, 0, "Short Path Info"  
End Sub
```

## Description

For files, returns the size, in bytes, of the specified file. For folders, returns the size, in bytes, of all files and subfolders contained in the folder.

## Syntax

*object*.**Size**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **Size** property with a **Folder** object:

```
Sub ShowFolderSize(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(filespec)
    s = UCase(f.Name) & " uses " & f.size & " bytes"
    MsgBox s, 0, "Folder Size Info"
End Sub
```

Source Property

Returns or sets a [string expression](#) specifying the name of the object or application that originally generated the error. Read/write.

## Remarks

The **Source** [property](#) specifies a string expression representing the object that generated the error; the [expression](#) is usually the object's [class](#) name or programmatic ID. Use **Source** to provide information when your code is unable to handle an error generated in an accessed object. For example, if you access Microsoft Excel and it generates a `Division by zero` error, Microsoft Excel sets **Err.Number** to its error code for that error and sets **Source** to `Excel.Application`.

When generating an error from code, **Source** is your application's programmatic ID. For [class modules](#), **Source** should contain a name having the form *project.class*. When an unexpected error occurs in your code, the **Source** property is automatically filled in. For errors in a [standard module](#), **Source** contains the [project](#) name. For errors in a class module, **Source** contains a name with the *project.class* form.

Returns or sets a value specifying the position of a **UserForm** when it first appears.

You can use one of four settings for **StartPosition**:

Setting	Value	Description
<b>Manual</b>	0	No initial setting specified.
<b>CenterOwner</b>	1	Center on the item to which the <b>UserForm</b> belongs.
<b>CenterScreen</b>	2	Center on the whole screen.
<b>WindowsDefault</b>	3	Position in upper-left corner of screen.

### Remarks

You can set the **StartPosition** property programmatically or from the **Properties** window.

## Description

Returns a **Folders** collection consisting of all folders contained in a specified folder, including those with Hidden and System file attributes set.

## Syntax

*object*.**SubFolders**

The *object* is always a **Folder** object.

## Remarks

The following code illustrates the use of the **SubFolders** property:

```
Sub ShowFolderList(folderspec)
    Dim fs, f, f1, s, sf
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(folderspec)
    Set sf = f.SubFolders
    For Each f1 in sf
        s = s & f1.name
    Next f1
End Sub
```

```
        s = s & vbCrLf
    Next
    MsgBox s
End Sub
```

## Description

Returns the total space, in bytes, of a drive or network share.

## Syntax

*object*.**TotalSize**

The *object* is always a **Drive** object.

## Remarks

The following code illustrates the use of the **TotalSize** property:

```
Sub ShowSpaceInfo(drvpath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set d = fs.GetDrive(fs.GetDriveName(fs.GetAbsolutePathName(drvpath)))
    s = "Drive " & d.DriveLetter & ":"
    s = s & vbCrLf
    s = s & "Total Size: " & FormatNumber(d.TotalSize, 0)
    s = s & vbCrLf
End Sub
```

```
        s = s & "Available: " & FormatNumber(d.Avai  
        MsgBox s  
End Sub
```

## Description

Returns information about the type of a file or folder. For example, for files ending in .TXT, "Text Document" is returned.

## Syntax

*object*.**Type**

The *object* is always a **File** or **Folder** object.

## Remarks

The following code illustrates the use of the **Type** property to return a folder type. In this example, try providing the path of the Recycle Bin or other unique folder to the procedure.

```
Sub ShowFileSize(filespec)
    Dim fs, f, s
    Set fs = CreateObject("Scripting.FileSystemObject")
    Set f = fs.GetFolder(filespec)
    s = UCase(f.Name) & " is a " & f.Type
```

```
        MsgBox s, 0, "File Size Info"  
End Sub
```

## Description

Sets or returns the volume name of the specified drive. Read/write.

## Syntax

*object*.**VolumeName** [= *newname*]

The VolumeName property has these parts:

Part	Description
<i>object</i>	Required. Always the name of a <b>Drive</b> object.
<i>newname</i>	Optional. If provided, <i>newname</i> is the new name of the specified <i>object</i> .

## Remarks

The following code illustrates the use of the **VolumeName** property:

```
Sub ShowVolumeInfo(drvpath)
    Dim fs, d, s
    Set fs = CreateObject("Scripting.FileSystem
```

```
Set d = fs.GetDrive(fs.GetDriveName(fs.GetA  
s = "Drive " & d.DriveLetter & ": - " & d.V  
MsgBox s  
End Sub
```

## AppActivate Statement

Activates an application window.

### Syntax

**AppActivate** *title*[, *wait*]

The **AppActivate** statement syntax has these [named arguments](#):

Part	Description
------	-------------

- title*** Required. [String expression](#) specifying the title in the title bar of the application window you want to activate. The task ID returned by the **Shell** function can be used in place of ***title*** to activate an application.
- wait*** Optional. [Boolean](#) value specifying whether the calling application has the focus before activating another. If **False** (default), the specified application is immediately activated, even if the calling application does not have the focus. If **True**, the calling application waits until it has the focus, then activates the specified application.

## Remarks

The **AppActivate** statement changes the focus to the named application or window but does not affect whether it is maximized or minimized. Focus moves from the activated application window when the user takes some action to change the focus or close the window. Use the **Shell** function to start an application and set the window style.

In determining which application to activate, ***title*** is compared to the title string of each running application. If there is no exact match, any application whose title string begins with ***title*** is activated. If there is more than one instance of the application named by ***title***, one instance is arbitrarily activated.

Beep Statement

Sounds a tone through the computer's speaker.

### **Syntax**

### **Beep**

### **Remarks**

The frequency and duration of the beep depend on your hardware and system software, and vary among computers.

Call Statement

Transfers control to a **Sub** procedure, **Function** procedure, or [dynamic-link library \(DLL\) procedure](#).

## Syntax

[**Call**] *name* [*argumentlist*]

The **Call** statement syntax has these parts:

Part	Description
<b>Call</b>	Optional; <a href="#">keyword</a> . If specified, you must enclose <i>argumentlist</i> in parentheses. For example: <code>Call MyProc(0)</code>
<i>name</i>	Required. Name of the procedure to call.
<i>argumentlist</i>	Optional. Comma-delimited list of <a href="#">variables</a> , <a href="#">arrays</a> , or <a href="#">expressions</a> to pass to the procedure. Components of <i>argumentlist</i> may include the keywords <b>ByVal</b> or <b>ByRef</b> to describe how the <a href="#">arguments</a> are treated by the called procedure. However, <b>ByVal</b> and <b>ByRef</b> can be used with <b>Call</b> only when calling a DLL procedure. On the Macintosh, <b>ByVal</b> and <b>ByRef</b> can be used with <b>Call</b> when making a call to a Macintosh code resource.

## Remarks

You are not required to use the **Call** keyword when calling a procedure. However, if you use the **Call** keyword to call a procedure that requires arguments, *argumentlist* must be enclosed in parentheses. If you omit the **Call** keyword, you also must omit the parentheses around *argumentlist*. If you use either **Call** syntax to call any intrinsic or user-defined function, the function's

return value is discarded.

To pass a whole array to a procedure, use the array name followed by empty parentheses.

## ChDir Statement

Changes the current directory or folder.

### Syntax

**ChDir** *path*

The required *path* [argument](#) is a [string expression](#) that identifies which directory or folder becomes the new default directory or folder. The *path* may include the drive. If no drive is specified, **ChDir** changes the default directory or folder on the current drive.

### Remarks

The **ChDir** statement changes the default directory but not the default drive. For example, if the default drive is C, the following statement changes the default directory on drive D, but C remains the default drive:

```
ChDir "D:\TMP"
```

On the Power Macintosh, the default drive always changes to the drive specified in *path*. Full path specifications begin with the volume name, and relative paths begin with a colon (:). **ChDir** resolves any aliases specified in the path:

```
ChDir "MacDrive:Tmp"      ' On the Macintosh.
```

Note that when making relative directory changes, different symbols are used in Microsoft Windows and on the Macintosh:

```
ChDir ".."      ' Moves up one directory in Micro  
ChDir "::"      ' Moves up one directory on the M
```

## ChDrive Statement

Changes the current drive.

### Syntax

#### **ChDrive** *drive*

The required *drive* [argument](#) is a [string expression](#) that specifies an existing drive. If you supply a zero-length string (""), the current drive doesn't change. If the *drive* argument is a multiple-character string, **ChDrive** uses only the first letter.

On the Macintosh, **ChDrive** changes the current folder to the root folder of the specified drive.

Close Statement

Concludes input/output (I/O) to a file opened using the **Open** statement.

## Syntax

**Close** [*filenumberlist*]

The optional *filenumberlist* [argument](#) can be one or more [file numbers](#) using the following syntax, where *filenumber* is any valid file number:

`[[#]filenumber] [, [#]filenumber] . . .`

## Remarks

If you omit *filenumberlist*, all active files opened by the **Open** statement are closed.

When you close files that were opened for **Output** or **Append**, the final buffer of output is written to the operating system buffer for that file. All buffer space associated with the closed file is released.

When the **Close** statement is executed, the association of a file with its file number ends.

## Const Statement

Declares [constants](#) for use in place of literal values.

### Syntax

**[Public | Private] Const** *constname* [**As** *type*] = *expression*

The **Const** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. <a href="#">Keyword</a> used at <a href="#">module level</a> to declare constants that are available to all <a href="#">procedures</a> in all <a href="#">modules</a> . Not allowed in procedures.
<b>Private</b>	Optional. Keyword used at module level to declare constants that are available only within the module where the <a href="#">declaration</a> is made. Not allowed in procedures.
<i>constname</i>	Required. Name of the constant; follows standard <a href="#">variable</a>

	naming conventions.
<i>type</i>	Optional. <a href="#">Data type</a> of the constant; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> , or <a href="#">Variant</a> . Use a separate <b>As type</b> clause for each constant being declared.
<i>expression</i>	Required. Literal, other constant, or any combination that includes all arithmetic or logical operators except <b>Is</b> .

## Remarks

Constants are private by default. Within procedures, constants are always private; their visibility can't be changed. In [standard modules](#), the default visibility of module-level constants can be changed using the **Public** keyword. In [class modules](#), however, constants can only be private and their visibility can't be changed using the **Public** keyword.

To combine several constant declarations on the same line, separate each constant assignment with a comma. When constant declarations are combined in this way, the **Public** or **Private** keyword, if used, applies to all of them.

You can't use variables, user-defined functions, or intrinsic Visual Basic functions (such as **Chr**) in [expressions](#) assigned to constants.

**Note** Constants can make your programs self-documenting and easy to modify. Unlike variables, constants can't be inadvertently changed while your program is running.

If you don't explicitly declare the constant type using **As type**, the constant has the data type that is most appropriate for *expression*.

Constants declared in a **Sub**, **Function**, or **Property** procedure are local to that procedure. A constant declared outside a procedure is defined throughout the module in which it is declared. You can use constants anywhere you can use an expression.

Sets the current system date.

### **Syntax**

**Date** = *date*

For systems running Microsoft Windows 95, the required *date* specification must be a date from January 1, 1980 through December 31, 2099. For systems running Microsoft Windows NT, *date* must be a date from January 1, 1980 through December 31, 2079. For the Macintosh, *date* must be a date from January 1, 1904 through February 5, 2040.

Declare Statement

Used at [module level](#) to declare references to external [procedures](#) in a [dynamic-link library](#) (DLL).

### Syntax 1

```
[Public | Private] Declare Sub name Lib "libname" [Alias "aliasname"]  
  [(arglist)]
```

### Syntax 2

```
[Public | Private] Declare Function name Lib "libname" [Alias "aliasname"]  
  [(arglist)] [As type]
```

The **Declare** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Used to declare procedures that are available to all other procedures in all <a href="#">modules</a> .
<b>Private</b>	Optional. Used to declare procedures that are available only within the module where the <a href="#">declaration</a> is made.
<b>Sub</b>	Optional (either <b>Sub</b> or <b>Function</b> must appear). Indicates that the procedure doesn't return a value.
<b>Function</b>	Optional (either <b>Sub</b> or <b>Function</b> must appear). Indicates that the procedure returns a value that can be used in an <a href="#">expression</a> .
<i>name</i>	Required. Any valid procedure name. Note that DLL entry points are case sensitive.
<b>Lib</b>	Required. Indicates that a DLL or code resource contains the procedure being declared. The <b>Lib</b> clause is required for all declarations.
<i>libname</i>	Required. Name of the DLL or code resource that contains the

declared procedure.

<b>Alias</b>	Optional. Indicates that the procedure being called has another name in the DLL. This is useful when the external procedure name is the same as a keyword. You can also use <b>Alias</b> when a DLL procedure has the same name as a public <a href="#">variable</a> , <a href="#">constant</a> , or any other procedure in the same <a href="#">scope</a> . <b>Alias</b> is also useful if any characters in the DLL procedure name aren't allowed by the DLL naming convention.
<i>aliasname</i>	Optional. Name of the procedure in the DLL or code resource. If the first character is not a number sign (#), <i>aliasname</i> is the name of the procedure's entry point in the DLL. If (#) is the first character, all characters that follow must indicate the ordinal number of the procedure's entry point.
<i>arglist</i>	Optional. List of variables representing <a href="#">arguments</a> that are passed to the procedure when it is called.
<i>type</i>	Optional. <a href="#">Data type</a> of the value returned by a <b>Function</b> procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (variable length only), or <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an <a href="#">object type</a> .

The *arglist* argument has the following syntax and parts:

[**Optional**] [**ByVal** | **ByRef**] [**ParamArray**] *varname*[( )] [**As** *type*]

Part	Description
<b>Optional</b>	Optional. Indicates that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword. <b>Optional</b> can't be used for any argument if <b>ParamArray</b> is used.
<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> <a href="#">array</a> of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an

	arbitrary number of arguments. The <b>ParamArray</b> keyword can't be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument being passed to the procedure; follows standard variable naming conventions.
<b>()</b>	Required for array variables. Indicates that <i>varname</i> is an array.
<i>type</i>	Optional. Data type of the argument passed to the procedure; may be <b>Byte</b> , <b>Boolean</b> , <b>Integer</b> , <b>Long</b> , <b>Currency</b> , <b>Single</b> , <b>Double</b> , <b>Decimal</b> (not currently supported), <b>Date</b> , <b>String</b> (variable length only), <b>Object</b> , <b>Variant</b> , a user-defined type, or an object type.

## Remarks

For **Function** procedures, the data type of the procedure determines the data type it returns. You can use an **As** clause following *arglist* to specify the return type of the function. Within *arglist*, you can use an **As** clause to specify the data type of any of the arguments passed to the procedure. In addition to specifying any of the standard data types, you can specify **As Any** in *arglist* to inhibit type checking and allow any data type to be passed to the procedure.

Empty parentheses indicate that the **Sub** or **Function** procedure has no arguments and that Visual Basic should ensure that none are passed. In the following example, *First* takes no arguments. If you use arguments in a call to *First*, an error occurs:

```
Declare Sub First Lib "MyLib" ()
```

If you include an argument list, the number and type of arguments are checked each time the procedure is called. In the following example, *First* takes one **Long** argument:

```
Declare Sub First Lib "MyLib" (X As Long)
```

**Note** You can't have fixed-length strings in the argument list of a **Declare** statement; only variable-length strings can be passed to procedures. Fixed-length

strings can appear as procedure arguments, but they are converted to variable-length strings before being passed.

**Note** The **vbNullString** constant is used when calling external procedures, where the external procedure requires a string whose value is zero. This is not the same thing as a zero-length string ("").

Deftype Statements

Used at [module level](#) to set the default [data type](#) for [variables](#), [arguments](#) passed to [procedures](#), and the return type for **Function** and **Property Get** procedures whose names start with the specified characters.

## Syntax

**DefBool** *letterrange*[, *letterrange*] ...

**DefByte** *letterrange*[, *letterrange*] ...

**DefInt** *letterrange*[, *letterrange*] ...

**DefLng** *letterrange*[, *letterrange*] ...

**DefCur** *letterrange*[, *letterrange*] ...

**DefSng** *letterrange*[, *letterrange*] ...

**DefDbl** *letterrange*[, *letterrange*] ...

**DefDec** *letterrange*[, *letterrange*] ...

**DefDate** *letterrange*[, *letterrange*] ...

**DefStr** *letterrange*[, *letterrange*] ...

**DefObj** *letterrange*[, *letterrange*] . . .

**DefVar** *letterrange*[, *letterrange*] . . .

The required *letterrange* argument has the following syntax:

*letter1*[-*letter2*]

The *letter1* and *letter2* arguments specify the name range for which you can set a default data type. Each argument represents the first letter of the variable, argument, **Function** procedure, or **Property Get** procedure name and can be any letter of the alphabet. The case of letters in *letterrange* isn't significant.

## Remarks

The statement name determines the data type:

Statement	Data Type
<b>DefBool</b>	<a href="#">Boolean</a>
<b>DefByte</b>	<a href="#">Byte</a>
<b>DefInt</b>	<a href="#">Integer</a>
<b>DefLng</b>	<a href="#">Long</a>
<b>DefCur</b>	<a href="#">Currency</a>
<b>DefSng</b>	<a href="#">Single</a>
<b>DefDbl</b>	<a href="#">Double</a>
<b>DefDec</b>	<a href="#">Decimal</a> (not currently supported)
<b>DefDate</b>	<a href="#">Date</a>
<b>DefStr</b>	<a href="#">String</a>
<b>DefObj</b>	<a href="#">Object</a>
<b>DefVar</b>	<a href="#">Variant</a>

For example, in the following program fragment, *Message* is a string variable:

```
DefStr A-Q
. . .
Message = "Out of stack space."
```

A **Def***type* statement affects only the [module](#) where it is used. For example, a **DefInt** statement in one module affects only the default data type of variables, arguments passed to procedures, and the return type for **Function** and **Property Get** procedures declared in that module; the default data type of variables, arguments, and return types in other modules is unaffected. If not explicitly declared with a **Def***type* statement, the default data type for all variables, all arguments, all **Function** procedures, and all **Property Get** procedures is **Variant**.

When you specify a letter range, it usually defines the data type for variables that begin with letters in the first 128 characters of the character set. However, when you specify the letter range A–Z, you set the default to the specified data type for all variables, including variables that begin with international characters from the extended part of the character set (128–255).

Once the range A–Z has been specified, you can't further redefine any subranges of variables using **Def***type* statements. Once a range has been specified, if you include a previously defined letter in another **Def***type* statement, an error occurs. However, you can explicitly specify the data type of any variable, defined or not, using a **Dim** statement with an **As** *type* clause. For example, you can use the following code at module level to define a variable as a **Double** even though the default data type is **Integer**:

```
DefInt A-Z  
Dim TaxRate As Double
```

**Def***type* statements don't affect elements of [user-defined types](#) because the elements must be explicitly declared.

DeleteSetting Statement

Deletes a section or key setting from an application's entry in the Windows [registry](#) or (on the Macintosh) information in the application's initialization file.

## Syntax

**DeleteSetting** *appname*, *section*[, *key*]

The **DeleteSetting** statement syntax has these [named arguments](#):

Part	Description
<b><i>appname</i></b>	Required. <a href="#">String expression</a> containing the name of the application or <a href="#">project</a> to which the section or key setting applies. On the Macintosh, this is the filename of the initialization file in the Preferences folder in the System folder.
<b><i>section</i></b>	Required. String expression containing the name of the section where the key setting is being deleted. If only <b><i>appname</i></b> and <b><i>section</i></b> are provided, the specified section is deleted along with all related key settings.
<b><i>key</i></b>	Optional. String expression containing the name of the key setting being deleted.

## Remarks

If all [arguments](#) are provided, the specified setting is deleted. A run-time error occurs if you attempt to use the **DeleteSetting** statement on a non-existent section or key setting.

Dim Statement

Declares [variables](#) and allocates storage space.

**Syntax**

**Dim** [**WithEvents**] *varname*[[*subscripts*]] [**As** [**New**] *type*] [, [**WithEvents**] *varname*[[*subscripts*]] [**As** [**New**] *type*]] . . .

The **Dim** statement syntax has these parts:

Part	Description
<b>WithEvents</b>	Optional. <a href="#">Keyword</a> that specifies that <i>varname</i> is an <a href="#">object variable</a> used to respond to events triggered by an <a href="#">ActiveX object</a> . <b>WithEvents</b> is valid only in <a href="#">class modules</a> . You can declare as many individual variables as you like using <b>WithEvents</b> , but you can't create <a href="#">arrays</a> with <b>WithEvents</b> . You can't use <b>New</b> with <b>WithEvents</b> .
<i>varname</i>	Required. Name of the variable; follows standard variable naming conventions.
<i>subscripts</i>	Optional. Dimensions of an array variable; up to 60 multiple dimensions may be declared. The <i>subscripts</i> argument uses the following syntax:  <p>[<i>lower To</i>] <i>upper</i> [, [<i>lower To</i>] <i>upper</i>] . . .</p> <p>When not explicitly stated in <i>lower</i>, the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.</p>
<b>New</b>	Optional. Keyword that enables implicit creation of an object. If you use <b>New</b> when declaring the object variable, a new instance of the object is created on first reference to it, so you don't have to use the <b>Set</b> statement to assign the object reference. The <b>New</b> keyword can't be used to declare variables of any intrinsic <a href="#">data type</a> , can't be used to declare instances of dependent objects, and can't be used with <b>WithEvents</b> .
<i>type</i>	Optional. Data type of the variable; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (for variable-length strings), <b>String</b> * <i>length</i> (for fixed-length strings), <a href="#">Object</a> , <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an <a href="#">object type</a> . Use a separate <b>As type</b> clause for each variable you declare.
<b>Remarks</b>	

Variables declared with **Dim** at the [module level](#) are available to all procedures within the [module](#). At the [procedure level](#), variables are available only within the procedure.

Use the **Dim** statement at module or procedure level to declare the data type of a variable. For example, the following statement declares a variable as an **Integer**.

```
Dim NumberOfEmployees As Integer
```

Also use a **Dim** statement to declare the object type of a variable. The following declares a variable for a new instance of a worksheet.

```
Dim X As New Worksheet
```

If the **New** keyword is not used when declaring an object variable, the variable that refers to the object must be assigned an existing object using the **Set** statement before it can be used. Until it is assigned an object, the declared object variable has the special value **Nothing**, which indicates that it doesn't refer to any particular instance of an object.

You can also use the **Dim** statement with empty parentheses to declare a dynamic array. After declaring a dynamic array, use the **ReDim** statement within a procedure to define the number of dimensions and elements in the array. If you try to redeclare a dimension for an array variable whose size was explicitly specified in a **Private**, **Public**, or **Dim** statement, an error occurs.

If you don't specify a data type or object type, and there is no **Default** statement in the module, the variable is **Variant** by default.

When variables are initialized, a numeric variable is initialized to 0, a variable-length string is initialized to a zero-length string (""), and a fixed-length string is filled with zeros. **Variant** variables are initialized to [Empty](#). Each element of a user-defined type variable is initialized as if it were a separate variable.

**Note** When you use the **Dim** statement in a procedure, you generally put the **Dim** statement at the beginning of the procedure.

Do...Loop Statement

Repeats a block of [statements](#) while a condition is **True** or until a condition becomes **True**.

### Syntax

```
Do [{ While | Until } condition]  
    [statements]  
    [Exit Do]  
    [statements]
```

## Loop

Or, you can use this syntax:

### Do

[*statements*]

[**Exit Do**]

[*statements*]

**Loop** [{**While** | **Until**} *condition*]

The **Do Loop** statement syntax has these parts:

Part	Description
<i>condition</i>	Optional. <a href="#">Numeric expression</a> or <a href="#">string expression</a> that is <b>True</b> or <b>False</b> . If <i>condition</i> is <a href="#">Null</a> , <i>condition</i> is treated as <b>False</b> .
<i>statements</i>	One or more statements that are repeated while, or until, <i>condition</i> is <b>True</b> .

### Remarks

Any number of **Exit Do** statements may be placed anywhere in the **Do...Loop** as an alternate way to exit a **Do...Loop**. **Exit Do** is often used after evaluating some condition, for example, **If...Then**, in which case the **Exit Do** statement transfers control to the statement immediately following the **Loop**.

When used within nested **Do...Loop** statements, **Exit Do** transfers control to the loop that is one nested level above the loop where **Exit Do** occurs.

End Statement

Ends a [procedure](#) or block.

## Syntax

**End**

**End Function**

**End If**

**End Property**

**End Select**

**End Sub**

**End Type**

**End With**

The **End** statement syntax has these forms:

Statement	Description
<b>End</b>	Terminates execution immediately. Never required by itself but may be placed anywhere in a procedure to end code execution, close files opened with the <b>Open</b> statement and to clear <a href="#">variables</a> .
<b>End Function</b>	Required to end a <b>Function</b> statement.
<b>End If</b>	Required to end a block <b>If...Then...Else</b> statement.
<b>End Property</b>	Required to end a <b>Property Let</b> , <b>Property Get</b> , or <b>Property Set</b> procedure.

<b>End Select</b>	Required to end a <b>Select Case</b> statement.
<b>End Sub</b>	Required to end a <b>Sub</b> statement.
<b>End Type</b>	Required to end a <a href="#">user-defined type</a> definition ( <b>Type</b> statement).
<b>End With</b>	Required to end a <b>With</b> statement.

## Remarks

When executed, the **End** statement resets all [module-level](#) variables and all static local variables in all [modules](#). To preserve the value of these variables, use the **Stop** statement instead. You can then resume execution while preserving the value of those variables.

**Note** The **End** statement stops code execution abruptly, without invoking the Unload, QueryUnload, or Terminate event, or any other Visual Basic code. Code you have placed in the Unload, QueryUnload, and Terminate events of [forms](#) and [class modules](#) is not executed. Objects created from class modules are destroyed, files opened using the **Open** statement are closed, and memory used by your program is freed. Object references held by other programs are invalidated.

The **End** statement provides a way to force your program to halt. For normal termination of a Visual Basic program, you should unload all forms. Your program closes as soon as there are no other programs holding references to objects created from your public class modules and no code executing.

Erase Statement

Reinitializes the elements of fixed-size [arrays](#) and releases dynamic-array storage space.

## Syntax

### **Erase** *arraylist*

The required *arraylist* [argument](#) is one or more comma-delimited array [variables](#) to be erased.

### Remarks

**Erase** behaves differently depending on whether an array is fixed-size (ordinary) or dynamic. **Erase** recovers no memory for fixed-size arrays. **Erase** sets the elements of a fixed array as follows:

Type of Array	Effect of Erase on Fixed-Array Elements
Fixed numeric array	Sets each element to zero.
Fixed string array (variable length)	Sets each element to a zero-length string ("").
Fixed string array (fixed length)	Sets each element to zero.
Fixed <a href="#">Variant</a> array	Sets each element to <a href="#">Empty</a> .
Array of <a href="#">user-defined types</a>	Sets each element as if it were a separate variable.
Array of objects	Sets each element to the special value <b>Nothing</b> .

**Erase** frees the memory used by dynamic arrays. Before your program can refer to the dynamic array again, it must redeclare the array variable's dimensions using a **ReDim** statement.

Error Statement

Simulates the occurrence of an error.

## Syntax

**Error** *errornumber*

The required *errornumber* can be any valid [error number](#).

## Remarks

The **Error** statement is supported for backward compatibility. In new code, especially when creating objects, use the **Err** object's **Raise** method to generate [run-time errors](#).

If *errornumber* is defined, the **Error** statement calls the error handler after the [properties](#) of **Err** object are assigned the following default values:

Property	Value
<b>Number</b>	Value specified as <a href="#">argument</a> to <b>Error</b> statement. Can be any valid error number.
<b>Source</b>	Name of the current Visual Basic <a href="#">project</a> .
<b>Description</b>	<a href="#">String expression</a> corresponding to the return value of the <b>Error</b> function for the specified <b>Number</b> , if this string exists. If the string doesn't exist, <b>Description</b> contains a zero-length string ("").
<b>HelpFile</b>	The fully qualified drive, path, and file name of the appropriate Visual Basic Help file.
<b>HelpContext</b>	The appropriate Visual Basic Help file context ID for the error corresponding to the <b>Number</b> property.
<b>LastDLLError</b>	Zero.

If no error handler exists or if none is enabled, an error message is created and displayed from the **Err** object properties.

**Note** Not all Visual Basic [host applications](#) can create objects. See your host application's documentation to determine whether it can create [classes](#) and objects.

Exit

Statement

Exits a block of **Do...Loop**, **For...Next**, **Function**, **Sub**, or **Property** code.

## Syntax

**Exit Do**

**Exit For**

**Exit Function**

**Exit Property**

**Exit Sub**

The **Exit** statement syntax has these forms:

Statement	Description
-----------	-------------

<b>Exit Do</b>	Provides a way to exit a <b>Do...Loop</b> statement. It can be used only inside a <b>Do...Loop</b> statement. <b>Exit Do</b> transfers control to the <a href="#">statement</a> following the <b>Loop</b> statement. When used within nested <b>Do...Loop</b> statements, <b>Exit Do</b> transfers control to the loop that is one nested level above the loop where <b>Exit Do</b> occurs.
<b>Exit For</b>	Provides a way to exit a <b>For</b> loop. It can be used only in a <b>For...Next</b> or <b>For Each...Next</b> loop. <b>Exit For</b> transfers control to the statement following the <b>Next</b> statement. When used within nested <b>For</b> loops, <b>Exit For</b> transfers control to the loop that is one nested level above the loop where <b>Exit For</b> occurs.
<b>Exit Function</b>	Immediately exits the <b>Function</b> <a href="#">procedure</a> in which it appears. Execution continues with the statement following the statement that called the <b>Function</b> .
<b>Exit Property</b>	Immediately exits the <b>Property</b> procedure in which it appears. Execution continues with the statement following the statement that called the <b>Property</b> procedure.
<b>Exit Sub</b>	Immediately exits the <b>Sub</b> procedure in which it appears. Execution continues with the statement following the statement that called the <b>Sub</b> procedure.

## Remarks

Do not confuse **Exit** statements with **End** statements. **Exit** does not define the end of a structure.

## FileCopy Statement

Copies a file.

### Syntax

**FileCopy** *source, destination*

The **FileCopy** statement syntax has these [named arguments](#):

Part	Description
<i>source</i>	Required. <a href="#">String expression</a> that specifies the name of the file to be copied. The <i>source</i> may include directory or folder, and drive.
<i>destination</i>	Required. String expression that specifies the target file name. The <i>destination</i> may include directory or folder, and drive.

### Remarks

If you try to use the **FileCopy** statement on a currently open file, an error occurs.

For Each...Next Statement

Repeats a group of [statements](#) for each element in an [array](#) or [collection](#).

**Syntax**

**For Each** *element* **In** *group* [*statements*]  
    [**Exit For**]  
    [*statements*]

**Next** [*element*]

The **For...Each...Next** statement syntax has these parts:

Part	Description
<i>element</i>	Required. <a href="#">Variable</a> used to iterate through the elements of the collection or array. For collections, <i>element</i> can only be a <a href="#">Variant</a> variable, a generic object variable, or any specific object variable. For arrays, <i>element</i> can only be a <b>Variant</b> variable.
<i>group</i>	Required. Name of an object collection or array (except an array of <a href="#">user-defined types</a> ).
<i>statements</i>	Optional. One or more statements that are executed on each item in <i>group</i> .

## Remarks

The **For...Each** block is entered if there is at least one element in *group*. Once the loop has been entered, all the statements in the loop are executed for the first element in *group*. If there are more elements in *group*, the statements in the loop continue to execute for each element. When there are no more elements in *group*, the loop is exited and execution continues with the statement following the **Next** statement.

Any number of **Exit For** statements may be placed anywhere in the loop as an alternative way to exit. **Exit For** is often used after evaluating some condition, for example **If...Then**, and transfers control to the statement immediately following **Next**.

You can nest **For...Each...Next** loops by placing one **For...Each...Next** loop within another. However, each loop *element* must be unique.

**Note** If you omit *element* in a **Next** statement, execution continues as if *element* is included. If a **Next** statement is encountered before its corresponding **For** statement, an error occurs.

You can't use the **For...Each...Next** statement with an array of user-defined types because a **Variant** can't contain a user-defined type.

For...Next Statement

Repeats a group of [statements](#) a specified number of times.

### **Syntax**

**For** *counter* = *start* **To** *end* [**Step** *step*]  
    [*statements*]  
    [**Exit For**]  
    [*statements*]

**Next** [*counter*]

The **For...Next** statement syntax has these parts:

Part	Description
<i>counter</i>	Required. Numeric <a href="#">variable</a> used as a loop counter. The variable can't be a <a href="#">Boolean</a> or an <a href="#">array</a> element.
<i>start</i>	Required. Initial value of <i>counter</i> .
<i>end</i>	Required. Final value of <i>counter</i> .
<i>step</i>	Optional. Amount <i>counter</i> is changed each time through the loop. If not specified, <i>step</i> defaults to one.
<i>statements</i>	Optional. One or more statements between <b>For</b> and <b>Next</b> that are executed the specified number of times.

## Remarks

The *step* [argument](#) can be either positive or negative. The value of the *step* argument determines loop processing as follows:

Value	Loop executes if
Positive or 0	<i>counter</i> <= <i>end</i>
Negative	<i>counter</i> >= <i>end</i>

After all statements in the loop have executed, *step* is added to *counter*. At this point, either the statements in the loop execute again (based on the same test that caused the loop to execute initially), or the loop is exited and execution continues with the statement following the **Next** statement.

**Tip** Changing the value of *counter* while inside a loop can make it more

difficult to read and debug your code.

Any number of **Exit For** statements may be placed anywhere in the loop as an alternate way to exit. **Exit For** is often used after evaluating of some condition, for example **If...Then**, and transfers control to the statement immediately following **Next**.

You can nest **For...Next** loops by placing one **For...Next** loop within another. Give each loop a unique variable name as its *counter*. The following construction is correct:

```
For I = 1 To 10
    For J = 1 To 10
        For K = 1 To 10
            ...
        Next K
    Next J
Next I
```

**Note** If you omit *counter* in a **Next** statement, execution continues as if *counter* is included. If a **Next** statement is encountered before its corresponding **For** statement, an error occurs.

Function Statement

Declares the name, [arguments](#), and code that form the body of a **Function procedure**.

## Syntax

```
[Public | Private | Friend] [Static] Function name [(arglist)] [As type]  
    [statements]  
    [name = expression]  
[Exit Function]  
    [statements]  
    [name = expression]
```

## End Function

The **Function** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Indicates that the <b>Function</b> procedure is accessible to all other procedures in all <a href="#">modules</a> . If used in a module that contains an <b>Option Private</b> , the procedure is not available outside the <a href="#">project</a> .
<b>Private</b>	Optional. Indicates that the <b>Function</b> procedure is accessible only to other procedures in the module where it is declared.
<b>Friend</b>	Optional. Used only in a <a href="#">class module</a> . Indicates that the <b>Function</b> procedure is visible throughout the project, but not visible to a controller of an instance of an object.
<b>Static</b>	Optional. Indicates that the <b>Function</b> procedure's local <a href="#">variables</a> are preserved between calls. The <b>Static</b> attribute doesn't affect variables that are declared outside the <b>Function</b> , even if they are used in the procedure.

<i>name</i>	Required. Name of the <b>Function</b> ; follows standard variable naming conventions.
<i>arglist</i>	Optional. List of variables representing arguments that are passed to the <b>Function</b> procedure when it is called. Multiple variables are separated by commas.
<i>type</i>	Optional. <a href="#">Data type</a> of the value returned by the <b>Function</b> procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> , or (except fixed length), <a href="#">Object</a> , <a href="#">Variant</a> , or any <a href="#">user-defined type</a> .
<i>statements</i>	Optional. Any group of statements to be executed within the <b>Function</b> procedure.
<i>expression</i>	Optional. Return value of the <b>Function</b> .

The *arglist* argument has the following syntax and parts:

[**Optional**] [**ByVal** | **ByRef**] [**ParamArray**] *varname*[( )] [**As type**] [= *defaultvalue*]

Part	Description
<b>Optional</b>	Optional. Indicates that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword. <b>Optional</b> can't be used for any argument if <b>ParamArray</b> is used.
<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> array of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an arbitrary number of arguments. It may not be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument; follows standard variable naming conventions.

<i>type</i>	Optional. Data type of the argument passed to the procedure; may be <b>Byte</b> , <b>Boolean</b> , <b>Integer</b> , <b>Long</b> , <b>Currency</b> , <b>Single</b> , <b>Double</b> , <b>Decimal</b> (not currently supported) <b>Date</b> , <b>String</b> (variable length only), <b>Object</b> , <b>Variant</b> , or a specific <a href="#">object type</a> . If the parameter is not <b>Optional</b> , a user-defined type may also be specified.
<i>defaultvalue</i>	Optional. Any <a href="#">constant</a> or constant expression. Valid for <b>Optional</b> parameters only. If the type is an <b>Object</b> , an explicit default value can only be <b>Nothing</b> .

## Remarks

If not explicitly specified using **Public**, **Private**, or **Friend**, **Function** procedures are public by default. If **Static** isn't used, the value of local variables is not preserved between calls. The **Friend** keyword can only be used in class modules. However, **Friend** procedures can be accessed by procedures in any module of a project. A **Friend** procedure doesn't appear in the [type library](#) of its parent class, nor can a **Friend** procedure be late bound.

**Caution** **Function** procedures can be recursive; that is, they can call themselves to perform a given task. However, recursion can lead to stack overflow. The **Static** keyword usually isn't used with recursive **Function** procedures.

All executable code must be in procedures. You can't define a **Function** procedure inside another **Function**, **Sub**, or **Property** procedure.

The **Exit Function** statement causes an immediate exit from a **Function** procedure. Program execution continues with the statement following the statement that called the **Function** procedure. Any number of **Exit Function** statements can appear anywhere in a **Function** procedure.

Like a **Sub** procedure, a **Function** procedure is a separate procedure that can take arguments, perform a series of statements, and change the values of its arguments. However, unlike a **Sub** procedure, you can use a **Function** procedure on the right side of an [expression](#) in the same way you use any intrinsic function,

such as **Sqr**, **Cos**, or **Chr**, when you want to use the value returned by the function.

You call a **Function** procedure using the function name, followed by the argument list in parentheses, in an expression. See the **Call** statement for specific information on how to call **Function** procedures.

To return a value from a function, assign the value to the function name. Any number of such assignments can appear anywhere within the procedure. If no value is assigned to *name*, the procedure returns a default value: a numeric function returns 0, a string function returns a zero-length string (""), and a **Variant** function returns [Empty](#). A function that returns an object reference returns **Nothing** if no object reference is assigned to *name* (using **Set**) within the **Function**.

The following example shows how to assign a return value to a function named `BinarySearch`. In this case, **False** is assigned to the name to indicate that some value was not found.

```
Function BinarySearch(. . .) As Boolean
    . . .
    ' Value not found. Return a value of False.
    If lower > upper Then
        BinarySearch = False
        Exit Function
    End If
    . . .
End Function
```

Variables used in **Function** procedures fall into two categories: those that are explicitly declared within the procedure and those that are not. Variables that are explicitly declared in a procedure (using **Dim** or the equivalent) are always local to the procedure. Variables that are used but not explicitly declared in a procedure are also local unless they are explicitly declared at some higher level outside the procedure.

**Caution** A procedure can use a variable that is not explicitly declared in the

procedure, but a naming conflict can occur if anything you defined at the [module level](#) has the same name. If your procedure refers to an undeclared variable that has the same name as another procedure, constant, or variable, it is assumed that your procedure refers to that module-level name. Explicitly declare variables to avoid this kind of conflict. You can use an **Option Explicit** statement to force explicit declaration of variables.

**Caution** Visual Basic may rearrange arithmetic expressions to increase internal efficiency. Avoid using a **Function** procedure in an arithmetic expression when the function changes the value of variables in the same expression.

Get Statement

Reads data from an open disk file into a [variable](#).

## Syntax

**Get** [#]*filename*, [*recnumber*], *varname*

The **Get** statement syntax has these parts:

Part	Description
<i>filename</i>	Required. Any valid <a href="#">file number</a> .
<i>recnumber</i>	Optional. <b>Variant (Long)</b> . Record number ( <b>Random</b> mode files) or byte number ( <b>Binary</b> mode files) at which reading begins.
<i>varname</i>	Required. Valid variable name into which data is read.

## Remarks

Data read with **Get** is usually written to a file with **Put**.

The first record or byte in a file is at position 1, the second record or byte is at position 2, and so on. If you omit *recnumber*, the next record or byte following the last **Get** or **Put** [statement](#) (or pointed to by the last **Seek** function) is read. You must include delimiting commas, for example:

**Get** #4,,FileBuffer

For files opened in **Random** mode, the following rules apply:

If the length of the data being read is less than the length specified in the **Len** clause of the **Open** statement, **Get** reads subsequent records on record-length boundaries. The space between the end of one record and the beginning of the next record is padded with the existing contents of the file buffer.

Because the amount of padding data can't be determined with any certainty, it is generally a good idea to have the record length match the length of the data being read.

If the variable being read into is a variable-length string, **Get** reads a 2-byte descriptor containing the string length and then reads the data that goes into the variable. Therefore, the record length specified by the **Len** clause in the **Open** statement must be at least 2 bytes greater than the actual length of the string.

If the variable being read into is a [Variant](#) of [numeric type](#), **Get** reads 2 bytes identifying the **VarType** of the **Variant** and then the data that goes into the variable. For example, when reading a **Variant** of **VarType** 3, **Get** reads 6 bytes: 2 bytes identifying the **Variant** as **VarType** 3 (**Long**) and 4 bytes containing the [Long](#) data. The record length specified by the **Len** clause in the **Open** statement must be at least 2 bytes greater than the actual number of bytes required to store the variable.

**Note** You can use the **Get** statement to read a **Variant** [array](#) from disk, but you can't use **Get** to read a scalar **Variant** containing an array. You also can't use **Get** to read objects from disk.

If the variable being read into is a **Variant** of **VarType** 8 (**String**), **Get** reads 2 bytes identifying the **VarType**, 2 bytes indicating the length of the string, and then reads the string data. The record length specified by the **Len** clause in the **Open** statement must be at least 4 bytes greater than the actual length of the string.

If the variable being read into is a dynamic array, **Get** reads a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * NumberOfDimensions$ . The record length specified by the **Len** clause in the

**Open** statement must be greater than or equal to the sum of all the bytes required to read the array data and the array descriptor. For example, the following array declaration requires 118 bytes when the array is written to disk.

```
Dim MyArray(1 To 5,1 To 10) As Integer
```

The 118 bytes are distributed as follows: 18 bytes for the descriptor ( $2 + 8 * 2$ ), and 100 bytes for the data ( $5 * 10 * 2$ ).

If the variable being read into is a fixed-size array, **Get** reads only the data. No descriptor is read.

If the variable being read into is any other type of variable (not a variable-length string or a **Variant**), **Get** reads only the variable data. The record length specified by the **Len** clause in the **Open** statement must be greater than or equal to the length of the data being read.

**Get** reads elements of [user-defined types](#) as if each were being read individually, except that there is no padding between elements. On disk, a dynamic array in a user-defined type (written with **Put**) is prefixed by a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * NumberOfDimensions$ . The record length specified by the **Len** clause in the **Open** statement must be greater than or equal to the sum of all the bytes required to read the individual elements, including any arrays and their descriptors.

For files opened in **Binary** mode, all of the **Random** rules apply, except:

The **Len** clause in the **Open** statement has no effect. **Get** reads all variables from disk contiguously; that is, with no padding between records.

For any array other than an array in a user-defined type, **Get** reads only the data. No descriptor is read.

**Get** reads variable-length strings that aren't elements of user-defined types without expecting the 2-byte length descriptor. The number of bytes read

equals the number of characters already in the string. For example, the following statements read 10 bytes from [file number](#) 1:

```
varString = String(10, " ")
```

```
Get #1,,VarString
```

GoSub...Return Statement

Branches to and returns from a subroutine within a [procedure](#).

**Syntax**

**GoSub** *line* ...  
*line*  
...

## **Return**

The *line* [argument](#) can be any [line label](#) or [line number](#).

## **Remarks**

You can use **GoSub** and **Return** anywhere in a procedure, but **GoSub** and the corresponding **Return** statement must be in the same procedure. A subroutine can contain more than one **Return** statement, but the first **Return** statement encountered causes the flow of execution to branch back to the [statement](#) immediately following the most recently executed **GoSub** statement.

**Note** You can't enter or exit **Sub** procedures with **GoSub...Return**.

**Tip** Creating separate procedures that you can call may provide a more structured alternative to using **GoSub...Return**.

GoTo Statement

Branches unconditionally to a specified line within a [procedure](#).

**Syntax**

## **GoTo** *line*

The required *line* [argument](#) can be any [line label](#) or [line number](#).

## **Remarks**

**GoTo** can branch only to lines within the procedure where it appears.

**Note** Too many **GoTo** statements can make code difficult to read and debug. Use structured control [statements](#) (**Do...Loop**, **For...Next**, **If...Then...Else**, **Select Case**) whenever possible.

If...Then...Else Statement

Conditionally executes a group of [statements](#), depending on the value of an [expression](#).

## Syntax

**If** *condition* **Then** [*statements*] [**Else** *elsestatements*]

Or, you can use the block form syntax:

**If** *condition* **Then** [*statements*]

[**ElseIf** *condition-n* **Then**  
    *elseifstatements*] . . .

[**Else**  
    *elsestatements*]]

**End If**

The **If...Then...Else** statement syntax has these parts:

Part	Description
<i>condition</i>	Required. One or more of the following two types of expressions: A <a href="#">numeric expression</a> or <a href="#">string expression</a> that evaluates to

**True** or **False**. If *condition* is [Null](#), *condition* is treated as **False**.

An expression of the form **TypeOf** *objectname* **Is** *objecttype*. The *objectname* is any object reference and *objecttype* is any valid object type. The expression is **True** if *objectname* is of the [object type](#) specified by *objecttype*; otherwise it is **False**.

<i>statements</i>	Optional in block form; required in single-line form that has no <b>Else</b> clause. One or more statements separated by colons; executed if <i>condition</i> is <b>True</b> .
<i>condition-n</i>	Optional. Same as <i>condition</i> .
<i>elseifstatements</i>	Optional. One or more statements executed if associated <i>condition-n</i> is <b>True</b> .
<i>elsestatements</i>	Optional. One or more statements executed if no previous <i>condition</i> or <i>condition-n</i> expression is <b>True</b> .

## Remarks

You can use the single-line form (first syntax) for short, simple tests. However, the block form (second syntax) provides more structure and flexibility than the single-line form and is usually easier to read, maintain, and debug.

**Note** With the single-line form, it is possible to have multiple statements executed as the result of an **If...Then** decision. All statements must be on the same line and separated by colons, as in the following statement:

```
If A > 10 Then A = A + 1 : B = B + A : C = C +
```

A block form **If** statement must be the first statement on a line. The **Else**, **ElseIf**, and **End If** parts of the statement can have only a [line number](#) or [line label](#) preceding them. The block **If** must end with an **End If** statement.

To determine whether or not a statement is a block **If**, examine what follows the **Then** [keyword](#). If anything other than a [comment](#) appears after **Then** on the same line, the statement is treated as a single-line **If** statement.

The **Else** and **ElseIf** clauses are both optional. You can have as many **ElseIf** clauses as you want in a block **If**, but none can appear after an **Else** clause. Block **If** statements can be nested; that is, contained within one another.

When executing a block **If** (second syntax), *condition* is tested. If *condition* is **True**, the statements following **Then** are executed. If *condition* is **False**, each **ElseIf** condition (if any) is evaluated in turn. When a **True** condition is found, the statements immediately following the associated **Then** are executed. If none of the **ElseIf** conditions are **True** (or if there are no **ElseIf** clauses), the statements following **Else** are executed. After executing the statements following **Then** or **Else**, execution continues with the statement following **End If**.

**Tip** **Select Case** may be more useful when evaluating a single expression that has several possible actions. However, the **TypeOf** *objectname* **Is** *objecttype* clause can't be used with the **Select Case** statement.

**Note** **TypeOf** cannot be used with hard data types such as Long, Integer, and so forth other than Object.

Input # Statement

Reads data from an open sequential file and assigns the data to [variables](#).

## Syntax

**Input #***filename, varlist*

The **Input #** statement syntax has these parts:

Part	Description
<i>filename</i>	Required. Any valid <a href="#">file number</a> .
<i>varlist</i>	Required. Comma-delimited list of variables that are assigned values read from the file — can't be an <a href="#">array</a> or <a href="#">object variable</a> . However, variables that describe an element of an array or <a href="#">user-defined type</a> may be used.

## Remarks

Data read with **Input #** is usually written to a file with **Write #**. Use this [statement](#) only with files opened in **Input** or **Binary** mode.

When read, standard string or numeric data is assigned to variables without modification. The following table illustrates how other input data is treated:

Data	Value assigned to variable
Delimiting comma or blank line	<a href="#">Empty</a>
#NULL#	<a href="#">Null</a>
#TRUE# or #FALSE#	<b>True</b> or <b>False</b>
#yyyy-mm-dd hh:mm:ss#	The date and/or time represented by the <a href="#">expression</a>
#ERROR <i>errornumber</i> #	<i>errornumber</i> (variable is a <a href="#">Variant</a> tagged as an error)

Double quotation marks (" ") within input data are ignored.

**Note** You should not write strings that contain embedded quotation marks, for example, "1,2""x" for use with the **Input #** statement: **Input #** parses this string as two complete and separate strings.

Data items in a file must appear in the same order as the variables in *varlist* and match variables of the same [data type](#). If a variable is numeric and the data is not numeric, a value of zero is assigned to the variable.

If you reach the end of the file while you are inputting a data item, the input is terminated and an error occurs.

**Note** To be able to correctly read data from a file into variables using **Input #**, use the **Write #** statement instead of the **Print #** statement to write the data to the files. Using **Write #** ensures each separate data field is properly delimited.

## Kill Statement

Deletes files from a disk.

### Syntax

**Kill** *pathname*

The required *pathname* [argument](#) is a [string expression](#) that specifies one or more file names to be deleted. The *pathname* may include the directory or folder, and the drive.

### Remarks

In Microsoft Windows, **Kill** supports the use of multiple-character (\*) and single-character (?) wildcards to specify multiple files. However, on the Macintosh, these characters are treated as valid file name characters and can't be used as wildcards to specify multiple files.

Since the Macintosh doesn't support the wildcards, use the file type to identify groups of files to delete. You can use the **MacID** function to specify file type instead of repeating the command with separate file names. For example, the following statement deletes all TEXT files in the current folder.

```
Kill MacID("TEXT")
```

If you use the **MacID** function with **Kill** in Microsoft Windows, an error occurs.

An error occurs if you try to use **Kill** to delete an open file.

**Note** To delete directories, use the **Rmdir** statement.

## Let Statement

Assigns the value of an [expression](#) to a [variable](#) or [property](#).

### Syntax

**[Let]** *varname* = *expression*

The **Let** statement syntax has these parts:

Part	Description
<b>Let</b>	Optional. Explicit use of the <b>Let</b> <a href="#">keyword</a> is a matter of style, but it is usually omitted.
<i>varname</i>	Required. Name of the variable or property; follows standard variable naming conventions.
<i>expression</i>	Required. Value assigned to the variable or property.

### Remarks

A value expression can be assigned to a variable or property only if it is of a [data type](#) that is compatible with the variable. You can't assign [string expressions](#) to numeric variables, and you can't assign [numeric expressions](#) to string variables. If you do, an error occurs at [compile time](#).

[Variant](#) variables can be assigned either string or numeric expressions. However, the reverse is not always true. Any **Variant** except a [Null](#) can be assigned to a string variable, but only a **Variant** whose value can be interpreted as a number can be assigned to a numeric variable. Use the **IsNumeric** function to determine if the **Variant** can be converted to a number.

**Caution** Assigning an expression of one [numeric type](#) to a variable of a different numeric type coerces the value of the expression into the numeric type of the resulting variable.

**Let** statements can be used to assign one record variable to another only when both variables are of the same [user-defined type](#). Use the **LSet** statement to assign record variables of different user-defined types. Use the **Set** statement to assign object references to variables.

Line Input # Statement

Reads a single line from an open sequential file and assigns it to a [String variable](#).

## Syntax

**Line Input #***filenumber, varname*

The **Line Input #** statement syntax has these parts:

Part	Description
<i>filenumber</i>	Required. Any valid <a href="#">file number</a> .
<i>varname</i>	Required. Valid <a href="#">Variant</a> or <b>String</b> variable name.

## Remarks

Data read with **Line Input #** is usually written from a file with **Print #**.

The **Line Input #** statement reads from a file one character at a time until it encounters a carriage return (**Chr(13)**) or carriage return–linefeed (**Chr(13)** + **Chr(10)**) sequence. Carriage return–linefeed sequences are skipped rather than appended to the character string.

## Load Statement

Loads an object but doesn't show it.

### Syntax

#### **Load** *object*

The *object* placeholder represents an [object expression](#) that evaluates to an object in the Applies To list.

### Remarks

When an object is loaded, it is placed in memory, but isn't visible. Use the **Show** method to make the object visible. Until an object is visible, a user can't interact with it. The object can be manipulated programmatically in its Initialize event procedure.

Lock,  
Unlock

Statements

Controls access by other processes to all or part of a file opened using the **Open** statement.

### Syntax

**Lock** [#]*filenumber*[, *recordrange*]

...

**Unlock** [#]*filenumber*[, *recordrange*]

The **Lock** and **Unlock** statement syntax has these parts:

Part	Description
<i>filenumber</i>	Required. Any valid <a href="#">file number</a> .
<i>recordrange</i>	Optional. The range of records to lock or unlock.

## Settings

The *recordrange* [argument](#) settings are:

*recnumber* | [*start*] **To** *end*

Setting	Description
<i>recnumber</i>	Record number ( <b>Random</b> mode files) or byte number ( <b>Binary</b> mode files) at which locking or unlocking begins.
<i>start</i>	Number of the first record or byte to lock or unlock.
<i>end</i>	Number of the last record or byte to lock or unlock.

## Remarks

The **Lock** and **Unlock** statements are used in environments where several processes might need access to the same file.

**Lock** and **Unlock** statements are always used in pairs. The arguments to **Lock** and **Unlock** must match exactly.

The first record or byte in a file is at position 1, the second record or byte is at position 2, and so on. If you specify just one record, then only that record is locked or unlocked. If you specify a range of records and omit a starting record (*start*), all records from the first record to the end of the range (*end*) are locked or unlocked. Using **Lock** without *recnumber* locks the entire file; using **Unlock** without *recnumber* unlocks the entire file.

If the file has been opened for sequential input or output, **Lock** and **Unlock** affect the entire file, regardless of the range specified by *start* and *end*.

**Caution** Be sure to remove all locks with an **Unlock** statement before closing a file or quitting your program. Failure to remove locks produces unpredictable results.

LSet Statement

Left aligns a string within a string [variable](#), or copies a variable of one [user-defined type](#) to another variable of a different user-defined type.

## Syntax

**LSet** *stringvar* = *string*

**LSet** *varname1* = *varname2*

The **LSet** statement syntax has these parts:

Part	Description
<i>stringvar</i>	Required. Name of string <a href="#">variable</a> .
<i>string</i>	Required. <a href="#">String expression</a> to be left-aligned within <i>stringvar</i> .
<i>varname1</i>	Required. Variable name of the user-defined type being copied to.
<i>varname2</i>	Required. Variable name of the user-defined type being copied from.

## Remarks

**LSet** replaces any leftover characters in *stringvar* with spaces.

If *string* is longer than *stringvar*, **LSet** places only the leftmost characters, up to the length of the *stringvar*, in *stringvar*.

**Warning** Using **LSet** to copy a variable of one user-defined type into a variable of a different user-defined type is not recommended. Copying data of one [data type](#) into space reserved for a different data type can cause unpredictable results.

When you copy a variable from one user-defined type to another, the binary data from one variable is copied into the memory space of the other, without regard for the data types specified for the elements.

Mid

Statement

Replaces a specified number of characters in a **Variant (String)** [variable](#) with characters from another string.

### Syntax

**Mid**(*stringvar*, *start*[, *length*]) = *string*

The **Mid** statement syntax has these parts:

Part	Description
<i>stringvar</i>	Required. Name of string variable to modify.
<i>start</i>	Required; <b>Variant (Long)</b> . Character position in <i>stringvar</i> where the replacement of text begins.
<i>length</i>	Optional; <b>Variant (Long)</b> . Number of characters to replace. If omitted, all of <i>string</i> is used.

*string* Required. [String expression](#) that replaces part of *stringvar*.

### Remarks

The number of characters replaced is always less than or equal to the number of characters in *stringvar*.

**Note** Use the **MidB** statement with byte data contained in a string. In the **MidB** statement, *start* specifies the byte position within *stringvar* where replacement begins and *length* specifies the numbers of bytes to replace.

## MkDir Statement

Creates a new directory or folder.

### Syntax

**MkDir** *path*

The required *path* [argument](#) is a [string expression](#) that identifies the directory or folder to be created. The *path* may include the drive. If no drive is specified, **MkDir** creates the new directory or folder on the current drive.

Name

Statement

Renames a disk file, directory, or folder.

## Syntax

**Name** *oldpathname* **As** *newpathname*

The **Name** statement syntax has these parts:

Part	Description
<i>oldpathname</i>	Required. <a href="#">String expression</a> that specifies the existing file name and location — may include directory or folder, and drive.
<i>newpathname</i>	Required. String expression that specifies the new file name and location — may include directory or folder, and drive. The file name specified by <i>newpathname</i> can't already exist.

## Remarks

The **Name** statement renames a file and moves it to a different directory or folder, if necessary. **Name** can move a file across drives, but it can only rename an existing directory or folder when both `newpathname` and `oldpathname` are located on the same drive. **Name** cannot create a new file, directory, or folder.

Using **Name** on an open file produces an error. You must close an open file before renaming it. **Name** [arguments](#) cannot include multiple-character (\*) and single-character (?) wildcards.

On Error Statement

Enables an error-handling routine and specifies the location of the routine within a [procedure](#); can also be used to disable an error-handling routine.

## Syntax

**On Error GoTo** *line*

**On Error Resume Next**

**On Error GoTo 0**

The **On Error** statement syntax can have any of the following forms:

Statement	Description
<b>On Error GoTo</b> <i>line</i>	Enables the error-handling routine that starts at <i>line</i> specified in the required <i>line</i> <a href="#">argument</a> . The <i>line</i> argument is any <a href="#">line label</a> or <a href="#">line number</a> . If a <a href="#">run-time error</a> occurs, control branches to <i>line</i> , making the error handler active. The specified <i>line</i> must be in the same procedure as the <b>On Error</b> statement; otherwise, a <a href="#">compile-time</a> error occurs.
<b>On Error Resume Next</b>	Specifies that when a run-time error occurs, control goes to the <a href="#">statement</a> immediately following the statement where the error occurred where execution continues.

Use this form rather than **On Error GoTo** when accessing objects.

**On Error GoTo 0** Disables any enabled error handler in the current procedure.

## Remarks

If you don't use an **On Error** statement, any run-time error that occurs is fatal; that is, an error message is displayed and execution stops.

An "enabled" error handler is one that is turned on by an **On Error** statement; an "active" error handler is an enabled handler that is in the process of handling an error. If an error occurs while an error handler is active (between the occurrence of the error and a **Resume**, **Exit Sub**, **Exit Function**, or **Exit Property** statement), the current procedure's error handler can't handle the error. Control returns to the calling procedure. If the calling procedure has an enabled error handler, it is activated to handle the error. If the calling procedure's error handler is also active, control passes back through previous calling procedures until an enabled, but inactive, error handler is found. If no inactive, enabled error handler is found, the error is fatal at the point at which it actually occurred. Each time the error handler passes control back to a calling procedure, that procedure becomes the current procedure. Once an error is handled by an error handler in any procedure, execution resumes in the current procedure at the point designated by the **Resume** statement.

**Note** An error-handling routine is not a **Sub** procedure or **Function** procedure. It is a section of code marked by a line label or line number.

Error-handling routines rely on the value in the **Number** property of the **Err** object to determine the cause of the error. The error-handling routine should test or save relevant property values in the **Err** object before any other error can occur or before a procedure that might cause an error is called. The property values in the **Err** object reflect only the most recent error. The error message associated with **Err.Number** is contained in **Err.Description**.

**On Error Resume Next** causes execution to continue with the statement immediately following the statement that caused the run-time error, or with the statement immediately following the most recent call out of the procedure

containing the **On Error Resume Next** statement. This statement allows execution to continue despite a run-time error. You can place the error-handling routine where the error would occur, rather than transferring control to another location within the procedure. An **On Error Resume Next** statement becomes inactive when another procedure is called, so you should execute an **On Error Resume Next** statement in each called routine if you want inline error handling within that routine.

**Note** The **On Error Resume Next** construct may be preferable to **On Error GoTo** when handling errors generated during access to other objects. Checking **Err** after each interaction with an object removes ambiguity about which object was accessed by the code. You can be sure which object placed the error code in **Err.Number**, as well as which object originally generated the error (the object specified in **Err.Source**).

**On Error GoTo 0** disables error handling in the current procedure. It doesn't specify line 0 as the start of the error-handling code, even if the procedure contains a line numbered 0. Without an **On Error GoTo 0** statement, an error handler is automatically disabled when a procedure is exited.

To prevent error-handling code from running when no error has occurred, place an **Exit Sub**, **Exit Function**, or **Exit Property** statement immediately before the error-handling routine, as in the following fragment:

```
Sub InitializeMatrix(Var1, Var2, Var3, Var4)
    On Error GoTo ErrorHandler
    . . .
    Exit Sub
ErrorHandler:
    . . .
    Resume Next
End Sub
```

Here, the error-handling code follows the **Exit Sub** statement and precedes the **End Sub** statement to separate it from the procedure flow. Error-handling code can be placed anywhere in a procedure.

Untrapped errors in objects are returned to the controlling application when the object is running as an executable file. Within the development environment, untrapped errors are only returned to the controlling application if the proper options are set. See your [host application's](#) documentation for a description of which options should be set during debugging, how to set them, and whether the host can create [classes](#).

If you create an object that accesses other objects, you should try to handle errors passed back from them unhandled. If you cannot handle such errors, map the error code in **Err.Number** to one of your own errors, and then pass them back to the caller of your object. You should specify your error by adding your error code to the **vbObjectError** constant. For example, if your error code is 1052, assign it as follows:

```
Err.Number = vbObjectError + 1052
```

**Note** System errors during calls to Windows [dynamic-link libraries](#) (DLL) or Macintosh code resources do not raise exceptions and cannot be trapped with Visual Basic error trapping. When calling DLL functions, you should check each return value for success or failure (according to the API specifications), and in the event of a failure, check the value in the **Err** object's **LastDLLError** property. **LastDLLError** always returns zero on the Macintosh.

On...GoSub, On...GoTo Statements

Branch to one of several specified lines, depending on the value of an [expression](#).

## Syntax

**On** *expression* **GoSub** *destinationlist*

**On** *expression* **GoTo** *destinationlist*

The **On...GoSub** and **On...GoTo** statement syntax has these parts:

Part	Description
<i>expression</i>	Required. Any <a href="#">numeric expression</a> that evaluates to a whole number between 0 and 255, inclusive. If <i>expression</i> is any number other than a whole number, it is rounded before it is evaluated.
<i>destinationlist</i>	Required. List of <a href="#">line numbers</a> or <a href="#">line labels</a> separated by commas.

## Remarks

The value of *expression* determines which line is branched to in *destinationlist*. If the value of *expression* is less than 1 or greater than the number of items in the list, one of the following results occurs:

If <i>expression</i> is	Then
Equal to 0	Control drops to the <a href="#">statement</a> following <b>On...GoSub</b> or <b>On...GoTo</b> .
Greater than number of items in list	Control drops to the statement following <b>On...GoSub</b> or <b>On...GoTo</b> .
Negative	An error occurs.
Greater than 255	An error occurs.

You can mix line numbers and line labels in the same list. You can use as many line labels and line numbers as you like with **On...GoSub** and **On...GoTo**. However, if you use more labels or numbers than fit on a single line, you must use the [line-continuation character](#) to continue the logical line onto the next physical line.

**Tip** **Select Case** provides a more structured and flexible way to perform multiple branching.

Open Statement

Enables input/output (I/O) to a file.

### Syntax

**Open** *pathname* **For** *mode* [**Access** *access*] [*lock*] **As** [#]*filenumber*  
[**Len**=*reclength*]

The **Open** statement syntax has these parts:

Part	Description
------	-------------

<i>pathname</i>	Required. <a href="#">String expression</a> that specifies a file name — may include directory or folder, and drive.
<i>mode</i>	Required. <a href="#">Keyword</a> specifying the file mode: <b>Append</b> , <b>Binary</b> , <b>Input</b> , <b>Output</b> , or <b>Random</b> . If unspecified, the file is opened for <b>Random</b> access.
<i>access</i>	Optional. Keyword specifying the operations permitted on the open file: <b>Read</b> , <b>Write</b> , or <b>Read Write</b> .
<i>lock</i>	Optional. Keyword specifying the operations restricted on the open file by other processes: <b>Shared</b> , <b>Lock Read</b> , <b>Lock Write</b> , and <b>Lock Read Write</b> .
<i>filenumber</i>	Required. A valid <a href="#">file number</a> in the range 1 to 511, inclusive. Use the <b>FreeFile</b> function to obtain the next available file number.
<i>reclength</i>	Optional. Number less than or equal to 32,767 (bytes). For files opened for random access, this value is the record length. For sequential files, this value is the number of characters buffered.

## Remarks

You must open a file before any I/O operation can be performed on it. **Open** allocates a buffer for I/O to the file and determines the mode of access to use with the buffer.

If the file specified by *pathname* doesn't exist, it is created when a file is opened for **Append**, **Binary**, **Output**, or **Random** modes.

If the file is already opened by another process and the specified type of access is not allowed, the **Open** operation fails and an error occurs.

The **Len** clause is ignored if *mode* is **Binary**.

**Important** In **Binary**, **Input**, and **Random** modes, you can open a file using a different file number without first closing the file. In **Append** and **Output** modes, you must close a file before opening it with a different file number.

Option Base Statement

Used at [module level](#) to declare the default lower bound for [array](#) subscripts.

## Syntax

**Option Base {0 | 1}**

## Remarks

Because the default base is **0**, the **Option Base** statement is never required. If used, the [statement](#) must appear in a [module](#) before any [procedures](#). **Option Base** can appear only once in a module and must precede array [declarations](#) that include dimensions.

**Note** The **To** clause in the **Dim**, **Private**, **Public**, **ReDim**, and **Static** statements provides a more flexible way to control the range of an array's subscripts. However, if you don't explicitly set the lower bound with a **To** clause, you can use **Option Base** to change the default lower bound to 1. The base of an array created with the the **ParamArray** keyword is zero; **Option Base** does not affect **ParamArray** (or the **Array** function, when qualified with the name of its type library, for example **VBA.Array**).

The **Option Base** statement only affects the lower bound of arrays in the module where the statement is located.

Option Compare Statement

Used at [module level](#) to declare the default comparison method to use when string data is compared.

## Syntax

**Option Compare {Binary | Text | Database}**

## Remarks

If used, the **Option Compare** statement must appear in a [module](#) before any [procedures](#).

The **Option Compare** statement specifies the [string comparison](#) method (**Binary**, **Text**, or **Database**) for a module. If a module doesn't include an **Option Compare** statement, the default text comparison method is **Binary**.

**Option Compare Binary** results in string comparisons based on a [sort order](#) derived from the internal binary representations of the characters. In Microsoft Windows, sort order is determined by the code page. A typical binary sort order is shown in the following example:

A < B < E < Z < a < b < e < z < À < Ê < Ø < à <

**Option Compare Text** results in string comparisons based on a case-insensitive text sort order determined by your system's [locale](#). When the same characters are sorted using **Option Compare Text**, the following text sort order is produced:

(A=a) < ( À=à) < (B=b) < (E=e) < (Ê=ê) < (Z=z)

**Option Compare Database** can only be used within Microsoft Access. This results in string comparisons based on the sort order determined by the locale ID of the database where the string comparisons occur.

Option Explicit Statement

Used at [module level](#) to force explicit declaration of all [variables](#) in that [module](#).

## Syntax

### Option Explicit

#### Remarks

If used, the **Option Explicit** statement must appear in a module before any [procedures](#).

When **Option Explicit** appears in a module, you must explicitly declare all variables using the **Dim**, **Private**, **Public**, **ReDim**, or **Static** statements. If you attempt to use an undeclared variable name, an error occurs at [compile time](#).

If you don't use the **Option Explicit** statement, all undeclared variables are of **Variant** type unless the default type is otherwise specified with a **DefType** statement.

**Note** Use **Option Explicit** to avoid incorrectly typing the name of an existing variable or to avoid confusion in code where the [scope](#) of the variable is not clear.

Option Private Statement

When used in host applications that allow references across multiple [projects](#), **Option Private Module** prevents a [module's](#) contents from being referenced outside its project. In host applications that don't permit such references, for example, standalone versions of Visual Basic, **Option Private** has no effect.

## Syntax

### Option Private Module

## Remarks

If used, the **Option Private** statement must appear at [module level](#), before any [procedures](#).

When a module contains **Option Private Module**, the public parts, for example, [variables](#), [objects](#), and [user-defined types](#) declared at module level, are still available within the [project](#) containing the module, but they are not available to other applications or projects.

**Note** **Option Private** is only useful for [host applications](#) that support simultaneous loading of multiple projects and permit references between the loaded projects. For example, Microsoft Excel permits loading of multiple projects and **Option Private Module** can be used to restrict cross-project visibility. Although Visual Basic permits loading of multiple projects, references

between projects are never permitted in Visual Basic.

Print # Statement

Writes display-formatted data to a sequential file.

## Syntax

**Print** #*filenumber*, [*outputlist*]

The **Print** # statement syntax has these parts:

Part	Description
<i>filenumber</i>	Required. Any valid <a href="#">file number</a> .
<i>outputlist</i>	Optional. <a href="#">Expression</a> or list of expressions to print.

## Settings

The *outputlist* [argument](#) settings are:

[{**Spc**(*n*) | **Tab**[(*n*)]}] [*expression*] [*charpos*]

Setting	Description
<b>Spc</b> ( <i>n</i> )	Used to insert space characters in the output, where <i>n</i> is the number of space characters to insert.
<b>Tab</b> ( <i>n</i> )	Used to position the insertion point to an absolute column number, where <i>n</i> is the column number. Use <b>Tab</b> with no argument to position the insertion point at the beginning of the next <a href="#">print zone</a> .
<i>expression</i>	<a href="#">Numeric expressions</a> or <a href="#">string expressions</a> to print.
<i>charpos</i>	Specifies the insertion point for the next character. Use a semicolon to position the insertion point immediately after the last character displayed. Use <b>Tab</b> ( <i>n</i> ) to position the insertion point to an absolute column number. Use <b>Tab</b> with no argument to position the insertion point at the beginning of the next print zone. If <i>charpos</i> is omitted, the next character is printed on the next line.

## Remarks

Data written with **Print #** is usually read from a file with **Line Input #** or **Input**.

If you omit *outputlist* and include only a list separator after *filename*, a blank line is printed to the file. Multiple expressions can be separated with either a space or a semicolon. A space has the same effect as a semicolon.

For [Boolean](#) data, either `True` or `False` is printed. The **True** and **False** keywords are not translated, regardless of the [locale](#).

[Date](#) data is written to the file using the standard short date format recognized by your system. When either the date or the time component is missing or zero, only the part provided gets written to the file.

Nothing is written to the file if *outputlist* data is [Empty](#). However, if *outputlist* data is [Null](#), **Null** is written to the file.

For **Error** data, the output appears as `Error errorcode`. The **Error** keyword is not translated regardless of the locale.

All data written to the file using **Print #** is internationally aware; that is, the data is properly formatted using the appropriate decimal separator.

Because **Print #** writes an image of the data to the file, you must delimit the data so it prints correctly. If you use **Tab** with no arguments to move the print position to the next print zone, **Print #** also writes the spaces between print fields to the file.

**Note** If, at some future time, you want to read the data from a file using the **Input #** statement, use the **Write #** statement instead of the **Print #** statement to write the data to the file. Using **Write #** ensures the integrity of each separate data field by properly delimiting it, so it can be read back in using **Input #**. Using **Write #** also ensures it can be correctly read in any locale.

Private Statement

Used at [module level](#) to declare private [variables](#) and allocate storage space.

## Syntax

```
Private [WithEvents] varname[([subscripts])] [As [New] type] [, [WithEvents]  
  varname[([subscripts])] [As [New] type]] . . .
```

The **Private** statement syntax has these parts:

Part	Description
------	-------------

<b>WithEvents</b>	Optional. <a href="#">Keyword</a> that specifies that <i>varname</i> is an <a href="#">object variable</a> used to respond to events triggered by an <a href="#">ActiveX object</a> . <b>WithEvents</b> is valid only in <a href="#">class modules</a> . You can declare as many individual variables as you like using <b>WithEvents</b> , but you can't create <a href="#">arrays</a> with <b>WithEvents</b> . You can't use <b>New</b> with <b>WithEvents</b> .
<i>varname</i>	Required. Name of the variable; follows standard variable naming conventions.
<i>subscripts</i>	Optional. Dimensions of an array variable; up to 60 multiple dimensions may be declared. The <i>subscripts</i> <a href="#">argument</a> uses the following syntax: <code>[lower To] upper [, [lower To] upper] . . .</code> When not explicitly stated in <i>lower</i> , the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.
<b>New</b>	Optional. Keyword that enables implicit creation of an object. If you use <b>New</b> when declaring the object variable, a new instance of the object is created on first reference to it, so you don't have to use the <b>Set</b> statement to assign the object reference. The <b>New</b> keyword can't be used to declare variables of any intrinsic <a href="#">data type</a> , can't be used to declare instances of dependent objects, and can't be used with <b>WithEvents</b> .
<i>type</i>	Optional. Data type of the variable; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (for variable-length strings), <b>String</b> * <i>length</i> (for fixed-length strings), <a href="#">Object</a> , <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an <a href="#">object type</a> . Use a separate <b>As type</b> clause for each variable being defined.

## Remarks

**Private** variables are available only to the module in which they are declared.

Use the **Private** statement to declare the data type of a variable. For example, the following statement declares a variable as an **Integer**:

## Private NumberOfEmployees As Integer

You can also use a **Private** statement to declare the object type of a variable. The following statement declares a variable for a new instance of a worksheet.

## Private X As New Worksheet

If the **New** keyword isn't used when declaring an object variable, the variable that refers to the object must be assigned an existing object using the **Set** statement before it can be used. Until it's assigned an object, the declared object variable has the special value **Nothing**, which indicates that it doesn't refer to any particular instance of an object.

If you don't specify a data type or object type, and there is no **Default** statement in the module, the variable is **Variant** by default.

You can also use the **Private** statement with empty parentheses to declare a dynamic array. After declaring a dynamic array, use the **ReDim** statement within a procedure to define the number of dimensions and elements in the array. If you try to redeclare a dimension for an array variable whose size was explicitly specified in a **Private**, **Public**, or **Dim** statement, an error occurs.

When variables are initialized, a numeric variable is initialized to 0, a variable-length string is initialized to a zero-length string (""), and a fixed-length string is filled with zeros. **Variant** variables are initialized to [Empty](#). Each element of a user-defined type variable is initialized as if it were a separate variable.

**Note** When you use the **Private** statement in a procedure, you generally put the **Private** statement at the beginning of the procedure.

Property Get Statement

Declares the name, [arguments](#), and code that form the body of a **Property procedure**, which gets the value of a [property](#).

## Syntax

```
[Public | Private | Friend] [Static] Property Get name [(arglist)] [As type]  
    [statements]  
    [name = expression]  
[Exit Property]  
    [statements]  
    [name = expression]
```

## End Property

The **Property Get** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Indicates that the <b>Property Get</b> procedure is accessible to all other procedures in all <a href="#">modules</a> . If used in a module that contains an <b>Option Private</b> statement, the procedure is not available outside the <a href="#">project</a> .
<b>Private</b>	Optional. Indicates that the <b>Property Get</b> procedure is accessible only to other procedures in the module where it is declared.
<b>Friend</b>	Optional. Used only in a <a href="#">class module</a> . Indicates that the <b>Property Get</b> procedure is visible throughout the project, but not visible to a controller of an instance of an object.
<b>Static</b>	Optional. Indicates that the <b>Property Get</b> procedure's local <a href="#">variables</a> are preserved between calls. The <b>Static</b> attribute doesn't affect variables that are declared outside the <b>Property</b>

	<b>Get</b> procedure, even if they are used in the procedure.
<i>name</i>	Required. Name of the <b>Property Get</b> procedure; follows standard variable naming conventions, except that the name can be the same as a <b>Property Let</b> or <b>Property Set</b> procedure in the same module.
<i>arglist</i>	Optional. List of variables representing arguments that are passed to the <b>Property Get</b> procedure when it is called. Multiple arguments are separated by commas. The name and <a href="#">data type</a> of each argument in a <b>Property Get</b> procedure must be the same as the corresponding argument in a <b>Property Let</b> procedure (if one exists).
<i>type</i>	Optional. Data type of the value returned by the <b>Property Get</b> procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (except fixed length), <a href="#">Object</a> , <a href="#">Variant</a> , <a href="#">user-defined type</a> , and <a href="#">Arrays</a> .  The return <i>type</i> of a <b>Property Get</b> procedure must be the same data type as the last (or sometimes the only) argument in a corresponding <b>Property Let</b> procedure (if one exists) that defines the value assigned to the property on the right side of an <a href="#">expression</a> .
<i>statements</i>	Optional. Any group of statements to be executed within the body of the <b>Property Get</b> procedure.
<i>expression</i>	Optional. Value of the property returned by the procedure defined by the <b>Property Get</b> statement.

The *arglist* argument has the following syntax and parts:

**[Optional] [ByVal | ByRef] [ParamArray] varname[( )] [As type] [= defaultvalue]**

Part	Description
<b>Optional</b>	Optional. Indicates that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword.

<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> array of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an arbitrary number of arguments. It may not be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument; follows standard variable naming conventions.
<i>type</i>	Optional. Data type of the argument passed to the procedure; may be <b>Byte</b> , <b>Boolean</b> , <b>Integer</b> , <b>Long</b> , <b>Currency</b> , <b>Single</b> , <b>Double</b> , <b>Decimal</b> (not currently supported), <b>Date</b> , <b>String</b> (variable length only), <b>Object</b> , <b>Variant</b> , or a specific <a href="#">object type</a> . If the parameter is not <b>Optional</b> , a user-defined type may also be specified.
<i>defaultvalue</i>	Optional. Any <a href="#">constant</a> or constant expression. Valid for <b>Optional</b> parameters only. If the type is an <b>Object</b> , an explicit default value can only be <b>Nothing</b> .

## Remarks

If not explicitly specified using **Public**, **Private**, or **Friend**, **Property** procedures are public by default. If **Static** is not used, the value of local variables is not preserved between calls. The **Friend** keyword can only be used in class modules. However, **Friend** procedures can be accessed by procedures in any module of a project. A **Friend** procedure doesn't appear in the [type library](#) of its parent class, nor can a **Friend** procedure be late bound.

All executable code must be in procedures. You can't define a **Property Get** procedure inside another **Property**, **Sub**, or **Function** procedure.

The **Exit Property** statement causes an immediate exit from a **Property Get** procedure. Program execution continues with the statement following the statement that called the **Property Get** procedure. Any number of **Exit Property**

statements can appear anywhere in a **Property Get** procedure.

Like a **Sub** and **Property Let** procedure, a **Property Get** procedure is a separate procedure that can take arguments, perform a series of statements, and change the values of its arguments. However, unlike a **Sub** or **Property Let** procedure, you can use a **Property Get** procedure on the right side of an expression in the same way you use a **Function** or a property name when you want to return the value of a property.

Property Let Statement

Declares the name, [arguments](#), and code that form the body of a **Property Let procedure**, which assigns a value to a [property](#).

## Syntax

```
[Public | Private | Friend] [Static] Property Let name ([arglist,] value)  
    [statements]  
[Exit Property]  
    [statements]
```

## End Property

The **Property Let** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Indicates that the <b>Property Let</b> procedure is accessible to all other procedures in all <a href="#">modules</a> . If used in a module that contains an <b>Option Private</b> statement, the procedure is not available outside the <a href="#">project</a> .
<b>Private</b>	Optional. Indicates that the <b>Property Let</b> procedure is accessible only to other procedures in the module where it is declared.
<b>Friend</b>	Optional. Used only in a <a href="#">class module</a> . Indicates that the <b>Property Let</b> procedure is visible throughout the <a href="#">project</a> , but

	not visible to a controller of an instance of an object.
<b>Static</b>	Optional. Indicates that the <b>Property Let</b> procedure's local <a href="#">variables</a> are preserved between calls. The <b>Static</b> attribute doesn't affect variables that are declared outside the <b>Property Let</b> procedure, even if they are used in the procedure.
<i>name</i>	Required. Name of the <b>Property Let</b> procedure; follows standard variable naming conventions, except that the name can be the same as a <b>Property Get</b> or <b>Property Set</b> procedure in the same module.
<i>arglist</i>	Required. List of variables representing arguments that are passed to the <b>Property Let</b> procedure when it is called. Multiple arguments are separated by commas. The name and <a href="#">data type</a> of each argument in a <b>Property Let</b> procedure must be the same as the corresponding argument in a <b>Property Get</b> procedure.
<i>value</i>	Required. Variable to contain the value to be assigned to the property. When the procedure is called, this argument appears on the right side of the calling <a href="#">expression</a> . The data type of <i>value</i> must be the same as the return type of the corresponding <b>Property Get</b> procedure.
<i>statements</i>	Optional. Any group of <a href="#">statements</a> to be executed within the <b>Property Let</b> procedure.

The *arglist* argument has the following syntax and parts:

[**Optional**] [**ByVal** | **ByRef**] [**ParamArray**] *varname*[( )] [**As type**] [= *defaultvalue*]

Part	Description
<b>Optional</b>	Optional. Indicates that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword. Note that it is not possible for the right side of a <b>Property Let</b> expression to be <b>Optional</b> .
<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> .

**ByRef** is the default in Visual Basic.

<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> array of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an arbitrary number of arguments. It may not be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument; follows standard variable naming conventions.
<i>type</i>	Optional. Data type of the argument passed to the procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (variable length only), <a href="#">Object</a> , <a href="#">Variant</a> , or a specific <a href="#">object type</a> . If the parameter is not <b>Optional</b> , a <a href="#">user-defined type</a> may also be specified.
<i>defaultvalue</i>	Optional. Any <a href="#">constant</a> or constant expression. Valid for <b>Optional</b> parameters only. If the type is an <b>Object</b> , an explicit default value can only be <b>Nothing</b> .

**Note** Every **Property Let** statement must define at least one argument for the procedure it defines. That argument (or the last argument if there is more than one) contains the actual value to be assigned to the property when the procedure defined by the **Property Let** statement is invoked. That argument is referred to as *value* in the preceding syntax.

## Remarks

If not explicitly specified using **Public**, **Private**, or **Friend**, **Property** procedures are public by default. If **Static** isn't used, the value of local variables is not preserved between calls. The **Friend** keyword can only be used in class modules. However, **Friend** procedures can be accessed by procedures in any module of a project. A **Friend** procedure doesn't appear in the [type library](#) of its parent class, nor can a **Friend** procedure be late bound.

All executable code must be in procedures. You can't define a **Property Let** procedure inside another **Property**, **Sub**, or **Function** procedure.

The **Exit Property** statement causes an immediate exit from a **Property Let**

procedure. Program execution continues with the statement following the statement that called the **Property Let** procedure. Any number of **Exit Property** statements can appear anywhere in a **Property Let** procedure.

Like a **Function** and **Property Get** procedure, a **Property Let** procedure is a separate procedure that can take arguments, perform a series of statements, and change the value of its arguments. However, unlike a **Function** and **Property Get** procedure, both of which return a value, you can only use a **Property Let** procedure on the left side of a property assignment expression or **Let** statement.

Property Set Statement

Declares the name, [arguments](#), and code that form the body of a **Property procedure**, which sets a reference to an [object](#).

## Syntax

[**Public** | **Private** | **Friend**] [**Static**] **Property Set** *name* ([*arglist*,] *reference*)  
[*statements*]  
[**Exit Property**]  
[*statements*]

## End Property

The **Property Set** statement syntax has these parts:

Part	Description
<b>Optional</b>	Optional. Indicates that the argument may or may not be supplied by the caller.
<b>Public</b>	Optional. Indicates that the <b>Property Set</b> procedure is accessible to all other procedures in all <a href="#">modules</a> . If used in a module that contains an <b>Option Private</b> statement, the procedure is not available outside the <a href="#">project</a> .
<b>Private</b>	Optional. Indicates that the <b>Property Set</b> procedure is accessible only to other procedures in the module where it is declared.
<b>Friend</b>	Optional. Used only in a <a href="#">class module</a> . Indicates that the <b>Property Set</b> procedure is visible throughout the <a href="#">project</a> , but not visible to a controller of an instance of an object.
<b>Static</b>	Optional. Indicates that the <b>Property Set</b> procedure's local <a href="#">variables</a> are preserved between calls. The <b>Static</b> attribute doesn't affect variables that are declared outside the <b>Property Set</b> procedure, even if they are used in the procedure.

<i>name</i>	Required. Name of the <b>Property Set</b> procedure; follows standard variable naming conventions, except that the name can be the same as a <b>Property Get</b> or <b>Property Let</b> procedure in the same module.
<i>arglist</i>	Required. List of variables representing arguments that are passed to the <b>Property Set</b> procedure when it is called. Multiple arguments are separated by commas.
<i>reference</i>	Required. Variable containing the object reference used on the right side of the object reference assignment.
<i>statements</i>	Optional. Any group of statements to be executed within the body of the <b>Property</b> procedure.

The *arglist* argument has the following syntax and parts:

[**Optional**] [**ByVal** | **ByRef**] [**ParamArray**] *varname*[( )] [**As type**] [= *defaultvalue*]

Part	Description
<b>Optional</b>	Optional. Indicates that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword. Note that it is not possible for the right side of a <b>Property Set</b> <a href="#">expression</a> to be <b>Optional</b> .
<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> array of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an arbitrary number of arguments. It may not be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument; follows standard variable naming conventions.
<i>type</i>	Optional. <a href="#">Data type</a> of the argument passed to the procedure;

may be [Byte](#), [Boolean](#), [Integer](#), [Long](#), [Currency](#), [Single](#), [Double](#), [Decimal](#) (not currently supported), [Date](#), [String](#) (variable length only), [Object](#), [Variant](#), or a specific [object type](#). If the parameter is not **Optional**, a [user-defined type](#) may also be specified.

*defaultvalue* Optional. Any [constant](#) or constant expression. Valid for **Optional** parameters only. If the type is an **Object**, an explicit default value can only be **Nothing**.

**Note** Every **Property Set** statement must define at least one argument for the procedure it defines. That argument (or the last argument if there is more than one) contains the actual object reference for the property when the procedure defined by the **Property Set** statement is invoked. It is referred to as *reference* in the preceding syntax. It can't be **Optional**.

## Remarks

If not explicitly specified using **Public**, **Private**, or **Friend**, **Property** procedures are public by default. If **Static** isn't used, the value of local variables is not preserved between calls. The **Friend** keyword can only be used in class modules. However, **Friend** procedures can be accessed by procedures in any module of a project. A **Friend** procedure doesn't appear in the [type library](#) of its parent class, nor can a **Friend** procedure be late bound.

All executable code must be in procedures. You can't define a **Property Set** procedure inside another **Property**, **Sub**, or **Function** procedure.

The **Exit Property** statement causes an immediate exit from a **Property Set** procedure. Program execution continues with the statement following the statement that called the **Property Set** procedure. Any number of **Exit Property** statements can appear anywhere in a **Property Set** procedure.

Like a **Function** and **Property Get** procedure, a **Property Set** procedure is a separate procedure that can take arguments, perform a series of statements, and change the value of its arguments. However, unlike a **Function** and **Property Get** procedure, both of which return a value, you can only use a **Property Set** procedure on the left side of an object reference assignment (**Set** statement).

Public Statement

Used at [module level](#) to declare public [variables](#) and allocate storage space.

### **Syntax**

**Public** [**WithEvents**] *varname*[(*subscripts*)] [**As** [**New**] *type*] [, [**WithEvents**] *varname*[(*subscripts*)] [**As** [**New**] *type*]] . . .

The **Public** statement syntax has these parts:

Part	Description
<b>WithEvents</b>	Optional. <a href="#">Keyword</a> specifying that <i>varname</i> is an <a href="#">object variable</a> used to respond to events triggered by an <a href="#">ActiveX object</a> . <b>WithEvents</b> is valid only in <a href="#">class modules</a> . You can declare as many individual variables as you like using <b>WithEvents</b> , but you can't create <a href="#">arrays</a> with <b>WithEvents</b> . You can't use <b>New</b> with <b>WithEvents</b> .
<i>varname</i>	Required. Name of the variable; follows standard <a href="#">variable</a> naming conventions.
<i>subscripts</i>	Optional. Dimensions of an array variable; up to 60 multiple dimensions may be declared. The <i>subscripts</i> <a href="#">argument</a> uses the following syntax:  $[lower \textbf{To} upper [, [lower \textbf{To} upper] \dots}]$ <p>When not explicitly stated in <i>lower</i>, the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.</p>
<b>New</b>	Optional. Keyword that enables implicit creation of an object. If you use <b>New</b> when declaring the object variable, a new instance of the object is created on first reference to it, so you don't have to use the <b>Set</b> statement to assign the object reference. The <b>New</b> keyword can't be used to declare variables of any intrinsic <a href="#">data type</a> , can't be used to declare instances of dependent objects, and can't be used with <b>WithEvents</b> .
<i>type</i>	Optional. Data type of the variable; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> , (for variable-length strings), <b>String</b> * <i>length</i> (for fixed-length strings), <a href="#">Object</a> , <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an <a href="#">object type</a> . Use a separate <b>As type</b> clause for each variable being defined.

**Remarks**

Variables declared using the **Public** statement are available to all procedures in all modules in all applications unless **Option Private Module** is in effect; in which case, the variables are public only within the [project](#) in which they reside.

**Caution** The **Public** statement can't be used in a class module to declare a fixed-length string variable.

Use the **Public** statement to declare the data type of a variable. For example, the following statement declares a variable as an **Integer**:

```
Public NumberOfEmployees As Integer
```

Also use a **Public** statement to declare the object type of a variable. The following statement declares a variable for a new instance of a worksheet.

```
Public X As New Worksheet
```

If the **New** keyword is not used when declaring an object variable, the variable that refers to the object must be assigned an existing object using the **Set** statement before it can be used. Until it is assigned an object, the declared object variable has the special value **Nothing**, which indicates that it doesn't refer to any particular instance of an object.

You can also use the **Public** statement with empty parentheses to declare a dynamic array. After declaring a dynamic array, use the **ReDim** statement within a procedure to define the number of dimensions and elements in the array. If you try to redeclare a dimension for an array variable whose size was explicitly specified in a **Private**, **Public**, or **Dim** statement, an error occurs.

If you don't specify a data type or object type and there is no **DefType** statement in the module, the variable is **Variant** by default.

When variables are initialized, a numeric variable is initialized to 0, a variable-length string is initialized to a zero-length string (""), and a fixed-length string is filled with zeros. **Variant** variables are initialized to [Empty](#). Each element of a user-defined type variable is initialized as if it were a separate variable.

Put Statement

Writes data from a [variable](#) to a disk file.

**Syntax**

**Put** [#]*filename*, [*recnumber*], *varname*

The **Put** statement syntax has these parts:

Part	Description
<i>filename</i>	Required. Any valid <a href="#">file number</a> .
<i>recnumber</i>	Optional. <b>Variant (Long)</b> . Record number ( <b>Random</b> mode files) or byte number ( <b>Binary</b> mode files) at which writing begins.
<i>varname</i>	Required. Name of variable containing data to be written to disk.

### Remarks

Data written with **Put** is usually read from a file with **Get**.

The first record or byte in a file is at position 1, the second record or byte is at position 2, and so on. If you omit *recnumber*, the next record or byte after the last **Get** or **Put** statement or pointed to by the last **Seek** function is written. You must include delimiting commas, for example:

**Put** #4,,FileBuffer

For files opened in **Random** mode, the following rules apply:

If the length of the data being written is less than the length specified in the **Len** clause of the **Open** statement, **Put** writes subsequent records on record-length boundaries. The space between the end of one record and the beginning of the next record is padded with the existing contents of the file buffer. Because the amount of padding data can't be determined with any certainty, it is generally a good idea to have the record length match the length of the data being written. If the length of the data being written is greater than the length specified in the **Len** clause of the **Open** statement, an error occurs.

If the variable being written is a variable-length string, **Put** writes a 2-byte descriptor containing the string length and then the variable. The record length specified by the **Len** clause in the **Open** statement must be at least 2

bytes greater than the actual length of the string.

If the variable being written is a [Variant](#) of a [numeric type](#), **Put** writes 2 bytes identifying the **VarType** of the **Variant** and then writes the variable. For example, when writing a **Variant** of **VarType** 3, **Put** writes 6 bytes: 2 bytes identifying the **Variant** as **VarType** 3 (**Long**) and 4 bytes containing the **Long** data. The record length specified by the **Len** clause in the **Open** statement must be at least 2 bytes greater than the actual number of bytes required to store the variable.

**Note** You can use the **Put** statement to write a **Variant** [array](#) to disk, but you can't use **Put** to write a scalar **Variant** containing an array to disk. You also can't use **Put** to write objects to disk.

If the variable being written is a **Variant** of **VarType** 8 (**String**), **Put** writes 2 bytes identifying the **VarType**, 2 bytes indicating the length of the string, and then writes the string data. The record length specified by the **Len** clause in the **Open** statement must be at least 4 bytes greater than the actual length of the string.

If the variable being written is a dynamic array, **Put** writes a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * NumberOfDimensions$ . The record length specified by the **Len** clause in the **Open** statement must be greater than or equal to the sum of all the bytes required to write the array data and the array descriptor. For example, the following array declaration requires 118 bytes when the array is written to disk.

```
Dim MyArray(1 To 5,1 To 10) As Integer
```

The 118 bytes are distributed as follows: 18 bytes for the descriptor ( $2 + 8 * 2$ ), and 100 bytes for the data ( $5 * 10 * 2$ ).

If the variable being written is a fixed-size array, **Put** writes only the data. No descriptor is written to disk.

If the variable being written is any other type of variable (not a variable-

length string or a **Variant**), **Put** writes only the variable data. The record length specified by the **Len** clause in the **Open** statement must be greater than or equal to the length of the data being written.

**Put** writes elements of [user-defined types](#) as if each were written individually, except there is no padding between elements. On disk, a dynamic array in a user-defined type written with **Put** is prefixed by a descriptor whose length equals 2 plus 8 times the number of dimensions, that is,  $2 + 8 * NumberOfDimensions$ . The record length specified by the **Len** clause in the **Open** statement must be greater than or equal to the sum of all the bytes required to write the individual elements, including any arrays and their descriptors.

For files opened in **Binary** mode, all of the **Random** rules apply, except:

The **Len** clause in the **Open** statement has no effect. **Put** writes all variables to disk contiguously; that is, with no padding between records.

For any array other than an array in a user-defined type, **Put** writes only the data. No descriptor is written.

**Put** writes variable-length strings that are not elements of user-defined types without the 2-byte length descriptor. The number of bytes written equals the number of characters in the string. For example, the following statements write 10 bytes to file number 1:

```
VarString$ = String$(10, " ")  
Put #1,,VarString$
```

Randomize Statement

Initializes the random-number generator.

### **Syntax**

**Randomize** [*number*]

The optional *number* [argument](#) is a [Variant](#) or any valid [numeric expression](#).

### **Remarks**

**Randomize** uses *number* to initialize the **Rnd** function's random-number generator, giving it a new [seed](#) value. If you omit *number*, the value returned by the system timer is used as the new seed value.

If **Randomize** is not used, the **Rnd** function (with no arguments) uses the same number as a seed the first time it is called, and thereafter uses the last generated number as a seed value.

**Note** To repeat sequences of random numbers, call **Rnd** with a negative argument immediately before using **Randomize** with a numeric argument. Using **Randomize** with the same value for *number* does not repeat the previous sequence.

ReDim Statement

Used at [procedure level](#) to reallocate storage space for dynamic array [variables](#).

### **Syntax**

**ReDim** [**Preserve**] *varname(subscripts)* [**As** *type*] [, *varname(subscripts)* [**As** *type*]] . . .

The **ReDim** statement syntax has these parts:

Part	Description
<b>Preserve</b>	Optional. <a href="#">Keyword</a> used to preserve the data in an existing <a href="#">array</a> when you change the size of the last dimension.
<i>varname</i>	Required. Name of the variable; follows standard variable naming conventions.
<i>subscripts</i>	Required. Dimensions of an array variable; up to 60 multiple dimensions may be declared. The <i>subscripts</i> <a href="#">argument</a> uses the following syntax:  [ <i>lower To</i> ] <i>upper</i> [, [ <i>lower To</i> ] <i>upper</i> ] . . .  When not explicitly stated in <i>lower</i> , the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.
<i>type</i>	Optional. <a href="#">Data type</a> of the variable; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (for variable-length strings), <b>String</b> * <i>length</i> (for fixed-length strings), <a href="#">Object</a> , <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an <a href="#">object type</a> . Use a separate <b>As</b> <i>type</i> clause for each variable being defined. For a <b>Variant</b> containing an array, <i>type</i> describes the type of each element of the array, but doesn't change the <b>Variant</b> to some other type.

## Remarks

The **ReDim** [statement](#) is used to size or resize a dynamic array that has already been formally declared using a **Private**, **Public**, or **Dim** statement with empty parentheses (without dimension subscripts).

You can use the **ReDim** statement repeatedly to change the number of elements and dimensions in an array. However, you can't declare an array of one data type and later use **ReDim** to change the array to another data type, unless the array is contained in a **Variant**. If the array is contained in a **Variant**, the type of the

elements can be changed using an **As** *type* clause, unless you're using the **Preserve** keyword, in which case, no changes of data type are permitted.

If you use the **Preserve** keyword, you can resize only the last array dimension and you can't change the number of dimensions at all. For example, if your array has only one dimension, you can resize that dimension because it is the last and only dimension. However, if your array has two or more dimensions, you can change the size of only the last dimension and still preserve the contents of the array. The following example shows how you can increase the size of the last dimension of a dynamic array without erasing any existing data contained in the array.

```
ReDim X(10, 10, 10)
. . .
ReDim Preserve X(10, 10, 15)
```

Similarly, when you use **Preserve**, you can change the size of the array only by changing the upper bound; changing the lower bound causes an error.

If you make an array smaller than it was, data in the eliminated elements will be lost. If you pass an array to a procedure by reference, you can't redimension the array within the procedure.

When variables are initialized, a numeric variable is initialized to 0, a variable-length string is initialized to a zero-length string (""), and a fixed-length string is filled with zeros. **Variant** variables are initialized to [Empty](#). Each element of a user-defined type variable is initialized as if it were a separate variable. A variable that refers to an object must be assigned an existing object using the **Set** statement before it can be used. Until it is assigned an object, the declared [object variable](#) has the special value **Nothing**, which indicates that it doesn't refer to any particular instance of an object.

**Caution** The **ReDim** statement acts as a declarative statement if the variable it declares doesn't exist at [module level](#) or [procedure level](#). If another variable with the same name is created later, even in a wider [scope](#), **ReDim** will refer to the later variable and won't necessarily cause a compilation error, even if **Option Explicit** is in effect. To avoid such conflicts, **ReDim** should not be used as a declarative statement, but simply for redimensioning arrays.

**Note** To resize an array contained in a **Variant**, you must explicitly declare the **Variant** variable before attempting to resize its array.

Rem Statement

Used to include explanatory remarks in a program.

## Syntax

### **Rem** *comment*

You can also use the following syntax:

*' comment*

The optional *comment* [argument](#) is the text of any [comment](#) you want to include. A space is required between the **Rem** [keyword](#) and *comment*.

### Remarks

If you use [line numbers](#) or [line labels](#), you can branch from a **GoTo** or **GoSub** [statement](#) to a line containing a **Rem** statement. Execution continues with the first executable statement following the **Rem** statement. If the **Rem** keyword follows other statements on a line, it must be separated from the statements by a colon (:).

You can use an apostrophe (') instead of the **Rem** keyword. When you use an apostrophe, the colon is not required after other statements.

## Reset Statement

Closes all disk files opened using the **Open** statement.

### Syntax

### Reset

### Remarks

The **Reset** statement closes all active files opened by the **Open** statement and writes the contents of all file buffers to disk.

Resume Statement

Resumes execution after an error-handling routine is finished.

**Syntax**

## Resume [0]

## Resume Next

## Resume *line*

The **Resume** statement syntax can have any of the following forms:

Statement	Description
<b>Resume</b>	If the error occurred in the same <a href="#">procedure</a> as the error handler, execution resumes with the statement that caused the error. If the error occurred in a called procedure, execution resumes at the <a href="#">statement</a> that last called out of the procedure containing the error-handling routine.
<b>Resume Next</b>	If the error occurred in the same procedure as the error handler, execution resumes with the statement immediately following the statement that caused the error. If the error occurred in a called procedure, execution resumes with the statement immediately following the statement that last called out of the procedure containing the error-handling routine (or <b>On Error Resume Next</b> statement).
<b>Resume <i>line</i></b>	Execution resumes at <i>line</i> specified in the required <i>line argument</i> . The <i>line</i> argument is a <a href="#">line label</a> or <a href="#">line number</a> and must be in the same procedure as the error handler.

## Remarks

If you use a **Resume** statement anywhere except in an error-handling routine, an error occurs.

## Rmdir Statement

Removes an existing directory or folder.

### Syntax

**Rmdir** *path*

The required *path* [argument](#) is a [string expression](#) that identifies the directory or folder to be removed. The *path* may include the drive. If no drive is specified, **Rmdir** removes the directory or folder on the current drive.

### Remarks

An error occurs if you try to use **Rmdir** on a directory or folder containing files. Use the **Kill** statement to delete all files before attempting to remove a directory or folder.

RSet Statement

Right aligns a string within a string [variable](#).

## Syntax

**RSet** *stringvar* = *string*

The **RSet** statement syntax has these parts:

Part	Description
------	-------------

*stringvar* Required. Name of string variable.  
*string* Required. [String expression](#) to be right-aligned within *stringvar*.

## Remarks

If *stringvar* is longer than *string*, **RSet** replaces any leftover characters in *stringvar* with spaces, back to its beginning.

**Note** **RSet** can't be used with [user-defined types](#).

SaveSetting Statement

Saves or creates an application entry in the application's entry in the Windows [registry](#) or (on the Macintosh) information in the application's initialization file.

## Syntax

**SaveSetting** *appname, section, key, setting*

The **SaveSetting** statement syntax has these [named arguments](#):

Part	Description
<b><i>appname</i></b>	Required. <a href="#">String expression</a> containing the name of the application or <a href="#">project</a> to which the setting applies. On the Macintosh, this is the filename of the initialization file in the Preferences folder in the System folder.
<b><i>section</i></b>	Required. String expression containing the name of the section where the key setting is being saved.
<b><i>key</i></b>	Required. String expression containing the name of the key setting being saved.
<b><i>setting</i></b>	Required. <a href="#">Expression</a> containing the value that <b><i>key</i></b> is being set to.

## Remarks

An error occurs if the key setting can't be saved for any reason.

Sets the position for the next read/write operation within a file opened using the **Open** statement.

## Syntax

**Seek** [#]*filenumber, position*

The **Seek** statement syntax has these parts:

Part	Description
<i>filenumber</i>	Required. Any valid <a href="#">file number</a> .
<i>position</i>	Required. Number in the range 1 – 2,147,483,647, inclusive, that indicates where the next read/write operation should occur.

## Remarks

Record numbers specified in **Get** and **Put** statements override file positioning performed by **Seek**.

Performing a file-write operation after a **Seek** operation beyond the end of a file extends the file. If you attempt a **Seek** operation to a negative or zero position, an error occurs.

Select Case Statement

Executes one of several groups of [statements](#), depending on the value of an [expression](#).

## Syntax

```
Select Case testexpression [Case expressionlist-n  
    [statements-n]] . . .  
    [Case Else  
        [elstatements]]
```

## End Select

The **Select Case** statement syntax has these parts:

Part	Description
<i>testexpression</i>	Required. Any <a href="#">numeric expression</a> or <a href="#">string expression</a> .
<i>expressionlist-n</i>	Required if a <b>Case</b> appears. Delimited list of one or more of the following forms: <i>expression</i> , <i>expression To expression</i> , <b>Is comparisonoperator expression</b> . The <b>To</b> <a href="#">keyword</a> specifies a range of values. If you use the <b>To</b> keyword, the smaller value must appear before <b>To</b> . Use the <b>Is</b> keyword with <a href="#">comparison operators</a> (except <b>Is</b> and <b>Like</b> ) to specify a range of values. If not supplied, the <b>Is</b> keyword is automatically inserted.
<i>statements-n</i>	Optional. One or more statements executed if <i>testexpression</i> matches any part of <i>expressionlist-n</i> .
<i>elstatements</i>	Optional. One or more statements executed if <i>testexpression</i> doesn't match any of the <b>Case</b> clause.

## Remarks

If *testexpression* matches any **Case** *expressionlist* expression, the *statements* following that **Case** clause are executed up to the next **Case** clause, or, for the last clause, up to **End Select**. Control then passes to the statement following **End Select**. If *testexpression* matches an *expressionlist* expression in more than one **Case** clause, only the statements following the first match are executed.

The **Case Else** clause is used to indicate the *elstatements* to be executed if no match is found between the *testexpression* and an *expressionlist* in any of the

other **Case** selections. Although not required, it is a good idea to have a **Case Else** statement in your **Select Case** block to handle unforeseen *testexpression* values. If no **Case expressionlist** matches *testexpression* and there is no **Case Else** statement, execution continues at the statement following **End Select**.

You can use multiple expressions or ranges in each **Case** clause. For example, the following line is valid:

```
Case 1 To 4, 7 To 9, 11, 13, Is > MaxNumber
```

**Note** The **Is** comparison operator is not the same as the **Is** keyword used in the **Select Case** statement.

You also can specify ranges and multiple expressions for character strings. In the following example, **Case** matches strings that are exactly equal to everything, strings that fall between nuts and soup in alphabetic order, and the current value of `TestItem`:

```
Case "everything", "nuts" To "soup", TestItem
```

**Select Case** statements can be nested. Each nested **Select Case** statement must have a matching **End Select** statement.

SendKeys Statement

Sends one or more keystrokes to the active window as if typed at the keyboard.

### **Syntax**

## **SendKeys** *string*[, *wait*]

The **SendKeys** statement syntax has these [named arguments](#):

Part	Description
<b><i>string</i></b>	Required. <a href="#">String expression</a> specifying the keystrokes to send.
<b><i>Wait</i></b>	Optional. <a href="#">Boolean</a> value specifying the wait mode. If <b>False</b> (default), control is returned to the <a href="#">procedure</a> immediately after the keys are sent. If <b>True</b> , keystrokes must be processed before control is returned to the procedure.

### Remarks

Each key is represented by one or more characters. To specify a single keyboard character, use the character itself. For example, to represent the letter A, use "A" for ***string***. To represent more than one character, append each additional character to the one preceding it. To represent the letters A, B, and C, use "ABC" for ***string***.

The plus sign (+), caret (^), percent sign (%), tilde (~), and parentheses ( ) have special meanings to **SendKeys**. To specify one of these characters, enclose it within braces ({}). For example, to specify the plus sign, use {+}. Brackets ([ ]) have no special meaning to **SendKeys**, but you must enclose them in braces. In other applications, brackets do have a special meaning that may be significant when [dynamic data exchange](#) (DDE) occurs. To specify brace characters, use {{}} and {}.

To specify characters that aren't displayed when you press a key, such as ENTER or TAB, and keys that represent actions rather than characters, use the codes shown below:

Key	Code
BACKSPACE	{BACKSPACE}, {BS}, or {BKSP}
BREAK	{BREAK}
CAPS LOCK	{CAPSLOCK}
DEL or DELETE	{DELETE} or {DEL}
DOWN ARROW	{DOWN}

END	{END}
ENTER	{ENTER} or ~
ESC	{ESC}

To specify keys combined with any combination of the SHIFT, CTRL, and ALT keys, precede the key code with one or more of the following codes:

Key	Code
SHIFT	+
CTRL	^
ALT	%

To specify that any combination of SHIFT, CTRL, and ALT should be held down while several other keys are pressed, enclose the code for those keys in parentheses. For example, to specify to hold down SHIFT while E and C are pressed, use "+(EC)". To specify to hold down SHIFT while E is pressed, followed by C without SHIFT, use "+EC".

To specify repeating keys, use the form {key number}. You must put a space between key and number. For example, {LEFT 42} means press the LEFT ARROW key 42 times; {h 10} means press H 10 times.

**Note** You can't use **SendKeys** to send keystrokes to an application that is not designed to run in Microsoft Windows or Macintosh. **Sendkeys** also can't send the PRINT SCREEN key {PRTSC} to any application.

Set Statement

Assigns an object reference to a [variable](#) or [property](#).

## Syntax

**Set** *objectvar* = {[**New**] *objectexpression* | **Nothing**}

The **Set** statement syntax has these parts:

Part	Description
<i>objectvar</i>	Required. Name of the variable or property; follows standard variable naming conventions.
<b>New</b>	Optional. <b>New</b> is usually used during declaration to enable implicit object creation. When <b>New</b> is used with <b>Set</b> , it creates a new instance of the <a href="#">class</a> . If <i>objectvar</i> contained a reference to an object, that reference is released when the new one is assigned. The <b>New</b> <a href="#">keyword</a> can't be used to create new instances of any intrinsic <a href="#">data type</a> and can't be used to create dependent objects.
<i>objectexpression</i>	Required. <a href="#">Expression</a> consisting of the name of an object, another declared variable of the same <a href="#">object type</a> , or a function or <a href="#">method</a> that returns an object of the same object type.
<b>Nothing</b>	Optional. Discontinues association of <i>objectvar</i> with any

specific object. Assigning **Nothing** to *objectvar* releases all the system and memory resources associated with the previously referenced object when no other variable refers to it.

## Remarks

To be valid, *objectvar* must be an object type consistent with the object being assigned to it.

The **Dim**, **Private**, **Public**, **ReDim**, and **Static** statements only declare a variable that refers to an object. No actual object is referred to until you use the **Set** statement to assign a specific object.

The following example illustrates how **Dim** is used to declare an [array](#) with the type `Form1`. No instance of `Form1` actually exists. **Set** then assigns references to new instances of `Form1` to the `myChildForms` variable. Such code might be used to create child forms in an MDI application.

```
Dim myChildForms(1 to 4) As Form1
Set myChildForms(1) = New Form1
Set myChildForms(2) = New Form1
Set myChildForms(3) = New Form1
Set myChildForms(4) = New Form1
```

Generally, when you use **Set** to assign an object reference to a variable, no copy of the object is created for that variable. Instead, a reference to the object is created. More than one [object variable](#) can refer to the same object. Because such variables are references to the object rather than copies of the object, any change in the object is reflected in all variables that refer to it. However, when you use the **New** keyword in the **Set** statement, you are actually creating an instance of the object.

SetAttr Statement

Sets attribute information for a file.

**Syntax**

## **SetAttr** *pathname, attributes*

The **SetAttr** statement syntax has these [named arguments](#):

Part	Description
<i>pathname</i>	Required. <a href="#">String expression</a> that specifies a file name — may include directory or folder, and drive.
<i>attributes</i>	Required. <a href="#">Constant</a> or <a href="#">numeric expression</a> , whose sum specifies file attributes.

### **Settings**

The *attributes* [argument](#) settings are:

Constant	Value	Description
<b>vbNormal</b>	0	Normal (default).
<b>vbReadOnly</b>	1	Read-only.
<b>vbHidden</b>	2	Hidden.
<b>vbSystem</b>	4	System file. Not available on the Macintosh.
<b>vbArchive</b>	32	File has changed since last backup.
<b>vbAlias</b>	64	Specified file name is an alias. Available only on the Macintosh.

**Note** These constants are specified by Visual Basic for Applications. The names can be used anywhere in your code in place of the actual values.

### **Remarks**

A [run-time error](#) occurs if you try to set the attributes of an open file.

Static Statement

Used at [procedure level](#) to declare [variables](#) and allocate storage space. Variables declared with the **Static** statement retain their values as long as the code is running.

## Syntax

**Static** *varname*[(*subscripts*)] [**As** [**New**] *type*] [, *varname*[(*subscripts*)] [**As** [**New**] *type*]] . . .

The **Static** statement syntax has these parts:

Part	Description
<i>varname</i>	Required. Name of the variable; follows standard variable naming conventions.
<i>subscripts</i>	Optional. Dimensions of an <a href="#">array</a> variable; up to 60 multiple dimensions may be declared. The <i>subscripts</i> <a href="#">argument</a> uses the following syntax:  [ <i>lower To</i> ] <i>upper</i> [, [ <i>lower To</i> ] <i>upper</i> ] . . .  When not explicitly stated in <i>lower</i> , the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.
<b>New</b>	Optional. <a href="#">Keyword</a> that enables implicit creation of an object. If you use <b>New</b> when declaring the <a href="#">object variable</a> , a new instance of the object is created on first reference to it, so you don't have to use the <b>Set</b> statement to assign the object reference. The <b>New</b> keyword can't be used to declare variables of any intrinsic <a href="#">data type</a> and can't be used to declare instances of dependent objects.
<i>type</i>	Optional. Data type of the variable; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> , (for variable-length strings), <b>String</b> *

*length* (for fixed-length strings), [Object](#), [Variant](#), a [user-defined type](#), or an [object type](#). Use a separate **As** *type* clause for each variable being defined.

## Remarks

Once [module](#) code is running, variables declared with the **Static** [statement](#) retain their value until the module is reset or restarted. In [class modules](#), variables declared with the **Static** statement retain their value in each class instance until that instance is destroyed. In [form modules](#), static variables retain their value until the form is closed. Use the **Static** statement in nonstatic [procedures](#) to explicitly declare variables that are visible only within the procedure, but whose lifetime is the same as the module in which the procedure is defined.

Use a **Static** statement within a procedure to declare the data type of a variable that retains its value between procedure calls. For example, the following statement declares a fixed-size array of integers:

```
Static EmployeeNumber(200) As Integer
```

The following statement declares a variable for a new instance of a worksheet:

```
Static X As New Worksheet
```

If the **New** keyword isn't used when declaring an object variable, the variable that refers to the object must be assigned an existing object using the **Set** statement before it can be used. Until it is assigned an object, the declared object variable has the special value **Nothing**, which indicates that it doesn't refer to any particular instance of an object. When you use the **New** keyword in the [declaration](#), an instance of the object is created on the first reference to the object.

If you don't specify a data type or object type, and there is no **DefType** statement in the module, the variable is **Variant** by default.

**Note** The **Static** statement and the **Static** keyword are similar, but used for different effects. If you declare a procedure using the **Static** keyword (as in `Static Sub CountSales ()`), the storage space for all local variables within the

procedure is allocated once, and the value of the variables is preserved for the entire time the program is running. For nonstatic procedures, storage space for variables is allocated each time the procedure is called and released when the procedure is exited. The **Static** statement is used to declare specific variables within nonstatic procedures to preserve their value for as long as the program is running.

When variables are initialized, a numeric variable is initialized to 0, a variable-length string is initialized to a zero-length string (""), and a fixed-length string is filled with zeros. **Variant** variables are initialized to [Empty](#). Each element of a user-defined type variable is initialized as if it were a separate variable.

**Note** When you use **Static** statements within a procedure, put them at the beginning of the procedure with other declarative statements such as **Dim**.

Stop Statement

Suspends execution.

### **Syntax**

### **Stop**

### **Remarks**

You can place **Stop** statements anywhere in [procedures](#) to suspend execution. Using the **Stop** statement is similar to setting a [breakpoint](#) in the code.

The **Stop** statement suspends execution, but unlike **End**, it doesn't close any files or clear [variables](#), unless it is in a compiled executable (.exe) file.

Sub Statement

Declares the name, [arguments](#), and code that form the body of a **Sub** [procedure](#).

## Syntax

```
[Private | Public | Friend] [Static] Sub name [(arglist)]  
    [statements]  
[Exit Sub]  
    [statements]
```

**End Sub**

The **Sub** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Indicates that the <b>Sub</b> procedure is accessible to all other procedures in all <a href="#">modules</a> . If used in a module that contains an <b>Option Private</b> statement, the procedure is not available outside the <a href="#">project</a> .
<b>Private</b>	Optional. Indicates that the <b>Sub</b> procedure is accessible only to other procedures in the module where it is declared.
<b>Friend</b>	Optional. Used only in a <a href="#">class module</a> . Indicates that the <b>Sub</b> procedure is visible throughout the <a href="#">project</a> , but not visible to a controller of an instance of an object.
<b>Static</b>	Optional. Indicates that the <b>Sub</b> procedure's local <a href="#">variables</a> are preserved between calls. The <b>Static</b> attribute doesn't affect variables that are declared outside the <b>Sub</b> , even if they are used in the procedure.
<i>name</i>	Required. Name of the <b>Sub</b> ; follows standard <a href="#">variable</a> naming conventions.
<i>arglist</i>	Optional. List of variables representing arguments that are passed to the <b>Sub</b> procedure when it is called. Multiple variables are separated by commas.
<i>statements</i>	Optional. Any group of <a href="#">statements</a> to be executed within the <b>Sub</b> procedure.

The *arglist* argument has the following syntax and parts:

[**Optional**] [**ByVal** | **ByRef**] [**ParamArray**] *varname*[( )] [**As type**] [= *defaultvalue*]

Part	Description
<b>Optional</b>	Optional. <a href="#">Keyword</a> indicating that an argument is not required. If used, all subsequent arguments in <i>arglist</i> must also be optional and declared using the <b>Optional</b> keyword. <b>Optional</b> can't be used for any argument if <b>ParamArray</b> is used.

<b>ByVal</b>	Optional. Indicates that the argument is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<b>ParamArray</b>	Optional. Used only as the last argument in <i>arglist</i> to indicate that the final argument is an <b>Optional</b> <a href="#">array</a> of <b>Variant</b> elements. The <b>ParamArray</b> keyword allows you to provide an arbitrary number of arguments. <b>ParamArray</b> can't be used with <b>ByVal</b> , <b>ByRef</b> , or <b>Optional</b> .
<i>varname</i>	Required. Name of the variable representing the argument; follows standard variable naming conventions.
<i>type</i>	Optional. <a href="#">Data type</a> of the argument passed to the procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (variable-length only), <a href="#">Object</a> , <a href="#">Variant</a> , or a specific <a href="#">object type</a> . If the parameter is not <b>Optional</b> , a <a href="#">user-defined type</a> may also be specified.
<i>defaultvalue</i>	Optional. Any <a href="#">constant</a> or constant <a href="#">expression</a> . Valid for <b>Optional</b> parameters only. If the type is an <b>Object</b> , an explicit default value can only be <b>Nothing</b> .

## Remarks

If not explicitly specified using **Public**, **Private**, or **Friend**, **Sub** procedures are public by default. If **Static** isn't used, the value of local variables is not preserved between calls. The **Friend** keyword can only be used in class modules.

However, **Friend** procedures can be accessed by procedures in any module of a project. A **Friend** procedure doesn't appear in the [type library](#) of its parent class, nor can a **Friend** procedure be late bound.

**Caution** **Sub** procedures can be recursive; that is, they can call themselves to perform a given task. However, recursion can lead to stack overflow. The **Static** keyword usually is not used with recursive **Sub** procedures.

All executable code must be in [procedures](#). You can't define a **Sub** procedure inside another **Sub**, **Function**, or **Property** procedure.

The **Exit Sub** keywords cause an immediate exit from a **Sub** procedure.

Program execution continues with the statement following the statement that called the **Sub** procedure. Any number of **Exit Sub** statements can appear anywhere in a **Sub** procedure.

Like a **Function** procedure, a **Sub** procedure is a separate procedure that can take arguments, perform a series of statements, and change the value of its arguments. However, unlike a **Function** procedure, which returns a value, a **Sub** procedure can't be used in an expression.

You call a **Sub** procedure using the procedure name followed by the argument list. See the **Call** statement for specific information on how to call **Sub** procedures.

Variables used in **Sub** procedures fall into two categories: those that are explicitly declared within the procedure and those that are not. Variables that are explicitly declared in a procedure (using **Dim** or the equivalent) are always local to the procedure. Variables that are used but not explicitly declared in a procedure are also local unless they are explicitly declared at some higher level outside the procedure.

**Caution** A procedure can use a variable that is not explicitly declared in the procedure, but a naming conflict can occur if anything you defined at the [module level](#) has the same name. If your procedure refers to an undeclared variable that has the same name as another procedure, constant or variable, it is assumed that your procedure is referring to that module-level name. To avoid this kind of conflict, explicitly declare variables. You can use an **Option Explicit** statement to force explicit declaration of variables.

**Note** You can't use **GoSub**, **GoTo**, or **Return** to enter or exit a **Sub** procedure.

Time Statement

Sets the system time.

### Syntax

**Time** = *time*

The required *time* [argument](#) is any [numeric expression](#), [string expression](#), or any combination, that can represent a time.

### Remarks

If *time* is a string, **Time** attempts to convert it to a time using the time separators you specified for your system. If it can't be converted to a valid time, an error occurs.

Type Statement

Used at [module level](#) to define a user-defined [data type](#) containing one or more elements.

## Syntax

```
[Private | Public] Type varname  
    elementname [[subscripts]] As type  
    [elementname [[subscripts]] As type]  
    ...
```

## End Type

The **Type** statement syntax has these parts:

Part	Description
<b>Public</b>	Optional. Used to declare <a href="#">user-defined types</a> that are available to all <a href="#">procedures</a> in all <a href="#">modules</a> in all <a href="#">projects</a> .
<b>Private</b>	Optional. Used to declare user-defined types that are available only within the module where the <a href="#">declaration</a> is made.
<i>varname</i>	Required. Name of the user-defined type; follows standard <a href="#">variable</a> naming conventions.
<i>elementname</i>	Required. Name of an element of the user-defined type. Element names also follow standard variable naming conventions, except that <a href="#">keywords</a> can be used.
<i>subscripts</i>	When not explicitly stated in <i>lower</i> , the lower bound of an array is controlled by the <b>Option Base</b> statement. The lower bound is zero if no <b>Option Base</b> statement is present.
<i>type</i>	Required. Data type of the element; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (for variable-length strings),

**String** \* *length* (for fixed-length strings), [Object](#), [Variant](#), another user-defined type, or an [object type](#).

## Remarks

The **Type** statement can be used only at module level. Once you have declared a user-defined type using the **Type** statement, you can declare a variable of that type anywhere within the [scope](#) of the declaration. Use **Dim**, **Private**, **Public**, **ReDim**, or **Static** to declare a variable of a user-defined type.

In [standard modules](#) and [class modules](#), user-defined types are public by default. This visibility can be changed using the **Private** keyword.

[Line numbers](#) and [line labels](#) aren't allowed in **Type...End Type** blocks.

User-defined types are often used with data records, which frequently consist of a number of related elements of different data types.

The following example shows the use of fixed-size arrays in a user-defined type:

```
Type StateData
    CityCode (1 To 100) As Integer      ' Declare
    County As String * 30
End Type
```

```
Dim Washington(1 To 100) As StateData
```

In the preceding example, `StateData` includes the `CityCode` static array, and the record `washington` has the same structure as `StateData`.

When you declare a fixed-size array within a user-defined type, its dimensions must be declared with numeric literals or [constants](#) rather than variables.

While...Wend Statement

Executes a series of [statements](#) as long as a given condition is **True**.

### **Syntax**

**While** *condition* [*statements*]

**Wend**

The **While...Wend** statement syntax has these parts:

---

Part	Description
<i>condition</i>	Required. <a href="#">Numeric expression</a> or <a href="#">string expression</a> that evaluates to <b>True</b> or <b>False</b> . If <i>condition</i> is <a href="#">Null</a> , <i>condition</i> is treated as <b>False</b> .
<i>statements</i>	Optional. One or more statements executed while <i>condition</i> is <b>True</b> .

## Remarks

If *condition* is **True**, all *statements* are executed until the **Wend** statement is encountered. Control then returns to the **While** statement and *condition* is again checked. If *condition* is still **True**, the process is repeated. If it is not **True**, execution resumes with the statement following the **Wend** statement.

**While...Wend** loops can be nested to any level. Each **Wend** matches the most recent **While**.

**Tip** The **Do...Loop** statement provides a more structured and flexible way to perform looping.

Width #

Statement

Assigns an output line width to a file opened using the **Open** statement.

## Syntax

**Width #***filename, width*

The **Width #** statement syntax has these parts:

Part	Description
<i>filename</i>	Required. Any valid <a href="#">file number</a> .
<i>width</i>	Required. <a href="#">Numeric expression</a> in the range 0–255, inclusive, that indicates how many characters appear on a line before a new line is started. If <i>width</i> equals 0, there is no limit to the length of a line. The default value for <i>width</i> is 0.

With Statement

Executes a series of [statements](#) on a single object or a [user-defined type](#).

## Syntax

**With** *object* [*statements*]

**End With**

The **With** statement syntax has these parts:

---

Part	Description
<i>object</i>	Required. Name of an object or a user-defined type.
<i>statements</i>	Optional. One or more statements to be executed on <i>object</i> .

## Remarks

The **With** statement allows you to perform a series of statements on a specified object without requalifying the name of the object. For example, to change a number of different [properties](#) on a single object, place the property assignment statements within the **With** control structure, referring to the object once instead of referring to it with each property assignment. The following example illustrates use of the **With** statement to assign values to several properties of the same object.

```
With MyLabel
    .Height = 2000
    .Width = 2000
    .Caption = "This is MyLabel"
End With
```

**Note** Once a **With** block is entered, *object* can't be changed. As a result, you can't use a single **With** statement to affect a number of different objects.

You can nest **With** statements by placing one **With** block within another. However, because members of outer **With** blocks are masked within the inner **With** blocks, you must provide a fully qualified object reference in an inner **With** block to any member of an object in an outer **With** block.

**Note** In general, it's recommended that you don't jump into or out of **With** blocks. If statements in a **With** block are executed, but either the **With** or **End With** statement is not executed, a temporary variable containing a reference to the object remains in memory until you exit the procedure.

Write # Statement

Writes data to a sequential file.

## Syntax

**Write #***filename*, [*outputlist*]

The **Write #** statement syntax has these parts:

Part	Description
<i>filename</i>	Required. Any valid <a href="#">file number</a> .
<i>outputlist</i>	Optional. One or more comma-delimited <a href="#">numeric expressions</a> or <a href="#">string expressions</a> to write to a file.

## Remarks

Data written with **Write #** is usually read from a file with **Input #**.

If you omit *outputlist* and include a comma after *filename*, a blank line is printed to the file. Multiple expressions can be separated with a space, a semicolon, or a comma. A space has the same effect as a semicolon.

When **Write #** is used to write data to a file, several universal assumptions are followed so the data can always be read and correctly interpreted using **Input #**, regardless of [locale](#):

Numeric data is always written using the period as the decimal separator.

For [Boolean](#) data, either #TRUE# or #FALSE# is printed. The **True** and **False** [keywords](#) are not translated, regardless of locale.

[Date](#) data is written to the file using the [universal date format](#). When either the date or the time component is missing or zero, only the part provided gets written to the file.

Nothing is written to the file if *outputlist* data is [Empty](#). However, for [Null](#) data, #NULL# is written.

If *outputlist* data is **Null** data, #NULL# is written to the file.

For **Error** data, the output appears as #ERROR errorcode#. The **Error** keyword is not translated, regardless of locale.

Unlike the **Print #** statement, the **Write #** statement inserts commas between items and quotation marks around strings as they are written to the file. You don't have to put explicit delimiters in the list. **Write #** inserts a newline character, that is, a carriage return–linefeed (**Chr(13) + Chr(10)**), after it has written the final character in *outputlist* to the file.

**Note** You should not write strings that contain embedded quotation marks, for example, "1,2""x" for use with the **Input #** statement: **Input #** parses this string as two complete and separate strings.

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Decription
<b>vbMethod</b>	1	Indicates that a method has been invoked.
<b>vbGet</b>	2	Indicates a <b>Property Get</b> procedure.
<b>vbLet</b>	4	Indicates a <b>Property Let</b> procedure.
<b>vbSet</b>	8	Indicates a <b>Property Set</b> procedure.

## Form Constants

The following [constants](#) can be used anywhere in your code in place of the actual values:

Constant	Value	Decription
<b>vbModeless</b>	0	<b>UserForm</b> is modeless.
<b>vbModal</b>	1	<b>UserForm</b> is modal (default).

## Returns for CStr

If <i>expression</i> is	CStr returns
<b>Boolean</b>	A string containing <b>True</b> or <b>False</b>
<b>Date</b>	A string containing a date in the short date format of your system
<a href="#">Null</a>	A <a href="#">run-time error</a>
<a href="#">Empty</a>	A zero-length string ("")
<b>Error</b>	A string containing the word <b>Error</b> followed by the <a href="#">error number</a>
Other numeric	A string containing the number

Enum Statement

Declares a type for an enumeration.

### Syntax

**[Public | Private] Enum** *name*

*membername* [= *constantexpression*]

*membername* [= *constantexpression*]

...

### End Enum

The **Enum** statement has these parts:

Part	Description
<b>Public</b>	Optional. Specifies that the <b>Enum</b> type is visible throughout the <a href="#">project</a> . <b>Enum</b> types are <b>Public</b> by default.
<b>Private</b>	Optional. Specifies that the <b>Enum</b> type is visible only within the <a href="#">module</a> in which it appears.
<i>name</i>	Required. The name of the <b>Enum</b> type. The <i>name</i> must be a valid Visual Basic identifier and is specified as the

	type when declaring <a href="#">variables</a> or <a href="#">parameters</a> of the <b>Enum</b> type.
<i>membername</i>	Required. A valid Visual Basic identifier specifying the name by which a constituent element of the <b>Enum</b> type will be known.
<i>constantexpression</i>	Optional. Value of the element (evaluates to a <b>Long</b> ). If no <i>constantexpression</i> is specified, the value assigned is either zero (if it is the first <i>membername</i> ), or 1 greater than the value of the immediately preceding <i>membername</i> .

## Remarks

Enumeration variables are variables declared with an **Enum** type. Both variables and parameters can be declared with an **Enum** type. The elements of the **Enum** type are initialized to constant values within the **Enum** statement. The assigned values can't be modified at [run time](#) and can include both positive and negative numbers. For example:

```
Enum SecurityLevel
    IllegalEntry = -1
    SecurityLevel1 = 0
    SecurityLevel2 = 1
End Enum
```

An **Enum** statement can appear only at [module level](#). Once the **Enum** type is defined, it can be used to declare variables, parameters, or [procedures](#) returning its type. You can't qualify an **Enum** type name with a module name. **Public Enum** types in a [class module](#) are not members of the class; however, they are written to the [type library](#). **Enum** types defined in [standard modules](#) aren't written to type libraries. **Public Enum** types of the same name can't be defined in both standard modules and class modules, since they share the same name space. When two **Enum** types in different type libraries have the same name, but different elements, a reference to a variable of the type depends on which type library has higher priority in the **References**.

You can't use an **Enum** type as the target in a **With** block.

## Event Statement

Declares a user-defined event.

### Syntax

**[Public] Event** *procedurename* [(*arglist*)]

The **Event** statement has these parts:

Part	Description
<b>Public</b>	Optional. Specifies that the <b>Event</b> visible throughout the <a href="#">project</a> . <b>Events</b> types are <b>Public</b> by default. Note that events can only be raised in the <a href="#">module</a> in which they are declared.
<i>procedurename</i>	Required. Name of the event; follows standard variable naming conventions.

The *arglist* argument has the following syntax and parts:

[**ByVal** | **ByRef**] *varname*[( )] [**As** *type*]

Part	Description
<b>ByVal</b>	Optional. Indicates that the <a href="#">argument</a> is passed <a href="#">by value</a> .
<b>ByRef</b>	Optional. Indicates that the argument is passed <a href="#">by reference</a> . <b>ByRef</b> is the default in Visual Basic.
<i>varname</i>	Required. Name of the variable representing the argument being passed to the <a href="#">procedure</a> ; follows standard variable naming conventions.
<i>type</i>	Optional. <a href="#">Data type</a> of the argument passed to the procedure; may be <a href="#">Byte</a> , <a href="#">Boolean</a> , <a href="#">Integer</a> , <a href="#">Long</a> , <a href="#">Currency</a> , <a href="#">Single</a> , <a href="#">Double</a> , <a href="#">Decimal</a> (not currently supported), <a href="#">Date</a> , <a href="#">String</a> (variable length only), <a href="#">Object</a> , <a href="#">Variant</a> , a <a href="#">user-defined type</a> , or an object type.

## Remarks

Once the event has been declared, use the **RaiseEvent** statement to fire the event. A syntax error occurs if an **Event** declaration appears in a [standard module](#). An event can't be declared to return a value. A typical event might be declared and raised as shown in the following fragments:

```
' Declare an event at module level of a class m
Event LogonCompleted (UserName as String)

Sub
    RaiseEvent LogonCompleted("AntoineJan")
End Sub
```

**Note** You can declare event arguments just as you do arguments of procedures, with the following exceptions: events cannot have named arguments, **Optional** arguments, or **ParamArray** arguments. Events do not have return values.
